Contents

1 Database System Overview 1
1.1 Database Logical Architecture 1
1.2 Query Request Handling Process 2
1.3 Managing Transactions 2
1.4 Concepts 6
2 Database Security 8
2.1 Users and Permissions 8
2.1.1 Default Permission Mechanism 8
2.1.2 Administrators 9
2.1.3 Separation of Duties 11
2.1.4 Users 13
2.1.5 Roles 14
2.1.6 Schemas 16
2.1.7 User Permissions 17
2.1.8 Row-Level Security Policy 18
2.2 Database Audit 20
3 Database Quick Start 23
3.1 Connecting to a Database 23
3.1.1 Using gsql to Connect to a Database 23
3.1.2 APIs 25
3.2 Operating a Database 26
3.2.1 Creating a Database Account 26
3.2.2 Managing Databases 26
3.2.3 Managing Tablespaces 29
3.2.4 Managing Tables 32
3.2.4.1 Creating a Table 32
3.2.4.2 Inserting Data to Tables 33
3.2.4.3 Updating Data in a Table 36
3.2.4.4 Viewing Data 38
3.2.4.5 Deleting Data from a Table 39
3.2.5 Querying System Catalogs 39
3.2.6 Other Operations 41

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.6.1 Managing Schemas....42
3.2.6.2 Managing Partitioned Tables....45
3.2.6.3 Managing Indexes....49
3.2.6.4 Managing Views....53
3.2.6.5 Managing Sequences....54
3.2.6.6 Managing Scheduled Jobs....56
4 Development and Design Proposal....60
4.1 Overview....60
4.2 Database Object Naming Conventions....60
4.3 Database Object Design....61
4.3.1 Database and Schema Design....61
4.3.2 Table Design....62
4.3.3 Column Design....66
4.3.4 Constraint Design....67
4.3.5 View and Joined Table Design....67
4.4 Tool Interconnection....68
4.4.1 JDBC Configuration....68
4.5 SQL Compilation....69
5 Application Development Guide....74
5.1 GaussDB Application Development Guide....74
5.2 Development Specifications....79
5.3 Development Based on JDBC....80
5.3.1 Development Process....80
5.3.2 Development Process....80
5.3.2.1 Obtaining the JAR Package of the Driver and Configuring the JDK Environment....80
5.3.2.2 Connecting to a Database....82
5.3.2.2.1 Connection Methods....82
5.3.2.2.2 Connection Parameter Reference....84
5.3.2.2.3 Connecting to a Database in Non-Encrypted Mode....124
5.3.2.2.4 Connecting to a Database in SSL Mode....129
5.3.2.2.5 Connecting to a Database in UDS Mode....130
5.3.2.2.6 Connecting to a Database in SM-based TLS Mode....131
5.3.2.3 Running SQL Statements....133
5.3.2.4 Processing Data in a Result Set....138
5.3.2.5 Closing a Database Connection....141
5.3.3 Typical Application Development Examples....141
5.3.3.1 Configuring Connection Parameters in Different Scenarios....141
5.3.3.2 Creating and Calling a Stored Procedure....143
5.3.3.3 Obtaining the Return Value of a Function....145
5.3.3.4 Batch Query....147
5.3.3.5 Using the Streaming Read Function....148
5.3.3.6 SQL Retry at an Application Layer....151

5.3.3.7 Logical Replication ... 155
5.3.3.8 Monitoring Database Connections ... 162
5.3.3.9 Using the Array Type ... 164
5.3.3.10 Using the Struct Type ... 176
5.3.4 JDBC Interface Reference ... 185
5.3.4.1 java.sql.Connection ... 185
5.3.4.2 java.sql.CallableStatement ... 195
5.3.4.3 java.sql.DatabaseMetaData ... 196
5.3.4.4 java.sql.Driver ... 205
5.3.4.5 java.sql.PreparedStatement ... 205
5.3.4.6 java.sql.ResultSet ... 209
5.3.4.7 java.sql.ResultSetMetaData ... 216
5.3.4.8 java.sql.Statement ... 217
5.3.4.9 javax.sql.ConnectionPoolDataSource ... 220
5.3.4.10 javax.sql.DataSource ... 220
5.3.4.11 javax.sql.PooledConnection ... 221
5.3.4.12 javax.naming.Context ... 221
5.3.4.13 javax.naming.spi.InitialContextFactory ... 222
5.3.4.14 CopyManager ... 222
5.3.4.15 PGReplicationConnection ... 224
5.3.4.16 PGReplicationStream ... 226
5.3.4.17 ChainedStreamBuilder ... 227
5.3.4.18 ChainedCommonStreamBuilder ... 228
5.4 Development Based on ODBC ... 229
5.4.1 Development Process ... 229
5.4.2 Development Process ... 230
5.4.2.1 Obtaining a Source Code Package, ODBC Packages, and Dependent Libraries ... 230
5.4.2.2 Connecting to a Database ... 231
5.4.2.2.1 Configuring a Data Source in the Linux OS ... 231
5.4.2.2.2 Configuring a Data Source in the Windows OS ... 244
5.4.2.2.3 APIs for Connecting to a Database ... 249
5.4.2.3 Running SQL Statements ... 250
5.4.2.4 Processing Data in a Result Set ... 251
5.4.2.5 Closing a Connection ... 252
5.4.3 Typical Application Development Examples ... 252
5.4.3.1 Typical Application Scenarios and Configurations ... 252
5.4.3.2 Obtaining and Processing Data in a Database ... 256
5.4.3.3 Batch Binding ... 258
5.4.3.4 High-Performance Binding Type ... 263
5.4.3.5 Enabling a Connection Pool ... 270
5.4.4 ODBC Interface Reference ... 273
5.4.4.1 SQLAllocEnv ... 273

6.2.3.4.9 Unique 506
6.2.3.4.10 LockRows 507
6.2.3.4.11 Materialize 509
6.2.3.4.12 Result 510
6.2.3.4.13 WindowAgg 512
6.2.3.4.14 StartWith Operator 513
6.2.3.4.15 Rownum 514
6.2.3.4.16 Unpivot 515
6.2.3.5 Distributed Operators 516
6.2.3.5.1 Data Node Scan 516
6.2.3.5.2 Streaming 517
6.2.3.5.3 Remote Query 518
6.2.3.6 Partition Pruning 519
6.2.3.6.1 Partition Iterator 519
6.2.3.7 Other Keywords 523
6.2.3.7.1 Initplan and Subplan 523
6.3 Optimization Process 524
6.4 Updating Statistics 525
6.5 Reviewing and Modifying a Table Definition 526
6.5.1 Overview 526
6.5.2 Selecting a Distribution Mode 527
6.5.3 Selecting Distribution Keys 528
6.5.4 Using Partitioned Tables 529
6.5.5 Selecting a Data Type 530
6.6 Reviewing the Plan Change Scenario 530
6.7 Typical SQL Optimization Methods 531
6.7.1 Optimizing SQL Self-Diagnosis 531
6.7.2 Optimizing Statement Pushdown 533
6.7.3 Optimizing Subqueries 545
6.7.4 Optimizing Statistics 554
6.7.5 Optimizing Operators 559
6.7.6 Optimizing Data Skew 561
6.7.7 Long-running Query and Transaction Optimization 567
6.8 Experience in Rewriting SQL Statements 568
6.9 Configuring Key Parameters for SQL Optimization 569
6.10 Hint-based Optimization 572
6.10.1 Plan Hint Optimization 572
6.10.2 Hint Specifying the Query Block Where the Hint Is Located 578
6.10.3 Hint Specifying the Query Block and Schema of a Table 581
6.10.4 Join Order Hints 582
6.10.5 Join Operation Hints 583
6.10.6 Rows Hints 584

6.10.7 Stream Operation Hints ... 586
6.10.8 Scan Hints ... 588
6.10.9 Sublink Name Hints ... 590
6.10.10 Skew Hints ... 591
6.10.11 Parameterized Path Hint ... 593
6.10.12 Hint Errors, Conflicts, and Other Warnings ... 595
6.10.13 Plan Hint Cases ... 597
6.10.14 GUC Parameter Hints ... 602
6.10.15 Hints for Selecting the Custom Plan or Generic Plan ... 603
6.10.16 Hints Specifying Not to Expand Subqueries ... 604
6.10.17 Hints Specifying Not to Use Global Plan Cache ... 605
6.10.18 Hints of Parameterized Paths at the Same Level ... 606
6.10.19 Hints for Setting Slow SQL Control Rules ... 608
6.10.20 Bitmap Scan Hints ... 609
6.10.21 Hint for Inner Table Materialization During Join ... 609
6.10.22 AGG Hint ... 610
6.10.23 Query Rewriting Hints ... 611
6.10.24 Hints for Specifying ANY Sublink Pullup ... 634
6.10.25 Hints for Specifying the Degree of Parallelism for Scans ... 635
6.10.26 Hints for Specifying Whether to Use Semi-Join ... 636
6.10.27 Hints for Specifying Whether to Use Minmax Optimization ... 637
6.10.28 Hints for Specifying Whether to Use Partition-wise Scan Optimization ... 638
6.11 Checking the Implicit Conversion Performance ... 640
6.12 Using the Vectorized Executor for Tuning ... 641
6.13 Performing Optimization with SQL Patches ... 643
6.14 Optimization Cases ... 650
6.14.1 Case: Selecting an Appropriate Distribution Key ... 650
6.14.2 Case: Creating an Appropriate Index ... 651
6.14.3 Case: Adjusting Distribution Keys ... 653
6.14.4 Case: Adjusting the GUC Parameter best_agg_plan ... 653
6.14.5 Case: Rewriting SQL Statements to Eliminate Subqueries ... 655
6.14.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference ... 656
6.14.7 Case: Rewriting SQL Statements and Deleting in-clause ... 657
6.14.8 Case: Modifying the GUC Parameter rewrite_rule ... 658
6.14.9 Case: Adjusting the GUC Parameter costbased_rewrite_rule for Cost-based Query Rewriting ... 665
6.14.10 Case: Using Global Secondary Indexes to Accelerate Query ... 682

1 Database System Overview

1.1 Database Logical Architecture

Each DN in a cluster stores data on disks. This section describes the objects on each DN from the logical view and the relationship between these objects, and how data is distributed on different nodes. **Figure 1-1** shows the database logical structure.

Figure 1-1 Database logical architecture

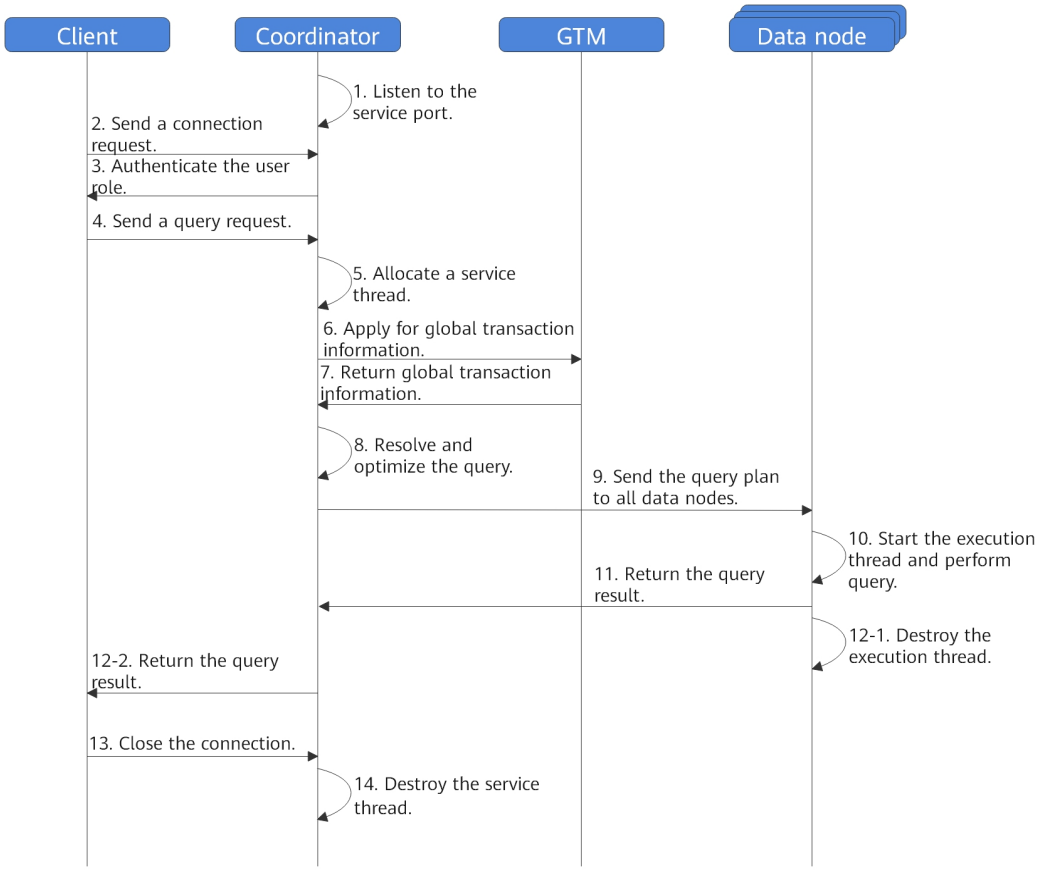
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- A tablespace is a directory. A cluster contains one or more tablespaces to store physical files of the database. Each tablespace can contain files belonging to different databases.
- A database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- A datafile segment stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The data file segments storing the data of the same table must be in the same tablespace.
- A block is a basic unit for database management. Its default size is 8 KB.
- Data can be distributed on DNs in replication, hash, range, or list mode. You can specify a mode when creating a table.

1.2 Query Request Handling Process

Figure 1-2 GaussDB service response process



1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. GaussDB supports the following transaction isolation levels: READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. SERIALIZABLE is equivalent to REPEATABLE READ.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Controlling Transactions

The following describes transaction operations supported by the database:

- Starting transactions

  You can use the START TRANSACTION or BEGIN syntax to start a transaction. For details, see **START TRANSACTION** and **BEGIN**.

- Setting transactions

  You can use the SET TRANSACTION or SET LOCAL TRANSACTION syntax to set transactions. For details, see **SET TRANSACTION**.

- Committing transactions

  You can commit all operations of a transaction using COMMIT or END. For details, see **COMMIT | END**.

- Rolling back transactions

  Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see **ROLLBACK**.

Transaction Isolation Levels

The transaction isolation level controls the processing behavior of different isolation level data when multiple transactions access the same data resource.

NOTE

The isolation level cannot be changed after the first data manipulation statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) in a transaction is executed.

- **READ COMMITTED**: At this level, a transaction can access only committed data. This is the default level.

  The SELECT statement accesses the snapshot of the database taken when the query begins. The SELECT statement can also access the data modifications in its transaction, regardless of whether they have been committed. Note that different database snapshots may be available to two consecutive SELECT statements for the same transaction, because data may be committed for other transactions while the first SELECT statement is executed.

  At the **READ COMMITTED** level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Check whether a single statement always accesses absolutely consistent data in a database.

  Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.

- **REPEATABLE READ**: At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data modifications in its transaction, regardless of whether they have been committed. **READ COMMITTED** differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the SELECT statement

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.

- **SERIALIZABLE**: Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to REPEATABLE READ.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

REPEATABLE READ is implemented based on multi-version snapshots and write skew may occur. To avoid this scenario, perform the SELECT FOR UPDATE operation on the rows involved in the transaction. An example of write skew is as follows:

Scenario 1: Table **a** has the **id** and **value** columns of the int type. Two data records are inserted. Assume that the sum of the values of the two data records must be less than or equal to 10 in the service logic of table **a**. Two transactions are concurrently started. The values are updated and modified based on the read values. After the modification, the sum of values is less than or equal to 10 in the transactions. After the modification is committed, the sum of values is 12, which violates the assumed service logic of table **a**.

```
gaussdb=# CREATE TABLE a(id int, value int);
CREATE TABLE
gaussdb=# INSERT INTO a VALUES(1,4);
INSERT 0 1
gaussdb=# INSERT INTO a VALUES(2,4);
INSERT 0 1
session1 :
gaussdb=# START TRANSACTION ISOLATION LEVEL REPEATABLE READ;
START TRANSACTION
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |     4
2 |     4
(2 rows)
gaussdb=# UPDATE a SET value = 6 WHERE id = 1;
UPDATE 1
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |     6
2 |     4
(2 rows)
session2:
gaussdb=# START TRANSACTION ISOLATION LEVEL REPEATABLE READ;
START TRANSACTION
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |     4
2 |     4
(2 rows)
gaussdb=# UPDATE a SET value = 6 WHERE id = 2;
UPDATE 1
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |     4
2 |     6
(2 rows)
session1:
gaussdb=# COMMIT;
COMMIT
session2:
gaussdb=# COMMIT;
COMMIT
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |     6
2 |     6
(2 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Scenario 2: Table **a** has the **id** and **value** columns of the int type. The **id** is the primary key. When the primary key is deleted and inserted concurrently, the values of two primary keys may be read in the transaction, violating the primary key constraint.

```
gaussdb=# CREATE TABLE a(id int PRIMARY KEY, value int);
NOTICE:  CREATE TABLE / PRIMARY KEY will create implicit index "a_pkey" for table "a"
CREATE TABLE
gaussdb=# INSERT INTO a VALUES(1,10);
INSERT 0 1
session1:
gaussdb=# START TRANSACTION ISOLATION LEVEL REPEATABLE READ;
START TRANSACTION
gaussdb=# DELETE a WHERE id = 1;
DELETE 1
session2:
gaussdb=# START TRANSACTION ISOLATION LEVEL REPEATABLE READ;
START TRANSACTION
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |    10
(1 row)
session1:
gaussdb=# COMMIT;
COMMIT
session2:
gaussdb=# INSERT INTO a VALUES(1, 100);
INSERT 0 1
gaussdb=# SELECT * FROM a;
id | value
----+-------
1 |    10
1 |   100
(2 rows)
```

1.4 Concepts

Database

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the PG_DEFAULT tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

Tablespace

In GaussDB, a tablespace is a directory storing physical files of the databases. Multiple tablespaces can coexist in a cluster. Files are physically isolated using tablespaces and managed by a file system.

Schemas

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

Users and Roles

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. Each user

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

can have only one role. In GaussDB, the difference between roles and users is that a role does not have the LOGIN permission by default. In GaussDB, you can put a user's role under a parent role for flexible management.

Transactions

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). It enables smooth data reads and writes. In GaussDB, an Astore stores historical version data together with the current tuple version. The GaussDB Astore uses a VACUUM thread instead of rollback segments to periodically delete historical version data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. The GaussDB Ustore stores historical version data to the undo rollback segments. The thread for purging undo deletes historical version data in a unified manner. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as BEGIN to explicitly start a transaction block).

2 Database Security

2.1 Users and Permissions

2.1.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, **separation of duties** is disabled after cluster installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrators can query, modify, and delete the object, and grant permissions for the object to other users through **GRANT** by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see **GRANT**.

To revoke a permission that has been granted, see **REVOKE**. Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions (SELECT, INSERT, UPDATE, and DELETE), for example, making tables read-only to themselves or others, except system administrators.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see **System Catalogs and System Views**.

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see **ALTER DATABASE**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

It is not recommended to modify the permissions on system catalogs and system views.

2.1.2 Administrators

Initial User

The account automatically generated during the cluster installation is called the initial user. The initial user is also the system administrator, security administrator, audit administrator, monitor administrator, O&M administrator, and security policy administrator. It has the highest permissions in the system and can perform all operations. If the initial username is not set during the installation, the username is the same as the name of the OS user who installs the cluster. If the password of the initial user is not set during the cluster installation, the password is empty after the installation. In this case, you need to change the password of the initial user on the gsql client before performing other operations. If the initial user password is empty, you cannot perform other SQL operations, such as upgrade, capacity expansion, and node replacement, except changing the password.

NOTE

- The OID of the initial user is 10, which can be queried in the gs_roles view.
- An initial user bypasses all permission checks. It is recommended that this user be used only as a database administrator for database management instead of service applications.

System Administrator

A system administrator is an account with the **SYSADMIN** attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the dbe_perf schema.

To create a database administrator, connect to the database as the initial user or a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **SYSADMIN** option.

```
gaussdb=# CREATE USER sysadmin WITH SYSADMIN password "********";
```

Or

```
gaussdb=# ALTER USER joe SYSADMIN;
```

When ALTER USER is executed, the user must exist.

Security Administrator

A security administrator is an account with the **CREATEROLE** attribute. It has the permission to create, modify, and delete users or roles, and grant or revoke the permission of any non-system administrator, built-in role, permanent user, or O&M administrator.

If you want to create a security administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database as a security administrator and use the **CREATE USER** or **ALTER USER** statement with the **CREATEROLE** option.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE USER createrole WITH CREATEROLE password "********";
```

Or

```
gaussdb=# ALTER USER joe CREATEROLE;
```

When ALTER USER is executed, the user must exist.

Audit Administrator

An audit administrator is an account with the **AUDITADMIN** attribute, which has the permission to view and delete audit logs.

If you want to create an audit administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database only as the initial user and use the **CREATE USER** or **ALTER USER** statement with the **AUDITADMIN** option.

```
gaussdb=# CREATE USER auditadmin WITH AUDITADMIN password "********";
```

Or

```
gaussdb=# ALTER USER joe AUDITADMIN;
```

When ALTER USER is executed, the user must exist.

Monitor Administrator

A monitor administrator is an account with the **MONADMIN** attribute and has the permission to view views and functions in the dbe_perf schema. The monitor administrator can also grant or revoke object permissions in the dbe_perf schema.

To create a monitor administrator, connect to the database as a system administrator and use the **CREATE USER** or **ALTER USER** statement with **MONADMIN** specified.

```
gaussdb=# CREATE USER monadmin WITH MONADMIN password "********";
```

Or

```
gaussdb=# ALTER USER joe MONADMIN;
```

When ALTER USER is executed, the user must exist.

O&M Administrator

An O&M administrator is an account with the **OPRADMIN** attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and use the **CREATE USER** or **ALTER USER** statement with **OPRADMIN** specified.

```
gaussdb=# CREATE USER opradmin WITH OPRADMIN password "********";
```

Or

```
gaussdb=# ALTER USER joe OPRADMIN;
```

When ALTER USER is executed, the user must exist.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Security Policy Administrator

A security policy administrator is an account with the **POLADMIN** attribute and has the permission to create resource tags, masking policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and use the **CREATE USER** or **ALTER USER** statement with **POLADMIN** specified.

```
gaussdb=# CREATE USER poladmin WITH POLADMIN password "********";
```

Or

```
gaussdb=# ALTER USER joe POLADMIN;
```

When ALTER USER is executed, the user must exist.

2.1.3 Separation of Duties

Descriptions in **Default Permission Mechanism** and **Administrators** are about the initial situation after a cluster is created. By default, system administrators with the SYSADMIN attribute have the highest permission in the system.

To avoid risks caused by centralized permissions, you can enable separation of duties to assign system administrators' user management permission to CREATEROLE and audit management permission to AUDITADMIN.

After separation of duties, system administrators do not have the CREATEROLE or AUDITADMIN attribute. That is, system administrators can neither create roles or users, nor view or maintain database audit logs. For details about the CREATEROLE and AUDITADMIN attributes, see **CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, it is recommended that this user be used only as a database administrator for database management instead of service applications.

Contact Huawei technical support before using it.

WARNING

If you need to use the separation of duties model, specify it during database initialization. You are advised not to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the SYSADMIN permission and AUDITADMIN permission, the permissions need to be tailored.

After separation of duties, system administrators do not have permissions for non-system schemas of other users. Therefore, system administrators cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 2-1** and **Table 2-2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 2-1 Default user permissions

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	Has all permissions.	Can create, modify, delete, access, or grant permissions for tablespaces.	Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted.		
Schemas		Has all permissions for all schemas except dbe_perf.	Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.		
User-defined function		Has all permissions for all user-defined functions.	Has all permissions for their own functions, and has only the call permission for other users' functions.		
User-defined table or view		Has all permissions for all user-defined tables or views.	Has all permissions for their own tables or views, but does not have permissions for other users' tables or views.		

Table 2-2 Changes in permissions after separation of duties

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Table space	N/A Has all permissions.	No change.	No change.		
Schema		Permissions reduced Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.	No change.		
User-defined function		Cannot access functions in non-system schemas of other users before being granted the permissions.	No change.		

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
User-defined table or view		Cannot access tables or views in non-system schemas of other users before being granted the permissions.	No change.		

NOTICE

PG_STATISTIC and PG_STATISTIC_EXT store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, a system administrator can still access the two system catalogs to obtain sensitive information in statistics.

2.1.4 Users

You can use CREATE USER and ALTER USER to create and manage database users, respectively. A database cluster can have one or more databases. Users and roles are shared within the entire cluster, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In modes other than **separation of duties**, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the **CREATEROLE** attribute. In separation-of-duties scenarios, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions of these objects to other users and roles. In addition to system administrators, users with the **CREATEDB** attribute can create databases and grant permissions on these databases.

Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **CREATE USER**.

  For example, create user **joe** and set the **CREATEDB** attribute for the user.

  ```
  gaussdb=# CREATE USER joe WITH CREATEDB PASSWORD "********";
  CREATE ROLE
  ```

- To create a system administrator, use the **CREATE USER** statement with the **SYSADMIN** option.
- To delete an existing user, use **DROP USER**.
- To change a user account (for example, rename the user or change the password), use **ALTER USER**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- To view a user list, query the **GS_USER** view.
  ```
  gaussdb=# SELECT * FROM gs_user;
  ```
- To view user attributes, query the **PG_AUTHID** system catalog.
  ```
  gaussdb=# SELECT * FROM pg_authid;
  ```

Permanent User

GaussDB provides a permanent user solution. You can create a permanent user with the **PERSISTENCE** attribute, which can use the service_reserved_connections channel to connect to the database.

NOTE

service_reserved_connections indicates the minimum number of connections reserved with the **PERSISTENCE** attribute. You are advised not to set this parameter to a large value.

```
gaussdb=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "********";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

2.1.5 Roles

After a role is granted to a user through GRANT, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the PUBLIC keyword in the REVOKE or GRANT statement.

To view all roles, query the system view **GS_ROLES**.

```
SELECT * FROM GS_ROLES;
```

Adding, Modifying, and Deleting Roles

In scenarios other than separation of duties, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In **separation-of-duties** scenarios, a role can be created, modified, and deleted only by an initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **CREATE ROLE**.
- To add or delete users in an existing role, use **ALTER ROLE**.
- To delete a role, use **DROP ROLE**. DROP ROLE deletes only a role, rather than member users in the role.

Built-in Roles

GaussDB provides a group of default roles whose names start with **gs_role_**. These roles are provided to access to specific, typically high-privileged operations. You

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. **Table 2-3** describes the permissions of built-in roles.

Table 2-3 Permission description of built-in roles

Roles	Permission
gs_role_signal_backend	Permission to call the pg_cancel_backend, pg_terminate_backend, and pg_terminate_session functions to cancel or terminate other sessions, or to call the pg_terminate_active_session_socket function to close active sessions and the socket connection of the client. However, this role cannot perform operations on sessions of the initial user or **PERSISTENCE** user.
gs_role_tablespace	Permission to create a tablespace.
gs_role_replication	Permission to call logical replication functions, such as kill_snapshot, pg_create_logical_replication_slot, pg_create_physical_replication_slot, pg_drop_replication_slot, pg_replication_slot_advance, pg_create_physical_replication_slot_extern, pg_logical_slot_get_changes, pg_logical_slot_peek_changes, pg_logical_slot_get_binary_changes, and pg_logical_slot_peek_binary_changes.
gs_role_account_lock	Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or users with the **PERSISTENCE** attribute.
gs_role_pldebugger	Permission to debug functions in **dbe_pldebugger**.
gs_role_public_dblink_drop	Permission to delete public database links.
gs_role_public_dblink_alter	Permission to modify public database links.
gs_role_seclabel	Permission to create, delete, and apply security labels.
gs_role_public_synonym_create	Permission to create public synonyms.
gs_role_public_synonym_drop	Permission to delete public synonyms.

The restrictions on built-in roles are as follows:

- The role names starting with **gs_role_** are reserved for built-in roles in the database. Do not create users, roles, or schemas starting with **gs_role_** or rename existing users, roles, or schemas to names starting with **gs_role_**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Do not perform ALTER or DROP operations on built-in roles.
- By default, built-in roles do not have the LOGIN permission and do not have preset passwords.
- The gsql meta-commands **\du** and **\dg** do not display information about built-in roles. However, if **pattern** is set to a specific built-in role, the information is displayed.
- When separation of duties is disabled, the initial user, users with the SYSADMIN permission, and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. When separation-of-duties is enabled, the initial user and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. For example:

```
GRANT gs_role_signal_backend TO user1;
REVOKE gs_role_signal_backend FROM user1;
```

2.1.6 Schemas

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the USAGE permission on this schema. In addition, each database has a pg_catalog schema, which contains system catalogs and all built-in data types, functions, and operators. Only the system administrator and initial user can create functions, stored procedures, and synonyms under the public and pg_catalog schemas. Other users cannot create these objects even if they are granted with the CREATE permission on the public and pg_catalog schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects under the pg_catalog schema.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both a_schema and b_schema can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see **Search Path**.

Creating, Modifying, and Deleting Schemas

- To create a schema, use **CREATE SCHEMA**. By default, the initial user and system administrator can create schemas. Other users can create schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in **GRANT**.
- To change the name or owner of a schema, use **ALTER SCHEMA**. The schema owner can change a schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- To delete a schema and its objects, use **DROP SCHEMA**. The schema owner can delete a schema.
- To create a table in a schema, use the *schema_name*.*table_name* format to specify the table. If *schema_name* is not specified, the table will be created in the first schema in **search path**.
- To view the owner of a schema, perform the following join query on the system catalog **PG_NAMESPACE** and the system view **GS_USER**. Replace *schema_name* in the statement with the name of the schema to be queried.

```
gaussdb=# SELECT s.nspname,u.usename AS nspowner FROM pg_namespace s, gs_user u WHERE
nspname='schema_name' AND s.nspowner = u.usesysid;
```

- To view a list of all schemas, query the system catalog PG_NAMESPACE.

```
gaussdb=# SELECT * FROM pg_namespace;
```

- To view a list of tables in a schema, query the system catalog **PG_TABLES**. For example, the following query will return a table list from PG_CATALOG in the schema.

```
gaussdb=# SELECT distinct(tablename),schemaname from pg_tables where schemaname =
'pg_catalog';
```

Search Path

A search path is defined in the GUC parameter **search_path**. The parameter value is a list of schema names separated by commas (,). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **SHOW**.

```
gaussdb=# SHOW SEARCH_PATH;
 search_path
----------------
 "$user",public
(1 row)
```

  The default value of **search_path** is **"***$user***",public**. *$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added only to the public schema.

- To change the default schema of the current session, run the SET statement.

  Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```

2.1.7 User Permissions

- To grant permissions for an object to a user, use **GRANT**.

  When permissions for a table or view in a schema are granted to a user or role, the USAGE permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

  In the following example, permissions for the schema tpcds are first granted to user **joe**, and then the SELECT permission for the **tpcds.web_returns** table is also granted:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.

  a. Create a role.

     Create a role **lily** and grant the system permission CREATEDB to the role.

     ```
     gaussdb=# CREATE ROLE lily WITH CREATEDB PASSWORD "********";
     ```

  b. To grant object permissions to a role, use **GRANT**.

     For example, first grant permissions for the schema tpcds to the role **lily**, and then grant the SELECT permission of the **tpcds.web_returns** table to **lily**.

     ```
     gaussdb=# GRANT USAGE ON SCHEMA tpcds TO lily;
     gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to lily;
     ```

  c. Grant the role permissions to a user.

     ```
     gaussdb=# GRANT lily to joe;
     ```

     NOTE

     When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **REVOKE**.

2.1.8 Row-Level Security Policy

The row-level security feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level security policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if an SQL statement meets the specified row-level security policies of the data table, the expressions that meet the specified condition will be combined by using AND or OR based on the attribute type (PERMISSIVE | RESTRICTIVE) and applied to the execution plan in the query optimization phase.

Row-level security policy is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include SELECT, UPDATE, and DELETE.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.
gaussdb=# CREATE USER alice PASSWORD '********';
gaussdb=# CREATE USER bob PASSWORD '********';
gaussdb=# CREATE USER peter PASSWORD '********';

-- Create the all_data table that contains user information.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Grant the read permission for the all_data table to users alice, bob, and peter.
gaussdb=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);

-- View table details.
gaussdb=# \d+ all_data
                          Table "public.all_data"
 Column |          Type          | Modifiers | Storage  | Stats target | Description
--------+------------------------+-----------+----------+--------------+-------------
 id     | integer                |           | plain    |              |
 role   | character varying(100) |           | extended |              |
 data   | character varying(100) |           | extended |              |
Row Level Security Policies:
    POLICY "all_data_rls" FOR ALL
      TO public
      USING (((role)::name = "current_user"()))
Has OIDs: no
Distribute By: HASH(id)
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
 id | role  |    data
----+-------+------------
  1 | alice | alice data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;

 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on all_data
         Filter: ((role)::name = 'alice'::name)
 Notice: This query is influenced by row level security feature
(5 rows)

-- Switch to user peter and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
 id | role  |    data
----+-------+------------
  3 | peter | peter data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
                        QUERY PLAN
-----------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on all_data
         Filter: ((role)::name = 'peter'::name)
 Notice: This query is influenced by row level security feature
(5 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- PG_STATISTIC and PG_STATISTIC_EXT store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain sensitive information in the statistical objects.
- PG_STATS, PG_EXT_STATS, and PG_GTT_STATS are statistics views and require that users have the SELECT permission on columns. If a common user has the SELECT permission and row-level security is configured on the table to query, the common user may retrieve some data that should not be retrieved but happens to be MCVs in the statistics views (not a whole row but a certain column value because the statistics are collected and calculated by column.)

2.2 Database Audit

Context

Database audit is critical to the security of the database system. Database audit administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to know the following about the audit function:

- The overall audit parameter **audit_enabled** supports dynamic loading. If you change the configuration when the database is running, the change takes effect immediately and you do not need to restart the database. Its default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit configuration, each audit item can be independently configured. The function of each audit item takes effect only after the configuration is enabled.
- The configuration of each audit item supports dynamic loading. If you change the audit configuration when the database is running, the change takes effect immediately and you do not need to restart the database.

Table 2-4 describes the audit items supported by GaussDB. If you need to modify a specific audit configuration item, contact an administrator.

Table 2-4 Audit items

Configuration Item	Description
User login and logout audit	Parameter: **audit_login_logout** Its default value is **7**, which indicates that the function of user login and logout audit is enabled. **0** indicates that the function of user login and logout audit is disabled. Other values are not recommended.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Description
Database startup, stop, recovery, and switchover audit	Parameter: **audit_database_process** Its default value is **1**, which indicates that the audit of database startup, stop, recovery, and switchover is enabled.
User locking and unlocking audit	Parameter: **audit_user_locked** Its default value is **1**, which indicates that the audit of user locking and unlocking is enabled.
Unauthorized access audit	Parameter: **audit_user_violation** Its default value is **0**, which indicates that the audit of unauthorized access disabled.
Permission granting and revoking audit	Parameter: **audit_grant_revoke** Its default value is **1**, which indicates that the audit of permission granting and revoking is enabled.
Full audit of user operations	Parameter: **full_audit_users** Its default value is an empty string, indicating that the default configuration is used and no full audit of user operations is configured.
Names and IP addresses of clients that do not need to be audited	Parameter: **no_audit_client** Its default value is an empty string, indicating that the default configuration is used and no clients and IP addresses are added to the audit blacklist.
Audit of CREATE, ALTER, and DROP operations on database objects	Parameter: **audit_system_object** Its default value is **67121159**, which indicates that the CREATE, ALTER, and DROP operations only on databases, schemas, users, and node groups are audited.
Audit of INSERT, UPDATE, and DELETE operations on a specific table	Parameter: **audit_dml_state** Its default value is **0**, which indicates that the audit of DML operations (except SELECT) on a specific table is disabled.
SELECT operation audit	Parameter: **audit_dml_state_select** Its default value is **0**, which indicates that the audit of the SELECT operation is disabled.
COPY operation audit	Parameter: **audit_copy_exec** Its default value is **1**, which indicates that the audit of COPY operations is enabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Configuration Item	Description
Audit of execution of stored procedures and user-defined functions	Parameter: **audit_function_exec** Its default value is **0**, which indicates that no execution audit logs of stored procedures and user-defined functions are recorded.
Audit of system functions in the whitelist	Parameter: **audit_system_function_exec** Its default value is **0**, which indicates that audit logs of system function execution are not recorded.
SET operation audit	Parameter: **audit_set_parameter** Its default value is **0**, which indicates that the audit of the SET operation is disabled.
Transaction ID record	Parameter: **audit_xid_info** Its default value is **0**, which indicates that the function of recording transaction IDs in audit logs is disabled.
Audit of internal tool connections and operations, and audit of logins and logouts from CNs on DNs	Parameter: **audit_internal_event** The default value is **off**, which indicates that the logins, logouts, and operations of internal tools CM Agent, gs_clean, and WDRXdb are not audited. In addition, the logins and logouts from CNs are not audited on DNs.

3 Database Quick Start

3.1 Connecting to a Database

Client tools used for connecting to a database include **gsql** and APIs (such as **ODBC** and **JDBC**).

- **gsql** is a client tool provided by GaussDB. As described in **Using gsql to Connect to a Database**, **gsql** is used to enter, edit, and run SQL statements in an interactive manner.
- As described in **APIs**, you can use standard database APIs, such as **ODBC** and **JDBC**, to develop GaussDB-based applications.

3.1.1 Using gsql to Connect to a Database

gsql is a database connection tool running in the CLI provided by GaussDB. gsql provides basic and advanced functions of databases to facilitate user operations. This section describes how to use gsql to connect to a database. For details about how to use gsql, see "Database Connection Tools > gsql for Connecting to a Database" in *Tool Reference*.

Precautions

By default, when a client has been idle for the period specified by GUC parameter **session_timeout** after connecting to a database, the client automatically disconnects from the database. To disable the timeout setting, set GUC parameter **session_timeout** to **0**.

Prerequisites

You have contacted the administrator for connection information.

Remotely Connecting to a Database

Step 1 Contact an administrator to configure the remote connection.

Step 2 On the host, upload the client tool package and configure environment variables for the gsql client.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. Log in to the client.
2. Create the **/tmp/tools** directory. (The **/tmp/tools** directory is only an example. You can also create another directory.)
   ```
   mkdir /tmp/tools
   ```
3. Obtain the tool package **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_gsql.tar.gz** from the software installation package and upload it to the **/tmp/tools** directory.

   NOTE

   - The software package is located where you put it before installation. Set it based on the actual situation.
   - The tool package name may vary in different OSs. Select the tool package suitable for your OS.
4. Decompress the package.
   ```
   cd /tmp/tools
   tar -zxvf GaussDB-Kernel_Database version number_OS version number_64bit_gsql.tar.gz
   ```
5. Set environment variables.

   Open the **~/.bashrc** file.

   ```
   vi ~/.bashrc
   ```

   Enter the following content and run **:wq!** to save and exit:

   ```
   export PATH=/tmp/tools/bin:$PATH
   export LD_LIBRARY_PATH=/tmp/tools/lib:$LD_LIBRARY_PATH
   ```
6. Make the environment variables take effect.
   ```
   source ~/.bashrc
   ```

Step 3 Connect to a database.

After the database is installed, a database named **postgres** is generated by default.

```
gsql -d postgres -h 10.10.0.11 -U jack -p 8000
Password for user jack:
```

postgres is the name of the database to be connected, **10.10.0.11** is the IP address of the server where the CN resides, **jack** is the username for logging in to the database, **8000** is the port number of the CN. The IP address and port number of the connected server can be replaced with those of the server where the DN resides. gsql allows you to use domain names instead of IP addresses.

In a multi-CN database environment, if you want to skip a faulty CN, you can use gsql to connect to a normal CN.

For example, if there are three CNs in a database instance, and the IP addresses and port numbers of the three CNs are **10.10.0.11:8000**, **10.10.0.12:8002**, and **10.10.0.13:8004**, respectively, you run the following command:

```
gsql -d postgres -h 10.10.0.11,10.10.0.12,10.10.0.13 -U jack -p 8000,8002,8004
```

gsql connects to the three IP addresses and port numbers in sequence. If any CN is not normal, gsql attempts to connect to the next IP address and port number until it successfully connects to a normal CN. You can set the value of the *PGTARGETSESSIONATTRS* environment variable to connect to different types of nodes. For more information, see the description of the **host** parameter in section "Database Connection Tools > gsql for Connecting to a Database" in *Tool Reference*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following command demonstrates how to use an IPv6 address to connect to a database:

```
gsql -d postgres -h 2407:c182:14f0:594:er63:49c5:493q:594c -U jack -p 8000
```

NOTE

- In the preceding example, user **jack** is a common user created by the database initial user.
- By default, the initial user of the database is not allowed to remotely connect to the database. If Kerberos authentication is enabled in a cluster, the initial user is allowed to remotely connect to the database in the cluster.

----End

3.1.2 APIs

You can use standard database APIs, such as ODBC and JDBC, to develop GaussDB-based applications.

Supported APIs

Each application is an independent GaussDB development project. APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability. **Table 3-1** lists the APIs supported by GaussDB and the download addresses.

Table 3-1 Database APIs

API	How to Obtain
ODBC	• Linux: Driver: **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Odbc.tar.gz** unixODBC source code package: **https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gz** • Windows: Driver: **GaussDB-Kernel**_*Database version number*_**Windows_Odbc.tar.gz**
JDBC	• Driver: **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Jdbc.tar.gz** • Driver: **com.huawei.gaussdb.jdbc.Driver**

The JDBC and ODBC APIs are used to connect to the database remotely. Therefore, you need to configure a remote connection in GaussDB. Contact an administrator for related operations.

For details about more APIs, see **Application Development Guide**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2 Operating a Database

This section explains how to use databases, including creating database accounts, databases, and tables, inserting data to tables, and querying data in tables.

3.2.1 Creating a Database Account

Only administrators that are created during the cluster installation can access the initial database by default. You can also create other database users.

```
gaussdb=# CREATE USER joe WITH PASSWORD '********';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

In this case, you have created a user account named **joe**, and the user password is **********. Set user **joe** as a system administrator.

```
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see **GRANT**.

NOTE

For more information about database users, see **Users and Permissions**.

3.2.2 Managing Databases

Figure 3-1 Creating and Managing Databases

```
CREATE DATABASE
gaussdb=# \l
                                  List of databases
     Name     | Owner | Encoding  | Collate | Ctype | Access privileges
--------------+-------+-----------+---------+-------+-------------------
 db_test      | omm   | SQL_ASCII | C       | C     |
 db_tpcc      | omm   | SQL_ASCII | C       | C     |
 postgres     | omm   | SQL_ASCII | C       | C     |
 template0    | omm   | SQL_ASCII | C       | C     | =c/omm           +
              |       |           |         |       | omm=CTc/omm
 template1    | omm   | SQL_ASCII | C       | C     | =c/omm           +
              |       |           |         |       | omm=CTc/omm
 template_pdb | omm   | SQL_ASCII | C       | C     |
 templatea    | omm   | SQL_ASCII | C       | C     |
 templatem    | omm   | SQL_ASCII | C       | C     | =c/omm           +
              |       |           |         |       | omm=CTc/omm
 testdb2      | jim   | SQL_ASCII | C       | C     |
(9 rows)

gaussdb=# ALTER DATABASE db_tpcc RENAME TO human_tpcds;
ALTER DATABASE
gaussdb=# DROP DATABASE human_tpcds;
DROP DATABASE
gaussdb=#
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prerequisites

You must have the permission to create a database or the SYSADMIN permission. For details about how to grant permissions, see **Users and Permissions**.

Context

- GaussDB has four default template databases **template0**, **template1**, **templatea**, and **templatem**, and a default user database **postgres**.
- CREATE DATABASE creates a database by copying a template database By default, **template0** is copied. Do not use a client or other methods to connect to or operate the two template databases.

  NOTE

  - The template database does not contain any user table. You can view the attributes of the template database in the PG_DATABASE system catalog.
  - The **template0** and **templatea** templates do not allow user connections. Only the initial user of the database and system administrators can connect to **template1** and **templatem**.
  - **templatem** is a database name reserved by the system and cannot be a name of database created by users.
  - The name of **templatea** or **templatem** cannot be changed.
- A database system consists of multiple databases. A client can connect to only one database at a time. Currently, cross-database query or cross-database transaction is not supported.
- If multiple databases exist in the database cluster, you can use the **-d** parameter of the client tool gsql to specify the target database for login. Alternatively, you can run the **\c** command to switch the database after the client program logs in to the database.

Precautions

Assume that the database encoding is SQL_ASCII. (You can run the **show server_encoding** command to query the encoding used for storing data in the current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Use UTF-8 as the default database storage code set (server_encoding).
- Exclude multi-byte characters from object names.
- If you fail to delete an object whose name is truncated mistakenly, specify its original name to delete it, or manually delete it from the corresponding system catalog on each node.

Procedure

Step 1 Create a database named **db_tpcds**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE DATABASE db_tpcds;
CREATE DATABASE
gaussdb=# CREATE DATABASE db_tpcc1 TEMPLATE templatea;
CREATE DATABASE
```

NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.
- New databases are created in the pg_default tablespace by default. Specify another tablespace.

  ```
  gaussdb=# CREATE DATABASE db_tpcds WITH TABLESPACE = hr_local;
  CREATE DATABASE
  ```

  hr_local indicates the tablespace name. For details about how to create a tablespace, see **Managing Tablespaces**.
- After creating the **db_tpcds** database, you can perform other operations in the default **postgres** database. Alternatively, you can perform the following operations to exit the **postgres** database, connect to the **db_tpcds** database as a new user, and perform operations such as creating tables:

  ```
  gaussdb=# \q
  gsql -d db_tpcds -p 8000 -U joe
  Password for user joe:
  gsql((GaussDB Kernel XXX.XXX.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit
  2935 last mr 6385 release)
  Non-SSL connection (SSL connection is recommended when requiring high-security)
  Type "help" for help.
  ```

Step 2 View databases.

- Run the **\l** meta-command to view the database list of the database system.

  ```
  gaussdb=# \l
  ```
- Query the database list in the pg_database system catalog.

  ```
  gaussdb=# SELECT datname FROM pg_database;
  ```

Step 3 Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Rename the database.

  ```
  gaussdb=# ALTER DATABASE db_tpcds RENAME TO human_tpcds;
  ALTER DATABASE
  ```

NOTE

After setting the parameters, you need to manually run the **CLEAN CONNECTION** command to clear the old connections. Otherwise, the parameter values between nodes may be inconsistent.

Step 4 Drop the database.

You can run the command in **DROP DATABASE** to drop a database. This command removes the database system catalog and permanently deletes the data

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

files on the disk. Only the database owner or users with the SYSADMIN permission can perform the drop operation. If there are active database connections, the drop operation will fail. Ensure that you have connected to other databases before performing the drop operation.

Drop the database.

```
gaussdb=# DROP DATABASE human_tpcds;
DROP DATABASE
```

----End

3.2.3 Managing Tablespaces

Figure 3-2 Creating and Managing Tablespaces

```
gaussdb=# CREATE TABLESPACE tbs_t1 RELATIVE LOCATION 'tablespace/tbs_t1';
CREATE TABLESPACE
gaussdb=# CREATE TABLE foo(i int) TABLESPACE tbs_t1;
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# \db
         List of tablespaces
    Name    | Owner |     Location
------------+-------+------------------
 pg_default | omm1  |
 pg_global  | omm1  |
 tbs_t1     | omm1  | tablespace/tbs_t1
 ts_t1      | omm1  | tablespace/ts_t1
(4 rows)

gaussdb=# ALTER TABLESPACE tbs_t1 RENAME TO fspace;
ALTER TABLESPACE
gaussdb=# DROP TABLE foo;
DROP TABLE
gaussdb=# DROP TABLESPACE fspace;
DROP TABLESPACE
gaussdb=#
```

Context

The administrator can use tablespaces to control the layout of disks where a database is installed. The advantages are as follows:

- If the disk partition or tablespace initially allocated to the database is full and the space cannot be logically extended, you can create and use tablespaces in other partitions until the system space is reconfigured.
- Tablespaces allow the administrator to distribute data based on the schema of database objects, improving system performance.
  - A frequently used index can be stored in a disk having stable performance and high computing speed, such as a solid-state device.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.

- You can use tablespaces to limit the disk space of databases. If a tablespace shares a partition with other tablespaces, the tablespace will never occupy the space allocated to other tablespaces.
- You can use tablespaces to manage the disk space used to store database data. The database will switch to the read-only mode when the disk usage of the tablespace reaches the value of the CM server parameter **datastorage_threshold_value_check**. Once the disk usage drops below the value of **datastorage_threshold_value_check**, the database will be restored to the read/write mode. The automatic disk check function of the CM component is enabled by default. If the function is disabled, contact the administrator to enable it.
- Each tablespace corresponds to a file system directory. If you have read and write permissions on an empty directory, such as *data directory*/**pg_location/mount1/path1**, you can create an absolute path tablespace in this directory.

  If **MAXSIZE** is used to manage tablespace quotas, the concurrent insertion performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each each DN. The difference between the actual tablespace capacity of each DN and the specified quota should be within 500 MB. Determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: pg_default and pg_global.

- Default tablespace pg_default: stores non-shared system catalogs, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the base directory in the instance data directory.
- Shared tablespace pg_global: stores shared system catalogs. The corresponding storage directory is the base directory in the global data directory.

Precautions

- You are advised not to use user-defined tablespaces in .

  This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media in . If the user-defined tablespace is not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.
- In the primary/standby environment, do not specify a file system directory with insufficient permissions on the standby node when creating a tablespace.

Procedure

Step 1 Create a tablespace.

1. Create user **jack** and set the password to *********.

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*********';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

2. Create a tablespace.

```
gaussdb=# CREATE TABLESPACE fastspace RELATIVE LOCATION 'my_tablespace/tablespace1';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

fastspace is the new tablespace, and *CN/DN data directory*/**pg_location/my_tablespace/tablespace1** is an empty directory on which users have read and write permissions.

3. Grant the permission of accessing the **fastspace** tablespace to user **jack** as a database system administrator.

```
gaussdb=# GRANT CREATE ON TABLESPACE fastspace TO jack;
```

If the following information is displayed, the grant operation is successful:

```
GRANT
```

Step 2 Create an object in a tablespace.

If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

Objects can be created in a tablespace in either of the following methods (take creating a table as an example):

- Create a table in a specified tablespace.

```
gaussdb=# CREATE TABLE foo(i int) TABLESPACE fastspace;
```

If the following information is displayed, the creation is successful:

```
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

- Run **set default_tablespace** to set the default tablespace and then create a table.

```
--- In this example, fastspace is the default tablespace, and foo2 is the created table.
gaussdb=# SET default_tablespace = 'fastspace';
SET
gaussdb=# CREATE TABLE foo2(i int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'i' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
```

Step 3 Query a tablespace.

You can query a tablespace in either of the following methods:

- Check the pg_tablespace system catalog. View all the tablespaces defined by the system and users.

```
gaussdb=# SELECT spcname FROM pg_tablespace;
```

- Run the meta-command provided by gsql to query the tablespace.

```
gaussdb=# \db
```

Step 4 Query the tablespace usage.

1. Query the current usage of the tablespace.

```
gaussdb=# SELECT pg_tablespace_size('fastspace');
```

Information similar to the following is displayed:

```
 pg_tablespace_size
--------------------
            2146304
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2146304 is the size of the tablespace, and its unit is byte.

2. Calculate the tablespace usage.

   Tablespace usage = Value of **pg_tablespace_size**/Size of the disk where the tablespace resides

Step 5 Modify a tablespace.

Rename tablespace **fastspace** to **fspace**.

```
gaussdb=# ALTER TABLESPACE fastspace RENAME TO fspace;
ALTER TABLESPACE
```

Step 6 Drop a tablespace.

1. Delete user **jack**.

   ```
   gaussdb=# DROP USER jack CASCADE;
   DROP ROLE
   ```

2. Delete tables **foo** and **foo2**.

   ```
   gaussdb=# DROP TABLE foo;
   gaussdb=# DROP TABLE foo2;
   ```

   If the following information is displayed, the deletion is successful:

   ```
   DROP TABLE
   ```

3. Drop tablespace **fspace**.

   ```
   gaussdb=# DROP TABLESPACE fspace;
   DROP TABLESPACE
   ```

   NOTE

   Only the tablespace owner or system administrators can drop a tablespace.

----End

3.2.4 Managing Tables

3.2.4.1 Creating a Table

Context

A table is created in a database and can be stored in different databases. Tables under different schemas in a database can have the same name.

Creating a Table

Create a table.

```
gaussdb=# CREATE TABLE customer_t1
(
    c_customer_sk             integer,
    c_customer_id             char(5),
    c_first_name              char(6),
    c_last_name               char(8)
)
DISTRIBUTE BY HASH (c_last_name);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

c_customer_sk, **c_customer_id**, **c_first_name**, and **c_last_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are types of the four columns.

NOTE

- By default, new database objects are created in the $user schema. For more details about schemas, see **Managing Schemas**.
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs. For details, see **Querying System Catalogs**.
- For more details about how to create a table, see **CREATE TABLE**.

3.2.4.2 Inserting Data to Tables

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data by running the command in **INSERT** and to insert data from a specified table. Contact an administrator if a large amount of data needs to be imported.

Context

In case of different character sets used on the client and server, the length of a character on both ends may differ. A string entered on the client will be processed based on the server's character set, and therefore the result may differ from the expected result.

Table 3-2 Comparison of outputs varying depending on character sets on the client and server

Procedure	Same Encoding on the Server and Client	Different Encoding on the Server and Client
No operations are performed on the string while it is saved and read.	Your expected result is returned.	Your expected result is returned (only if the encoding on the client remains unchanged).
Operations (such as executing string functions) are performed on the string while it is saved and read.	Your expected result is returned.	The result may differ from the expected result, depending on the operations performed on the string.
An ultra long string is truncated while it is saved.	Your expected result is returned.	If the character sets used on the client and server have different character length, the result may differ from the expected result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The preceding string function operations and the automatic truncation mechanism may affect each other. For example, if the character sets of the client and server are inconsistent, and both the string function operations and automatic truncation mechanism exist, the system continues to perform secondary truncation after the string processing is complete. As a result, unexpected results occur. For details, see **Table 3-3**.

NOTE

Ultra long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** (compatible with Teradata) and the GUC parameter **td_compatible_truncation** is set to **on**.

Create **table1** and **table2** to be used in the examples.

```
gaussdb=# CREATE TABLE table1(id int, a char(6), b varchar(6),c varchar(6));
gaussdb=# CREATE TABLE table2(id int, a char(20), b varchar(20),c varchar(20));
```

Table 3-3 Examples

No.	1	2	3	4
Character Set on the Server	SQL_ASCII	SQL_ASCII	SQL_ASCII	SQL_ASCII
Character Set on the Client	UTF8	UTF8	UTF8	UTF8
Automatic Truncation Enabled	Yes	Yes	Yes	No

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description	A string is reversed on the server and then truncated. Because character sets used by the server and client are different, character A is displayed in multiple bytes on the client and the result is unexpected.	A string is reversed and then automatically truncated. Therefore, the result is unexpected.	The column length in the string type is an integer multiple of the length in client character encoding. Therefore, the result is as expected after truncation.	Similar to the first example, multi-byte characters are different from the original characters after being reversed.

Procedure

Create a table before inserting data to it. For details about how to create a table, see **Managing Tables**.

- Insert a row to table **customer_t1**.

  Data values are arranged in the same order as the columns in the table and are separated by commas (,). Data values are usually text (constants), but expressions are also allowed.

  ```
  gaussdb=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
  ```

  If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

  ```
  gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
  ```

  If you do not know some of the column values, you can omit them. In the INSERT statement, if the column name of the specified target table is not displayed, the values to be inserted in the VALUES clause correspond to the columns of the target table based on the column number. That is, the first value in the VALUES clause corresponds to the first column of the target table, the second value of the VALUES clause corresponds to the second column of the target table, and so on. Columns that do not have corresponding values in the VALUES clause are automatically filled with default values or NULL. If no value is specified for a column, the column is set to the default value. For example:

  ```
  gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');

  gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello');
  ```

  You can also specify the default value of a column or row.

  ```
  gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);

  gaussdb=# INSERT INTO customer_t1 DEFAULT VALUES;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Insert multiple rows to a table.

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES
    (6885, 'maps', 'Joes'),
    (4321, 'tpcds', 'Lily'),
    (9527, 'world', 'James');
```

  You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

- Assume that you have created a backup table **customer_t2** for table **customer_t1**. To insert data from **customer_t1** to **customer_t2**, run the following commands:

```
gaussdb=# CREATE TABLE customer_t2
(
    c_customer_sk             integer,
    c_customer_id             char(5),
    c_first_name              char(6),
    c_last_name               char(8)
);

gaussdb=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

  NOTE

  If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- Use a table alias without AS to insert data into the table.

```
gaussdb=# CREATE TABLE table_name(a int,b text,c timestamp,d float);
gaussdb=# INSERT INTO table_name alias_name VALUES(1,'ha','1997-01-01
10:00:00'::timestamp,1.234);
gaussdb=# INSERT INTO table_name alias_name(b,c,d) VALUES('ha','1997-01-01
10:00:00'::timestamp,1.234);
```

  NOTE

  - When the INSERT statement is used without AS, the table alias cannot be a keyword (such as SELECT or VALUE) or an expression. The alias must comply with the identifier naming rule.
  - When the INSERT statement is used without AS, the table alias does not support this format: INSERT INTO table_name alias_name(alias_name.col1,...,alias_name.coln) VALUES(xxx).
  - When the INSERT statement is used without AS, data cannot be inserted to the specified partition.

- Drop a backup table.

```
gaussdb=# DROP TABLE customer_t2 CASCADE;
```

  NOTE

  If the table to be deleted is dependent on other tables, you need to delete the corresponding tables first.

3.2.4.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following information is required when the UPDATE statement is used to update rows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Table name and column name of the data to be updated
- New column value
- Rows to be updated

SQL does not provide a unique identifier for data rows. Therefore, the WHERE clause is used to locate the target row. If a primary key is defined in a table, the primary key value can be used to accurately specify the row to be updated. Otherwise, the update must depend on the combination of service logic conditions.

For details about how to create a table and insert data to it, see **Creating a Table** and **Inserting Data to Tables**.

The value of **c_customer_sk** in the table **customer_t1** must be changed from **9527** to **9876**.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

The table name can also be qualified with a schema name. Otherwise, the table is queried from the default schema of the database. SET is followed by the column and the new column value. The new column value can be a constant or an expression.

For example, increase all the values in the **c_customer_sk** column by 100.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

This statement does not contain the WHERE clause, and therefore all rows are updated. If the statement contains the WHERE clause, only the rows matching the clause are updated.

In the SET clause, the equal sign (=) indicates value setting. In the WHERE clause, the equal sign indicates comparison. A WHERE condition does not have to be an equality comparison, and can be another operator.

You can use an UPDATE statement to update multiple columns by specifying multiple values in the SET clause, for example:

```
gaussdb=# UPDATE customer_t1 SET  c_customer_id = 'Admin', c_first_name = 'Local' WHERE
c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks may greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically run **VACUUM FULL** to ensure the query performance.

Updating Data in a Table in Batches

When you update a table that contains millions of records in batches, the table will be locked if you directly perform the update operation, which significantly affects the performance of other operations. To avoid this, you can use the following methods to optimize batch update operations:

- Updating data in batches

  You can split a large-scale update into multiple small batches. Only some data is updated each time to shorten the time for locking a table at a time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For example, the original batch update statement is UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics';

Optimization solution: Split the batch update statement into multiple UPDATE statements by ID and update some data each time.

```
gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id >= 1 and id <= 10000;
gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id > 10000 and id <= 20000;
gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id > 20000 and id <= 30000;
...
```

- Using a temporary table

  If a transaction contains complex queries, you can insert the records to be updated into a temporary table and then update the main table from the temporary table to prevent the data rows from being locked for a long time.

  For example, the original batch update statement is UPDATE products SET price = price * 1.1 WHERE (size = 101 OR size = 102) AND categroy = 'Electronics' AND amount > 150;

  Optimization solution: Create a temporary table to store the target records that meet the conditions, update the records, and then update the main table from the temporary table.

  ```
  gaussdb=# CREATE TEMPORARY TABLE temp_products AS SELECT id, price * 1.1 as new_price from products WHERE (size = 101 OR size = 102) AND categroy = 'Electronics' AND amount > 150;
  gaussdb=# UPDATE products p SET price = t.new_price FROM temp_products t where p.id = t.id;
  gaussdb=# DROP TABLE temp_products;
  ```

- Using parallel updates

  In a multi-thread or multi-process environment, you can update records in parallel, that is, multiple threads update different records at the same time. This requires that the records processed by each thread do not overlap.

  For example, the original batch update statement is UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics';

  Optimization solution: Split the data into multiple small batches by ID, start multiple sessions to execute the UPDATE operation at the same time, and reduce the total time required for batch operations through parallel updates. Ensure that the tuples updated by each session do not overlap.

  session1:

  ```
  gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id >= 1 and id <= 10000;
  ```

  session2:

  ```
  gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id > 10000 and id <= 30000;
  ```

  session3:

  ```
  gaussdb=# UPDATE products SET price = price * 1.1 WHERE categroy = 'Electronics' AND id > 30000;
  ```

3.2.4.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg_tables**:
  ```
  gaussdb=# SELECT * FROM pg_tables;
  ```
- Run the **\d+** command of the **gsql** tool to query table attributes:
  ```
  gaussdb=# \d+ customer_t1
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Run the following command to query the data volume of table **customer_t1**:
  ```
  gaussdb=# SELECT count(*) FROM customer_t1;
  ```
- Run the following command to query all data in the table **customer_t1**:
  ```
  gaussdb=# SELECT * FROM customer_t1;
  ```
- Run the following command to query only the data in the column **c_customer_sk**:
  ```
  gaussdb=# SELECT c_customer_sk FROM customer_t1;
  ```
- Run the following command to filter repeated data in the column **c_customer_sk**:
  ```
  gaussdb=# SELECT DISTINCT( c_customer_sk ) FROM customer_t1;
  ```
- Run the following command to query all data whose column **c_customer_sk** is **3869**:
  ```
  gaussdb=# SELECT * FROM customer_t1 WHERE c_customer_sk = 3869;
  ```
- Run the following command to collate data based on the column **c_customer_sk**:
  ```
  gaussdb=# SELECT * FROM customer_t1 ORDER BY c_customer_sk;
  ```

3.2.4.5 Deleting Data from a Table

Expired data may need to be deleted from a table being used. In this case, you must delete the entire row from the table.

In SQL, you can only access and delete an independent row by declaring conditions. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

For example, delete all the rows whose **c_customer_sk** column is **3869** from the table **customer_t1**.

```
gaussdb=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

Run the following command to delete all rows from the table:

```
gaussdb=# DELETE FROM customer_t1;
```

Or

```
gaussdb=# TRUNCATE TABLE customer_t1;
```

NOTE

If you need to delete an entire table, you are advised to use the TRUNCATE statement rather than DELETE.

Delete the created table.

```
gaussdb=# DROP TABLE customer_t1;
```

3.2.5 Querying System Catalogs

In addition to the created tables, a database contains many system catalogs. These system catalogs contain cluster installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs.

In **System Catalogs and System Views**, the description about each table specifies whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the initial user.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

GaussDB provides the following types of system catalogs and views:

- PG-compatible system catalogs and views, prefixed with PG.
- New system catalogs and views in GaussDB, prefixed with GS.
- ORA-compatible system catalogs and views, prefixed with ALL, DBA, USER, or PV.

Querying Database Tables

Create the following tables in the public schema:

```
gaussdb=# CREATE TABLE public.search_table_t1(a int) DISTRIBUTE BY HASH(a);
CREATE TABLE
gaussdb=# CREATE TABLE public.search_table_t2(b int) DISTRIBUTE BY HASH(b);
CREATE TABLE
gaussdb=# CREATE TABLE public.search_table_t3(c int) DISTRIBUTE BY HASH(c);
CREATE TABLE
gaussdb=# CREATE TABLE public.search_table_t4(d int) DISTRIBUTE BY HASH(d);
CREATE TABLE
gaussdb=# CREATE TABLE public.search_table_t5(e int) DISTRIBUTE BY HASH(e);
CREATE TABLE
```

In the **PG_TABLES** system catalog, view the tables prefixed with search_table in the public schema.

```
gaussdb=# SELECT DISTINCT(tablename) FROM pg_tables WHERE SCHEMANAME = 'public' AND
TABLENAME LIKE 'search_table%';
```

The result is as follows:

```
   tablename
-----------------
 search_table_t1
 search_table_t2
 search_table_t3
 search_table_t4
 search_table_t5
(5 rows)
```

Viewing Database Users

You can use **PG_USER** to view the list of all users in the database, and view the user ID (**USESYSID**) and permissions.

```
gaussdb=# SELECT * FROM gs_user;
 usename | usesysid | usecreatedb | usesuper | usecatupd | userepl |  passwd  | valbegin | valuntil |
respool    | parent | spacelimit | useconfig | nodegroup | tempspacelimit | spillsp
acelimit | usemonitoradmin | useoperatoradmin | usepolicyadmin
---------+----------+-------------+----------+-----------+---------+----------+----------+----------+--------------
+--------+------------+-----------+-----------+----------------+--------
---------+-----------------+------------------+----------------
 omm     |       10 | t           | t        | t         | t       | ******** |          |          | default_pool |      0 |
|          |         |            |
        | t             | t             | t
(1 row)
```

Viewing and Stopping the Running Query Statements

You can view the running query statements in the **PG_STAT_ACTIVITY** view. You can use the following methods:

Step 1 Set the parameter **track_activities** to **on**.

```
gaussdb=# SET track_activities = on;
```

The database obtains the running information about active queries only if the parameter is set to **on**.

Step 2 View the running query statements. View the database names, users performing queries, query status, and the corresponding PID which are connected to the running query statements.

```
gaussdb=# SELECT datname, usename, state, pid FROM pg_stat_activity;
 datname  | usename | state  |       pid
----------+---------+--------+-----------------
 testdb | Ruby    | active | 140298793514752
 testdb | Ruby    | active | 140298718004992
 testdb | Ruby    | idle   | 140298650908416
 testdb | Ruby    | idle   | 140298625742592
 testdb | omm | active | 140298575406848
(5 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

View the query statements that are not in the idle state.

```
gaussdb=# SELECT datname, usename, state, pid FROM pg_stat_activity WHERE state != 'idle';
```

Step 3 To cancel queries that have been running for a long time, use the **pg_terminate_backend(pid int)** function to end sessions based on the thread ID (corresponding to the PID in **Step 2**).

```
gaussdb=# SELECT PG_TERMINATE_BACKEND(140298793514752);
```

If information similar to the following is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
---------------------
 t
(1 row)
```

If information similar to the following is displayed, a user has terminated the current session:

```
FATAL:  terminating connection due to administrator command
FATAL:  terminating connection due to administrator command
```

NOTE

- When the gsql client calls the **pg_terminate_backend(pid int)** function to terminate the backend thread of the current session, the connection behavior depends on the user identity.
  - Initial user: The client remains connected and is automatically reset (the message " The connection to the server was lost. Attempting reset: Succeeded." is displayed).
  - Non-initial user: The client connection is interrupted and fails to be reset (the message " The connection to the server was lost. Attempting reset: Failed." is displayed).

  Reason: The initial user has the password-free login permission, but common users do not have this permission.
- If the **pg_terminate_backend(pid int)** function is used to end inactive backend threads, and the thread pool is enabled, idle sessions do not have thread IDs and cannot be terminated. In non-thread pool mode, terminated sessions are not automatically reconnected.

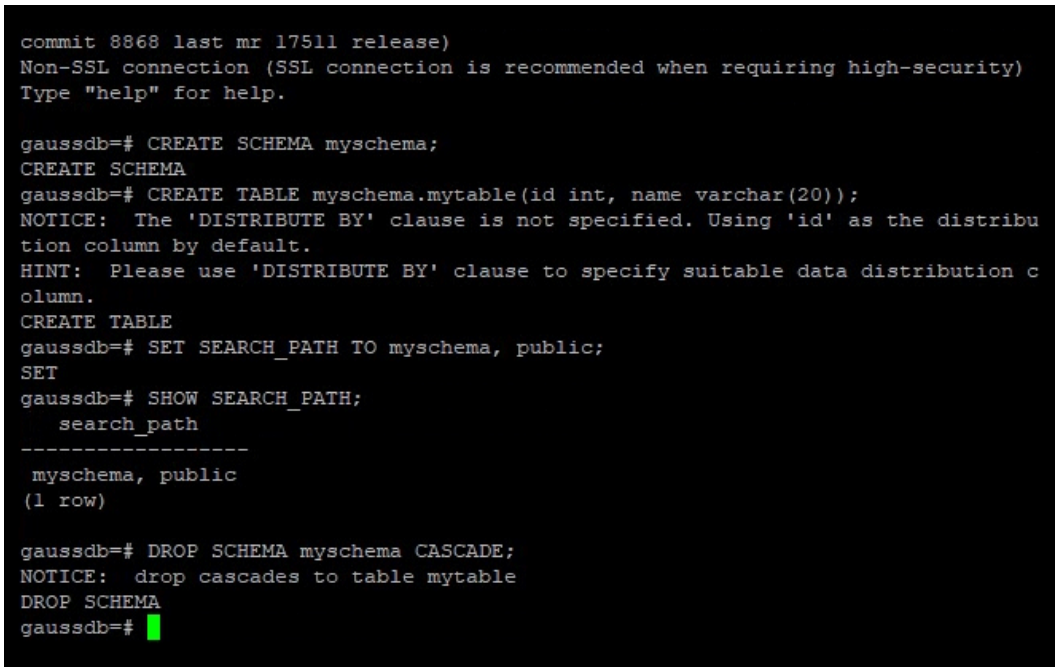
----End

3.2.6 Other Operations

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3.2.6.1 Managing Schemas

Figure 3-3 Creating and managing schemas



Context

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

Precautions

- A database cluster can have one or more databases. Users and user groups are shared within the entire cluster, but their data is not shared. Any user who has connected to a server can access only the database specified in the connection request.
- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both schema1 and schema2 can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- You cannot create a schema prefixed with PG_. Such schemas are reserved for the database system.
- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- To reference a table that is not modified with a schema name, the system uses **search_path** to find the schema that the table belongs to. pg_temp and pg_catalog are always the first two schemas to be searched no matter whether or how they are specified in **search_path**. **search_path** is a schema name list, and the first table detected in it is the target table. If no target table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search_path**, the search fails as well.) The first schema in **search_path** is called "current schema." This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.
- Each database has a pg_catalog schema, which contains system catalogs and all built-in data types, functions, and operators. pg_catalog is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search_path**. This search order ensures that database built-in objects can be found. If you need to create a user-defined object with the same name as a built-in object, you can perform operations in the schema to which the object belongs to avoid name conflicts.

Creating a Schema

For details, see **CREATE SCHEMA**.

- Create a schema.
  ```
  gaussdb=# CREATE SCHEMA myschema;
  ```
  If the following information is displayed, the schema named **myschema** is successfully created:
  ```
  CREATE SCHEMA
  ```
  To create or access an object in the schema, specify the complete object name, which consists of the schema name and the object names separated by periods (.). Example: **myschema.table**.
- Specify the owner when creating a schema.
  ```
  gaussdb=# CREATE SCHEMA myschema AUTHORIZATION omm;
  ```
  If the following information is displayed, the **myschema** schema that belongs to the **omm** user is created successfully:
  ```
  CREATE SCHEMA
  ```

Using a Schema

If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).

- Create the **mytable** table in myschema.
  ```
  gaussdb=# CREATE TABLE myschema.mytable(id int, name varchar(20));
  CREATE TABLE
  ```
- Query all data of the **mytable** table in **mySchema**.
  ```
  gaussdb=# SELECT * FROM myschema.mytable;
  id | name
  ----+------
  (0 rows)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Schema Search Path

You can set **search_path** to define the schema search order of objects in a database. The first schema in the search path is called the current default schema. If no schema is explicitly specified when an object is created, the object is automatically created in the default schema.

- View the search path.
```
gaussdb=# SHOW search_path;
 search_path
----------------
 "$user",public
(1 row)
```
- Set the search path to **mySchema, public** to configure the schema search order in the database. The system searches for objects in the myschema schema first. If no object is found, the system continues to search for objects in the public schema.
```
gaussdb=# SET search_path TO myschema, public;
SET
```

Schema Permission Control

By default, a user can only access database objects in their own schema. To access objects in other schemas, the target schema owner must grant the corresponding USAGE permission.

By granting the CREATE permission for a schema to a user, the user can create objects in this schema. By default, all roles have the USAGE permission in the public schema, but common users do not have the CREATE permission in the public schema. If a common user has the permission to connect to a specified database and create objects in the public schema, security risks may occur. If the common user has the CREATE permission on the public schema, you are advised to run the following statement to revoke the permission:

- Revoke **PUBLIC**'s permission to create objects in the public schema. In the following statement, the first **public** indicates the schema and the second **PUBLIC** indicates all predefined user roles:
```
gaussdb=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```
- Run the following command to view the current schema:
```
gaussdb=# SELECT current_schema();
 current_schema
----------------
 myschema
(1 row)
```
- Create user **jack** and grant the usage permission for myschema to the user.
```
gaussdb=# CREATE USER jack IDENTIFIED BY '********';
CREATE ROLE
gaussdb=# GRANT USAGE ON SCHEMA myschema TO jack;
GRANT
```
- Revoke the usage permission for myschema from **jack**.
```
gaussdb=# REVOKE USAGE ON SCHEMA myschema FROM jack;
REVOKE
```

Dropping a Schema

For details, see **DROP SCHEMA**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If a schema is empty, that is, it contains no database objects, you can run the **DROP SCHEMA** command. For example, drop a null schema named **nullschema**.
  ```
  gaussdb=# DROP SCHEMA IF EXISTS nullschema;
  DROP SCHEMA
  ```
- To drop a schema that is not null, use the keyword CASCADE to drop it and all its objects. For example, drop **myschema** and all its objects.
  ```
  gaussdb=# DROP SCHEMA myschema CASCADE;
  DROP SCHEMA
  ```

After the schema is dropped, run the following command to drop user **jack**:

```
gaussdb=# DROP USER jack;
DROP ROLE
```

3.2.6.2 Managing Partitioned Tables

Context

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is widely used. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can search for only the partition data that matches the search criteria, improving the search efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.
- Balanced I/O: Partitions can be mapped to different disks to balance I/O and improve the overall system performance.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

Procedure

This section uses range partitioning as an example to describe the related operations. For details about other partitioning examples, see **CREATE TABLE PARTITION**. Before performing the operations in this section, ensure that you have created the **tpcds** schema.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example 1: Use the default tablespace.

- Create a partitioned table. For details, see **CREATE TABLE PARTITION**.

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
    ca_address_sk       integer               NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                    ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                   ,
    ca_suite_number     character(10)                    ,
    ca_city             character varying(60)           ,
    ca_county           character varying(30)            ,
    ca_state            character(2)                   ,
    ca_zip              character(10)                  ,
    ca_country          character varying(20)            ,
    ca_gmt_offset       numeric(5,2)                    ,
    ca_location_type    character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

  If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

  Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

  Create the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table in the database and insert the data in the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
    ca_address_sk       integer               NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                    ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                   ,
    ca_suite_number     character(10)                    ,
    ca_city             character varying(60)           ,
    ca_county           character varying(30)            ,
    ca_state            character(2)                   ,
    ca_zip              character(10)                  ,
    ca_country          character varying(20)            ,
    ca_gmt_offset       numeric(5,2)                    ,
    ca_location_type    character(20)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
```

```
    PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0
```

- Modify the row movement attributes of the partitioned table.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Delete a partition.

  Drop partition **P8**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Add a partition.

  Add partition **P8** and set its range to [40000,MAXVALUE).

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN (MAXVALUE);
ALTER TABLE
```

- Rename a partition.
  - Rename partition **P8** to **P_9**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
```

  - Rename partition **P_9** to **P8**.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE
```

- Query a partition.

  Query partition **P6**.

```
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
```

- Drop partitioned tables and tablespaces.

```
gaussdb=# DROP TABLE tpcds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpcds.web_returns_p2;
DROP TABLE
```

Example 2: Use a user-defined tablespace.

Perform the following operations on a range partitioned table:

- Create a tablespace.

```
gaussdb=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
gaussdb=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
gaussdb=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
gaussdb=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
```

  If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

- Create a partitioned table.

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
    ca_address_sk       integer                 NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                      ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                      ,
    ca_suite_number     character(10)                      ,
    ca_city             character varying(60)              ,
    ca_county           character varying(30)              ,
    ca_state            character(2)                       ,
    ca_zip              character(10)                      ,
    ca_country          character varying(20)              ,
    ca_gmt_offset       numeric(5,2)                       ,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    ca_location_type    character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

  Insert data from the **tpcds.customer_address** table to the **tpcds.web_returns_p2** table.

  Suppose that the backup table **tpcds.web_returns_p2** of the **tpcds.customer_address** table has been created in the database. You can insert the data of the **tpcds.customer_address** table into the backup table **tpcds.web_returns_p2**.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
    ca_address_sk       integer                 NOT NULL   ,
    ca_address_id       character(16)           NOT NULL   ,
    ca_street_number    character(10)                      ,
    ca_street_name      character varying(60)              ,
    ca_street_type      character(15)                      ,
    ca_suite_number     character(10)                      ,
    ca_city             character varying(60)              ,
    ca_county           character varying(30)              ,
    ca_state            character(2)                       ,
    ca_zip              character(10)                      ,
    ca_country          character varying(20)              ,
    ca_gmt_offset       numeric(5,2)                       ,
    ca_location_type    character(20)
)
TABLESPACE example1
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_sk)
(
        PARTITION P1 VALUES LESS THAN(5000),
        PARTITION P2 VALUES LESS THAN(10000),
        PARTITION P3 VALUES LESS THAN(15000),
        PARTITION P4 VALUES LESS THAN(20000),
        PARTITION P5 VALUES LESS THAN(25000),
        PARTITION P6 VALUES LESS THAN(30000),
        PARTITION P7 VALUES LESS THAN(40000),
        PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpcds.web_returns_p2 SELECT * FROM tpcds.customer_address;
INSERT 0 0
```

- Modify the row movement attributes of the partitioned table.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Delete a partition.

  Drop partition **P8**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# ALTER TABLE tpcds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Add a partition.

  Add partition **P8** and set its range to [40000,MAXVALUE).

  ```
  gaussdb=# ALTER TABLE tpcds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN (MAXVALUE);
  ALTER TABLE
  ```

- Rename a partition.
  - Rename partition **P8** to **P_9**.

    ```
    gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION P8 TO P_9;
    ALTER TABLE
    ```

  - Rename partition **P_9** to **P8**.

    ```
    gaussdb=# ALTER TABLE tpcds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
    ALTER TABLE
    ```

- Change the tablespace of a partition.
  - Change the tablespace of partition **P6** to **example3**.

    ```
    gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P6 TABLESPACE example3;
    ALTER TABLE
    ```

  - Change the tablespace of partition **P4** to **example4**.

    ```
    gaussdb=# ALTER TABLE tpcds.web_returns_p2 MOVE PARTITION P4 TABLESPACE example4;
    ALTER TABLE
    ```

- Query a partition.

  Query partition **P6**.

  ```
  gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION (P6);
  gaussdb=# SELECT * FROM tpcds.web_returns_p2 PARTITION FOR (35888);
  ```

- Drop partitioned tables and tablespaces.

  ```
  gaussdb=# DROP TABLE tpcds.customer_address;
  DROP TABLE
  gaussdb=# DROP TABLE tpcds.web_returns_p2;
  DROP TABLE
  gaussdb=# DROP TABLESPACE example1;
  gaussdb=# DROP TABLESPACE example2;
  gaussdb=# DROP TABLESPACE example3;
  gaussdb=# DROP TABLESPACE example4;
  DROP TABLESPACE
  ```

3.2.6.3 Managing Indexes

Context

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, you need to evaluate the necessity of creating an index and decide on the selection of the index column. You can determine whether to create an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, when creating an index, you need to evaluate the selection criteria of the target column. You can evaluate the necessity of creating an index based on the following conditions and select the column for which the index is to be created:

- Column that is often searched and queried. This speeds up searches.
- Column that is used as the primary key. The primary key must be unique and sorted in order.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Column that is often joined. This increases the join efficiency.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Column where the WHERE clause is executed frequently. This speeds up condition judgment.
- Column that often appears after the keywords ORDER BY, GROUP BY, and DISTINCT.

  NOTE

  - After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
  - After an index is successfully created, it must be synchronized with the table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.
  - Partitioned table indexes are classified into local indexes and global indexes. A local index corresponds to a specific partition, and a global index corresponds to the entire partitioned table.

- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use **USING INDEX** to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

Procedure

Create a partitioned table before performing operations. For details, see **Managing Partitioned Tables**.

- Create an index. For details, see **CREATE INDEX**.
  - Create the partitioned table index **tpcds_web_returns_p2_index1** without specifying the partition name.

    ```
    gaussdb=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2
    (ca_address_id) LOCAL;
    ```

    If the following information is displayed, the creation is successful:

    ```
    CREATE INDEX
    ```

  - Create the partitioned table index **tpcds_web_returns_p2_index2** with the partition name specified.

    ```
    gaussdb=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2
    (ca_address_sk) LOCAL
    (
        PARTITION web_returns_p2_P1_index,
        PARTITION web_returns_p2_P2_index TABLESPACE example3,
        PARTITION web_returns_p2_P3_index TABLESPACE example4,
        PARTITION web_returns_p2_P4_index,
        PARTITION web_returns_p2_P5_index,
        PARTITION web_returns_p2_P6_index,
        PARTITION web_returns_p2_P7_index,
        PARTITION web_returns_p2_P8_index
    ) TABLESPACE example2;
    ```

    If the following information is displayed, the creation is successful:

    ```
    CREATE INDEX
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Change the tablespace of an index partition.
  - Change the tablespace of index partition **web_returns_p2_P2_index** to **example1**.
    ```
    gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION web_returns_p2_P2_index TABLESPACE example1;
    ```
    If the following information is displayed, the modification is successful:
    ```
    ALTER INDEX
    ```
  - Change the tablespace of index partition **web_returns_p2_P3_index** to **example2**.
    ```
    gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION web_returns_p2_P3_index TABLESPACE example2;
    ```
    If the following information is displayed, the modification is successful:
    ```
    ALTER INDEX
    ```
- Rename an index partition.

  Rename the index partition **web_returns_p2_P8_index** to **web_returns_p2_P8_index_new**.
  ```
  gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 RENAME PARTITION web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
  ```
  If the following information is displayed, the rename operation is successful:
  ```
  ALTER INDEX
  ```
- Query indexes.
  - Query all indexes defined by the system and users.
    ```
    gaussdb=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i';
    ```
  - Query information about a specified index.
    ```
    gaussdb=# \di+ tpcds.tpcds_web_returns_p2_index2
    ```
- Drop indexes.
  ```
  gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index1;
  gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index2;
  ```
  If the following information is displayed, the deletion is successful:
  ```
  DROP INDEX
  ```

Introduction to Indexes

GaussDB supports four methods for creating indexes. For details, see **Table 3-4**.

Table 3-4 Indexing methods

Indexing Method	Description
Unique index	An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB.
Composite index	An index that can be defined for multiple attributes of a table. Currently, composite indexes can be created only for B-tree in GaussDB and up to 32 columns can share a composite index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Indexing Method	Description
Partial index	An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.
Expression index	An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the expression used during query is the same as that used during creation.

- Create an ordinary table.

```
gaussdb=# CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;
INSERT 0 0
```

- Create an ordinary index.

  For the **tpcds.customer_address_bak** table, you need to perform the following operations frequently:

```
gaussdb=# SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE ca_address_sk=14888;
```

  When the database system queries the **tpcds.customer_address_bak** table, if the WHERE condition is matched row by row in full table scan mode, the operation will cause a significant performance bottleneck in the scenario where the table contains a large amount of data but only a few rows (even zero) are matched. If the database system maintains an index on the **ca_address_sk** attribute to quickly locate matched tuples, the database system only needs to traverse a small number of index nodes to obtain matched tuples, greatly improving the query efficiency. Furthermore, indexes can improve the update and deletion operation performance in the database.

  Create an index.

```
gaussdb=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak
(ca_address_sk);
CREATE INDEX
```

- Create a unique index.

  Create a unique index on the **SM_SHIP_MODE_SK** column in the **tpcds.ship_mode_t1** table.

```
gaussdb=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

- Create a composite index.

  Assume that you need to frequently query records with **ca_address_sk** being **5050** and **ca_street_number** smaller than **1000** in the **tpcds.customer_address_bak** table. Run the following commands:

```
gaussdb=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE
ca_address_sk = 5050 AND ca_street_number < 1000;
```

  Define a composite index on the **ca_address_sk** and **ca_street_number** columns.

```
gaussdb=# CREATE INDEX more_column_index ON
tpcds.customer_address_bak(ca_address_sk ,ca_street_number );
CREATE INDEX
```

- Create a partial index.

  If you only want to find records with **ca_address_sk** being **5050**, you can create a partial index to facilitate your query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE
ca_address_sk = 5050;
CREATE INDEX
```

- Create an expression index.

  Assume that you need to frequently query records with **ca_street_number** smaller than **1000**. Run the following command:

  ```
  gaussdb=# SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000;
  ```

  The following expression index can be created for this query task:

  ```
  gaussdb=# CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));
  CREATE INDEX
  ```

- Drop the **tpcds.customer_address_bak** table.

  ```
  gaussdb=# DROP TABLE tpcds.customer_address_bak;
  DROP TABLE
  ```

3.2.6.4 Managing Views

Figure 3-4 Creating and managing views

```
gaussdb=# CREATE TABLE mytable (c1 int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# CREATE OR REPLACE VIEW myview AS SELECT * FROM mytable WHERE trunc(c1) > 1000;
CREATE VIEW
gaussdb=# SELECT * FROM myview;
 c1
----
(0 rows)

gaussdb=# \d+ myview
                View "public.myview"
 Column |  Type   | Modifiers | Storage | Description
--------+---------+-----------+---------+-------------
 c1     | integer |           | plain   |
View definition:
 SELECT  *
   FROM mytable
  WHERE trunc(mytable.c1::double precision) > 1000::double precision;

gaussdb=# DROP VIEW myview;
DROP VIEW
gaussdb=# DROP TABLE mytable
```

Context

If you need to frequently query a combination of specific columns in multiple tables, you can define a view to avoid repeated query statements. A view abstracts the underlying table structure through a virtual table to simplify common query operations.

A view is a logical table. Different from a physical base table, a view does not actually reside on disks. The database stores only the query definition of the view. The actual data is always stored in the joined base table. When data in the base table changes, the view query result dynamically synchronizes the changes. The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

view is like a real-time data window, allowing users to access the mirrored data they are concerned about. Each time a view is accessed, the system re-executes its definition query to obtain the latest data.

Managing Views

Create a table before performing operations. For details, see **Creating a Table**.

- Create a view. For details, see **CREATE VIEW**.

  Create the **myview** view. In the command, **tpcds.web_returns** indicates the created user table that contains the **wr_refunded_cash** integer column.

  ```
  gaussdb=# CREATE OR REPLACE VIEW myview AS SELECT * FROM tpcds.web_returns WHERE trunc(wr_refunded_cash) > 10000;
  CREATE VIEW
  ```

  NOTE

  The OR REPLACE clause in CREATE VIEW is optional. If this clause is used, the database system automatically replaces the original view definition if the view already exists.

- Query a view.

  Query **myview**.

  ```
  gaussdb=# SELECT * FROM myview;
  ```

- Query views of the current user.

  ```
  gaussdb=# SELECT * FROM my_views;
  ```

- Query all views.

  ```
  gaussdb=# SELECT * FROM adm_views;
  ```

- Query details about a specified view.

  View details about **myview**.

  ```
  gaussdb=# \d+ myview
                      View "PG_CATALOG.myview"
    Column  |         Type          | Modifiers | Storage  | Description
  ----------+-----------------------+-----------+----------+-------------
   USERNAME | CHARACTER VARYING(64) |           | extended |
  View definition:
   SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
     FROM PG_AUTHID;
  ```

- Drop a view.

  Drop **myview**.

  ```
  gaussdb=# DROP VIEW myview;
  DROP VIEW
  ```

3.2.6.5 Managing Sequences

Context

A sequence is a database object that generates unique integers.

If **NO CYCLE** is specified, sequence numbers are integers that automatically increase according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Declare the column type as **Table 7-4**. The database automatically creates a sequence for the column.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Use the statement in **CREATE SEQUENCE** to create a sequence and reference nextval('sequence_name') in the default value of a table column to automatically generate a unique identifier.

Precautions

Sequence values are generated by the GTM. By default, each request for a sequence value is sent to the GTM. The GTM calculates the result of the current value plus the step and then returns the result. The GTM is a globally unique node and is the performance bottleneck. Therefore, you are advised not to generate sequence values frequently and numerously, such as to use BulkLoad to import data. For example, in the following scenario, the execution efficiency of the INSERT INTO SELECT FROM statement is significantly lower than expected.

```
gaussdb=# CREATE SEQUENCE newSeq1;
gaussdb=# CREATE TABLE newT1
        (
          id   int not null default nextval('newSeq1'),
          name text
        );
gaussdb=# INSERT INTO newT1(name) SELECT name FROM T1;
```

Assume that data imported from table **T1** to table **newT1** has 10,000 rows. The following statements achieve better performance:

```
gaussdb=# INSERT INTO newT1(id, name) SELECT id,name FROM T1;
gaussdb=# SELECT SETVAL('newSeq1',10000);
```

NOTE

Rollback is not supported by sequence functions, including nextval() and setval(). The value of the setval function immediately takes effect on nextval in the current session in any cases and take effect in other sessions only when no cache is specified for them. If cache is specified for a session, it takes effect only after all the cached values have been used. To avoid duplicate values, use setval only when necessary. Do not set it to an existing sequence value or a cached sequence value.

To generate the default sequence value using BulkLoad, set sufficient cache for **newSeq1** and do not set **Maxvalue** or **Minvalue**. The database will push down the calling of nextval('sequence_name') to DNs to improve performance. Currently, the concurrent connection requests that can be processed by the GTM are limited. If there are too many DNs, a large number of concurrent connection requests will be sent to the GTM. In this case, you need to limit the bulk loading concurrency, so that DNs do not fully occupy GTM connections. If the target table is a replication table (DISTRIBUTE BY REPLICATION), pushdown cannot be performed. When the data volume is large, the performance is affected and the space may bloat sharply. After the import is complete, you need to run the **vacuum full** command to restore the data. The best way is not to use BulkLoad to generate the default sequence value.

After a sequence is created, one single-row table is maintained on each node to store the sequence definition and value, which is obtained from the last interaction with the GTM rather than updated in real time. The single-row table on a node does not update when other nodes request a new value from the GTM or when the sequence is modified using setval.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Procedure

Declare the column type as sequence integer to define the identifier column. For example:

```
gaussdb=# CREATE TABLE T1
(
   id    serial,
   name  text
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Create a sequence and use the nextval('sequence_name') function to specify the default value of a column. You can cache a specific number of sequence values to reduce the requests to the GTM, improving the performance.

1. Create a sequence. For details, see **CREATE SEQUENCE**.

   ```
   gaussdb=# CREATE SEQUENCE seq1 cache 100;
   ```

   If the following information is displayed, the creation is successful:

   ```
   CREATE SEQUENCE
   ```

2. Set the created sequence as the default value of a column. Then, the column has a unique identifier.

   ```
   gaussdb=# CREATE TABLE T2
   (
      id   int not null default nextval('seq1'),
      name text
   );
   ```

   If the following information is displayed, the default value has been specified:

   ```
   CREATE TABLE
   ```

3. Associate a sequence with a column.

   Associate a sequence with a specified column included in a table. In this way, the sequence will be dropped when you drop its joined column or the table where the column belongs to.

   ```
   gaussdb=# ALTER SEQUENCE seq1 OWNED BY T2.id;
   ```

   If the following information is displayed, the operation is successful:

   ```
   ALTER SEQUENCE
   ```

NOTE

The preceding methods are similar, except that the second method specifies cache for the sequence. However, once cache is defined, the sequence values may be discontinuous (for example, 1, 4, and 5 are generated) and the sequence cannot be preserved. If a dependent column is specified for a sequence, the sequence will be deleted when the dependent column is deleted. A sequence shared by multiple columns is not forbidden in a database, but you are advised not to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

3.2.6.6 Managing Scheduled Jobs

Context

Time-consuming jobs, such as summarizing statistics or synchronizing data from another database, affect service performance if they are performed during the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

daytime and incur overtime hours if performed at night. To solve this problem, the GaussDB Kernel database is compatible with the scheduled job function in the ORA database. You can create scheduled jobs that are automatically triggered to reduce O&M workload.

This function calls APIs provided by the **DBE_SCHEDULER** and **DBE_TASK** packages to create scheduled jobs, execute jobs automatically, delete jobs, and modify job attributes (including job ID, the enabled/disabled status of a job, job triggering time, triggering interval, and job content). The DBE_SCHEDULER API is recommended to ensure high availability and reliability and support more flexible job scheduling. For details about the API description and migration guide examples, see **DBE_SCHEDULER**.

NOTE

- The **next_run_date** column in the PG_JOB system catalog indicates the actual start time of a scheduled job, not the expected start time of a scheduled job.
- The start time of the current scheduled job depends on the actual execution time of the previous job. If **freq** is not specified, the execution time has a short deviation.

```
gaussdb=# SELECT start_date, next_run_date, interval FROM pg_job WHERE job_name = 'job1';
         start_date         |       next_run_date        |      interval
----------------------------+----------------------------+--------------------
 2024-12-03 15:24:11.94422 | 2024-12-03 15:26:12.197623 | interval'1 minute'
(1 row)
```

Managing Scheduled Jobs

Step 1 Create a test table.

```
gaussdb=# CREATE TABLE test(id int, time date);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Step 2 Create a user-defined stored procedure.

```
gaussdb=# CREATE OR REPLACE PROCEDURE PRC_JOB_1()
AS
N_NUM integer :=1;
BEGIN
FOR I IN 1..1000 LOOP
INSERT INTO test VALUES(I,SYSDATE);
END LOOP;
END;
/
```

If the following information is displayed, the creation is successful:

```
CREATE PROCEDURE
```

Step 3 Create a job.

- Create a job with unspecified **job_id** and execute the **PRC_JOB_1** stored procedure every minute.

```
gaussdb=# CALL dbe_task.submit('CALL public.prc_job_1(); ', sysdate, 'interval ''1 minute''', :a);
id
-----
1
(1 row)
```

- Specify **job_id** to create a job. The value of **job_id** ranges from 1 to 32767.

```
gaussdb=# CALL dbe_task.id_submit(1,'call public.prc_job_1(); ', sysdate, 'interval ''1 minute''');
id_submit
----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
```

Step 4 View details of jobs created by the current user.

```
gaussdb=# SELECT job,dbname,start_date,last_date,this_date,next_date,broken,status,interval,failures,what
FROM my_jobs;
job | dbname |     start_date      |         last_date          |         this_date          |      next_date      | broken |
status |      interval       | failures |           what
-----+--------+---------------------+----------------------------+----------------------------+---------------------
+--------+--------+---------------------+----------+--------------------------
1 | testdb   | 2017-07-18 11:38:03 | 2017-07-18 13:53:03.607838 | 2017-07-18 13:53:03.607838 | 2017-07-18
13:54:03 | n      | s      | interval '1 minute' |        0 | call public.prc_job_1();
(1 row)
```

Step 5 Stop a job.

```
gaussdb=# CALL dbe_task.finish(1,true);
finish
--------

(1 row)
```

Step 6 Start a job.

```
gaussdb=# CALL dbe_task.finish(1,false);
finish
--------

(1 row)
```

Step 7 Modify job attributes.

- Modify the **next_time** parameter information about the job.

  ```
  -- Set next_time of Job1 to 1 hour so that Job1 will be executed in one hour.
  gaussdb=# CALL dbe_task.next_time(1, sysdate+1.0/24);
  next_time
  -----------

  (1 row)
  ```

- Modify the **interval** parameter of a job.

  ```
  -- Set interval of Job1 to 1 hour so that Job1 will be executed every one hour.
  gaussdb=# CALL dbe_task.interval(1,'sysdate + 1.0/24');
  interval
  ----------

  (1 row)
  ```

- Modify the **what** parameter of a job.

  ```
  -- Set what to INSERT INTO public.test VALUES(333, sysdate+5); for Job1.
  gaussdb=# CALL dbe_task.content(1,'INSERT INTO public.test VALUES(333, sysdate+5);');
  content
  ------

  (1 row)
  ```

- Modify **next_date**, **interval**, and **what** parameters of a job.

  ```
  gaussdb=# CALL dbe_task.update(1, 'CALL public.prc_job_1();', sysdate, 'interval ''1 minute''');
  update
  --------

  (1 row)
  ```

Step 8 View the job execution status.

If a job fails to be automatically executed (that is, the value of **job_status** is **'f'**), contact the administrator to view the gs_log run log to view the failure information of the job.

From **detail error msg**, you can see the failure causes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
LOG:  Execute Job Detail:
        job_id: 1
        what: call public.test();
        start_date: 2017-07-19 23:30:47.401818
        job_status: failed
        detail error msg: relation "test" does not exist
        end_date: 2017-07-19 23:30:47.401818
        next_run_date: 2017-07-19 23:30:56.855827
```

Step 9 Delete a job.

```
gaussdb=# CALL dbe_task.cancel(1);
cancel
--------

(1 row)
```

----End

Set job permissions.

- During the creation of a job, the job is bound to the user and database that created the job. Accordingly, the user and database are added to **dbname** and **log_user** columns in the pg_job system catalog, respectively.
- The **DBA** user, system administrators, or the user who creates the job can delete or modify the job parameters through the **remove**, **change**, **next_data**, **what**, or **interval** parameter. Otherwise, the system displays a message indicating that the user has no permissions to perform operations on this job.
- If the current database is the one that created a job, you can delete or modify parameter settings of the job using the **cancel**, **update**, **next_data**, **content**, or **interval** parameter.
- When deleting the database that created a job, the system automatically deletes the job records of the database.
- When deleting the user who created a job, the system automatically deletes the job records of the user.

Manage job concurrency.

You can configure the GUC parameter **job_queue_processes** to adjust the number of jobs running at the same time.

- Setting **job_queue_processes** to **0** indicates that the scheduled job function is disabled and all jobs will not be executed.
- Setting **job_queue_processes** to a value greater than 0 indicates that the scheduled job function is enabled and this value is the maximum number of jobs that can be concurrently processed.

Too many concurrent jobs consume many system resources, so you need to set the number of concurrent jobs to be processed. If the current number of concurrent jobs reaches the value of **job_queue_processes** and some of them expire, these jobs will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **Interval** parameter of the submit API) based on the execution duration of each job to avoid the problem that jobs in the next polling period cannot be properly processed because of overlong job execution time.

Note: For clusters that do not use jobs, set **job_queue_processes** to **0** to disable job functions to reduce the resource consumption.

4 Development and Design Proposal

4.1 Overview

This section describes the design specifications for database modeling and application development. Modeling based on these specifications fits the distributed processing architecture of GaussDB and outputs efficient SQL code.

The meaning of "Proposal" and "Notice" in this section is as follows:

- **Proposal**: Design rules. Services compliant with the rules can run efficiently, and those violating the rules may have low performance or logic errors.
- **Notice**: Details requiring attention during service development. This term identifies SQL behavior that complies with SQL standards but users may have misconceptions about, and default behavior that users may be unaware of in a program.

4.2 Database Object Naming Conventions

Database object names must meet the following requirements:

- The length of a table of an identifier cannot exceed 63 bytes. If you need to copy or import GDS data to a table with a global secondary index (GSI), the length of the table name cannot exceed 38 bytes.
- An identifier starts with a letter or underscore (_) and can contain letters, digits, underscores (_), dollar signs ($), and number signs (#).
- If an identifier is enclosed in backquotes (``) in MySQL-compatible mode or double quotation marks (""), any combination of valid characters can be used, for example, "123gs_column".
- Identifiers are case-insensitive. They are case-sensitive only when they are enclosed in backquotes (``) in MySQL-compatible mode or double quotation marks ("").
- The gsql shortcut commands (except **\sf**) cannot be used to query the object names enclosed in backquotes.
- Do not use reserved or non-reserved keywords to name database objects.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> To query the GaussDB keywords, run **SELECT * FROM pg_get_keywords()** or refer to **Keywords**.

- Do not use a string enclosed in double quotation marks ("") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes problem location difficult.
- Use the same naming format for database objects.
  - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.
  - You are advised to use multiple words separated with underscores (_).
  - You are advised to use intelligible names and common acronyms or abbreviations for database objects. Acronyms or abbreviations that are generally understood are recommended. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a cluster.
  - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
  - An ordinary table name should indicate the business relevant to a data set.
  - Temporary tables are named in the format of **tmp**_*Suffix*.
  - Unlogged tables are named in the format of **ul**_*Suffix*.
  - Foreign tables are named in the format of **f**_*Suffix*.
  - Do not create database objects whose names start with **redis**_.
  - Do not create database objects named **pgxc_redistb**.
  - Do not create database objects whose names start with **mlog**_ or **matviewmap**_.
  - Do not create database objects whose names start with **gs_role**_.
- The name of a table object shall not exceed 63 bytes. If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the actual name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.
- If you need to copy or import GDS data to a table with a global secondary index (GSI), the length of the table name cannot exceed 38 bytes. If the length exceeds the maximum, the temporary table name created during COPY or GDS import may be truncated. As a result, the data import process is interrupted and unexpected characters are generated.

4.3 Database Object Design

4.3.1 Database and Schema Design

In GaussDB, services can be isolated by databases and schemas. Databases share little resources and cannot directly access each other. Connections to and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

permissions on them are also isolated. Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled using the GRANT and REVOKE syntax.

- You are advised to use schemas to isolate services for convenience and resource sharing.
- It is recommended that system administrators create schemas and databases and then assign required permissions to users.

Database Design

- Create databases as required by your business. Do not use the default **postgres** database of a cluster.
- In a cluster, the recommended number of user-defined databases is 3. It is recommended that the number of user-defined databases be less than or equal to 10. If there are too many user-defined databases, O&M operations, such as upgrade and backup, will be inefficient.
- To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- When you create a database, exercise caution when you set **ENCODING** and **DBCOMPATIBILITY** configuration items. GaussDB supports the TD-, ORA-, MySQL-, and PG-compatible modes which are compatible with the Teradata syntax, Oracle syntax, MySQL syntax, and PostgreSQL syntax, respectively. The syntax behavior varies according to the compatibility mode. By default, the MySQL-compatible mode is used.
- By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when deleting a permission.

Schema Design

- It is recommended that the number of schemas in the actual user environment be no more than 100. If there are too many schemas in a database, operations that depend on the number of schemas, such as gs_dump, becomes slow.
- To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the SYSADMIN permission or is the schema owner.
- To let a user create an object in the schema, grant the CREATE permission for the schema to the user.
- By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when deleting a permission.

4.3.2 Table Design

GaussDB uses a distributed architecture. Data is distributed on DNs. Generally, well-designed table must comply with the following rules:

- Evenly distribute data on each DN to prevent data skew. If most data is stored on several DNs, the effective capacity of a cluster decreases. Select a proper distribution key to avoid data skew.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Evenly scan each DN when querying tables. Otherwise, DNs most frequently scanned will become the performance bottleneck. For example, when you use equivalent filter conditions on a fact table, the nodes are not evenly scanned.
- Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- Minimize random I/Os. Through clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.
- Avoid data shuffle. To shuffle data is to physically transfer it from one node to another. This unnecessarily occupies many network resources. To reduce network pressure, locally process data, and to improve cluster performance and concurrency, you can minimize data shuffling by using proper join and grouping conditions.

Selecting a Distribution Mode

Table 2 Table distribution modes and scenarios shows how to select a table distribution mode.

Table 4-1 Table distribution modes and scenarios

Distribution Mode	Description	Application Scenario
Hash	Table data is distributed on all DNs in a cluster by hash.	Fact tables containing a large amount of data
Replication	Full data in a table is stored on every DN in the cluster.	Dimension tables and fact tables containing a small amount of data
Range	Table data is mapped to specified columns based on the range and distributed to the corresponding DNs.	Users need to customize distribution rules.
List	Table data is mapped to specified columns based on specific values and distributed to corresponding DNs.	Users need to customize distribution rules.

The example of defining a distributed table is as follows:

```
-- Define a table with each row stored in all DNs.
CREATE TABLE warehouse_d1
(
    W_WAREHOUSE_SK            INTEGER               NOT NULL,
    W_WAREHOUSE_ID            CHAR(16)              NOT NULL,
    W_WAREHOUSE_NAME          VARCHAR(20)                   ,
    W_WAREHOUSE_SQ_FT         INTEGER                       ,
    W_STREET_NUMBER           CHAR(10)                      ,
    W_STREET_NAME             VARCHAR(60)                   ,
    W_STREET_TYPE             CHAR(15)                      ,
    W_SUITE_NUMBER            CHAR(10)                      ,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    W_CITY                  VARCHAR(60)                ,
    W_COUNTY                VARCHAR(30)                ,
    W_STATE                 CHAR(2)                    ,
    W_ZIP                   CHAR(10)                   ,
    W_COUNTRY               VARCHAR(20)                ,
    W_GMT_OFFSET            DECIMAL(5,2)
)DISTRIBUTE BY REPLICATION;

-- Define a hash table.
CREATE TABLE warehouse_d2
(
    W_WAREHOUSE_SK          INTEGER               NOT NULL,
    W_WAREHOUSE_ID          CHAR(16)              NOT NULL,
    W_WAREHOUSE_NAME        VARCHAR(20)                ,
    W_WAREHOUSE_SQ_FT       INTEGER                    ,
    W_STREET_NUMBER         CHAR(10)                   ,
    W_STREET_NAME           VARCHAR(60)                ,
    W_STREET_TYPE           CHAR(15)                   ,
    W_SUITE_NUMBER          CHAR(10)                   ,
    W_CITY                  VARCHAR(60)                ,
    W_COUNTY                VARCHAR(30)                ,
    W_STATE                 CHAR(2)                    ,
    W_ZIP                   CHAR(10)                   ,
    W_COUNTRY               VARCHAR(20)                ,
    W_GMT_OFFSET            DECIMAL(5,2),
    CONSTRAINT W_CONSTR_KEY3 UNIQUE(W_WAREHOUSE_SK)
)DISTRIBUTE BY HASH(W_WAREHOUSE_SK);

-- Define a table using RANGE distribution.
CREATE TABLE warehouse_d3
(
W_WAREHOUSE_SK          INTEGER               NOT NULL,
W_WAREHOUSE_ID          CHAR(16)              NOT NULL,
W_WAREHOUSE_NAME        VARCHAR(20)                ,
W_WAREHOUSE_SQ_FT       INTEGER                    ,
W_STREET_NUMBER         CHAR(10)                   ,
W_STREET_NAME           VARCHAR(60)                ,
W_STREET_TYPE           CHAR(15)                   ,
W_SUITE_NUMBER          CHAR(10)                   ,
W_CITY                  VARCHAR(60)                ,
W_COUNTY                VARCHAR(30)                ,
W_STATE                 CHAR(2)                    ,
W_ZIP                   CHAR(10)                   ,

);
```

For details about the table distribution syntax, see **CREATE TABLE**.

Selecting a Distribution Key

A distribution key is important for a distributed table. An improper distribution key may cause data skew. As a result, the I/O load is heavy on several DNs, affecting the overall query performance. Therefore, after determining the distribution policy of a distributed table, you need to check the table data skew to ensure that data is evenly distributed. Comply with the following rules to select a distribution key:

- Select a column containing discrete data as the distribution key, so that data can be evenly distributed on each DN. If the data in a single column is not discrete enough, consider using multiple columns as distribution keys. You can select the primary key of a table as the distribution key. For example, in an employee information table, select the certificate number column as the distribution key.
- If the first rule is met, do not select a column having constant filter conditions as the distribution key. For example, in a query on the **dwcjk** table, if the **zqdh** column contains the constant filter condition **zqdh='000001'**, avoid selecting the **zqdh** column as the distribution key.
- If the first and second rules are met, select the join conditions in a query as distribution keys. If a join condition is used as a distribution key, the data involved in a join task is locally distributed on DNs, which greatly reduces the data flow cost among DNs.

Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- Create partitions on columns that indicate certain ranges, such as dates and regions.
- A partition name should show the data characteristics of a partition. For example, its format can be *Keyword*+*Range* characteristics.
- Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.
- [Recommendation] Do not define the same or similar partitioning and distribution rules. Otherwise, partitions on some DNs cannot be mapped to data.

Table 4-2 Table partitioning modes and scenarios

Partitioning Mode	Description
Range	Table data is partitioned by range.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Partitioning Mode	Description
List	Table data is partitioned by a specified column based on a specific value.
Hash	Table data is partitioned by hash.

The example of defining a partitioned table is as follows:

```
-- Create a range partitioned table.
CREATE TABLE staffS_p1
(
  staff_ID       NUMBER(6) not null,
  FIRST_NAME     VARCHAR2(20),
  LAST_NAME      VARCHAR2(25),
  EMAIL          VARCHAR2(25),
  PHONE_NUMBER   VARCHAR2(20),
  HIRE_DATE      DATE,
  employment_ID  VARCHAR2(10),
  SALARY         NUMBER(8,2),
  COMMISSION_PCT NUMBER(4,2),
  MANAGER_ID     NUMBER(6),
  section_ID     NUMBER(4)
)
PARTITION BY RANGE (HIRE_DATE)
(
   PARTITION HIRE_19950501 VALUES LESS THAN ('1995-05-01 00:00:00'),
   PARTITION HIRE_19950502 VALUES LESS THAN ('1995-05-02 00:00:00'),
   PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);

-- Create a list partitioned table.
CREATE TABLE test_list (col1 int, col2 int)
partition by list(col1)
(
partition p1 values (2000),
partition p2 values (3000),
partition p3 values (4000),
partition p4 values (5000)
);

-- Create a hash partitioned table.
CREATE TABLE test_hash (col1 int, col2 int)
partition by hash(col1)
(
partition p1,
partition p2
);
```

For details about the table partition syntax, see **CREATE TABLE PARTITION**.

4.3.3 Column Design

Selecting a Data Type

To improve query efficiency, comply with the following rules when designing columns:

- Use the most efficient data types allowed.

  If all of the following number types provide the required service precision, they are recommended in descending order of priority: integer, floating point, and numeric.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- In tables that are logically related, columns having the same meaning should use the same data type.
- For string data, you are advised to use variable-length strings and specify the maximum length. Ensure that the specified maximum length is greater than the maximum number of characters to be stored. Otherwise, an error is reported, causing service interruption. You are advised not to use CHAR(n), BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.

  For details about string types, see **Common String Types**.

Common String Types

Every column requires a data type suitable for its data characteristics. **Character Types** lists common string types in GaussDB.

4.3.4 Constraint Design

DEFAULT and NULL Constraints

- If all the column values can be obtained from services, you are advised not to use the DEFAULT constraint. Otherwise, unexpected results will be generated during data loading.
- Add NOT NULL constraints to columns that never have NULL values. The optimizer automatically optimizes the columns in certain scenarios.
- Explicitly name all constraints excluding **NOT NULL** and **DEFAULT**.

Unique Constraints

- The constraint name should indicate that it is a unique constraint, for example, **UNI***Column name*.

Primary Key Constraints

- The constraint name should indicate that it is a primary key constraint, for example, **PK***Column name*.

Check Constraints

- The constraint name should indicate that it is a check constraint, for example, **CK***Column name*.

4.3.5 View and Joined Table Design

View Design

- Do not nest views unless they have strong dependency on each other.
- Try to avoid collation operations in a view definition.

Joined Table Design

- Minimize joined columns across tables.
- Use the same data type for joined columns.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The names of joined columns should indicate their relationship. For example, they can use the same name.

4.4 Tool Interconnection

4.4.1 JDBC Configuration

Currently, third-party tools are connected to GaussDB through JDBC. This section describes the precautions for configuring the tool. For details about JDBC-related operations, see **Development Based on JDBC**.

Connection Parameters

- When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following configuration parameters are added. For details, see the implementation of the ConnectionFactoryImpl class in the JDBC code.

```
params = {
          { "user", user },
          { "database", database },
          { "client_encoding", "UTF8" },
          { "DateStyle", "ISO" },
          { "extra_float_digits", "3" },
          { "TimeZone",  createPostgresTimeZone() },
        };
```

  These parameters may cause the JDBC and gsql clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

  If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

  When the database is connected through JDBC, **extra_float_digits** is set to **3**. When the database is connected using gsql, **extra_float_digits** is set to **0**. As a result, the precision of the same data displayed in JDBC clients may be different from that displayed in gsql clients.

  In M-compatible databases, the default value of **extra_float_digits** is **0**.

- In precision-sensitive scenarios, the numeric type is recommended.
- When JDBC connects to the database, ensure that the following three time zones are the same:
  - Time zone of the host where the JDBC client is located
  - Time zone of the host where the GaussDB cluster is located
  - Time zone during GaussDB cluster configuration

    NOTE

    For details about how to set the time zone, contact an administrator.

fetchsize

To use **fetchsize** in applications, disable **autocommit**. Enabling the **autocommit** switch makes the **fetchsize** configuration invalid.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

autocommit

You are advised to enable **autocommit** in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure that transactions are committed. For example, explicitly commit translations after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

Connection Releasing

- You are advised to use connection pools to limit the number of connections from applications. You are advised not to connect to a database each time an SQL statement is executed.
- After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.
- Reset the session environment before releasing connections to the JDBC connection pool. Otherwise, historical session information may cause object conflicts.
  - If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
  - If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

CopyManager

In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use the CopyManager API driven by the GaussDB JDBC to import data in batches during application development.

4.5 SQL Compilation

DDL

- In GaussDB, you are advised to perform DDL operations (such as table creation and COMMENT) in a unified manner. Prevent DDL operations in batch processing jobs so that performance is not affected.
- Perform the TRUNCATE operation immediately after the unlogged table is used. GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- Suggestions on the storage mode of temporary and unlogged tables are the same as those on base tables.
- The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- Do not delete objects using DROP...CASCADE, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

For details about the DDL syntax, see **DDL Syntax Overview**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Data Loading and Unloading

- Explicitly set the inserted column list in the INSERT statement. Example:
  ```
  INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');
  ```
- After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.
- To clear all data in a table, you are advised to use TRUNCATE TABLE instead of DELETE TABLE. DELETE TABLE is not efficient and cannot release disk space occupied by the deleted data.

Type Conversion

- Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.
- If **sql_compatibility** is set to **ORA**, null strings will be automatically converted to NULL during data import. If null strings need to be retained, set **sql_compatibility** to **TD**.

For details about data types, see **Data Types**.

Query Operation

- Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- Perform DDL and DML operations encapsulated in transactions. For example, operations such as TRUNCATE TABLE, UPDATE TABLE, DELETE TABLE, and DROP TABLE cannot be restored once they are committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.
- During query compilation, you are advised to list all columns to be queried and avoid using SELECT *. Doing so reduces output columns, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- The cost of joining more than three tables or views, especially full joins, is difficult to be estimated. You are advised to use the WITH TABLE AS statement to create interim tables to improve the readability of SQL statements.
- Avoid using Cartesian products or full joins. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- Only IS NULL and IS NOT NULL can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for NULL<>NULL, NULL=NULL, and NULL<>1.
- Do not use count(col) instead of count(*) to count the total number of records in a table. count(*) counts the NULL value (actual rows) while count(col) does not.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- While executing count(col), the number of NULL record rows is counted as 0. While executing sum(col), NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- To count multiple columns using count(), column names must be enclosed in parentheses. For example, count ((col1, col2, col3)). Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when count(*) is executed.
- NULL records are not counted when count(distinct col) is used to calculate the number of non-NULL columns that are not repeated.
- If all statistical columns are NULL when count(distinct (col1,col2,...)) is used to count the number of unique values in multiple columns, Null records are also counted, and the records are considered the same.
- Use the connection operator || to replace the concat function for string connection, because the output of the concat function depends on the data type of the strings to be connected. When the execution plan is generated, the value cannot be calculated in advance. As a result, the query performance deteriorates severely.
- Use the time-related macros listed in **Table 1** to replace the now function and obtain the current time, because the execution plan generated by the now function cannot be pushed down to disks. As a result, the query performance severely deteriorates.

Table 4-3 Time-related macros

Macro Name	Description	Example
CURRENT_DATE	Obtains the current date, excluding the hour, minute, and second details.	gaussdb=# SELECT CURRENT_DATE; date ------------ 2018-02-02 (1 row)
CURRENT_TIME	Obtains the current time, excluding the year, month, and day.	gaussdb=# SELECT CURRENT_TIME; timetz -------------------- 00:39:34.633938+08 (1 row)
CURRENT_TIMESTAMP(n)	Obtains the current date and time, including the year, month, day, hour, minute, second, and time zone. **NOTE** *n* indicates the number of digits after the decimal point in the time string.	gaussdb=# SELECT CURRENT_TIMESTAMP(6); timestamptz ------------------------------- 2018-02-02 00:39:55.231689+08 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Do not use scalar subquery statements. A scalar subquery is a subquery in the output list of the SELECT statement. In the following example, "SELECT COUNT(*) FROM films f WHERE f.did = s.id" is a scalar subquery statement:
  ```
  SELECT id, (SELECT COUNT(*) FROM films f WHERE f.did = s.id) FROM staffs_p1 s;
  ```
  Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table associations based on the service logic.
- In WHERE clauses, the filter conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.
- Filter conditions in WHERE clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. The format is *col op expression*, where *col* indicates a table column, *op* indicates a comparison operator, such as = and >, and *expression* indicates an expression that does not contain a column name. For example:
  ```
  SELECT id, from_image_id, from_person_id, from_video_id FROM face_data WHERE
  current_timestamp(6) - time < '1 days'::interval;
  ```
  The modification is as follows:
  ```
  SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time >
  current_timestamp(6) - '1 days'::interval;
  ```
- Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, ORDER BY and LIMIT can be combined to reduce resource overhead. By default, GaussDB performs collation by ASC & NULL LAST.
- When the ORDER BY clause is used for collation, specify collation modes (**ASC** or **DESC**), and use NULL FIRST or NULL LAST for NULL record sorting.
- Do not rely on only the LIMIT clause to return the result set displayed in a specific sequence. Combine ORDER BY and LIMIT clauses if some specific result sets are returned, and use OFFSET to skip specific results if necessary.
- If the service logic is accurate, you are advised to use UNION ALL instead of UNION.
- If a filter condition contains only an OR expression, convert the OR expression to UNION ALL to improve performance. SQL statements that use OR expressions cannot be optimized, resulting in slow execution. For example, the conversion of the following statements:
  ```
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 ANDinline=301);
  ```
  Convert the statement to the following:
  ```
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 300 AND inline=301)
  union all
  SELECT * FROM scdc.pub_menu
  WHERE (cdp= 301 AND inline=302)
  union all
  SELECT * FROM tablename
  WHERE (cdp= 302 AND inline=301)
  ```
- If an IN(val1, val2, val3…) expression contains a large number of columns, you are advised to replace it with the IN (VALUES (val1), (val2),(val3)…) statement. The optimizer will automatically convert the IN constraint into a non-correlated subquery to improve the query performance.
- Use (NOT) EXIST instead of (NOT) IN when associated columns do not contain null values. For example, in a query statement, if the **T1.C1** column

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

does not contain any **NULL** value, add the **NOT NULL** constraint to the **T1.C1** column, and then rewrite the statements.

```
SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
```

Rewrite the statement as follows:

```
SELECT * FROM T1 WHERE NOT EXISTS (SELECT  * FROM T2 WHERE T1.C1=T2.C2);
```

NOTE

- If the value of the **T1.C1** column is not **NOT NULL**, the preceding rewriting cannot be performed.
- If the **T1.C1** column is the output of a subquery, check whether the output is **NOT NULL** based on the service logic.

- Use cursors instead of the LIMIT OFFSET syntax to perform pagination queries to avoid resource overheads caused by multiple executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

For details, see **SELECT**.

5 Application Development Guide

5.1 GaussDB Application Development Guide

In GaussDB, you can connect to and perform operations on a database through APIs such as JDBC, ODBC, libpq, Psycopg, ECPG, and Go.

JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access APIs for different relational databases. It allows Java applications to use SQL statements to perform database operations, such as querying, inserting, updating, and deleting data.

Some key features and usage of JDBC are as follows:

1. Database connection management: JDBC allows applications to establish connections to databases and manages the lifecycle of these connections.
2. SQL execution: JDBC can be used to query, update, and delete SQL statements. This is achieved by constructing SQL statements in Java code and sending them to the database.
3. Transaction management: JDBC APIs can be used to start, commit, or roll back transactions to ensure the consistency and integrity of database operations.
4. Exception handling: JDBC defines a group of exception classes to handle various exceptions that may occur during database operations. Developers can use the try-catch block to capture and handle these exceptions.
5. Batch processing: JDBC provides the batch processing function, which allows multiple SQL statements to be executed concurrently, improving the efficiency of database operations.
6. Metadata access: JDBC can be used to obtain the metadata information of the database, such as the table structure, column name, and data type. Developers then can dynamically construct SQL query statements or perform operations based on the database structure.

In conclusion, JDBC provides a flexible and powerful bridge that enables Java applications to interact with various databases and to implement data persistence

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and management. GaussDB supports JDBC 4.2 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridge.

For details about JDBC-based development, see **Development Based on JDBC**.

ODBC

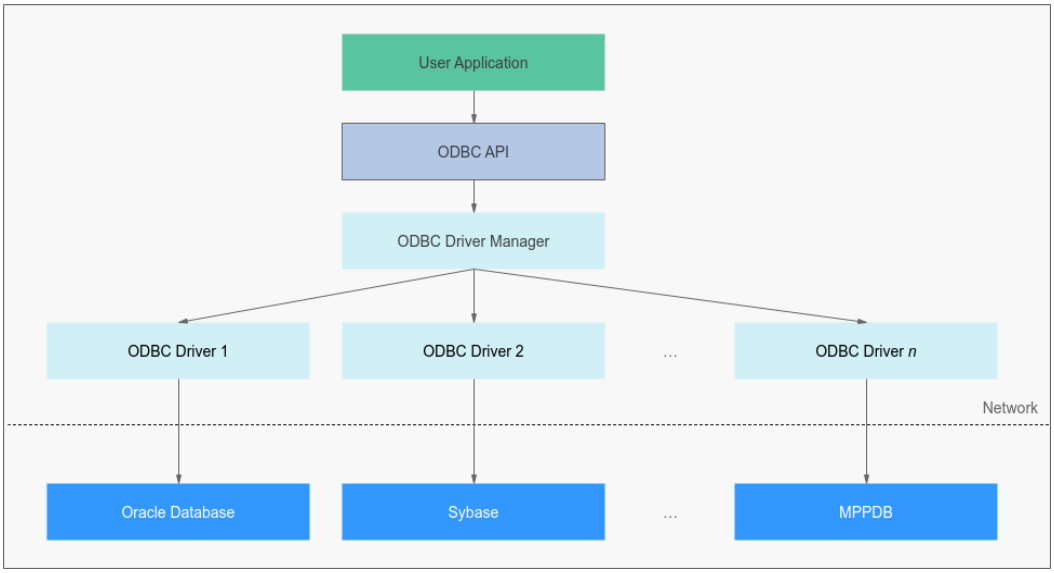
Open Database Connectivity (ODBC) is a Microsoft API for accessing databases in C/C++ based on the X/OPEN CLI. It provides a unified method for applications to access various database management systems (DBMSs) without considering specific database types or OS platforms. ODBC allows applications to use SQL to query, insert, update, and delete data in a database. Applications interact with the database through the APIs provided by ODBC, which enhances their portability, scalability, and maintainability.

The ODBC architecture consists of three main components: application, ODBC driver manager, and ODBC driver. Applications use ODBC APIs to communicate with the ODBC driver manager which loads and manages ODBC driver. The ODBC drivers are responsible for communicating with a specific database, executing SQL queries, and returning results. For details, see **Figure 5-1**.

In conclusion, ODBC provides a flexible and cross-platform method that allows users to easily connect applications to various databases without worrying about the details of a specific database system.

For details about ODBC-based development, see **Development Based on ODBC**.

Figure 5-1 ODBC system architecture



GaussDB supports ODBC 3.5 in the following environments.

Table 5-1 Platforms supported by ODBC

OS	Platform
EulerOS V2.0SP5	x86_64

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

OS	Platform
EulerOS V2.0SP9	Arm64
EulerOS V2.0SP10	x86_64
EulerOS V2.0SP10	Arm64
Windows 7	x86_32
Windows 7	x86_64
Windows Server 2008	x86_32
Windows Server 2008	x86_64
Kylin V10	x86_64
Kylin V10	Arm64
UnionTech V20	x86_64
UnionTech V20	Arm64
Huawei Cloud EulerOS 2.0	x86_64
Huawei Cloud EulerOS 2.0	Arm64
Suse 12.5	x86_64

The ODBC Driver Manager running on Unix or Linux can be unixODBC or iODBC. unixODBC-2.3.7 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel** > **Administrative Tools**.

NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with Huawei-developed data types such as tinyint, smalldatetime, and nvarchar2.

By default, there is no libltdl library on SUSE 12 SP5. You need to install the libltdl library before using the ODBC.

ODBC restrictions:

- ODBC does not support user-defined types and does not support user-defined parameters in stored procedures.
- When the **proc_outparam_override** parameter is enabled for the database, ODBC cannot properly call the stored procedure that contains the **out** parameter.
- ODBC does not support read on standby in a cluster for DR.
- For a hash bucket table, slice bucket table, or replication table, ODBC does not support the updatable cursor function.
- ODBC does not support zero characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

libpq

libpq is a C application programming interface to GaussDB. libpq contains a set of library functions that allow client programs to send query requests to GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB application interfaces, such as ODBC.

For details about libpq-based development, see **Development Based on libpq**.

NOTE

libpq does not support zero characters.

Psycopg

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 encapsulates libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and adapts to GaussDB data types. Through a flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

For details about Psycopg-based development, see **Psycopg-based Development**.

Table 5-2 Platforms supported by psycopg

OS	Platform	Python Version
EulerOS V2.0SP5	• Arm64 • x86_64	3.8.5
SUSE 12.5	x86_64	3.8.5
EulerOS V2.0SP9	Arm64	3.7.4
EulerOS V2.0SP10, Kylin V10, and UnionTech20	• Arm64 • x86_64	3.7.9
EulerOS V2.0SP11	• Arm64 • x86_64	3.9.11
Huawei Cloud EulerOS 2.0	• Arm64 • x86_64	3.9.9

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

During psycopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL_1_1_1f' not found" is displayed, use the environment variable *LD_LIBRARY_PATH* to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

For example, when the application software **client.py** that calls psycopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/pyscopg2/lib** indicates the directory where the OpenSSL library on which the GaussDB depends is located. Change it as required.

ecpg

Embedded SQL C Preprocessor for GaussDB Kernel (ECPG) is an embedded SQL preprocessor for C programs. An embedded SQL program consists of code written in a general-purpose programming language (C language in this example) and SQL commands. To build such program, source code (*.pgc) is first converted into an ordinary C language program (*.c) through an embedded SQL preprocessor, and then processed by a compiler. The converted ecpg program calls functions in the libpq library through the embedded SQL library (ecpglib), and communicates with a GaussDB Kernel server using the normal frontend-backend protocol.

Embedded SQL program is a C language program with special code inserted to perform database-related actions. This special code form is usually as follows:

```
EXEC SQL ...;
```

These statements replace a C statement in syntax and can appear globally or in a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and allow nested C code-style comments (part of the SQL standard). However, the C part of the program follows the standards of the C program and does not support nested comments.

For details about ecpg-based development, see **ECPG-based Development**.

Go

Go language driver (Go driver) used to connect to and operate GaussDB. It provides some APIs for connecting to and operating GaussDB. You can use these APIs to perform operations such as query, insert, update, and delete.

Some functions and usage of a Go driver are as follows:

1. Database connection: A Go driver can connect to a database through db.Open. The connection string can be in URL or DSN format.
2. SQL execution and query: A Go driver provides APIs such as db.Exec and db.Query for SQL execution and query.
3. Transaction management: A Go driver provides the Tx API for transaction management. It implements methods such as starting, committing, and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

rolling back transactions to ensure the consistency and atomicity of database operations.

4. Metadata access: A Go driver provides the ColumnType API to query column attribute information in the database, including whether the column can be empty, database type name, length, and number of decimal places.
5. Reusability: A Go driver provides the Prepare method for preparing SQL statements. The SQL statements can be executed for multiple times. You only need to change the input parameters to improve database reusability.

For details about Go-based development, see **Development Based on the Go Driver**.

5.2 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection state in the connection pool will remain, which affects subsequent operations using the connection pool.

Table 5-3 describes the compatibility of application development drivers.

Table 5-3 Compatibility Description

Driver	Compatibility Description
JDBC, Go, ODBC, libpq, Psycopg, and ecpg	The new drivers are forward compatible with the database. To use the new features added to the driver and database, you must upgrade the database.

NOTICE

- In principle, you need to set the compatibility parameter after the database creation, instead of switching the parameters when using the database.
- The JDBC driver must be upgraded to that maps to GaussDB Kernel 503.1.0 or later if the following features are used:
  - JDBC is required to use user-defined nested types such as record, array, and tableof.
  - The s2 compatibility parameter is enabled and the validity check of **sessiontimezone** is set.
- If the driver of an earlier version is connected to the database of a later version on which new features are involved, exceptions may occur. You are advised to use the driver and database of the matching version.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

If the driver is used in a multi-thread environment:

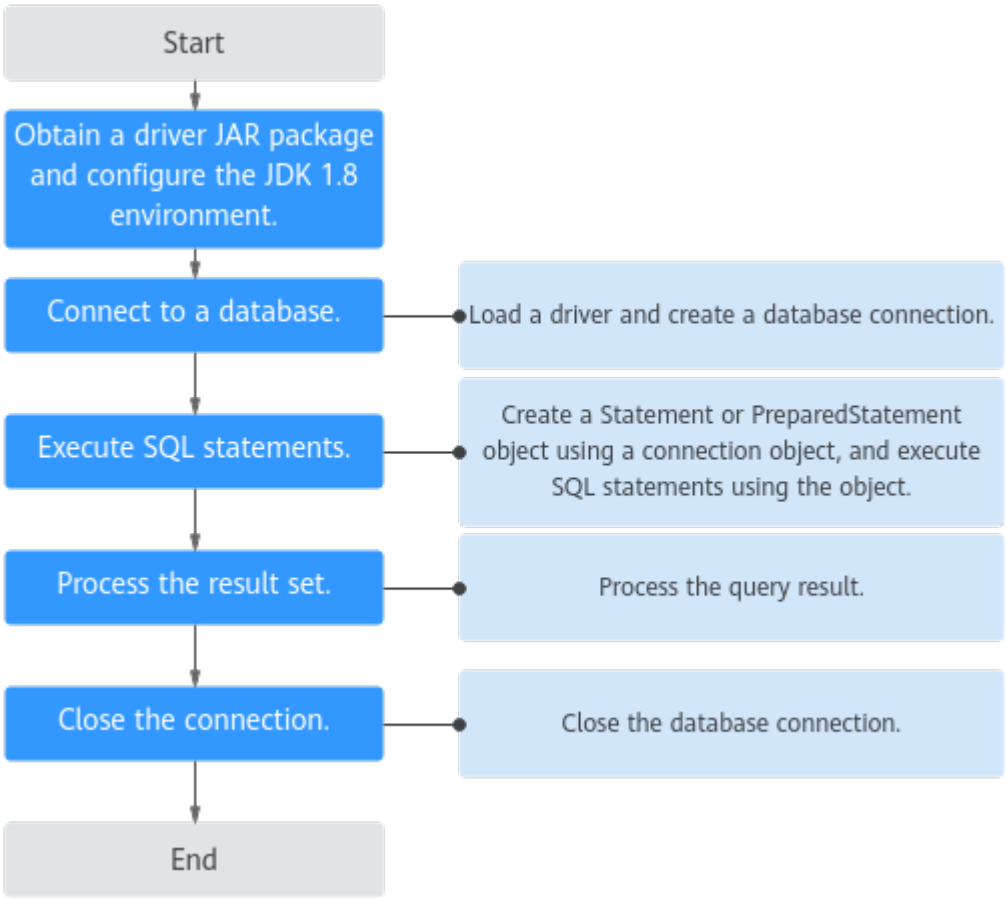
The JDBC driver is not thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

5.3 Development Based on JDBC

5.3.1 Development Process

Application development based on JDBC covers obtaining the driver JAR package and configuring JDK 1.8, connecting to a database, running SQL statements, processing result sets, and closing the connection.

Figure 5-2 Application development process based on JDBC



5.3.2 Development Process

5.3.2.1 Obtaining the JAR Package of the Driver and Configuring the JDK Environment

Environment preparation includes obtaining the driver JAR package and configuring the JDK environment.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Decompressing the Driver Package

Decompress the obtained driver package, find the JDBC driver package **GaussDB-Kernel**_*Database version number*_*OS*_**64bit_Jdbc.tar.gz**, and decompress it. The following JAR driver packages can be obtained:

- **gaussdbjdbc.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of the database connection is **jdbc:gaussdb**. This driver package is recommended. The Java code examples in this section use the **gaussdbjdbc.jar** package by default.
- **gscejdbc.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of the database connection is **jdbc:gaussdb**. This driver package contains the dependent libraries related to encryption and decryption that need to be loaded to the encrypted database. You are advised to use this driver package in encrypted scenarios. Currently, only EulerOS is supported.
- **gaussdbjdbc-JRE7.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of the database connection is **jdbc:gaussdb**. The **gaussdbjdbc-JRE7.jar** package is used in the JDK 1.7 environment.

NOTICE

- Before using the **gscejdbc.jar** driver package, you need to set the environment variable *LD_LIBRARY_PATH*. For details, see section "Setting Encrypted Equality Queries > Using JDBC to Operate an Encrypted Database" in *Feature Guide*.
- In JDK 1.8, you are advised to use **gaussdbjdbc.jar** instead of **gaussdbjdbc-JRE7.jar**.
- The JAR packages of the JDBC release package are classified by architecture. The **gscejdbc.jar** package can be used only when it is consistent with the deployment environment. Other JAR packages do not need to be consistent with the deployment environment.
- For details about other JDBC JAR packages, see **JDBC Compatibility Package**.

Configuring the JDK Environment

The JDK environment must be configured on the client. Currently, JDK 1.8 and JDK 1.7 are supported. This section uses JDK 1.8 as an example. JDK supports multiple platforms such as Windows and Linux. The following example describes the configuration method using Windows:

Step 1 Enter the following command in the MS-DOS window (command prompt in Windows) to check the JDK version.

```
java -version
```

Ensure that the JDK version is JDK 1.8. If JDK is not installed, download the installation package from the **official website** and install it.

Step 2 Configure system environment variables.

1. Right-click **My computer** and choose **Properties**.
2. In the **System** window, click **Advanced system settings** in the navigation pane.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

3. In the **System Properties** dialog box, click **Environment Variables** on the **Advanced** tab page.
4. In the **System variables** area of the **Environment Variables** dialog box, click **New** or **Edit** to configure system variables. For details about the variables, see **Table 5-4**.

Table 5-4 Variables

Variable	Operation	Variable Value
JAVA_HOME	– If the variable exists, click **Edit**. – If the variable does not exist, click **New**.	Specifies the Java installation directory. Example: **C:\Program Files\Java\jdk1.8.0_131**
Path	Click **Edit**.	– If *JAVA_HOME* is configured, add *%JAVA_HOME%***\bin** before the variable value. – If *JAVA_HOME* is not configured, add the following full Java installation path before the variable value: C:\Program Files\Java\jdk1.8.0_131\bin
CLASSPATH	Click **New**.	%JAVA_HOME%\lib;%JAVA_HOME%\lib\tools.jar

----End

5.3.2.2 Connecting to a Database

After you have obtained the driver JAR package and configured JDK 1.8, GaussDB allows you to connect to a database in four methods. This section describes how to connect to a database in the four methods.

5.3.2.2.1 Connection Methods

The database connection method is usually selected based on factors such as security, performance, scalability, and implementation complexity. For details, see **Table 5-5**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-5 Connection Methods

Connection Method	Advantage	Disadvantage	Selection Principle
Non-encrypted	• This method is easy to implement and does not require additional encryption and decryption operations. • It features high performance because no encryption or decryption operation is required, which reduces the overhead of data transmission.	• It provides low security and data is easily intercepted or tampered with during transmission. • It is not suitable for sensitive data transmission and may violate privacy protection laws and regulations.	It applies only to internal networks or environments that have low security requirements.
SSL	• It provides encrypted transmission. Data is protected during transmission, ensuring high security. • It supports client/server identity authentication, which enhances security.	• It is complex in configuration and management, and certificates need to be issued and updated. • Some performance overhead may be added, especially when it is used for encrypting and decrypting large amounts of data.	It applies to environments that require high data transmission security, such as finance and healthcare industries.
UDS	• It applies to local communication without passing through the network, featuring a high transmission speed. • No extra network overhead is required, and it is not vulnerable to network attacks.	• It is used only for the communication between processes on the same host but cannot be used for remote connections.	It applies to local communication scenarios, for example, data exchange between local services and applications.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Connection Method	Advantage	Disadvantage	Selection Principle
SM-based TLS	• It supports the ShangMi (SM) cryptographic algorithm, which complies with the legal requirements for encryption algorithms in China. • It provides as good security as the standard TLS and applies to scenarios that have special requirements on encryption standards.	• It may be restricted in other countries because other countries may not support the SM cryptographic algorithm. • Performance overhead may be added because the SM cryptographic algorithm may be more complex than traditional encryption algorithms.	It applies to specific industries in China, such as government and finance, where legal requirements are posed on encryption standards in China.

5.3.2.2.2 Connection Parameter Reference

All connection properties of the **info** parameter are case-sensitive. **Table 5-6** describes the common properties.

Table 5-6 Connection properties of the info parameter

Property	Description	Value
PGDBNAME	Specifies the database name. You do not need to set this parameter in the URL because it is automatically parsed from the .properties file.	Property type: string

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
PGHOST	Specifies the IP address of the host. You do not need to set this parameter in the URL because it is automatically parsed from the .properties file. Both IPv4 and IPv6 addresses are supported. If multiple CNs are configured, use colons (:) to separate their IP addresses and port numbers, and use commas (,) to separate CNs.	Property type: string
PGPORT	Specifies the port number of the host. You do not need to set this parameter in the URL because it is automatically parsed from the .properties file.	Property type: integer
user	Specifies the database user who creates the connection.	Property type: string
password	Specifies the password of the database user.	Property type: string
driverInfoMode	Controls the output mode of the driver description information.	Property type: string Value range: **postgresql** or **gaussdb**. • **postgresql** indicates that the driver description related to PG is displayed. • **gaussdb** indicates that the driver description related to GaussDB is displayed. Default value: **postgresql**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
enable_ce	Specifies the encrypted equality query capability.	Property type: string Value range: • **enable_ce=1** indicates that JDBC supports the basic capability of encrypted equality query. • **enable_ce=3** indicates that JDBC supports the basic capability of encrypted equality query. Default value: No default value is provided. If this property is not set, encrypted equality query is disabled.
key_info	This parameter is used together with **enable_ce** to set parameters for accessing an external key manager in an encrypted database.	Property type: string Default value: No default value is provided.
refreshClientEncryption	Specifies whether the encrypted database supports cache update on the client.	Property type: string Value range: • The value **1** or **NULL** indicates that the encrypted database supports cache update on the client. • Other character strings indicate that the encrypted database does not support cache update on the client. Default value: **NULL**
loggerLevel	Specifies the logging level.	Property type: string Value range: **OFF**, **INFO**, **DEBUG**, and **TRACE** (case-insensitive). • **OFF**: The log function is disabled. • **INFO**, **DEBUG**, and **TRACE** logs record information of different levels. Default value: **OFF**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
loggerFile	Specifies the log output path (directory and file name). Generally, the log directory and file name must be specified. It is used to specify the path for exporting monitoring logs only when the connection monitoring function is enabled. To export JDBC logs to a specified path, configure it in the **java.util.logging** .properties file or system properties. This command can be used only when connection monitoring is enabled.	Property type: string Default value: No default value is provided. If no directory is specified, log files are generated in the directory where the client program is running.
logger	Specifies the log output framework used by the JDBC driver. The JDBC driver supports the log output framework used for interconnecting with user applications.	Property type: string Value range: **Slf4JLogger** • If it is left empty, the JDBC driver uses JdkLogger. • Currently, only the Slf4j-API-based third-party log output framework is supported. For details, see **Log Management**.
allowEncodingChanges	If this parameter is set to **true**, the character set type can be changed. This parameter is used together with **characterEncoding** to set the character set. The two parameters are separated by ampersands (&). Example: **allowEncodingChanges=true&characterEncoding=UTF8**.	Property type: Boolean Value range: • **true**: The character set type can be changed. • **false**: The character set type cannot be changed. Default value: **false**
characterEncoding	It must be used together with **allowEncodingChanges**. When **allowEncodingChanges** is set to **false**, **characterEncoding** can be set only to **UTF8**. When **allowEncodingChanges** is set to **true**, set **characterEncoding** as permitted.	Property type: string Value range: **UTF8**, **GBK**, **LATIN1**, **GB18030**, **GB18030_2022**, or **ZHS16GBK**. Default value: **UTF8**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
currentSchema	Specifies the schema of the current connection. You need to specify a schema in **search-path**. If the schema name contains special characters except letters, digits, and underscores (_), you need to enclose the schema name in quotation marks. Note that the schema name is case-sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Example: **currentSchema=schema_a,"schema-b","schema/c"**	Property type: string Default value: If this parameter is not set, the default schema is the username used for the connection.
loadBalanceHosts	Specifies whether to enable the load balancing function.	Property type: Boolean Value range: ● **true**: The shuffle algorithm is used to randomly select a host from the candidate hosts to establish a connection. ● **false**: Multiple hosts specified in the URL are connected in sequence. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value

autoBalance	Specifies a load balancing policy.
	CAUTION
	1. Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced.
	2. This parameter can be used only in distributed scenarios and cannot be used in centralized scenarios.
	3. If the load balancing function is enabled when the standby cluster for DR is connected, query requests are sent to the primary cluster. As a result, the query performance is affected.
	4. When load balancing is enabled, the floating IP address or data IP address can be configured in the URL. If the floating IP address is configured, the system obtains the corresponding data IP address based on the floating IP address and performs load balancing based on the obtained data IP address. Therefore, when configuring the floating IP address or data IP address in the URL, ensure that the network connection of the data IP address is normal. Otherwise, the load balancing function is abnormal.
		Property type: string
		Value range:
		• If this parameter is set to **true**, **balance**, or **roundrobin**, the JDBC load balancing function is enabled to balance multiple connections of an application to each CN available in the database cluster.
		Example:
		`jdbc:gaussdb://host1:port1,host2:port2/database?autoBalance=true`
		JDBC periodically updates the list of available CNs in the entire cluster (data IP addresses of hosts in the CN list). The update interval can be configured using the **refreshCNIpListTime** parameter. The default value is 10 seconds. For example, the obtained list is as follows:
		`host1:port1,host2:port2,host3:port3,host4:port4`
		When load balancing is enabled, **host1** and **host2** ensure high availability only when they are connected for the first time. Then, the driver selects available CNs from **host1**, **host2**, **host3**, and **host4** in sequence to refresh the available CN list. New connections will use the round robin algorithm to select CNs from **host1**, **host2**, **host3**, and **host4** for connection.
		• If this parameter is set to **priority***n*, the JDBC-based load balancing function is enabled. Multiple connections of an application are balanced to the first *n* available CNs configured in the URL. When the first *n* CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. *n* is a positive integer and is less than the number of CNs configured

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value

		in the URL. When **parseCandidatesByDomain** is set to **true**, the priority configuration of **priority***n* does not take effect. In this scenario, the priority is specified by **priorityDomains**. When **priority***n* is used for load balancing, the host cannot use an IPv6 address. In the scenario where multiple processes establish connections, this policy may cause load imbalance.
		For example:
		`jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=priority2`
		JDBC periodically obtains the list of all available CNs in the entire cluster.
		`host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6`
		host1 and **host2** are in **AZ1**, and **host3** and **host4** are in **AZ2**. The driver preferentially selects **host1** and **host2** for load balancing. If both **host1** and **host2** are unavailable, the driver randomly selects a CN from **host3**, **host4**, **host5**, and **host6** for connection.
		• If this parameter is set to **shuffle**, JDBC random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.
		For example:
		`jdbc:gaussdb://host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle`
		JDBC periodically obtains the list of all available CNs in the entire cluster.
		`host1:port1,host2:port2,host3:port3,host4:port4`
		host1, **host2**, and **host3** ensure high availability only when they are connected for the first time.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
		Later, they use the shuffle algorithm to randomly select a CN from the refreshed CN list for connection. ● If this parameter is set to **specified**, the JDBC load balancing function is enabled and connections are established only on nodes specified in the user URL. For example: `jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=specified&priorityServers=2` JDBC identifies **host1** and **host2** as the nodes for establishing connections in the primary cluster, and identifies **host3** and **host4** as the nodes for establishing connections in the standby cluster. When a connection is set up, JDBC evenly distributes the connections to **host1** and **host2**. If all the nodes (**host1** and **host2**) in the primary cluster are faulty, JDBC does not attempt to connect to the remaining nodes. After a switchover, JDBC evenly distributes connections to **host3** and **host4**. If all nodes (**host3** and **host4**) in the standby cluster are faulty, JDBC does not attempt to connect to the remaining nodes. ● If this parameter is set to **shuffle***n*, the JDBC random load balancing function preferred on specified nodes is enabled. Multiple connections of an application are balanced to the first *n* available CNs configured in the URL. When the first *n* CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. *n* is a positive integer and is less than

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value

		or equal to the number of CNs configured in the URL.
		When **parseCandidatesByDomain** is set to **true**, the priority configuration of **shuffle***n* does not take effect. In this scenario, the priority is specified by **priorityDomains**. When **shuffle***n* is used for load balancing, the host cannot use an IPv6 address. In the scenario where multiple processes establish connections, this policy can be used to implement load balancing for connections to specified preferred nodes.
		For example:
		`jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4/database?autoBalance=shuffle2`
		JDBC periodically obtains the list of all available CNs in the entire cluster.
		`host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6`
		The driver preferentially selects **host1** and **host2** for random load balancing. If both **host1** and **host2** are unavailable, the driver randomly selects a CN from **host3**, **host4**, **host5**, and **host6** for connection.
		– When **parseCandidatesByDomain** is set to **true**, the priority configuration of **shuffle***n* does not take effect. In this scenario, the priority is specified by **priorityDomains**. When **shuffle***n* is used for load balancing, the host cannot use an IPv6 address. In the scenario where multiple processes establish connections, this policy can be used to implement load balancing for connections to specified preferred nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
		– Example: • If this parameter is set to **false**, the JDBC load balancing and priority-based load balancing functions are disabled. Default value: **false**
refreshCNIpListTime	Obtains the cache validity period of the CNs. During connection establishment, the CN status in the database cluster is checked and is reliable within the period specified by **refreshCNIpListTime**. After the period expires, the status becomes invalid. The IP address list of available CNs is obtained again during the next connection establishment.	Property type: integer Unit: s The value ranges from 1 to 9999. Default value: **10** Suggestion: Adjust the value based on service requirements and use it together with **autoBalance**.
hostRecheckSeconds	After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the duration specified by **hostRecheckSeconds**. After the period expires, the status becomes invalid.	Property type: integer Unit: s Value range: The minimum value is **0** and the maximum value is unlimited. Default value: **10**
ssl	Specifies that the database is connected in SSL mode. When **ssl** is set to **true**, the **NonValidatingFactory** channel and certificate mode are supported.	Property type: Boolean Value range: • **true**: The database is connected in SSL mode. • **false**: The database is not connected in SSL mode. Default value: No default value is provided. If this property is not set, the value **false** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
sslmode	Specifies the SSL authentication mode.	Property type: string Value range: **disable**, **allow**, **prefer**, **require**, **verify-ca**, and **verify-full**. ● **disable**: SSL connection is disabled. ● **allow**: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. ● **prefer**: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. ● **require**: The system only attempts to set up an SSL connection. It neither checks whether the server certificate is issued by a trusted CA, nor checks whether the host name of the server is the same as that in the certificate. ● **verify-ca**: The system attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA. ● **verify-full**: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate. Default value: No default value is provided. If this property is not set, the value **require** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
sslgmcipher	Specifies the encryption algorithm suite used by SM-based TLS.	Property type: string Value range: • **ECC_SM4_SM3**: SM-based one-way and two-way authentication modes are supported. • **ECDHE_SM4_SM3**: Only SM-based two-way authentication is supported.
sslcert	Specifies the complete path of the client certificate file. The certificate type is **End Entity**.	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslkey	Specifies the complete path of the key file. You need to convert the key to the DER format before using it. `openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt`	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslenccert	Specifies the complete path of the encryption certificate for the SM-based TLS client. The certificate type is **End Entity**.	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslenckey	Specifies the complete path of the SM-based TLS encryption key file. You need to convert the key to the DER format before using it. `openssl pkcs8 -topk8 -outform DER -in client_enc.key -out client_enc.key.pk8 -nocrypt`	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslrootcert	Specifies the name of the SSL root certificate. The root certificate type is CA.	Property type: string Default value: No default value is provided. If this property is not set, the root directory of the user is read.
sslpassword	Specifies the SSL password, which is provided for ConsoleCallbackHandler.	Property type: string

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
sslpasswordcallback	Specifies the class name of the SSL password provider.	Property type: string Default value: **com.huawei.gaussdb.jdbc.ssl.jdbc4.LibPQFactory.ConsoleCallbackHandler**
sslfactory	Specifies the class name used by SSLSocketFactory to establish an SSL connection.	Property type: string Default value: No default value is provided.
sslprivatekeyfactory	Specifies the fully qualified name of the implementation class of the com.huawei.gaussdb.jdbc.ssl.PrivateKeyFactory API that implements the private key decryption method. If it is not provided, try the default JDK private key decryption algorithm. If the decryption fails, use com.huawei.gaussdb.jdbc.ssl.BouncyCastlePrivateKeyFactory. You need to provide the **bcpkix-jdk15on.jar** package. The recommended version is 1.65 or later.	Property type: string Default value: No default value is provided. If this property is not set, the system attempts to use the default JDK private key decryption algorithm for decryption.
sslfactoryarg	The value is an optional parameter of the constructor function of the sslfactory class. (This parameter is not recommended.)	Property type: string Default value: No default value is provided.
sslhostnameverifier	Specifies the class name of the host name verifier. The API must implement javax.net.ssl.HostnameVerifier. The default value is **com.huawei.gaussdb.jdbc.ssl.PGjdbcHostnameVerifier**.	Property type: string Default value: No default value is provided. If this property is not set, **com.huawei.gaussdb.jdbc.ssl.PGjdbcHostnameVerifier** is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
loginTimeout	Specifies the waiting time for establishing the database connection. When multiple IP addresses are configured in the URL, if the time for obtaining the connection exceeds this value, the connection fails and the subsequent IP addresses are not tried. The value of **loginTimeout** is related to **connectTimeout** and **socketTimeoutInConnecting**. The calculation formula is as follows: **loginTimeout** = (**connectTimeout** + Connection authentication time + Initialization statement execution time) x Number of nodes.	Property type: integer Unit: s Value range: 0 to 2147483647. The value **0** indicates that the timeout mechanism does not take effect. Default value: **0** Suggestion: After this parameter is set, an asynchronous thread is started each time a connection is established. If there are a large number of connections, the pressure on the client may increase. You are advised to set it as follows: max(connectTimeout, socketTimeoutInConnecting) x Number of nodes. This prevents connection failures when the network is abnormal and the *n*th IP address is the IP address of the primary node. You can adjust it based on the actual service situation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
	NOTICE • This parameter sets the time for attempting to connect to all IP addresses in a list. If this parameter is set to a small value, the subsequent IP addresses in the list may fail to be connected. For example, if three IP addresses are set, **loginTimeout** is set to **5s**, and it takes 5s to connect to the first two IP addresses, the third IP address cannot be connected. • When any of the CPU, memory, and I/O load approaches 100%, the connection is slow, which may cause connection timeout. You can locate the fault as follows: 1. Log in to a physical machine with slow connections or use a management tool to query the resource load. You can run the **top** command to check the CPU usage, run the **free** command to check the memory usage, and run the **iostat** command to check the I/O load. In addition, you can check the monitoring logs in the CM Agent and the monitoring records on the database O&M platform. 2. For peak load scenarios caused by a large number of slow queries in a short period of time, you can use the port specified by [*Port number of the database server* + 1] to query the pg_stat_activity view. For slow queries, you can use the **pg_terminate_backend(pid int)** function to kill sessions. 3. If service overloading exists for a long time (that is, there is no obvious slow query, or new queries still become slow after slow queries are killed), reduce the service load and increase database resources.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
connectTimeout	Specifies the timeout interval for connecting to a server OS. If the time taken to connect to a server OS exceeds the value specified, the connection is interrupted. When multiple IP addresses are configured in the URL, it indicates the timeout interval for connecting to a single IP address.	Property type: integer Unit: s Value range: 0 to 2147483647. The value **0** indicates that the timeout mechanism does not take effect. Default value: **0**
socketTimeout	Specifies the timeout interval for a socket read operation. If the time taken to read data streams from a server exceeds the value specified, the connection is closed. If this parameter is not set, the client waits for a long time when the database process is abnormal. You are advised to set this parameter based on the SQL execution time acceptable to services. **NOTE** When the timeout is triggered on the JDBC and the connection is closed, the running services delivered by the JDBC to the database are forcibly terminated. The capability of forcibly terminating a service is controlled by the GUC parameter **check_disconnect_query**. If this parameter is set to **on**, the capability is supported. If this parameter is set to **off**, the capability is not supported.	Property type: integer Unit: s Value range: 0 to 2147483647. The value **0** indicates that the timeout mechanism does not take effect. Default value: **0**
socketTimeoutInConnecting	Specifies the timeout interval for a socket read operation during the connection establishment. If the time of reading data streams from the server exceeds the threshold, it attempts to search for the next node for connection.	Property type: integer Unit: s Value range: 0 to 2147483647. Default value: **5**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
statementTimeout	Specifies the timeout interval for executing a statement in a connection. If the execution time of a statement exceeds this value, the statement execution is canceled.	Property type: integer Unit: ms Value range: 0 to 2147483647. The value **0** indicates that the timeout mechanism does not take effect. Default value: **0**
cancelSignalTimeout	A cancel message may cause a block. This property controls "connect timeout" and "socket timeout" in a cancel command. If the cancel command does not respond within the specified time, the connection is interrupted to reduce the occupation of client resources.	Property type: integer Unit: s Value range: 0 to 2147483647. Default value: **10**
tcpKeepAlive	Specifies whether to enable TCP keepalive detection.	Property type: Boolean Value range: ● **true**: TCP keepalive detection is enabled. ● **false**: TCP keepalive detection is disabled. Default value: **false**
logUnclosedConnections	The client may leak a connection object because it does not call the connection object's close() method. These objects will be collected as garbage and finalized using the finalize() method.	Property type: Boolean Value range: ● **true**: If the user does not call the close() method, the finalize() method closes the connection object. ● **false**: If the user does not call the close() method, the connection object is not closed. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
assumeMinServerVersion (Deprecated)	Specifies the version of the server to be connected. If the value of **assumeMinServerVersion** is greater than or equal to **9.0**, the number of packets to be sent are reduced during connection establishment. The client does not send a request to set the floating point to 3 (that is, retain the original floating point 2).	Property type: string Default value: No default value is provided.
ApplicationName	Specifies the name of the JDBC driver that is being connected. You can query the pgxc_stat_activity table on CN to view the information about the client that is being connected. The **application_name** field indicates the JDBC driver name.	Property type: string Default value: **PostgreSQL JDBC Driver**
connectionExtraInfo	Specifies whether the driver reports the driver deployment path, process owner, and URL connection configuration information to the database.	Property type: Boolean Value range: • **true**: The JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the **connection_info** parameter. In this case, you can query the information from PG_STAT_ACTIVITY or PGXC_STAT_ACTIVITY. • **false**: The driver does not report the driver deployment path, process owner, and URL connection configuration information to the database. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
autosave	Specifies the action that the driver should perform upon a query failure.	Property type: string Value range: **always**, **never**, and **conservative**. ● **always**: The JDBC driver sets a savepoint before each query and rolls back to the savepoint if the query fails. ● **never**: There is no savepoint. ● **conservative**: A savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. Default value: **never**
protocolVersion	Specifies the connection protocol version.	Property type: integer Value range: **1** and **3**. ● If it is set to **1**, only the V1 server is connected. ● If it is set to **3**, only the V5 server is connected. Default value: No default value is provided. If this property is not set, the value **3** is used.
prepareThreshold	Specifies the number of times that the PreparedStatement object is executed before the parsed statement on the server is used. **NOTE** You are advised not to use JDBC and prepareStatement to execute password-related statements (for example, **CREATE USER user_name WITH PASSWORD** '********'). This is because when the number of execution times reaches the value specified by **prepareThreshold**, the database caches SQL statements but does not cache the passwords for security purposes. When the prepareStatement is executed again, error message "Password must contain at least 8 characters" will be displayed.	Property type: integer Value range: 0 to 2147483647. Default value: **5**. The default value indicates that when the same PreparedStatement object is executed for five or more times, the parse message is not sent to the server to parse the statement. Instead, the statement that has been parsed on the server is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
preparedStatementCacheQueries	Specifies the maximum number of cached queries in each connection (queries are cached after PreparedStatement triggers prepareThreshold).	Property type: integer Value range: 0 to 2147483647. The value **0** indicates that the cache function is disabled. Default value: **256**. If more than 256 different queries are used in the prepareStatement() call, the least recently used query cache will be discarded. Suggestion: Set the value based on service requirements. This parameter is used together with **prepareThreshold**.
preparedStatementCacheSizeMiB	Specifies the size of the space for caching queries in each connection (queries are cached after PreparedStatement triggers prepareThreshold).	Property type: integer Unit: MB Value range: 0 to 2147483647. The value **0** indicates that the cache function is disabled. Default value: **5**. If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded.
databaseMetadataCacheFields	Specifies the maximum number of columns that can be cached in each connection.	Property type: integer Value range: 0 to 2147483647. The value **0** indicates that the cache function is disabled. Default value: **65536**
databaseMetadataCacheFieldsMiB	Specifies the maximum size of columns that can be cached in each connection.	Property type: integer Unit: MB Value range: 0 to 2147483647. The value **0** indicates that the cache function is disabled. Default value: **5**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
stringtype	Specifies the type of the parameter passed to the database when the java.sql.PreparedStatement#setString method is called.	Property type: string Value range: **unspecified** and **varchar**. ● **varchar**: The parameters are sent to the server as varchar parameters. ● **unspecified**: The parameters are sent to the server without specifying the type, and the server will attempt to infer the appropriate type. Default value: **varchar**
batchMode	Specifies whether to use the batch mode. **NOTE** If **batchMode** is set to **on**, the data type of each column is the same as that specified by the first data record. If the data types are mixed, an error may be reported or the inserted data may be abnormal.	Property type: string Value range: ● **on**: The batch mode is enabled to improve the batch update performance. If **batchMode** is set to **on**, the returned result is [count, 0, 0...0]. The first element in the array is the total number of records affected in batches. ● **off**: The batch mode is disabled. If **batchMode** is set to **off**, the returned result is [1, 1, 1...1]. Each element in the array corresponds to the number of affected records in a single modification. Default value: **on** Suggestion: If the service framework (such as hibernate) checks the return value during batch update, you can set this parameter to solve the problem.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
fetchsize	Specifies the default **fetchsize** for statements in the created connection. Specifies the number of rows read by fetch in ResultSet at a time. It has the same function as **defaultRowFetchSize**. If **fetchsize** and **defaultRowFetchSize** are set at the same time, **fetchsize** prevails.	Property type: integer Value range: 0 to 2147483647. Default value: **0**. It indicates that all results are obtained from the database at a time. **Suggestion**: You are advised to set this parameter based on the amount of data queried by services and the memory of the client. When setting **fetchsize**, disable automatic commit (set **autocommit** to **false**). Otherwise, the setting of **fetchsize** does not take effect.
defaultRowFetchSize	Specifies the number of rows read by fetch in ResultSet at a time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding out of memory exception.	Property type: integer Value range: 0 to 2147483647. Default value: **0**. It indicates that all results are obtained from the database at a time.
reWriteBatchedInserts	Specifies whether to rewrite SQL statements during batch insertion. When this parameter is used, **batchMode** must be set to **off**.	Property type: Boolean Value range: • **true**: Combine *N* insert statements into one: insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN) • **false**: Do not rewrite SQL statements during batch insertion. Default value: **false**
unknownLength	Specifies the length of the unknown length type when the data of some GaussDB types (such as TEXT) is returned by functions such as ResultSetMetaData.getColumnDisplaySize and ResultSetMetaData.getPrecision.	Property type: integer Value range: 0 to 2147483647. Default value: **2147483647**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
uppercaseAttributeName	Converts the query result of the API for obtaining metadata to uppercase letters. The application scenario is as follows: All metadata stored in the database is in lowercase, but the metadata in uppercase must be used as the input and output parameters. For details about the involved APIs, see **java.sql.DatabaseMetaData** and **java.sql.ResultSetMetaData**. **NOTE** After the **uppercaseAttributeName** parameter is enabled, if the database contains metadata with a mixture of uppercase and lowercase letters, only the metadata in lowercase letters can be queried and output in uppercase letters. Before using the metadata, ensure that the metadata is stored in lowercase letters to prevent data errors.	Property type: string Value range: • **true** and **upper** indicate that metadata is converted to uppercase letters. • **false**: The configuration of GUC parameter **uppercase_attribute_name** is used. • **lower** indicates that metadata is converted to lowercase letters. Default value: **false**
binaryTransfer	Specifies whether data is sent and received in binary format.	Property type: Boolean Value range: • **true**: enabled. • **false**: disabled. Default value: **false**
binaryTransferEnable	Specifies types for which binary transmission is enabled. Every two types are separated by commas (,), for example, **binaryTransferEnable=Integer4_ARRAY,Integer8_ARRAY**. You can select either the OID or name. For example, if the name is BLOB and the OID is 88, set **binaryTransferEnable** to **BLOB** or **88**.	Property type: string Default value: No default value is provided.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
binaryTransferDisable	Specifies types for which binary transmission is disabled. Every two types are separated by commas (,). You can select either the OID or name. If **binaryTransferDisable** and **binaryTransferEnable** have the same value, the disabling function is used.	Property type: string Default value: No default value is provided.
blobMode	Sets the setBinaryStream() method to assign values to different types of data. You are advised to set this parameter to **on** for systems migrated from ORA and MySQL and to **off** for systems migrated from PG.	Property type: string Value range: • **on**: Values are assigned to BLOB data. • **off**: Values are assigned to bytea data. Default value: **on**
socketFactory	Specifies the name of the class used to create a socket connection with the server. This class must implement the javax.net.SocketFactory API and define a constructor with no parameter or a single string parameter.	Property type: string
socketFactoryArg	The value is an optional parameter of the constructor function of the socketFactory class and is not recommended.	Property type: string
receiveBufferSize	It is used to set **SO_RCVBUF** on the connection stream.	Property type: integer Unit: byte Value range: –1 to 2147483647. Default value: **–1**. It indicates that the buffer size is not set.
sendBufferSize	It is used to set **SO_SNDBUF** on the connection stream.	Property type: integer Unit: byte Value range: –1 to 2147483647. Default value: **–1**. It indicates that the buffer size is not set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
preferQueryMode	Specifies the query mode.	Property type: string Value range: **simple**, **extended**, **extendedForPrepared**, and **extendedCacheEverything**. ● In **simple** mode, only Q messages are sent. Only text is supported. The parse and bind operations are not supported. ● In **extended** mode, parse, bind, and execute operations are supported. ● In **extendedForPrepared** mode, extended query applies to only the Prepared Statement objects, and the Statement objects support only simple query. ● In **extendedCacheEverything** mode, the query generated by each Statement object is cached. Default value: **extended**
ApplicationType	Sets whether to enable distributed write and query. This parameter is valid only when the database is in the GTM-free mode.	Property type: string Value range: **not_perfect_sharding_type** and **perfect_sharding_type** ● **not_perfect_sharding_type**: enables distributed write and query. ● **perfect_sharding_type**: disables distributed write and query by default. Distributed write and query can be performed only after /* multinode */ is added to the SQL statement. **Default value**: **not_perfect_sharding_type**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
priorityServers	Specifies that the first *n* nodes configured in the URL are preferentially connected as the primary cluster. It is used in streaming DR scenarios. Example: **jdbc:gaussdb://host1:port1,host2:port2,host3:port3,host4:port4,/database?priorityServers=2**. That is, **host1** and **host2** are primary cluster nodes, and **host3** and **host4** are standby cluster nodes for DR.	Property type: integer Value range: a number greater than 0 and less than the number of CNs configured in the URL. Default value: **NULL**
usingEip	Specifies whether to use an elastic IP address to implement load balancing. **NOTICE** If **usingEip** is set to **true**, the hosts in the URL must use elastic IP addresses. If **usingEip** is set to **false**, the hosts in the URL must use data IP addresses. Otherwise, the priority*n* and shuffle*n* load balancing policies will become invalid.	Property type: Boolean Value range: • **true**: Elastic IP addresses are used to implement load balancing. • **false**: Data IP addresses are used to implement load balancing. Default value: **true**
traceInterfaceClass	Specifies the fully qualified name of the implementation class of the com.huawei.gaussdb.jdbc.log.Tracer API that implements the method for obtaining **traceId**.	Property type: string Default value: **NULL**
use_boolean	Sets the OID type bound to the setBoolean method in extended mode.	Property type: Boolean Value range: • **false**: The int2 type is bound. • **true**: The Boolean type is bound. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
allowReadOnly	Specifies whether to enable the read-only mode for a connection.	Property type: Boolean Value range: • **true**: The read-only mode is enabled. • **false**: The read-only mode is disabled. In this case, calling connection.setReadOnly(true) does not take effect, and data can still be modified. Default value: **true**
TLSCiphersSupperted	Specifies the supported TLS cipher suite.	Property type: string Default value: **TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384**
stripTrailingZeros	Specifies whether trailing 0s of the numeric type are removed. It is valid only for **ResultSet.getObject(int columnIndex)**.	Property type: Boolean Value range: • **true**: Trailing 0s of the numeric type are removed. • **false**: Trailing 0s of the numeric type are not removed. Default value: **false**
enableTimeZone	Specifies whether to enable the time zone setting on the client.	Property type: Boolean Value range: • **true**: The time zone setting on the client is enabled. The JVM time zone is obtained to specify the database time zone. • **false**: The time zone setting on the client is disabled. Instead, the database time zone is used. Default value: **true**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
enableStandbyRead	Specifies whether to enable the read mode of the standby node.	Property type: Boolean Value range: • **true**: enabled. • **false**: disabled. Default value: **false**
compatibilityTags	Is used to restore some features of the driver to an earlier version to ensure forward compatibility. You can configure one or more tags. Each tag indicates that the corresponding forward compatibility feature is enabled. Different tags are separated by commas (,). Currently, the following tag is supported: **typeMapInitNull**: After this tag is used, the behavior of earlier driver versions is compatible. The initial value of **typeMap** in **java.sql.Connection** is **NULL**. If this tag is not used, the initial value is an empty map. **NOTICE** Generally, this parameter is not recommended unless there is an obvious forward compatibility issue.	Property type: string Default value: No default value is provided.
parseCandidatesByDomain	Specifies whether to obtain candidate nodes based on domain names.	Property type: Boolean Value range: • **true**: enabled. After this function is enabled, you need to configure the host information in the URL in the format of domain name plus port number. The driver obtains the IP address based on the domain name, generates a standby node set, and works with the **autoBalance** parameter for load balancing. • **false**: disabled. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
primaryDomains	Specifies that the first *n* domain names configured in the URL are preferentially connected as the primary cluster. A value greater than 0 indicates that the primary cluster is preferentially connected. This parameter takes effect only when **parseCandidatesByDomain** is set to **true**. The domain names in the URL are divided into two groups. The first group is the primary cluster, and the second group is the standby cluster. After a switchover, the two groups switch their positions. The first group is the primary cluster, and the second group is the standby cluster. It applies to streaming DR and Dorado dual-cluster scenarios. Example: **jdbc:gaussdb://domain1:port1,domain2:port2,domain3:port3,domain4:port4/database?parseCandidatesByDomain=true&primaryDomains=2**, in which **domain1** and **domain2** correspond to the primary cluster and the IP addresses corresponding to **domain1** and **domain2** are preferentially connected. If a switchover occurs, **domain3** and **domain4** are marked as the primary cluster, and connections are preferentially established to **domain3** and **domain4**.	Property type: integer Value range: 0 to the number of domain names configured in the URL. Default value: **0**, indicating that the function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
priorityDomains	Specifies the first *n* domain names configured in the URL as the domain names to be preferentially connected. A value greater than 0 indicates that the function is enabled. This parameter takes effect only when **parseCandidatesByDomain** is set to **true**. Example: **jdbc:gaussdb://domain1:port1,domain2:port2,domain3:port3,domain4:port4/database?parseCandidatesByDomain=true&primaryDomains=2&priorityDomains=1**, in which **domain1** and **domain2** correspond to the primary cluster but the IP address corresponding to **domain1** is preferentially connected. **domain2** is the standby domain name. The system attempts to connect to **domain2** only when **domain1** cannot be connected. If a switchover occurs, **domain3** and **domain4** are marked as the primary cluster. However, the IP address corresponding to **domain3** is preferentially connected. If **domain3** cannot be connected, the IP address corresponding to **domain4** is connected.	Property type: integer Value range: 0 to the number of domain names configured in the URL. If **primaryDomains** is configured, the value must be less than the value of **primaryDomains**. Default value: **0**, indicating that the function is disabled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
refreshDomainResolveTime	It specifies the interval for updating the domain name resolution result and takes effect only when **parseCandidatesByDomain** is set to **true**. After it takes effect, the domain name resolution update time involved in the URL is set to a specified value and the domain name resolution result is periodically updated in the asynchronous thread. **NOTICE** Driver obtains domain name resolution results only from the DNS service in the environment where the application is located. To ensure that domain name binding changes can be detected by Driver in a timely manner, the DNS service in the environment where the application is located must ensure that the domain name binding changes take effect in a timely manner.	Property type: integer Unit: s Value range: 1 to 2147483647 Default value: **10**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
oracleCompatible	This is used to set the ORA-compatible features of driver APIs.	Property type: string Value range: 1. **true** or **on**: enables all ORA compatibility features on the driver side. 2. **false** or **off**: disables all ORA compatibility features on the driver side. 3. **tag1,tag2,tag3**: configures one or more tags. Use commas (,) to separate tags, indicating that the ORA-compatible features on the driver side are enabled. Each tag corresponds to an ORA-compatible feature. Currently, the following tags are supported: ● getProcedureColumns: The behavior of the DatabaseMetaData#getProcedureColumns API is compatible with that in ORA. ● getCallableStatementResults: The database is compatible with ORA when the getLong, getInt, getShort, and getByte APIs of CallableStatement are called. When the registered output parameter type is java.sql.Types#NUMERIC, you can call the getLong, getInt, getShort, and getByte APIs of CallableStatement to receive the value of **out**. The SQLException message is displayed only when the value of **out** exceeds the value range of the Java numeric data type. ● batchInsertAffectedRows: After reWriteBatchedInserts is enabled, the result returned by the Statement#executeBatch API is compatible with that in ORA.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
		• setDateTime: After it is enabled, when parameters of the date, time, and timestamp types are bound in PBE mode, the OID is specified and delivered to the kernel. Default value: **false**
mCompatible	Specifies that the M-compatible features of the driver are controlled by users.	Property type: string Value range: • **true** or **on**: enables all M-compatible features on the driver side. • **false** or **off**: disables all M-compatible features on the driver side. • **tag1,tag2,tag3**: configures one or more tags. Use commas (,) to separate tags, indicating that the M-compatible features on the driver side are enabled. Each tag corresponds to an M-compatible feature. Currently, the tag can be set to **DatetimeAsTimeStampType**. After this function is enabled, an object of the Timestamp type is returned when the java.sql.ResultSet#getObject API is used to obtain a column of the Datetime data type. Default value: **false**
printSqlInLog	Specifies whether to output SQL statements in exception information or logs.	Property type: Boolean Value range: • **true**: enabled. • **false**: disabled. Default value: **true**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
useGsClobBlobClass	Specifies the objects returned when the java.sql.ResultSet#getObject API is used to obtain the CLOB and BLOB columns.	Property type: Boolean Value range: ● If it is set to **true**, an object of the PGClob type is returned when the java.sql.ResultSet#getObject API is used to obtain the CLOB columns, and an object of the PGBlob type is returned when the java.sql.ResultSet#getObject API is used to obtain the BLOB columns. If the type name of the CLOB column is obtained through the metadata API java.sql.ResultSetMetaData#getColumnClassName, java.sql.CLOB is returned. If the type name of the BLOB column is obtained, java.sql.BLOB is returned. ● If it is set to **false**, an object of the PGClob type is returned when the java.sql.ResultSet#getObject API is used to obtain the CLOB columns, and an object of the byte[] type is returned when the java.sql.ResultSet#getObject API is used to obtain the BLOB columns. If the type name of the CLOB column is obtained through the metadata API java.sql.ResultSetMetaData#getColumnClassName, java.sql.CLOB is returned. If the type name of the BLOB column is obtained, java.sql.BLOB is returned. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
sessionType	Specifies the type of the current session. An execution plan is generated based on the actual value.	Property type: string Value range: **singleNode**, **globalReadOnly**, and **normal**. • **normal**: indicates a common session. The plan is executed based on the original logic of the database. • **singleNode**: indicates a single-node session. The read and write operations of the session can be pushed down. In single-node session mode, a CN sends a one-to-one session to a specified target DN. This parameter must be used together with **execTargetNode**. Set **execTargetNode** to the name of the target DN. JDBC preferentially connects to the local CN corresponding to the target DN. • **globalReadOnly**: indicates a cross-node read-only session. In this mode, distributed plans are generated normally, but distributed write operations are prohibited. **Default value**: **normal**
execTargetNode	Specifies a DN in single-node session mode. This parameter must be used together with **sessionType** and takes effect only when **sessionType** is set to **singleNode**. **NOTE** If **sessionType** is set to **singleNode** and **execTargetNode** is not specified, the effect is the same as that when **sessionType** is set to **normal**.	Property type: string **Value range**: names of all DNs in the current cluster. Default value: **NULL**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
executeUpdateQueryable	Specifies whether to enable the executeUpdate() method to execute DQL statements. **NOTE** You are advised not to enable this parameter.	Property type: Boolean Value range: • **true**: enabled. After this method is enabled, **–1** is returned when the executeUpdate() method executes DQL statements, and a result set can be obtained. • **false**: disabled. Default value: **false**
dbMonitor	Specifies whether to enable the connection monitoring function for JDBC. **NOTE** • The connection monitoring function can monitor the following JDBC metrics: number of connections enabled by applications, number of connections disabled by applications, number of abnormal disconnections, database access volume, client CPU usage, memory usage, uplink and downlink transmission rates, and network delay, jitter, and packet loss rate between applications and databases. • If **dbMonitor** is set to **true**, **loggerLevel** is set to **debug**, and **loggerFile** is set to **filePath**, the client connection monitoring information is recorded in the **filePath** log file. For details, see **Monitoring Database Connections**.	Property type: Boolean Value range: • **true**: enabled. • **false**: disabled. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
enableStreamingQuery	Specifies whether to enable the streaming read function. Streaming read function: All data is read at a time by the server and sent to the socket buffer of a client until the buffer is full. If there is free space, the data continues to be sent to the buffer. At the same time, a JVM reads data from the buffer row by row. The advantage is that the result is processed fast and no JVM memory overflow occurs. The disadvantage is that streaming read can only traverse backwards. Before data processing is complete or the statement is closed, no other operations can be performed in the current connection. For details, see **Using the Streaming Read Function**.	Property type: Boolean Value range: • If this parameter is set to **true** and statement.setFetchSize(Integer.MIN_VALUE) or statement.enableStreamingResults() is used, the streaming read function is enabled. • If this parameter is set to **false**, this function is disabled. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
yearIsDateType	Specifies whether the returned data object is displayed in the date type when the java.sql.ResultSet#getObject and java.sql.ResultSet#getString APIs are used to obtain columns of the year type.	Property type: Boolean Value range: ● **true**: An object of the date type is returned when the java.sql.ResultSet#getObject API is used to obtain columns of the year type. A date character string in the yyyy-mm-dd format is returned when the java.sql.ResultSet#getString API is used to obtain year data. A year value is returned when the java.sql.ResultSet#getInt/ getLong/getShort API is used to obtain data. ● **false**: An object of the integer type is returned when the java.sql.ResultSet#getObject API is used to obtain columns of the year data type. A year character string is returned when the java.sql.ResultSet#getString API is used to obtain year data. A year value is returned when the java.sql.ResultSet#getInt/ getLong/getShort API is used to obtain data. Default value: **true**
enableObjectTypeConv	Specifies whether to allow the getObject(int, Class<?>) method in the ResultSet API to support compatible type conversion. Currently, conversion between the integer type and the long, double, or bigdecimal types, and conversion between the CLOB type and the string type are supported.	Property type: Boolean Value range: ● **true**: Compatible type conversion is allowed. ● **false**: Compatible type conversion is not allowed. Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
disasterToleranceCluster	Specifies whether to connect to the primary cluster or the standby cluster for DR when the load balancing function is enabled and only standby cluster nodes are configured in the URL for the JDBC to connect to the database. This parameter cannot be used together with the **priorityServers** parameter.	Property type: Boolean Value range: • **true**: Load balancing is enabled on nodes in the standby cluster for DR. • **false**: Load balancing is performed among nodes in the primary cluster. Default value: **false**
pgCompatible	Specifies whether the SQL syntax parsing mode of JDBC is compatible with PG.	Property type: Boolean Value range: • **true**: The syntax parsing is compatible with PG. A statement can contain multiple SQL statements separated by semicolons (;). After this function is enabled, SQL statements containing semicolons (;) cannot be executed. • **false**: The default SQL statement parsing mode is used, which is incompatible with PG. Default value: **false**
setFloat	Specifies whether the OID passed to the kernel is an OID of float4 when **setFloat** is called or **setObject** is set to **float**.	Property type: Boolean Value range: • If it is set to **true** and **setFloat** or **setObject** is called to specify the type as float, the OID passed to the kernel is of the float4 type. • If it is set to **false** and **setFloat** or **setObject** is called to specify the type as float, the OID passed to the kernel is of the float8 type. Default value: **false**
enableGaussArrayAndStruct	After this function is enabled, a projection column or output parameter of the collection or array type can be obtained as a GaussArray or GaussStruct object.	Property type: Boolean Value range: **true** and **false** Default value: **false**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Property	Description	Value
actualErrorCodeForBatch	Specifies whether the error code 0 or the actual error code is returned when an error is reported during the execution of the executeBatch API.	Property type: Boolean Value range: • **true**: The actual error code is returned when an error is reported during the execution of the executeBatch API. • **false**: The error code 0 is returned when an error is reported during the execution of the executeBatch API. Default value: **false**

The JDBC driver supports the normal execution of database DDL operations after the table structure is modified.

jdbc.version_num is used only to transfer the JDBC version number to the kernel during connection establishment. Do not use it for other purposes.
jdbc.version_num is supported in 503.1 and later versions. (The **jdbc.version** parameter was used to implement this function and will be deprecated in later versions.) The usage rules of **jdbc.version_num** are as follows.

jdbc.version_num	Version	Range	Usage Rule	Kernel Judgment Rule	Remarks
502xx	505.2	50200–50299	The minimum available value must be used in the version.	Version number ≥ 502*xx* (latest value)	Related compatibility changes must be incorporated into branches of later versions.
501xx	505.1	50100–50199	The minimum available value must be used in the version.	Version number ≥ 501*xx* (latest value)	Related compatibility changes must be incorporated into branches of later versions.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

500xx	505.0	50000–50099	The minimum available value must be used in the version.	Version number ≥ 500*xx* (latest value)	Related compatibility changes must be incorporated into branches of later versions.
301xx	503.1	30100–30199	The minimum available value must be used in the version.	Version number ≥ 301*xx* (latest value)	Related compatibility changes must be incorporated into branches of later versions.

5.3.2.2.3 Connecting to a Database in Non-Encrypted Mode

To connect to a database in non-encrypted mode, you need to load a driver and then establish a database connection. This section describes methods of loading drivers, APIs for creating database connections, and APIs for non-encrypted connections.

Methods of Loading Drivers

You can load drivers in the following ways:

- Load a driver at any position in code before creating a connection.
  ```
  Class.forName("com.huawei.gaussdb.jdbc.Driver");
  ```
- Pass parameters when a JVM is started. **jdbctest** is the name of the test case program.
  ```
  java -Djdbc.drivers=com.huawei.gaussdb.jdbc.Driver jdbctest;
  ```

NOTE

1. GaussDB is compatible with PG in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. JDBC of this version does not support identity & access management suite (IAM) for authentication.
3. GaussDB JDBC driver has the following enhanced features:
   1. SHA-256 is supported for encrypted login.
   2. The third-party log framework that implements the sf4j API can be connected.
   3. Distributed load balancing at the connection level is supported.
   4. DR failover is supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

APIs for Creating Database Connections

JDBC provides three APIs for creating database connections. For details about the **url**, **info**, **user**, and **password** parameters, see **Table 5-7**.

API 1: DriverManager.getConnection(String url). You need to write a database username and password in a URL, which is insecure and not recommended.

API 2: DriverManager.getConnection(String url, String user, String password). For details, see **Connecting to a Database Using API 2**.

API 3: DriverManager.getConnection(String url, Properties info). For details, see **Connecting to a Database Using API 3**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-7 Database connection parameters

Parameter	Description
url	**gaussdbjdbc.jar** database connection descriptor. If **host** is set to a server name or an IPv4 address, formats are as follows: • jdbc:gaussdb: • jdbc:gaussdb:database • jdbc:gaussdb://host/database • jdbc:gaussdb://host:port/database • jdbc:gaussdb://host:port/database?param1=value1&param2=value2 • jdbc:gaussdb://host1:port1,host2:port2/database?param1=value1&param2=value2 If **host** is set to an IPv6 address, formats are as follows: • jdbc:gaussdb: • jdbc:gaussdb:database • jdbc:gaussdb://host/database or jdbc:gaussdb:///[host]/database • jdbc:gaussdb://[host]:port/database • jdbc:gaussdb://[host]:port/database?param1=value1&param2=value2 • jdbc:gaussdb://[host1]:port1,[host2]:port2/database?param1=value1&param2=value2

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
	NOTE • **database** indicates the name of the database to connect. The database name is the same as the username by default. • **host** indicates the name or IP address of the database server. Both IPv4 and IPv6 addresses are supported. For security purposes, the database CN forbids access from other nodes in the cluster without authentication. To access the CN from inside the cluster, deploy the JDBC program on the host where the CN is located and set **host** to **127.0.0.1**. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed. It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected. By default, the localhost is used to connect to the server.localhost • **port** indicates the port number of the database server. By default, the database on port 5432 of the localhost is connected. • If **host** is set to an IPv6 address and the port number is specified in the URL, use square brackets ([]) to enclose the IP address. The format is [IP address]:Port number. • **param** indicates a database connection attribute. Parameters can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign values to parameters, and uses ampersands (&) to separate parameters. • **value** indicates the database connection attribute values. • The **connectTimeout** and **socketTimeout** parameters must be set for connection. If they are not set, the default value **0** is used, indicating that the connection will not time out. When the network between a DN and the client is faulty, the client cannot receive the ACK packet from the DN and retries transmission repeatedly. A timeout error is reported only when the number of retransmission times reaches **15** (the default value). As a result, the RTO is high. • You are advised to ensure the validity of the URL when using the standard JDBC API to establish a connection. Otherwise, connection may fail. If the error information contains the original URL character string, it may cause sensitive information leakage.
info	Database connection property. For details about all parameters, see **Connection Parameter Reference**.
user	Database user.
password	Password of the database user.

Connecting to a Database Using API 2

Use the DriverManager.getConnection(String url, String user, String password) API to establish a database connection. The procedure is as follows:

Step 1 Import java.sql.Connection and java.sql.DriverManager.

java.sql.Connection is a database connection API. The getConnection() method of java.sql.DriverManager is used to connect applications to a database. In addition,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

you need to import other APIs and classes based on the actual application scenario. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
```

Step 2 Specify the database **sourceURL** (change *$ip*, *$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:gaussdb://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

Step 3 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).
2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

   ```
   String driver = "com.huawei.gaussdb.jdbc.Driver";
   Class.forName(driver);
   ```

Step 4 Establish a database connection.

Call DriverManager.getConnection(String url, String user, String password) to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL, userName, password);
```

----End

Connecting to a Database Using API 3

Use the DriverManager.getConnection(String url, Properties info) API to establish a database connection. The procedure is as follows:

Step 1 Import java.sql.Connection, java.sql.DriverManager, and java.util.Properties.

The setProperty() method of java.util.Properties is used to set attribute values of the Properties object. In addition, you need to import other APIs and classes based on the actual application scenario. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *$ip*, *$port*, and *database* as required), username, and password.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables.

```
String sourceURL = "jdbc:gaussdb://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

Step 3 Create a Properties object and set **userName** and **password** as the attribute values of the object.

```
Properties info = new Properties();
info.setProperty("user", userName);
info.setProperty("password", password);
```

Step 4 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

```
String driver = "com.huawei.gaussdb.jdbc.Driver";
Class.forName(driver);
```

Step 5 Establish a database connection.

Call DriverManager.getConnection(String url, Properties info) to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL, info);
```

----End

5.3.2.2.4 Connecting to a Database in SSL Mode

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet. In this section, the DriverManager.getConnection(String url, Properties info) API is used to connect to the database.

Using a Certificate for Authentication

Before performing the steps below, log in to the GaussDB management console. On the **Instances** page, click the instance name to go to the **Basic Information** page. On the displayed page, click under **SSL** to download the root certificate or certificate bundle, and save the **ca.pem** root certificate to the client.

To configure certificates on the client to connect to a database, perform the following steps:

Step 1 Import **java.sql.Connection**, **java.sql.DriverManager**, and **java.util.Properties**.

Additionally, import other APIs and classes as needed based on your application requirements. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *$ip*, *$port*, and *database* in the URL as required), username, and password.

Storing usernames and passwords directly in code poses significant security risks. Instead, use environment variables to securely manage credentials.

```
String sourceURL = "jdbc:gaussdb://$ip:$port/database";
Properties urlProps = new Properties();
urlProps.setProperty("user", System.getenv("EXAMPLE_USERNAME_ENV"));
urlProps.setProperty("password", System.getenv("EXAMPLE_PASSWORD_ENV"));
```

Step 3 Set the SSL attribute to **true** and configure the **ca.pem** root certificate on the client.

```
urlProps.setProperty("ssl", "true");
urlProps.setProperty("sslrootcert", "ca.pem");;
```

Step 4 Configure **sslmode**.

Set **sslmode** to **require**, **verify-ca**, or **verify-full**. For details about these values, see **sslmode**. Choose the appropriate option based on your requirements.

```
/* Set sslmode to require. */
urlProps.setProperty("sslmode", "require");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
/* Set sslmode to verify-ca. */
urlProps.setProperty("sslmode", "verify-ca");
/* Set sslmode to verify-full (verification in Linux). */
urlProps.setProperty("sslmode", "verify-full");
```

Step 5 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).
2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

```
Class.forName("com.huawei.gaussdb.jdbc.Driver");
```

Step 6 Create a database connection.

Call **DriverManager.getConnection(String url, Properties info)** to connect to the database.

```
Connection conn = DriverManager.getConnection(sourceURL,urlProps);
```

----End

5.3.2.2.5 Connecting to a Database in UDS Mode

The UDS is used for data exchange between different processes on the same host. You can add **junixsocket** to obtain the socket factory.

Prerequisites: You have referenced **junixsocket-core-*XXX*.jar**, **junixsocket-common-*XXX*.jar**, and **junixsocket-native-common-*XXX*.jar**. *XXX* indicates the version number. The version numbers of the referenced JAR packages must be consistent.

To connect to a database in UDS mode, perform the following steps:

Step 1 Import java.sql.Connection, java.sql.DriverManager, and java.util.Properties.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the username and password of the database.

Writing the username and password to code has great security risks. You are advised to store the username and password in environment variables. Set the username and password to the property values of the Properties object.

```
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Properties properties = new Properties();
properties.setProperty("user", userName);
properties.setProperty("password", password);
```

Step 3 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).
2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

```
String driver = "com.huawei.gaussdb.jdbc.Driver";
Class.forName(driver);
```

Step 4 Specify the database *$ip*, *$port*, *database*, **socketFactory**, and **socketFactoryArg**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Change *$ip*, *$port* as required. Set *database* to **localhost**, **socketFactory** to **org.newsclub.net.unix.AFUNIXSocketFactory$FactoryArg**, and **socketFactoryArg** to *[path-to-the-unix-socket]* to connect to the database in UDS mode. For details about the **socketFactory** and **socketFactoryArg** parameters, see **socketFactory** and **socketFactoryArg**.

```
Connection conn = DriverManager.getConnection("jdbc:gaussdb://$ip:$port/localhost?
socketFactory=org.newsclub.net.unix" +
    ".AFUNIXSocketFactory$FactoryArg&socketFactoryArg=[path-to-the-unix-socket]",properties);
System.out.println("Connection Successful!");
```

NOTE

Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix_socket_directory**.

----End

5.3.2.2.6 Connecting to a Database in SM-based TLS Mode

When connecting to the GaussDB server through JDBC, you can enable SM-based TLS to encrypt the communication between the client and server. This mode provides a highly secure channel for sensitive data transmission on the Internet. You can connect to a database in SM-based TLS mode using either of the following methods: SM-based TLS with one-way authentication and SM-based TLS with two-way authentication. In one-way authentication, only the client needs to verify the server identity. In two-way authentication, the client and server need to verify each other.

Method 1: SM-based TLS with One-Way Authentication

Prerequisites: You have obtained the SM-based TLS certificate and private key file required by a server and configured the server. In addition, you have obtained the **cacert.pem** root certificate required by a client. **Step 4** describes how to configure the root certificate on the client.

NOTE

For details about how to generate and obtain a certificate, contact an administrator. For details about how to configure the certificate on the server, contact an administrator.

Connect to a database in SM-based TLS mode with one-way authentication as follows:

Step 1 Import **java.sql.Connection**, **java.sql.DriverManager**, and **java.util.Properties**.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *$ip*, *$port*, and *database* as required), username, and password.

Obtain the username and password from the environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* respectively, and set them as property values of the Properties object.

```
String urls = "jdbc:gaussdb://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Properties urlProps = new Properties();
urlProps.setProperty("user", userName);
urlProps.setProperty("password", password);
```

Step 3 Set the SSL attribute to **true** and **sslmode** to **verify-ca**.

```
urlProps.setProperty("ssl", "true");
urlProps.setProperty("sslmode", "verify-ca");
```

Step 4 Configure the **cacert.pem** root certificate on the client and set **sslgmcipher** to **ECC_SM4_SM3** only.

For details about the **sslrootcert** and **sslgmcipher** parameters, see **sslrootcert** and **sslgmcipher**.

```
urlProps.setProperty("sslrootcert", "cacert.pem");
urlProps.setProperty("sslgmcipher", "ECC_SM4_SM3");
```

Step 5 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).
2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

```
Class.forName("com.huawei.gaussdb.jdbc.Driver");
```

Step 6 Create a database connection.

Call DriverManager.getConnection(String url, Properties info) to connect to the database.

```
Connection conn = DriverManager.getConnection(urls,urlProps);
```

----End

Method 2: SM-based TLS with Two-Way Authentication

Prerequisites: You have obtained the SM-based TLS certificate and private key file required by a server and configured the server. In addition, you have obtained the **client.key.pk8**, **client_enc.key.pk8**, **client.crt**, **client_enc.crt**, **cacert.pem** certificates and private key file required by a client. **Step 4** describes how to configure the certificates on the client.

NOTE

For details about how to generate and obtain a certificate, contact an administrator. For details about how to configure the certificate on the server, contact an administrator.

Connect to a database in SM-based TLS mode with two-way authentication as follows:

Step 1 Import **java.sql.Connection**, **java.sql.DriverManager**, and **java.util.Properties**.

In addition, you need to import other APIs and classes based on the actual application scenario. For details, see **JDBC Interface Reference**.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.Properties;
```

Step 2 Specify the database **sourceURL** (change *$ip*, *$port*, and *database* as required), username, and password.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Obtain the username and password from the environment variables *EXAMPLE_USERNAME_ENV* and *EXAMPLE_PASSWORD_ENV* respectively, and set them as property values of the Properties object.

```
String urls = "jdbc:gaussdb://$ip:$port/database";
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Properties urlProps = new Properties();
urlProps.setProperty("user", userName);
urlProps.setProperty("password", password);
```

Step 3 Set the SSL attribute to **true** and **sslmode** to **verify-ca**.

```
urlProps.setProperty("ssl", "true");
urlProps.setProperty("sslmode", "verify-ca");
```

Step 4 Configure the **client.key.pk8**, **client_enc.key.pk8**, **client.crt**, **client_enc.crt** and **cacert.pem** certificates on the client. Set **sslgmcipher** to **ECC_SM4_SM3** or **ECDHE_SM4_SM3**. For details, see **sslgmcipher**.

```
urlProps.setProperty("sslrootcert", "cacert.pem");
urlProps.setProperty("sslgmcipher", "ECDHE_SM4_SM3");
urlProps.setProperty("sslcert", "client.crt");
urlProps.setProperty("sslkey", "client.key.pk8");
urlProps.setProperty("sslenccert", "client_enc.crt");
urlProps.setProperty("sslenckey", "client_enc.key.pk8");
```

Step 5 Load the driver.

1. Add the **gaussdbjdbc.jar** package to the runtime environment (for example, the IDE).
2. Load the database driver **com.huawei.gaussdb.jdbc.Driver**.

```
Class.forName("com.huawei.gaussdb.jdbc.Driver");
```

Step 6 Create a database connection.

Call DriverManager.getConnection(String url, Properties info) to connect to the database.

```
Connection conn = DriverManager.getConnection(urls,urlProps);
```

----End

NOTE

- To use the SM-based TLS capability of the JDBC client, the BGMProvider open-source software (**bgmprovider-1.*X.X*-jar-with-dependencies.jar**) of version 1.1 or later is required.
- To use the SM-based TLS capability of the JDBC client, the JDK version must be 8u302 or later.
- SM algorithms feature strict principles, complex computing, and high security. Therefore, after SM-based TLS encrypted transmission is configured, the performance deteriorates significantly compared with that during TLS encrypted transmission based on other international algorithms.

5.3.2.3 Running SQL Statements

This section shows you the processes of creating the **customer_t1** table by **Running a Common SQL Statement**, inserting data in batches by **Executing a Prepared Statement for Insertion**, updating data by **Executing a Prepared Statement for Update**, and **Creating and Calling a Stored Procedure**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Running a Common SQL Statement

SQL statements are run on applications to operate a database. Operations such as SELECT, UPDATE, INSERT, and DELETE can be performed on XML data.

The prerequisite is that you have connected to the database using the connection object conn. Create the **customer_t1** table as follows:

Step 1 Create a statement object by calling the createStatement method of the Connection API.

```
Statement stmt = conn.createStatement();
```

Step 2 Run the SQL statement by calling the executeUpdate method of the Statement API.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");
```

Step 3 Close the statement object stmt by calling the close method of the Statement API.

```
stmt.close();
```

----End

NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the statements are packed into a transaction. The VACUUM operation is not supported in a transaction block. If one statement fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- JDBC caches SQL statements in prepareStatement, which may cause memory bloat. If the JVM memory is small, you are advised to adjust **preparedStatementCacheSizeMiB** or **preparedStatementCacheQueries**.

Executing a Prepared Statement for Insertion

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency.

The prerequisite is that the **customer_t1** table has been created by executing the preceding basic SQL statements. Execute the prepared statement to insert data in batches as follows:

Step 1 Create the prepared statement object **pst** by calling the prepareStatement method of the Connection API.

```
PreparedStatement pst = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?,?)");
```

Step 2 Call the corresponding API to set parameters for each piece of data and call addBatch to add SQL statements to the batch processing.

```
for (int i = 0; i < 3; i++) {
  pst.setInt(1, i);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    pst.setString(2, "data " + i);
    pst.addBatch();
}
```

Step 3 Perform batch processing by calling the executeBatch method of the PreparedStatement API.

```
pst.executeBatch();
```

Step 4 Close the prepared statement object **pst** by calling the close method of the PreparedStatement API.

```
pst.close();
```

----End

NOTE

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several lines at a time. The statement for disabling automatic commit is as follows:

```
conn.setAutoCommit(false);
```

Executing a Prepared Statement for Update

Prepared statements are complied and optimized once but can be used in different scenarios by assigning different values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a prepared statement.

The prerequisite is that the preceding prepared statement has been executed and data has been inserted into the **customer_t1** table in batches. Update data by running a prepared SQL statement as follows:

Step 1 Create the prepared statement object **pstmt** by calling the prepareStatement method of the Connection API.

```
PreparedStatement pstmt = conn.prepareStatement("UPDATE customer_t1 SET c_customer_name = ? WHERE c_customer_sk = 1");
```

Step 2 Set parameters by calling the setString method of the PreparedStatement API.

```
pstmt.setString(1, "new Data");
```

Step 3 Execute the prepared statement by calling the executeUpdate method of the PreparedStatement API.

```
int rowcount = pstmt.executeUpdate();
```

Step 4 Close the prepared statement object **pstmt** by calling the close method of the PreparedStatement API.

```
pstmt.close();
```

----End

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

After binding parameters are set in prepareStatement, a B packet or U packet is constructed and sent to the server when the SQL statement is executed. However, the maximum length of a B packet or U packet cannot exceed 1023 MB. If the data bound at a time is too large, an exception may occur because the packet is too long. Therefore, when setting binding parameters in prepareStatement, you need to evaluate and control the size of the bound data to avoid exceeding the upper packet limit.

Creating and Calling a Stored Procedure

GaussDB can call stored procedures through JDBC. The prerequisite is that the database connection is established using the connection object conn.

Create the **testproc** stored procedure as follows:

```
// Create the stored procedure (containing the out parameter) in the database as follows:
CREATE or REPLACE procedure testproc
(
    psv_in1 in integer,
    psv_in2 in integer,
    psv_inout inout integer
)
AS
BEGIN
    psv_inout := psv_in1 + psv_in2 + psv_inout;
END;
/
```

Call the **testproc** stored procedure as follows:

Step 1 Create a call statement object **cstmt** by calling the prepareCall method of Connection.

```
CallableStatement cstmt = conn.prepareCall("{? = CALL testproc(?,?,?)}");
```

Step 2 Set parameters by calling the setInt method of CallableStatement.

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
```

Step 3 Register an output parameter by calling the **registerOutParameter** method in **CallableStatement**.

```
cstmt.registerOutParameter(4, Types.INTEGER);  // Register an OUT parameter of the integer type.
```

Step 4 Execute SQL statements by calling the execute method of CallableStatement.

```
cstmt.execute();
```

Step 5 Obtain the out parameter by calling the getInt method of CallableStatement.

```
int out = cstmt.getInt(4);
```

Step 6 Close the call statement object **cstmt** by calling the close method of CallableStatement.

```
cstmt.close();
```

----End

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in **conn.prepareCall("{? = CALL testproc(?,?,?)}")** during a stored procedure call, you can bind parameters and register the first parameter as the output parameter according to the placeholder sequence or the fourth parameter as the output parameter according to the parameter sequence in the stored procedure. The preceding example registers the fourth parameter.
- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
- A stored procedure and a basic SQL statement must be run separately.
- Output parameters must be registered for parameters of the inout type in the stored procedure.

Adding Single-Shard Execution Syntaxes to Statements

The prerequisite is that the database has been connected using the conn connection object, the **test** table has been created, and data has been inserted into the table.

Step 1 Call the setClientInfo(String name,String value) method of the Connection object to set the **nodeName** parameter.

```
conn.setClientInfo("nodeName","datanode1");
```

Step 2 Execute the SQL statements by using the executeQuery(String sql) and execute(String sql) methods in Statement and the executeQuery() and execute() methods in PreparedStatement.

```
PreparedStatement pstm = conn.prepareStatement("SELECT * FROM test");
pstm.execute();
pstm.executeQuery();
Statement stmt=conn.createStatement();
stmt.execute("SELECT * FROM test");
stmt.executeQuery("SELECT * FROM test");
```

Step 3 Set the parameter to an empty string to disable it.

```
conn.setClientInfo("nodeName","");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- This function is adapted based on the single-shard execution function of the kernel. Therefore, before using this function, check whether the database kernel supports single-shard execution.
- If the **nodeName** parameter is enabled, you need to manually disable the parameter after executing SQL statements. Otherwise, the execution of other query statements will be affected.
- Once the parameter is enabled, all statements of the current connection will be executed on the specified DN.
- After the parameter is enabled, the cache mechanism of PreparedStatement will be affected, cached statements will be cleared, and subsequent statements executed for single-shard queries will not be cached until the parameter is disabled.
- The parameter is a connection parameter. Therefore, the parameter value takes effect once. The API cannot be used to execute the statements on different shards at the same time.

----End

5.3.2.4 Processing Data in a Result Set

Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on requirements. Before running an SQL statement, you must create a statement object. Some methods of creating statement objects can set the type of a result set. The java.sql.Connection API provides the following three methods for creating statement objects:

```
// Create a Statement object. This object will generate a ResultSet object with a specified type and concurrency.
createStatement(int resultSetType, int resultSetConcurrency);

// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and concurrency.
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);

// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and concurrency.
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-8 Result set types

Parameter	Description
resultSetType	Type of a result set. There are three types of result sets: • **ResultSet.TYPE_FORWARD_ONLY**: The ResultSet object can only be navigated forward. It is the default value. • **ResultSet.TYPE_SCROLL_SENSITIVE**: You can view the modified result by scrolling to the modified row. • **ResultSet.TYPE_SCROLL_INSENSITIVE**: The ResultSet object is insensitive to changes in the underlying data source. **NOTE** After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is **ResultSet.TYPE_SCROLL_SENSITIVE**. To obtain up-to-date data of the record pointed by the cursor from the database, call the refreshRow() method in a ResultSet object.
resultSetConcurrency	Concurrency type of a result set. There are two types of concurrency. • **ResultSet.CONCUR_READ_ONLY**: Data in a result set cannot be updated except that an updated statement has been created in the result set data. • **ResultSet.CONCUR_UPDATEABLE**: changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable.

Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The next method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to the next method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. **Table 5-9** describes these methods.

Table 5-9 Methods for positioning a cursor in a result set

Method	Description
next()	Moves cursor to the next row from its current position.
previous()	Moves cursor to the previous row from its current position.
beforeFirst()	Places cursor before the first row.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Description
afterLast()	Places cursor after the last row.
first()	Places cursor to the first row.
last()	Places cursor to the last row.
absolute(int row)	Places cursor to a specified row.
relative(int rows)	Moves the result set downwards by the number of rows specified by **rows** when **rows** is set to a positive number, or moves the result set upwards by the number of rows specified by **rows** when **rows** is set to a negative number.

Obtaining the Cursor Position from a Result Set

This cursor positioning method will be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. **Table 5-10** describes these methods.

Table 5-10 Methods for obtaining a cursor position in a result set

Method	Description
isFirst()	Checks whether it is in the first row.
isLast()	Checks whether it is in the last row.
isBeforeFirst()	Checks whether it is before the first row.
isAfterLast()	Checks whether it is after the last row.
getRow()	Obtains its current row number.

Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. **Table 5-11** describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-11 Common methods for obtaining data from a result set

Method	Description
getInt(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as an integer.
getInt(String columnLabel)	Retrieves the value of the column designated by a column label in the current row as an integer.
getString(int columnIndex)	Retrieves the value of the column designated by a column index in the current row as a string.
getString(String columnLabel)	Retrieves the value of the column designated by a column label in the current row as a string.
getDate(int columnIndex)	Obtains date data by column index.
getDate(String columnLabel)	Retrieves the value of the column designated by a column name in the current row as a date.

5.3.2.5 Closing a Database Connection

After you complete required data operations in the database, close the database connection.

You can call the close method to close the connection.

```
conn.close();
```

NOTE

Many database classes such as Connection, Statement, and ResultSet have a close() method. Close these classes after using their objects. Closing Connection objects is to close all the related Statement objects, and closing a Statement object is to close its ResultSet object.

5.3.3 Typical Application Development Examples

The Java code examples in this section use the **gaussdbjdbc.jar** package by default.

5.3.3.1 Configuring Connection Parameters in Different Scenarios

NOTE

In the following example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

DR

A customer has two database clusters. Cluster A is the production cluster, and cluster B is the DR cluster. When the customer performs a DR failover, cluster A becomes the DR cluster, and cluster B becomes the production cluster. In this case, to avoid application restart or re-release caused by configuration file modification, the customer can write clusters A and B to the connection string when initializing the configuration file. In this case, if the primary cluster cannot be connected, the driver attempts to connect to the DR cluster. Assume that cluster A is {node1,node2,node3} and cluster B is {node4,node5,node6}.

Take the dual-cluster Dorado as an example. To connect to the new primary cluster after the switchover, you can set the URL as follows:

```
jdbc:gaussdb://node1,node2,node3,node4,node5,node6/database
```

Load Balancing

A customer has a database cluster that contains the following nodes: {node1,node2,node3,node4,node5,node6,node7,node8,node9,node10,node11,node12}.

- The customer establishes 120 persistent connections for application A and expects that the connections of application A can be evenly distributed on each node in the cluster. The URL can be configured as follows:

  ```
  jdbc:gaussdb://node1,node2,node3/database?autoBalance=true
  ```

- The customer develops two applications B and C and expects that the three applications to be evenly distributed on specified nodes. For example, the connections of application A are distributed on {node1,node2,node3,node4}; the connections of application B are distributed on {node5,node6,node7,node8}; and the connections of application C are distributed on {node9,node10,node11,node12}. The URLs can be configured as follows (If the first four nodes in the URL cannot be connected, the application connects to the fifth node based on the information in the pgxc_node system catalog. All available nodes in the cluster are connected in polling mode.):

  Application A:

  ```
  jdbc:gaussdb://node1,node2,node3,node4,node5/database?autoBalance=priority4
  ```

  Application B:

  ```
  jdbc:gaussdb://node5,node6,node7,node8,node9/database?autoBalance=priority4
  ```

  Application C:

  ```
  jdbc:gaussdb://node9,node10,node11,node12,node1/database?autoBalance=priority4
  ```

- The customer develops more applications, uses the same connection configuration string, and expects that the application connections can be evenly distributed on each node in the cluster. The URL can be configured as follows:

  ```
  jdbc:gaussdb://node1,node2,node3,node4/database?autoBalance=shuffle
  ```

- The customer has developed some applications and wants to establish connections in single-node session mode. The URL can be configured as follows:

  ```
  jdbc:gaussdb://node1,node2,node3,node4/database?
  sessionType=singleNode&execTargetNode=dn_name
  ```

- If the customer does not use the load balancing function, configure the URL as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
jdbc:gaussdb://node1/database
```

Or

```
jdbc:gaussdb://node1/database?autoBalance=false
```

NOTE

When the **autoBalance** parameter is enabled, the interval for the JDBC to refresh the available CN list is 10s by default. You can use **refreshCNIpListTime** to set the interval:

```
jdbc:gaussdb://node1,node2,node3,node4/database?autoBalance=true&refreshCNIpListTime=3
```

Log Diagnosis Scenario

If you encounter slow data import or some errors that are difficult to analyze, the trace log function can be enabled for diagnosis. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?loggerLevel=trace
```

High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold** parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows:

```
jdbc:gaussdb://node1/database?batchMode=on
```

5.3.3.2 Creating and Calling a Stored Procedure

It also demonstrates how to connect to a database and create and call stored procedures.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.Types;

public class DBTest {

 // Establish a database connection in non-encrypted mode.
 public static Connection GetConnection(String username, String passwd) {
   String driver = "com.huawei.gaussdb.jdbc.Driver";
   String sourceURL = "jdbc:gaussdb://$ip:$port/database";
   Connection conn = null;
   try {
     // Load the database driver.
     Class.forName(driver);
   } catch (Exception e) {
     e.printStackTrace();
     return null;
   }

   try {
     // Create a database connection.
     conn = DriverManager.getConnection(sourceURL, username, passwd);
     System.out.println("Connection succeed!");
   } catch (Exception e) {
     e.printStackTrace();
     return null;
   }

   return conn;
 };

 // Create a stored procedure.
 public static void CreateCallable(Connection conn) {
   Statement stmt = null;
   try {
     stmt = conn.createStatement();
     // Create a stored procedure and return the sum of the three input values.
     stmt.execute("create or replace procedure testproc \n" +
         "(\n" +
         "    psv_in1 in integer,\n" +
         "    psv_in2 in integer,\n" +
         "    psv_inout inout integer\n" +
         ")\n" +
         "as\n" +
         "begin\n" +
         "    psv_inout := psv_in1 + psv_in2 + psv_inout;\n" +
         "end;\n" +
         "/");
   } catch (SQLException e) {
     throw new RuntimeException(e);
   } finally {
     if (stmt != null) {
       try {
         stmt.close();
       } catch (SQLException e) {
         throw new RuntimeException(e);
       }
     }
   }
 }

 // Call the stored procedure.
 public static void ExecCallableSQL(Connection conn) {
   CallableStatement cstmt = null;
   try {
     cstmt=conn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
     cstmt.setInt(2, 50);
     cstmt.setInt(1, 20);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    cstmt.setInt(3, 90);
    cstmt.registerOutParameter(4, Types.INTEGER);  // Register an OUT parameter of the integer type.
    cstmt.execute();
    int out = cstmt.getInt(4);  // Obtain the OUT parameter.
    System.out.println("The CallableStatment TESTPROC returns:"+out);
    cstmt.close();
  } catch (SQLException e) {
    if (cstmt != null) {
      try {
        cstmt.close();
      } catch (SQLException e1) {
        e1.printStackTrace();
      }
    }
    e.printStackTrace();
  }
}

 /**
  * Main process. Call static methods one by one.
  * @param args
 */
 public static void main(String[] args) {
   // Create a database connection.
   String userName = System.getenv("EXAMPLE_USERNAME_ENV");
   String password = System.getenv("EXAMPLE_PASSWORD_ENV");
   Connection conn = GetConnection(userName, password);

   // Create a stored procedure.
   CreateCallable(conn);

   // Call the stored procedure.
   ExecCallableSQL(conn);

   // Close the database connection.
   try {
     conn.close();
   } catch (SQLException e) {
     e.printStackTrace();
   }

 }

}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
The CallableStatment TESTPROC returns:160
```

5.3.3.3 Obtaining the Return Value of a Function

JDBC obtains the return value when calling a function. The following example shows the return values of the bit and float8 types. For other data types, refer to this example.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
```

```
environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.CallableStatement;
import java.sql.SQLException;
import java.sql.PreparedStatement;
import java.sql.Types;

public class Type {
    public static void main(String[] args) throws SQLException {
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL = "jdbc:gaussdb://$ip:$port/database";
        Connection conn = null;

        try {
            // Load the database driver.
            Class.forName(driver);
        } catch (Exception e) {
            e.printStackTrace();
        }

        try {
            // Establish a database connection in non-encrypted mode.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
        }

        // Create a table.
        String createsql = "create table if not exists t_bit(col_bit bit, col_bit1 int)";
        Statement stmt = conn.createStatement();
        stmt.execute(createsql);
        stmt.close();
        // Example of using the bit type. Note that the value range of the bit type is [0,1].
        Statement st = conn.createStatement();
        String sqlstr = "create or replace function fun_1()\n" + "returns bit AS $$\n"
            + "select col_bit from t_bit limit 1;\n" + "$$\n" + "LANGUAGE SQL;";
        st.execute(sqlstr);
        CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
        // Register the output type, which is a bit string.
        c.registerOutParameter(1, Types.BIT);
        c.execute();
        // Use the Boolean type to obtain the result.
        System.out.println(c.getBoolean(1));

        // Example of using the float8 type.
        st.execute("create table if not exists t_float(col1 float8,col2 int)");
        PreparedStatement pstm = conn.PreparedStatement("insert into t_float values(?)");
        pstm.setDouble(1, 123456.123);
        pstm.execute();
        pstm.close();

        // Example of using the function whose return value is of the float8 type.
        st.execute(
            "create or replace function func_float() " + "return float8 " + "as declare " + "var1 float8; " + "begin
"
                + " select col1 into var1 from t_float limit 1; " + " return var1; " + "end;");
        CallableStatement cs = conn.prepareCall("{? = call func_float()}");
        cs.registerOutParameter(1, Types.DOUBLE);
        cs.execute();
        System.out.println(cs.getDouble(1));
        st.close();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        // Close the connection to the database.
        try {
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
false
123456.123
```

5.3.3.4 Batch Query

In this example, setFetchSize adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and affect performance to some extent. The cursor is valid within a transaction. Therefore, disable automatic transaction commit and then manually commit the transaction.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.PreparedStatement;

public class Batch {
    public static void main(String[] args) throws SQLException {
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL = "jdbc:gaussdb://$ip:$port/database";
        Connection conn = null;

        try {
            // Load the database driver.
            Class.forName(driver).newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }

        try {
            // Establish a database connection in non-encrypted mode.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");
        } catch (Exception e) {
            e.printStackTrace();
        }

        // Disable automatic commit.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        conn.setAutoCommit(false);

        // Create a table.
        Statement st = conn.createStatement();
        st.execute("create table mytable (cal1 int);");

        // Insert 200 rows of data into the table.
        PreparedStatement pstm = conn.prepareStatement("insert into mytable values (?)");
        for (int i = 0; i < 200; i++) {
            pstm.setInt(1, i + 1);
            pstm.addBatch();
        }
        pstm.executeBatch();
        conn.commit();
        pstm.close();

        // Open the cursor and obtain 50 rows of data each time.
        st.setFetchSize(50);
        int fetchCount = 0;
        ResultSet rs = st.executeQuery("SELECT * FROM mytable");
        while (rs.next()) {
            fetchCount++;
        }
        System.out.println(fetchCount == 200);
        conn.commit();
        rs.close();

        // Disable the server cursor.
        st.setFetchSize(0);
        fetchCount = 0;
        rs = st.executeQuery("SELECT * FROM mytable");
        while (rs.next()) {
            fetchCount++;
        }
        System.out.println(fetchCount == 200);
        conn.commit();
        rs.close();

        // Close the statement object and database connection.
        st.close();
        conn.close();

    }
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
true
true
```

Enable automatic commit.

```
conn.setAutoCommit(true);
```

5.3.3.5 Using the Streaming Read Function

Streaming read: All data is read at a time by the server and sent to the socket buffer of a client until the buffer is full. If there is free space, the data continues to be sent to the buffer. At the same time, a JVM reads data from the buffer row by row.

The advantage is that the result is processed fast and no JVM memory overflow occurs. The disadvantage is that streaming read can only traverse backwards. Before data processing is complete or the statement is closed, no other operations can be performed in the current connection.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

    // Generate a prepared statement.
        pst = conn.prepareStatement("INSERT INTO t_user VALUES (?,?)");
        for (int i = 0; i < 20; i++) {
            // Add parameters.
            pst.setInt(1, i + 1);
            pst.setString(2, "name " + (i + 1));
            pst.addBatch();
        }
        // Perform batch processing.
        pst.executeBatch();
        pst.close();
    } catch (SQLException e) {
        if (pst != null) {
            try {
                pst.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }
}

// Enable streaming read and query the content in the t_user table.
public static void StreamingQuery(Connection conn) {
    PreparedStatement pst = null;
    ResultSet resultSet = null;

    try {
        // Query all values in the t_user table.
        pst = conn.prepareStatement("SELECT * FROM t_user ORDER BY id");
        pst.setFetchSize(Integer.MIN_VALUE);
        resultSet = pst.executeQuery();
        while (resultSet.next()) {
            System.out.println(resultSet.getInt(1));
        }
    } catch (SQLException e) {
        throw new RuntimeException(e);
    } finally {
        if (resultSet != null) {
            try {
                resultSet.close();
            } catch (SQLException e) {
                throw new RuntimeException(e);
            }
        }

        if (pst != null) {
            try {
                pst.close();
            } catch (SQLException e) {
                throw new RuntimeException(e);
            }
        }
    }
}

public static void main(String[] args) throws Exception {
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");

    Connection conn = getConnection(userName, password);

```
        StreamingQuery(conn);

        // Close the connection to the database.
        try {
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
1
2
3
4
5
6
7
8
9
10
11
12
13
14
15
16
17
18
19
20
```

NOTICE

When the streaming read function is used, you need to call resultSet.close() or statement.close() after the result set is used. Otherwise, the current connection is unavailable.

5.3.3.6 SQL Retry at an Application Layer

If the primary DN is faulty and cannot be restored within 10s, the standby DN is automatically promoted to primary to ensure the normal running of the GaussDB cluster. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the DN failover, refer to the following example to construct an SQL retry mechanism at the service layer.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.
```

5.3.3.7 Logical Replication

This section describes how to use the logical replication function through JDBC APIs. For details about the configuration options of logical replication, see section "Logical Replication > Logical Decoding" in *Feature Guide*. In addition, the following configuration items are added for streaming decoding tools such as JDBC:

1. Decoding thread concurrency

   Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

   Configure **decode-style** to specify the decoding format. The value can be **'j'**, **'t'** or **'b'** of the char type, indicating the JSON, text, or binary format, respectively. This option is set only when parallel decoding is allowed and binary decoding is supported only in the parallel decoding scenario. For the JSON and TEXT formats, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and **0** indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is **0**, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first_lsn**, **commit** corresponds to **end_lsn**, and other values correspond to the LSN of the statement).
3. The next one-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. If **B** is used in the step 3:
    1. The next eight bytes (uint64) indicate the CSN.
    2. The next eight bytes (uint64) indicate **first_lsn**.
    3. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
    4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction username. The following characters with the same length are the transaction username.
    5. There may still be a decoding statement subsequently, with a 1-byte letter **P** or **F** as a separator between statements. **P** indicates that there are still decoding statements in this batch, and **F** indicates that decoding in this batch is complete.
5. If **C** is used in the step 3:
    1. (Optional) If the next one-byte letter is **X**, the following eight bytes (uint64) indicate the XID.
    2. (Optional) If the next one-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
    3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next 1-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the batch decoding ends.
6. If **I**, **U**, or **D** is used in the step 3:
    1. The following two bytes (uint16) indicate the length of the schema name.
    2. The schema name is read based on the preceding length.
    3. The following two bytes (uint16) indicate the length of the table name.
    4. The table name is read based on the preceding length.
    5. (Optional) If the next one-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
        1. The following two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
        2. The following procedure is repeated for *attrnum* times:
            1. The next two bytes (uint16) indicate the length of the column name.
            2. The column name is read based on the preceding length.
            3. The following four bytes (uint32) indicate the OID of the current column type.
            4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates null. If the value is **0**, it indicates a character string whose length is 0.
            5. The column value is read based on the preceding length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6. Because there may still be a decoding statement after, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.

3. Decoding only on the standby node

   Configure the **standby-connection** option to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false** (or **0**).

4. Batch sending

   Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 type is added indicating the length of the decoding result (excluding the current uint32 type), and a uint64 type is added, indicating the LSN corresponding to the current decoding result.

5. Length of the parallel decoding queue

   Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.

6. Memory threshold for logical decoding

   The **max-txn-in-memory** configuration item specifies the memory threshold for caching the intermediate decoding result of a single transaction, in MB. In parallel decoding mode, this parameter does not take effect. In serial decoding mode, the value range is [0,100]. The default value is **0**, indicating that the memory usage is not controlled.

   The **max-reorderbuffer-in-memory** configuration item specifies the memory threshold for caching intermediate decoding results of all transactions, in GB. In serial decoding mode, the value range is [0,100]. The default value is **0**, indicating that the memory usage is not controlled. In parallel decoding mode, the value ranges from 1 to 50% of the value of **max_process_memory**. The default value is the larger value between 1 and **max_process_memory**/ 1048576 x 10%. **1048576** indicates the unit conversion from KB to GB.

   When the memory usage exceeds the threshold, intermediate decoding results are written into a temporary file during decoding, affecting the logical decoding performance. The size of the temporary file is proportional to the amount of data modified by the transaction. If there are too many temporary files, the disk may enter the read-only state.

7. Memory threshold for the logical decoding table metadata

   The **desc-memory-limit** configuration item specifies the upper limit for the memory overhead of all table metadata maintained by the logical decoding task. The unit is MB. The value range is [10,1024], and the default value is **100**. During decoding, if the total memory occupied by the maintained table

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

metadata exceeds the threshold, the FIFO memory elimination mechanism of the table metadata is triggered to clear some memory.

8. Logical decoding sending timeout threshold

   The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logical decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of the GUC parameter **logical_sender_timeout**. The value **0** indicates that logical decoding does not proactively disconnect from the client. A small value, for example, 1 ms, indicates that decoding tasks may be interrupted.

9. User blacklist options for logical decoding

   Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logical decoding result. The options are as follows:

   a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the user OIDs exist. The OIDs of the same service user on different DNs may be different. Therefore, the OID of the service user on each DN needs to be transferred for logical decoding of directly connected DNs in distributed mode. Otherwise, the logical decoding results of some DNs may be filtered while those of some DNs are not filtered.

   b. **exclude-users**: specifies blacklisted usernames. Multiple usernames are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.

   c. **dynamic-resolution**: specifies whether to dynamically parse blacklisted usernames. The default value is **true**. If the parameter is set to **false**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

10. Output options for transaction logic logs

    a. **include-xids**: specifies whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.

    b. **include-timestamp**: specifies whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.

    c. **include-user**: specifies whether the BEGIN logical log of a transaction outputs the username of the transaction. The default value is **false**. The username of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The username does not change during the execution of the transaction.

11. By default, **socketTimeout** for the logical decoding connection in JDBC is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

withStatusInterval(10000,TimeUnit.MILLISECONDS) to adjust the timeout interval and retain the connection.

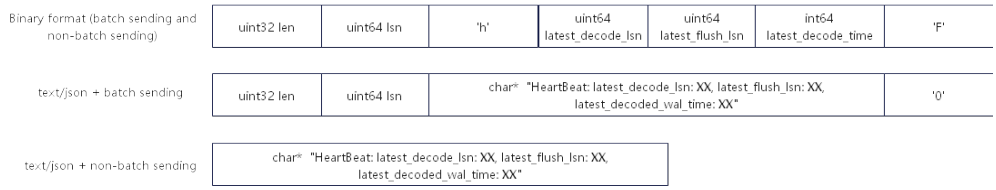
12. Heartbeat log output option

    enable-heartbeat: specifies whether to generate heartbeat logs. The default value is **false**.

    NOTE

    The following information is about parsing heartbeat logs with figure showing the format of the logs (in consideration of forward compatibility, the LSN naming mode is retained. The actual meaning depends on the actual scenario):

    - In the binary format, the message starts with the character 'h', indicating a heartbeat log.
    - The following is the heartbeat log content. For the first 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the end position of the WAL read when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the decoding log transaction CSN that has been sent when the heartbeat logical log is sent. For the second 8-byte uint64 string, in the decoding scenario where DNs are directly connected, this string is an LSN, indicating the location of the WAL that has been flushed to disks when the heartbeat logical log is sent; in the decoding scenario where distributed strong consistency is required, this string is a CSN, indicating the CSN to be obtained by the next transaction committed by the cluster. The last 8-byte int64 string indicates the generation timestamp (starting from January 1, 1970) of the latest decoded transaction log or checkpoint log.
    - Message terminator: If in binary format, it is 'F'. If the format is TEXT or JSON and the message is sent in batches, the terminator is '0'. Otherwise, there is no terminator. The message content is transmitted in big-endian mode.



13. Specifies the DDL statement reverse parsing process and output format for logical decoding.

    a. **enable-ddl-decoding**: The default value is **false**, indicating that logical decoding of DDL statements is disabled. The value **true** indicates that logical decoding of DDL statements is enabled.

    b. **enable-ddl-json-format**: The default value is **false**, indicating that the DDL statement reverse parsing result is output in text format. The value **true** indicates that the DDL statement reverse parsing result is output in JSON format.

Prerequisites for code running:

1. Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.
2. Add the IP address (for example, 10.11.12.34) of the JDBC user to the whitelist of the data replication permission. The command is as follows:

```
// Distributed strongly-consistent decoding on CNs (CN_IP indicates the IP address of the CN where a logical decoding task is started; to query it, run the cm_ctl query -Cvip command):
gs_guc reload -Z datanode -N all -I all -h  'host replication all CN_IP/24 trust'
gs_guc reload -Z coordinator -N all -I all -h 'host replication all 10.11.12.34/32 sha256'
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
// Distributed decoding on directly connected DNs:
gs_guc reload -Z datanode -N all -I all -h 'host replication all 10.11.12.34/32 sha256'
```

3. Set **wal_level** to **logical**. For details, contact the administrator.
4. Create tables **t1** and **t2** and perform DDL or DML operations on the tables.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.
// The logical replication class PGReplicationStream is a non-thread-safe class. Concurrent calls may cause data exceptions.

```
}
// Note: The preceding code cannot directly read the logical logs in binary format. You need to read the logical logs according to the binary encoding rules.
```

The following is an example of the decoding result in text format (that is, 't' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
table public t1 INSERT: a[integer]:1 b[integer]:2 c[text]:'hello'
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
table public t1 UPDATE: old-key: a[integer]:1 b[integer]:2 c[text]:'hello' new-tuple: a[integer]:1 b[integer]:5 c[text]:'hello'
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
table public t1 DELETE: a[integer]:1 b[integer]:5 c[text]:'hello'
COMMIT XID: 15506
```

The following is an example of the decoding result in JSON format (that is, 'j' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
{"table_name":"public.t1","op_type":"INSERT","columns_name":["a","b","c"],"columns_type":["integer","integer","text"],"columns_val":["1","2","'hello'"],"old_keys_name":[],"old_keys_type":[],"old_keys_val":[]}
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
{"table_name":"public.t1","op_type":"UPDATE","columns_name":["a","b","c"],"columns_type":["integer","integer","text"],"columns_val":["1","5","'hello'"],"old_keys_name":["a","b","c"],"old_keys_type":["integer","integer","text"],"old_keys_val":["1","2","'hello'"]}
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
{"table_name":"public.t1","op_type":"DELETE","columns_name":[],"columns_type":[],"columns_val":[],"old_keys_name":["a","b","c"],"old_keys_type":["integer","integer","text"],"old_keys_val":["1","5","'hello'"]}
COMMIT XID: 15506
```

5.3.3.8 Monitoring Database Connections

The connection monitoring function can monitor the following JDBC metrics: number of connections enabled by applications, number of connections disabled by applications, number of abnormal disconnections, database access volume, client CPU usage, memory usage, uplink and downlink transmission rates, and network delay, jitter, and packet loss rate between applications and databases. This example demonstrates how to use the connection monitoring function of the JDBC driver.

Prerequisites for code running: Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
// You need to change the values of $ip, $port, and database.

import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;

public class DBMonitorTest {
```

    public static void main(String[] args){
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String sourceURL
            = "jdbc:gaussdb://$ip.$port/database?
dbMonitor=true&loggerLevel=debug&loggerFile=dbMonitor.log";
        try {
      // Load the database driver.
            Class.forName(driver);
        } catch (Exception e) {
            e.printStackTrace();
        }

        Connection conn = null;
        Statement statement = null;
        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
            System.out.println("Connection succeed!");

            // Create a table.
            statement = conn.createStatement();
            String createTableQuery = "CREATE TABLE IF NOT EXISTS mytable (id INT PRIMARY KEY, name
VARCHAR(50))";
            statement.executeUpdate(createTableQuery);

            // Insert data.
            String insertQuery = "INSERT INTO mytable (id, name) VALUES (1, 'John')";
            statement.executeUpdate(insertQuery);

            // Query data.
            String selectQuery = "SELECT * FROM mytable ";
            ResultSet resultSet = statement.executeQuery(selectQuery);
            while (resultSet.next()) {
                int id = resultSet.getInt("id");
                String name = resultSet.getString("name");
                System.out.println("id: " + id + ", name: " + name);
            }

            // Drop the table.
            String dropTableQuery = "DROP TABLE IF EXISTS mytable";
            statement.executeUpdate(dropTableQuery);
        } catch (SQLException e) {
            e.printStackTrace();
        } finally {
            try {
                if (statement != null) {
                    statement.close();
                }
                if (conn != null) {
                    conn.close();
                }
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }

        try {
            Thread.sleep(10000);
        } catch (InterruptedException e) {
            throw new RuntimeException(e);
        }
    }
}
```

The execution result of the preceding example is as follows:

```
Connection succeed!
id: 1, name: John
```

```

5.3.3.9 Using the Array Type

This section describes how to use the array type of a JDBC driver.

Prerequisites for code running:

1. The **gaussdbjdbc.jar** package is added as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.
2. An ORA-compatible database is connected, and the database version is 503.0 or later.

Example 1: The JDBC driver uses the table of type in the kernel.

```
// Writing the username and password used for authentication directly into code may cause security risks. It is recommended that you store them in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (variable names are subject to the actual situation).
// Change the values of $ip, $port, and database.

            System.out.println(element);
        }

        // Print the element type name.
        System.out.println(array.getBaseTypeName());

        // Print whether sqlType of an element is Types.INTEGER.
        System.out.println(array.getBaseType() == Types.INTEGER);

        // Delete the test object.
        cleanTestObject(conn);
    }
}
```

The execution result of the preceding example is as follows:

```
true
true
1
2
3
1
2
int4
true
```

Example 3: An empty element of the string type is converted to **null** when it is passed to the database.

```
// Writing the username and password used for authentication directly into code may cause security risks. It is recommended that you store them in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (variable names are subject to the actual situation).
// Change the values of $ip, $port, and database.

NOTICE

- The type name is case-sensitive and cannot contain decimal points.
- The type name does not support synonyms.
- The type name can be in the *Schema*.*Package*.*Type*, *Package*.*Type*, *Schema*.*Type*, or *Type* format. If no schema name is transferred, the current schema is used by default. If the schema or package name contains a decimal point, it must be enclosed in double quotation marks.
- To construct ArrayDescriptor using the built-in native array type, the input type name must contain the schema name (the current schema does not have the built-in native array type).
- The element supports the following basic types: int2, int4, int8, float4, float8, numeric, bool, bpchar, varchar, nvarchar2, name, text, timestamp, timestamptz, time, timetz, clob, bytea, and blob. Possible aliases of the preceding types include smallint, int, integer, bigint, number, float, boolean, char, and varchar2.
- The element supports the following user-defined types: array, collection, and record.
- After JDBC enables the URL parameter **enableGaussArrayAndStruct**, the output parameters and return values of the collection or array type can be obtained as array objects. To output parameters, the GUC parameter **behavior_compat_options** needs to be set to **'proc_outparam_override'** for the database.
- The output parameter or return value cannot be a multi-dimensional array. The array start index of the output parameter or return value cannot be 1.
- JDBC relies on the database to verify type modifiers. For example:
  1. The element length cannot be verified. For example, for the table of varchar(5) type, if the length of the input string is greater than 5 when an array is constructed, JDBC will not report an error.
  2. The element precision cannot be verified. For example, for the table of numeric(3) type, if the number of input digits is greater than 3 when an array is constructed, JDBC will not report an error.
  3. The element precision cannot be converted. For example, for the varray of numeric(3, 1) type, if the input value is 2.55 when an array is constructed, JDBC will not convert it to 2.6.
  4. The varray length cannot be verified. For example, for the varray(2) of int type, if the number of input elements is greater than 2 when an array is constructed, JDBC will not report an error.
- When an array object passed to the database contains empty elements, the database converts them to **null**. For example, an empty element of the string type is converted to **null** when being passed to the database. Similarly, if the length of a string stored in an element of the CLOB type is 0, the element is converted to **null** when being passed to the database. In addition, if the length of a binary array stored in an element of the BLOB or BYTEA type is 0, the element is converted to **null** when being passed to the database.

  You are advised not to store empty elements in the constructed array object because empty elements are converted to **null** when they are passed to the database. For example, an empty element of the string type is converted to **null**. For details, see Example 3.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When the array object sent from the database to the client contains empty elements, the client also converts these elements to **null**.

- Implicit conversion is supported between different array types. If the registered type is different from the output parameter type of the stored procedure, the instance type returned by the output parameter is subject to the output parameter type of the stored procedure. For details, see Example 4.
- For details about array APIs, see the description of standard APIs supported by GaussArray objects.
- ArrayDescriptor is a non-standard API. Its getSQLType API returns the fixed value **java.sql.Types.ARRAY**.

  For details about the type names returned by the getSQLTypeName API of ArrayDescriptor, see **Data Type Mapping**.

The following table lists standard array APIs.

Method	Return Type	Throws	Supported or Not
getBaseTypeName()	String	SQLException	Supported
getBaseType()	Integer	SQLException	Supported
getArray()	Object	SQLException	Supported
getArray(java.util.Map<String,Class<?>> map)	Object	SQLException	Not supported
getArray(long index, int count)	Object	SQLException	Supported
getArray(long index, int count, java.util.Map<String,Class<?>> map)	Object	SQLException	Not supported
getResultSet()	ResultSet	SQLException	Not supported
getResultSet(java.util.Map<String,Class<?>> map)	ResultSet	SQLException	Not supported
getResultSet(long index, int count)	ResultSet	SQLException	Not supported
getResultSet (long index, int count, java.util.Map<String,Class<?>> map)	ResultSet	SQLException	Not supported
free()	Void	SQLException	Not supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- For details about the array types obtained by the getArray and getArray(long index, int count) APIs, see the **Java Variable Type** column of the table in **Data Type Mapping**.

  For example, if the element type is varchar, the object type obtained through the getArray API is String[].

  Special notes: For an element of the int2 or smallint type, if the element type is changed to short when the element is accessed, the object type obtained by the getArray API is Short[].
- For details about **sqlType** obtained by the getBaseType API, see the **JDBC Type Index** column of the table in **Data Type Mapping**.
- For details about the element type names obtained by getBaseTypeName, see **Data Type Mapping**. The type name mapping rules for the collection, array, and record types are as follows:
  1. If a type is defined in a package, its name is generally in the *Schema*.*Package*.*Type* format.

     If any of schema, package, and type names does not comply with the rules, the type name is in the "*Schema*"."*Package*"."*Type*" format.
     - Only digits, letters, and underscores (_) are allowed.
     - The first character cannot be a digit.
  2. If a type is defined in a schema, its name is generally in the *Schema*.*Type* format.

     If any of schema and type names does not comply with the rules, the type name is in the "*Schema*"."*Type*" format.
     - Only digits, letters, and underscores (_) are allowed.
     - The first character cannot be a digit.
- For the getArray(long index, int count) API:
  1. The value of **index** is 1 for the start element.
  2. The value of **index** ranges from 1 to 2147483647. If the input value is out of this range, an error is reported.
  3. The value of **count** ranges from 0 to 2147483647. If the input value is out of this range, an error is reported.
  4. If the value of **index** exceeds the number of elements, an empty array whose length is 0 is returned.
  5. If the value of **count** exceeds the maximum number of elements that can be obtained based on the current index, an array consisting of the remaining elements is returned.

5.3.3.10 Using the Struct Type

This section describes how to use the struct type of a JDBC driver.

Prerequisites for code running:

1. Add the **gaussdbjdbc.jar** package as required. For example, if you use an IDE to run code, you need to add the **gaussdbjdbc.jar** package to the local IDE.
2. An ORA-compatible database is connected, and the database version is 503.0 or later.

Example 1: The JDBC driver uses the record type in the kernel.

```
// Writing the username and password used for authentication directly into code may cause security risks. It is recommended that you store them in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
```

        testReturnStructParam(conn);

        // Input and output struct parameters.
        testInputOutputStructParam(conn);

        // Delete the test object.
        cleanTestObject(conn);
    }
}
```

The execution result of the preceding example is as follows:

```
===========  testConstructStruct1  ===========
666
aaabbbccc
===========  testConstructStruct2  ===========
666
aaabbbccc
===========  testReturnStructParam  ===========
123
abc
===========  testInputOutputStructParam  ===========
124
abcd
```

Example 2: Struct object APIs are used.

```
// Writing the username and password used for authentication directly into code may cause security risks. It is recommended that you store them in the configuration file or environment variables (the password must
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (variable names are subject to the actual situation).
// Change the values of $ip, $port, and database.

import com.huawei.gaussdb.jdbc.jdbc.GaussStruct;
import com.huawei.gaussdb.jdbc.jdbc.StructDescriptor;

import java.sql.*;

public class StructTest2 {
    // Establish a database connection in non-encrypted mode.
    public static Connection getConnection() {
        String username = System.getenv("EXAMPLE_USERNAME_ENV");
        String passwd = System.getenv("EXAMPLE_PASSWORD_ENV");
        String driver = "com.huawei.gaussdb.jdbc.Driver";
        String sourceURL = "jdbc:gaussdb://$ip:$port/database?enableGaussArrayAndStruct=true";
        Connection conn = null;
        try {
            // Load the database driver.
            Class.forName(driver);
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        try {
            // Create a database connection.
            conn = DriverManager.getConnection(sourceURL, username, passwd);
        } catch (Exception e) {
            e.printStackTrace();
            return null;
        }

        return conn;
    }

    /**
     * Create a frontend database object.
     *
     * @param conn conn

     *
     * @param conn conn
     * @throws SQLException if an exception occurred while executing the statement
     */
    public static void cleanTestObject(Connection conn) throws SQLException {
        Statement stmt = conn.createStatement();
        stmt.execute("drop package test_pkg");
    }

    /**
    * Main program. Call static methods one by one.
     *
     * @param args args
     */
    public static void main(String[] args) throws SQLException {
      // Create a database connection.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        Connection conn = getConnection();

        // Create a frontend test object.
        prepareTestObject(conn);

        String typeName = conn.getSchema() + ".test_pkg.test_rec";
        // Obtain the type descriptor of the test_array type.
        StructDescriptor desc = StructDescriptor.getDescriptor(typeName, conn);

        // Create a GaussStruct object based on the type descriptor and element data.
        GaussStruct struct = new GaussStruct(desc, new Object[]{123, "abc"});

        // Obtain the record type descriptor.
        desc = struct.getDescriptor();

        // Use type descriptor APIs (non-standard).
        // Print whether the type name is $currentSchema.test_pkg.test_rec.
        System.out.println(typeName.equals(desc.getSQLTypeName()));
        // Print whether sqlType of the type is Types.STRUCT.
        System.out.println(desc.getSQLType() == Types.STRUCT);

        // Use a struct API.
        // Obtain and traverse the struct elements.
        Object[] attributes = struct.getAttributes();
        for (Object attribute : attributes) {
            System.out.println(attribute);
        }

        // Delete the test object.
        cleanTestObject(conn);
    }
}
```

The execution result of the preceding example is as follows:

```
true
true
123
abc
```

Example 3: An empty element of the string type is converted to **null** when it is passed to the database.

```
// Writing the username and password used for authentication directly into code may cause security risks. It is recommended that you store them in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (variable names are subject to the actual situation).
// Change the values of $ip, $port, and database.

        prepareTestObject(conn);

        // Transfer a struct with empty elements to the database as input parameters.
        inParamWithEmptyElement(conn);

        // Delete the test object.
        cleanTestObject(conn);
    }
}
```

The execution result of the preceding example is as follows:

```
attribute is empty
attribute is empty
attribute is null
s is null
s is null
s is null
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The type name is case-sensitive and cannot contain decimal points.
- The type name does not support synonyms.
- The type name can be in the *Schema*.*Package*.*Type*, *Package*.*Type*, *Schema*.*Type*, or *Type* format. If no schema name is transferred, the current schema is used by default. If the schema or package name contains a decimal point, it must be enclosed in double quotation marks.
- The element supports the following basic types: int2, int4, int8, float4, float8, numeric, bool, bpchar, varchar, nvarchar2, name, text, timestamp, timestamptz, time, timetz, clob, bytea, and blob. Possible aliases of the preceding types include smallint, int, integer, bigint, number, float, boolean, char, and varchar2.
- The element supports the following user-defined types: array, collection, and record.
- After JDBC enables the URL parameter **enableGaussArrayAndStruct**, the output parameters and return values of the collection or array type can be obtained as struct objects. To output parameters, the GUC parameter **behavior_compat_options** needs to be set to **'proc_outparam_override'** for the database.
- JDBC relies on the database to verify type modifiers. For example:
  1. The element precision cannot be converted. For example, for the record(c1 numeric(3, 1), c2 numeric(3, 1)) type, if the value of the input column element is 2.55 when a struct is constructed, JDBC will not convert it to 2.6.
  2. The element length cannot be verified. For example, for the record(c1 varchar(5), c2 varchar(5)) type, if the length of the input string is greater than 5 when the struct is constructed, JDBC will not report an error.
  3. NOT NULL verification is not supported. For example, for the record(c1 int not null, c2 int) type, if the first column contains **null** when the struct is constructed, JDBC will not report an error.
- When a struct object passed to the database contains empty elements, the database converts them to **null**. For example, an empty element of the string type is converted to **null** when being passed to the database. Similarly, if the length of a string stored in an element of the CLOB type is 0, the element is converted to **null** when being passed to the database. In addition, if the length of a binary array stored in an element of the BLOB or BYTEA type is 0, the element is converted to **null** when being passed to the database.

  You are advised not to store empty elements in the constructed struct object because empty elements are converted to **null** when they are passed to the database. For example, an empty element of the string type is converted to **null**. For details, see Example 3.

  When the struct object sent from the database to the client contains empty elements, the client also converts these elements to **null**.
- For details about struct APIs, see the description of standard APIs supported by GaussStruct objects.
- StructDescriptor is a non-standard API. Its getSQLType API returns the fixed value **java.sql.Types.STRUCT**.

  For details about the type name returned by the getSQLTypeName API of StructDescriptor, see **Data Type Mapping**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following table lists standard struct APIs.

Method	Return Type	Throws	Supported or Not
getSQLTypeName()	String	SQLException	Supported
getAttributes()	Object[]	SQLException	Supported
getAttributes(java.util.Map<String,Class<?>> map)	Object[]	SQLException	Not supported

NOTE

- The object type obtained by the getAttribute API is Object[]. For details about the type of each element in the returned array, see the **Java Variable Type** column in **Data Type Mapping**.

  For example, for the record(c1 int, c2 varchar(5)) type, the first element in Object[] returned by getAttribute is **null** or an integer, and the second element is **null** or a string.

  Special notes: For an element of the int2 or smallint type, the element type is changed to short when the element is accessed.
- For details about the type names returned by the getSQLTypeName API, see **Data Type Mapping**. The mapping rules for the type names of the collection, array, and record types are as follows:
  1. If a type is defined in a package, its name is generally in the *Schema*.*Package*.*Type* format.

     If any of schema, package, and type names does not comply with the rules, the type name is in the "*Schema*"."*Package*"."*Type*" format.

     - Only digits, letters, and underscores (_) are allowed.
     - The first character cannot be a digit.
  2. If a type is defined in a schema, its name is generally in the *Schema*.*Type* format.

     If any of schema and type names does not comply with the rules, the type name is in the "*Schema*"."*Type*" format.

     - Only digits, letters, and underscores (_) are allowed.
     - The first character cannot be a digit.

5.3.4 JDBC Interface Reference

This section describes common JDBC interfaces. For more interfaces, check JDK1.8 (software package) and JDBC 4.2.

5.3.4.1 java.sql.Connection

java.sql.Connection is an API for connecting to a database.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-12 Support status for java.sql.Connection

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
abort(Executor executor)	Aborts an open connection.	void	SQLException	Yes
clearWarnings()	Clears all warnings reported for this connection object.	void	SQLException	Yes
close()	Releases the database and JDBC resources of this connection object immediately instead of waiting for them to be automatically released.	void	SQLException	Yes
commit()	Makes all changes made since the last commit/rollback permanent and releases any database locks currently held by this connection object. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
createArrayOf(String typeName, Object[] elements)	Creates an array object using this factory method.	Array	SQLException	Yes
createBlob()	Constructs an object that implements the BLOB API. The returned object does not contain data initially. The setBinaryStream and setBytes methods of the BLOB API can be used to add data to BLOBs.	Blob	SQLException	Yes
createClob()	Constructs an object that implements the CLOB API. The returned object does not contain data initially. The setAsciiStream, setCharacterStream, and setString methods of the CLOB API can be used to add data to CLOBs.	Clob	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
createSQLXML()	Constructs an object that implements the SQLXML API. The returned object does not contain data initially. You can use the createXmlStreamWriter object of the SQLXML API and the setString method to add data to an SQLXML object.	SQLXML	SQLException	Yes
createStatement()	Creates a statement object that sends SQL statements to a database.	Statement	SQLException	Yes
createStatement(int resultSetType, int resultSetConcurrency)	Creates a statement object that will generate a ResultSet object with a given type and concurrency.	Statement	SQLException	Yes
createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a statement object that will generate a ResultSet object with a given type and concurrency.	Statement	SQLException	Yes
getAutoCommit()	Retrieves the current autocommit mode for this connection object.	boolean	SQLException	Yes
getCatalog()	Obtains the current directory name of this connection object.	String	SQLException	Yes
getClientInfo()	Returns a list containing the name and current value of each client information property supported by the driver. If the client information property has not been set and has no default value, the value of this attribute may be **NULL**. Currently, only ApplicationName and ApplicationType are obtained.	Properties	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
getClientInfo(String name)	Returns the value of the client information property specified by name. This method may return **NULL** if the specified client information property has not been set and there is no default value. This method also returns **NULL** if the driver does not support the specified client information property name.	String	SQLException	Yes
getHoldability()	Obtains the current holdability of the ResultSet object created using this connection object.	int	SQLException	Yes
getMetaData()	Retrieves the DatabaseMetaData object that contains metadata about the database to which this connection object represents the connection. Metadata includes information about database tables, supported SQL syntax, stored procedures, and functions of the connection.	DatabaseMetaData	SQLException	Yes
getNetworkTimeout()	Obtains the number of milliseconds the driver will wait for a database request to complete. If the limit is exceeded, SQLException is thrown.	int	SQLException	Yes
getSchema()	Retrieves the current schema name of this connection object.	String	SQLException	Yes
getTransactionIsolation()	Retrieves the current transaction isolation level of this connection object.	int	SQLException	Yes
getTypeMap()	Retrieves the map object associated with this connection object. Unless the application adds an entry, the returned type mapping will be empty.	Map<String,Class<?>>	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
getWarnings()	Retrieves the first warning reported by calls on this connection object. If there are multiple warnings, subsequent warnings are linked to the first warning and can be retrieved by calling the SQLWarning.getNextWarning method on the previously retrieved warning.	SQLWarning	SQLException	Yes
isClosed()	Checks whether this connection object has been closed. If a method has been called to close the connection, or if some major error occurs, the connection is closed. Ensure that **true** is returned only when this method is called after the close ction.Close method is called.	boolean	SQLException	Yes
isReadOnly()	Checks whether this connection object is in read-only mode.	boolean	SQLException	Yes
isValid(int timeout)	Returns **true** if the connection has not been closed and is still valid. The driver should commit a query to the connection, or use other mechanisms to affirmatively verify that the connection is still valid when this method is called.	Boolean	SQLException	Yes
nativeSQL(String sql)	Converts a given SQL statement to the native SQL syntax of the system. The driver can convert the JDBC SQL syntax to the native SQL syntax of its system before sending it. This method returns the native form of the statement that the driver should have sent.	String	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
prepareCall(String sql)	Creates a CallableStatement object that calls a database stored procedure. The CallableStatement object provides methods for setting its IN and OUT parameters, as well as methods for executing calls to stored procedures.	CallableStatement	SQLException	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency)	Creates a CallableStatement object. This object will generate a ResultSet object with the given type and concurrency. This method is the same as the preparation call method above, but it allows overwriting the default result set type and concurrency.	CallableStatement	SQLException	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a CallableStatement object. This object will generate a ResultSet object with the given type and concurrency. This method is the same as the preparation call method above, but it allows overwriting the default result set type, result set concurrency type, and holdability.	CallableStatement	SQLException	Yes
prepareStatement(String sql)	Creates a prepared statement object for sending parameterized SQL statements to a database.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int autoGeneratedKeys)	Creates a default prepared statement object that can retrieve automatically generated keys. The given constant tells the driver whether it should make the automatically generated key available for retrieval. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, this parameter is ignored.	PreparedStatement	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
prepareStatement(String sql, int[] columnIndexes)	Creates a default prepared statement object that can return an automatically generated key specified by a given array. This array contains the indexes of the columns in the target table that contain the automatically generated keys, which should be available. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, the driver ignores the array.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency)	Creates a prepared statement object that will generate a ResultSet object with a given type and concurrency. This method is the same as the prepared statement method above, but it allows overwriting the default result set type and concurrency.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Creates a prepared statement object that will generate a ResultSet object with a given type, concurrency, and holdability.	PreparedStatement	SQLException	Yes
prepareStatement(String sql, String[] columnNames)	Creates a default prepared statement object that can return an automatically generated key specified by a given array. This array contains the names of the columns in the target table that contain the automatically generated keys, which should be returned. If the SQL statement is not an INSERT statement or an SQL statement that can return an automatically generated key, the driver ignores the array.	PreparedStatement	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
releaseSavepoint(Savepoint savepoint)	Deletes the specified savepoint and subsequent savepoint objects from the current transaction. Any reference to the savepoint after it is deleted will cause an SQL exception to be thrown.	void	SQLException	Yes
rollback()	Undoes all changes made in the current transaction and releases any database locks currently held by this connection object. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
rollback(Savepoint savepoint)	Undoes all changes made after a given savepoint object is set. This method should be used only when the autocommit mode is disabled.	void	SQLException	Yes
setAutoCommit(boolean autoCommit)	Sets the auto-commit mode of this connection to the given state. If a connection is in autocommit mode, all its SQL statements are executed and committed as a single transaction. Otherwise, its SQL statements are grouped into transactions that are terminated by calls to method commits or method rollbacks. By default, new connections are in autocommit mode.	void	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
setClientInfo(Properties properties)	Sets the client information property value of the connection. The properties object contains the names and values of the client information properties to be set. The client information property set contained in the attribute list replaces the current client information property set on the connection. If the property currently set on the connection is not in the property list, the property is cleared. Currently, only ApplicationName and ApplicationType in the client are replaced.	void	SQLClientInfoException	Yes
setClientInfo(String name,String value)	Sets the client **info** property value specified by **name** to that specified by **value**. Currently, only ApplicationName and ApplicationType in the client are replaced.	void	SQLClientInfoException	Yes
setHoldability(int holdability)	Changes the default holdability of the ResultSet object created with this connection object to the given holdability. The default holdability of the ResultSet object can be determined by calling DatabaseMetaData.getResultSetHoldability.	void	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Description	Return Type	throws	Support JDBC 4 (Yes/No)
setNetworkTimeout(Executor executor, int milliseconds)	Sets the maximum time that a connection or an object created from a connection waits for the database to reply to any request. If any request is still not answered, the waiting method returns SQLException, and the connection or object created from the connection is marked as closed. Any subsequent use of the object other than the Close, isCabled, or Connection.isValid method will result in SQLException.	void	SQLException	Yes
setReadOnly(boolean readOnly)	Sets this connection to read-only mode as a hint for the driver to enable database optimization.	void	SQLException	Yes
setSavepoint()	Creates an unnamed savepoint in the current transaction and returns a new savepoint object representing it.	Savepoint	SQLException	Yes
setSavepoint(String name)	Creates a savepoint with the given name in the current transaction and returns a new savepoint object representing it.	Savepoint	SQLException	Yes
setSchema(String schema)	Sets the given schema name to access.	void	SQLException	Yes
setTransactionIsolation(int level)	Attempts to change the transaction isolation level of this connection object to a given level. Constants defined in the connection API are possible transaction isolation levels.	void	SQLException	Yes
setTypeMap(Map<String,Class<?>> map)	Installs the given TypeMap object as the type mapping for this connection object. Type mappings will be used for SQL structured types and custom mappings for different types.	void	SQLException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

1. The autocommit mode is used by default within the API. If you disable it by running **setAutoCommit(false)**, all the statements executed later will be packaged in explicit transactions, and you cannot execute statements that cannot be executed within transactions.
2. Fully-encrypted databases cannot use setClientInfo("send_token", null) to transmit keys or use setClientInfo("clear_token", null) to destroy keys.
3. When you create a PreparedStatement class, using the RETURNING clause in the SQL statement does not take effect.

5.3.4.2 java.sql.CallableStatement

java.sql.CallableStatement is an API for executing stored procedures.

Table 5-13 Support status for java.sql.CallableStatement

Method Name	Return Type	JDBC4 Supported or Not
getArray(int parameterIndex)	Array	Yes
getBigDecimal(int parameterIndex)	BigDecimal	Yes
getBlob(int parameterIndex)	Blob	Yes
getBoolean(int parameterIndex)	boolean	Yes
getByte(int parameterIndex)	byte	Yes
getBytes(int parameterIndex)	byte[]	Yes
getClob(int parameterIndex)	Clob	Yes
getDate(int parameterIndex)	Date	Yes
getDate(int parameterIndex, Calendar cal)	Date	Yes
getDouble(int parameterIndex)	double	Yes
getFloat(int parameterIndex)	float	Yes
getInt(int parameterIndex)	int	Yes
getLong(int parameterIndex)	long	Yes
getObject(int parameterIndex)	Object	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Return Type	JDBC4 Supported or Not
getObject(int parameterIndex, Class<T> type)	Object	Yes
getShort(int parameterIndex)	short	Yes
getSQLXML(int parameterIndex)	SQLXML	Yes
getString(int parameterIndex)	String	Yes
getNString(int parameterIndex)	String	Yes
getTime(int parameterIndex)	Time	Yes
getTime(int parameterIndex, Calendar cal)	Time	Yes
getTimestamp(int parameterIndex)	Timestamp	Yes
getTimestamp(int parameterIndex, Calendar cal)	Timestamp	Yes
registerOutParameter(int parameterIndex, int type)	void	Yes
registerOutParameter(int parameterIndex, int sqlType, int type)	void	Yes
wasNull()	boolean	Yes

NOTE

- The batch operation of statements containing OUT parameter is not allowed.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, and setFetchSize.
- The following methods are inherited from java.sql.PreparedStatement: addBatch, clearParameters, execute, executeQuery, executeUpdate, getMetaData, setBigDecimal, setBoolean, setByte, setBytes, setDate, setDouble, setFloat, setInt, setLong, setNull, setObject, setString, setTime, and setTimestamp.
- The registerOutParameter(int parameterIndex, int sqlType, int type) method is used only to register the composite data type.

5.3.4.3 java.sql.DatabaseMetaData

java.sql.DatabaseMetaData is an API for defining database objects.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-14 Support status for java.sql.DatabaseMetaData

Method	Return Type	JDBC 4 Supported or Not
allProceduresAreCallable()	Boolean	Yes
allTablesAreSelectable()	Boolean	Yes
autoCommitFailureClosesAll-ResultSets()	Boolean	Yes
dataDefinitionCausesTran-sactionCommit()	Boolean	Yes
dataDefinitionIgnoredIn-Transactions()	Boolean	Yes
deletesAreDetected(int type)	Boolean	Yes
doesMaxRowSizeInclude-Blobs()	Boolean	Yes
generatedKeyAlwaysRe-turned()	Boolean	Yes
getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)	ResultSet	Yes
getCatalogs()	ResultSet	Yes
getCatalogSeparator()	String	Yes
getCatalogTerm()	String	Yes
getClientInfoProperties()	ResultSet	Yes
getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)	ResultSet	Yes
getConnection()	Connection	Yes
getCrossReference(String parentCatalog, String parentSchema, String parentTable, String foreignCatalog, String foreignSchema, String foreignTable)	ResultSet	Yes
getDefaultTransactionIsola-tion()	int	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getExportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getExtraNameCharacters()	String	Yes
getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern, String columnNamePattern)	ResultSet	Yes
getFunctions(String catalog, String schemaPattern, String functionNamePattern)	ResultSet	Yes
getIdentifierQuoteString()	String	Yes
getImportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate)	ResultSet	Yes
getMaxBinaryLiteralLength()	int	Yes
getMaxCatalogName-Length()	int	Yes
getMaxCharLiteralLength()	int	Yes
getMaxColumnName-Length()	int	Yes
getMaxColumnsInGroupBy()	int	Yes
getMaxColumnsInIndex()	int	Yes
getMaxColumnsInOrderBy()	int	Yes
getMaxColumnsInSelect()	int	Yes
getMaxColumnsInTable()	int	Yes
getMaxConnections()	int	Yes
getMaxCursorNameLength()	int	Yes
getMaxIndexLength()	int	Yes
getMaxLogicalLobSize()	default long	Yes
getMaxProcedureName-Length()	int	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getMaxRowSize()	int	Yes
getMaxSchemaName-Length()	int	Yes
getMaxStatementLength()	int	Yes
getMaxStatements()	int	Yes
getMaxTableNameLength()	int	Yes
getMaxTablesInSelect()	int	Yes
getMaxUserNameLength()	int	Yes
getNumericFunctions()	String	Yes
getPrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getPartitionTablePrimary-Keys(String catalog, String schema, String table)	ResultSet	Yes
getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)	ResultSet	Yes
getProcedures(String catalog, String schemaPattern, String procedureNamePattern)	ResultSet	Yes
getProcedureTerm()	String	Yes
getSchemas()	ResultSet	Yes
getSchemas(String catalog, String schemaPattern)	ResultSet	Yes
getSchemaTerm()	String	Yes
getSearchStringEscape()	String	Yes
getSQLKeywords()	String	Yes
getSQLStateType()	int	Yes
getStringFunctions()	String	Yes
getSystemFunctions()	String	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)	ResultSet	Yes
getTimeDateFunctions()	String	Yes
getTypeInfo()	ResultSet	Yes
getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)	ResultSet	Yes
getURL()	String	Yes
getVersionColumns(String catalog, String schema, String table)	ResultSet	Yes
insertsAreDetected(int type)	Boolean	Yes
locatorsUpdateCopy()	Boolean	Yes
othersDeletesAreVisible(int type)	Boolean	Yes
othersInsertsAreVisible(int type)	Boolean	Yes
othersUpdatesAreVisible(int type)	Boolean	Yes
ownDeletesAreVisible(int type)	Boolean	Yes
ownInsertsAreVisible(int type)	Boolean	Yes
ownUpdatesAreVisible(int type)	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes

storesUpperCaseIdentifiers()	Boolean	Yes
supportsBatchUpdates()	Boolean	Yes
supportsCatalogsInDataManipulation()	Boolean	Yes
supportsCatalogsInIndexDefinitions()	Boolean	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
supportsCatalogsInPrivilegeDefinitions()	Boolean	Yes
supportsCatalogsInProcedureCalls()	Boolean	Yes
supportsCatalogsInTableDefinitions()	Boolean	Yes
supportsCorrelatedSubqueries()	Boolean	Yes
supportsDataDefinitionAndDataManipulationTransactions()	Boolean	Yes
supportsDataManipulationTransactionsOnly()	Boolean	Yes
supportsGetGeneratedKeys()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
supportsMultipleOpenResults()	Boolean	Yes
supportsNamedParameters()	Boolean	Yes
supportsOpenCursorsAcrossCommit()	Boolean	Yes
supportsOpenCursorsAcrossRollback()	Boolean	Yes
supportsOpenStatementsAcrossCommit()	Boolean	Yes
supportsOpenStatementsAcrossRollback()	Boolean	Yes
supportsPositionedDelete()	Boolean	Yes
supportsPositionedUpdate()	Boolean	Yes
supportsRefCursors()	Boolean	Yes
supportsResultSetConcurrency(int type, int concurrency)	Boolean	Yes
supportsResultSetType(int type)	Boolean	Yes
supportsSchemasInIndexDefinitions()	Boolean	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
supportsSchemasInPrivilege-Definitions()	Boolean	Yes
supportsSchemasInProce-dureCalls()	Boolean	Yes
supportsSchemasInTableDe-finitions()	Boolean	Yes
supportsSelectForUpdate()	Boolean	Yes
supportsStatementPooling()	Boolean	Yes
supportsStoredFunctionsU-singCallSyntax()	Boolean	Yes
supportsStoredProcedures()	Boolean	Yes
supportsSubqueriesInCom-parisons()	Boolean	Yes
supportsSubqueriesInExists()	Boolean	Yes
supportsSubqueriesInIns()	Boolean	Yes
supportsSubqueriesInQuan-tifieds()	Boolean	Yes
supportsTransactionIsola-tionLevel(int level)	Boolean	Yes
supportsTransactions()	Boolean	Yes
supportsUnion()	Boolean	Yes
supportsUnionAll()	Boolean	Yes
updatesAreDetected(int type)	Boolean	Yes
getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)	ResultSet	Yes
getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)	ResultSet	Yes
getTableTypes()	ResultSet	Yes
getUserName()	String	Yes
isReadOnly()	Boolean	Yes
nullsAreSortedHigh()	Boolean	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
nullsAreSortedLow()	Boolean	Yes
nullsAreSortedAtStart()	Boolean	Yes
nullsAreSortedAtEnd()	Boolean	Yes
getDatabaseProductName()	String	Yes
getDatabaseProductVersion()	String	Yes
getDriverName()	String	Yes
getDriverVersion()	String	Yes
getDriverMajorVersion()	int	Yes
getDriverMinorVersion()	int	Yes
usesLocalFiles()	Boolean	Yes
usesLocalFilePerTable()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
supportsMixedCaseQuotedIdentifiers()	Boolean	Yes
storesUpperCaseQuotedIdentifiers()	Boolean	Yes
storesLowerCaseQuotedIdentifiers()	Boolean	Yes
storesMixedCaseQuotedIdentifiers()	Boolean	Yes
supportsAlterTableWithAddColumn()	Boolean	Yes
supportsAlterTableWithDropColumn()	Boolean	Yes
supportsColumnAliasing()	Boolean	Yes
nullPlusNonNullIsNull()	Boolean	Yes
supportsConvert()	Boolean	Yes
supportsConvert(int fromType, int toType)	Boolean	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
supportsTableCorrelation-Names()	Boolean	Yes
supportsDifferentTableCorre-lationNames()	Boolean	Yes
supportsExpressionsInOrder-By()	Boolean	Yes
supportsOrderByUnrelated()	Boolean	Yes
supportsGroupBy()	Boolean	Yes
supportsGroupByUnrelated()	Boolean	Yes
supportsGroupByBeyondSe-lect()	Boolean	Yes
supportsLikeEscapeClause()	Boolean	Yes
supportsMultipleResultSets()	Boolean	Yes
supportsMultipleTransac-tions()	Boolean	Yes
supportsNonNullableCol-umns()	Boolean	Yes
supportsMinimumSQLGram-mar()	Boolean	Yes
supportsCoreSQLGrammar()	Boolean	Yes
supportsExtendedSQLGram-mar()	Boolean	Yes
supportsANSI92EntryLevelS QL()	Boolean	Yes
supportsANSI92Intermediate SQL()	Boolean	Yes
supportsANSI92FullSQL()	Boolean	Yes
supportsIntegrityEnhance-mentFacility()	Boolean	Yes
supportsOuterJoins()	Boolean	Yes
supportsFullOuterJoins()	Boolean	Yes
supportsLimitedOuterJoins()	Boolean	Yes
isCatalogAtStart()	Boolean	Yes
supportsSchemasInDataMa-nipulation()	Boolean	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
supportsSavepoints()	Boolean	Yes
supportsResultSetHoldability(int holdability)	Boolean	Yes
getResultSetHoldability()	int	Yes
getDatabaseMajorVersion()	int	Yes
getDatabaseMinorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes

NOTE

The getPartitionTablePrimaryKeys(String catalog, String schema, String table) method is used to obtain the primary key column of a partitioned table that contains global indexes. The following is an example:

```
PgDatabaseMetaData dbmd = (PgDatabaseMetaData)conn.getMetaData();
dbmd.getPartitionTablePrimaryKeys("catalogName", "schemaName", "tableName");
```

5.3.4.4 java.sql.Driver

This section describes **java.sql.Driver**, the database driver interface.

Table 5-15 Support status for java.sql.Driver

Method	Return Type	JDBC 4 Supported or Not
acceptsURL(String url)	boolean	Yes
connect(String url, Properties info)	Connection	Yes
jdbcCompliant()	boolean	Yes
getMajorVersion()	int	Yes
getMinorVersion()	int	Yes
getParentLogger()	Logger	Yes
getPropertyInfo(String url, Properties info)	DriverPropertyInfo[]	Yes

5.3.4.5 java.sql.PreparedStatement

java.sql.PreparedStatement is a prepared statement API.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-16 Support status for java.sql.PreparedStatement

Method	Return Type	JDBC 4 Supported or Not
clearParameters()	void	Yes
execute()	boolean	Yes
executeQuery()	ResultSet	Yes
excuteUpdate()	int	Yes
executeLargeUpdate()	long	No
getMetaData()	ResultSetMetaData	Yes
getParameterMetaData()	ParameterMetaData	Yes
setArray(int parameterIndex, Array x)	void	Yes
setAsciiStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, long length)	void	Yes
setBlob(int parameterIndex, InputStream inputStream)	void	Yes
setBlob(int parameterIndex, InputStream inputStream, long length)	void	Yes
setBlob(int parameterIndex, Blob x)	void	Yes
setCharacterStream(int parameterIndex, Reader reader)	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
setCharacterStream(int parameterIndex, Reader reader, int length)	void	Yes
setClob(int parameterIndex, Reader reader)	void	Yes
setClob(int parameterIndex, Reader reader, long length)	void	Yes
setClob(int parameterIndex, Clob x)	void	Yes
setDate(int parameterIndex, Date x, Calendar cal)	void	Yes
setNull(int parameterIndex, int sqlType)	void	Yes
setNull(int parameterIndex, int sqlType, String typeName)	void	Yes
setObject(int parameterIndex, Object x)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength)	void	Yes
setSQLXML(int parameterIndex, SQLXML xmlObject)	void	Yes
setTime(int parameterIndex, Time x)	void	Yes
setTime(int parameterIndex, Time x, Calendar cal)	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
setTimestamp(int parameterIndex, Timestamp x)	void	Yes
setTimestamp(int parameterIndex, Timestamp x, Calendar cal)	void	Yes
setUnicodeStream(int parameterIndex, InputStream x, int length)	void	Yes
setURL(int parameterIndex, URL x)	void	Yes
setBoolean(int parameterIndex, boolean x)	void	Yes
setBigDecimal(int parameterIndex, BigDecimal x)	void	Yes
setByte(int parameterIndex, byte x)	void	Yes
setBytes(int parameterIndex, byte[] x)	void	Yes
setDate(int parameterIndex, Date x)	void	Yes
setDouble(int parameterIndex, double x)	void	Yes
setFloat(int parameterIndex, float x)	void	Yes
setInt(int parameterIndex, int x)	void	Yes
setLong(int parameterIndex, long x)	void	Yes
setShort(int parameterIndex, short x)	void	Yes
setString(int parameterIndex, String x)	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
setNString(int parameterIndex, String x)	void	Yes
addBatch()	void	Yes
executeBatch()	int[]	Yes

NOTE

- Execute **addBatch()** and **execute()** only after running **clearBatch()**.
- Batch is not cleared by calling executeBatch(). Clear batch by explicitly calling clearBatch().
- After bounded variables of a batch are added, if you want to reuse these values, you do not need to use set*() again. Instead, add a batch.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, setFetchSize, and enableStreamingResults.
- The executeLargeUpdate() method can only be used in JDBC 4.2 or later.

5.3.4.6 java.sql.ResultSet

java.sql.ResultSet is an execution result set API.

Table 5-17 Support status for java.sql.ResultSet

Method	Return Type	JDBC 4 Supported or Not
absolute(int row)	boolean	Yes
afterLast()	void	Yes
beforeFirst()	void	Yes
cancelRowUpdates()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
deleteRow()	void	Yes
findColumn(String columnLabel)	int	Yes
first()	boolean	Yes
getArray(int columnIndex)	Array	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getArray(String columnLabel)	Array	Yes
getAsciiStream(int columnIndex)	InputStream	Yes
getAsciiStream(String columnLabel)	InputStream	Yes
getBigDecimal(int columnIndex)	BigDecimal	Yes
getBigDecimal(String columnLabel)	BigDecimal	Yes
getBinaryStream(int columnIndex)	InputStream	Yes
getBinaryStream(String columnLabel)	InputStream	Yes
getBlob(int columnIndex)	Blob	Yes
getBlob(String columnLabel)	Blob	Yes
getBoolean(int columnIndex)	boolean	Yes
getBoolean(String columnLabel)	boolean	Yes
getByte(int columnIndex)	byte	Yes
getBytes(int columnIndex)	byte[]	Yes
getByte(String columnLabel)	byte	Yes
getBytes(String columnLabel)	byte[]	Yes
getCharacterStream(int columnIndex)	Reader	Yes
getCharacterStream(String columnLabel)	Reader	Yes
getClob(int columnIndex)	Clob	Yes
getClob(String columnLabel)	Clob	Yes
getConcurrency()	int	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getCursorName()	String	Yes
getDate(int columnIndex)	Date	Yes
getDate(int columnIndex, Calendar cal)	Date	Yes
getDate(String columnLabel)	Date	Yes
getDate(String columnLabel, Calendar cal)	Date	Yes
getDouble(int columnIndex)	double	Yes
getDouble(String columnLabel)	double	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getFloat(int columnIndex)	float	Yes
getFloat(String columnLabel)	float	Yes
getInt(int columnIndex)	int	Yes
getInt(String columnLabel)	int	Yes
getLong(int columnIndex)	long	Yes
getLong(String columnLabel)	long	Yes
getMetaData()	ResultSetMetaData	Yes
getObject(int columnIndex)	Object	Yes

updateObject(String columnLabel, Object x, int scaleOrLength)	void	Yes
updateRow()	void	Yes
updateShort(int columnIndex, short x)	void	Yes
updateShort(String columnLabel, short x)	void	Yes
updateSQLXML(int columnIndex, SQLXML xmlObject)	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
updateSQLXML(String columnLabel, SQLXML xmlObject)	void	Yes
updateString(int columnIndex, String x)	void	Yes
updateString(String columnLabel, String x)	void	Yes
updateTime(int columnIndex, Time x)	void	Yes
updateTime(String columnLabel, Time x)	void	Yes
updateTimestamp(int columnIndex, Timestamp x)	void	Yes
updateTimestamp(String columnLabel, Timestamp x)	void	Yes
wasNull()	boolean	Yes

NOTE

- One statement cannot have multiple open ResultSets.
- The cursor that is used for traversing the ResultSet cannot be open after being committed.

5.3.4.7 java.sql.ResultSetMetaData

This section describes **java.sql.ResultSetMetaData**, which provides details about ResultSet object information.

Table 5-18 Support status for java.sql.ResultSetMetaData

Method Name	Return Type	Support JDBC4 (Yes/No)
getCatalogName(int column)	String	Yes
getColumnClassName(int column)	String	Yes
getColumnCount()	int	Yes
getColumnDisplaySize(int column)	int	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Return Type	Support JDBC4 (Yes/No)
getColumnLabel(int column)	String	Yes
getColumnName(int column)	String	Yes
getColumnType(int column)	int	Yes
getColumnTypeName(int column)	String	Yes
getPrecision(int column)	int	Yes
getScale(int column)	int	Yes
getSchemaName(int column)	String	Yes
getTableName(int column)	String	Yes
isAutoIncrement(int column)	boolean	Yes
isCaseSensitive(int column)	boolean	Yes
isCurrency(int column)	boolean	Yes
isDefinitelyWritable(int column)	boolean	Yes
isNullable(int column)	int	Yes
isReadOnly(int column)	boolean	Yes
isSearchable(int column)	boolean	Yes
isSigned(int column)	boolean	Yes
isWritable(int column)	boolean	Yes

5.3.4.8 java.sql.Statement

java.sql.Statement is an SQL statement API.

Table 5-19 Support status for java.sql.Statement

Method	Return Type	JDBC 4 Supported or Not
addBatch(String sql)	void	Yes
clearBatch()	void	Yes
clearWarnings()	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
close()	void	Yes
closeOnCompletion()	void	Yes
execute(String sql)	boolean	Yes
execute(String sql, int autoGeneratedKeys)	boolean	Yes
execute(String sql, int[] columnIndexes)	boolean	Yes
execute(String sql, String[] columnNames)	boolean	Yes
executeBatch()	boolean	Yes
executeQuery(String sql)	ResultSet	Yes
executeUpdate(String sql)	int	Yes
executeUpdate(String sql, int autoGeneratedKeys)	int	Yes
executeUpdate(String sql, int[] columnIndexes)	int	Yes
executeUpdate(String sql, String[] columnNames)	int	Yes
getConnection()	Connection	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getGeneratedKeys()	ResultSet	Yes
getMaxFieldSize()	int	Yes
getMaxRows()	int	Yes
getMoreResults()	boolean	Yes
getMoreResults(int current)	boolean	Yes
getResultSet()	ResultSet	Yes
getResultSetConcurrency()	int	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
getResultSetHoldability()	int	Yes
getResultSetType()	int	Yes
getQueryTimeout()	int	Yes
getUpdateCount()	int	Yes
getWarnings()	SQLWarning	Yes
isClosed()	boolean	Yes
isCloseOnCompletion()	boolean	Yes
isPoolable()	boolean	Yes
setCursorName(String name)	void	Yes
setEscapeProcessing(boolean enable)	void	Yes
setFetchDirection(int direction)	void	Yes
setMaxFieldSize(int max)	void	Yes
setMaxRows(int max)	void	Yes
setPoolable(boolean poolable)	void	Yes
setQueryTimeout(int seconds)	void	Yes
setFetchSize(int rows)	void	Yes
cancel()	void	Yes
executeLargeUpdate(String sql)	long	No
getLargeUpdateCount()	long	No
executeLargeBatch()	long	No
executeLargeUpdate(String sql, int autoGeneratedKeys)	long	No
executeLargeUpdate(String sql, int[] columnIndexes)	long	No

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	JDBC 4 Supported or Not
executeLargeUpdate(String sql, String[] columnNames)	long	No
enableStreamingResults()	void	Yes

NOTE

- Using setFetchSize can reduce the memory occupied by result sets on the client. Result sets are packaged into cursors and segmented for processing, which will increase the communication traffic between the database and the client, affecting performance.
- Database cursors are valid only within their transactions. If **setFetchSize** is set, set **setAutoCommit(false)** and commit transactions on the connection to flush service data to a database.
- The LargeUpdate method can only be used in JDBC 4.2 or later.
- enableStreamingResults() is a customized API for enabling streaming read. This API indirectly calls setFetchSize(Integer.MIN_VALUE). To enable the streaming read function, set **enableStreamingQuery** in the URL to **true** and call setFetchSize(Integer.MIN_VALUE) or enableStreamingResults(). Except that the streaming read function is enabled, the input parameter of setFetchSize() can only be a positive number or **0**.

5.3.4.9 javax.sql.ConnectionPoolDataSource

This section describes javax.sql.ConnectionPoolDataSource, the interface for data source connection pools.

Table 5-20 Support status for javax.sql.ConnectionPoolDataSource

Method Name	Return Type	Support JDBC4 (Yes/No)
getPooledConnection()	PooledConnection	Yes
getPooledConnection(String user,String password)	PooledConnection	Yes

5.3.4.10 javax.sql.DataSource

This section describes javax.sql.DataSource, the interface for data sources.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-21 Support status for javax.sql.DataSource

Method Name	Return Type	Support JDBC4 (Yes/No)
getConneciton()	Connection	Yes
getConnection(String username,String password)	Connection	Yes
getLoginTimeout()	int	Yes
getLogWriter()	PrintWriter	Yes
setLoginTimeout(int seconds)	void	Yes
setLogWriter(PrintWriter out)	void	Yes

5.3.4.11 javax.sql.PooledConnection

This section describes javax.sql.PooledConnection, the connection interface created by a connection pool.

Table 5-22 Support status for javax.sql.PooledConnection

Method Name	Return Type	Support JDBC4 (Yes/No)
addConnectionEventListener (ConnectionEventListener listener)	void	Yes
close()	void	Yes
getConnection()	Connection	Yes
removeConnectionEventListener (ConnectionEventListener listener)	void	Yes

5.3.4.12 javax.naming.Context

This section describes javax.naming.Context, the context interface for connection configuration.

Table 5-23 Support status for javax.naming.Context

Method Name	Return Type	Support JDBC4 (Yes/No)
bind(Name name, Object obj)	void	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method Name	Return Type	Support JDBC4 (Yes/No)
bind(String name, Object obj)	void	Yes
lookup(Name name)	Object	Yes
lookup(String name)	Object	Yes
rebind(Name name, Object obj)	void	Yes
rebind(String name, Object obj)	void	Yes
rename(Name oldName, Name newName)	void	Yes
rename(String oldName, String newName)	void	Yes
unbind(Name name)	void	Yes
unbind(String name)	void	Yes

5.3.4.13 javax.naming.spi.InitialContextFactory

This section describes javax.naming.spi.InitialContextFactory, the initial context factory interface.

Table 5-24 Support status for javax.naming.spi.InitialContextFactory

Method Name	Return Type	Support JDBC4 (Yes/No)
getInitialContext(Hashtable<?,?> environment)	Context	Yes

5.3.4.14 CopyManager

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB clusters in batches.

Inheritance Relationship of CopyManager

The CopyManager class is in the **com.huawei.gaussdb.jdbc.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager
extends Object
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Constructor Method

public CopyManager(BaseConnection connection)

throws SQLException

Common Methods

Table 5-25 Common methods of CopyManager

Method	Return Type	Description	throws	JDBC 4 Supported or Not
copyIn(String sql)	CopyIn	-	SQLException	Yes
copyIn(String sql, InputStream from)	long	Uses **COPY FROM STDIN** to quickly load data to tables in the database from InputStream.	SQLException,IOException	Yes
copyIn(String sql, InputStream from, int bufferSize)	long	Uses **COPY FROM STDIN** to quickly load data to tables in the database from InputStream.	SQLException,IOException	Yes
copyIn(String sql, Reader from)	long	Uses **COPY FROM STDIN** to quickly load data to tables in the database from Reader.	SQLException,IOException	Yes
copyIn(String sql, Reader from, int bufferSize)	long	Uses **COPY FROM STDIN** to quickly load data to tables in the database from Reader.	SQLException,IOException	Yes
copyOut(String sql)	CopyOut	-	SQLException	Yes
copyOut(String sql, OutputStream to)	long	Sends the result set of **COPY TO STDOUT** from the database to the OutputStream class.	SQLException,IOException	Yes
copyOut(String sql, Writer to)	long	Sends the result set of **COPY TO STDOUT** from the database to the Writer class.	SQLException,IOException	Yes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.3.4.15 PGReplicationConnection

PGReplicationConnection is an API class provided by the JDBC driver in GaussDB. It is used to implement functions related to logical replication.

Inheritance Relationship of PGReplicationConnection

PGReplicationConnection is a logical replication API. Its implementation class is PGReplicationConnectionImpl, which is in the **com.huawei.gaussdb.jdbc.replication** package. The declaration of the class is as follows:

```
public class PGReplicationConnection implements PGReplicationConnection
```

Constructor

public PGReplicationConnection(BaseConnection connection)

Common Methods

Table 5-26 Common methods of PGReplicationConnection

Method	Return Type	Description	Throws
createReplicationSlot()	ChainedCreateReplicationSlotBuilder	Creates a logical replication slot. Only cluster-level (CSN-based) logical replication slots can be created for connecting to CNs, and replication slots with the same name can be created on other CNs and primary DNs. Only local (LSN-based) logical replication slots can be created for connecting to DNs. For details about how to create an LSN-based logical replication slot on a CN or a CSN-based logical replication slot on a DN, see the SQL function pg_create_logical_replication_slot for logical replication.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	Description	Throws
dropReplicationSlot(String slotName)	void	Deletes a logical replication slot. When you connect to a CN to delete a logical replication slot, if the logical replication slot is an LSN-based logical replication slot, only the replication slot of the current node is deleted. Replication slots with the same name on other nodes are not affected. When a CSN-based logical replication slot with the same name exists on other nodes, no error is reported because some nodes do not have replication slots. In addition, replication slots with the same name on all nodes are successfully deleted. If no replication slot exists on any node, an error is reported. If an LSN-based logical replication slot remains on the current CN and a CSN-based logical replication slot with the same name remains on other nodes, connecting to a CN to delete a replication slot will delete only the local LSN-based logical replication slot. After the deletion is complete, perform the deletion operation again to delete the replication slots with the same name on other nodes.	SQLException,IOException
replicationStream()	ChainedStreamBuilder	Enables logical replication.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.3.4.16 PGReplicationStream

PGReplicationStream is an API class provided by the GaussDB JDBC driver. It is used to operate logical replication streams.

Inheritance Relationship of PGReplicationStream

PGReplicationStream is a logical replication API. Its implementation class is V3PGReplicationStream, which is in the **com.huawei.gaussdb.jdbc.core.v3.replication** package. The declaration of the class is as follows:

```
public class V3PGReplicationStream implements PGReplicationStream
```

Constructor

public V3PGReplicationStream(CopyDual copyDual, LogSequenceNumber startLSN, long updateIntervalMs, ReplicationType replicationType)

Common Methods

Table 5-27 Common methods of PGReplicationStream

Method	Return Type	Description	throws
close()	void	Ends the logical replication and releases resources.	SQLException
forceUpdateStatus()	void	Forcibly sends the LSN status received, refreshed, and applied last time to the backend.	SQLException
getLastAppliedLSN()	LogSequenceNumber	Obtains the LSN when the primary node replays logs last time.	-
getLastFlushedLSN()	LogSequenceNumber	Obtains the LSN flushed by the primary node last time, that is, the LSN pushed by the current logic decoding.	-
getLastReceiveLSN()	LogSequenceNumber	Obtains the last received LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots).	-
isClosed()	boolean	Determines whether the replication stream is disabled.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	Description	throws
read()	ByteBuffer	Reads the next WAL record from the backend. If the data cannot be read, this method blocks the I/O read.	SQLException
readPending()	ByteBuffer	Reads the next WAL record from the backend. If the data cannot be read, this method does not block the I/O read.	SQLException
setAppliedLSN(LogSequenceNumber applied)	void	Sets the applied LSN.	-
setFlushedLSN(LogSequenceNumber flushed)	void	Updates the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots), which is sent to the backend at the next update to update the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots) on the server.	-

5.3.4.17 ChainedStreamBuilder

ChainedStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to build replication streams.

Inheritance Relationship of ChainedStreamBuilder

ChainedStreamBuilder is a logical replication API. Its implementation class is ReplicationStreamBuilder, which is in the **com.huawei.gaussdb.jdbc.replication.fluent** package. The declaration of the class is as follows:

```
public class ReplicationStreamBuilder implements ChainedStreamBuilder
```

Constructor

public ReplicationStreamBuilder(final BaseConnection connection)

Common Methods

Table 5-28 Common methods of ReplicationStreamBuilder

Method	Return Type	Description	throws
logical()	ChainedLogicalStreamBuilder	Creates a logical replication stream.	-
physical()	ChainedPhysical-StreamBuilder	Creates a physical replication stream.	-

5.3.4.18 ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to specify common parameters for logical and physical replication.

Inheritance Relationship of ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API for logical replication. The implementation abstract class is AbstractCreateSlotBuilder. The inheritance class is LogicalCreateSlotBuilder which is in the **com.huawei.gaussdb.jdbc.replication.fluent.logical** package. The declaration of this class is as follows:

```
public class LogicalCreateSlotBuilder
    extends AbstractCreateSlotBuilder<ChainedLogicalCreateSlotBuilder>
    implements ChainedLogicalCreateSlotBuilder
```

Constructor

public LogicalCreateSlotBuilder(BaseConnection connection)

Common Methods

Table 5-29 Common methods of LogicalCreateSlotBuilder

Method	Return Type	Description	throws
withSlotName(String slotName)	T	Specifies the name of a replication slot.	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Return Type	Description	throws
withOutputPlugin(String outputPlugin)	ChainedLogicalCreateSlotBuilder	Specifies a plug-in name. Currently, **mppdb_decoding**, **sql_decoding**, **parallel_binary_decoding**, **parallel_json_decoding**, and **parallel_text_decoding** are supported. **mppdb_decoding**: a decoding output format. After this value is set, the output content is in JSON format. The output result contains the attribute information and attribute values of the related data. **sql_decoding**, **parallel_binary_decoding**, **parallel_json_decoding** and **parallel_text_decoding** are output in SQL, binary, JSON, and text format respectively based on the plug-in format.	-
make()	void	Creates a slot with the specified parameters in the database.	SQLException
self()	ChainedLogicalCreateSlotBuilder	Returns the implementation of ChainedLogicalCreate-SlotBuilder.	-

5.4 Development Based on ODBC

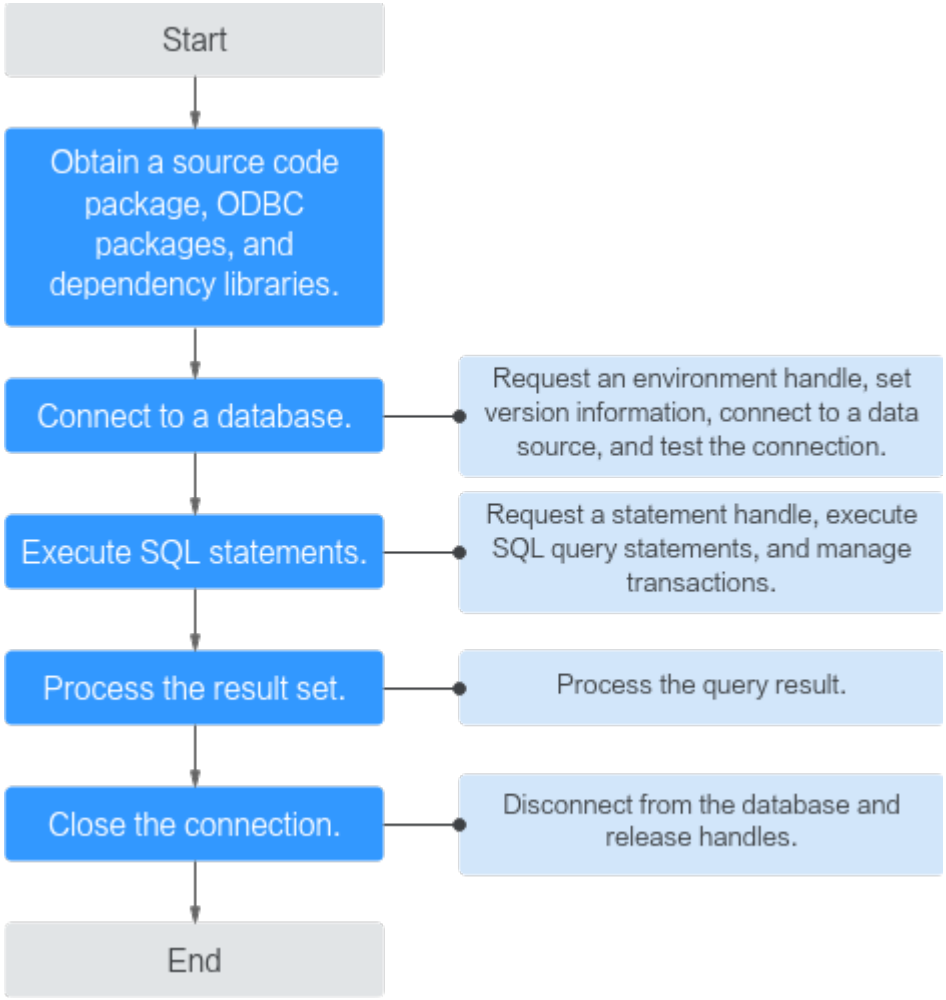
5.4.1 Development Process

Figure 5-3 shows the ODBC-based development process.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The process includes obtaining a source code package, ODBC packages, and dependency libraries, connecting to a database, executing SQL statements, processing the result set, and closing the connection.

Figure 5-3 ODBC-based development process



5.4.2 Development Process

5.4.2.1 Obtaining a Source Code Package, ODBC Packages, and Dependent Libraries

You need to obtain the unixODBC source code package, ODBC packages, and dependency libraries for ODBC-based development.

Obtaining the Source Package

- To obtain the unixODBC source code package, visit **https://www.unixodbc.org/unixODBC-2.3.7.tar.gz**.
- To obtain the MD5 file, visit **https://www.unixodbc.org/unixODBC-2.3.7.tar.gz.md5**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Use the MD5 file to verify the integrity of the unixODBC source code package. (Check whether the MD5 value is the same as that in the source code package.)

Obtaining ODBC Packages and Dependency Libraries

ODBC packages and dependency libraries support both Linux and Windows systems. You can select one as required.

- For Linux:

  Obtain the package **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Odbc.tar.gz** from the driver package. In the Linux OS, unixODBC header files (including **sql.h** and **sqlext.h**) and the library (**libodbc.so**) are required in application development.

  The header files and the library can be obtained from the unixODBC-2.3.7 source code package.

- For Windows:

  Obtain the package **GaussDB-Kernel**_*Database version number*_**Windows_X86_Odbc.tar.gz** (32-bit) or **GaussDB-Kernel**_*Database version number*_**Windows_X64_Odbc.tar.gz** (64-bit) from the driver package.

  In the Windows OS, the required header files and library files are system-resident.

5.4.2.2 Connecting to a Database

5.4.2.2.1 Configuring a Data Source in the Linux OS

Before using ODBC to connect to a database, you need to prepare the required resources. To connect to a database, you need to configure the ODBC data source or use the ODBC APIs or the driver to implement the communication and interaction between an application and a database. This section describes how to configure a data source and connect to a database in the Linux OS.

Procedure

Step 1 Install unixODBC. (By default, the unixODBC source code package has been obtained during environment preparation.) It does not matter if unixODBC of another version has been installed.

For example, install unixODBC-2.3.7.

```
tar zxvf unixODBC-2.3.7.tar.gz
cd unixODBC-2.3.7

./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter --build=aarch64-unknown-linux-gnu.
make
# The installation may require root permissions.
make install
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Currently, unixODBC-2.2.1 is not supported.
- By default, it is installed in the **/usr/local** directory. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.
- You can compile unixODBC with the **--enable-fastvalidate=yes** option to achieve higher performance. However, this option may cause an application that passes an invalid handle to the ODBC API to fail instead of returning an SQL_INVALID_HANDLE error.

Step 2 Replace the GaussDB client driver.

Decompress **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Odbc.tar.gz**. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

Step 3 Configure a data source.

1. Configure the ODBC driver file.

   Add the following content to the **/usr/local/etc/odbcinst.ini** file:

   ```
   [GaussMPP]
   Driver64=/usr/local/lib/gsqlodbcw.so
   setup=/usr/local/lib/gsqlodbcw.so
   ```

   For descriptions of the parameters in the **odbcinst.ini** file, see **Table 5-30**.

   Table 5-30 odbcinst.ini configuration parameters

Parameter	Description	Example
[DriverName]	Driver name, corresponding to the driver in DSN.	[GaussMPP]
Driver64	Path of the dynamic driver library.	Driver64=/usr/local/lib/gsqlodbcw.so
setup	Driver installation path, which is the same as the dynamic library path in Driver64.	setup=/usr/local/lib/gsqlodbcw.so

2. Configure the data source file.

   Add the following content to the **/usr/local/etc/odbc.ini** file:

   ```
   [gaussdb]
   Driver=GaussMPP
   Servername=127.0.0.1 # Database server IP address
   Database=db1  # Database name
   Username=omm  # Database username
   Password=  # Database user password
   Port=8000  # Database listening port
   Sslmode=allow
   ```

   For descriptions of the parameters in the **odbc.ini** file, see **Table 5-31**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-31 odbc.ini configuration parameters

Parameter	Description	Example
[DSN]	Data source name.	[gaussdb]
Driver	Driver name, corresponding to **DriverName** in **odbcinst.ini**.	Driver=Gauss MPP
Servername	Server IP address. Multiple IP addresses can be configured. Both IPv4 and IPv6 are supported.	Servername=127.0.0.1
Database	Name of the database to connect.	Database=db1
Username	Database username.	Username=omm
Password	Password of the database user. **NOTE** After a user establishes a connection, the ODBC driver automatically clears their password stored in memory. However, if this parameter is configured, unixODBC will cache data source files, which may cause the password to be stored in the memory for a long time. When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored. **NOTICE** The password in the configuration file must comply with the following HTTP rules: 1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the characters. 2. A plus sign (+) will be replaced by a space.	Password=**********
Port	Port number of the server. When load balancing is enabled, multiple port numbers can be configured and must correspond to multiple IP addresses. If multiple IP addresses are configured and only one port number is configured when load balancing is enabled, all IP addresses share the same port number by default, that is, the configured port number.	Port=8000

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
Sslmode	Specifies whether to enable the SSL connection. **NOTE** **Table 3 Sslmode options** describes the valid values of **Sslmode**.	Sslmode=allow
Debug	Specifies whether to enable the debugging mode. Value range: 0 to *INT_MAX*. – The value **0** means disabled. – If the value is greater than 0, the **mylog** file of the gsqlODBC driver will be printed, and the log will be generated in the directory **/tmp/**. The default value is **0**.	Debug=1
UseServerSidePrepare	Specifies whether to enable the extended query protocol for the database. Value range: **0** and **1** – The value **0** means disabled. – The value **1** means enabled. The default value is **1**.	UseServerSidePrepare=1
UseBatchProtocol	Specifies whether to enable the batch query protocol. If it is enabled, DML performance can be improved. Value range: **0** and **1** – If the value is **0**, the batch query protocol is disabled (mainly for communication with earlier database versions). – If the value is **1** and **support_batch_bind** is set to **on**, the batch query protocol is enabled. The default value is **1**.	UseBatchProtocol=1
ForExtensionConnector	Specifies whether the savepoint is sent. Value range: **0** and **1** – If the value is **0**, the savepoint is sent. – If the value is **1**, the savepoint is not sent. The default value is **1**.	ForExtensionConnector=1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
ConnectionExtraInfo	Specifies whether to display the driver deployment path and process owner in the GUC parameter **connection_info**. Value range: **0** and **1** – If the value is **0**, the function is disabled. – If the value is **1**, the function is enabled. The default value is **0**. **NOTE** If the value is **1**, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the GUC parameter **connection_info**. In this case, you can query the information from **PG_STAT_ACTIVITY** or **PGXC_STAT_ACTIVITY**.	ConnectionExtraInfo=1
BoolsAsChar	Specifies whether to process Boolean values as characters. Value range: **0** and **1** – If the value is **0**, the Boolean values are mapped to the SQL_BIT type. – If the value is **1**, the Boolean values are mapped to the SQL_CHAR type. The default value is **1**.	BoolsAsChar = 1
RowVersioning	Specifies whether to allow the application to check whether a row of data is modified by another user when the row of data is updated. Value range: **0** and **1** – If the value is **0**, application detection is not allowed. – If the value is **1**, application detection is allowed. The default value is **0**.	RowVersioning =1
ShowSystemTables	Specifies whether to regard the system catalog as a common SQL table by default. Value range: **0** and **1** – If the value is **0**, the driver does not regard the system catalog as a common SQL table by default. – If the value is **1**, the driver regards the system catalog as a common SQL table by default. The default value is **0**.	ShowSystemTables=1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
AutoBalance	Specifies whether to enable ODBC load balancing. Value range: **0** and **1** – If the value is **0**, load balancing is disabled. – If the value is **1**, load balancing is enabled. The default value is **0**. **NOTE** If the version of the connected database is earlier than 505.2.0.SPC0200, load balancing of the DR cluster is not supported.	AutoBalance=1
RefreshCNListTime	Time for refreshing the CN list. This parameter can be configured when load balancing is enabled. The value is an integer, in seconds. Value range: 0 to *INT_MAX*. – If the value is **0**, this parameter is disabled. – If the value is greater than 0, the value is the time for refreshing the CN list. The default value is **10**.	RefreshCNListTime=5
Priority	This parameter can be configured when load balancing is enabled. Value range: **0** and **1** – If the value is **0**, this parameter is disabled. – If the value is **1**, this parameter is enabled. The default value is **0**. **NOTE** When **Priority** is enabled, all connections initiated by applications are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are sent to the remaining CNs.	Priority=1

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
UsingEip	This parameter can be configured when load balancing is enabled. Value range: **0** and **1** – If the value is **0**, this parameter is disabled. – If the value is **1**, it is enabled. The default value is **0**. **NOTE** This value specifies whether to use an elastic IP address for load balancing. If **UsingEip** is enabled, the elastic IP address is used for load balancing. If **UsingEip** is disabled, the data IP address is used for load balancing.	UsingEip=1
MaxCacheQueries	Controls the number of prepared statements cached for each connection. Value range: 0 to 4096 The default value is **0**. **NOTE** If the value is **0**, the prepared statement cache pool is disabled on the client. If the value is greater than 4096, the value **4096** is used. If the number of executed statements exceeds the upper limit specified by **MaxCacheQueries**, the least recently used statements are eliminated.	MaxCacheQueries=128
MaxCacheSizeMiB	Controls the total size of prepared statements cached for each connection. This parameter takes effect when the value of **MaxCacheQueries** is greater than 0. Value range: 0 to 4096 The default value is **1**. **NOTE** If the total size of cached statements is greater than the value of **MaxCacheSizeMiB**, the least recently used statements are eliminated. If the value is greater than 4096, the value **4096** is used. The unit is MB.	MaxCacheSizeMiB=10
TcpUserTimeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the **TCP_USER_TIMEOUT** socket option. Value range: 0 to *INT_MAX*. The default value is **0**. **NOTE** The value **0** is used by default. Ignore this parameter for UDS connections. The unit is millisecond.	TcpUserTimeout=5000

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
StandbyRead	Specifies whether to enable the read on standby mode in a distributed system. Value range: **0** and **1** – The value **0** indicates that the read on standby mode is disabled. – The value **1** indicates that the read on standby mode is enabled. The default value is **0**.	StandbyRead=1
KeepaliveTime	The number of seconds of inactivity after which TCP should send a keepalive message to the server. Ignore this parameter for UDS connections or if keepalive is disabled. Value range: 0 to *INT_MAX*. The default value is **0**.	KeepaliveTime=2
KeepaliveInterval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. Ignore this parameter for UDS connections or if keepalive is disabled. Value range: 0 to *INT_MAX*. The default value is **0**.	KeepaliveInterval=2
KeepaliveCount	Controls the number of times that keepalive messages are sent through TCP. Ignore this parameter for UDS connections or if keepalive is disabled. Value range: 0 to *INT_MAX*. The default value is **0**.	KeepaliveCount=2
SocketTimeout	Specifies a socket read/write timeout interval after a connection is successfully established between a client and a server. The unit is second. The default value is **0**. **NOTE** This parameter includes the timeout interval for executing database statements. If the value is too small, the statement execution may time out. The default value is **0**. Set this parameter based on the actual situation. You are advised to set this parameter to a non-zero value.	SocketTimeout=5

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
SocketTimeoutInConnect	Controls the socket read/write timeout interval during the connection establishment between a client and a server after a TCP three-way handshake is successful. The unit is second. The default value is **5**. **NOTE** Different from **SocketTimeout**, this parameter may block the connection between a client and a server after a three-way handshake is successful. Therefore, you need to set the socket read/write timeout interval to a value that does not affect the statement execution timeout.	SocketTimeoutInConnect=5
CancelTimeout	Specifies the timeout interval for an application to send a cancel message. The unit is second. The default value is **0**.	CancelTimeout=5
TcpSYNRetries	Controls the maximum number of SYN retransmissions during the TCP three-way handshake. If the connection fails to be established after the number of SYN retransmissions exceeds the threshold, an error is reported. The default value is **0**. **NOTE** Specifies the number of retries due to SYN packet transmission failures during the three-way handshake phase when a client establishes a connection on an OS that supports the **TCP_SYNCNT** socket option. The value **0** is used by default. Ignore this parameter for UDS connections.	TcpSYNRetries=3
TextAsLongVarchar	Map the TEXT type on the kernel side to the SQL_LONGVARCHAR or SQL_VARCHAR type on the driver side. Value range: **0** and **1** The value **0** indicates that the TEXT type on the kernel side is mapped to the SQL_VARCHAR type on the driver side. The value **1** indicates that the TEXT type on the kernel side is mapped to the SQL_LONGVARCHAR type on the driver side. The default value is **1**.	TextAsLongVarchar=1
MaxLongVarcharSize	Maximum length of the SQL_LONGVARCHAR type on the driver side. Value range: 0 to *INT_MAX*. The default value is **8190**.	MaxLongVarcharSize=8190

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
MaxVarcharSize	Maximum length of the SQL_VARCHAR type on the driver side. Value range: 0 to *INT_MAX*. The default value is **255**.	MaxVarcharSize=255
EnableUpdateCursorCache	Specifies whether to enable the updatable cursor cache capability. This capability is enabled by default and is supported only in ORA-compatible mode.	EnableUpdateCursorCache=1
TargetServerType	Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. The setting principles are as follows: – **primary** (default value): Only the primary node in the primary/standby system can be connected. – **cluster-primary**: Only CNs in the primary cluster can be connected. – **cluster-mainnode**: Only CNs in the standby cluster for DR can be connected. **NOTE** The **cluster-primary** and **cluster-mainnode** options support only streaming DR.	TargetServerType=cluster-primary
EnableHostCache	Specifies whether to enable the node cache function. **0** indicates disabled and **1** (default) indicates enabled.	EnableHostCache=1

Table 5-32 Sslmode options

Sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Sslmode	Enable SSL Encryption	Description
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by **verify-ca**, the system checks whether the name of the host where the database resides is the same as that in the certificate. GaussDB does not support this mode.

NOTE

When establishing connections to the GaussDB server using ODBC, you can enable SSL connections to encrypt client and server communications. To enable SSL connection, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

Step 4 Configure the environment variables on the client.

```
vim ~/.bashrc
```

Add the following information to the configuration file:

```
export LD_LIBRARY_PATH=/usr/local/lib/:$LD_LIBRARY_PATH
export ODBCSYSINI=/usr/local/etc
export ODBCINI=/usr/local/etc/odbc.ini
```

Step 5 Run the following command to validate the addition:

```
source ~/.bashrc
```

Step 6 Test the connection.

After the installation, the generated binary file is stored in the **/usr/bin** directory. You can run the **isql -v** *gaussdb* command (*gaussdb* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds:

```
+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| quit                                  |
|                                       |
+---------------------------------------+
```

- If error information is displayed, the configuration is incorrect. Check whether the preceding configuration steps are correctly performed.
- In a cluster environment, you need to copy and configure the unixODBC file on all nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> When ODBC is used to connect to a database, the kernel parameters are set as follows:
> ```
> SET extra_float_digits = 2;
> SET DateStyle = 'ISO';
> ```
> These parameters may cause the ODBC and gsql clients to display inconsistent data in aspects such as date data display mode and floating-point precision representation. If the result is not as expected, you are advised to explicitly set these parameters in the ODBC application code.
>
> In M-compatible databases, the default value of **extra_float_digits** is **0**.

----End

Troubleshooting

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/gsqlodbcw.so':file not found.

  Possible causes:

  – The path configured in the **odbcinst.ini** file is incorrect.

  Run **ls** to check the path in the error information, ensuring that the **gsqlodbcw.so** file exists and you have execution permissions on it.

  – The dependent library of **gsqlodbcw.so** does not exist or is not in system environment variables.

  Run the **ldd** command to check the path in the error information. If the unixODBC library such as **libodbc.so.1** is missing, reconfigure unixODBC according to the procedure, ensure that the **lib** directory in the installation path is added to *LD_LIBRARY_PATH*. If the problem persists after reinstallation, manually copy the content in the **unixodbc/lib** directory of the database installation package to the **lib** directory in the installation path of the unixODBC. If other libraries do not exist, add the **lib** directory under the ODBC driver package to *LD_LIBRARY_PATH*. If other standard libraries are missing, install them.

- [UnixODBC]connect to server failed: no such file or directory

  Possible causes:

  – An incorrect or unreachable database IP address or port was configured.

  Check the **Servername** and **Port** configuration items in data sources.

  – Server monitoring is improper.

  If **Servername** and **Port** are correctly configured, ensure the proper NIC and port are monitored by following the database server configurations in the procedure in this section.

  – Firewall and network gatekeeper settings are improper.

  Check firewall settings, and ensure that the database communication port is trusted.

  Check to ensure that network gatekeeper settings are proper (if any).

- [unixODBC]The password-stored method is not supported.

  Possible causes:

  The **sslmode** configuration item is not configured in the data sources.

  Solution:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Set the configuration item to **allow** or a higher level. For details, see **Table 5-32**.

- Server common name "xxxx" does not match host name "xxxxx"

  Possible causes:

  When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.

  Solution:

  To solve this problem, use **verify-ca** to stop checking host names, or generate a set of server certificates containing the actual host names.

- Driver's SQLAllocHandle on SQL_HANDLE_DBC failed

  Possible causes:

  The executable file (such as the **isql** of unixODBC) and the database driver (**gsqlodbcw.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

  ```
  ldd `which isql` | grep odbc
  ldd gsqlodbcw.so | grep odbc
  ```

  If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **gsqlodbcw.so** require **libodbc.so** to be loaded. If they load different physical files, two sets of function lists with the same name are generated in a visible domain (the **libodbc.so.**** function export lists of unixODBC are the same). This results in conflicts and the database driver cannot be loaded.

  Solution:

  Uninstall the unnecessary unixODBC, such as **libodbc.so.2**, and create a soft link with the same name and the .so.2 suffix for the remaining **libodbc.so.1** library.

- FATAL: Forbid remote connection with trust method!

  For security reasons, the database CN prevents unauthorized access from other nodes within the cluster.

  To access the CN from inside the cluster, deploy the ODBC program on the host where the CN is located and use 127.0.0.1 as the server address. It is recommended that the service system be deployed outside the cluster. If it is deployed inside, database performance may be affected.

- [unixODBC][Driver Manager]Invalid attribute value

  This problem occurs when you use SQL on other GaussDB. The possible cause is that the unixODBC version is not the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version.

- authentication method 10 not supported.

  If this error occurs on an open-source client, the cause may be:

  The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see **ALTER USER**), or create a user (see **CREATE USER**) with the same permissions and then connect to the database as the new user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

  The database version is too early or the database is an open-source database.

  Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

  In **gs_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again.

- isql: error while loading shared libraries:xxx

  The dynamic library does not exist in the environment. You need to install the corresponding library.

5.4.2.2.2 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

Procedure

Step 1 Replace the GaussDB client driver.

Decompress the **GaussDB-Kernel**_*Database version number*_**Windows_X64_Odbc.tar.gz** (64-bit) driver package or **GaussDB-Kernel**_*Database version number*_**Windows_X86_Odbc.tar.gz** (32-bit) driver package, and click **gsqlodbc.exe** to install the driver.

Step 2 Open the driver manager.

Use the ODBC driver manager corresponding to the ODBC version. If the 64-bit ODBC driver is used, the 64-bit ODBC driver manager must be used. Assume that the OS is installed on drive C (if the OS is installed on another drive, change the path accordingly):

- If you want to use 32-bit ODBC driver manager in a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)**.

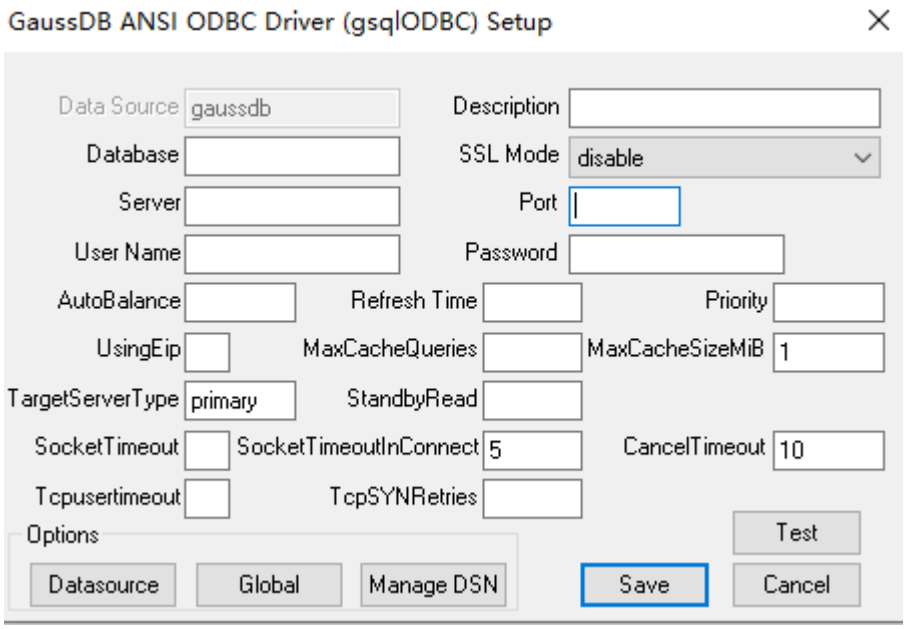
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> WoW64 is short for Windows 32-bit on Windows 64-bit. **C:\Windows\SysWOW64** stores the 32-bit environment on a 64-bit system. **C:\Windows\System32** stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open **C:\Windows\System32\odbcad32.exe** or choose **Computer** > **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)** to open Driver Manager.
- For a 64-bit OS, choose **Control Panel** > **Administrative Tools** > **Data Sources (ODBC)** to enable driver management.

Step 3 Configure a data source.

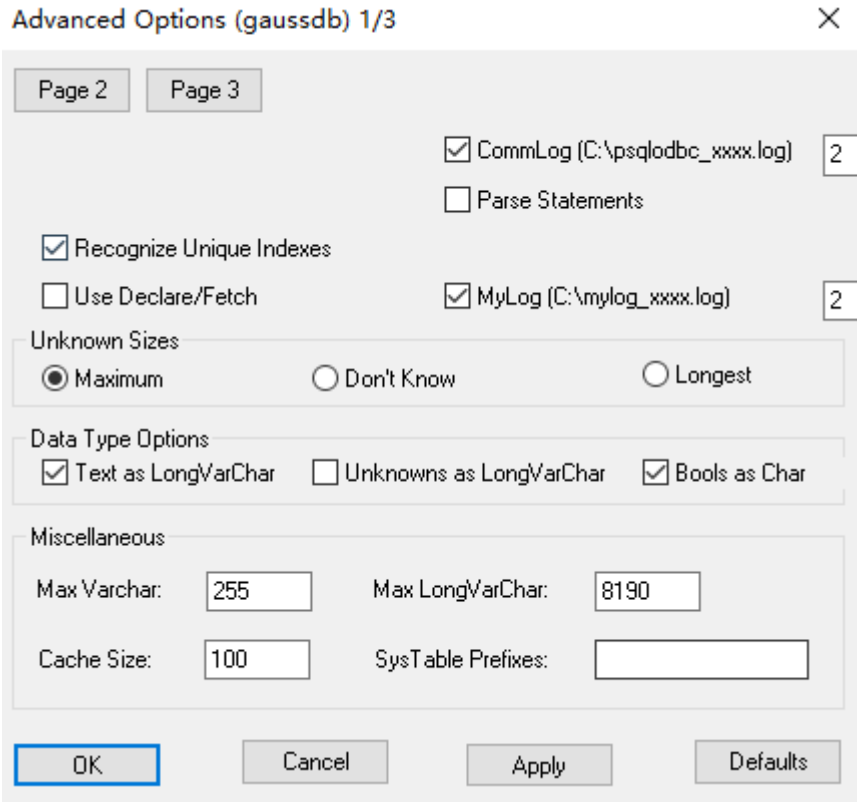
On the **User DSN** tab, click **Add** and choose **GaussDB Unicode** for setup.



For details about the parameters, see **Configuring a Data Source in the Linux OS**.

You can click **Datasource** to configure whether to print logs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.



NOTICE

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

Step 4 Enable the SSL mode.

Change the value of **SSL Mode** in **Step 3** to **require**.

Table 5-33 sslmode options

sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sslmode	Enable SSL Encryption	Description
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the certificate-based authentication.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by **verify-ca**, the system checks whether the name of the host where the database resides is the same as that in the certificate. Currently, Windows ODBC does not support the certificate-based authentication.

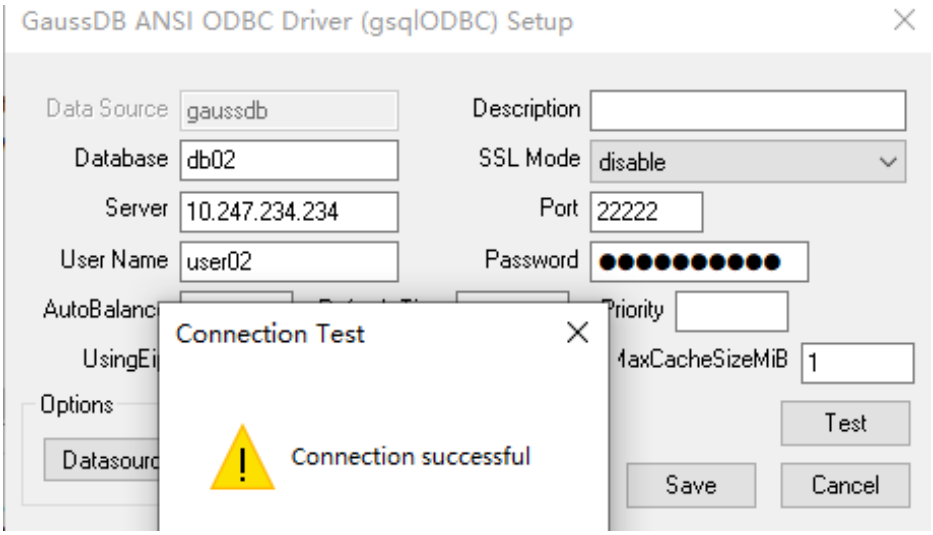
NOTE

When establishing connections to the GaussDB server using ODBC, you can enable SSL connections to encrypt client and server communications. To enable SSL connection, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

Step 5 Test the connection.

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.



- If error information is displayed, the configuration is incorrect. Check whether the preceding configurations are correct.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When ODBC is used to connect to a database, the kernel parameters are set as follows:

```
SET extra_float_digits = 2;
SET DateStyle = 'ISO';
```

  These parameters may cause the ODBC and gsql clients to display inconsistent data in aspects such as date data display mode and floating-point precision representation. If the result is not as expected, you are advised to explicitly set these parameters in the ODBC application code.

----End

Troubleshooting

- connect to server failed: no such file or directory

  Possible causes:

  – An incorrect or unreachable database IP address or port was configured.

  Check the **Server** and **Port** configuration items in data sources.

  – Server monitoring is improper.

  If **Server** and **Port** are correctly configured, ensure the proper NIC and port are monitored by following the database server configurations in the procedure in this section.

  – Firewall and network gatekeeper settings are improper.

  Check firewall settings, and ensure that the database communication port is trusted.

  Check to ensure that network gatekeeper settings are proper (if any).

- The password-stored method is not supported.

  Possible causes:

  sslmode is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see **Table 5-33**.

- authentication method 10 not supported.

  If this error occurs on an open-source client, the cause may be:

  The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

  NOTE

  - The database stores the hashes of user passwords instead of actual passwords.
  - If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
  - An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
  - The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

  To solve this problem, you can update the user password (see **ALTER USER**), or create a user (see **CREATE USER**) with the same permissions and then connect to the database as the new user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

  In **gs_hba.conf** of the target CN, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again.

5.4.2.2.3 APIs for Connecting to a Database

After the database connection test is successful, the ODBC APIs provide a group of functions to connect to the database, as shown in **Table 5-34**.

Table 5-34 API description

Function	API
Allocate a handle.	**SQLAllocHandle** is a generic function for allocating a handle. It can replace the following functions: • **SQLAllocEnv**: allocates an environment handle. • **SQLAllocConnect**: allocates a connection handle. • **SQLAllocStmt**: allocates a statement handle.
Set environment attributes.	**SQLSetEnvAttr**
Set connection attributes.	**SQLSetConnectAttr**
Connect to a database.	**SQLConnect**

The following uses the development source program **DBtest.c** as an example (for details about the complete example, see **Obtaining and Processing Data in a Database**).

```
// DBtest.c (compile with: libodbc.so)
// For details about program header files and global variables, see the complete example.

// Allocate an environment handle.
V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
   printf("Error AllocHandle\n");
   exit(0);
}

// Set the version information (environment attributes).
SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);

// Allocate a connection handle.
V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
   SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
   exit(0);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
}

// Obtain the username and password.
char *userName;
userName = getenv("EXAMPLE_USERNAME_ENV");
char *password;
password = getenv("EXAMPLE_PASSWORD_ENV");

// Set connection attributes.
SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT,(SQLPOINTER *)SQL_AUTOCOMMIT_ON, 0);

// Connect to the database. userName and password indicate the username and password for connecting to the database, respectively.
// If the username and password have been set in the odbc.ini file, you can retain "". However, you are advised not to do so because the username and password will be disclosed if the permission for odbc.ini is abused.
V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,
                      (SQLCHAR*) userName, SQL_NTS,  (SQLCHAR*) password, SQL_NTS);
if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
{
  printf("Error SQLConnect %d\n",V_OD_erg);
  SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
  exit(0);
}
printf("Connected !\n");
```

5.4.2.3 Running SQL Statements

To help users interact with the database, the ODBC provides APIs for executing SQL statements, as shown in **Table 5-35**.

Table 5-35 API description

Function	API
Set statement attributes.	**SQLSetStmtAttr**
Prepare an SQL statement for execution.	**SQLPrepare**
Run a prepared SQL statement.	**SQLExecute**
Bind the parameter marker of an SQL statement to a buffer.	**SQLBindParameter**
Run an SQL statement directly.	**SQLExecDirect**

NOTE

- ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information (such as a plaintext password) is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.
- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following is an example (for details about the complete example, see **Obtaining and Processing Data in a Database**):

```
// Set statement attributes.
SQLSetStmtAttr(V_OD_hstmt, SQL_ATTR_QUERY_TIMEOUT, (SQLPOINTER *)3, 0);

// Allocate a statement handle.
SQLAllocHandle(SQL_HANDLE_STMT, V_OD_hdbc, &V_OD_hstmt);

// Run an SQL statement directly.
SQLExecDirect(V_OD_hstmt, "drop table IF EXISTS customer_t1", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));", SQL_NTS);
SQLExecDirect(V_OD_hstmt, "insert into customer_t1 values(25, 'li')", SQL_NTS);

// Prepare for execution.
SQLPrepare(V_OD_hstmt, "insert into customer_t1 values(?)", SQL_NTS);

// Bind parameters.
SQLBindParameter(V_OD_hstmt,1, SQL_PARAM_INPUT, SQL_C_SLONG, SQL_INTEGER, 0, 0,
            &value, 0, NULL);

// Run the prepared statement.
SQLExecute(V_OD_hstmt);      SQLExecDirect(V_OD_hstmt, "select c_customer_sk from customer_t1",
SQL_NTS);
```

5.4.2.4 Processing Data in a Result Set

The ODBC obtains data from the database and provides the data to the application program for processing. Functions of ODBC processing include but are not limited to: retrieving data, displaying data, processing data, transmitting data, and implementing service logic.

The ODBC provides APIs for processing data in a result set, as shown in **Table 5-36**.

Table 5-36 API description

Function	API
Bind a buffer to a column in the result set.	**SQLBindCol**
Fetch the next row (or rows) from a result set.	**SQLFetch**
Return data in a column of a result set.	**SQLGetData**
Get the column information from a result set.	**SQLColAttribute**
Return the error message of the last operation.	**SQLGetDiagRec**

The following is an example (for details about the complete example, see **Obtaining and Processing Data in a Database**):

```
// After the SQL statement is executed, obtain the attributes of a column in the result set.
SQLColAttribute(V_OD_hstmt,1,SQL_DESC_TYPE,typename,100,NULL,NULL);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
printf("SQLColAtrribute %s\n",typename);

// Bind the result set.
SQLBindCol(V_OD_hstmt,1,SQL_C_SLONG, (SQLPOINTER)&V_OD_buffer,150,
        (SQLLEN *)&V_OD_err);

// Use SQLFetch to obtain data from the result set.
V_OD_erg=SQLFetch(V_OD_hstmt);

// Use SQLGetData to obtain and return data.
while(V_OD_erg != SQL_NO_DATA)
{
  SQLGetData(V_OD_hstmt,1,SQL_C_SLONG,(SQLPOINTER)&V_OD_id,0,NULL);
  printf("SQLGetData ----ID = %d\n",V_OD_id);
  V_OD_erg=SQLFetch(V_OD_hstmt);
};
printf("Done !\n");
```

5.4.2.5 Closing a Connection

The ODBC provides APIs for disconnecting from a database and releasing resources, as shown in **Table 5-37**.

Table 5-37 API description

Function	API
Disconnect from a data source.	**SQLDisconnect**
Release a handle.	**SQLFreeHandle** is a generic function for releasing a handle. It can replace the following functions: • **SQLFreeEnv**: releases an environment handle. • **SQLFreeConnect**: releases a connection handle. • **SQLFreeStmt**: releases a statement handle.

The following is an example (for details about the complete example, see **Obtaining and Processing Data in a Database**):

```
// Disconnect from the data source and release handles.
SQLFreeHandle(SQL_HANDLE_STMT,V_OD_hstmt);
SQLDisconnect(V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_DBC,V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
```

5.4.3 Typical Application Development Examples

5.4.3.1 Typical Application Scenarios and Configurations

Log Diagnosis

ODBC logs are classified into unixODBC driver manager logs and gsqlODBC driver logs. The former is used to trace whether the application API is successfully

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/gsqlodbcw.so
setup=/usr/local/lib/gsqlodbcw.so
```

For gsqlODBC logs, you only need to add the following content to **odbc.ini**:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 # Database server IP address
...
Debug=1 # Enable the debug log function of the driver.
```

NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The gsqlODBC generates the **mylog**_*xxx*.**log** file in the **/tmp/** directory.

Load Balancing

Load balancing can be enabled when there are a large number of concurrent applications.

- Load balancing is to randomly distribute concurrent connections to all CNs to prevent a single CN from being overloaded and improve performance.
- Set **AutoBalance** to **1** to enable load balancing.
- Set **RefreshCNListTime** to **5** as required. The default refresh interval is 10s.
- Set **Priority** to **1** as required. In this case, concurrent connections are preferentially sent to the CNs configured in the configuration file. If all the configured CNs are unavailable, the connections are distributed to the remaining CNs.

Example:

Six CNs, namely, CN1, CN2, CN3, CN4, CN5, and CN6, are configured in the cluster, and four CNs, namely, CN1, CN2, CN3, and CN4, are configured in the configuration file.

Example content of the **odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.145.130.26,10.145.130.27,10.145.130.28,10.145.130.29  # IP address of the database server.
Database=db1  # Database name.
Username=omm  # Database username.
Password=  # Database user password.
Port=8000  # Database listening port.
Sslmode=allow
AutoBalance=1
RefreshCNListTime=3
Priority=1
```

If the configuration file and cluster environment are the same as those in the example, concurrent connections are randomly and evenly distributed to CN1, CN2, CN3, and CN4. When CN1, CN2, CN3, and CN4 are all unavailable, concurrent connections are randomly and evenly sent to CN5 and CN6. If any CN

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

among CN1, CN2, CN3, and CN4 becomes available, the connections are not sent to CN5 and CN6 but to the available CN.

Read on the Standby Node

Configure the CN in the configuration file and set **StandbyRead** to **1** to enable read on the standby node in a distributed system.

Example content of the **odbc.ini** file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.145.130.26,10.145.130.27,10.145.130.28,10.145.130.29  # IP address of the database server.
Database=db1  # Database name.
Username=omm  # Database username.
Password=  # Database user password.
Port=8000  # Database listening port.
StandbyRead=1  # Enable read on the standby node.
Sslmode=allow
AutoBalance=1  # Enable the load balancing mode.
```

Connection Pool Scenario

The connection pool allows applications to reuse pre-established connections without re-establishing connections each time. Once a connection is created and put into the connection pool, the application can reuse the connection, avoiding repeated execution of the complete connection process.

The use of connection pool can significantly improve performance, especially for middle-layer applications or applications requiring network connections that need to establish and close connections frequently.

In addition to the performance advantage, the connection pool architecture enables connections in the environment to be shared by multiple components in a single process. This means that different components in the same process can share connections in the connection pool without interfering with each other, further improving system efficiency and resource utilization.

NOTE

In a connection pool, an open connection may be reused by multiple users. If your application script changes the database connection status, data leakage may occur. For security purposes, exercise caution when using a connection pool.

Configuration in the Linux OS

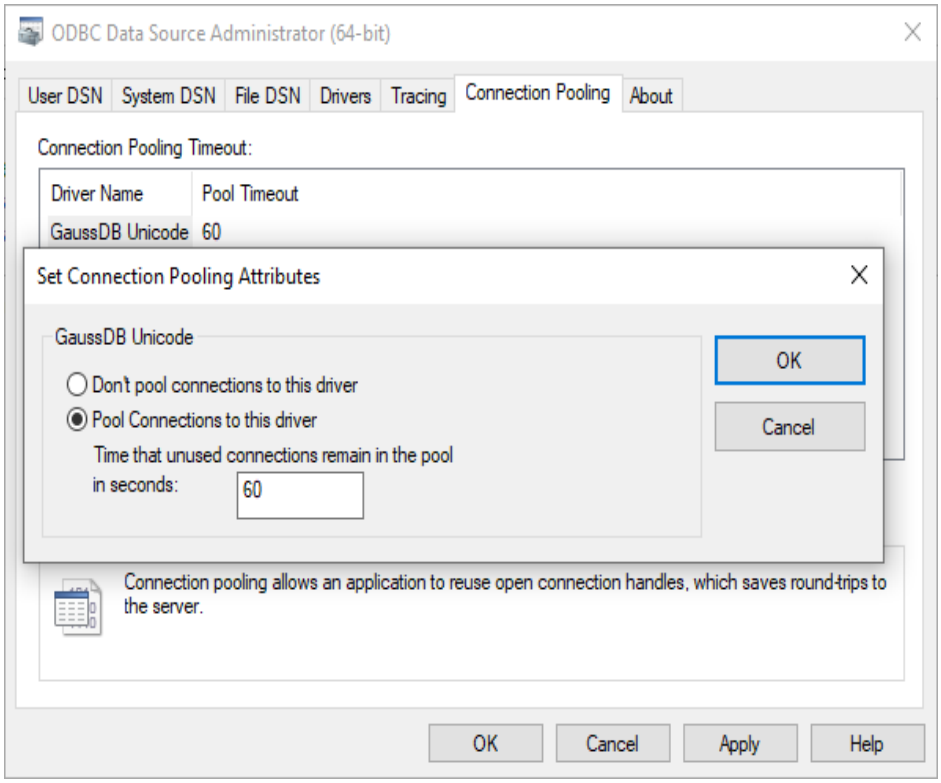
Enable the connection pool in the **odbcinst.ini** configuration file. The reference configuration of the connection pool is as follows:

```
[ODBC]
Pooling=Yes # Enable the connection pool.
[GaussMPP]
CPTimeout=60 # Timeout for releasing a connection that is not reused in the connection pool. The default value is 0. To enable the connection pool, set this parameter to a value greater than 0.
CPTimeToLive=60 # Lifetime of the connection pool under the driver.
[GaussMPP2]
CPTimeout=0 # Disable the connection pool.
```

Configuration in the Windows OS

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

On the **Connection Pool** tab, double-click **GaussDB Unicode**, and select **Pool Connections to this driver** (the default value is **60s**). This parameter is the same as **CPTimeout** configured in the Linux OS. The reference figure is as follows.



NOTE

1. To configure the connection pool parameters in the application, you need to call **SQLSetEnvAttr** to set the connection pool parameters before creating the environment handle. The environment handle must be set to **null**, which makes **SQL_ATTR_CONNECTION_POOLING** a process-level attribute. Currently, **SQL_ATTR_CONNECTION_POOLING** can be set to either of the following values on Windows:
   - **SQL_CP_OFF**: The connection pool is disabled. This is the default value.
   - **SQL_CP_ONE_PER_DRIVER**: Enable the connection pool. Each driver supports a connection pool, and all connections in the driver share the same connection pool.
2. When an application calls **SQLConnect** or **SQLDriverConnect**, the connection is extracted from the connection pool. If the connection times out or no connection matches the request in the pool, a new connection is opened. The connection pool is transparent to the application.
3. When an application calls **SQLDisconnect**, the connection is not released but put back to the connection pool for the next use.
4. Before **SQLFreeHandle** is called in the environment to release the environment handle, all environment attributes that are successfully set by the application persist.
5. If a connection of an application is inactive (not used) for a period of time, the connection is deleted from the pool. The size of the connection pool is limited only by the memory and server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.4.3.2 Obtaining and Processing Data in a Database

NOTE

- In Windows, ODBC application code can be compiled using the Minimalist GNU for Windows (MinGW) compiler. The compilation command is as follows:
  ```
  gcc  odbctest.c -o odbctest -lodbc32
  ```
  Run the following command:
  ```
  ./odbctest.exe
  ```
- In Linux, ODBC application code can be compiled using the GNU Compiler Collection (GCC). The compilation command is as follows:
  ```
  gcc odbctest.c -o odbctest -lodbc
  ```
  Run the following command:
  ```
  ./odbctest
  ```
  If **sql.h** or API cannot be found during compilation, manually connect to the header file and dynamic library of unixODBC.
  ```
  gcc -I /home/omm/unixodbc/include -L /home/omm/unixodbc/lib odbctest.c -o odbctest -lodbc
  ```

This example illustrates how to obtain and process data in GaussDB through ODBC.

Prerequisite: The data source has been configured successfully. For Linux OS, see **Configuring a Data Source in the Linux OS**. For Windows OS, see **Configuring a Data Source in the Windows OS**.

```
// DBtest.c (compile with: libodbc.so)
// In this example, the username and password are stored in environment variables. Before running this example, set the environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment.
#ifdef WIN32
#include <windows.h>
#endif
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
SQLHENV       V_OD_Env;        // Handle ODBC environment
SQLHSTMT      V_OD_hstmt;      // Handle statement
SQLHDBC       V_OD_hdbc;       // Handle connection
char          typename[100];
SQLINTEGER    value = 100;
SQLINTEGER    V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }

    // 2. Set the version information (environment attributes).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);

    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }

    // Obtain the username and password.
    char *userName;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    userName = getenv("EXAMPLE_USERNAME_ENV");
    char *password;
    password = getenv("EXAMPLE_PASSWORD_ENV");

    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT,(SQLPOINTER *)SQL_AUTOCOMMIT_ON, 0);

    // 5. Connect to the database. userName and password indicate the username and password for
connecting to the database, respectively.
   // If the username and password have been set in the odbc.ini file, you do not need to set userName or
password here, retaining "" for them. However, you are advised not to do so because the username and
password will be disclosed if the permission for odbc.ini is abused.

The running result is as follows:

```
Complete.
```

Part of database query result is as follows:

```
 id  |          col
-----+-----------------------
   0 | column test value 0
   1 | column test value 1
   2 | column test value 2
   3 | column test value 3
   4 | column test value 4
   5 | column test value 5
   6 | column test value 6
   7 | column test value 7
   8 | column test value 8
...
```

5.4.3.4 High-Performance Binding Type

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- You need to set **UseBatchProtocol** to **1** in the **odbc.ini** file and **support_batch_bind** to **on** in the database.
- The ODBC program binding type must be the same as that in the database.
- The character set of the client is the same as that of the database.
- The transaction is committed manually.

odbc.ini configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 # Database server IP address
...
UseBatchProtocol=1 # Enabled by default
ConnSettings=set client_encoding=UTF8 # Set the character code on the client to be the same as that on the server.
```

The binding type example is as follows:

Prerequisite: The data source has been configured successfully. For Linux OS, see **Configuring a Data Source in the Linux OS**. For Windows OS, see **Configuring a Data Source in the Windows OS**.

```
#ifdef WIN32
#include <windows.h>
#endif
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>

#define MESSAGE_BUFFER_LEN  128

```

NOTE

In the preceding example, the **number** column is defined. When the SQLBindParameter API is called, the performance of binding SQL_NUMERIC is higher than that of SQL_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

The running result is as follows:

```
Complete!
```

5.4.3.5 Enabling a Connection Pool

Prerequisite: The data source has been configured successfully. For Linux OS, see **Configuring a Data Source in the Linux OS**. For Windows OS, see **Configuring a Data Source in the Windows OS**.

Enabling a connection pool in a Linux or Windows OS can significantly improve the performance of middle-layer applications that need to establish and close connections frequently. For details about the reference configuration, see **Connection Pool Scenario**. The sample code is as follows:

```
#ifdef WIN32
#include <windows.h>
#endif
```

```
void InitializeEnvironment()
{

    /* Enable the connection pool. Configure connection pool parameters in the Windows OS before
allocating an environment handle. */
    SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER *)SQL_CP_ONE_PER_DRIVER, 0);

    /* Close the connection pool in the Windows OS. */
    // SQLSetEnvAttr(env, SQL_ATTR_CONNECTION_POOLING, (SQLINTEGER*)SQL_CP_OFF, 0);

    // Allocate an environment handle.
    SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &env);
    // Configure the ODBC version.
    SQLSetEnvAttr(env, SQL_ATTR_ODBC_VERSION, (SQLPOINTER)SQL_OV_ODBC3, 0);
    // Configure the timeout interval for establishing a connection.
    SQLSetConnectAttr(conn, SQL_LOGIN_TIMEOUT, (SQLPOINTER *)5, 0);
}

void test_connect()
{
    SQLRETURN ret;
    SQLCHAR str[1024];
    SQLSMALLINT strl;
    SQLCHAR dsn[1024];
    SQLUINTEGER uIntVal;

    SQLAllocHandle(SQL_HANDLE_DBC, env, &conn);

    /* Adjust the connection string based on the scenario. */
    char *config = "Driver=GaussMPP;DSN=gaussdb;";
    ret = SQLSetConnectAttr(conn, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER)(1), 0);

    ret = SQLDriverConnect(conn, 0, (SQLCHAR *)config, SQL_NTS, (SQLCHAR *)NULL, SQL_NTS, 0,
SQL_DRIVER_NOPROMPT);

    if (SQL_SUCCEEDED(ret)) {
        // printf("Connected\n");
    } else {
        print_diag("SQLDriverConnect failed.", SQL_HANDLE_DBC, conn);
        SQLFreeHandle(SQL_HANDLE_DBC, conn);
        SQLFreeHandle(SQL_HANDLE_ENV, env);
        exit(1);
    }

    /* Put the connection into the connection pool to reuse the connection. */
    if (conn != SQL_NULL_HDBC) {
        SQLDisconnect(conn);
        SQLFreeHandle(SQL_HANDLE_DBC, conn);
        conn = SQL_NULL_HDBC;
    }
}

int main()
{
    int count = 0;
    int timeuser;
    gettimeofday(&start, NULL);
    InitializeEnvironment();

    for (int i = 0; i < CONN_COUNT; i++) {
        test_connect();
        count++;
    }

    // Release an environment handle.
    SQLFreeHandle(SQL_HANDLE_ENV, env);
    printf("Connection count: %d\n", count);
    gettimeofday(&end, NULL);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    timeuser = 1000000 * (end.tv_sec - start.tv_sec) + end.tv_usec - start.tv_usec;
    printf("Connection time: %.3f s \n", (double)timeuser / 1000000);
    return 0;
}
```

The result varies with the environment. When the connection pool is enabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 14.175 s
```

When the connection pool is disabled, the running result of this example is as follows:

```
Connection count: 15000
Connection time: 691.768 s
```

NOTE

The application code in the Windows OS is the same as that in the Linux OS. The connection string needs to be configured based on the scenario.

5.4.4 ODBC Interface Reference

The ODBC interface is a set of functions provided to users. This chapter describes its common interfaces. For details on other interfaces, see "ODBC Programmer's Reference" at MSDN (https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177(v=vs.85).aspx).

5.4.4.1 SQLAllocEnv

In ODBC 3.*x*, SQLAllocEnv (a function in ODBC 2.*x*) was deprecated and replaced by SQLAllocHandle.

For details, see **SQLAllocHandle**.

5.4.4.2 SQLAllocConnect

In ODBC 3.*x*, SQLAllocConnect (a function in ODBC 2.*x*) was deprecated and replaced by SQLAllocHandle.

For details, see **SQLAllocHandle**.

5.4.4.3 SQLAllocHandle

Description

Allocates environment, connection, statement, or descriptor handles. This function replaces the deprecated ODBC 2.x functions SQLAllocEnv, SQLAllocConnect, and SQLAllocStmt.

Prototype

```
SQLRETURN SQLAllocHandle(SQLSMALLINT   HandleType,
                         SQLHANDLE     InputHandle,
                         SQLHANDLE     *OutputHandlePtr);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-38 SQLAllocHandle parameters

Keyword	Description
HandleType	Type of handle to be allocated by SQLAllocHandle. The value must be one of the following: • **SQL_HANDLE_ENV** (environment handle) • **SQL_HANDLE_DBC** (connection handle) • **SQL_HANDLE_STMT** (statement handle) • **SQL_HANDLE_DESC** (descriptor handle) The handle allocation sequence is: environment handle > connection handle > statement handle. A later allocated handle depends on a previously allocated handle.
InputHandle	Existing handle to use as a context for the new handle being allocated. The **InputHandle** parameter specifies the parent handle of the handle to be created to establish the hierarchical relationship between handles. Handles of different types have different hierarchical relationships. The **InputHandle** parameter is used to specify the relationship. • If **HandleType** is **SQL_HANDLE_ENV**, the value is **SQL_NULL_HANDLE**, indicating that there is no parent handle. • If **HandleType** is **SQL_HANDLE_DBC**, this must be an environment handle, indicating that the connection handle is created in this environment. • If **HandleType** is **SQL_HANDLE_STMT** or **SQL_HANDLE_DESC**, it must be a connection handle, indicating that the statement handle is created under the connection.
OutputHandlePtr	**Output parameter**: **OutputHandlePtr** is a pointer that points to the SQLHANDLE type and is used to return a new handle allocated.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

If SQLAllocHandle returns **SQL_ERROR** when it is used to allocate a non-environment handle, it sets **OutputHandlePtr** to **SQL_NULL_HDBC**, **SQL_NULL_HSTMT**, or **SQL_NULL_HDESC**. The application can then call **SQLGetDiagRec**, with **HandleType** and **Handle** set to the value of **IntputHandle**, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.4 SQLAllocStmt

In ODBC 3.*x*, SQLAllocStmt (a function in ODBC 2.*x*) was deprecated and replaced by SQLAllocHandle.

For details, see **SQLAllocHandle**.

5.4.4.5 SQLBindCol

Description

Binds application data buffers to columns in a result set.

Prototype

```
SQLRETURN SQLBindCol(SQLHSTMT       StatementHandle,
                     SQLUSMALLINT   ColumnNumber,
                     SQLSMALLINT    TargetType,
                     SQLPOINTER     TargetValuePtr,
                     SQLLEN     BufferLength,
                     SQLLEN     *StrLen_or_IndPtr);
```

Parameters

Table 5-39 SQLBindCol parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Number of the column to be bound. The column number starts with 0 and increases in ascending order. Column 0 is the bookmark column. If no bookmark column is set, column numbers start with 1.
TargetType	C data type in the buffer.
TargetValuePtr	**Output parameter**: pointer to the buffer bound with the column. The SQLFetch function returns data in the buffer. If this parameter is a null pointer, **StrLen_or_IndPtr** is a valid value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
BufferLength	Size of the **TargetValuePtr** buffer in bytes.
StrLen_or_IndPtr	**Output parameter**: pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLBindCol returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.6 SQLBindParameter

Description

Binds parameter markers in an SQL statement to a buffer.

Prototype

```
SQLRETURN SQLBindParameter(SQLHSTMT       StatementHandle,
                           SQLUSMALLINT   ParameterNumber,
                           SQLSMALLINT    InputOutputType,
                           SQLSMALLINT    ValuetType,
                           SQLSMALLINT    ParameterType,
                           SQLULEN    ColumnSize,
                           SQLSMALLINT    DecimalDigits,
                           SQLPOINTER     ParameterValuePtr,
                           SQLLEN     BufferLength,
                           SQLLEN     *StrLen_or_IndPtr);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-40 SQLBindParameter parameters

Keyword	Description
StatementHandle	Statement handle.
ParameterNumber	Parameter marker number, starting with 1 and increasing in ascending order.
InputOutputType	Input/output type of the parameter. The value can be **SQL_PARAM_INPUT**, **SQL_PARAM_OUTPUT** or **SQL_PARAM_INPUT_OUTPUT**.
ValueType	C data type of the parameter. The value can be **SQL_C_CHAR**, **SQL_C_LONG** or **SQL_C_DOUBLE**.
ParameterType	SQL data type of the parameter. The value can be **SQL_CHAR**, **SQL_INTEGER**, or **SQL_DOUBLE**.
ColumnSize	Size of the column or expression marked by the corresponding parameter.
DecimalDigits	Decimal number of the column or expression marked by the corresponding parameter.
ParameterValuePtr	Pointer to the storage parameter buffer.
BufferLength	Size of the ParameterValuePtr buffer in bytes.
StrLen_or_IndPtr	Pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLBindParameter returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.7 SQLColAttribute

Description

Returns the descriptor information about a column in the result set.

Prototype

```
SQLRETURN SQLColAttibute(SQLHSTMT        StatementHandle,
                         SQLUSMALLINT    ColumnNumber,
                         SQLUSMALLINT    FieldIdentifier,
                         SQLPOINTER      CharacterAtrributePtr,
                         SQLSMALLINT     BufferLength,
                         SQLSMALLINT     *StringLengthPtr,
                         SQLLEN          *NumericAttributePtr);
```

Parameters

Table 5-41 SQLColAttribute parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Column number of the field to be queried, starting with 1 and increasing in ascending order.
FieldIdentifier	Field identifier of **ColumnNumber** in IRD.
CharacterAttribu-tePtr	**Output parameter**: pointer to the buffer that returns the **FieldIdentifier** value.
BufferLength	• This parameter indicates the length of the buffer if **FieldIdentifier** is an ODBC-defined field and **CharacterAttributePtr** points to a string or a binary buffer. • Ignore this parameter if **FieldIdentifier** is an ODBC-defined field and **CharacterAttributePtr** points to an integer.
StringLengthPtr	**Output parameter**: pointer to a buffer in which the total number of valid bytes (for string data) is stored in ***CharacterAttributePtr**. Ignore the value of **BufferLength** if the data is not a string.
NumericAttributePtr	**Output parameter**: pointer to an integer buffer in which the value of the **FieldIdentifier** field in the **ColumnNumber** row of the IRD is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLColAttribute returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.8 SQLConnect

Description

Establishes a connection between a driver and a data source. After the connection is established, the connection handle can be used to access all information about the data source, including its application operating status, transaction processing status, and error information.

Prototype

```
SQLRETURN  SQLConnect(SQLHDBC       ConnectionHandle,
                      SQLCHAR       *ServerName,
                      SQLSMALLINT   NameLength1,
                      SQLCHAR       *UserName,
                      SQLSMALLINT   NameLength2,
                      SQLCHAR       *Authentication,
                      SQLSMALLINT   NameLength3);
```

Parameters

Table 5-42 SQLConnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.
ServerName	Name of the data source to connect.
NameLength1	Length of **ServerName**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
UserName	Username of the database in the data source.
NameLength2	Length of **UserName**.
Authentication	User password of the database in the data source.
NameLength3	Length of **Authentication**.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLConnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.9 SQLDisconnect

Description

Closes the connection associated with a database connection handle.

Prototype

```
SQLRETURN SQLDisconnect(SQLHDBC     ConnectionHandle);
```

Parameter

Table 5-43 SQLDisconnect parameter

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLDisconnect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.10 SQLExecDirect

Description

Executes a prepared statement specified in this parameter. This is the fastest method for executing only one SQL statement at a time.

Prototype

```
SQLRETURN SQLExecDirect(SQLHSTMT         StatementHandle,
                        SQLCHAR          *StatementText,
                        SQLINTEGER       TextLength);
```

Parameters

Table 5-44 SQLExecDirect parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
StatementText	SQL statement to be executed. Multiple statements cannot be executed at a time.
TextLength	Length of **StatementText**.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.

Precautions

If SQLExecDirect returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.11 SQLExecute

Description

If a statement contains a parameter marker, the SQLExecute function uses the current value of the parameter marker to execute a prepared SQL statement.

Prototype

```
SQLRETURN SQLExecute(SQLHSTMT    StatementHandle);
```

Parameters

Table 5-45 SQLExecute parameters

Keyword	Description
StatementHandle	Statement handle to be executed.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_NEED_DATA** indicates that parameters provided before executing the SQL statement are insufficient.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLExecute returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.12 SQLFetch

Description

Advances the cursor to the next row of the result set and retrieves any bound columns.

Prototype

```
SQLRETURN SQLFetch(SQLHSTMT    StatementHandle);
```

Parameter

Table 5-46 SQLFetch parameter

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLFetch returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.13 SQLFreeStmt

In ODBC 3.*x*, SQLFreeStmt (a function in ODBC 2.*x*) was deprecated and replaced with SQLFreeHandle.

For details, see **SQLFreeHandle**.

5.4.4.14 SQLFreeConnect

In ODBC 3.*x*, SQLFreeConnect (a function in ODBC 2.*x*) was deprecated and replaced with SQLFreeHandle.

For details, see **SQLFreeHandle**.

5.4.4.15 SQLFreeHandle

Description

Releases resources associated with a specific environment, connection, or statement handle. It replaces the ODBC 2.x functions: SQLFreeEnv, SQLFreeConnect, and SQLFreeStmt.

Prototype

```
SQLRETURN SQLFreeHandle(SQLSMALLINT   HandleType,
                        SQLHANDLE     Handle);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-47 SQLFreeHandle parameters

Keyword	Description
HandleType	Type of handle to be freed by SQLFreeHandle. The value must be one of the following: • **SQL_HANDLE_ENV** • **SQL_HANDLE_DBC** • **SQL_HANDLE_STMT** • **SQL_HANDLE_DESC** If none of them is the value of **HandleType**, SQLFreeHandle returns **SQL_INVALID_HANDLE**.
Handle	Name of the handle to be freed.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLFreeHandle returns **SQL_ERROR**, the handle is still valid.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.16 SQLFreeEnv

In ODBC 3.*x*, SQLFreeEnv (a function in ODBC 2.*x*) was deprecated and replaced with SQLFreeHandle.

For details, see **SQLFreeHandle**.

5.4.4.17 SQLPrepare

Description

Prepares an SQL statement to be executed.

Note that ODBC does not support the kernel reuse plan when sending prepared statements. As a result, a new plan needs to be generated for each execution,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

causing high CPU usage. If services have requirements on plan reuse, you are advised to use the JDBC client.

Prototype

```
SQLRETURN SQLPrepare(SQLHSTMT      StatementHandle,
                     SQLCHAR       *StatementText,
                     SQLINTEGER    TextLength);
```

Parameters

Table 5-48 SQLPrepare parameters

Keyword	Description
StatementHandle	Statement handle.
StatementText	SQL text string.
TextLength	Length of **StatementText**.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLPrepare returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.18 SQLGetData

Description

SQLGetData is used to retrieve data for a single column in the result set. It can be called multiple times to partially retrieve variable-length data.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
SQLRETURN SQLGetData(SQLHSTMT        StatementHandle,
                     SQLUSMALLINT    Col_or_Param_Num,
                     SQLSMALLINT     TargetType,
                     SQLPOINTER      TargetValuePtr,
                     SQLLEN          BufferLength,
                     SQLLEN          *StrLen_or_IndPtr);
```

Parameters

Table 5-49 SQLGetData parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
Col_or_Param_Num	Column number for which the data retrieval is requested. The column number starts with 1 and increases in ascending order. The number of the bookmark column is 0.
TargetType	C data type in the TargetValuePtr buffer. If **TargetType** is **SQL_ARD_TYPE**, the driver uses the data type of the **SQL_DESC_CONCISE_TYPE** column in ARD. If it is **SQL_C_DEFAULT**, the driver selects a default data type according to the source SQL data type.
TargetValuePtr	**Output parameter**: pointer to the pointer that points to the buffer where the data is located.
BufferLength	Size of the buffer pointed to by **TargetValuePtr**.
StrLen_or_IndPtr	**Output parameter**: pointer to the buffer where the length or identifier value is returned.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_NO_DATA** indicates that the SQL statement does not return a result set.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.
- **SQL_STILL_EXECUTING** indicates that the statement is being executed.

Precautions

If SQLGetData returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQLSTATE value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.19 SQLGetDiagRec

Description

Returns the current values of multiple fields in a diagnostic record that contains error, warning, and status information.

Prototype

```
SQLRETURN  SQLGetDiagRec(SQLSMALLINT    HandleType,
                         SQLHANDLE      Handle,
                         SQLSMALLINT    RecNumber,
                         SQLCHAR        *SQLState,
                         SQLINTEGER     *NativeErrorPtr,
                         SQLCHAR        *MessageText,
                         SQLSMALLINT    BufferLength
                         SQLSMALLINT    *TextLengthPtr);
```

Parameters

Table 5-50 SQLGetDiagRec parameters

Keyword	Description
HandleType	A handle-type identifier that describes the type of handle for which diagnostics are desired. The value must be one of the following: • **SQL_HANDLE_ENV** • **SQL_HANDLE_DBC** • **SQL_HANDLE_STMT** • **SQL_HANDLE_DESC**
Handle	A handle for the diagnostic data structure. Its type is indicated by **HandleType**. If **HandleType** is **SQL_HANDLE_ENV**, **Handle** may be a shared or non-shared environment handle.
RecNumber	Status record from which the application seeks information. Status records are numbered from 1.
SQLState	**Output parameter**: pointer to a buffer that saves the 5-character **SQLSTATE** code pertaining to **RecNumber**.
NativeErrorPtr	**Output parameter**: pointer to a buffer that saves the native error code.
MessageText	Pointer to a buffer that saves text strings of diagnostic information.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
BufferLength	Length of **MessageText**.
TextLengthPtr	**Output parameter**: pointer to the buffer, the total number of bytes in the returned **MessageText**. If the number of bytes available to return is greater than **BufferLength**, then the diagnostics information text in **MessageText** is truncated to **BufferLength** minus the length of the null termination character.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

SQLGetDiagRec does not release diagnostic records for itself. It uses the following return values to report execution results:

- **SQL_SUCCESS** indicates that the function successfully returns diagnostic information.
- **SQL_SUCCESS_WITH_INFO** indicates that the **MessageText** buffer is too small to hold the requested diagnostic information. No diagnostic records are generated.
- **SQL_INVALID_HANDLE** indicates that the handle indicated by **HandleType** and **Handle** is an invalid handle.
- **SQL_ERROR** indicates that the value of **RecNumber** is less than or equal to **0** or the value of **BufferLength** is less than **0**.

If an ODBC function returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, you can call SQLGetDiagRec to obtain the **SQLSTATE** value. **Table 2 SQLSTATE values** lists the possible **SQLSTATE** values.

Table 5-51 SQLSTATE values

SQLSTATE	Error	Description
HY000	General error.	An error occurs when there is no specific SQLSTATE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQLSTATE	Error	Description
HY001	Memory allocation error.	The driver is unable to allocate memory required to support execution or completion of the function.
HY008	Operation canceled.	SQLCancel is called to terminate the statement execution, but the StatementHandle function is still called.
HY010	Function sequence error.	The function is called prior to sending data to data parameters or columns being executed.
HY013	Memory management error.	The function fails to be called. The error may be caused by low memory conditions.
HYT01	Connection timeout.	The timeout period expired before the application was able to connect to the data source.
IM001	Function not supported by the driver.	The called function is not supported by the StatementHandle driver.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.20 SQLSetConnectAttr

Description

Sets connection attributes.

Prototype

```
SQLRETURN SQLSetConnectAttr(SQLHDBC      ConnectionHandle,
                            SQLINTEGER   Attribute,
                            SQLPOINTER   ValuePtr,
                            SQLINTEGER   StringLength);
```

Parameters

Table 5-52 SQLSetConnectAttr parameters

Keyword	Description
ConnectionHandle	Connection handle.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
Attribute	Attribute to set.
ValuePtr	Pointer to the **Attribute** value. **ValuePtr** depends on the **Attribute** value, and is a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the **ValuePtr** parameter is driver-specific value, it may be a signed integer.
StringLength	If **ValuePtr** points to a string or a binary buffer, **StringLength** is the length of ***ValuePtr**. If **ValuePtr** points to an integer, **StringLength** is ignored.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLSetConnectAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.21 SQLSetEnvAttr

Description

Sets environment attributes.

Prototype

```
SQLRETURN SQLSetEnvAttr(SQLHENV      EnvironmentHandle,
                        SQLINTEGER   Attribute,
                        SQLPOINTER   ValuePtr,
                        SQLINTEGER   StringLength);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-53 SQLSetEnvAttr parameters

Keyword	Description
EnvironmentHandle	Environment handle.
Attribute	Environment attribute to be set. The value must be one of the following: • **SQL_ATTR_ODBC_VERSION**: ODBC version. • **SQL_CONNECTION_POOLING**: connection pool attribute. • **SQL_OUTPUT_NTS**: string type returned by the driver.
ValuePtr	Pointer to the **Attribute** value. **ValuePtr** depends on the **Attribute** value, and can be a 32-bit integer value or a null-terminated string.
StringLength	If **ValuePtr** points to a string or a binary buffer, **StringLength** is the length of ***ValuePtr**. If **ValuePtr** points to an integer, **StringLength** is ignored.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLSetEnvAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, set **HandleType** and **Handle** to **SQL_HANDLE_ENV** and **EnvironmentHandle**, and obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.4.4.22 SQLSetStmtAttr

Description

Sets attributes related to a statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
SQLRETURN SQLSetStmtAttr(SQLHSTMT      StatementHandle,
                         SQLINTEGER    Attribute,
                         SQLPOINTER    ValuePtr,
                         SQLINTEGER    StringLength);
```

Parameters

Table 5-54 SQLSetStmtAttr parameters

Keyword	Description
StatementHandle	Statement handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the **Attribute** value. **ValuePtr** depends on the **Attribute** value, and can be a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the **ValuePtr** parameter is driver-specific value, it may be a signed integer.
StringLength	If **ValuePtr** points to a string or a binary buffer, **StringLength** is the length of ***ValuePtr**. If **ValuePtr** points to an integer, **StringLength** is ignored.

Return Values

- **SQL_SUCCESS** indicates that the call succeeded.
- **SQL_SUCCESS_WITH_INFO** indicates that some warning information is displayed.
- **SQL_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL_INVALID_HANDLE** indicates that invalid handles are called. This value may also be returned by other APIs.

Precautions

If SQLSetStmtAttr returns **SQL_ERROR** or **SQL_SUCCESS_WITH_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL_HANDLE_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

Examples

For details, see **Typical Application Development Examples**.

5.5 Development Based on libpq

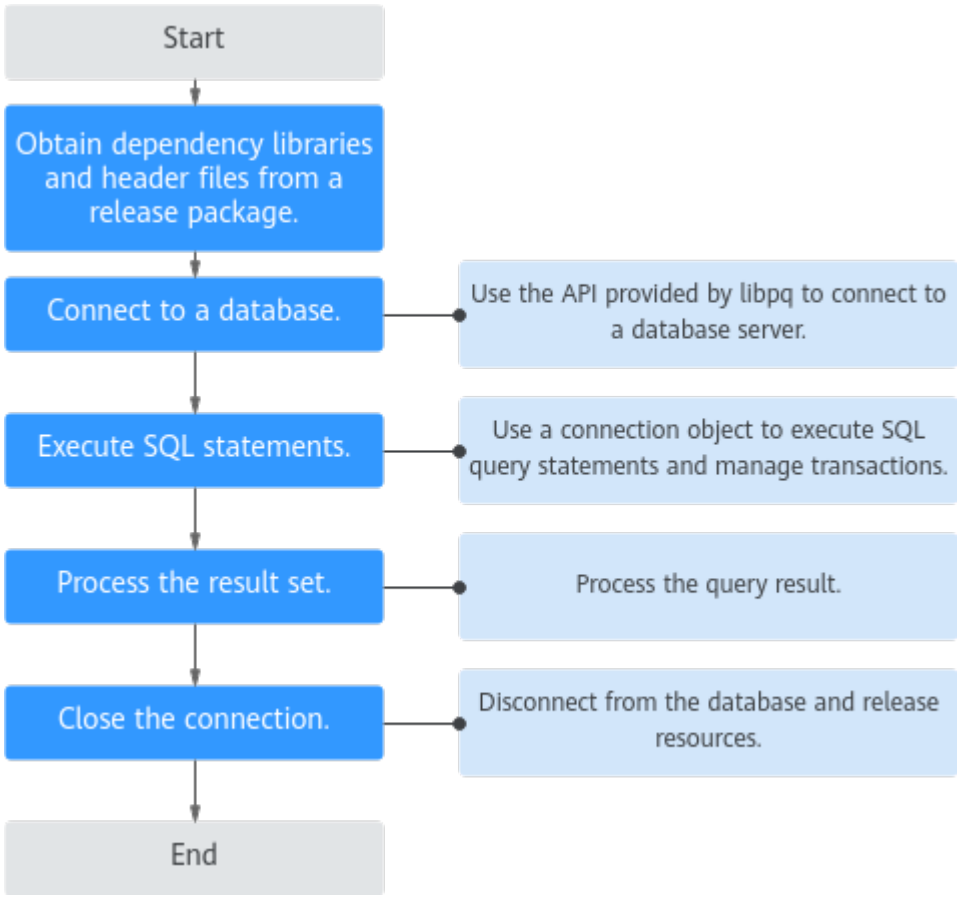
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.1 Development Process

Figure 5-4 shows the libpq-based development process.

The process includes obtaining dependency libraries and header files from a release package, connecting to a database, executing SQL statements, processing the result set, and closing the connection.

Figure 5-4 libpq-based development process



5.5.2 Development Process

5.5.2.1 Obtaining a Driver Package, a Dependent Library, and Header Files

Obtain a dependent library and header files of libpq from **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Libpq.tar.gz** or **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Libpq_Static.tar.gz** in the driver package. The required header file is stored in the **include** folder, and the **lib** folder contains the required libpq library file. Programs that use libpq must include the header file **libpq-fe.h** and must connect to the libpq library.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> In addition to **libpq-fe.h**, the **include** folder contains the header files **postgres_ext.h**, **gs_thread.h**, and **gs_threadlocal.h** by default. These three header files are the dependency files of **libpq-fe.h**.

> **NOTE**
>
> The functions of the Libpq_Static driver package are the same as those of the libpq driver package. You can select a proper **libpq.so** library based on the actual application scenario. Differences are as follows:
>
> - The **libpq.so** file in the libpq driver package dynamically links the OpenSSL libraries (**libssl.so** and **libcrypto.so**).
> - The **libpq.so** file in the Libpq_Static driver package is statically linked to the OpenSSL libraries to resolve the conflict caused by inconsistency between the OpenSSL version provided by the OS and that provided by the OS in some customer scenarios.

5.5.2.2 Connecting to a Database

Connecting to a database is the first step in developing an application using libpq. In this case, you can use functions, such as **PQconnectdb** or **PQsetdbLogin**, to connect to the database server. These functions return a connection object. You need to save the connection object for subsequent database operations.

The following uses the development source program **testlibpq.c** as an example (for details about the complete example, see **Establishing a Database Connection, Executing SQL Statements, and Returning Results**).

```
/*
 * Note: testlibpq.c source program provides basic and common application scenarios of libpq.
 * The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database connections, execute SQL statements, obtain returned results, and clear resources.
 * Header file. For details about user-defined functions, see the complete example.
 */

/* The values of variables such as user and passwd must be read from environment variables or configuration files. Environment variables need to be configured as required. If no environment variable is used, a character string can be directly assigned. */
const char conninfo[1024];
PGconn     *conn;
PGresult   *res;
int        nFields;
int        i,j;
char       *passwd = getenv("EXAMPLE_PASSWD_ENV");
char       *port = getenv("EXAMPLE_PORT_ENV");
char       *host = getenv("EXAMPLE_HOST_ENV");
char       *username = getenv("EXAMPLE_USERNAME_ENV");
char       *dbname = getenv("EXAMPLE_DBNAME_ENV");

/*
 * This value is used when the user provides the value of the conninfo character string in the command line.
 * Otherwise, the environment variables or all other connection parameters
 * use the default values.
 */
if (argc > 1)
    strcpy(conninfo, argv[1]);
else
    sprintf(conninfo,
        "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s password=%s",
        dbname, port, host, username, passwd);

/* Connect to the database. */
conn = PQconnectdb(conninfo);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
/* Check whether the backend connection has been successfully established. */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    exit_nicely(conn);
}
```

5.5.2.3 Running SQL Statements

You can use the function **PQexec** to execute SQL query statements through the connection object. This includes querying data (SELECT), inserting data, updating data, and deleting data. If multiple SQL statements are executed concurrently as a transaction, use the transaction control function. For example, run SQL statements such as BEGIN, COMMIT, and ROLLBACK to control the start, committing, and rollback of a transaction. Handle the errors after executing the SQL query statements.

The following is an example (for details about the complete example, see **Establishing a Database Connection, Executing SQL Statements, and Returning Results**):

```
/*
 * After the connection is successful
 * Since a cursor is used in the test case, a transaction block is required.
 * Put all data in one "select * from pg_database".
 * PQexec() is too simple and is not recommended.
 */

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.2.4 Processing Data in a Result Set

libpq provides functions, such as **PQnfields** and **PQfname**, to help you properly parse and process the results of SELECT queries.

The following is an example (for details about the complete example, see **Establishing a Database Connection, Executing SQL Statements, and Returning Results**):

```
/* Print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

/* Release the memory of the result object to avoid memory leakage. */
PQclear(res);
```

5.5.2.5 Closing a Connection

libpq usually uses the function **PQfinish** to close the connection to the database. If your application has established multiple connections, make sure that each connection is closed correctly.

The following is an example (for details about the complete example, see **Establishing a Database Connection, Executing SQL Statements, and Returning Results**):

```
/* Close the portal. We do not need to check for errors. */
res = PQexec(conn, "CLOSE myportal");
PQclear(res);

/* End the transaction. */
res = PQexec(conn, "END");
PQclear(res);

/* Close the database connection and clean up the database. */
PQfinish(conn);
```

5.5.3 Typical Application Development Examples

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.3.1 Establishing a Database Connection, Executing SQL Statements, and Returning Results

NOTE

To compile the libpq source program by running **gcc**, use the **-I** *directory* option to provide the installation location of header files. (Sometimes the compiler looks for the default directory, so this option can be ignored.) Example:

```
gcc -I (Directory where header files are located) -L (Directory where the libpq library is located) -o testlibpq testlibpq.c -lpq
```

Run the following command:

```
./testlibpq.c
```

If a makefile is used, add the following options to variables *CPPFLAGS*, *LDFLAGS*, and *LIBS*:

```
CPPFLAGS += -I (Directory of header files)
LDFLAGS += -L (Directory of the libpq library)
LIBS += -lpq
Example:
CPPFLAGS += -I$(GAUSSHOME)/include/libpq
LDFLAGS += -L$(GAUSSHOME)/lib
```

```
/*
 * testlibpq.c
 * Note: testlibpq.c source program provides basic and common application scenarios of libpq.
* The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database connections, execute SQL statements, obtain returned results, and clear resources.
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int main(int argc, char **argv)
{
    /* The values of variables such as user and passwd must be read from environment variables or configuration files. Environment variables need to be configured as required. If no environment variable is used, a character string can be directly assigned. */
    const char conninfo[1024];
    PGconn     *conn;
    PGresult   *res;
    int         nFields;
    int         i,j;
    char        *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char        *port = getenv("EXAMPLE_PORT_ENV");
    char        *host = getenv("EXAMPLE_HOST_ENV");
    char        *username = getenv("EXAMPLE_USERNAME_ENV");
    char        *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /*
     * This value is used when the user provides the value of the conninfo character string in the command line.
     * Otherwise, the environment variables or the default values
     * are used for all other connection parameters.
     */
    if (argc > 1)
        strcpy(conninfo, argv[1]);
    else
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application_name=test connect_timeout=5 sslmode=allow user=%s password=%s",
            dbname, port, host, username, passwd);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
/* Connect to the database. */
conn = PQconnectdb(conninfo);

/* Check whether the backend connection has been successfully established. */
if (PQstatus(conn) != CONNECTION_OK)
{
    fprintf(stderr, "Connection to database failed: %s",
            PQerrorMessage(conn));
    exit_nicely(conn);
}

/*
 * After the connection is successful
 * Since a cursor is used in the test case, a transaction block is required.
 * Put all data in one "select * from pg_database".
 * PQexec() is too simple and is not recommended.
 */

/* Start a transaction block. */
res = PQexec(conn, "BEGIN");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "BEGIN command failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/*
 * PQclear PGresult should be executed when it is no longer needed, to avoid memory leakage.
 */
PQclear(res);

/*
 * Fetch data from the pg_database system catalog.
 */
res = PQexec(conn, "DECLARE myportal CURSOR FOR select * from pg_database");
if (PQresultStatus(res) != PGRES_COMMAND_OK)
{
    fprintf(stderr, "DECLARE CURSOR failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}
PQclear(res);

res = PQexec(conn, "FETCH ALL in myportal");
if (PQresultStatus(res) != PGRES_TUPLES_OK)
{
    fprintf(stderr, "FETCH ALL failed: %s", PQerrorMessage(conn));
    PQclear(res);
    exit_nicely(conn);
}

/* Print out the attribute name. */
nFields = PQnfields(res);
for (i = 0; i < nFields; i++)
    printf("%-15s", PQfname(res, i));
printf("\n\n");

/* Print lines. */
for (i = 0; i < PQntuples(res); i++)
{
    for (j = 0; j < nFields; j++)
        printf("%-15s", PQgetvalue(res, i, j));
    printf("\n");
}

/* Release the memory of the result object to avoid memory leakage. */
PQclear(res);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    /* Close the portal. We do not need to check for errors. */
    res = PQexec(conn, "CLOSE myportal");
    PQclear(res);

    /* End the transaction. */
    res = PQexec(conn, "END");
    PQclear(res);

    /* Close the database connection and clean up the database. */
    PQfinish(conn);

    return 0;
}
```

In the following command output, **user_name** indicates the username of a database administrator, which varies according to the actual environment:

```

tuple 0: got
 i = (4 bytes) 2
 t = (8 bytes) 'ho there'
```

5.5.4 libpq Interface Reference

NOTICE

Calls to the PQfn interface using libpq is not supported yet.

5.5.4.1 Database Connection Control Functions

Database connection control functions control the connections to GaussDB servers. An application can connect to multiple servers at a time. For example, a client connects to multiple databases. Each connection is represented by a PGconn object, which is obtained from the function PQconnectdb, PQconnectdbParams, or PQsetdbLogin. You can also obtain a connection object by using the PQconnectStart API together with the asynchronous PQconnectPoll polling method. Note that these functions will always return a non-null object pointer, unless memory allocation fails. The API for establishing a connection is stored in the PGconn object. The PQstatus function can be called to check the return value for a successful connection. The PGconn object stores the SSL context in a local thread. Therefore, the PGconn released thread must be the same as the allocated thread.

5.5.4.1.1 PQconnectdbParams

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQconnectdbParams(const char* const* keywords, const char* const* values, int expand_dbname);
```

Parameters

Table 5-55 PQconnectdbParams parameters

Keyword	Description
keywords	An array of strings, each of which is a keyword.
values	Value assigned to each keyword.
expand_dbname	When **expand_dbname** is non-zero, the **dbname** keyword value can be recognized as a connection string. Only **dbname** that first appears is treated in this way, and any subsequent **dbname** value is treated as a database name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Values

PGconn * points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

This function establishes a new database connection using the parameters taken from two NULL-terminated arrays. Unlike PQsetdbLogin, the parameter set can be extended without changing the function signature. Therefore, use of this function (or its non-blocking analogs PQconnectStartParams and PQconnectPoll) is preferred for new application programming.

5.5.4.1.2 PQconnectdb

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQconnectdb(const char* conninfo);
```

Parameters

Table 5-56 PQconnectdb parameter

Keyword	Description
conninfo	Connection string. For details about the columns in the string, see **Connection Parameters**.

Return Values

PGconn * points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

- This function opens a new connection with the parameters specified by **conninfo**.
- The input parameter can be empty, indicating that all default parameters can be used. It can contain one or more values separated by spaces or contain a URL.

Examples

For details, see **Typical Application Development Examples**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.4.1.3 PQbackendPID

Supplementary Explanation

In GaussDB, the return value of the PQbackendPID function indicates the slot ID of the background thread, not the backend PID of the background thread.

Due to the preceding difference, you are advised not to execute this function by following the PostgreSQL semantics.

To obtain the backend PID of the connection, you can use the pg_backend_pid system function. In addition, other driver APIs which depend on libpq and have the same names as PostgreSQL's APIs (such as the get_backend_pid function of the Python connection driver psycopg2) also comply with the preceding rule.

5.5.4.1.4 PQconninfoParse

Description

Returns parsed connection options based on the connection.

Prototype

```
PQconninfoOption* PQconninfoParse(const char* conninfo, char** errmsg);
```

Parameters

Table 5-57

Keyword	Description
conninfo	Passed string. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URL.
errmsg	Error information.

Return Values

PQconninfoOption pointers

5.5.4.1.5 PQconnectStart

Description

Establishes a non-blocking connection with the database server.

Prototype

```
PGconn* PQconnectStart(const char* conninfo);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter

Table 5-58

Keyword	Description
conninfo	String of connection information. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URL.

Return Values

PGconn pointers

5.5.4.1.6 PQerrorMessage

Description

Returns error information on a connection.

Prototype

```
char* PQerrorMessage(const PGconn* conn);
```

Parameter

Table 5-59

Keyword	Description
conn	Connection handle.

Return Values

char pointers

5.5.4.1.7 PQsetdbLogin

Description

Establishes a new connection with the database server.

Prototype

```
PGconn* PQsetdbLogin(const char* pghost, const char* pgport, const char* pgoptions, const char* pgtty,
    const char* dbName, const char* login, const char* pwd);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-60 PQsetdbLogin parameters

Keyword	Description
pghost	Name of the host to be connected. For details, see the **host** column described in **Connection Parameters**.
pgport	Port number of the host server. For details, see the **port** column described in **Connection Parameters**.
pgoptions	Command-line options to be sent to the server during running. For details, see the **options** column described in **Connection Parameters**.
pgtty	Ignored. (This option declares the output direction of server logs.)
dbName	Name of the database to be connected. For details, see the **dbname** column described in **Connection Parameters**.
login	Username for connection. For details, see the **user** column described in **Connection Parameters**.
pwd	Password used for authentication during connection. For details, see the **password** column described in **Connection Parameters**.

Return Value

PGconn * points to the object pointer that contains a connection. The memory is allocated by the function internally.

Precautions

- This function is the predecessor of PQconnectdb with a fixed set of parameters. When an undefined parameter is called, its default value is used. The default value can be **NULL** or an empty string.
- If the **dbName** value contains an equal sign (=) or a valid prefix in the connection URL, it is taken as a conninfo string and passed to PQconnectdb, and the other parameters are consistent with those of PQconnectdbParams.

5.5.4.1.8 PQfinish

Description

Closes the connection to the server and releases the memory used by the PGconn object.

Prototype

```
void PQfinish(PGconn* conn);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter

Table 5-61 PQfinish parameter

Keyword	Description
conn	Object pointer that contains the connection information.

Precautions

If the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to release the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.

Examples

For details, see **Typical Application Development Examples**.

5.5.4.1.9 PQreset

Function

Resets the communication port to the server.

Prototype

```
void PQreset(PGconn* conn);
```

Parameter

Table 5-62 PQreset parameter

Keyword	Parameter Description
conn	The object pointer that contains the connection information.

Precautions

This function will close the connection to the server and attempt to establish a new connection to the same server by using all the parameters previously used. This function is applicable to fault recovery after a connection exception occurs.

5.5.4.1.10 PQstatus

Description

Returns the connection status.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
ConnStatusType PQstatus(const PGconn* conn);
```

Parameters

Table 5-63 PQ status parameter

Keyword	Description
conn	Object pointer that contains the connection information.

Return Values

ConnStatusType indicates the connection status. The enumerated values are as follows:

```
CONNECTION_STARTED
Waiting for the connection to be established.

CONNECTION_MADE
Connection succeeded; waiting to send.

CONNECTION_AWAITING_RESPONSE
Waiting for a response from the server.

CONNECTION_AUTH_OK
Authentication received; waiting for backend startup to complete.

CONNECTION_SSL_STARTUP
Negotiating SSL encryption.

CONNECTION_SETENV
Negotiating environment-driven parameter settings.

CONNECTION_OK
Normal connection.

CONNECTION_BAD
Failed connection.
```

Precautions

The connection status can be one of the preceding values. After the asynchronous connection procedure is complete, only two of them, **CONNECTION_OK** and **CONNECTION_BAD**, can return. **CONNECTION_OK** indicates that the connection to the database is normal. **CONNECTION_BAD** indicates that the connection to the database fails. Generally, the normal state remains until PQfinish is called. However, a communication failure may cause the connection status to become to **CONNECTION_BAD** before the connection procedure is complete. In this case, the application can attempt to call PQreset to restore the communication.

Examples

For details, see **Typical Application Development Examples**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.4.2 Database Statement Execution Functions

After the connection to the database server is successfully established, you can use the functions described in this section to execute SQL queries and commands.

5.5.4.2.1 PQexec

Description

Commits a command to the server and waits for the result.

Prototype

```
PGresult* PQexec(PGconn* conn, const char* query);
```

Parameters

Table 5-64 PQexec parameters

Keyword	Description
conn	Object pointer that contains the connection information.
query	Query string to be executed.

Return Values

PGresult indicates the object pointer that contains the query result.

Precautions

The PQresultStatus function should be called to check the return value for any errors (including the value of a null pointer, in which **PGRES_FATAL_ERROR** will be returned). The PQerrorMessage function can be called to obtain more information about such errors.

NOTICE

The command string can contain multiple SQL commands separated by semicolons (;). Multiple queries sent in a PQexec call are processed in one transaction, unless there are specific BEGIN/COMMIT commands in the query string to divide the string into multiple transactions. Note that the returned PGresult structure describes only the result of the last command executed from the string. If a command fails, the string processing stops and the returned PGresult describes the error condition.

Examples

For details, see **Typical Application Development Examples**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.4.2.2 PQprepare

Description

Commits a request to create a prepared statement with given parameters and waits for completion.

Prototype

```
PGresult* PQprepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

Parameters

Table 5-65 PQprepare parameters

Keyword	Description
conn	Object pointer that contains the connection information.
stmtName	Name of a prepared statement to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Values

PGresult indicates the object pointer that contains the query result.

Precautions

- PQprepare creates a prepared statement for later execution with PQexecPrepared. This function allows commands to be repeatedly executed, without being parsed and planned each time they are executed. PQprepare is supported only in protocol 3.0 or later. It will fail when protocol 2.0 is used.
- This function creates a prepared statement named **stmtName** from the query string, which must contain an SQL command. **stmtName** can be **""** to create an unnamed statement. In this case, any pre-existing unnamed statement will be automatically replaced. Otherwise, this is an error if the statement name has been defined in the current session. If any parameters are used, they are referred to in the query as $1, $2, and so on. **nParams** is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be **NULL** when **nParams** is **0**.) paramTypes[] specifies the data types to be assigned to the parameter symbols by OID. If **paramTypes** is **NULL**, or any element in the array is **0**, the server assigns a data type to the parameter symbol in the same way as it does for an untyped literal string. In addition, the query can use parameter symbols whose numbers are greater than **nParams**. Data types of these symbols will also be inferred.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

You can also execute the **SQLPREPARE** statement to create a prepared statement that is used with PQexecPrepared. Although there is no libpq function of deleting a prepared statement, the SQL DEALLOCATE statement can be used for this purpose.

Examples

For details, see **Typical Application Development Examples**.

5.5.4.2.3 PQclear

Description

Releases the storage associated with PGresult. Any query result should be released by PQclear when it is no longer needed.

Prototype

```
void PQclear(PGresult* res);
```

Parameter

Table 5-66 PQclear parameter

Keyword	Description
res	Object pointer that contains the query result.

Precautions

PGresult is not automatically released. That is, it does not disappear when a new query is committed or even if you close the connection. To delete it, you must call PQclear. Otherwise, memory leakage occurs.

Examples

For details, see **Typical Application Development Examples**.

5.5.4.2.4 PQfnumberEx

Description

Returns the column number associated with the given column name. Columns are numbered starting at 0.

Prototype

```
int PQfnumberEx(const PGresult* res, const char* field_name, bool case_sensitive);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Table 5-67 PQfnumberEx parameters

Keyword	Description
res	Handle to the operation result.
field_name	Column name.
case_sensitive	Specifies whether the column name is case sensitive.

Return Value

An integer of the int type.

5.5.4.2.5 PQexecParams

Description

Runs a command to bind parameters.

Prototype

```
PGresult* PQexecParams(PGconn* conn,
                       const char* command,
                       int nParams,
                       const Oid* paramTypes,
                       const char* const* paramValues,
                       const int* paramLengths,
                       const int* paramFormats,
                       int resultFormat);
```

Parameters

Table 5-68 PQexecParams parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
paramTypes	Types of parameters to be bound.
paramValues	Values of parameters to be bound.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramLengths	Parameter length. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

Return Values

PGresult pointers.

5.5.4.2.6 PQexecParamsBatch

Description

Runs a command to bind batches of parameters.

Prototype

```
PGresult* PQexecParamsBatch(PGconn* conn,
                            const char* command,
                            int nParams,
                            int nBatch,
                            const Oid* paramTypes,
                            const char* const* paramValues,
                            const int* paramLengths,
                            const int* paramFormats,
                            int resultFormat);
```

Parameters

Table 5-69 PQexecParamsBatch parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
nBatch	Number of batch operations.
paramTypes	Types of parameters to be bound.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramValues	Values of parameters to be bound.
paramLengths	Parameter length. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

Return Values

PGresult pointers.

5.5.4.2.7 PQexecPrepared

Description

Sends a request to execute a prepared statement with given parameters and waits for the result.

Prototype

```
PGresult* PQexecPrepared(PGconn* conn,
                         const char* stmtName,
                         int nParams,
                         const char* const* paramValues,
                         const int* paramLengths,
                         const int* paramFormats,
                         int resultFormat);
```

Parameters

Table 5-70 PQexecPrepared parameters

Keyword	Description
conn	Connection handle.
stmtName	*stmt* name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.
nParams	Parameter quantity.
paramValues	Actual values of parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramLengths	Actual data lengths of parameters. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

Return Values

PGresult pointers.

5.5.4.2.8 PQexecPreparedBatch

Description

Sends a request to execute a prepared statement with batches of given parameters and waits for the result.

Prototype

```
PGresult* PQexecPreparedBatch(PGconn* conn,
                              const char* stmtName,
                              int nParams,
                              int nBatchCount,
                              const char* const* paramValues,
                              const int* paramLengths,
                              const int* paramFormats,
                              int resultFormat);
```

Parameters

Table 5-71 PQexecPreparedBatch parameters

Keyword	Description
conn	Connection handle.
stmtName	*stmt* name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.
nParams	Parameter quantity.
nBatchCount	Number of batches.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramValues	Actual values of parameters.
paramLengths	Actual data lengths of parameters. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

Return Values

PGresult pointers.

5.5.4.3 Asynchronous Command Processing Functions

The PQexec function is adequate for committing commands in common, synchronous applications. However, it has several defects, which may be important to some users:

- PQexec waits for the end of the command, but the application may have other work to do (for example, maintaining a user interface). In this case, PQexec would not want to be blocked to wait for the response.
- As the client application is suspended while waiting for the result, it is difficult for the application to determine whether to cancel the ongoing command.
- PQexec can return only one PGresult structure. If the committed command string contains multiple SQL commands, all the PGresult structures except the last PGresult are discarded by PQexec.
- PQexec always collects the entire result of the command and caches it in a PGresult. Although this mode simplifies the error handling logic for applications, it is impractical for results that contain multiple rows.

Applications that do not want to be restricted by these limitations can use the following functions that PQexec is built from: PQsendQuery and PQgetResult. The functions PQsendQueryParams, PQsendPrepare, and PQsendQueryPrepared can also be used with PQgetResult.

5.5.4.3.1 PQsendQuery

Description

Commits a command to the server without waiting for the result. If the query is successful, **1** is returned. Otherwise, **0** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
int PQsendQuery(PGconn * conn, const char * query);
```

Parameters

Table 5-72 PQsendQuery parameters

Keyword	Description
conn	Object pointer that contains the connection information.
query	Query string to be executed.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

After PQsendQuery is successfully called, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult returns a null pointer, indicating that the command execution is complete.

5.5.4.3.2 PQsendQueryParams

Description

Commits a command with separated parameters to the server without waiting for the result.

Prototype

```
int PQsendQueryParams(PGconn* conn, const char* command, int nParams, const Oid* paramTypes,
    const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

Parameters

Table 5-73 PQsendQueryParams parameters

Keyword	Description
conn	Object pointer that contains the connection information.
command	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Parameter type.
paramValues	Parameter value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramLengths	Parameter length. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

Return Values

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

This function is equivalent to PQsendQuery. The only difference is that query parameters can be specified separately from the query string. The parameter processing of this function is similar to that of PQexecParams. It cannot work on connections using protocol v2.0, and it allows only one command to appear in the query string.

5.5.4.3.3 PQsendPrepare

Description

Sends a request to create a prepared statement with given parameters, without waiting for completion.

Prototype

```
int PQsendPrepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

Parameters

Table 5-74 PQsendPrepare parameters

Keyword	Description
conn	Object pointer that contains the connection information.
stmtName	Name of a prepared statement to be executed.
query	Query string to be executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

Return Values

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

PQsendPrepare is an asynchronous version of PQprepare. If it can dispatch a request, **1** is returned. Otherwise, **0** is returned. After a successful calling of PQsendPrepare, call PQgetResult to check whether the server successfully created the prepared statement. PQsendPrepare parameters are handled in the same way as PQprepare parameters. Like PQprepare, PQsendPrepare cannot work on connections using protocol v2.0.

Examples

For details, see **Typical Application Development Examples**.

5.5.4.3.4 PQsendQueryPrepared

Description

Sends a request to execute a prepared statement with given parameters, without waiting for the result.

Prototype

```
int PQsendQueryPrepared(PGconn* conn, const char* stmtName, int nParams, const char* const*
paramValues,
    const int* paramLengths, const int* paramFormats, int resultFormat);
```

Parameters

Table 5-75 PQsendQueryPrepared parameters

Keyword	Description
conn	Object pointer that contains the connection information.
stmtName	Name of a prepared statement to be executed.
nParams	Parameter quantity.
paramValues	Parameter value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
paramLengths	Parameter length. **NOTICE** In the following cases, the parameter length is forcibly set to the corresponding value of **paramLengths**: • The parameter is in binary format. • The parameter is in text format and the value of **force_no_truncation** is **1**. In these cases, **paramLengths** cannot be empty, and the caller must ensure the correctness of the parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

Return Values

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

Precautions

This function is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of providing a query string. The parameters of this function are processed in the same way as PQexecPrepared. Like PQexecPrepared, it cannot work on connections using protocol v2.0.

5.5.4.3.5 PQflush

Description

Tries to flush any queued output data to the server.

Prototype

```
int PQflush(PGconn * conn);
```

Parameter

Table 5-76 PQflush parameter

Keyword	Description
conn	Object pointer that contains the connection information.

Return Value

int indicates the operation result. If the operation is successful (or the send queue is empty), **0** is returned. If the operation fails, **-1** is returned. If all data in the send

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

queue fails to be sent, **1** is returned. (This case occurs only when the connection is non-blocking.) The failure cause is stored in **conn->errorMessage**.

Precautions

Call PQflush after sending any command or data over a non-blocking connection. If **1** is returned, wait for the socket to become read- or write-ready. If the socket becomes write-ready, call PQflush again. If the socket becomes read-ready, call PQconsumeInput and then call PQflush again. Repeat the operation until the value **0** is returned for PQflush. It is necessary to check read-ready and use PQconsumeInput to exhaust input because the server may prevent attempts to send data (such as NOTICE messages) to the client and does not read the client's data until the client reads its data. Once PQflush returns **0**, wait for the socket to be read-ready and then read the response as described above.

5.5.4.4 Functions for Canceling Query Processing

A client application can use the functions described in this section to cancel a command that is still being processed by the server.

5.5.4.4.1 PQgetCancel

Description

Creates a data structure that contains the information required to cancel a command issued through a specific database connection.

Prototype

```
PGcancel* PQgetCancel(PGconn* conn);
```

Parameter

Table 5-77 PQgetCancel parameter

Keyword	Description
conn	Object pointer that contains the connection information.

Return Value

PGcancel points to the object pointer that contains the cancel information.

Precautions

PQgetCancel creates a PGcancel object for a given PGconn connection object. If the given connection object (**conn**) is NULL or an invalid connection, it will return NULL. The PGcancel object is an opaque structure that cannot be directly accessed by applications. It can be transferred only to PQcancel or PQfreeCancel.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.4.4.2 PQfreeCancel

Function

Releases the data structure created by PQgetCancel.

Prototype

```
void PQfreeCancel(PGcancel * cancel);
```

Parameter

Table 5-78 PQfreeCancel parameter

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.

Precautions

PQfreeCancel releases a data object previously created by PQgetCancel.

5.5.4.4.3 PQcancel

Function

Requests the server to abandon processing of the current command.

Prototype

```
int PQcancel(PGcancel* cancel, char* errbuf, int errbufsize);
```

Parameter

Table 5-79 PQcancel parameters

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.
errbuf	Buffer for storing error information.
errbufsize	Size of the buffer for storing error information.

Return Value

int indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **errbuf**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Precautions

- Successful sending does not guarantee that the request will have any effect. If the cancellation is valid, the current command is terminated early and an error is returned. If the cancellation fails (for example, because the server has processed the command), no result is returned.
- If **errbuf** is a local variable in a signal handler, you can safely call PQcancel from the signal handler. For PQcancel, the PGcancel object is read-only, so it can also be called from a thread that is separate from the thread that is operating the PGconn object.

5.5.4.5 Functions for Processing Database Result

5.5.4.5.1 PQgetvalue

Description

Returns a single threshold for a row of PGresult. Row and column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

Prototype

```
char* PQgetvalue(const PGresult* res, int tup_num, int field_num);
```

Parameters

Table 5-80 PQgetvalue parameters

Keyword	Description
res	Handle to the operation result.
tup_num	Number of rows.
field_num	Number of columns.

Return Values

For data in text format, PQgetvalue returns a null-terminated string representation of the threshold.

For binary data, the value is a binary representation determined by the typsend and typreceive functions of the data type.

If the threshold is empty, an empty string is returned.

5.5.4.5.2 PQnfields

Description

Returns the number of columns (fields) in each row of the query result.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
int PQnfields(const PGresult* res);
```

Parameters

Table 5-81 PQnfields parameters

Keyword	Description
res	Handle to the operation result.

Return Values

Value of the int type

5.5.4.5.3 PQntuples

Description

Returns the number of rows (tuples) in the query result.

Prototype

```
int PQntuples(const PGresult* res);
```

Parameters

Table 5-82 PQntuples parameters

Keyword	Description
res	Handle to the operation result.

NOTICE

PQntuples returns an integer result. An overflow may occur if the return value is out of the value range allowed in a 32-bit OS.

Return Values

Value of the int type

Examples

For details, see **Typical Application Development Examples**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.5.4.5.4 PQfname

Description

Returns the column name associated with the given column number. Column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

Prototype

```
char* PQfname(const PGresult* res, int field_num);
```

Parameters

Table 5-83 PQfname parameters

Keyword	Description
res	Handle to the operation result.
field_num	Number of columns.

Return Values

char pointers.

5.5.4.5.5 PQresultStatus

Description

Returns the result status of a command.

Prototype

```
ExecStatusType PQresultStatus(const PGresult* res);
```

Parameters

Table 5-84 PQresultStatus parameter

Keyword	Description
res	Object pointer that contains the query result.

Return Values

PQresultStatus indicates the command execution status. The enumerated values are as follows:

```
PQresultStatus can return one of the following values:
PGRES_EMPTY_QUERY
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The string sent to the server was empty.

PGRES_COMMAND_OK
A command that does not return data was successfully executed.

PGRES_TUPLES_OK
A query (such as SELECT or SHOW) that returns data was successfully executed.

PGRES_COPY_OUT
The data copied from the server begins to transmit.

PGRES_COPY_IN
The data copied to the server begins to transmit.

PGRES_BAD_RESPONSE
The response from the server cannot be understood.

PGRES_NONFATAL_ERROR
A non-fatal error (notification or warning) occurred.

PGRES_FATAL_ERROR
A fatal error occurred.

PGRES_COPY_BOTH
The data copied to and from the server begins to transmit. This state occurs only in streaming replication.

PGRES_SINGLE_TUPLE
PGresult contains a result tuple from the current command. This state occurs in a single-row query.

Precautions

- Note that the SELECT command that happens to retrieve zero rows still returns **PGRES_TUPLES_OK**. **PGRES_COMMAND_OK** is used for commands that can never return rows (such as INSERT or UPDATE, without return clauses). The result status **PGRES_EMPTY_QUERY** might indicate a bug in the client software.
- The result status **PGRES_NONFATAL_ERROR** will never be returned directly by PQexec or other query execution functions. Instead, such results will be passed to the notice processor.

Examples

For details, see **Typical Application Development Examples**.

5.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is the encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and adapts to GaussDB data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-85 Platforms supported by psycopg

OS	Platform	Python Version
EulerOS V2.0SP5	• Arm64 • x86_64	3.8.5
SUSE 12.5	• x86_64	3.8.5
EulerOS V2.0SP9	• Arm64 • x86_64	3.7.4
EulerOS V2.0SP10, Kylin V10, and UnionTech20	• Arm64 • x86_64	3.7.9
EulerOS V2.0SP11	• Arm64 • x86_64	3.9.11
Huawei Cloud EulerOS 2.0	• Arm64 • x86_64	3.9.9

NOTICE

During psycopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL_1_1_1f' not found" is displayed, use the environment variable *LD_LIBRARY_PATH* to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

For example, when the application software **client.py** that calls psycopg2 is executed, the environment variable is explicitly assigned to the application software.

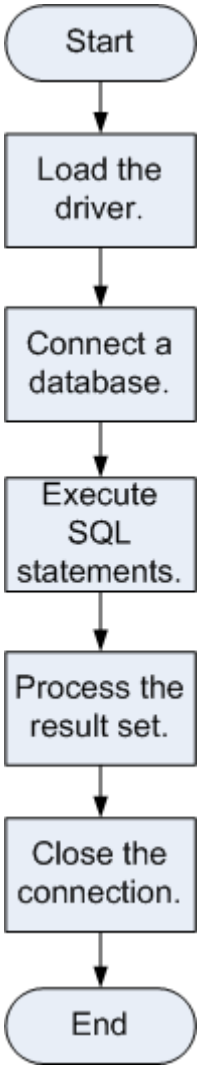
```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/pyscopg2/lib** indicates the directory where the OpenSSL library on which the GaussDB depends is located. Change it as required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.6.1 Development Process

Figure 5-5 Application development process based on psycopg2



5.6.2 Psycopg Package

Connecting to a Database

Step 1 Prepare related drivers and dependent libraries. Obtain the package **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Python.tar.gz** from the driver package.

After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file.
- **lib**: **lib** library file.

Step 2 Load the driver.

- Before using the driver, perform the following operations:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

a. Decompress the driver package of the corresponding version.
```
tar zxvf xxxx-Python.tar.gz
```
b. Copy **psycopg2** to the **site-packages** folder in the Python installation directory as the **root** user.
```
su root
cp psycopg2 $(python3 -c 'import site; print(site.getsitepackages()[0])') -r
```
c. Change the **psycopg2** directory permission to **755**.
```
chmod 755 $(python3 -c 'import site; print(site.getsitepackages()[0])')/psycopg2 -R
```
d. Add the **psycopg2** directory to the environment variable *$PYTHONPATH* and validate it.
```
export PYTHONPATH=$(python3 -c 'import site; print(site.getsitepackages()[0])'):$PYTHONPATH
```
e. For non-database users, configure the **lib** directory in *LD_LIBRARY_PATH* after decompression.
```
export LD_LIBRARY_PATH=path/to/lib:$LD_LIBRARY_PATH
```

- Load a database driver before creating a database connection.
```
import  psycopg2
```

Step 3 Connect to a database.

Connect to the database in non-SSL mode.

1. Use the psycopg2.connect function to obtain the connection object.
2. Use the connection object to create a cursor object.

Connect to the database in SSL mode.

When you use psycopy2 to connect to the GaussDB server, you can enable SSL to encrypt the communication between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the .ini file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.
   a. **sslmode**: For details about the options, see **Table 5-86**.
   b. **sslcert**: client certificate path.
   c. **sslkey**: client key path.
   d. **sslrootcert**: root certificate path.
3. Use the psycopg2.connect function to obtain the connection object.
4. Use the connection object to create a cursor object.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **CAUTION**
>
> To use SSL to connect to the database, ensure that the Python interpreter is compiled in the mode of generating a dynamic link library (.so) file. You can perform the following steps to check the connection mode of the Python interpreter:
>
> 1. Run the **import ssl** command in the Python interpreter to import SSL.
> 2. Run the **ps ux** command to query the PID of the Python interpreter. Assume that the PID is ******.
> 3. In the shell CLI, run the **pmap -p** *******| **grep ssl** command and check whether the command output contains the path related to **libssl.so**. If the command output contains the path, the Python interpreter is compiled in dynamic link mode.

Table 5-86 sslmode options

sslmode	Enable SSL Encryption	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required, but only data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required, and the validity of the server CA must be verified.
verify-full	Yes	The SSL connection must be enabled, which is not supported by GaussDB currently.

Step 4 Run SQL statements.

1. Construct an operation statement and use %s as a placeholder. During execution, psycopg2 will replace the placeholder with the parameter value. You can add the RETURNING clause to obtain the automatically generated column values.
2. Use the cursor.execute method to execute one row of SQL statement, and use the cursor.executemany method to execute multiple rows of SQL statements.

Step 5 Process the result set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. cursor.fetchone(): fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. cursor.fetchall(): fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

NOTE

For database-specific data types, such as tinyint, the corresponding columns in the query result are character strings.

Step 6 Disable the connection.

After you complete required data operations in a database, close the database connection. Call the close method such as connection.close() to close the connection.

CAUTION

This method closes the database connection and does not automatically call commit(). If you close the database connection without calling commit(), changes will be lost.

----End

5.6.3 Examples: Common Operations

```
import psycopg2
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

# Create a connection object.
conn=psycopg2.connect(database="database", user=user, password=password, host="localhost", port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="database", user=user, password=password, host="localhost", port=port,
        sslmode="verify-ca", sslcert="client.crt",sslkey="client.key",sslrootcert="cacert.pem")

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Insert data in batches.
stus = ((4,'John','M'),(5,'Alice','F'),(6,'Peter','M'))
cur.executemany("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",stus)

# Obtain the result.
cur.execute('SELECT * FROM student')
results=cur.fetchall()
print (results)

# Perform a commit.
conn.commit()
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
# Insert a data record.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(7,'Lucy','F'))

# Perform a rollback.
conn.rollback()

# Close the connection.
cur.close()
conn.close()

Common connection modes of psycopg2
1. conn = psycopg2.connect(dbname="dbname", user=user, password=password, host="localhost",
port=port)
2. conn = psycopg2.connect(f"dbname=dbname user={user} password={password}  host=localhost
port=port")
3. Using logs
import logging
import psycopg2
from psycopg2.extras import LoggingConnection
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": user,
    "password": password,
    "host": "localhost",
    "database": "dbname",
    "port": port
}

# LoggingConnection records all SQL statements by default. You can filter unnecessary or sensitive SQL
statements. The following is an example of filtering password-related SQL statements.
class SelfLoggingConnection(LoggingConnection):

    def filter(self, msg, curs):
        if db_settings['password'] in msg.decode():
            return b'queries containing the password will not be recorded'
        return msg

conn = psycopg2.connect(connection_factory=SelfLoggingConnection, **db_settings)
conn.initialize(logger)
```

CAUTION

- By default, **LoggingConnection** records all SQL information and does not anonymize sensitive information. You can use the filter function to define the output SQL content.
- The log function is an additional function provided by psycopg2 for developers to explicitly debug full SQL statements. By default, the log function is not used. This function prints SQL statements before pyscopg2 executes SQL statements. However, the SQL statements can be printed only when the log level is **DEBUG**. This function is not a default function. It is used only when there are special requirements. You are advised not to use this function unless there are special requirements. For details, visit https://www.psycopg.org/docs/extras.html?highlight=loggingconnection.

5.6.4 Psycopg API Reference

Psycopg APIs are a set of methods provided for users. This section describes some common APIs.

5.6.4.1 psycopg2.connect()

Description

Creates a database session and returns a new connection object.

Prototype

```
import os
conn=psycopg2.connect(dbname="test",user=os.getenv('user'),password=os.getenv('password'),host="127.0.0.1",port="5432")
```

Parameters

Table 5-87 psycopg2.connect parameters

Keyword	Description
dbname	Database name.
user	Username.
password	Password.
host	IP address of the database. You can specify multiple IP addresses and separate them with commas (,). By default, the UDS is used.
port	Connection port number. The default value is **5432**. If the host has multiple IP addresses and the port numbers are the same, specify one port number. Otherwise, the port numbers must correspond to the IP addresses one by one and are separated by commas (,).
sslmode	SSL mode, which is used for SSL connection.
sslcert	Path of the client certificate, which is used for SSL connection.
sslkey	Path of the client key, which is used for SSL connection.
sslrootcert	Path of the root certificate, which is used for SSL connection.
hostaddr	IP address of the database.
connect_timeout	Client connection timeout interval.
client_encoding	Encoding format of the client.
application_name	Value of **application_name**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
fallback_application_name	Rollback value of **application_name**.
keepalives	Determines whether to enable the TCP connection on the client. The default value is **1**, indicating that the TCP connection is enabled. The value **0** indicates that the TCP connection is disabled. If the UDS connection is used, ignore this parameter.
options	Specifies the command line options sent to the server when the connection starts.
keepalives_idle	Describes inactivity before keepalive messages are sent to the server. If **keepalive** is disabled, ignore this parameter.
keepalives_interval	Determines whether keepalive messages that are not confirmed by the server need to be resent. If **keepalive** is disabled, ignore this parameter.
keepalives_count	Specifies the number of TCP connections that may be lost before the client is disconnected from the server.
replication	Ensures that the connection uses the replication protocol instead of the common protocol.
requiressl	Supports the SSL mode.
sslcompression	Specifies the SSL compression. If this parameter is set to **1**, the data sent through the SSL connection is compressed. If this parameter is set to **0**, the compression is disabled. If no SSL connection is established, ignore this parameter.
sslcrl	Specifies the path of the certificate revocation list (CRL), which is used to check whether the SSL server certificate is available.
requirepeer	Specifies the OS username of the server.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Keyword	Description
target_session_attrs	Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting **target_session_attrs** are as follows: • **any**: All types of hosts can be connected. • **read-write**: The connection is set up only when the connected host is readable and writable. • **read-only**: Only readable hosts can be connected. • **primary** (default value): Only the primary node in the primary/standby system can be connected. • **standby**: Only the standby node in the primary/standby system can be connected. • **prefer-standby**: The system first attempts to find a standby node for connection. If all hosts in the **hosts** list fail to be connected, try the **any** mode.
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the **TCP_USER_TIMEOUT** socket option. The value **0** indicates that the default value is used. Ignore this parameter for UDS connections.
rw_timeout	Sets the read and write timeout interval of the client connection. When the timeout is triggered on the libpq and the connection is closed, the running services delivered by the libpq to the database are forcibly terminated. This capability is controlled by the GUC parameter **check_disconnect_query**. If this parameter is set to **on**, the capability is supported. If this parameter is set to **off**, the capability is not supported.

Return Value

Connection object (for connecting to a database instance)

Examples

For details, see **Examples: Common Operations**.

5.6.4.2 connection.cursor()

Function

This method returns a new cursor object.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
cursor(name=None, cursor_factory=None, scrollable=None, withhold=False)
```

Parameter

Table 5-88 connection.cursor parameters

Keyword	Description
name	Cursor name. The default value is **None**.
cursor_factory	Creates a non-standard cursor. The default value is **None**.
scrollable	Sets the SCROLL option. The default value is **None**.
withhold	Sets the HOLD option. The default value is **False**.

Return Value

Cursor object (used for cusors that are programmed using Python in the entire database)

Example

For details, see **Examples: Common Operations**.

5.6.4.3 cursor.execute(query,vars_list)

Function

This method executes the parameterized SQL statements (that is, placeholders instead of SQL literals). The psycopg2 module supports placeholders marked with **%s**.

Prototype

```
curosr.execute(query,vars_list)
```

Parameters

Table 5-89 curosr.execute parameters

Keyword	Description
query	SQL statement to be executed.
vars_list	Variable list, which matches the **%s** placeholder in the query.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return Value

None

Example

For details, see **Examples: Common Operations**.

5.6.4.4 cursor.executemany(query,vars_list)

Description

This method executes an SQL command against all parameter sequences or mappings found in the sequence SQL.

Prototype

```
cursor.executemany(query,vars_list)
```

Parameter

Table 5-90 cursor.executemany

Keyword	Description
query	SQL statement that you want to execute.
vars_list	Variable list, which matches the **%s** placeholder in the query.

Return Value

None

Example

For details, see **Examples: Common Operations**.

5.6.4.5 connection.commit()

Description

This method commits the currently pending transaction to the database.

CAUTION

By default, Psycopg opens a transaction before executing the first command. If **commit()** is not called, the effect of any data operation will be lost.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Prototype

```
connection.commit()
```

Parameters

None

Return Values

None

Examples

For details, see **Examples: Common Operations**.

5.6.4.6 connection.rollback()

Function

This method rolls back the current pending transaction.

> **CAUTION**
>
> If you close the connection using **close()** but do not commit the change using **commit()**, an implicit rollback will be performed.

Prototype

```
connection.rollback()
```

Parameter

None

Return Value

None

Example

For details, see **Examples: Common Operations**.

5.6.4.7 cursor.fetchone()

Function

This method extracts the next row of the query result set and returns a tuple.

Prototype

```
cursor.fetchone()
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter

None

Return Value

A single tuple is the first result in the result set. If no more data is available, **None** is returned.

Example

For details, see **Examples: Common Operations**.

5.6.4.8 cursor.fetchall()

Function

This method gets all the (remaining) rows of the query result and returns them as a list of tuples.

Prototype

```
cursor.fetchall()
```

Parameter

None

Return Value

Tuple list, which contains all results of the result set. An empty list is returned when no rows are available.

Example

For details, see **Examples: Common Operations**.

5.6.4.9 cursor.close()

Function

This method closes the cursor of the current connection.

Prototype

```
cursor.close()
```

Parameter

None

Return Value

None

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example

For details, see **Examples: Common Operations**.

5.6.4.10 connection.close()

Function

This method closes the database connection.

CAUTION

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

Prototype

```
connection.close()
```

Parameter

None

Return Value

None

Example

For details, see **Examples: Common Operations**.

5.7 ECPG-based Development

Embedded SQL C Preprocessor (ECPG) for GaussDB is an embedded SQL preprocessor for C programs. An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code (*.pgc) is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program (*.c), and afterwards it can be processed by a C compiler. Converted ECPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the GaussDB server using the normal frontend-backend protocol.

Programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...;
```

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

and allow nested C code-style comments (part of the SQL standard). However, the C part of the program follows the standards of the C program and does not support nested comments.

5.7.1 Development Process

The overall development process of ECPG includes preparing related components, compiling embedded SQL-C programs, preprocessing using ECPG, compiling C programs, and executing C programs.

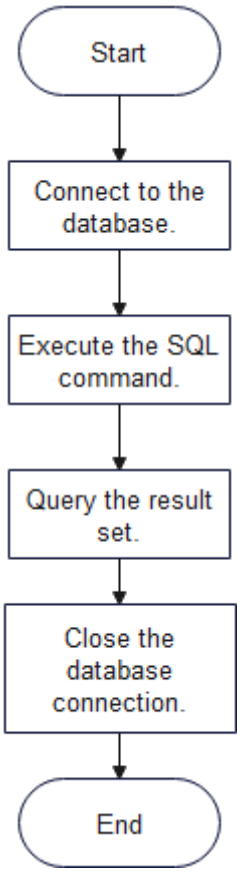
For details, see **Figure 5-6**.

Figure 5-7 shows the process of developing an embedded SQL-C program.

Figure 5-6 ECPG-based development process

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 5-7 Embedded SQL-C program development process



5.7.2 ECPG Components

- Platforms supported by ECPG

  Table 5-91 Platforms supported by ECPG

OS	Platform
EulerOS V2.0SP5	x86_64
EulerOS V2.0SP9	Arm64
Kylin V10	x86_64
Kylin V10	Arm64

- ecpg components
  - ecpg: an executable binary file used to preprocess C programs with embedded SQL statements.
  - libecpg: dynamic library provided by ecpg to implement connections, SQL statements, and transactions, including **libecpg.so**, **libecpg.so.6**, and **libecpg.so.6.4**. It is referenced by the **-lecpg** parameter during C program compilation and execution.
  - libpgtypes: dynamic library provided by the ECPG for operating data of the numeric, date, timestamp, and interval types, including **libpgtypes.so**,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

libecpg.so.6, and **libecpg.so.6.4**. The library is referenced by the **-lpgtypes** parameter during C program compilation and execution.

- Paths for obtaining ECPG components
  - ECPG binary file: *$GAUSSHOME*/**bin**
  - Dynamic library on which the ECPG depends: *$GAUSSHOME*/**lib**
  - Header file required by ECPG: *$GAUSSHOME*/**include/ecpg**

5.7.3 ECPG Preprocessing and Compiling

Prepare C programs with embedded SQL statements with the extension .pgc. ECPG converts them into C programs that can be compiled by the C compiler.

The generated C program is compiled into an executable file by the GCC compiler. The executable file is run to enable the client program to access the database. For details, see **Examples**.

- ecpg preprocessing and C compilation process
  a. Preprocessing: ecpg -I $GAUSSHOME/include -o test.c test.pgc

     To execute ECPG preprocessing, run the following command:

     ```
     ecpg [OPTION]...
     ```

     The options are as follows:

     - **-o** *OUTFILE*: writes the result to an outfile, which is a C file.
     - **-I** *DIRECTORY*: specifies the path of the header file.
     - **-c**: automatically generates a C file.
     - **--version**: checks the current ecpg version.
     - **-C** *MODE*: specifies the preprocessing compatibility mode. **ORA** indicates O-compatible.
     - **-r** *OPTION*: specifies the running behavior. *OPTION* can be **no_indicator**, **prepare**, **questionmarks**, or **with_hold**.
       - **no_indicator**: A special value is used to indicate a null value.
       - **prepare**: All statements are prepared before using them.
       - **questionmarks**: A question mark can be used as a placeholder.
       - **with_hold**: For a cursor created without the HOLD keyword, the cursor behavior is **WITH HOLD** by default after this option is specified. (This function requires that the ecpg version be the same as the kernel version.)

  b. Compilation: gcc -I $GAUSSHOME/include/ecpg -I $GAUSSHOME/include -I $GAUSSHOME/include/gaussdb/server/ -L $GAUSSHOME/lib -lecpg -lrt -lpq -lpgtypes -lpthread test_ecpg.c -o test_ecpg

  c. Execution: ./test

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- ECPG is a compilation preprocessing tool. If an error message is displayed indicating that the related header file or function implementation cannot be found during preprocessing or compilation, you can specify the header file or link the dynamic library as required.
- ECPG requires compilation preprocessing tools such as GCC and ld. You are advised to use GCC 7.3.0.
- Other dynamic libraries and header files on which the ecpg depends are usually stored in *$GAUSSHOME*/**include/libpq** and *$GAUSSHOME*/**include**.
- Common dynamic library dependencies during compilation include: -lpq, -lpq_ce, and -lpthread. If the libpq communications library is required during development, connect to -lpq and -lpq_ce. If the multi-thread connection is required during development, connect to -lpthread.

5.7.4 Managing Database Connections

This section describes how to establish and switch a database connection.

5.7.4.1 Connecting to a Database

You can run the following command to connect to the database:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The target can be declared using the following methods. The italic part is a variable. Change it based on the actual situation.

- *dbname*[@*hostname*][:*port*]
- tcp:gaussdb://*hostname*[:*port*][/*dbname*][?*options*]
- unix:gaussdb://*hostname*[:*port*][/*dbname*][?*options*]
- An SQL string containing one of the above forms

ECPG supports IPv6 addresses. Enclose *hostname* with square brackets ([]). Examples of IPv6 format are as follows:

```
db1@[::1]
db1@[::1]:5432
tcp:gaussdb://[::1]/db1
tcp:gaussdb://[::1]:5432/db1
unix:gaussdb://[::1]/db1
unix:gaussdb://[::1]:5432/db1
```

NOTE

Currently, ECPG supports the following IPv6 formats:

1. Uppercase abbreviated format
2. Lowercase abbreviated format
3. Uppercase full format
4. Lowercase full format

The IPv6 loopback address is **::1** or **0:0:0:0:0:0:0:1**. Therefore, the Unix domain protocol supports only these two IPv6 formats.

There are also different ways to specify the username:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- *username*/*password*
- *username* SQLIDENTIFIED BY *password*
- *username* USING *password*

As mentioned above, the **username** and **password** parameters can be an SQL identifier, an SQL string, or a reference to a character variable.

connection_name indicates the connection name. If a program uses only one connection, you can omit it. The most recently opened connection becomes the current connection.

An example is as follows:

```
#include <stdlib.h>
EXEC SQL CONNECT TO mydb@sql.mydomain.com;

EXEC SQL CONNECT TO unix:gaussdb://sql.mydomain.com/mydb AS myconnection USER username;

EXEC SQL BEGIN DECLARE SECTION;
/* The values of target, user, and passwd must be read from environment variables or configuration files. Environment variables need to be configured as required. If no environment variable is used, a character string can be directly assigned. */
const char *target = getenv("EXAMPLE_TARGET_ENV");
const char *user = getenv("EXAMPLE_USERNAME_ENV");
const char *passwd = getenv("EXAMPLE_PASSWD_ENV");
EXEC SQL END DECLARE SECTION;
...
EXEC SQL CONNECT TO :target USER :user USING :passwd;
/* or EXEC SQL CONNECT TO :target USER :user/:passwd; */
```

For details about the complete usage example, see the example of using the connection syntax in **CONNECT**.

NOTE

- In the last form, character variables are referenced. For details about how to reference C variables in SQL statements, see **Host Variables**.
- The format of the connection target is not described in the SQL standard. Therefore, to develop a portable application, you can use the method in the last example to encapsulate the connection target string into a variable.
- For details about the ecpg compatibility, see **ecpg Compatibility**.

NOTICE

- If **ip-port** is specified in the connection statement, username and password must be specified. This rule is determined by the GaussDB kernel communication authentication. If **ip-port** is not specified, the local *$PGPORT* (UDS) is used for communication.
- If the SSL protocol is used for connection, run the **tcp:gaussdb://** *hostname***[:***port***][/***dbname***][?***options***]** command and set **sslmode** to **disable** **\require** in **options**.

5.7.4.2 Managing Connections

SQL statements in embedded SQL programs are by default executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, use either of the following methods:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Method 1: Explicitly select a connection for each SQL statement.
  ```
  EXEC SQL AT connection-name SELECT ...;
  ```
  This method is particularly suitable if the application needs to use several connections in mixed order.

  If the application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread.
- Method 2: Execute a statement to switch the connection.
  ```
  EXEC SQL SET CONNECTION connection-name;
  ```
  This method is particularly suitable if many statements are executed on the same connection.

An example of managing connections is as follows:

```
#include <stdio.h>
EXEC SQL BEGIN DECLARE SECTION;
   char dbname[1024];
EXEC SQL END DECLARE SECTION;

int main()
{
    EXEC SQL CONNECT TO testdb1 AS con1 USER testuser;
    EXEC SQL CONNECT TO testdb2 AS con2 USER testuser;
    EXEC SQL CONNECT TO testdb3 AS con3 USER testuser;

    /* This query will be executed in the most recently opened database testdb3. */
    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb3)\n", dbname);

    /* Use AT to run a query in testdb2. */
    EXEC SQL AT con2 SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb2)\n", dbname);

    /* Switch to connection to testdb1. */
    EXEC SQL SET CONNECTION con1;

    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb1)\n", dbname);

    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output:

```
current=testdb3 (should be testdb3)
current=testdb2 (should be testdb2)
current=testdb1 (should be testdb1)
```

NOTICE

- In multi-thread mode, different threads cannot use the same connection name. The connection name of each thread must be unique.
- A connection must be established and closed in the same process or thread.

5.7.5 Running SQL Commands

The format of embedded SQL commands is EXEC SQL [Command]. In embedded SQL applications, you can run common standard SQL statements supported by GaussDB or extended SQL statements provided by ECPG. Currently, features or

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

syntaxes such as stored procedures, packages, anonymous blocks, and flashback are not supported.

5.7.5.1 Running SQL Statements

Step 1 Create a table.

```
EXEC SQL CREATE TABLE foo (a int, b varchar);
```

Step 2 Insert a row.

```
EXEC SQL INSERT INTO foo VALUES (5, 'abc');
```

Step 3 Delete a row.

```
EXEC SQL DELETE FROM foo WHERE a = 5;
```

Step 4 Update table data.

```
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
```

Step 5 Query data in a single row.

```
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
```

----End

A complete example is as follows:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main ()
{
   ECPGdebug (1, stderr);

   EXEC SQL BEGIN DECLARE SECTION;
   int var_a;
   EXEC SQL END DECLARE SECTION;
   /* Create testdb in advance. */
   EXEC SQL CONNECT TO testdb;
   // Create a table.
   EXEC SQL CREATE TABLE foo (a int, b varchar);
      // Insert data.
   EXEC SQL INSERT INTO foo VALUES (5, 'abc');
   EXEC SQL INSERT INTO foo VALUES (6, 'def');
   EXEC SQL INSERT INTO foo VALUES (7, 'ghi');

   // Delete a row.
   EXEC SQL DELETE FROM foo WHERE a = 5;
   // Update table data.
   EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
   // Query table data in a single row.
   EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
   // Print the query results.
   printf("select res is %d\n", var_a);

   EXEC SQL DISCONNECT;

   return 0;
}
```

5.7.5.2 Using Cursors

To retrieve a result set holding multiple rows, an application has to declare a cursor and fetch each row from the cursor.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Step 1 Declare a cursor.

```
EXEC SQL DECLARE c CURSOR FOR select * from tb1;
```

Step 2 Open a cursor.

```
EXEC SQL OPEN c;
```

Step 3 Fetch a row of data from a cursor.

```
EXEC SQL FETCH 1 in c into :a, :str;
```

Step 4 Close a cursor.

```
EXEC SQL CLOSE c;
```

----End

NOTE

When the GUC parameter **enable_ecpg_cursor_duplicate_operation** is enabled (enabled by default) and ecpg is used to connect to the ORA-compatible database, a cursor can be opened or closed repeatedly in the following ways:

```
EXEC SQL OPEN c;
EXEC SQL OPEN c;
EXEC SQL CLOSE c;
EXEC SQL CLOSE c;
```

For details about how to use cursors, see **DECLARE**. For details about the **FETCH** command, see **FETCH**.

A complete example is as follows:

```
#include <string.h>
#include <stdlib.h>

int main(void)
{
exec sql begin declare section;
    int *a = NULL;
    char *str = NULL;
exec sql end declare section;

    int count = 0;
    /* Create testdb in advance. */
    exec sql connect to testdb ;
    exec sql set autocommit to off;
    exec sql begin;
    exec sql drop table if exists tb1;
    exec sql create table tb1(id int, info text);
    exec sql insert into tb1 (id, info) select generate_series(1, 100000), 'test';
    exec sql select count(*) into :a from tb1;
    printf ("a is %d\n", *a);
    exec sql commit;

    // Define a cursor.
    exec sql declare c cursor for select * from tb1;
    // Open the cursor.
    exec sql open c;
    exec sql whenever not found do break;
    while(1) {
        // Capture data.
        exec sql fetch 1 in c into :a, :str;
        count++;
        if (count == 100000) {
            printf("Fetch res: a is %d, str is %s", *a, str);
        }
    }
    // Close the cursor.
    exec sql close c;
    exec sql set autocommit to on;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    exec sql drop table tb1;
    exec sql disconnect;

    ECPGfree_auto_mem();
    return 0;

}
```

WHERE CURRENT OF cursor_name

cursor_name: specifies the name of a cursor.

When the cursor points to a row in a table, you can use this syntax to update or delete the row. For details about the restrictions, see **UPDATE**.

A complete example is as follows:

```
#include <string.h>
#include <stdlib.h>

int main(void)
{
exec sql begin declare section;
    int va;
    int vb;
exec sql end declare section;

    int count = 0;
    /* Create testdb in advance. */
    exec sql connect to testdb ;
    exec sql set autocommit to off;
    exec sql begin;
    exec sql drop table if exists t1;
    exec sql create table t1(c1 int, c2 int);
    exec sql insert into t1 values(generate_series(1,10000), generate_series(1,10000));
    exec sql commit;
    exec sql declare cur1 cursor for select * from t1 where c1 < 100 for update;
    /* Open the cursor. */
    exec sql open cur1;
    exec sql fetch 1 in cur1 into :va, :vb;
    printf("c1:%d, c2:%d\n", va, vb);
    /* Use the WHERE CURRENT OF clause to delete the current line. */
    exec sql delete t1 where current of cur1;
    exec sql fetch 1 in cur1 into :va, :vb;
    exec sql fetch 1 in cur1 into :va, :vb;
    printf("c1:%d, c2:%d\n", va, vb);
    /* Use the WHERE CURRENT OF clause to update the current line. */
    exec sql update t1 set c2 = 21 where current of cur1;
    exec sql select c2 into :vb from t1 where c1 = :va;
    printf("c1:%d, c2:%d\n", va, vb);
    /* Close the cursor. */
    exec sql close cur1;
    exec sql set autocommit to on;
    exec sql drop table t1;
    exec sql disconnect;

    ECPGfree_auto_mem();
    return 0;

}
```

5.7.5.3 Transaction

In the default mode, statements are committed only when EXEC SQL COMMIT is issued. The embedded SQL interface also supports autocommit of transactions by executing the **EXEC SQL SET AUTOCOMMIT TO ON** statement. In autocommit mode, each command is automatically committed unless it is inside an explicit

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

transaction block. This mode can be explicitly turned off by using **EXEC SQL SET AUTOCOMMIT TO OFF**.

Common transaction management commands are as follows:

- **EXEC SQL COMMIT**: commits an ongoing transaction.
- **EXEC SQL ROLLBACK**: rolls back an ongoing transaction.
- **EXEC SQL SET AUTOCOMMIT TO ON**: enables the autocommit mode.
- **SET AUTOCOMMIT TO OFF**: disables the autocommit mode. This is the default mode.

5.7.5.4 Prepared Statements

Prepared statements can be used when the value passed to an SQL statement is unknown at compile time or the same statement will be used multiple times.

- Statements are prepared using the **PREPARE** command. For the values that are not known yet, use the question mark (?) as the placeholder.
  ```
  EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg_database WHERE oid = ?";
  ```
- If a statement returns a single row, the application can call EXECUTE after PREPARE to execute the statement, supplying the actual values for the placeholders with a USING clause:
  ```
  EXEC SQL EXECUTE stmt1 INTO :dboid, :dbname USING 1;
  ```
- If a statement returns multiple rows, the application can use a cursor declared based on the prepared statement. To bind input parameters, the cursor must be opened with a USING clause:
  ```
  EXEC SQL PREPARE stmt1 FROM "SELECT oid,datname FROM pg_database WHERE oid > ?";
  EXEC SQL DECLARE foo_bar CURSOR FOR stmt1;
  /* When the end of the result set is reached, exit the while loop. */
  EXEC SQL WHENEVER NOT FOUND DO BREAK;
  EXEC SQL OPEN foo_bar USING 100;
  ...
  while (1)
  {
      EXEC SQL FETCH NEXT FROM foo_bar INTO :dboid, :dbname;
      ...
  }
  EXEC SQL CLOSE foo_bar;
  ```
- When a prepared statement is no longer needed, it should be deallocated.
  ```
  EXEC SQL DEALLOCATE PREPARE name;
  ```

5.7.5.5 Embedded SQL Commands

5.7.5.5.1 ALLOCATE DESCRIPTOR

Function

Allocates a newly named SQL descriptor area.

Syntax

```
ALLOCATE DESCRIPTOR name
```

Parameter Description

name

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

Example

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

DEALLOCATE DESCRIPTOR, **GET DESCRIPTOR**, and **SET DESCRIPTOR**

5.7.5.5.2 CONNECT

Description

Establishes a connection between the client and the SQL server.

Syntax

```
CONNECT TO connection_target [ AS connection_name ] [ USER connection_user ]
```

Parameters

- **connection_target**

  Specifies the target server to be connected in one of the following formats:

  - [*database_name*] [@ *host*] [: *port*]: connection over TCP/IP.
  - unix:gaussdb://*host* [: *port*] / [*database_name*] [? *connection_option*]: connection over UDSs.
  - tcp:gaussdb://*host* [:*port*] / [*database_name*] [?*connection_option*]: connection over TCP/IP.
  - **SQL string constant**: one of the preceding forms.

  CAUTION

  For details about **connection_target**, see **ecpg Compatibility**.

- **connection_name**

  An optional identifier used for the connection, which can be referenced in other commands. It can be an SQL identifier or a host variable.

- **connection_user**

  Username for database connection.

  You can use *user_name*/*password*, *user_name* **SQLIDENTIFIED BY** *password*, or *user_name* **USING** *password* to specify the username and password.

  The username and password can be SQL identifiers, string constants, or host variables.

NOTE

In the preceding parameters, the information in italics refers to variables. Replace them based on the actual situation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

Here are several variants of specifying connection parameters:

```
EXEC SQL CONNECT TO "connectdb" AS main;
EXEC SQL CONNECT TO "connectdb" AS second;
EXEC SQL CONNECT TO 'connectdb' AS main;
EXEC SQL CONNECT TO REGRESSDB1 as main;
EXEC SQL CONNECT TO connectdb AS :id;
EXEC SQL CONNECT TO connectdb AS main USER connectuser/connectdb;
EXEC SQL CONNECT TO connectdb AS main USER connectuser USING "connectdb";
EXEC SQL CONNECT TO connectdb AS main;
EXEC SQL CONNECT TO tcp:gaussdb://localhost/connectdb USER connectuser IDENTIFIED BY connectpw;
EXEC SQL CONNECT TO tcp:gaussdb://localhost:$PORT/connectdb USER connectuser SQLIDENTIFIED BY
connectpw;
EXEC SQL CONNECT TO unix:gaussdb://localhost/connectdb USER connectuser SQLIDENTIFIED BY
"connectpw";
EXEC SQL CONNECT TO unix:gaussdb://localhost/connectdb USER connectuser USING "connectpw";
```

The following is an example of using the connection syntax:

```
#include <stdlib.h>
#include <string.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
// Define the host by defining columns such as database and password required by the connection string. The actual values are read from environment variables or configuration files. Environment variables need to be configured as required. If no environment variable is used, a character string can be directly assigned.
exec sql begin declare section;
    const int max_str_len = 200;
    char db[max_str_len] = getenv("EXAMPLE_DATABASENAME_ENV");
    char pw[max_str_len] = getenv("EXAMPLE_PASSWD_ENV");
    char new_pw[max_str_len] = getenv("EXAMPLE_NEW_PASSWD_ENV");
exec sql end declare section;

    // Print debug logs.
    ECPGdebug(1, stderr);

    // The connection statement involves the database, username, and password. The user must be created in advance and have related operation permissions.

    //Connection mode: EXEC SQL CONNECT TO [ database_name ][ @host ][ :port ] [ USER connection_user ]
    // Case 1: Use the default local connection mode to connect to the postgres database.
    exec sql connect to postgres;
    // Case 2: Use the default local connection mode to connect to the postgres database. The connection alias is conn1.
    exec sql connect to postgres as conn1;
    // Case 3: Use the ip+port mode (localhost indicates the local address listened by the database, and $PORT indicates the listening port of the database) to connect to the connectdb database, specify the database alias, and specify the user password.
    exec sql connect to connectdb@localhost:$PORT as conn2 user connectuser using :pw;
    // Case 4: Use the ip+port mode (127.0.0.1 indicates the local IP address listened by the database, and $PORT indicates the listening port of the database) to connect to the connectdb database, specify the database alias, and specify the user password.
    exec sql connect to connectdb@127.0.0.1:$PORT as conn3 user connectuser sqlidentified by :pw;
    // Case 5: Close the connection to the database.
    exec sql disconnect postgres;
    exec sql disconnect conn1;
    exec sql disconnect conn2;
    exec sql disconnect conn3;

    // Connection mode: EXEC SQL CONNECT TO <tcp|unix>:gaussdb://host [ :port ]/[ database_name ][ ? connection_option ]
    // Case 1: Replace the URL variables with the host variables pw and db.
    strcpy(pw, new_pw);
    strcpy(db, "tcp:gaussdb://localhost/connectdb");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    exec sql connect to :db user connectuser using :pw;
    // Case 2: 127.0.0.1 indicates the IP address listened by the database, and connectdb indicates the
database.
    exec sql connect to tcp:gaussdb://127.0.0.1/connectdb as conn4 user connectuser using :pw;
    // Case 3: 127.0.0.1 indicates the IP address listened by the database, connectdb indicates the database,
and connect_timeout=14 indicates the connection string configuration parameter.
    exec sql connect to tcp:gaussdb://localhost/connectdb?connect_timeout=14 as conn5 user connectuser
sqlidentified by :pw;
    // Case 4: Close all connections.
    exec sql close all;
    // Connect to the database and execute the service.
    exec sql connect to tcp:gaussdb://127.0.0.1/connectdb as conn4 user connectuser using :pw;
    exec sql set autocommit = on;
    exec sql create table t1(a int);
    exec sql insert into t1 values(1),(2);
    exec sql select a from t1 where a > 1;
    exec sql drop table t1;
    exec sql disconnect current;
    return 0;
}
```

The following is an example of using a host variable to specify connection parameters:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    /* The values of dbname, user, and pwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
    char *dbname     = getenv("EXAMPLE_DBNAME_ENV");    /* Database name */
    char *user       = getenv("EXAMPLE_USERNAME_ENV");  /* Username for connection */
    char *pwd        = getenv("EXAMPLE_PASSWD_ENV"); /* Password */
    char *connection = "tcp:gaussdb://localhost:$PORT/testdb";  /* Connection string */
    char ver[256];                /* Buffer for storing version strings */
EXEC SQL END DECLARE SECTION;

    ECPGdebug(1, stderr);
    EXEC SQL CONNECT TO :dbname;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL SELECT version() INTO :ver;
    EXEC SQL DISCONNECT;

    printf("version: %s\n", ver);
    EXEC SQL CONNECT TO :connection USER :user USING :pwd;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL SELECT version() INTO :ver;
    EXEC SQL DISCONNECT;

    printf("version: %s\n", ver);
    return 0;
}
```

Helpful Links

DISCONNECT and **SET CONNECTION**

5.7.5.5.3 DEALLOCATE DESCRIPTOR

Function

Deallocates an SQL descriptor area.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
DEALLOCATE DESCRIPTOR name
```

Parameter Description

name

SQL descriptor name. It is case sensitive and is an SQL identifier or a host variable.

Example

```
DEALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

ALLOCATE DESCRIPTOR, **GET DESCRIPTOR**, and **SET DESCRIPTOR**

5.7.5.5.4 DECLARE

Description

Declares a cursor for iterating over the result set of a prepared statement. This command is slightly semantically different from the SQL command **DECLARE**: Whereas the latter executes a query and prepares the result set for retrieval, this embedded SQL command merely declares a name as a "loop variable" for iterating over the result set of a query; the actual execution happens when the cursor is opened with the **OPEN** command.

Syntax

```
DECLARE cursor_name [ BINARY ]  [ NO  SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR prepared_name
DECLARE cursor_name [ BINARY ]  [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

Parameters

- **cursor_name**

  Cursor name, which is case sensitive. It can be an SQL identifier or a host variable.

- **prepared_name**

  Name of the prepared query, which can be an SQL identifier or a host variable.

- **query**

  A SELECT command for providing the rows to be returned by the cursor.

NOTE

For details about the cursor options, see **DECLARE**.

Examples

Examples of declaring a cursor used for query:

```
EXEC SQL DECLARE C CURSOR FOR SELECT * FROM My_Table;
EXEC SQL DECLARE C CURSOR FOR SELECT Item1 FROM T;
EXEC SQL DECLARE cur1 CURSOR FOR SELECT version();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example of declaring a cursor for a prepared statement:

```
EXEC SQL PREPARE stmt1 AS SELECT version();
EXEC SQL DECLARE cur1 CURSOR FOR stmt1;
```

Helpful Links

OPEN

5.7.5.5.5 DESCRIBE

Description

Retrieves metadata information for the result columns contained in prepared statements.

Syntax

```
DESCRIBE [ OUTPUT ] prepared_name USING  SQL  DESCRIPTOR descriptor_name
DESCRIBE [ OUTPUT ] prepared_name INTO SQL  DESCRIPTOR descriptor_name
DESCRIBE [ OUTPUT ] prepared_name INTO sqlda_name
```

Parameters

- **prepared_name**

  Name of a prepared statement, which can be an SQL identifier or a host variable.

- **descriptor_name**

  Descriptor name, which is case-sensitive. It can be an SQL identifier or a host variable.

- **sqlda_name**

  SQLDA variable name. For details, see **SQLDA**.

Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;
EXEC SQL PREPARE stmt1 FROM :sql_stmt;
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :charvar = NAME;
EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
```

Helpful Links

ALLOCATE DESCRIPTOR and **GET DESCRIPTOR**

5.7.5.5.6 DISCONNECT

Description

Closes one or all database connections.

Syntax

```
DISCONNECT connection_name
DISCONNECT [ CURRENT ]
DISCONNECT DEFAULT
DISCONNECT ALL
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **connection_name**

  Specifies the name of the database connection established by the **CONNECT** command.

- **current**

  Closes the current connection, which can be a recently opened connection or a connection set by the SET CONNECTION command. This is also the default if no parameter is passed to the DISCONNECT command.

- **default**

  Closes the default connection.

- **all**

  Closes all open connections.

Example

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
    /* Create the testdb database in advance. */
    EXEC SQL CONNECT TO testdb AS DEFAULT;
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL CONNECT TO testdb AS con2;
    EXEC SQL CONNECT TO testdb AS con3;
    EXEC SQL DISCONNECT CURRENT;  /* Close connection 3. */
    EXEC SQL DISCONNECT DEFAULT;  /* Close the default connection. */
    EXEC SQL DISCONNECT ALL;      /* Close connections 2 and 1. */
    return 0;
}
```

Helpful Links

CONNECT, **SET CONNECTION**

5.7.5.5.7 EXECUTE IMMEDIATE

Function

Immediately prepares and executes a dynamically specified SQL statement without retrieving result rows.

Syntax

```
EXECUTE IMMEDIATE string
```

Parameter Description

string

A C string or host variable that contains the SQL statement to be executed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example

The following is an example of executing the INSERT statement using EXECUTE IMMEDIATE and a host variable named **command**:

```
sprintf(command, "INSERT INTO test (name, amount, letter) VALUES ('db: ''r1''', 1, 'f')");
EXEC SQL EXECUTE IMMEDIATE :command;
```

5.7.5.5.8 GET DESCRIPTOR

Description

Retrieves information about a query result set and stores it into host variables. A descriptor area is typically populated using FETCH or SELECT before using this command to transfer the information into host language variables. This command can be in either of the following formats:

- Retrieves the descriptor "header" items, which applies to the result set in its entirety.
- Retrieves information about a particular column, requiring the column number as additional parameter.

Syntax

```
GET DESCRIPTOR descriptor_name VALUE column_number :cvariable = descriptor_item [, ... ]
GET DESCRIPTOR descriptor_name:cvariable = descriptor_header_item [, ... ]
```

Parameters

- **descriptor_name**

  Descriptor name.

- **descriptor_header_item**

  Header item to be retrieved. Currently, only COUNT that is used to obtain the number of columns in the result set is supported.

- **column_number**

  Number of the column about which information is to be retrieved. The count starts at 1.

- **descriptor_item**

  Information item about a column to be retrieved.

- **cvariable**

  A host variable that will receive the data retrieved from the descriptor area.

Examples

Retrieve the number of columns in a result set.

```
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
```

Retrieve the data length in the first column.

```
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
```

Retrieve the data body of the second column as a string.

```
EXEC SQL GET DESCRIPTOR d VALUE 2 :d_data = DATA;
```

Run **SELECT current_database();**. The number of columns, column data length, and column data are displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int  d_count = 0;
    char d_data[1024] = {0};
    int  d_returned_octet_length = 0;
EXEC SQL END DECLARE SECTION;
   /* Create testdb in advance. */
    EXEC SQL CONNECT TO test;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL ALLOCATE DESCRIPTOR d;

    /* Declare and open a cursor, and allocate a descriptor to the cursor. */
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database();
    EXEC SQL OPEN cur;
    EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;

    /* Obtain the total number of columns. */
    EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
    printf("d_count = %d\n", d_count);

    /* Obtain the length of a returned column. */
    EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
    printf("d_returned_octet_length = %d\n", d_returned_octet_length);

    /* Fetch the returned column as a string. */
    EXEC SQL GET DESCRIPTOR d VALUE 1 :d_data = DATA;
    printf("d_data = %s\n", d_data);

    /* Closed */
    EXEC SQL CLOSE cur;
    EXEC SQL COMMIT;

    EXEC SQL DEALLOCATE DESCRIPTOR d;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

The following is the command output:

```
d_count                = 1
d_returned_octet_length = 6
d_data                 = testdb
```

Helpful Links

ALLOCATE DESCRIPTOR, **DEALLOCATE DESCRIPTOR**, **SET DESCRIPTOR**

5.7.5.5.9 OPEN

Description

Opens a cursor and optionally binds actual values to placeholders in the cursor declaration. The cursor must have been declared using the DECLARE command. Executing the OPEN command triggers the query on the server.

Syntax

```
OPEN cursor_name
OPEN cursor_name USING value [, ... ]
OPEN cursor_name USING SQL DESCRIPTOR descriptor_name
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **cursor_name**

  Name of the cursor to be opened. It can be an SQL identifier or a host variable.

- **value**

  A value that is to be bound to a placeholder in the cursor declaration. It can be an SQL constant, a host variable, or a host variable with an indicator.

- **descriptor_name**

  Name of the descriptor that contains the value to be bound to the placeholder in the cursor declaration. It can be an SQL identifier or a host variable.

Example

```
EXEC SQL OPEN a;
EXEC SQL OPEN d USING 1, 'test';
EXEC SQL OPEN c1 USING SQL DESCRIPTOR mydesc;
EXEC SQL OPEN :curname1;
```

Helpful Links

DECLARE

5.7.5.5.10 PREPARE

Description

Prepares the statement to be executed.

Syntax

```
PREPARE name FROM string
```

Parameters

- **name**

  An identifier for the prepared query.

- **string**

  A C string or host variable that contains a prepared statement, which can be SELECT, INSERT, UPDATE, or DELETE.

Examples

```
char *stmt = "SELECT * FROM test1 WHERE a = ? AND b = ?";
EXEC SQL ALLOCATE DESCRIPTOR outdesc;
EXEC SQL PREPARE foo FROM :stmt;
EXEC SQL EXECUTE foo USING SQL DESCRIPTOR indesc INTO SQL DESCRIPTOR outdesc;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The PREPARE statement provided by ecpg is not equivalent to the PREPARE syntax provided by the kernel. Example:

GaussDB kernel syntax:

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

Embedded SQL statement:

```
EXEC SQL PREPARE I(int, int) AS INSERT INTO T VALUES ( $1, $2 );
EXEC SQL EXECUTE I(1, 2);
```

When the preceding statement is executed, an error message "too few arguments on" is reported. ecpg provides a dynamic SQL statement to solve the problem in the **PREPARE name [(data_type [, ...])] AS statement** syntax scenario.

Example of using dynamic SQL syntax rules to solve the preceding problem:

```
EXEC SQL PREPARE I AS INSERT INTO T VALUES ( $1, $2 );
EXEC SQL EXECUTE I using 1, 2;
```

5.7.5.5.11 SET AUTOCOMMIT

Description

Sets the automatic commit behavior of the current database session.

By default, embedded SQL programs do not automatically commit, so you need to explicitly issue COMMIT. This command can change the session to the automatic commit mode so that each individual statement is implicitly committed.

Syntax

```
SET AUTOCOMMIT { = | TO } { ON | OFF }
```

5.7.5.5.12 SET CONNECTION

Function

Sets a database connection.

Syntax

```
SET CONNECTION [ TO | = ] connection_name
```

Parameter Description

- **connection_name**

  Name of a database connection established by the CONNECT command.

Example

```
EXEC SQL SET CONNECTION TO con2;
EXEC SQL SET CONNECTION = con1;
```

Helpful Links

CONNECT and **DISCONNECT**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.7.5.5.13 SET DESCRIPTOR

Description

Populates an SQL descriptor area, which is usually used to bind parameters in a prepared query execution. This command can be in either of the following formats:

- Applies to the descriptor "header", which is independent of specific data.
- Assigns a value to specific data identified by a number.

Syntax

```
SET DESCRIPTOR descriptor_name descriptor_header_item = value [, ... ]
SET DESCRIPTOR descriptor_name VALUE number descriptor_item = value [, ...]
```

Parameters

- **descriptor_name**

  SQL descriptor name.

- **descriptor_header_item**

  Identifies the header information item to be set. Currently, only COUNT that can be used to set the number of descriptor items is supported.

- **number**

  Number of descriptor items to be set. The count starts at 1.

- **descriptor_item**

  Identifies which descriptor item is to be set. Currently, only DATA, TYPE, and LENGTH are supported.

- **value**

  Value to be stored in the descriptor item. The value can be an SQL constant or a host variable.

Examples

```
EXEC SQL SET DESCRIPTOR indesc COUNT = 1;
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = 2;
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = :val1;
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val1, DATA = 'some string';
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val2null, DATA = :val2;
```

Helpful Links

ALLOCATE DESCRIPTOR, **DEALLOCATE DESCRIPTOR**, and **GET DESCRIPTOR**

5.7.5.5.14 TYPE

Function

Defines a new data type. This command is identified only when ecpg is run with the **-c** option.

Syntax

```
TYPE type_name IS ctype
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter Description

type_name

Data type name

ctype

C type description.

Example

```
EXEC SQL TYPE customer IS
    struct
    {
        varchar name[50];
        int     phone;
    };

EXEC SQL TYPE cust_ind IS
    struct ind
    {
        short   name_ind;
        short   phone_ind;
    };

EXEC SQL TYPE c IS char reference;
EXEC SQL TYPE ind IS union { int integer; short smallint; };
EXEC SQL TYPE intarray IS int[AMOUNT];
EXEC SQL TYPE str IS varchar[BUFFERSIZ];
EXEC SQL TYPE string IS char[11];
```

Example of using EXEC SQL TYPE (note that the **-c** parameter needs to be added in the ecpg preprocessing phase when the following example is used):

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

EXEC SQL WHENEVER SQLERROR SQLPRINT;
EXEC SQL TYPE tt IS
    struct
    {
        varchar v[256];
        int     i;
    };
EXEC SQL TYPE tt_ind IS
    struct ind {
        short   v_ind;
        short   i_ind;
    };

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    tt t;
    tt_ind t_ind;
EXEC SQL END DECLARE SECTION;
     EXEC SQL CONNECT TO testdb AS con1;
     EXEC SQL SELECT current_database(), 256 INTO :t:t_ind LIMIT 1;

     printf("t.v = %s\n", t.v.arr);
     printf("t.i = %d\n", t.i);

     printf("t_ind.v_ind = %d\n", t_ind.v_ind);
     printf("t_ind.i_ind = %d\n", t_ind.i_ind);

     EXEC SQL DISCONNECT con1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    return 0;
}
```

The output of this example is as follows:

```
t.v = testdb
t.i = 256
t_ind.v_ind = 0
t_ind.i_ind = 0
```

5.7.5.5.15 VAR

Function

Assigns a new C data type to a host variable. The host variable must have been declared in a DECLARE segment.

NOTE

- Exercise caution when using VAR. Using VAR to change the data type my cause the memory address to be invalid. As a result, the data variable is invalid and the value cannot be assigned.
- If the data type has been defined in the host variable DECLARE segment, you do not need to use the VAR statement.

Syntax

```
VAR varname IS ctype
```

Parameter Description

- **varname**

  Name of a C variable.

- **ctype**

  C type description.

Example

```
EXEC SQL BEGIN DECLARE SECTION;
   short a;
EXEC SQL END DECLARE SECTION;
EXEC SQL VAR a IS int;
```

5.7.5.5.16 WHENEVER

Description

Defines a behavior that is called when an SQL execution exception occurs (row not found, SQL alarm, or error).

Syntax

```
WHENEVER { NOT FOUND | SQLERROR | SQLWARNING } action
```

Parameters

For details about the parameter description, see **Setting Callbacks**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
EXEC SQL WHENEVER NOT FOUND CONTINUE;
EXEC SQL WHENEVER NOT FOUND DO BREAK;
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLWARNING DO warn();
EXEC SQL WHENEVER SQLERROR sqlprint;
EXEC SQL WHENEVER SQLERROR SQLCALL print2();
EXEC SQL WHENEVER SQLERROR DO handle_error("select");
EXEC SQL WHENEVER SQLERROR DO sqlnotice(NULL, NONO);
EXEC SQL WHENEVER SQLERROR DO sqlprint();
EXEC SQL WHENEVER SQLERROR GOTO error_label;
EXEC SQL WHENEVER SQLERROR STOP;
```

Use WHENEVER NOT FOUND BREAK to process the loop of the result set. The following is a complete example:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main(void)
{
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL ALLOCATE DESCRIPTOR d;
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database(), 'hoge', 256;
    EXEC SQL OPEN cur;
    EXEC SQL BEGIN DECLARE SECTION;
    char* d1;
    char* d2;
    EXEC SQL END DECLARE SECTION;
    /* When the end of the result set is reached, exit the loop. */
    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;
        exec sql get descriptor d value 1 :d1=DATA;
        exec sql get descriptor d value 2 :d2=DATA;
        printf("d1 is %s,%s\n", d1, d2) ;
    }
     EXEC SQL CLOSE cur;
     EXEC SQL COMMIT;
     EXEC SQL DEALLOCATE DESCRIPTOR d;
     EXEC SQL DISCONNECT ALL;
     return 0;
}
```

5.7.6 Querying the Result Set

- The SELECT statement that returns the result of a single row can be directly executed using EXEC SQL. For details, see **Running SQL Commands**.

  Example:

  ```
  /* Create a table and insert data. */
  EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
  EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);

  /* The query result is in a single row. :num is the host variable. */
  EXEC SQL SELECT number1 INTO :num FROM test_table WHERE number2 = 1;
  ```

- To process a multi-row result set, you must use a cursor. For details, see **Using Cursors**. (In special cases, an application can fetch multiple rows of results at a time and write them to the host variable of the array type. For details, see **Host Variables with Non-primitive Types**.)

  Example:

  ```
  /* Create a table and insert data. */
  EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);
    EXEC SQL INSERT INTO test_table (number1, number2) VALUES (3, 1);
    EXEC SQL INSERT INTO test_table (number1, number2) VALUES (4, 1);
    EXEC SQL INSERT INTO test_table (number1, number2) VALUES (5, 1);

/* Define the host variable. */
EXEC SQL BEGIN DECLARE SECTION;
    int v1;
    int v2;
EXEC SQL END DECLARE SECTION;

    /* Declare a cursor. */
    EXEC SQL DECLARE test_bar CURSOR FOR SELECT number1, number2 FROM test_table ORDER BY
number1;
    /* Open the cursor. */
    EXEC SQL OPEN test_bar;
    /* When the cursor reaches the end of the result set, exit the loop. */
    EXEC SQL WHENEVER NOT FOUND DO BREAK;
    /* Obtain the query result set. */
    while(1)
    {
        EXEC SQL FETCH NEXT FROM test_bar INTO :v1, :v2;
        printf("number1 = %d, number2 = %d\n",v1,v2);
    }
    /* Close the cursor. */
    EXEC SQL CLOSE test_bar;
```

5.7.7 Closing a Database Connection

Close the database connection after the database is used.

Close a connection.

```
EXEC SQL DISCONNECT [connection];
```

Declare the connection by using the following methods:

- connection-name
- default
- current
- all

5.7.8 Host Variables

This section describes how to use host variables to pass data between C programs and embedded SQL programs. In C programs with embedded SQL statements, we use the C language as the host language and regard EXEC SQL [Command] statements as embedded SQL statements of the host language. Therefore, variables used for embedded SQL statements in C programs are called host variables.

5.7.8.1 Overview

Passing data between a C program and SQL statements is particularly simple in embedded SQL. Instead of having the program paste data into the statements, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. The following is an example:

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement references two C variables named v1 and v2 and uses a regular SQL string, indicating that you are not restricted to use one kind of data or the other.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.7.8.2 DECLARE Section

To implement data interaction between a C program with embedded SQL statements and a database, for example, to pass parameters in a query of the C program to the database, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so that the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION;
```

And ends with:

```
EXEC SQL END DECLARE SECTION;
```

Between them, there must be regular C variable declarations. An example is as follows:

```
int   x = 4;
char  foo[16], bar[16];
```

NOTICE

- The type of the host variables declared between the start and end of the marked section must be one of the supported data types. For details, see **Table 5-92**.
- You can also declare variables with the following syntax which implicitly creates a DECLARE section: EXEC SQL int i = 4.
- Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.
- The definition of a structure or union also must be listed inside a DECLARE section. Otherwise, the preprocessor cannot process these types.

5.7.8.3 Retrieving Query Results

To retrieve the results of a query, embedded SQL provides special variants of the usual commands SELECT and FETCH. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in. SELECT is used for a query that returns only a single row, and FETCH is used for a query that returns multiple rows, using a cursor.

- Use SELECT.

```
/*
 * Assume a table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */
EXEC SQL BEGIN DECLARE SECTION;
    int v1;
    VARCHAR v2;
EXEC SQL END DECLARE SECTION;

    ...

    EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;
```

The INTO clause appears between the SELECT list and the FROM clause. The number of elements in the SELECT list and the list after INTO (also called the target list) must be equal.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Use FETCH.

```
EXEC SQL BEGIN DECLARE SECTION;
   int v1;
   VARCHAR v2;
EXEC SQL END DECLARE SECTION;
   ...

   EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;
   ...
   do
   {
      ...
      EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
      ...
   } while (...);
```

The INTO clause appears after all SQL clauses.

5.7.8.4 Type Mapping

When ecpg applications exchange values between the GaussDB server and the C program, such as when retrieving query results from the server or executing SQL statements with input parameters, the values need to be converted between GaussDB data types and host language variable types (C language data types, concretely). There are two data types available: Simple GaussDB data types, such as integer and text, can be directly read and written by applications. Other GaussDB data types, such as timestamp and numeric, can be accessed only by using special library functions. For details, see **ECPG API Reference**.

Table 5-92 Mapping between GaussDB data types and C variable types

GaussDB Data Type	Host Variable Type
smallint	short
integer	int
bigint	long long int
boolean	boolean
character(n), varchar(n), text	char[n+1], VARCHAR[n+1]
double precision	double
real	float
smallserial	short
serial	int
bigserial	long long int
oid	unsigned int
name	char[NAMEDATALEN]
date	date [a]
timestamp	timestamp [a]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

GaussDB Data Type	Host Variable Type
interval	interval [a]
decimal	decimal [a]
numeric	numeric [a]

NOTE

[a] This type can be accessed through **Accessing Special Data Types**.

NOTICE

- Currently, only basic data types of the C language can be used or combined. The string data type in the C++ language cannot be used as the host variable type.
- Currently, ecpg maps only common data types of GaussDB SQL. For details about the supported data types, see **Table 5-92**.

5.7.8.5 Handling Character Strings

To handle SQL character string data types, such as varchar and text, there are two possible methods to declare the host variables.

1. Method 1: Use char[] (a char string), which is the most common method for processing character data in C programs.

   ```
   EXEC SQL BEGIN DECLARE SECTION;
       char str[50];
   EXEC SQL END DECLARE SECTION;
   ```

   Note that you have to take care of the length yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

2. Method 2: Use the VARCHAR type, which is a special type provided by ECPG. The definition on an array of type VARCHAR is converted into a named struct for every variable. The statement is as follows:

   ```
   VARCHAR var[180];
   ```

   It will be converted into:

   ```
   struct varchar_var
   {
       int len;
       char arr[180];
   } var;
   ```

   To store a string in a VARCHAR host variable, the host variable has to be declared as a string including the zero-byte terminator. **arr** stores the string including a terminating zero byte. **len** stores the length of the string stored in **arr** without the terminating zero byte. The terminator is not included when the length is calculated. When a host variable is used as input for a query, if the values of **strlen(arr)** and **len** are different, the shorter one is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CAUTION

- VARCHAR can be written in upper or lower case, but not in mixed case.
- char and VARCHAR host variables can also hold values of other SQL types, which will be stored in their string forms.

5.7.8.6 Host Variables with Non-primitive Types

Non-primitive host variables can be arrays, typedefs, structures, and pointers.

- Arrays

  There are two use cases for arrays as host variables. The first case is to store some text strings in char[] or VARCHAR[]. The second case is to retrieve multiple rows from a query result without using a cursor. Without an array, to process a query result consisting of multiple rows, it is required to use a cursor and the FETCH command. But with array host variables, multiple rows can be retrieved at once. The length of the array has to be defined to be able to accommodate all rows; otherwise, a buffer overflow will occur.

  For example, scan the pg_database system catalog and display the OIDs and names of all available databases.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int dbid[8];
    char dbname[8][16];
    int i;
EXEC SQL END DECLARE SECTION;

    memset(dbname, 0, sizeof(char)* 16 * 8);
    memset(dbid, 0, sizeof(int) * 8);
  /* Connect to the testdb database. The testdb database must be created in advance. */
    EXEC SQL CONNECT TO testdb;
    /* Retrieve multiple rows to arrays at a time. */
    EXEC SQL SELECT oid,datname INTO :dbid, :dbname FROM pg_database;
    for (i = 0; i < 8; i++)
        printf("oid=%d, dbname=%s\n", dbid[i], dbname[i]);
    EXEC SQL COMMIT;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

  The following is the example output (the exact value depends on the local environment).

```
oid=1, dbname=template1
oid=11510, dbname=template0
oid=11511, dbname=postgres
oid=313780, dbname=testdb
oid=0, dbname=
oid=0, dbname=
oid=0, dbname=
```

- Structures

  A structure whose member names match the column names of a query result, can be used to retrieve multiple columns at once. The structure enables handling multiple column values in a single host variable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following example retrieves OIDs, names, and sizes of the available databases from the pg_database system catalog and using the pg_database_size() function. In this example, a structure variable with members whose names match each column in the SELECT result is used to retrieve one result row without putting multiple host variables in the FETCH statement.

```
EXEC SQL BEGIN DECLARE SECTION;
   typedef struct
   {
      int oid;
      char datname[65];
      long long int size;
   } dbinfo_t;

   dbinfo_t dbval;
EXEC SQL END DECLARE SECTION;
   memset(&dbval, 0, sizeof(dbinfo_t));

   EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
   EXEC SQL OPEN cur1;

   /* Exit the while loop when the end of the result set is reached. */
   EXEC SQL WHENEVER NOT FOUND DO BREAK;

   while (1)
   {
      /* Fetch multiple columns into one structure. */
      EXEC SQL FETCH FROM cur1 INTO :dbval;
      /* Print the members of the structure. */
      printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, dbval.size);
   }
   EXEC SQL CLOSE cur1;
```

The following is the example output (the exact value depends on the local environment).

```
oid=1, datname=template1, size=4324580
oid=11510, datname=template0, size=4243460
oid=11511, datname=postgres, size=4324580
oid=313780, datname=testdb, size=8183012
```

Structure host variables "absorb" as many columns in the query result as the structure columns. Additional columns can be allocated to other host variables. The above program could also be restructured like this, with the **size** variable outside the structure:

```
EXEC SQL BEGIN DECLARE SECTION;
   typedef struct
   {
      int oid;
      char datname[65];
   } dbinfo_t;

   dbinfo_t dbval;
   long long int size;
EXEC SQL END DECLARE SECTION;

   memset(&dbval, 0, sizeof(dbinfo_t));

   EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
   EXEC SQL OPEN cur1;

   /* Exit the while loop when the end of the result set is reached. */
   EXEC SQL WHENEVER NOT FOUND DO BREAK;
   while (1)
   {
      /* Fetch multiple columns into one structure. */
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    EXEC SQL FETCH FROM cur1 INTO :dbval, :size;
    /* Print the members of the structure. */
    printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, size);
}

EXEC SQL CLOSE cur1;
```

- typedef

  Use the typedef keyword to map new types to existing types.

  ```
  EXEC SQL BEGIN DECLARE SECTION;
  typedef char mychartype[40];
  typedef long serial_t;
  EXEC SQL END DECLARE SECTION;
  ```

  You can also run the following command:

  ```
  EXEC SQL TYPE serial_t IS long;
  ```

  This declaration does not need to be part of a DECLARE section.

- Pointers

  You can declare pointers to the most common types.

  ```
  EXEC SQL BEGIN DECLARE SECTION;
  int   *intp;
  char **charp;
  EXEC SQL END DECLARE SECTION;
  ```

5.7.8.7 Accessing Special Data Types

ECPG supports the numeric, decimal, date, timestamp, and interval data types. These data types cannot be mapped to primitive host variable types because they have a complex internal structure. Applications deal with these types by declaring host variables in special types and accessing them using functions in the pgtypes library. For details about the functions in the pgtypes library, see **ECPG API Reference**.

- timestamp and date

  First, the program must include the header file for the timestamp type.

  ```
  #include <pgtypes_timestamp.h>
  ```

  Then, declare a host variable of the timestamp type in the DECLARE section.

  ```
  EXEC SQL BEGIN DECLARE SECTION;
    timestamp ts;
  EXEC SQL END DECLARE SECTION;
  ```

  After the value is read to the host variable, the pgtypes library function is used for processing. In the following example, the PGTYPEStimestamp_to_asc() function is used to convert the **timestamp** value to the text format:

  ```
  EXEC SQL SELECT now()::timestamp INTO :ts;
  printf("ts = %s\n", PGTYPEStimestamp_to_asc(ts));
  ```

  A command output example is as follows:

  ```
  ts = 2022-06-27 18:03:56.949343
  ```

  In addition, the date type can be processed in the same way. The program must contain the **pgtypes_date.h** header file, declare a host variable as the date type, and use the PGTYPEdata_to_asc() function to convert the variable to the text format.

- interval

  The handling of the interval type is also similar to the timestamp and date types. However, to allocate memory for an interval type value explicitly, the memory space for the variable must be allocated from the heap memory.

  The following is an example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_interval.h>
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
   interval *in;
EXEC SQL END DECLARE SECTION;
   /* Connect to the testdb database. The testdb database must be created in advance.*/
   EXEC SQL CONNECT TO testdb;
   in = PGTYPESinterval_new();
   EXEC SQL SELECT '1 min'::interval INTO :in;
   printf("interval = %s\n", PGTYPESinterval_to_asc(in));
   PGTYPESinterval_free(in);
   EXEC SQL COMMIT;
   EXEC SQL DISCONNECT ALL;
   return 0;
}
```

- numeric and decimal

  The handling of the numeric and decimal types is similar to the interval type: It requires defining a pointer, allocating some memory space from the heap, and accessing the variable using the pgtypes library functions.

  Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_numeric.h>
EXEC SQL WHENEVER SQLERROR STOP;
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
   numeric *num;
   numeric *num2;
   decimal *dec;
EXEC SQL END DECLARE SECTION;

   /* Connect to the testdb database. The testdb database must be created in advance.*/
   EXEC SQL CONNECT TO testdb;

   num = PGTYPESnumeric_new();
   dec = PGTYPESdecimal_new();

   EXEC SQL SELECT 12.345::numeric(4,2), 23.456::decimal(4,2) INTO :num, :dec;
   printf("numeric = %s\n", PGTYPESnumeric_to_asc(num, 0));
   printf("numeric = %s\n", PGTYPESnumeric_to_asc(num, 1));
   printf("numeric = %s\n", PGTYPESnumeric_to_asc(num, 2));
   /* Convert decimal to numeric to show a decimal value. */
   num2 = PGTYPESnumeric_new();
   PGTYPESnumeric_from_decimal(dec, num2);
   printf("decimal = %s\n", PGTYPESnumeric_to_asc(num2, 0));
   printf("decimal = %s\n", PGTYPESnumeric_to_asc(num2, 1));
   printf("decimal = %s\n", PGTYPESnumeric_to_asc(num2, 2));
   PGTYPESnumeric_free(num2);
   PGTYPESdecimal_free(dec);
   PGTYPESnumeric_free(num);

   EXEC SQL COMMIT;
   EXEC SQL DISCONNECT ALL;
   return 0;
}
```

5.7.8.8 Handling Non-primitive SQL Data Types

This section describes how to handle non-scalar and user-defined SQL-level data types in ECPG applications. Note that this is distinct from the handling of host

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

variables of non-primitive types described in **Host Variables with Non-primitive Types**.

- Arrays

  Multi-dimensional SQL-level arrays are not directly supported in ECPG. One-dimensional SQL-level arrays can be mapped into C array host variables and vice-versa. However, when creating a statement, ECPG does not know the types of the columns, so that it cannot check if a C array is input into a corresponding SQL-level array. When processing the output of an SQL statement, ECPG has to check if both are arrays.

  If a query accesses elements of an array separately, a host variable with a type that can be mapped to the element type should be used. For example, if a column type is array of integer, a host variable of type int can be used. Also if the element type is varchar or text, a host variable of type char[] or VARCHAR[] can be used.

  Example:

```
CREATE TABLE t3 (
    ii integer[]
);
testdb=> SELECT * FROM t3;
     ii
-------------
 {1,2,3,4,5}
(1 row)
```

  The following example retrieves the fourth element of an array and stores it in a host variable of the int type:

```
EXEC SQL BEGIN DECLARE SECTION;
    int ii;
EXEC SQL END DECLARE SECTION;

    EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[4] FROM t3;
    EXEC SQL OPEN cur1;

    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH FROM cur1 INTO :ii ;
        printf("ii=%d\n", ii);
    }
    EXEC SQL CLOSE cur1;
```

  Example output:

```
ii=4
```

  To map multiple array elements to the multiple elements in an array type host variable, each element of the array column and each element of the host variable array must be managed separately. For example:

```
EXEC SQL BEGIN DECLARE SECTION;
    int ii_a[8];
EXEC SQL END DECLARE SECTION;

    EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[1], ii[2], ii[3], ii[4] FROM t3;
    EXEC SQL OPEN cur1;

    EXEC SQL WHENEVER NOT FOUND DO BREAK;
    while (1)
    {
        EXEC SQL FETCH FROM cur1 INTO :ii_a[0], :ii_a[1], :ii_a[2], :ii_a[3];
        ...
    }
```

  Note:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
EXEC SQL BEGIN DECLARE SECTION;
    int ii_a[8];
EXEC SQL END DECLARE SECTION;

    EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii FROM t3;
    EXEC SQL OPEN cur1;

    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        /* Error */
        EXEC SQL FETCH FROM cur1 INTO :ii_a;
        ...
    }
```

It does not work out because you cannot map an array type column to an array host variable directly.

- Composite types

  Composite types are not directly supported in ECPG. For example, you cannot declare member variables as date type in a structure. However, you can access each attribute separately or use the external string representation.

  In the following example, each attribute can be accessed separately:

  ```
  CREATE TYPE comp_t AS (intval integer, textval varchar(32));
  CREATE TABLE t4 (compval comp_t);
  INSERT INTO t4 VALUES ( (256, 'GaussDB') );
  ```

  The following program retrieves data from the example table by selecting each attribute of the comp_t type separately:

  ```
  EXEC SQL BEGIN DECLARE SECTION;
      int intval;
      varchar textval[33];
  EXEC SQL END DECLARE SECTION;

      /* Put each element of the composite type column in the SELECT list. */
      EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
      EXEC SQL OPEN cur1;

      EXEC SQL WHENEVER NOT FOUND DO BREAK;
      while (1)
      {
          /* Fetch each element of the composite type column into host variables. */
          EXEC SQL FETCH FROM cur1 INTO :intval, :textval;
          printf("intval=%d, textval=%s\n", intval, textval.arr);
      }
      EXEC SQL CLOSE cur1;
  ```

  The host variables storing values in the **FETCH** command can be gathered into one structure. For more details about the host variables in the structure form, see **Handling Character Strings**. In the following example, the two host variables, *intval* and *textval*, become members of the comp_t structure, and the structure is specified in the **FETCH** command:

  ```
  EXEC SQL BEGIN DECLARE SECTION;
      typedef struct
      {
          int intval;
          varchar textval[33];
      } comp_t;
      comp_t compval;
  EXEC SQL END DECLARE SECTION;

      /* Put each element of the composite type column in the SELECT list. */
      EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
      EXEC SQL OPEN cur1;

      EXEC SQL WHENEVER NOT FOUND DO BREAK;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    while (1)
    {
        /* Put all values in the SELECT list into one structure. */
        EXEC SQL FETCH FROM cur1 INTO :compval;
        printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
    }
    EXEC SQL CLOSE cur1;
```

Although a structure is used in the FETCH command, the attribute names in the SELECT clause are specified one by one. This can be enhanced by using a * to ask for all attributes of the composite type value. For example:

```
...
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).* FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Put all values in the SELECT list into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :compval;
    printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
...
```

In this way, composite types can be mapped into structures, even though ECPG does not understand the composite type itself.

- User-defined base types

  When ECPG uses host variables to store query results, only the data types provided by ECPG are supported. User-defined data types are not supported. Data types created using CREATE TYPE cannot be mapped using host variables.

  However, you can use external string representations and host variables of the char[] or VARCHAR[] type to handle user-defined types.

  The external string representation of that type is (%lf,%lf), which is defined in function complex_in(). The following example inserts complex type values **(1,1)** and **(3,3)** into columns **a** and **b** and then queries them from the table.

```
EXEC SQL BEGIN DECLARE SECTION;
    varchar a[64];
    varchar b[64];
EXEC SQL END DECLARE SECTION;
    EXEC SQL INSERT INTO test_complex VALUES ('(1,1)', '(3,3)');
    EXEC SQL DECLARE cur1 CURSOR FOR SELECT a, b FROM test_complex;
    EXEC SQL OPEN cur1;

    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH FROM cur1 INTO :a, :b;
        printf("a=%s, b=%s\n", a.arr, b.arr);
    }
    EXEC SQL CLOSE cur1;
```

Example output:

```
a=(1,1), b=(3,3)
```

5.7.9 Executing Dynamic SQL Statements

In most cases, the SQL statements executed by an application are known when the application is written. However, in some cases, SQL statements are constructed at runtime or provided by external sources. In these cases, the SQL statements

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

cannot be directly embedded into the C source code, but dynamic SQL statements allow you to call the provided SQL statements in a string variable.

5.7.9.1 Executing Statements Without a Result Set

An example of running the **EXECUTE IMMEDIATE** command is as follows:

```
EXEC SQL BEGIN DECLARE SECTION;
   const char *stmt = "CREATE TABLE test1 (...);";
EXEC SQL END DECLARE SECTION;
   EXEC SQL EXECUTE IMMEDIATE :stmt;
```

EXECUTE IMMEDIATE can be used for SQL statements that do not return a result set, such as DDL, INSERT, UPDATE, and DELETE statements. However, statements for retrieving data, such as SELECT statements, cannot be executed in this way.

5.7.9.2 Executing a Statement with Input Parameters

Prepare a normal statement and execute a specific version of it by replacing its parameters (with question marks). Use the EXECUTE statement to execute the prepared statement by specifying parameters in the USING clause.

Example:

```
EXEC SQL BEGIN DECLARE SECTION;
   const char *stmt = "INSERT INTO test1 VALUES(?, ?);";
EXEC SQL END DECLARE SECTION;
   /* PREPARE Prepare a statement for execution. */
   EXEC SQL PREPARE mystmt FROM :stmt;
   ...
   /* Single quotation marks are valid characters. If a character string is used, use double quotation marks. */
   EXEC SQL EXECUTE mystmt USING 42, 'foobar';

   /* When you no longer need a prepared statement, you should deallocate it. */
   EXEC SQL DEALLOCATE PREPARE name;
```

5.7.9.3 Executing a Statement with a Result Set

EXECUTE can be used to execute SQL statements with a result set. To save the result, add an INTO clause. The following is an example.

```
EXEC SQL BEGIN DECLARE SECTION;
   const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";
   int v1, v2;
   VARCHAR v3[50];
EXEC SQL END DECLARE SECTION;

   EXEC SQL PREPARE mystmt FROM :stmt;
   ...
   EXEC SQL EXECUTE mystmt INTO :v1, :v2, :v3 USING 37;
```

NOTE

The EXECUTE statement supports the INTO and USING clauses.

If a query may return multiple result rows, use cursors. For details about cursors, see **Using Cursors**. Example:

```
EXEC SQL BEGIN DECLARE SECTION;
   char dbaname[128];
   char datname[128];
   char *stmt = "SELECT u.usename as dbaname, d.datname "
                "  FROM pg_database d, gs_user u "
                "  WHERE d.datdba = u.usesysid";
EXEC SQL END DECLARE SECTION;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
EXEC SQL CONNECT TO testdb AS con1 USER testuser;

EXEC SQL PREPARE stmt1 FROM :stmt;

EXEC SQL DECLARE cursor1 CURSOR FOR stmt1;
EXEC SQL OPEN cursor1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH cursor1 INTO :dbaname,:datname;
    printf("dbaname=%s, datname=%s\n", dbaname, datname);
}
EXEC SQL CLOSE cursor1;

EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
```

5.7.10 Error Handling

There are two non-exclusive methods to handle errors and warnings in an embedded SQL program:

- Callbacks can be configured to handle errors or warnings using the WHENEVER command.
- Detailed information about the errors or warnings can be obtained from the *sqlca* variable.

5.7.10.1 Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. To set the callback, run the following command:

```
EXEC SQL WHENEVER condition action;
```

condition can be one of the following:

- **SQLERROR**: The specified action is called whenever an error occurs during the execution of an SQL statement.
- **SQLWARNING**: The specified action is called whenever a warning occurs during the execution of an SQL statement.
- **NOT FOUND**: The specified action is called whenever an SQL statement retrieves or affects zero rows.

action can be one of the following:

- **CONTINUE**: ignores the callback error condition and continues the execution. It is usually used to stop a break condition. This is the default value.
- **GOTO** *label*/**GO TO** *label*: jumps to a specified label (using the C goto statement).
- **SQLPRINT**: prints a message to the standard error.
- **STOP**: calls exit(1) to terminate the program.
- **DO BREAK**: executes the C statement BREAK. This statement is used only in loops or switch statements.

The following is an example.

```
/* It prints a simple message when a warning occurs and aborts the program when an error happens. */
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLERROR STOP;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- The statement EXEC SQL WHENEVER is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first EXEC SQL WHENEVER and the SQL statement causing the condition, regardless of the flow of control in the C program. Therefore, neither of the following C programs can achieve the expected effect:

```
/*
 * ERROR
 */
void func()
{
    ...
    if (verbose) {
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;
    }
    ...
    EXEC SQL SELECT ...;
    ...
}
/*
 * ERROR
 */
void func()
{
    ...
    set_error_handler();
    ...
    EXEC SQL SELECT ...;
    ...
}
static void set_error_handler(void)
{
    EXEC SQL WHENEVER SQLERROR STOP;
}
```

- DO BREAK can be used only in the while, for, and switch scenarios. After DO BREAK is used, use the CONTINUE statement to ignore it.

5.7.10.2 sqlca

The embedded SQL API provides a global variable *sqlca* (short for SQL communication area). *sqlca* covers warnings and errors. If multiple warnings or errors occur during the execution of a statement, then *sqlca* will only contain information about the last one. In a multithreaded program, every thread automatically gets its own copy of *sqlca*.

The data structure is as follows:

```
struct
{
    char sqlcaid[8];
    long sqlabc;
    long sqlcode;
    struct
    {
        int sqlerrml;
        char sqlerrmc[SQLERRMC_LEN];
    } sqlerrm;
    char sqlerrp[8];
    long sqlerrd[6];
    char sqlwarn[8];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    char sqlstate[5];
} sqlca;
```

If no error occurred in the last SQL statement, **sqlca.sqlcode** will be **0** and **sqlca.sqlstate** will be **00000**. If a warning or error occurred, then **sqlca.sqlcode** will be negative and **sqlca.sqlstate** will be different from **00000**. For details about the values of **SQLSTATE** and **SQLCODE**, see **SQLSTATE and SQLCODE**.

If the last SQL statement was successful, then **sqlca.sqlerrd[1]** contains the OID of the processed row, if applicable, and **sqlca.sqlerrd[2]** contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, **sqlca.sqlerrm.sqlerrmc** will contain a string that describes the error. **sqlca.sqlerrm.sqlerrml** contains the length of the error message that is stored in **sqlca.sqlerrm.sqlerrmc**, that is, the result of **strlen()**. Note that some messages are too long to fit in the fixed-size sqlerrmc array; they will be truncated.

When a warning is generated, **sqlca.sqlwarn[2]** is set to **W**.

The columns **sqlcaid**, **sqlcabc**, **sqlerrp**, and the remaining elements of **sqlerrd** and **sqlwarn** currently contain no useful information.

Example:

```
/* Integrate WHENEVER and sqlca to implement error handling. */
EXEC SQL WHENEVER SQLERROR SQLCALL print_sqlca();

void print_sqlca()
{
    fprintf(stderr, "==== sqlca ====\n");
    fprintf(stderr, "sqlcode: %ld\n", sqlca.sqlcode);
    fprintf(stderr, "sqlerrm.sqlerrml: %d\n", sqlca.sqlerrm.sqlerrml);
    fprintf(stderr, "sqlerrm.sqlerrmc: %s\n", sqlca.sqlerrm.sqlerrmc);
    fprintf(stderr, "sqlerrd: %ld %ld %ld %ld %ld %ld\n", sqlca.sqlerrd[0],sqlca.sqlerrd[1],sqlca.sqlerrd[2],
                                                          sqlca.sqlerrd[3],sqlca.sqlerrd[4],sqlca.sqlerrd[5]);
    fprintf(stderr, "sqlwarn: %d %d %d %d %d %d %d %d\n", sqlca.sqlwarn[0], sqlca.sqlwarn[1],
sqlca.sqlwarn[2],
                                                          sqlca.sqlwarn[3], sqlca.sqlwarn[4], sqlca.sqlwarn[5],
                                                          sqlca.sqlwarn[6], sqlca.sqlwarn[7]);
    fprintf(stderr, "sqlstate: %5s\n", sqlca.sqlstate);
    fprintf(stderr, "===============\n");
}
```

The output is similar to the following (here is a misspelled table name):

```
==== sqlca ====
sqlcode: -400
sqlerrm.sqlerrml: 49
sqlerrm.sqlerrmc: relation "pg_databasep" does not exist on line 38
sqlerrd: 0 0 0 0 0 0
sqlwarn: 0 0 0 0 0 0 0 0
sqlstate: 42P01
===============
```

5.7.10.3 SQLSTATE and SQLCODE

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. For example, the code 00000 indicates the success state.

SQLCODE is a simple integer. The value **0** indicates success, a positive value indicates success with additional information, and a negative value indicates an

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

error. The SQL standard only defines the positive value + 100, which indicates that the last command returned or affected zero rows, and no specific negative values.

Table 5-93 Mapping between SQLSTATE and SQLCODE

SQLCODE Value	SQLSTATE Value	Description
0 (ECPG_NO_ERROR)	SQLSTATE 00000	Indicates no error.

100 (ECPG_NOT_FOUND)	SQLSTATE 02000	This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor.
		When processing a cursor in a loop, you could use this code as a way to detect when to abort the loop. The following is an example:
		`while (1)`
		`{`
		`  EXEC SQL FETCH ... ;`
		`  if (sqlca.sqlcode == ECPG_NOT_FOUND)`
		`  break;`
		`}`
		Actually, WHENEVER NOT FOUND DO BREAK effectively does this internally, so there is usually no advantage in writing this out explicitly.

-12 (ECPG_OUT_OF_MEMORY)	SQLSTATE YE001	Indicates that your virtual memory is exhausted. The numeric value is defined as **–ENOMEM**.
-200 (ECPG_UNSUPPORTED)	SQLSTATE YE000	Indicates that the preprocessor has generated something that the library does not know about.
-201 (ECPG_TOO_MANY_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified more host variables than the command expected.
-202 (ECPG_TOO_FEW_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified fewer host variables than the command expected.
-203 (ECPG_TOO_MANY_MATCHES)	SQLSTATE 21000	Indicates that a query has returned multiple rows, but the statement is ready to store only one result row.
-204 (ECPG_INT_FORMAT)	SQLSTATE 42804	The host variable is of the int type and the data in the database is of a different type and contains a value that cannot be interpreted as an int. The library uses strtol() for this conversion.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQLCODE Value	SQLSTATE Value	Description
-205 (ECPG_UINT_FORMAT)	SQLSTATE 42804	The host variable is of the unsigned int type and the data in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion.
-206 (ECPG_FLOAT_FORMAT)	SQLSTATE 42804	The host variable is of the float type and the data in the database is of another type and contains a value that cannot be interpreted as a float value. The library uses strtod() for this conversion.
-207 (ECPG_NUMERIC_FORMAT)	SQLSTATE 42804	The host variable is of the numeric type and the data in the database is of another type and contains a value that cannot be interpreted as a numeric value.
-208 (ECPG_INTERVAL_FORMAT)	SQLSTATE 42804	The host variable is of the interval type and the data in the database is of another type and contains a value that cannot be interpreted as an interval value.
-209 (ECPG_DATE_FORMAT)	SQLSTATE 42804	The host variable is of the date type and the data in the database is of another type and contains a value that cannot be interpreted as a date value.
-210 (ECPG_TIMESTAMP_FORMAT)	SQLSTATE 42804	The host variable is of the timestamp type and the data in the database is of another type and contains a value that cannot be interpreted as a timestamp value.
-211 (ECPG_CONVERT_BOOL)	SQLSTATE 42804	The host variable is of the Boolean type, but the data in the database is neither 't' nor 'f'.
-212 (ECPG_EMPTY)	SQLSTATE YE000	The statement sent to the SQL server was empty. (This usually does not occur in an embedded SQL program, so it may point to an internal error.)
-213 (ECPG_MISSING_INDICATOR)	SQLSTATE 22002	A null value was returned and no null indicator variable was provided.
-214 (ECPG_NO_ARRAY)	SQLSTATE 42804	An ordinary variable was used in a place that requires an array.
-215 (ECPG_DATA_NOT_ARRAY)	SQLSTATE 42804	The database returned an ordinary variable in a place that requires array value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQLCODE Value	SQLSTATE Value	Description
-216 (ECPG_ARRAY_INSERT)	SQLSTATE 42804	The value cannot be inserted into the array.
-220 (ECPG_NO_CONN)	SQLSTATE 08003	The program tried to access a connection that does not exist.
-221 (ECPG_NOT_CONN)	SQLSTATE YE000	The program tried to access a connection that does exist but is not open. (This is an internal error.)
-230 (ECPG_INVALID_STMT)	SQLSTATE 26000	The statement you are trying to use has not been prepared.
-239 (ECPG_INFORMIX_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-240 (ECPG_UNKNOWN_DESCRIPTOR)	SQLSTATE 33000	The specified descriptor was not found. The statement you are trying to use has not been prepared.
-241 (ECPG_INVALID_DESCRIPTOR_INDEX)	SQLSTATE 07009	The specified descriptor was out of range.
-242 (ECPG_UNKNOWN_DESCRIPTOR_ITEM)	SQLSTATE YE000	An invalid descriptor item was requested. (This is an internal error.)
-243 (ECPG_VAR_NOT_NUMERIC)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric.
-244 (ECPG_VAR_NOT_CHAR)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric.
-284 (ECPG_INFORMIX_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-400 (ECPG_PGSQL)	-	Some error caused by the SQL server. This message contains an error message from the SQL server.
-401 (ECPG_TRANS)	SQLSTATE 08007	The SQL server notified that the transaction cannot be started, committed, or rolled back.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQLCODE Value	SQLSTATE Value	Description
-402 (ECPG_CONNECT)	SQLSTATE 08001	The connection attempt to the database did not succeed.
-403 (ECPG_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-404 (ECPG_SUBSELECT_NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-602 (ECPG_WARNING_UNKNOWN_PORTAL)	SQLSTATE 34000	An invalid cursor name was specified.
-603 (ECPG_WARNING_IN_TRANSACTION)	SQLSTATE 25001	A transaction is in progress.
-604 (ECPG_WARNING_NO_TRANSACTION)	SQLSTATE 25P01	There is no active (in-progress) transaction.
-605 (ECPG_WARNING_PORTAL_EXISTS)	SQLSTATE 42P03	An existing cursor name was specified.

CAUTION

- The SQLSTATE codes 22002, 07001, 07002, 07006, 07009, 33000, 42601, 42804, 42P03, YE000, and YE001 are newly added to ecpg for embedded SQL statements. Other SQLSTATE codes are inherited from the kernel SQLSTATE codes.
- If the value of **SQLSCODE** is **–400**, ECPG detects that the kernel server returns an error. The error code of the kernel SQLSTATE is used.

5.7.11 Preprocessor Directives

This section describes the preprocessing instructions provided by ECPG. The preprocessing instructions are used to process program instructions for macro definition, file inclusion, and conditional compilation.

5.7.11.1 Including Files

To include an external file in an embedded SQL program, use the following statements:

```
EXEC SQL INCLUDE filename;
EXEC SQL INCLUDE <filename>;
EXEC SQL INCLUDE "filename";
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- ECPG searches for files in the following sequence:
  1. Current directory
  2. /usr/local/include
  3. GaussDB directory, which is defined at build time
  4. /usr/include
- When **EXEC SQL INCLUDE** *"filename"* is used, only the current directory is searched.
- In each directory, ECPG will first look for the file name as given, and if not found will append .h to the file name and try again (unless the specified file name already has that suffix).
- The file name is case sensitive.

5.7.11.2 Directives: ifdef, ifndef, else, elif, and endif

ecpg provides ifdef, ifndef, else, elif, and endif conditional compilation instructions.

During preprocessing, different parts of the program are compiled based on different conditions. When using the program, you need to add the EXEC SQL prefix keyword.

5.7.11.3 Directives define and undef

Similar to the directive **#define** that is known from C, embedded SQL has a similar concept.

```
EXEC SQL DEFINE name;
EXEC SQL DEFINE name value;
EXEC SQL UNDEF name;
```

Example:

```
/* Define a name. */
EXEC SQL DEFINE HAVE_FEATURE;

/* Define constants. */
EXEC SQL DEFINE MYNUMBER 12;
EXEC SQL DEFINE MYSTRING 'abc';

/* Use undef to remove a previous definition. */
EXEC SQL UNDEF MYNUMBER;
```

You can also use the C versions **#define** and **#undef** in your embedded SQL program. The difference is where your defined values get evaluated. If you use **EXEC SQL DEFINE**, then ECPG evaluates the definitions and substitutes the values. In the following example, ECPG does the substitution and the compiler will never see any name or identifier **MYNUMBER**:

```
EXEC SQL DEFINE MYNUMBER 12;
...
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

NOTICE

Note that you cannot use **#define** for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.7.12 Using Library Functions

- ECPGdebug(int on, FILE *stream): If the first parameter of the function is not 0, the debug log function is enabled. The second parameter indicates the standard output stream of the log to be printed. Debug logs are executed on the standard output stream. The logs contain all input SQL statements and results from the GaussDB server.

  Example:

  ```
  #include <stdio.h>
  #include <stdlib.h>
  #include <string.h>
  #include "sqlca.h"

  int main()
  {
      ECPGdebug(1, stderr);
      /* Create testdb in advance. */
      EXEC SQL CONNECT TO testdb;
      EXEC SQL SET AUTOCOMMIT TO ON;
      EXEC SQL CREATE TABLE T1(a int);
      return (0);
  }
  ```

- ECPGget_PGconn(const char **connection_name*): returns the database connection handle identified by the given name. If *connection_name* is set to **NULL**, the current connection handle is returned. If no connection handle can be identified, the function returns **NULL**.

  Example:

  ```
  #include <stdio.h>
  #include <stdlib.h>
  #include <string.h>
  #include "sqlca.h"

  int main()
  {
      ECPGdebug(1, stderr);
      /* Create testdb in advance. */
      EXEC SQL CONNECT TO testdb as con1;
      EXEC SQL SET AUTOCOMMIT TO ON;
      EXEC SQL DROP TABLE IF EXISTS T1;
      PGconn     *conn;
      conn = ECPGget_PGconn("con1");
      printf("conn = %p\n", conn);
      conn = ECPGget_PGconn(NULL);
      printf("conn = %p\n", conn);
      EXEC SQL CREATE TABLE T1(a int);
      return (0);
  }
  ```

- ECPGtransactionStatus(const char * *connection_name*): returns the current transaction status of the *connection_name* connection. The possible return values are as follows:

  ```
      PQTRANS_IDLE,    /* connection idle */
      PQTRANS_ACTIVE,  /* command in progress */
      PQTRANS_INTRANS, /* idle, within transaction block */
      PQTRANS_INERROR, /* idle, within failed transaction */
      PQTRANS_UNKNOWN  /* cannot determine status */
  ```

  Example:

  ```
  #include <stdio.h>
  #include <stdlib.h>
  #include <string.h>
  #include "sqlca.h"

  int main()
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
{
    ECPGdebug(1, stderr);
    /* Create testdb in advance. */
    EXEC SQL CONNECT TO testdb as con1;
    EXEC SQL DROP TABLE IF EXISTS T1;
    int a = ECPGtransactionStatus("con1");
    printf("%d\n", a);
    EXEC SQL CREATE TABLE T1(a int);
    EXEC SQL COMMIT;
    return (0);
}
```

- ECPGfree_auto_mem(): releases all memory allocated for output host variables. This function is called (return\exit) when the program ends.

  Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
  EXEC SQL BEGIN DECLARE SECTION;
  int *ip1=0;
  char **cp2=0;
  int *ipointer1=0;
  int *ipointer2=0;
  int column;
  EXEC SQL END DECLARE SECTION;
  int i;

  ECPGdebug(1, stderr);

  EXEC SQL WHENEVER SQLERROR DO sqlprint();
  EXEC SQL CONNECT TO REGRESSDB1;
  /* Create testdb in advance. */

  EXEC SQL CREATE TABLE test (a int, b text);
  EXEC SQL INSERT INTO test VALUES (1, 'one');
  EXEC SQL INSERT INTO test VALUES (2, 'two');
  EXEC SQL INSERT INTO test VALUES (NULL, 'three');
  EXEC SQL INSERT INTO test VALUES (NULL, NULL);

  EXEC SQL ALLOCATE DESCRIPTOR mydesc;
  EXEC SQL SELECT * INTO SQL DESCRIPTOR mydesc FROM test;
  EXEC SQL GET DESCRIPTOR mydesc :column=COUNT;
  EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :ip1=DATA, :ipointer1=INDICATOR;
  EXEC SQL GET DESCRIPTOR mydesc VALUE 2 :cp2=DATA, :ipointer2=INDICATOR;

  printf("Result (%d columns):\n", column);
  for (i=0;i < sqlca.sqlerrd[2];++i)
  {
    if (ipointer1[i]) printf("NULL, ");
    else printf("%d, ",ip1[i]);

    if (ipointer2[i]) printf("NULL, ");
    else printf("'%s', ",cp2[i]);
    printf("\n");
  }
  ECPGfree_auto_mem();
  printf("\n");

  EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
  EXEC SQL ROLLBACK;
  EXEC SQL DISCONNECT;
  return 0;
}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.7.13 SQL Descriptor Area

An SQL descriptor area (SQLDA) is a more sophisticated method for processing the result of a SELECT, FETCH, or DESCRIBE statement. An SQLDA groups the data of one row of data together with metadata items into one data structure. ecpg provides two ways to use descriptor areas: named SQLDA and C-structure SQLDA.

5.7.13.1 Named SQLDA

A named SQLDA consists of a header and one or more item descriptor areas. The header contains information concerning the entire descriptor area, and each item descriptor area describes a column in the result row.

- Before using an SQLDA, you need to allocate it.
  ```
  EXEC SQL ALLOCATE DESCRIPTOR identifier;
  ```
- When you no longer need the SQLDA, deallocate it in time.
  ```
  EXEC SQL DEALLOCATE DESCRIPTOR identifier;
  ```
- To use a descriptor area, declare it using the INTO clause.
  ```
  EXEC SQL FETCH NEXT FROM mycursor INTO SQL DESCRIPTOR mydesc;
  ```
  If the result set is empty, the descriptor area still contains the metadata from the query.
- For a prepared query that has not been executed, you can use DESCRIBE to obtain the metadata of its result set.
  ```
  EXEC SQL BEGIN DECLARE SECTION;
     char *sql_stmt = "SELECT * FROM table1";
  EXEC SQL END DECLARE SECTION;

     EXEC SQL PREPARE stmt1 FROM :sql_stmt;
     EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;
  ```
  In DESCRIBE and FETCH statements, the INTO and USING keywords are used similarly: they produce a result set and metadata in a descriptor area.
- To retrieve the value in a descriptor area from the header and store it into a host variable, use the following command:
  ```
  EXEC SQL GET DESCRIPTOR name :hostvar = field;
  ```
- Currently, only one header descriptor area **COUNT** is defined, which tells how many item descriptor areas exist (that is, how many columns are contained in the result). The host variable must be of the integer type. To retrieve a specific value from the item descriptor area, run the following command:
  ```
  EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field;
  ```
  num can be a character integer or a host variable that contains an integer. Possible data types are as follows:
  - CARDINALITY (integer): number of rows in the result set
  - DATA: actual data item (therefore, the data type of this field depends on the query)
  - DATETIME_INTERVAL_CODE (integer): When **TYPE** is **9**, **DATETIME_INTERVAL_CODE** will have a value of **1** for DATE, **2** for TIME, **3** for TIMESTAMP, **4** for TIME WITH TIME ZONE, or **5** for TIMESTAMP WITH TIME ZONE.
  - INDICATOR (integer): indicator (indicating a null value or a value truncation)
  - LENGTH (integer): data length in characters

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - NAME(string): column name
  - OCTET_LENGTH (integer): length of the character representation of the data in bytes
  - PRECISION (integer): precision (for the numeric type)
  - RETURNED_LENGTH (integer): data length in characters
  - RETURNED_OCTET_LENGTH (integer): length of the character representation of the data in bytes
  - SCALE (integer): ratio (for the numeric type)
  - TYPE (integer): numeric code of the data type of the column
- Retrieve the column value and store it in a host variable.
  ```
  EXEC SQL GET DESCRIPTOR mydesc  VALUE num :hostvar = field
  ```
  num can be a character integer or a host variable that contains an integer. Possible columns are as follows:
  - DATA
  - Actual data item (the data type of this column depends on the query)
  - NAME(string)
  - Column name
- To manually create a descriptor area to provide input parameters for a query or cursor, run the following command:
  ```
  EXEC SQL SET DESCRIPTOR name VALUE numfield = :hostvar;
  ```
- To retrieve multiple rows of records in a FETCH statement and use a host variable of the array type to store data, run the following commands:
  ```
  EXEC SQL BEGIN DECLARE SECTION;
     int id[5];
  EXEC SQL END DECLARE SECTION;
     EXEC SQL FETCH 5 FROM mycursor INTO SQL DESCRIPTOR mydesc;
     EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :id = DATA;
  ```

5.7.13.2 SQLDA

SQLDA is a C language structure used to store a query result set. A structure stores a record of a result set.

```
EXEC SQL include sqlda.h;
sqlda_t         *mysqlda;
EXEC SQL FETCH 3 FROM mycursor INTO DESCRIPTOR mysqlda;
```

Note that the SQL keyword is omitted. The paragraphs about the use cases of the INTO and USING keywords in section **Named SQLDA** also apply here. In a DESCRIBE statement, if the INTO keyword is used, the DESCRIPTOR keyword can be omitted.

```
EXEC SQL DESCRIBE prepared_statement INTO mysqlda;
```

- Procedure
  a. Prepare a query and declare a cursor for it.
  b. Declare an SQLDA for the result row.
  c. Declare SQLDA for input parameters, initialize parameters, and allocate memory.
  d. Open a cursor with the input SQLDA.
  e. Fetch rows from the cursor and store them in the output SQLDA.
  f. Read the value from the output SQLDA to the host variable.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

g. Close the cursor.

h. Deallocate the memory allocated to the SQLDA.

- There are three types of SQLDA data structures: sqlda_t, sqlvar_t, and struct sqlname.

  a. sqlda_t

  The definition of sqlda_t is as follows:

```
struct sqlda_struct
{
    char            sqldaid[8];
    long            sqldabc;
    short           sqln;
    short           sqld;
    struct sqlda_struct *desc_next;
    struct sqlvar_struct sqlvar[1];
};
typedef struct sqlda_struct sqlda_t;
```

  The structure members are described as follows:

  - **sqldaid**: contains a string "SQLDA".
  - **sqldabc**: contains the size (in bytes) of the allocated space.
  - **sqln**: contains the number of input parameters for a parameterized query in case it is passed into OPEN, DECLARE or EXECUTE statements using the USING keyword. When **sqln** is used as the output of a SELECT, EXECUTE, or FETCH statement, its value is the same as that of **sqld**.
  - **sqld**: contains the number of fields in a result set.
  - **desc_next**: If the query returns more than one record, multiple linked SQLDA structures are returned, and **desc_next** holds a pointer to the next SQLDA structure in the list.
  - **sqlvar**: indicates the array of the columns in the result set.

  b. sqlvar_t

  The structure type sqlvar_t holds a column value and metadata (such as type and length). The definition of this type is as follows:

```
struct sqlvar_struct
{
    short         sqltype;
    short         sqllen;
    char         *sqldata;
    short        *sqlind;
    struct sqlname sqlname;
};
typedef struct sqlvar_struct sqlvar_t;
```

  The structure members are described as follows:

  - **sqltype**: contains the type identifier of the field.
  - **sqllen**: contains the binary length of the field, for example, 4 bytes for ECPGt_int.
  - **sqldata**: points to the data. For details about the data format, see **Type Mapping**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **sqlind**: points to a null indicator. The value **0** indicates not null, and the value **–1** indicates null.
- **sqlname**: indicates the name of the field.

c. struct sqlname

A struct sqlname structure holds a column name. It is treated as a member of the sqlvar_t structure. The definition of this type is as follows:

```
#define NAMEDATALEN 64
struct sqlname
{
    short       length;
    char        data[NAMEDATALEN];
};
```

The structure members are described as follows:

- **length**: contains the length of the field name.
- **data**: contains the actual field name.

- Use an SQLDA to retrieve a result set.

  The general procedure for retrieving a query result set through an SQLDA is as follows:

  a. Declare an sqlda_t structure to receive the result set.
  b. Execute the **FETCH**, **EXECUTE**, or **DESCRIBE** command to process a query for which an SQLDA has been declared.
  c. Check the number of records in the result set by looking at sqln, a member of the sqlda_t structure.
  d. Fetch the values of each column from sqlvar[0], sqlvar[1], ..., members of the sqlda_t structure.
  e. Go to next row (sqlda_t) by following the desc_next pointer, a member of the sqlda_t structure.
  f. Repeat the preceding steps as required.

  Example:

```
/* Declare an sqlda_t structure to receive the result set. */
sqlda_t *sqlda1;
/* Next, specify an SQLDA in a command. This is an example of the FETCH command. */
EXEC SQL FETCH NEXT FROM cur1 INTO DESCRIPTOR sqlda1;
/* Run a loop to retrieve rows along the linked list. */
sqlda_t *cur_sqlda;
for (cur_sqlda = sqlda1;
     cur_sqlda != NULL;
     cur_sqlda = cur_sqlda->desc_next)
{
    ...
}
/* Inside the loop, run another loop to retrieve the data of each column in the row (sqlvar_t). */
for (i = 0; i < cur_sqlda->sqld; i++)
{
    sqlvar_t v = cur_sqlda->sqlvar[i];
    char *sqldata = v.sqldata;
    short sqllen  = v.sqllen;
    ...
}
/* To fetch the values of a column, check the value of the sqltype member of the sqlvar_t structure.
Then, switch to an appropriate method based on the column type to copy data from the sqlvar field
to a host variable. */
char var_buf[1024];
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
switch (v.sqltype)
{
    case ECPGt_char:
        memset(&var_buf, 0, sizeof(var_buf));
        memcpy(&var_buf, sqldata, (sizeof(var_buf) <= sqllen ? sizeof(var_buf) - 1 : sqllen));
        break;

    case ECPGt_int:
        memcpy(&intval, sqldata, sqllen);
        snprintf(var_buf, sizeof(var_buf), "%d", intval);
        break;
    ...
}
```

- Use an SQLDA to pass query parameters.

  The general procedure for passing input parameters to a prepared query using an SQLDA is as follows:

  a. Create a prepared query (prepared statement).
  b. Declare an sqlda_t structure as an SQLDA.
  c. Allocate a memory area for the SQLDA.
  d. Set (copy) the input values in the allocated memory.
  e. Open a cursor declaring the SQLDA.

  Example:

```
/* First, create a prepared statement. */
EXEC SQL BEGIN DECLARE SECTION;
    char query[1024] = "SELECT d.oid, * FROM pg_database d, pg_stat_database s WHERE d.oid =
s.datid AND (d.datname = ? OR d.oid = ?)";
EXEC SQL END DECLARE SECTION;
    EXEC SQL PREPARE stmt1 FROM :query;

    /* Allocate memory for an SQLDA and set the number of input parameters in the sqln member
variable of the sqlda_t structure.
    * When the prepared query requires two or more input parameters, the application must allocate
extra memory space. The space size is calculated as follows: (Number of parameters – 1) x
sizeof(sqlvar_t).
    * The example here shows how to allocate memory space for two input parameters.
     */
    sqlda_t *sqlda2;
    sqlda2 = (sqlda_t *) malloc(sizeof(sqlda_t) + sizeof(sqlvar_t));
    memset(sqlda2, 0, sizeof(sqlda_t) + sizeof(sqlvar_t));
    sqlda2->sqln = 2; /* Number of input variables */
    /* After memory allocation, store the parameter values into the sqlvar[] array. (This is same array
used for retrieving column values when the SQLDA is receiving a result set.)
    * In this example, the input parameters are testdb (string type) and 1 (integer type). */
    sqlda2->sqlvar[0].sqltype = ECPGt_char;
    sqlda2->sqlvar[0].sqldata = "testdb";
    sqlda2->sqlvar[0].sqllen  = 8;
    int intval = 1;
    sqlda2->sqlvar[1].sqltype = ECPGt_int;
    sqlda2->sqlvar[1].sqldata = (char *) &intval;
    sqlda2->sqlvar[1].sqllen  = sizeof(intval);
    /* Input parameters are passed to the prepared statement by opening a cursor and declaring the
SQLDA that has been created. */
    EXEC SQL OPEN cur1 USING DESCRIPTOR sqlda2;
    /* Finally, the allocated memory must be explicitly released after you use the input SQLDA, which is
different from the SQLDA used to receive query results. */
    free(sqlda2);
```

5.7.14 Examples

ECPG Example Code

```
#include <locale.h>
#include <string.h>
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example Code of the pgtypes Library Function

Example 1: Use library functions to perform different operations on time and date types. For details, see **Using Library Functions**.

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <limits.h>
#include <pgtypes_date.h>
#include <pgtypes_timestamp.h>

char *dates[] = { "19990108foobar",
                  "19990108 foobar",
                  "1999-01-08 foobar",
                  "January 8, 1999",
                  "1999-01-08",
                  "1/8/1999",
                  "1/18/1999",
                  "01/02/03",
                  "1999-Jan-08",
                  "Jan-08-1999",
                  "08-Jan-1999",
                  "99-Jan-08",
                  "08-Jan-99",
                  "08-Jan-06",
                  "Jan-08-99",
                  "19990108",
                  "990108",
                  "1999.008",
                  "J2451187",
                  "January 8, 99 BC",
                  NULL
                 };

/* The value cannot conflict with the value of times of libc. */
static char *times[] = { "0:04",
                         "1:59 PDT",
                         "13:24:40 -8:00",
                         "13:24:40.495+3",
                          NULL
                        };

char *intervals[] = { "1 minute",
```

```
                    "1 12:59:10",
                    "2 day 12 hour 59 minute 10 second",
                    "1 days 12 hrs 59 mins 10 secs",
                    "1 days 1 hours 1 minutes 1 seconds",
                    "1 year 59 mins",
                    "1 year 59 mins foobar",
                    NULL

5.7.15 ecpg and Pro*C Compatibility Comparison

ecpg, provided by GaussDB, is an embedded SQL preprocessor for C programs. It differs from the Pro*C preprocessor of the ORA-compatible database in the behavior and semantics of compiling and executing commands, syntax, and embedded statements.

Comparison between ecpg and Pro*C:

- Currently, ecpg does not support EXEC SQL CONTEXT ALLOCATE, EXEC SQL CONTEXT USE, and EXEC SQL Context FREE.

  NOTE

  Currently, ecpg does not support context allocation, use, and release. ecpg has an independent memory management mechanism. In multi-thread mode, ecpg independently establishes connections, executes SQL statements, and releases related resources in each thread. This usage mode is the same as the processing logic for each thread to allocate and release contexts in Pro*C multi-thread mode.

- Currently, ecpg does not support EXEC SQL COMMIT WORK RELEASE.

  NOTE

  In ecpg, after the COMMIT statement is executed, the **RELEASE** option is not available. You need to execute the EXEC SQL DISCONNECT and EXEC SQL CLOSE statements to release related resources. In Pro*C, EXEC SQL COMMIT has the **RELEASE** option, which is used to release all resource information such as connections and cursors held by the program.

- Currently, ecpg does not support EXEC SQL ENABLE THREAD.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> To enable macro definition in the ecpg compilation options, you need to define ENABLE_THREAD_SAFETY in the .pgc file of the main function.

- Currently, ecpg does not support features or syntaxes such as stored procedures, packages, anonymous blocks, and flashback.

5.7.16 ECPG API Reference

The ECPG API reference describes the data type-related interfaces provided by the pgtypes library for users to use in embedded SQL-C programs. The pgtypes library maps SQL data types to C data types and provides some interfaces to implement basic functions and calculations.

5.7.16.1 Interval Type

Table 5-94 lists the common APIs for interval data provided by the ECPG.

Table 5-94 Common interval type APIs

API	Description	Remarks
interval* PGTYPESinterval_new(void)	Returns a pointer to an allocated interval variable.	This function creates an interval variable on the heap. The return value is of the interval* type.
void PGTYPESinterval_free(interval* inval)	Releases the memory that has been allocated to an interval variable.	This function releases the memory allocated to the interval* variable created by the PGTYPESinterval_new function.
interval* PGTYPESinterval_from_asc(char* str, char** endptr)	Parses an interval from its textual representation.	This function parses the input string **str** and returns a pointer to an allocated interval variable. Currently, ECPG parses the entire character string and does not support storing the address of the first invalid character in ***endptr**. You can set **endptr** to **NULL**.
char* PGTYPESinterval_to_asc(interval* span)	Converts a variable of the interval type into its textual representation.	This function converts the interval variable to which the span points into a char*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESinterval_copy(interval* intvlsrc, interval* intvldest)	Copies a variable of the interval type.	This function copies the interval variable that intvlsrc points to into the variable that intvldest points to.

Examples

For details, see **Examples**.

5.7.16.2 Numeric Types

Table 5-95 lists the common APIs for numeric (numeric or decimal) data provided by the ECPG.

Table 5-95 Common numeric type APIs

API	Description	Remarks
numeric* PGTYPESnumeric_new(void)	Requests a pointer to a newly allocated numeric variable.	This function creates a numeric variable on the heap. The return value is of the numeric* type.
decimal* PGTYPESdecimal_new(void)	Requests a pointer to a newly allocated decimal variable.	This function creates a decimal variable on the heap. The return value is of the decimal* type.
void PGTYPESnumeric_free(numeric* var)	Frees the memory of a variable of the numeric type.	This function frees a numeric* variable created by using the PGTYPESnumeric_new function.
void PGTYPESdecimal_free(decimal*)	Frees the memory of a variable of the decimal type.	This function frees a decimal* variable created by using the PGTYPESdecimal_new function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
numeric* PGTYPESnumeric_from_asc(char* str, char** endptr)	Converts a string to the numeric type.	For example, the valid formats are –2, .794, +3.44, 592.49E07, or –32.84e–4. If the value could be parsed successfully, a valid pointer is returned; otherwise, a null pointer is returned. ECPG only parses complete character strings. Currently, ECPG does not support storing the address of the first invalid character in ***endptr**. However, **endptr** can be set to null.
char* PGTYPESnumeric_to_asc(numeric* num, int dscale)	Returns a pointer to a string allocated by malloc that contains the string representation of the numeric type num.	The numeric value will be printed using dscale decimal places and will be rounded if necessary.
int PGTYPESnumeric_add(numeric* var1, numeric* var2, numeric* result)	Adds two numeric variables to the third numeric variable.	This function adds the variables *var1* and *var2* to the result variable *result*. The function returns **0** on success and **–1** in case of error.
int PGTYPESnumeric_sub(numeric* var1, numeric* var2, numeric* result)	Subtracts two numeric variables and returns the result to the third numeric variable.	This function subtracts *var2* from *var1*. The result of this operation is stored in the variable *result*. The function returns **0** on success and **–1** in case of error.
int PGTYPESnumeric_mul(numeric* var1, numeric* var2, numeric* result)	Multiplies two numeric variables and returns the result to the third numeric variable.	This function multiplies variables *var1* and *var2*. The result of this operation is stored in the variable *result*. The function returns **0** on success and **–1** in case of error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESnumeric_div(numeric* var1, numeric* var2, numeric* result)	Divides two numeric variables and returns the result to the third numeric variable.	This function divides variable *var1* by variable *var2*. The result of this operation is stored in the variable *result*. The function returns **0** on success and **–1** in case of error.
int PGTYPESnumeric_cmp(numeric* var1, numeric* var2)	Compares two numeric variables.	This function compares two numeric variables. If an error occurs, *INT_MAX* is returned. On success, this function returns one of the following three possible results: • If *var1* is greater than *var2*, **1** is returned. • If *var1* is smaller than *var2*, **–1** is returned. • If *var1* and *var2* are equal, **0** is returned.
int PGTYPESnumeric_from_int(signed int int_val, numeric* var)	Converts an int variable into a numeric variable.	This function accepts a signed int variable and stores it in the numeric variable *var*. The function returns **0** on success and **–1** in case of failure.
int PGTYPESnumeric_from_long(signed long int long_val, numeric* var)	Converts a long int variable into a numeric variable.	This function accepts a long int variable and stores it in the numeric variable *var*. The function returns **0** on success and **–1** in case of failure.
int PGTYPESnumeric_copy(numeric* src, numeric* dst)	Copies a numeric variable to another one.	This function copies the value of the variable that **src** points to into the variable that **dst** points to. The function returns **0** on success and **–1** in case of error.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESnumeric_from_double(double d, numeric* dst)	Converts a double-precision variable into a numeric variable.	This function accepts a double-precision variable and stores the result in the variable that **dst** points to. The function returns **0** on success and **–1** in case of error.
int PGTYPESnumeric_to_double(numeric* nv, double* dp)	Converts a numeric variable into a double-precision variable.	This function converts the numeric value in the variable that **nv** points to into a double-precision variable that **dp** points to. The function returns **0** on success and **–1** in case of error (or overflow). When overflow occurs, the global variable **errno** is additionally set to **PGTYPES_NUM_OVERFLOW**.
int PGTYPESnumeric_to_int(numeric* nv, int* ip)	Converts a numeric variable into an int variable.	This function converts the numeric value in the variable that **nv** points to into an int variable that the IP address points to. The function returns **0** on success and **–1** in case of error (or overflow). When overflow occurs, the global variable **errno** is additionally set to **PGTYPES_NUM_OVERFLOW**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESnumeric_to_long(numeric* nv, long* ip)	Converts a numeric variable into a long int variable.	This function converts the numeric value in the variable that **nv** points to into a long int variable that the IP points to. The function returns **0** on success and **–1** in case of error (or overflow). When overflow occurs, the global variable **errno** is additionally set to **PGTYPES_NUM_OVERFLOW**.
int PGTYPESnumeric_to_decimal(numeric* src, decimal* dst)	Converts a numeric variable into a decimal variable.	This function converts the numeric value in the variable that **src** points to into a decimal variable that **dst** points to. The function returns **0** on success and **–1** in case of error (or overflow). When overflow occurs, the global variable **errno** is additionally set to **PGTYPES_NUM_OVERFLOW**.
int PGTYPESnumeric_from_decimal(decimal* src, numeric* dst)	Converts a decimal variable into a numeric variable.	This function converts the decimal value in the variable that **src** points to into a numeric variable that **dst** points to. The function returns **0** on success and **–1** in case of error (or overflow).

Examples

For details, see **Examples**.

5.7.16.3 Date Type

Table 5-96 lists the common date type APIs provided by ECPG.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-96 Common date type APIs

API	Description	Remarks
date* PGTYPESdate_new(void)	Returns a pointer to an allocated date variable.	This function creates a date variable on the heap. The return value is of the date* type.
void PGTYPESdate_free(date*)	Releases the memory that has been allocated to a date variable.	Frees a date* variable created using the PGTYPESdate_free function.
date PGTYPESdate_from_asc(char* str, char** endptr)	Parses a date from its textual representation.	This function accepts a C string **str** and a pointer to a C string **endptr**. ECPG converts the date expressed in text into a character string. Currently, ECPG does not support storing the address of the first invalid character in ***endptr**. However, **endptr** can be set to null. Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within ECPG.
char* PGTYPESdate_to_asc(date dDate)	Returns the textual representation of a date variable.	This function accepts the date **dDate** as its unique parameter. It will output the date in the YYYY-MM-DD format.
date PGTYPESdate_from_timestamp(timestamp dt)	Extracts the date part from a timestamp.	This function accepts a timestamp as its unique parameter and returns the extracted date part from the timestamp.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
void PGTYPESdate_julmdy(date jd, int* mdy)	Extracts the values of day, month, and year from a variable of the date type.	This function accepts the date **jd** and a pointer to an array of three integer values **mdy**. The variable name indicates the sequence. **mdy[0]** indicates the month, **mdy[1]** indicates the day, and **mdy[2]** indicates the year.
void PGTYPESdate_mdyjul(int * mdy, date* jdate)	Creates a date using the specified integer value.	This function accepts an array consisting of three integers (**mdy**) as its first parameter. The three integers are used to indicate the day, month, and year, respectively. The second parameter is a pointer to a variable of the date type, which is used to store the result of the operation.
int PGTYPESdate_dayofweek(date d)	Returns a number indicating the day of a week for a date value.	This function accepts the date variable **d** as its unique parameter and returns an integer indicating the day of the week.
void PGTYPESdate_today(date * d)	Returns the current date.	This function accepts a pointer to a date variable *d* and sets the parameter to the current date. • **0**: Sunday • **1**: Monday • **2**: Tuesday • **3**: Wednesday • **4**: Thursday • **5**: Friday • **6**: Saturday

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESdate_defmt_asc(date* d, const char* fmt, char* str)	Converts a C char* string to a value of the date type using a format mask.	This function accepts a pointer **d** pointing to a date value for storing the operation result, a format mask **fmt** for parsing the date, and a C char* string **str** containing the textual representation of the date. The textual representation is expected to match the format mask. However, you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals "yy" or "yyyy" that indicate the position of the year, "mm" indicating the position of the month and "dd" indicating the position of the day. Example of valid input (fmt, str): `yy/mm/dd 1994, February 3rd`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPESdate_fmt_asc(dat dDate, const char* fmtstring, char* outbuf)	Converts a variable of the date type into its textual representation using a format mask.	This function accepts the date **dDate** to be converted, the format mask **fmtstring**, and the string **outbuf** of the textual representation of the date to be saved. The function returns **0** on success and a negative value in case of error. The following is an example of valid input: 112359 //mmddyy 59/11/23 //yy/mm/dd Nov.23,1959 //mmm.dd,yyyy Mon,Nov.23,1959 // ddd,mmm.dd,yyyy Format: • **dd**: indicates the day of a month. • **mm**: indicates the month of a year. • **yy**: indicates a two-digit year. • **yyyy**: indicates a four-digit year. • **ddd**: indicates the day of a week. • **mmm**: indicates the month.

Examples

For details, see **Examples**.

5.7.16.4 Timestamp Type

Table 5-97 lists the common APIs for timestamp data provided by ECPG.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-97 Common timestamp type APIs

API	Description	Remarks
timestamp PGTYPEStimestamp_from_asc(char *str, char **endptr)	Parses a timestamp from its textual representation into a timestamp variable.	This function accepts a string **str** to parse and a pointer to a C char* **endptr**. It returns the parsed timestamp on success and **PGTYPESInvalidTimestamp** in case of error. In addition, **errno** is set to **PGTYPES_TS_BAD_TIMESTAMP** when an error occurs. The valid input of **PGTYPEStimestamp_from_asc** is as follows: 1999-01-08 04:05:06 January 8 04:05:06 1999 PST 1999-Jan-08 04:05:06.789-8 1999-01-08 04:05:06.789 (time zone specifier ignored) J2451187 04:05-08:00 1999-01-08 04:05:00 (time zone specifier ignored)
char *PGTYPEStimestamp_to_asc(timestamp tstamp)	Converts a date to a C char* string.	This function accepts the timestamp **tstamp** as its unique parameter and returns an allocated string containing the textual representation of the timestamp. The result must be released using PGTYPESchar_free().
void PGTYPEStimestamp_current(timestamp *ts)	Returns the current timestamp.	This function obtains the current timestamp and saves it to the timestamp variable that **ts** points to.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPEStimestamp_fmt_asc(timestamp *ts, char *output, int str_len, char *fmtstr)	Converts a timestamp variable into a char* using a format mask.	This function accepts a pointer pointing to the timestamp **ts** to be converted, a pointer pointing to the output buffer **output**, the maximum length allocated to the output buffer **str_len**, and the format mask **fmtstr** for conversion as its parameters. The function returns **0** on success and a negative value in case of error.
int PGTYPEStimestamp_sub(timestamp *ts1, timestamp *ts2, interval *iv)	Subtracts a timestamp from another timestamp and saves the result in an interval variable.	This function subtracts the timestamp variable that **ts2** points to from the timestamp variable that **ts1** points to, and stores the result in the interval variable that **iv** points to. The function returns **0** on success and a negative value in case of error.
int PGTYPEStimestamp_defmt_asc(char *str, char *fmt, timestamp *d)	Parses the timestamp value from its textual representation using a format mask.	This function accepts a timestamp textual representation placed in the variable **str** and a format mask placed in the variable **fmt** that will be used for conversion. The result will be stored in the variable that **d** points to. If the format mask **fmt** is null, the function rolls back to use the default format **mask %Y- %m-%d %H: %M: %S**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description	Remarks
int PGTYPEStimestamp_add_interval(timestamp *tin, interval *span, timestamp *tout)	Adds an interval variable to a timestamp variable.	This function accepts a pointer **tin** pointing to the timestamp variable and a pointer **span** pointing to the interval variable. It adds the interval to the timestamp and then saves the result timestamp in the variable that **tout** points to. The function returns **0** on success and a negative value in case of error.
int PGTYPEStimestamp_sub_interval(timestamp* tin, interval* span, timestamp* tout)	Subtracts an interval variable from a timestamp variable.	This function subtracts the interval variable that **span** points to from the timestamp variable that **tin** points to, and then saves the result in the variable that **tout** points to. The function returns **0** on success and a negative value in case of error.

Examples

For details, see **Examples**.

5.8 Development Based on the Go Driver

5.8.1 Setting Up the Go Driver Environment

Environment Class

- **Configure the Go environment.**

  You need to configure the following parameters in the environment variables:

  - **GO111MODULE**: Set **GO111MODULE** to **on** when installing the Go driver by importing a file online. If you do not want to reconstruct the **go mod** project, set **GO111MODULE** to **off** and manually download the dependency package. The dependency package must be at the same level as the driver root directory and service code.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - **GOPROXY**: When importing data online, you need to configure the path that contains the Go driver package.
  - You can configure other Go environment variables based on your scenario parameters.

  Run the **go env** command to view the Go environment variable configuration result and check whether the Go version is 1.13 or later.

- **Install the Go driver.**
  - Obtain the Go driver package **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Go.tar.gz** from the driver package. Decompress the package to obtain the Go driver source code package.
  - Go to the root path of the Go driver code and run the **go mod tidy** command to download related dependencies. You need to configure **GOPATH=***${Path for storing the Go driver dependency package}* in the environment variables.
  - If the dependencies have been downloaded to the localhost, you can add a line "Replace the Go driver package with the local Go driver package address through replace" to **go.mod**, indicating that all import Go driver packages in the code are stored in the local path and the dependencies are not downloaded from the proxy.

CAUTION

- When you run the **go mod tidy** command to download dependencies, some of them may be downloaded as an earlier version. If the earlier version has vulnerabilities, you can change the dependency version in the **go.mod** file and update the dependency to the version after the vulnerability is fixed to avoid risks.
- Users are not involved in the driver development and can call Go driver 1.13 or later. The runtime library needs to be updated to 1.18 or later.

Driver Class

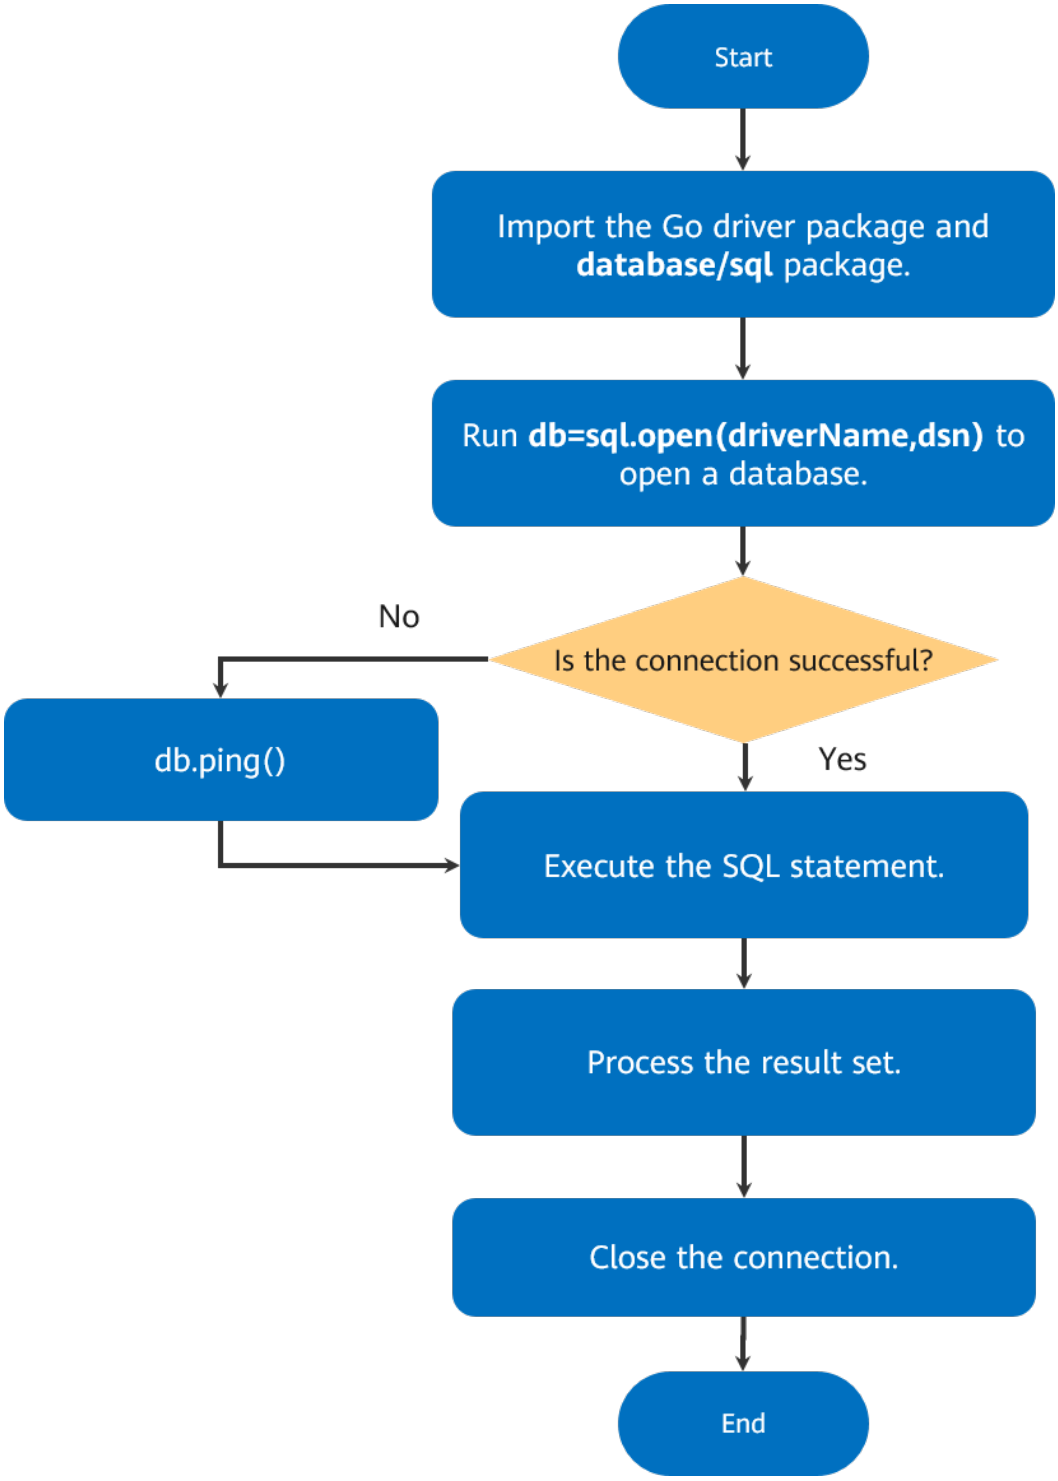
When creating a database connection, you need to enter the database driver name **gaussdb**. For details about the Go driver, see **Go Driver Compatibility**.

5.8.2 Development Process

The Go driver of the database complies with the rule of the Go language third-party library. You only need to import the driver to the application program and save the driver code in the directory specified by *GOPATH*.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 5-8 Application development process based on Go



According to **Figure 5-8**, the Go driver application development process depends on the native SQL package of Go driver and the driver developed by GaussDB. The SQL package provides standard interfaces that are used for the implementation of GaussDB for users.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.8.3 Connecting to a Database

When you call the standard SQL API **open** of the Go language to create a database connection, a connection object is returned to transfer the driver name and description string.

Function Prototype

The Go driver provides the following method to generate a database connected object:

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Parameter description:

- **driverName** indicates the driver name. The database driver name is **gaussdb**.
- **dataSourceName** indicates the data source to be connected. The value can be in DSN or URL format.
  - DSN format: key1 = value1 key2 = value2.... Different groups of keywords are separated by space. The space on the left and right of the equal sign (=) is optional.
  - URL format: driverName://[userspec@][hostspec][/dbname][?paramspec]

    driverName indicates the driver name. The database driver name is **gaussdb**.

    userspec indicates user[:password]. When a URL is used for connection, the password cannot contain separators in the URL string. If the password contains separators, the DSN format is recommended.

    hostspec indicates [host][:port][, ...].

    dbname indicates the database name. Note: The initial user cannot be used for remote login. **paramspec** indicates name=value[&...].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- In the DSN format, if there are multiple IP addresses:
  - When the value of **num(ip)** is the same as that of **num(port)**, the IP address matches the port number.
  - When the value of **num(ip)** is greater than that of **num(port)**, the IP address that cannot match the port number matches the first port number. For example, the mapping condition result of **host = ip1, ip2, ip3 port = port1, port2** is **ip1:port1, ip2:port2, ip3:port1**.
  - If the value of **num(ip)** is smaller than that of **num(port)**, the extra port numbers are discarded. For example, the mapping result of **host = ip1, ip2, ip3 port = port1, port2, port3, port4** is **ip1:port1, ip2:port2, ip3:port3**.
- In the URL format, if there are multiple IP addresses:
  - In the URL, *ip*:*port* must appear in pairs, that is, the value of **num(ip)** is the same as that of **num(port)**. Use commas (,) to separate multiple pairs. Example: **gaussdb://user:password@ip1:port1, ip2:port2, ip3:port3/gaussdb**.
  - The URL contains only multiple IP addresses. The port number is specified by the environment variable or uses the default value **5432**. For example, in the case of **gaussdb://user:password@ip1, ip2, ip3/gaussdb**, if the environment variable is set as **PGPORT = "port1, port2"**, the mapping is **ip1:port1, ip2:port2, ip3:port1**; If the environment variable is not set, the mapping is **ip1:5432,ip2:5432,ip3:5432**.
- If you enter an IPv6 address, enclose the IP address in square brackets ([]) in a URL connection string, for example, **gaussdb://user:password@[ip1]:port1, [ip2]:port2, [ip3]:port3/gaussdb**.

Parameters

Table 5-98 Database connection parameters

Parameter	Description
host	IP address of the host server, which can also be specified by the environment variable *${PGHOST}*
port	Port number of the host server, which can also be specified by the environment variable *${PGPORT}*
dbname	Database name, which can also be specified by the environment variable *${PGDATABASE}*
user	Username to be connected, which can also be specified by the environment variable *${PGUSER}*
password	Password of the user to be connected

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
connect_timeout	Timeout interval for connecting to the server, which can also be specified by the environment variable *${PGCONNECT_TIMEOUT}*
sslmode	SSL encryption mode, which can also be specified by the environment variable *${PGSSLMODE}* Value range: ● **disable**: SSL connection is disabled. ● **allow**: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. ● **prefer**: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. ● **require**: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. ● **verify-ca**: SSL connection is required, and whether the server certificate is issued by a trusted CA is verified. ● **verify-full**: SSL connection is required, and whether the server certificate is issued by a trusted CA and whether the host name of the server is the same as that in the certificate are verified.
sslkey	Key location of the client certificate. If SSL connection is required and this parameter is not specified, you can set the environment variable *${PGSSLKEY}* to specify the location.
sslcert	File name of the client SSL certificate, which can also be specified by the environment variable *${PGSSLCERT}*
sslrootcert	Name of the file that contains the SSL CA certificate, which can also be specified by the environment variable *${PGSSLROOTCERT}*
sslcrl	File name of the SSL CRL. If a certificate listed in this file exists, the server certificate authentication will be rejected and the connection will fail. The value can also be specified by the environment variable *${PGSSLCRL}*.
sslpassword	Passphrase used to decrypt a key into plaintext. If this parameter is specified, the SSL key is an encrypted file. Currently, the SSL key supports DES encryption and AES encryption. **NOTE** The DES encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
disable_prepared_binary_result	The value of this parameter is a string. If it is set to **yes**, the connection should not use the binary format when the query results are received from prepared statements. This parameter is used only for debugging. Value range: **yes** and **no**.
binary_parameters	Specifies whether **[]byte** is always sent in binary format. The value is a string. Value range: **yes** and **no**. If this parameter is set to **yes**, you are advised to bind parameters based on **[]byte** to reduce internal type conversion.
target_session_attrs	Connection type of the database, which can also be specified by the environment variable *${PGTARGETSESSIONATTRS}*. This parameter is used to identify the primary and standby nodes. There are six value options, namely, **any**, **master**, **slave**, **preferSlave**, **read-write**, and **read-only**. The default value is **any**. ● **any**: attempts to connect to any DN in the URL connection string. ● **master**: attempts to connect to a primary node in the URL connection string. If the primary node cannot be found, an exception is thrown. ● **slave**: attempts to connect to a standby node in the URL connection string. If the standby node cannot be found, an exception is thrown. ● **preferSlave**: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN. ● **read-write**: specifies that only the primary node can be connected. ● **read-only**: specifies that only the standby node can be connected.
loggerLevel	Log level, which is used to print debugging information. The value can also be specified by the environment variable *${PGLOGGERLEVEL}*. The value can be **trace**, **debug**, **info**, **warn**, **error**, or **none**, in descending order of priority. **NOTE** If logs or error information contains security-related keywords (such as PASSWORD, GS_ENCRYPT, and IDENTIFIED), the Go driver uses ********** to replace related information.
application_name	Name of the Go driver that is being connected. The default value is **go-driver**. You are advised not to configure this parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
RuntimeParams	Value of the GUC parameter of the set type that is run by default when a session is connected, for example, **search_path**, **application_name**, and **timezone**. For details about the parameters, see the default settings of the client connection. You can run the **SHOW** command to check whether the parameters are set successfully.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description

autoBalance	Character string type. Use this parameter to enable load balancing connections in the distributed environment. The value can be **true**, **balance**, **roundrobin**, **shuffle**, **priorityn** and **false**. The default value is **false**.
	1. If this parameter is set to **true**, **balance**, or **roundrobin**, the Go SQL load balancing function is enabled to balance multiple connections of an application to each CN available in the cluster.
	Example:
	`gaussdb://user:password@host1:port1,host2:port2/database?autoBalance=true`
	The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is **host1:port1,host2:port2,host3:port3,host4:port4**. The **refreshCNIpsTime** parameter specifies the interval for obtaining the list, and the default value is **10s**.
	When **autoBalance** is enabled on **host1** and **host2**, HA is implemented only for the first connection. The driver will select available CNs from **host1**, **host2**, **host3**, and **host4** in sequence to update the available CN list and **Connector.Connect** will be called on **host1**, **host2**, **host3**, and **host4** using the round robin algorithm.
	2. **priority***n* indicates that the driver priority-based load balancing function is enabled. Multiple connections of an application are balanced to the first *n* available CNs configured in the URL. When the first *n* CNs are unavailable, connections are randomly allocated to other available CNs in the database cluster. *n* is a number not less than 0 and less than the number of CNs configured in the URL.
	Example:
	`gaussdb://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=priority2`
	The driver periodically obtains the list of available CNs in the entire cluster (defined by **refreshCNIpsTime**). For example, the obtained list is **host1:port1,host2:port2,host3:port3,host4:port4,host5:port5,host6:port6**, where **host1** and **host2** are in **AZ1**, and **host3** and **host4** are in **AZ2**.
	The driver preferentially selects **host1** and **host2** for load balancing. If both **host1** and **host2** are unavailable, the driver randomly selects a CN from **host3**, **host4**, **host5**, and **host6** for connection.
	3. If this parameter is set to **shuffle**, the driver random load balancing is enabled to randomly and evenly distribute multiple connections of the application to available CNs in the database cluster.
	Example:
	`gaussdb://user:password@host1:port1,host2:port2,host3:port3/database?autoBalance=shuffle`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
	The driver periodically obtains the list of available CNs in the entire cluster. For example, the obtained list is **host1:port1,host2:port2,host3:port3,host4:port4**. The **refreshCNIpsTime** parameter specifies the interval for obtaining the list, and the default value is **10s**. For the first connection, **host1:port1,host2:port2,host3:port3** is used for HA. For subsequent connections, the shuffle algorithm is used to randomly select a CN from the refreshed CN list. 4. If this parameter is set to **false** in the centralized scenarios, the driver load balancing and priority-based load balancing functions are disabled. The default value is **false**. **NOTE** Load balancing is based on the connection level rather than the transaction level. If the connection is persistent and the load on the connection is unbalanced, the load on the CN may be unbalanced. Load balancing can be used only in distributed scenarios and cannot be used in centralized scenarios.
recheckTime	Integer type. Use this parameter to specify the interval at which the driver periodically checks the status of CNs in the database cluster and obtains the IP address list of available CNs. The value ranges from 5s to 60s and the default value is **10s**.
usingEip	Character string. This value specifies whether to use an elastic IP address for load balancing. The default value is **yes**, indicating that an elastic IP address is used for load balancing. The value **no** indicates that a data IP address is used for load balancing.

5.8.4 Connecting to the Database (Using SSL)

The Go driver supports SSL connections to the database. After the SSL mode is enabled, if the Go driver connects to the database server in SSL mode, the Go driver uses the standard TLS 1.3 protocol by default, and the TLS version must be 1.2 or later. This section describes how applications configure the client in SSL mode through the Go driver.

NOTE

In SSL-based certificate authentication mode, you do not need to specify the user password in the connection string.

Configuring the Client

Before performing the steps below, log in to the GaussDB management console. On the **Instances** page, click the instance name to go to the **Basic Information**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

page. On the displayed page, click under **SSL** to download the root certificate or certificate bundle, and save the **ca.pem** root certificate to the client.

Example:

```
package main
// Set the dependency package using its path from the environment.
import (
 "database/sql"
 "fmt"
 _ [Go_driver_module_name] /* Replace it with the actual Go driver module name. */
 "log"
)
// One-way authentication is used as an example. In this example, the username and password are stored in environment variables. Before running this example, set environment variables in the local environment as required.
func main() {
 hostip := os.Getenv("GOHOSTIP")    // GOHOSTIP indicates the IP address written into the environment variable.
 port := os.Getenv("GOPORT")        // GOPORT indicates the port number written into the environment variable.
 usrname := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the environment variable.
 passwd := os.Getenv("GOPASSWD")    // GOPASSWDW indicates the user password written into the environment variable.
 sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the environment variable.
 dsnStr := "host=" + hostip + " port=" + port + " user=" + usrname + " password=" + passwd + " dbname=gaussdb"
 parameters := []string{
  " sslmode=verify-ca sslrootcert=certs/ca.pem",
 }
 for _, param := range parameters {
  db, err := sql.Open("gaussdb", dsnStr+param)
  if err != nil {
   log.Fatal(err)
  }
  var f1 int
  err = db.QueryRow("select 1").Scan(&f1)
  if err != nil {
   log.Fatal(err)
        } else {
   fmt.Printf("RESULT: select 1: %d\n", f1)
  }
  db.Close()
 }
}
```

5.8.5 Go APIs

5.8.5.1 sql.Open

The following table describes sql.Open.

Method	Description	Return Value
Open(driverName, dataSourceName string)	Opens a database based on a specified database driver and the dedicated data source of the driver.	*DB and error

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

For details about driverName and dataSourceName, see **Connecting to a Database**.

5.8.5.2 type DB

The following table describes type DB.

Method	Description	Return Value
(db *DB)Begin()	Starts a transaction. The isolation level of the transaction is determined by the driver.	*Tx and error
(db *DB)BeginTx(ctx context.Context, opts *TxOptions)	Starts a transaction with a specified transaction isolation level. A specified context is used until the transaction is committed or rolled back. If the context is canceled, the SQL package rolls back the transaction.	*Tx and error
(db *DB)Close()	Closes the database and releases all the opened resources.	error
(db *DB)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(db *DB)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(db *DB)Ping()	Checks whether the database connection is still valid and establishes a connection if necessary.	error
(db *DB)PingContext(ctx context.Context)	Checks whether the database connection is still valid in a specified context and establishes a connection if necessary.	error
(db *DB)Prepare(query string)	Creates a prepared statement for subsequent queries or executions.	*Stmt and error
(db *DB)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions in a specified context.	*Stmt and error
(db *DB)Query(query string, args ...interface{})	Executes a query and returns multiple rows of data.	*Rows and error

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Method	Description	Return Value
(db *DB)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query and returns multiple rows of data in a specified context.	*Rows and error
(db *DB)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(db *DB)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row

Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see **Examples**.
opts	Transaction isolation level and transaction access mode. The transaction isolation level (opts.Isolation) supports sql.LevelReadUncommitted,sql.LevelReadCommitted,sql.LevelRepeatableRead,sql.LevelSerializable. The transaction access mode (**opts.ReadOnly**) can be **true** (read only) or **false** (read write).

NOTICE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables in the local environment (set the environment variable names based on the actual situation).
package main
/* The location of the Go driver dependency package is set based on the configured go.mod. */
import (
 "database/sql"
 _ [Go driver module name] /* Replace it with the actual Go driver module name. */
 "log"
)

func main() {
 hostip := os.Getenv("GOHOSTIP")    // GOHOSTIP indicates the IP address written into the environment variable.
 port := os.Getenv("GOPORT")        // GOPORT indicates the port number written into the environment variable.
 usrname := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username for writing environment variables.
 passwd := os.Getenv("GOPASSWD")    // GOPASSWDW indicates the user password written into the environment variable.
 str := "host=" + hostip + " port=" + port + " user=" + usrname + " password=" + passwd + " dbname=gaussdb sslmode=disable"
 db, err := sql.Open("gaussdb", str)
 if err != nil {
  log.Fatal(err)
 }
 defer db.Close()

 err = db.Ping()
 if err != nil {
  log.Fatal(err)
 }

 _, err = db.Exec("create table test_bound(id int, name text)")

    // Binding by location
    _, err = db.Exec("insert into test_bound(id, name) values(:1, :2)", 1, "Zhang San")
 if err != nil {
  log.Fatal(err)
 }

    // Binding by name
    _, err = db.Exec("insert into test_bound(id, name) values(:id, :name)", sql.Named("id", 1), sql.Named("name", "Zhang San"))
 if err != nil {
  log.Fatal(err)
 }
}
```

5.8.5.3 type Stmt

The following table describes type Stmt.

Method	Description	Return Value
(s *Stmt)Close()	Closes a specified prepared statement.	error

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(s *Stmt)Exec(args ...interface{})	Executes a prepared statement with specified parameters and returns a **Result** value. The Prepare-Bind-Execute (PBE) feature is supported. PBE is a method of sending and executing queries. The CN can receive PBE packets through complex query protocols to execute statements.	Result and error

	NOTE 1. The placeholder of a prepared statement can be a dollar sign ($) or a question mark (?). 2. The number of placeholders in a prepared statement is determined by the database. When the number of table columns exceeds the database limit or does not match the number of current table columns, the server returns an error. 3. Batch PBE processing supports addition, deletion, and modification. During the batch operation, the maximum length of a U packet is limited to 1 GB minus 1 byte, that is, 0x3fffffff bytes. If the length exceeds the limit, "bind message length XXX too long. This can be caused by very large or incorrect length specifications on InputStream parameters" will be reported. 4. When a record is inserted, the performance of PBE deteriorates greatly compared with that of a single-query statement (conn.simpleExec). Therefore, you are advised to use single-query statements, rather than the PBE statement. 5. After the underlying error processing of the driver is reconstructed, the PBE performance decreases by less than 5%.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(s *Stmt)ExecContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns a **Result** value.	Result and error
(s *Stmt)Query(args ...interface{})	Executes a prepared statement with specified parameters and returns ***Rows** as the query result.	*Rows and error
(s *Stmt)QueryContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns ***Rows** as the query result.	*Rows and error
(s *Stmt)QueryRow(args ...interface{})	Executes a prepared statement with specified parameters and returns ***Row** as the result.	*Row
(s *Stmt)QueryRowContext (ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns ***Row** as the result.	*Row

Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see **Examples** in section "type DB."

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

5.8.5.4 type Tx

The following table describes type Tx.

Method	Description	Return Value
(tx *Tx)Commit()	Commits a transaction.	error
(tx *Tx)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(tx *Tx)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(tx *Tx)Prepare(query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.	*Stmt and error

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(tx *Tx)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back. The specified context will be used in the preparation phase, not in the transaction execution phase. The statement returned by this method will be executed in the transaction context.	*Stmt and error
(tx *Tx)Query(query string, args ...interface{})	Executes a query that returns rows of data.	*Rows and error
(tx *Tx)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns rows of data in a specified context.	*Rows and error
(tx *Tx)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(tx *Tx)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row
(tx *Tx) Rollback()	Rolls back a transaction.	error

(tx *Tx)Stmt(stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement.
	Example:
	`str, err := db.Prepare("insert into t1 values(:1, :2)")`
	`tx, err := db.Begin()`
	`res, err := tx.Stmt(str).Exec(1, "aaa")`
		*Stmt

(tx *Tx)StmtContext(ctx context.Context, stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement in a specified context.	*Stmt

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see **Examples** in section "type DB."
stmt	Existing prepared statement, which is generally the prepared statement returned by the PREPARE statement

NOTICE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

5.8.5.5 type Rows

The following table describes type Rows.

Method	Description	Return Value
(rs *Rows)Close()	Closes **Rows** to stop the iteration of the data set.	error
(rs *Rows)ColumnTypes()	Returns column information.	[]*ColumnType and error
(rs *Rows)Columns()	Returns the name of each column.	[]string and error
(rs *Rows)Err()	Returns any errors that occur during iteration.	error

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(rs *Rows)Next()	Prepares the next data row to be read with the Scan method. If there is an additional result set, **true** is returned. Otherwise, **false** is returned.	boolean
(rs *Rows)Scan(dest ...interface{})	Copies the columns of the current iterated row of data to the value specified by **dest**.	error
(rs *Rows)NextResultSet()	Specifies whether there is an additional result set.	boolean

Parameters

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

5.8.5.6 type Row

The following table describes type Row.

Method	Description	Return Value
(r *Row)Scan(dest ...interface{})	Copies the columns in the current row of data to the value specified by **dest**.	error
(r *Row)Err()	Returns errors that occur during execution.	error

Parameter Description

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

5.8.5.7 type ColumnType

The following table describes type ColumnType.

Method	Description	Return Value

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

(ci *ColumnType)DatabaseTypeName()	Returns the name of the column-type database system. If an empty string is returned, driver-type names are not supported.	error
(ci *ColumnType)DecimalSize()	Returns the scale and precision of the decimal type. If the value of **ok** is **false**, the specified type is unavailable or not supported.	precision, scale int64, ok boolean
(ci *ColumnType)Length()	Returns the length of the data column type. If the value of **ok** is **false**, the specified type does not have a length.	length int64, ok boolean
(ci *ColumnType)ScanType()	Returns a Go type that can be used for scanning by using Rows.Scan.	reflect.Type
(ci *ColumnType)Name()	Returns the name of a data column.	string

5.8.5.8 type Result

The following table describes type Result.

Method	Description	Return Value
(res Result)RowsAffected()	Returns the number of rows affected by the INSERT, DELETE, UPDATE, SELECT, MOVE, FETCH, and COPY operations.	int64 and error

5.9 Compatibility Reference

JDBC Compatibility Package

Obtain the driver JAR package from the driver package **GaussDB-Kernel**_*Database version number*_*OS version number*_**64bit_Jdbc.tar.gz**.

The JDBC-compatible JAR packages are as follows:

- **gsjdbc4.jar**: The main class name is **org.postgresql.Driver**, and the URL prefix of the database connection is **jdbc:postgresql**. This driver package applies to the scenario where services are migrated from PG database. The driver class and loading path are the same as those before the migration, but the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

supported APIs are different. The APIs that are not supported need to be adjusted on the service side.

- **gsjdbc200.jar**: This driver package applies to the scenario where services are migrated from Gauss200. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**, and the URL prefix of the database connection is **jdbc:opengauss**. This driver package is used when both the PG database and GaussDB are accessed in a JVM process.

NOTICE

- The loading paths and URL prefixes of driver classes vary in different driver packages, but the functions are the same.
- The **gsjdbc4** driver package cannot be used to operate the PG database. Although the connection can be successfully established in some versions, some API behaviors are different from those of PG JDBC, which may cause unknown errors.
- The PG driver package cannot be used to operate GaussDB. Although the connection can be successfully established in some versions, some API behaviors are different from those of GaussDB JDBC, which may cause unknown errors.

Go Driver Compatibility

- The Go driver provided by the database does not adapt to mature ORM frameworks (such as XORM) in the industry. As such, the driver name input during database connection creation must be compatible with Postgres and PostgreSQL.
- The Go driver of the database cannot coexist with that of PostgreSQL.

ecpg Compatibility

ecpg provides the URL connection syntax which supports GaussDB and is compatible with PostgreSQL.

Connection syntax:

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

To support PostgreSQL, **target** is set as follows:

- tcp:postgresql://*hostname*[:*port*][/*dbname*][?*options*]
- unix:postgresql://*hostname*[:*port*][/*dbname*][?*options*]

5.10.1.1 Data Type Mapping

The relationships among data types, Java variable types, and JDBC type indexes are as follows (ORA: Oracle-compatible; MYSQL: MySQL-compatible).

Compatibility Mode	GaussDB Data Type	Java Variable Type	JDBC Type Index
ORA/MYSQL	oid	java.lang.Long	java.sql.Types.BIGINT
ORA/MYSQL	numeric	java.math.BigDecimal	java.sql.Types.NUMERIC
ORA/MYSQL	tinyint	java.lang.Integer	java.sql.Types.TINYINT
ORA/MYSQL	smallint	java.lang.Integer	java.sql.Types.SMALLINT
ORA/MYSQL	bigint	java.lang.Long	java.sql.Types.BIGINT
ORA/MYSQL	float4	java.lang.Float	java.sql.Types.REAL
ORA/MYSQL	float8	java.lang.Double	java.sql.Types.DOUBLE
ORA/MYSQL	char	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	character	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	bpchar	java.lang.String	java.sql.Types.CHAR
ORA/MYSQL	character varying	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	varchar	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	text	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	name	java.lang.String	java.sql.Types.VARCHAR
ORA/MYSQL	bytea	byte[]	java.sql.Types.BINARY
ORA/MYSQL	Blob	java.sql.Blob	java.sql.Types.BLOB
ORA/MYSQL	Clob	java.sql.Clob	java.sql.Types.CLOB
ORA/MYSQL	Boolean	java.lang.Boolean	java.sql.Types.BIT
ORA	Set	java.sql.Array	java.sql.Types.ARRAY
ORA	Array	java.sql.Array	java.sql.Types.ARRAY
ORA	Record	java.sql.Struct	java.sql.Types.STRUCT
MYSQL	date	java.sql.Date	java.sql.Types.DATE
ORA/MYSQL	time	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timetz	java.sql.Time	java.sql.Types.TIME
ORA/MYSQL	timestamp	java.sql.Timestamp	java.sql.Types.TIMESTAMP

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Compatibility Mode	GaussDB Data Type	Java Variable Type	JDBC Type Index
ORA/MYSQL	smalldatetime	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	timestamptz	java.sql.Timestamp	java.sql.Types.TIMESTAMP
ORA/MYSQL	refcursor	java.sql.ResultSet	java.sql.Types.REF_CURSOR java.sql.Types.OTHER

5.10.1.2 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

- Use the SLF4J log framework for interconnecting with applications.
- Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see the official documents (SLF4J: **http://www.slf4j.org/manual.html**; JdkLogger: **https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html**).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** needs to be configured in the URL. This mode supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

The SLF4J may be implemented by using Log4j or Log4j2. When Log4j is used to implement SLF4J, you need to add the **log4j-*.jar**, **slf4j-api-*.jar**, and **slf4j-log4*-*.jar** packages (*varies according to versions). In addition, specify the path (absolute or relative path) of the **log4j.properties** configuration file.

If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-*.jar**, **log4j-core-*.jar**, **log4j-slf4j18-impl-*.jar**, and **slf4j-api-*-alpha1.jar** (*varies according to versions). In addition, specify the path (absolute or relative path) of the **log4j2.xml** configuration file.

NOTICE

This method depends on the general SLF4J APIs, such as **org.slf4j.LoggerFactory.getLogger(String name)**, **org.slf4j.Logger.debug(String var1)**, **org.slf4j.Logger.info(String var1)**, **org.slf4j.Logger.warn(String warn)**, and **org.slf4j.Logger.warn(String warn)**. If these APIs are changed, logs cannot be recorded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
// Note: The path of the log4j.propertie or log4j2.xml file must be specified during calling.

// Use the log4j.properties file to configure the attributes of the log recorder, such as the log level and output target. These properties are loaded into the application by calling the configure method of PropertyConfigurator and passing the path of the log4j.properties file.
//PropertyConfigurator.configure("log4j.properties");

// Create the Log4j2 configuration source, specify the path of the log4j2.xml configuration file, and initialize the log system.
//ConfigurationSource source = new ConfigurationSource(new FileInputStream("log4j2.xml"));
//Configurator.initialize(null, source);

public static Connection GetConnection(String username, String passwd){

    String sourceURL = "jdbc:gaussdb://$ip:$port/database?logger=Slf4JLogger";
    Connection conn = null;

    try{
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL,username,passwd);
        System.out.println("Connection succeed!");
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
    return conn;
}
```

log4j.properties configuration file:

```
log4j.logger.com.huawei.gaussdb.jdbc=ALL, log_gsjdbc

# Default file output configuration
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender
log4j.appender.log_gsjdbc.Append=true
log4j.appender.log_gsjdbc.File=gsjdbc.log
log4j.appender.log_gsjdbc.Threshold=TRACE
log4j.appender.log_gsjdbc.MaxFileSize=10MB
log4j.appender.log_gsjdbc.MaxBackupIndex=5
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

log4j2.xml configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
    <appenders>
        <Console name="Console" target="SYSTEM_OUT">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </Console>
        <File name="FileTest" fileName="test.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
        </File>
        <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds 10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
        <RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
            <PatternLayout pattern="%d %p %t %c - %m%n"/>
            <Policies>
                <SizeBasedTriggeringPolicy size="10 MB"/>
            </Policies>
        </RollingFile>
    </appenders>
    <loggers>
        <root level="all">
            <appender-ref ref="Console"/>
            <appender-ref ref="FileTest"/>
        </root>
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
    <logger name="com.huawei.gaussdb.jdbc" level="all" additivity="false">
      <appender-ref ref="RollingFileJdbc"/>
    </logger>
  </loggers>
</configuration>
```

NOTICE

- In the configuration file, you can specify the configuration paths for JDBC and upper-layer services to store JDBC logs and service logs to different files.
- When multiple GaussDB data sources are configured in the same project, if **logger** is set to **Slf4JLogger** in some services, it will affect the logging configuration of each other. In this case, you are advised to configure the connection strings in a unified manner.

Method 2: Use the JdkLogger log framework for interconnecting with applications.

You can use the **logging.properties** configuration file or directly configure the parameters in the sample code.

- The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

  logging.properties configuration file:

  ```
  # Specify the processing program as a file.
  handlers= java.util.logging.FileHandler

  # Specify the default global log level.
  .level= ALL

  # Specify the log output control standard.
  java.util.logging.FileHandler.level=ALL
  java.util.logging.FileHandler.pattern = gsjdbc.log
  java.util.logging.FileHandler.limit = 500000
  java.util.logging.FileHandler.count = 30
  java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
  java.util.logging.FileHandler.append=false
  ```

- Configure the parameters in the sample code:

  ```
  System.setProperty("java.util.logging.FileHandler.pattern","jdbc.log");
  FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
  Formatter formatter = new SimpleFormatter();
  fileHandler.setFormatter(formatter);
  Logger logger = Logger.getLogger("com.huawei.gaussdb.jdbc");
  logger.addHandler(fileHandler);
  logger.setLevel(Level.ALL);
  logger.setUseParentHandlers(false);
  ```

Link Trace Function

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application requests. This function requires application developers to implement the com.huawei.gaussdb.jdbc.log.Tracer API class and specify the full class name of the API implementation class in the URL.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

URL example:

```
String url = "jdbc:gaussdb://$ip:$port/database?traceInterfaceClass=xxx.xxx.xxx.gaussdbTraceImpl";
```

The com.huawei.gaussdb.jdbc.log.Tracer API class is defined as follows:

```
public interface Tracer {
// Retrieves the value of traceId.
String getTraceId();
}
```

The following is an example of the com.huawei.gaussdb.jdbc.log.Tracer API implementation class:

```
import com.huawei.gaussdb.jdbc.log.Tracer;

public class gaussdbTraceImpl implements Tracer {
    private static MDC mdc = new MDC();

    private final String TRACE_ID_KEY = "traceId";

    public void set(String traceId) {
        mdc.put(TRACE_ID_KEY, traceId);
    }

    public void reset() {
        mdc.clear();
    }

    @Override
    public String getTraceId() {
        return mdc.get(TRACE_ID_KEY);
    }
}
```

The following is an example of context mapping which is used to store trace IDs generated for different requests:

```
import java.util.HashMap;

public class MDC {
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();

    public void put(String key, String val) {
        if (key == null || val == null) {
            throw new IllegalArgumentException("key or val cannot be null");
        } else {
            if (threadLocal.get() == null) {
                threadLocal.set(new HashMap<>());
            }
            threadLocal.get().put(key, val);
        }
    }

    public String get(String key) {
        if (key == null) {
            throw new IllegalArgumentException("key cannot be null");
        } else if (threadLocal.get() == null) {
            return null;
        } else {
            return threadLocal.get().get(key);
        }
    }

    public void clear() {
        if (threadLocal.get() == null) {
            return;
        } else {
            threadLocal.get().clear();
        }
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    }
}
```

Take the service **traceId** as an example. The prerequisite is that the table **test_trace_id (id int,name varchar(20))** is created.

```
String traceId = UUID.randomUUID().toString().replaceAll("-", "");
gaussdbTraceImpl gaussdbTrace = new gaussdbTraceImpl();
gaussdbTrace.set(traceId);
Connection con = DriverManager.getConnection(url, user, password);
pstm = con.prepareStatement("SELECT * FROM test_trace_id WHERE id = ?");
pstm.setInt(1, 1);
pstm.execute();
pstm = con.prepareStatement("INSERT INTO test_trace_id VALUES(?,?)");
pstm.setInt(1, 2);
pstm.setString(2, "test");
pstm.execute();
gaussdbTrace.reset();
```

NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceId** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceId**.
- The value of **traceId** specified by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

5.10.1.3 FAQ

5.10.1.3.1 Incorrect batchMode Settings

Symptom

Set the URL parameters **batchMode** to **on** and **reWriteBatchedInserts** to **true**. After JDBC is used to insert data in batches, a message is displayed, indicating that the number of binding parameters is inconsistent with the number of parameters required by the statement.

```
bind message supplies * parameters, but prepared statement "" requires *
```

Example:

```
// conn is a created connection object. The URL parameters for creating the connection contain &batchMode=on&reWriteBatchedInserts=true.
// Bind parameters in batches and then execute the statement. The number of bound parameters does not match the number of columns in the rewritten INSERT statement. As a result, an exception is reported.
// java.sql.BatchUpdateException: bind message supplies 3 parameters, but prepared statement "" requires 6

PreparedStatement stmt = conn.prepareStatement("insert into test_tbl values (?, ?, ?)");

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.executeBatch();
```

Cause Analysis

When **reWriteBatchedInserts** is set to **true**, multiple SQL statements are combined into one. As a result, the number of reserved parameter columns in the statement changes. If **batchMode** is set to **on**, parameters are bound based on the SQL statements before combination. As a result, the number of bound parameters is inconsistent with the number of parameters required by the statement.

Solution

If **reWriteBatchedInserts** is set to **true**, set **batchMode** to **off**.

5.10.1.3.2 Error Is Reported When Verification Is Enabled for Data Insertion in the Hibernate Framework

Symptom

The customer migrates data from the ORA-compatible database to GaussDB, and uses the DRS tool to migrate table structures. After the migration, the original service code of the customer is unavailable, and an error is reported when the Hibernate framework verifies the table structure.

```
Schema-validation: wrong column type encountered in column [execute_time] in table [abnormal_event]; found [int8 (Types#BIGINT)], but expecting [int4 (Types#INTEGER)]
```

Example:

- The structure of the **Student** table in the ORA-compatible database is as follows:
  ```
  id number(15,0)
  sid number(15,0)
  age number(10,0)
  ```
- After migrated to GaussDB using DRS, the **Student** table structure is as follows:
  ```
  id bigint
  sid bigint
  age Integer
  ```
- When the **Student** entity class information in the actual database is as follows:
  ```
  Long id
  Long sid
  Long age  -- An error is reported when the Hibernate framework verifies the table structure.
  ```

Configuration file **hibernate.cfg.xml**:

```
<hibernate-configuration>
   <session-factory>
      <!-- GaussDB connection information -->
      <property name="connection.driver_class">com.huawei.gaussdb.jdbc.Driver</property>
      <property name="connection.url">jdbc:gaussdb://x.x.x.x:xx/postgres?currentSchema=public</property>
      <property name="connection.username">xxxxxx</property>
      <property name="connection.password">xxxxxx</property>

      <!-- The following configurations are optional: -->
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
        <!-- Specify whether to support dialects. -->
        <!-- In PG-compatible mode, the following configuration must exist: -->
         <property name="dialect">org.hibernate.dialect.PostgreSQL92Dialect</property>
        <!-- In A-compatible mode, you are advised to change the configuration as follows: -->
<!--        <property name="dialect">org.hibernate.dialect.OracleDialect</property>-->

        <property name="met"></property>

        <!-- Specify whether to print SQL statements when CURD is executed. -->
        <property name="show_sql">true</property>
        <!-- The table is created automatically. -->
<!--        <property name="hbm2ddl.auto">create</property>-->
        <!-- Enable the verification when inserting data. -->
        <property name="hbm2ddl.auto">validate</property>
        <!-- Disable the verification. -->
<!--        <property name="hbm2ddl.auto">none</property>-->

        <!-- Resource registration (entity class mapping file) -->
        <mapping resource="student.xml"/>
    </session-factory>
</hibernate-configuration>
```

Main function for inserting data:

```
// Create the object to be tested.
Student student = new Student();
student.setId(20L);
student.setAge(222L);
student.setSid(222L);

// Start a transaction and obtain an object based on the session.
Configuration conf = new Configuration().configure();
SessionFactory sessionFactory = conf.buildSessionFactory();
Session session = sessionFactory.openSession();
Transaction transaction = session.beginTransaction();

// Save data using sessions.
session.save(student);

// Commit a transaction.
transaction.commit();

// After the operation is complete, close the session connection object.
session.close();
```

Cause Analysis

1. If the data can be successfully inserted into the ORA-compatible database and passes the verification: When verifying data, the Hibernate framework compares **TypeCode** of the inserted data type java.lang.Long with that of the number type in the table structure. If they are inconsistent, the Hibernate framework compares **sqlType** of the inserted data of the long type with **Type** of the table structure and the long type is converted to number(19,0) (the mapping is maintained by the org.hibernate.dialect.OracleDialect). The type of the table structure is number, and number(19,0) starts with **number**. Therefore, the verification is successful. When the ORA-compatible database is used, the service code involves data of the integer type. You can use the java.lang.Long type in Java to insert the data.
2. If the GaussDB verification is different and the data is inserted successfully after the verification is disabled: When the Hibernate framework verifies the inserted data, the service code is of the java.lang.Long type, which corresponds to **TypeCode** of the table data type bigint. Therefore, no error is reported. If the table data type is integer, the system checks **TypeCode** of the java.lang.Long type in the service code and compares it with that of the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

integer type in the table data. If they are inconsistent, the system converts the long type to int8 based on the org.hibernate.dialect.PostgreSQLDialect mapping, the table data type integer is converted to int4, which cannot be matched. As a result, the verification fails. When GaussDB is used, the service code involves data of the integer type. Therefore, the Java integer corresponding to the table type must be used.

Solution

You can use the following methods to rectify the fault:

- Disable the verification function.
- Modify the service code at the customer side and use the corresponding Java integer for different table data types.

5.10.1.3.3 Error Is Reported or Connection Is Blocked in SSL Mode

Symptom

When JDBC establishes a connection in SSL mode, a strong random number is obtained on the client. During the connection establishment, the following error information may be reported.

Scenario 1: Error report.

```
"Thread-0" #18 prio=5 os_prio=0 tid=0x00007f2ad0385000 nid=0x5429 runnable [0x00007f2aa069b000]
   java.lang.Thread.State: RUNNABLE
        at java.io.FileInputStream.readBytes(Native Method)
        at java.io.FileInputStream.read(FileInputStream.java:255)
        at sun.security.provider.NativePRNG$RandomIO.readFully(NativePRNG.java:424)
        at sun.security.provider.NativePRNG$RandomIO.ensureBufferValid(NativePRNG.java:526)
        at sun.security.provider.NativePRNG$RandomIO.implNextBytes(NativePRNG.java:545)
        - locked <0x000000067273a950> (a java.lang.Object)
        at sun.security.provider.NativePRNG$RandomIO.access$400(NativePRNG.java:331)
        at sun.security.provider.NativePRNG$Blocking.engineNextBytes(NativePRNG.java:268)
        at java.security.SecureRandom.nextBytes(SecureRandom.java:468)
        at java.security.SecureRandom.next(SecureRandom.java:491)
        at java.util.Random.nextInt(Random.java:329)
        at sun.security.ssl.SSLContextImpl.engineInit(SSLContextImpl.java:106)
        at javax.net.ssl.SSLContext.init(SSLContext.java:282)
        at org.postgresql.ssl.LibPQFactory.<init>(LibPQFactory.java:175)
        at org.postgresql.core.SocketFactoryFactory.getSslSocketFactory(SocketFactoryFactory.java:62)
        at org.postgresql.ssl.MakeSSL.convert(MakeSSL.java:33)
        at org.postgresql.core.v3.ConnectionFactoryImpl.enableSSL(ConnectionFactoryImpl.java:723)
        at org.postgresql.core.v3.ConnectionFactoryImpl.tryConnect(ConnectionFactoryImpl.java:203)
        at org.postgresql.core.v3.ConnectionFactoryImpl.openConnectionImpl(ConnectionFactoryImpl.java:330)
        at org.postgresql.core.ConnectionFactory.openConnection(ConnectionFactory.java:58)
        at org.postgresql.jdbc.PgConnection.<init>(PgConnection.java:357)
```

Scenario 2: The connection is blocked. If **loginTimeout** is set in the URL connection string, the message "Connection attempt timed out" is displayed. If this parameter is not set, the connection is blocked.

Cause Analysis

The random number generation on the client is too slow to meet product requirements. The entropy source is insufficient. As a result, the service fails to be started. This problem exists in some Linux environments.

Solution

Solution 1: Start the haveged service on the client and increase the entropy value of the system entropy pool to improve the speed of reading random numbers. The startup command is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
systemctl start haveged
```

Method 2: Adjust the JDK configuration on the client.

Open the *$JAVA_PATH*/**jre/lib/security/java.security** file and modify the following configuration items:

```
securerandom.source=file:/dev/./urandom
securerandom.strongAlgorithms=NativePRNGNonBlocking:SUN
```

NOTICE

The essence of solution 2 is to use pseudo-random numbers instead of strong random numbers to reduce the entropy value to be consumed. All applications that use the JDK on the client are affected. Pseudo-random numbers are used to instead of strong random numbers.

5.10.2 libpq

5.10.2.1 Connection Parameters

Table 5-99 Connection parameters

Parameters	Description
host	Name of the host to connect to. If the host name starts with a slash (/), UDS communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If **host** is not specified, the default behavior is to connect to the UDS in the **/tmp** directory (or the socket directory specified during GaussDB installation). On a machine without a UDS, the default behavior is to connect to **localhost**. You can specify multiple host names by using a character string separated by commas (,). Multiple host names can be specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
hostaddr	IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If the machine supports IPv6, IPv6 address can also be used. If a non-null string is specified, TCP/IP communications are used. You can specify multiple IP addresses by using a character string separated by commas (,). Multiple IP addresses can be specified. Replacing **host** with **hostaddr** can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used: 1. If **host** is specified but **hostaddr** is not, a query for the host name will be executed. 2. If **hostaddr** is specified but **host** is not, the value of **hostaddr** is the server network address. If the host name is required for authentication, the connection attempt fails. 3. If both **host** and **hostaddr** are specified, the value of **hostaddr** is the server network address. The value of **host** is ignored unless it is required by authentication, in which case it is used as the host name. **NOTICE** • If **host** is not the server name in the network address specified by **hostaddr**, the authentication may fail. • If neither **host** nor **hostaddr** is specified, libpq will use a local UDS for connection. If the machine does not have a UDS, it will attempt to connect to **localhost**.
port	Port number of the host server, or the socket file name extension for UDS connections. You can specify multiple port numbers by using a character string separated by commas (,). Multiple port numbers can be specified.
user	Name of the user to be connected. By default, the username is the same as the OS name of the user running the application.
dbname	Database name. The default value is the same as the username.
password	Password to be used if the server requires password authentication.
connect_timeout	Maximum timeout period of the connection, in seconds (written as a decimal integer string). The value **0** or null indicates infinity. You are advised not to set the connection timeout period to a value less than 2 seconds.
client_encoding	Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use **auto** to determine the correct encoding from the current environment in the client (the *LC_CTYPE* environment variable in the Unix system).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
tty	This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent).
options	Adds command-line options to send to the server at runtime.
application_name	Current user identity.
fallback_application_name	Specifies a backup value for the **application_name** parameter. This value is used if no value is set for **application_name** through a connection parameter or the *PGAPPNAME* environment variable. In a common tool program, if you set a default name but do not want the default name to be overwritten by the user, you can specify a backup value.
keepalives	Specifies whether TCP keepalive is enabled on the client side. The default value is **1**, indicating that the function is enabled. The value **0** indicates that the function is disabled. Ignore this parameter for UDS connections.
keepalives_idle	The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value **0** indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_interval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value **0** indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
keepalives_count	Controls the number of times that keepalive messages are sent through TCP. The value **0** indicates that the default value is used. Ignore this parameter for UDS connections or if keepalive is disabled.
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the **TCP_USER_TIMEOUT** socket option. The value **0** indicates that the default value is used. Ignore this parameter for UDS connections.
tcp_syn_retries	Specifies the number of retries due to SYN packet transmission failures in the three-way handshake phase when a client establishes a connection on an OS that supports the **TCP_SYNCNT** socket option. **0** indicates that the default value is used. Ignore this parameter for UDS connections.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
rw_timeout	Sets the read and write timeout interval of the client connection. When the timeout is triggered on the libpq and the connection is closed, the running services delivered by the libpq to the database are forcibly terminated. This capability is controlled by the GUC parameter **check_disconnect_query**. If this parameter is set to **on**, the capability is supported. If this parameter is set to **off**, the capability is not supported.
sslmode	Specifies whether to enable SSL encryption. • **disable**: SSL connection is disabled. • **allow**: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified. • **prefer**: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified. • **require**: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified. • **verify-ca**: SSL connection is required. Currently, Windows ODBC does not support the certificate-based authentication. • **verify-full**: SSL connection is required. Currently, Windows ODBC does not support the certificate-based authentication.
sslcompression	If this parameter is set to **1** (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If this parameter is set to **0**, compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput.
sslcert	This parameter specifies the file name of the client SSL certificate. If no SSL connection is established, this parameter is ignored.
sslkey	This parameter specifies the location of the key used for the client certificate. It can specify a key obtained from an external "engine" (the engine is a loadable module of OpenSSL). The description of an external engine should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored.
sslrootcert	This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
sslcrl	This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected.
requirepeer	This parameter specifies the OS user of the server, for example, **requirepeer=postgres**. When a UDS connection is established, if this parameter is set, the client checks whether the server process is running under the specified username at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the UDS is in **/tmp** or another public writable location, any user can start a server for listening to the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method.
krbsrvname	This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration.
gsslib	This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If this parameter is set to **gssapi**, **libpq** is forced to use the GSSAPI library to replace the default SSPI for authentication.
service	This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in **pg_service.conf** that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained.
authtype	**authtype** is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the **conninfo** string from old applications that might still try to set it.
remote_nodename	Specifies the name of the remote node connected to the local node.
localhost	Specifies the localhost in a connection channel.
localport	Specifies the local port in a connection channel.
fencedUdfRPCMode	Specifies whether the fenced UDF RPC protocol uses UDSs or special socket file names. The default value is **0**, indicating that the UDS mode is used and the file type is .s.PGSQL.%d. To use the fenced UDF mode, set this parameter to **1**. In this case, the file type is .s.fencedMaster_unixdomain.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
replication	Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as **pg_basebackup**, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported: • **true**, **on**, **yes**, and **1**: Specifies that the physical replication mode is connected. • **database** Specifies that the logical replication mode and the database specified by **dbname** are connected. • **false**, **off**, **no**, and **0**: Specifies that the connection is a regular connection, which is the default behavior. In physical or logical replication mode, only simple query protocols can be used.
backend_version	Specifies the backend version to be passed to the remote end.
prototype	Sets the current protocol level. The default value is **PROTO_TCP**.
enable_ce	Specifies whether a client is allowed to connect to a fully-encrypted database. The default value is **0** (disabled). To enable the encrypted equality query, set this parameter to **1** or **3**.
key_info	This parameter is used together with **enable_ce** to set parameters for accessing an external key manager in an encrypted database.
connection_info	The value of **connection_info** is a JSON character string consisting of **driver_name**, **driver_version**, **driver_path**, and **os_user**. If the value is not **NULL**, use **connection_info** and ignore **connectionExtraInf**. If the value is null, a connection information string related to **libpq** is generated. When **connectionExtraInf** is set to **false**, the value of **connection_info** consists of only **driver_name** and **driver_version**.
connectionExtraInf	Specifies whether the value of **connection_info** contains extension information. The default value is **0**. If the value contains other information, set this parameter to **1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters	Description
target_session_attrs	Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting **target_session_attrs** are as follows: • **any**: All types of hosts can be connected. • **read-write**: The connection is set up only when the connected host is readable and writable. • **read-only**: Only readable hosts can be connected. • **primary** (default value): Only the primary node in the primary/standby system can be connected. • **standby**: Only the standby node in the primary/standby system can be connected. • **prefer-standby**: The system first attempts to find a standby node for connection. If all hosts in the **hosts** list fail to be connected, try the **any** mode.
force_no_truncation	When some database statement execution functions and asynchronous command processing functions specify parameters in text format (the corresponding value in **paramFormats** is **0**), the parameter length (the corresponding value in **paramLengths**) specified by the function caller is forcibly used. The rules for setting **force_no_truncation** are as follows: • **1**: enabled. • **0** (default value): disabled. After **force_no_truncation** is enabled, the following database statement execution functions and asynchronous command processing functions are affected: • PQexecParams • PQexecParamsBatch • PQexecPrepared • PQexecPreparedBatch • PQsendQueryParams • PQsendQueryPrepared
enable_host_cache	Specifies whether to enable the node cache function. **0** (default) indicates disabled and **1** indicates enabled.
driver_type	Upper-layer driver type of libpq. The default value is **GaussDB LIBPQ Driver**. You are advised not to set this parameter, that is, retain the default value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

5.10.3 Parameters Related to Log Output

To control the output of log files and better understand the operating status of the database, modify specific configuration parameters in the **gaussdb.conf** file in the instance data directory.

Table 5-100 describes the adjustable configuration parameters.

Table 5-100 Configuration parameters

Parameter	Description	Value Range	Remarks
client_min_messages	Level of messages to be sent to clients.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • LOG • NOTICE • WARNING • ERROR • FATAL • PANIC Default value: **NOTICE**	Messages of the set level or lower will be sent to clients. The lower the level is, the fewer the messages will be sent.
log_min_messages	Level of messages to be recorded in server logs.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • INFO • NOTICE • WARNING • ERROR • LOG • FATAL • PANIC Default value: **WARNING**	Messages higher than the set level will be recorded in logs. The higher level indicates that the fewer server logs will be recorded.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Remarks
log_min_error_statement	Level of SQL error statements to be recorded in server logs.	• DEBUG5 • DEBUG4 • DEBUG3 • DEBUG2 • DEBUG1 • INFO • NOTICE • WARNING • ERROR • FATAL • PANIC Default value: **ERROR**	SQL error statements of the set level or higher will be recorded in server logs. Only a system administrator is allowed to modify this parameter.
log_min_duration_statement	Minimum execution duration of a statement. If the execution duration of a statement is equal to or longer than the set milliseconds, the statement and its duration will be recorded in logs. Enabling this function can help you track the query attempts to be optimized.	INT type. Default value: **–1**. Unit: millisecond	The value **–1** indicates that the function is disabled. Only a system administrator is allowed to modify this parameter.
log_connections/ log_disconnections	Specifies whether to record a server log message when each session is connected or disconnected.	• **on**: The system records a log server when each session is connected or disconnected. • **off**: The system does not record a log server when each session is connected or disconnected. Default value: **off**	-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Value Range	Remarks
log_duration	Specifies whether to record the duration of each executed statement.	• **on**: The system records the duration of each executed statement. • **off**: The system does not record the duration of each executed statement. Default value: **off**	Only a system administrator is allowed to modify this parameter.
log_statement	SQL statements to be recorded in logs.	• **none**: The system does not record any SQL statements. • **ddl**: The system records data definition statements. • **mod**: The system records data definition statements and data operation statements. • **all**: The system records all statements. Default value: **none**	Only a system administrator is allowed to modify this parameter.
log_hostname	Specifies whether to record host names.	• **on**: The system records host names. • **off**: The system does not record host names. Default value: **off**	By default, connection logs only record the IP addresses of connected hosts. With this function, the host names will also be recorded. This parameter has an impact on viewing audit results, **PG_STAT_ACTIVITY**, and the GUC parameter **log_line_prefix**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 5-101 describes the parameter levels of **Table 5-100**.

Table 5-101 Description of log level parameters

Level	Description
DEBUG[1-5]	Provides information that can be used by developers. Level 1 is the lowest level whereas level 5 is the highest level.
INFO	Provides information about users' hidden requests, for example, information about the VACUUM VERBOSE process.
NOTICE	Provides information that may be important to users, for example, truncations of long identifiers or indexes created as a part of a primary key.
WARNING	Provides warning information for users, for example, COMMIT out of transaction blocks.
ERROR	Reports an error that causes a command to terminate.
LOG	Reports information that administrators may be interested in, for example, the activity levels of checkpoints.
FATAL	Reports the reason that causes a session to terminate.
PANIC	Reports the reason that causes all sessions to terminate.

6 SQL Optimization

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, disk I/O, and network I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a combination of Seq Scan and filter (that is, read each tuple and match the point query condition). You can also use Index Scan, which can implement the query at a lower cost but achieve the same effect.

You can determine a proper cluster deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper cluster solution in the software installation guide and performed database design based on the guide for database design and development.

6.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in **Figure 6-1** and described in **Table 6-1**. The texts in red are steps where database administrators can optimize queries.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 6-1 Execution process of query-related SQL statements by the SQL engine

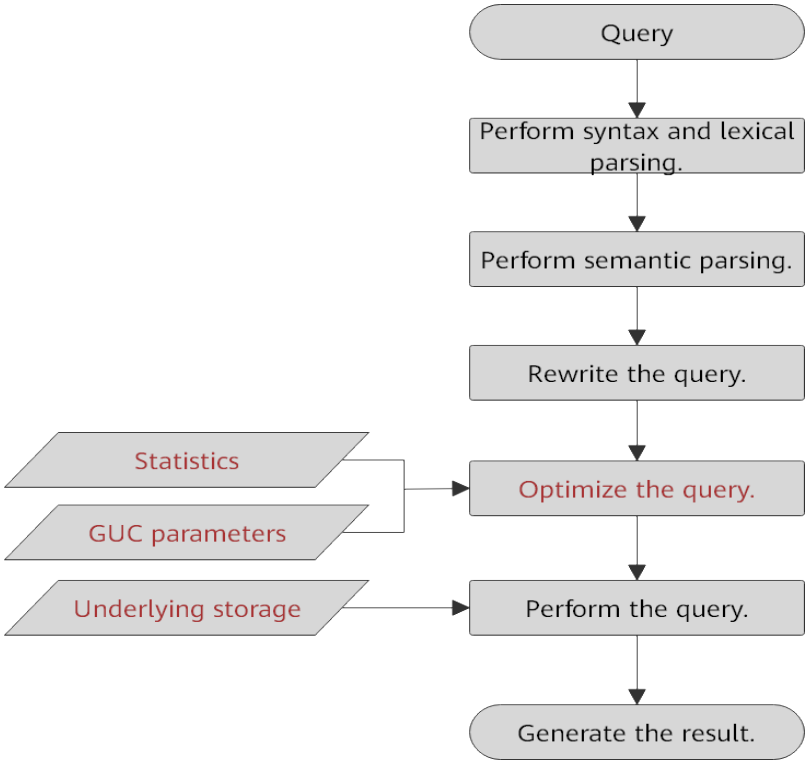

Table 6-1 Execution process of query-related SQL statements by the SQL engine

Step	Description
1. Perform syntax and lexical parsing.	Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules.
2. Perform semantic parsing.	Converts the formatted structure obtained from the previous step into objects that can be recognized by the database.
3. Rewrite the query statements.	Converts the output of the previous step into the structure that optimizes the query execution.
4. Optimize the query.	Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see **Optimizing Queries Using Statistics** and **Optimizing Queries Using GUC parameters**.
5. Perform the query.	Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Optimizing Queries Using Statistics

The GaussDB optimizer is a typical cost-based optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each step under each execution plan based on the number of table tuples, column width, null record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the analyzer select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using ANALYZE. You are advised to periodically execute ANALYZE or execute it immediately after you modified most contents in a table.

Note that DDL operations may cause statistics to change, resulting in plan changes. After DDL operations are performed on a table, check whether statistics need to be collected again.

Optimizing Queries Using GUC parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set size and the execution cost of each join mode based on the statistics on the **customer** and **store_sales** tables. It then compares the costs and selects the one costing the least.

As mentioned above, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting GUC parameters. For example, the **random_page_cost** parameter indicates the optimizer's calculation of the cost of a non-sequentially-fetched disk page. The default value is **4**. When the random read speed of a machine disk (for example, an SSD) is high, you can decrease the value of this parameter. After the change, the cost of index scan is reduced, and the index scan mode is preferred when a plan is generated.

Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.2 Introduction to the SQL Execution Plan

6.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of **EXPLAIN** has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node, The following is an example:

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
                                QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.17..29.07 rows=20 width=180)
   Node/s: All datanodes
   ->  Hash Join  (cost=13.29..27.75 rows=20 width=180)
         Hash Cond: (t2.c2 = t1.c1)
         ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..14.31 rows=20 width=104)
               Spawn on: All datanodes
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=104)
         ->  Hash  (cost=13.13..13.13 rows=21 width=76)
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=76)
(9 rows)
```

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as VALUES clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

Execution Plan Display Format

GaussDB provides four display formats: normal, pretty, summary, and run.

- normal: indicates that the default printing format is used.
- pretty: indicates that the new plan display format improved by GaussDB is used. The new format contains a plan node ID, directly and effectively analyzing performance.
- summary: indicates that the printing information analysis is added based on the pretty format.
- run: indicates that the information based on the summary format is exported as a CSV file for further analysis.

An example of an execution plan using the pretty format is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  explain select * from t1,t2 where t1.c1=t2.c2;
 id |               operation               | E-rows | E-width | E-costs
----+---------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)          |     20 |     180 | 29.07
  2 |    ->  Hash Join (3,5)                |     20 |     180 | 27.75
  3 |       ->  Streaming(type: REDISTRIBUTE) |     20 |     104 | 14.31
  4 |         ->  Seq Scan on t2            |     20 |     104 | 13.13
  5 |       ->  Hash                        |     21 |      76 | 13.13
  6 |         ->  Seq Scan on t1            |     20 |      76 | 13.13
(6 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Hash Join (3,5)
         Hash Cond: (t2.c2 = t1.c1)
(2 rows)
```

You can change the display format of execution plans by setting the GUC parameter **explain_perf_mode**. Later examples use the pretty format by default.

Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different EXPLAIN syntax to display execution plan information in detail. The following lists the common EXPLAIN syntax. For details about more EXPLAIN syntax, see **EXPLAIN**.

- EXPLAIN *statement*: only generates an execution plan and does not execute. The *statement* indicates SQL statements.
- EXPLAIN ANALYZE *statement*: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.
- EXPLAIN PERFORMANCE *statement*: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of EXPLAIN ANALYZE or EXPLAIN PERFORMANCE adds profiling overhead to query execution. Executing EXPLAIN ANALYZE or EXPLAIN PERFORMANCE on a query sometimes takes more time than a normal query. The amount of time that exceeds depends on the complexity of the query itself and the platform used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the execution plan and information to locate the fault.

6.2.2 Execution Plan Details

6.2.2.1 Execution Plans

The following SQL statement in pretty mode is used as an example:

```
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE t1 (c1 int, c2 int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#CREATE TABLE t2 (c1 int, c2 int);
gaussdb=#SET explain_perf_mode = pretty;
```

Run the **EXPLAIN** command and the output is as follows:

```
gaussdb=#EXPLAIN SELECT * FROM t1,t2 WHERE t1.c1 = t2.c2;
 id |               operation               | E-rows | E-width | E-costs
----+---------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)          |     20 |      16 | 28.69
  2 |    ->  Hash Join (3,5)                |     20 |      16 | 27.75
  3 |       ->  Streaming(type: REDISTRIBUTE) |     20 |       8 | 14.31
  4 |          ->  Seq Scan on t2           |     20 |       8 | 13.13
  5 |       ->  Hash                        |     21 |       8 | 13.13
  6 |          ->  Seq Scan on t1           |     20 |       8 | 13.13
(6 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Hash Join (3,5)
         Hash Cond: (t2.c2 = t1.c1)
(2 rows)

-- Drop the table.
gaussdb=#DROP TABLE t1,t2;
```

- Interpretation of the execution plan columns (horizontal):
  - **id**: execution operator node ID.
  - **operation**: name of an execution operator.
  - **E-rows**: number of output rows estimated by each operator.
  - **E-width**: estimated width of an output tuple of each operator.
  - **E-costs**: execution cost estimated by each operator.
    - **E-costs** is measured by the optimizer based on an overhead unit. Usually, fetching a disk page sequence is defined as a unit. Other overhead parameters are set based on the unit.
    - The overhead of each node (specified by **E-costs**) includes the overheads of all its child nodes.
    - Such an overhead reflects only what the optimizer is concerned about, but does not consider the time for passing result rows to the client. Although the time may play an important role in the actual total time, it is ignored by the optimizer because it cannot be changed by modifying the plan.
- Interpretation of the execution plan layers (vertical). The plan tree is from bottom to top. In pretty mode, operators at each layer are indented with **->**. The bottom layer is generally a scan operator.
  - Operators id-4 and id-6 are the scan operators at the bottom layer.
    i. Seq Scan on t1

       The table scan operator scans the table **t1** using Seq Scan. At this layer, data in the table **t1** is read from a buffer or disk, and then transferred to the upper-layer node for hash join calculation.

    ii. Seq Scan on t2

       The table scan operator scans the table **t2** using Seq Scan. At this layer, data in the table **t2** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Layer 2: **Hash**

  The hash operator calculates the hash value of the operator transferred from the lower layer and generates a hash table for subsequent hash join operations.

- Layer 2: Streaming(type: REDISTRIBUTE)

  Streaming is a special operator that implements the core data shuffle function of the distributed architecture. Streaming (type: REDISTRIBUTE) redistributes data to all DNs based on the selected column. This operator redistributes data of **t2** to each DN based on the join column to prepare for t1 join. For details about the Streaming operator, see the subsequent operator description.

- Layer 3: Hash Join (3,5)

  The hash join operator is used to join data in the **t1** and **t2** tables in hash join mode and output the result data. **(3,5)** indicates that the result of the operator whose ID is 3 is joined with the result of the operator whose ID is 5.

- Layer 4: Streaming (type: GATHER)

  Streaming (type: GATHER) collects data from DNs for the CN.

6.2.2.2 Distributed Plan

Currently, the GaussDB optimizer can use three methods to develop statement execution policies in the distributed framework: generating a statement pushdown plan, a distributed execution plan, or a distributed execution plan for sending statements.

- A statement pushdown plan pushes query statements from a CN down to DNs for execution and returns the execution results to the CN.
- In a distributed execution plan, a CN compiles and optimizes query statements, generates a plan tree, and then sends the plan tree to DNs for execution. After the statements have been executed, execution results will be returned to the CN.
- A distributed execution plan for sending statements pushes queries that can be pushed down (mostly base table scanning statements) to DNs for execution. Then, the plan obtains the intermediate results and sends them to the CN, on which the remaining queries are to be executed.

Statement pushdown plan:

```
gaussdb=#CREATE TABLE t1(c1 int,c2 int);
gaussdb=#CREATE TABLE t2(c1 int,c2 int);
gaussdb=#EXPLAIN SELECT * FROM t1;
                  QUERY PLAN
-------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

Interpretation of plan columns:

- Data Node Scan

  The SQL statement is pushed down to DNs for plan generation and execution.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Node/s: All datanodes

  The SQL statement will be executed on all DNs.

Run the **EXPLAIN VERBOSE** command to view the delivered SQL statements.

```
gaussdb=#EXPLAIN VERBOSE SELECT * FROM t1;
                QUERY PLAN
--------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Output: t1.c1, t1.c2
   Node/s: All datanodes
   Remote query: SELECT c1, c2 FROM public.t1
(4 rows)
```

The execution plan contains the **Remote query** column, which describes the delivered SQL statement. To further view the plan after the SQL statement is pushed down to DNs, set the **max_datanode_for_plan** parameter. This parameter indicates the number of plans on DNs. The number of plans on DNs is determined by the smaller one between the number of DNs in the cluster and the value of this parameter.

```
gaussdb=#SET max_datanode_for_plan = 1;
gaussdb=#EXPLAIN VERBOSE SELECT * FROM t1;
                    QUERY PLAN
------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Output: t1.c1, t1.c2
   Node/s: All datanodes
   Remote query: SELECT c1, c2 FROM public.t1

 Remote SQL: SELECT c1, c2 FROM public.t1
 Datanode Name: datanode1
   Seq Scan on public.t1  (cost=0.00..1.06 rows=6 width=8)
     Output: c1, c2

(10 rows)
```

The plan on datanode1 is displayed.

Distributed execution plan:

If an SQL statement cannot be pushed down, a distributed execution plan is generated first.

```
gaussdb=# SET query_mem = '256MB';
SET
gaussdb=#EXPLAIN SELECT * FROM t1 JOIN t2 ON t1.c1 = t1.c2;
 id |              operation               | E-rows | E-memory | E-width | E-costs
----+--------------------------------------+--------+----------+---------+---------
  1 | ->  Streaming (type: GATHER)         |     10 |          |      16 | 2.79
  2 |    ->  Nested Loop (3,5)             |     10 | 1MB      |      16 | 2.32
  3 |       ->  Streaming(type: BROADCAST) |      2 | 2MB      |       8 | 1.22
  4 |          ->  Seq Scan on t1          |      1 | 1MB      |       8 | 1.06
  5 |       ->  Seq Scan on t2             |     10 | 1MB      |       8 | 1.05
(5 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   4 --Seq Scan on t1
         Filter: (c1 = c2)
(2 rows)

   ====== Query Summary =====
---------------------------------
 System available mem: 8193638KB
 Query Max mem: 8280473KB
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Query estimated mem: 5152KB
(3 rows)
```

When **query_mem** is set to **0**, the information in **Query Summary** is not displayed.

A distributed execution plan contains a special streaming operator. It implements the core data shuffle function of the distributed architecture. Streaming has three types, which correspond to different data shuffle functions in the distributed architecture:

- Streaming (type: GATHER): The CN collects data from DNs.
- Streaming (type: REDISTRIBUTE): Data is redistributed to all the DNs based on selected columns.
- Streaming (type: BROADCAST): Data on the current DN is broadcast to other DNs.

Distributed execution plan for sending statements:

If neither of the two execution plans can be generated, an execution plan for sending statements is generated.

```
gaussdb=#ANALYZE t1;
ANALYZE
gaussdb=# EXPLAIN SELECT * FROM t1 limit 1;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Limit  (cost=0.00..0.00 rows=1 width=15)
   ->  Data Node Scan on "__REMOTE_LIMIT_QUERY__"  (cost=0.00..0.00 rows=1 width=15)
         Node/s: All datanodes
(3 rows)

-- Drop the table.
gaussdb=#DROP TABLE t1,t2;
```

A CN with the LIMIT statement cannot simply send statements to DNs and collect data, which is inconsistent with the semantics of the LIMIT statement. The execution plan distributes the LIMIT 1 statement to all DNs. After the intermediate result is collected to the CN, the CN performs LIMIT processing.

6.2.2.3 Execution Information

In SQL optimization process, you can use EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the SQL statement execution information. By comparing estimation differences between actual implementation and the optimizer, basis for service optimization is provided. EXPLAIN PERFORMANCE provides the execution information on each DN, whereas EXPLAIN ANALYZE does not.

The execution result of the following SQL statement in pretty mode is used as an example:

```
-- Create a table and insert data into the table.
gaussdb=#CREATE TABLE t1 (c1 int, c2 int);
gaussdb=#CREATE TABLE t2 (c1 int, c2 int);
gaussdb=#INSERT INTO t1 SELECT generate_series(1,10), generate_series(1,10);
gaussdb=#INSERT INTO t2 SELECT generate_series(1,10), generate_series(1,10);
gaussdb=#ANALYZE t1;
gaussdb=#ANALYZE t2;
```

The output of running EXPLAIN PERFORMANCE is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#EXPLAIN PERFORMANCE SELECT sum(t2.c1) FROM t1,t2 WHERE t1.c1 = t2.c2 GROUP BY t1.c2;
 id |                  operation                  |     A-time      | A-rows | E-rows | E-distinct |  Peak Memory   | E-
memory | A-width | E-width | E-costs
----+---------------------------------------------+-----------------+--------+--------+------------+----------------
+----------+---------+---------+---------
  1 | ->  Streaming (type: GATHER)                | 64.022          |     10 |     10 |            | 82KB           |

-- Drop the table.
gaussdb=#DROP TABLE t1,t2;
```

In the preceding example, the execution information consists of the following parts:

1. The plan is displayed as a table, which contains the following columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The meanings of the plan-type columns (**id**, **operation**, or columns started with **E**) are the same as those when EXPLAIN is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

executed. For details, see **Execution Plans**. The definition of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:

- **A-time**: execution completion time of the current operator. The values in the brackets indicate the minimum and maximum DN completion time.
- **A-rows**: number of actual output tuples of the operator
- **E-distinct**: estimated distinct values at both ends of the hash join operator.
- **E-memory**: estimated memory to be used by the operator. (When the value of **query_mem** is **0**, this row is not displayed in the result.)
- **Peak Memory**: peak memory used by the operator during execution.
- **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and (Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.

2. **Predicate Information (identified by plan id)**:

   This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.

   In this example:

   - In **4 --Hash Join (5,7)**, **4** indicates the operator whose ID is 4, and **(5,7)** indicates that the operator whose ID is 5 and the operator whose ID is 7 are joined.
   - **Hash Cond: (t2.c2 = t1.c1)** indicates the hash join condition.

3. **Memory Information (identified by plan id)**:

   This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **estimate memory**, **width**, **auto spread num**, and **early spilled**, as well as spill details, including **spill Time(s)**, **inner/outer partition spill num**, **temp file num**, spilled data volume, and **written disk IO [***min, max***]**.

4. **Targetlist Information (identified by plan id)**:

   This part displays the target columns provided by each operator.

5. **DataNode Information (identified by plan id)**:

   The execution time, CPU, and buffer usage of each operator are printed in this part.

6. **User Define Profiling**:

   This part displays the thread interaction between CNs and DNs in the stream plan.

7. **====== Query Summary =====**:

   This part displays the total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases, available system memory when the current statement is executed, and estimated statement memory.

6.2.3 Operators

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.2.3.1 Keyword Overview

Table access modes

- Seq Scan

  Scans all rows of the table in sequence.

- Index Scan

  Scans indexes. The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

  If there are separate indexes on multiple columns referenced in WHERE, the optimizer might choose to use an AND or OR combination of the indexes. However, this requires the visiting of both indexes, so it is not necessarily a win compared to using just one index and treating the other condition as a filter.

  The following index scans featured with different sorting mechanisms are involved:

  – Bitmap index scan

    Fetches data pages using a bitmap.

  – Index scan using index_name

    Uses simple index search, which fetches data from an index table in the sequence of index keys. This mode is commonly used when only a small amount of data needs to be fetched from a large data table or when the ORDER BY condition is used to match the index sequence to reduce the sorting time.

  – Index-Only Scan

    Scans the index that contains all required data, instead of referencing a table.

- Bitmap Heap Scan

  Reads pages from bitmaps created by other operations and filters out the rows that do not meet the conditions. Bitmap heap scan can avoid random I/Os and accelerate read speed.

- TID Scan

  Scans a table by a tuple ID.

- Index Ctid Scan

  Scans a table based on the CTID index.

- CTE Scan

  Specifies that CTE evaluates subquery operations and stores query results as a temporary table. The temporary table is scanned by the CTE Scan operator.

- Foreign Scan

  Reads data from a remote data source.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Function Scan

  Obtains result sets returned by functions and returns them as the rows read from tables.

- Sample Scan

  Queries and returns sampled data.

- Subquery Scan

  Reads subquery results.

- Values Scan

  Reads constants as part of the **VALUES** command.

- WorkTable Scan

  Scans a work table. Data is read in the middle of an operation which is usually a recursive operation declared using WITH RECURSIVE.

Table join modes

- Nested Loop

  A nested loop is used for queries that have a smaller data set connected. In a nested-loop join, the outer table drives the inner table and each row returned from the outer table should have a matching row in the inner table. The returned result set of all queries should be less than 10,000. The table that returns a smaller subset will work as an outer table, and indexes are recommended for connection columns of the inner table.

- (Sonic) Hash Join

  A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.

- Merge Join

  In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is required during the merge join, its performance excels.

Operators

- Sort

  Sorts the result set.

- Filter

  The EXPLAIN output shows the WHERE clause being applied as a filter condition attached to the Seq Scan plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows has been reduced because of the WHERE clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu_operator_cost**) to reflect the extra CPU time spent on checking the WHERE condition.

- Limit

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Limits the number of output execution results. If a LIMIT condition is added, not all rows are retrieved.

- Append

  Appends sub-operation results.

- Aggregate

  Aggregates the results generated from querying rows. It can be an aggregation of statements such as GROUP BY, UNION, and SELECT DISTINCT.

- BitmapAnd

  Specifies the AND operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

- BitmapOr

  Specifies the OR operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

- Gather

  Gathers data of parallel threads.

- Group

  Groups rows to perform the GROUP BY operation.

- GroupAggregate

  Aggregates the pre-sorted rows of the GROUP BY operation.

- Hash

  Hashes rows for the parent query. It is usually used to perform the JOIN operation.

- HashAggregate

  Aggregates the result rows of GROUP BY by using a hash table.

- Merge Append

  Merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition.

- ProjectSet

  Executes a function on the returned result set.

- Recursive Union

  Performs a union operation on all steps of a recursive function.

- SetOp

  Specifies a set operation, such as INTERSECT or EXCEPT.

- Unique

  Removes duplicates from an ordered result set.

- HashSetOp

  Specifies a strategy for set operations such as INTERSECT or EXCEPT. It uses Append to avoid pre-sorted input.

- LockRows

  Locks problematic rows to prevent other queries from writing, but allows reading.

- Materialize

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Stores subquery results in the memory so that the parent query can quickly access and obtain the subquery results.

- Result

  Returns a value without scanning.

- WindowAgg

  Specifies a window aggregate function, which is generally triggered by the OVER statement.

- Merge

  Performs a merge operation.

- StartWith Operator

  Specifies the hierarchical query operator, which is used to perform recursive query operations.

- Rownum

  Filters the row number in the query result. It usually appears in the ROWNUM clause.

- Index Cond

  Specifies the index scan conditions.

- Unpivot

  Specifies a transpose operator.

Partition pruning

- Partition Iterator

  Partition iterator, which usually indicates that a subquery is an operation on a partition.

- Iterations

  Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used.

  For example, **Iterations: 4** indicates that the iteration operator needs to traverse four level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.

- Selected Partitions

  Specifies the selected level-1 partitions for pruning. **m..n** indicates that partitions **m** to **n** are selected. Multiple consecutive partitions are separated by commas (,).

  For example, **Selected Partitions: 2..4,7** indicates that partitions 2, 3, 4, and 7 are selected.

- Sub Iterations

  Specifies the number of iterations performed by the partition iteration operator on level-2 partitions. If **PART** is displayed, dynamic pruning is used.

  For example, **Sub Iterations: 4** indicates that the iteration operator needs to traverse four level-2 partitions. **Iterations: PART** indicates that the number of level-2 partitions to be traversed is determined by parameter conditions of the partition key.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Selected Subpartitions

  Specifies the selected level-2 partitions for pruning, which is in the format like: Level-1 partition number:Level-2 partition number.

  For example, **Selected Subpartitions: 2:1 3:2** indicates that level-2 partition 1 of the second level-1 partition and level-2 partition 2 of the third level-1 partition are selected. **Selected Subpartitions: ALL** indicates that all level-2 partitions are selected.

Distributed Keywords

- Data Node Scan

  Performs plan generation and execution on DNs.
- Node/s: All datanodes

  Specifies the nodes to which the plan is delivered.
- Remote query

  Specifies the delivered SQL statement.
- Streaming

  Specifies streaming operators, including gather, redistribute, and broadcast.

Other keywords

- InitPlan

  Indicates a non-related subplan.
- SubPlan

  Correlated subplan.

6.2.3.2 Table Access Modes

This section describes how to disable the function of pushing down operators to DNs to facilitate operator display and description.

```
gaussdb=#SET enable_fast_query_shipping = off;
```

6.2.3.2.1 Seq Scan

Description

The seq scan operator is a universal one. It scans a table in a certain direction (forward or backward) and returns all rows that meet the filter criteria.

Typical Scenarios

- The table has no index and needs to be scanned.
- The table has indexes, but most of the data in the table needs to be scanned.

Examples

Example 1: The table has no index and needs to be scanned. In this section, the normal mode is used for demonstration. In this example, the scenario in normal mode is as follows:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SET explain_perf_mode = normal;
SET

-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1 (c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,100), 2, 3);
INSERT 0 100

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 WHERE c1 = 2;
                        QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=96)
   Node/s: datanode1
   ->  Seq Scan on t1  (cost=0.00..13.16 rows=1 width=96)
         Filter: (c1 = 2::numeric)
(4 rows)

-- Drop the table.
gaussdb=#DROP TABLE t1;
```

In the preceding example, the output of the seq scan operator is described in **Table 6-2**.

Table 6-2 Output information of the seq scan operator

Item	Description
Seq Scan	Operator name.
Filter	Filter predicate of the operator. In the example, the filter condition is the value of column **c1** is **2**. When a query is executed, rows that meet these conditions are included in the final result set.

Example 2: The table has indexes, but most of the data in the table needs to be scanned.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1(c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#CREATE INDEX idx_c1 on t1(c1);
CREATE INDEX
gaussdb=#INSERT INTO t1 VALUES(generate_series(1, 100000), 2, 3);
INSERT 0 100000

-- Collect statistics.
gaussdb=#ANALYZE t1;

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 WHERE c1 <= 80000;
                          QUERY PLAN
---------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..4698.38 rows=80136 width=16)
   Node/s: All datanodes
   ->  Seq Scan on t1  (cost=0.00..942.00 rows=80136 width=16)
         Filter: (c1 <= 80000::numeric)
(4 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop the table.
gaussdb=#DROP TABLE t1;
```

In the preceding example, the output of the seq scan operator is described in **Table 6-3**.

Table 6-3 Output information of the seq scan operator

Item	Description
Seq Scan	Operator name.
Filter	Filter predicate of the operator. In the example, the filter condition is the value of column **c1** is less than or equal to 80000. When a query is executed, rows that meet these conditions are included in the final result set.

6.2.3.2.2 Index Scan

Description

In an index scan, the database uses the index column specified by a statement to retrieve rows by traversing the index tree. When the database scans an index for a value, the value to be searched for can be found after *n* I/Os occur, where *n* is the height of the B-tree index. Generally, index scan is used to retrieve table data. The database reads the index block sequentially, finds the corresponding index key value, and then reads the corresponding table tuple based on the TID corresponding to the index key. When the data volume is large but the query result set is small, the index scan efficiency is higher than the Seq Scan efficiency.

Typical Scenarios

- Querying specific rows in a table: When a query statement contains a WHERE clause whose conditions can be matched by index columns, GaussDB uses the index scan to search for rows that meet the conditions.
- Sorting: When a query statement contains the ORDER BY clause whose columns can be sorted by index, GaussDB uses the index scan for sorting.
- Aggregating: When a query statement contains the GROUP BY clause whose columns can be grouped by index, GaussDB uses the index scan for aggregation.
- Connecting: When a query statement contains a JOIN operation whose columns can be matched by index, GaussDB uses the index scan to perform the join operation.

Examples

Example 1: Conditions in the WHERE clause can be matched by index columns.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS test;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#CREATE TABLE test (c1 int, c2 int);
CREATE TABLE
gaussdb=#CREATE INDEX c1_idx ON test (c1);
CREATE INDEX
gaussdb=#INSERT INTO test SELECT generate_series(1, 1000000), random()::integer;
INSERT 0 1000000
gaussdb=#INSERT INTO test SELECT generate_series(1, 1000000), random()::integer;
INSERT 0 1000000
gaussdb=#INSERT INTO test SELECT generate_series(1, 1000000), random()::integer;
INSERT 0 1000000

-- Collect statistics.
gaussdb=#ANALYZE test;
gaussdb=#EXPLAIN SELECT /*+ indexscan(test c1_idx) */ * FROM test WHERE c1 > 990000;
                                QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..25494.30 rows=31127 width=8)
   Node/s: All datanodes
   ->  Index Scan using c1_idx on test  (cost=0.00..24035.17 rows=31127 width=8)
         Index Cond: (c1 > 990000)
(4 rows)
```

In the preceding example, the output of the index scan operator is as follows.

Item	Description
Index Scan	Operator name.
Index Cond	Filter predicate of the operator. In the example, the filter condition is the value of column **c1** is greater than 990000. When a query is executed, rows that meet these conditions are included in the final result set.

Example 2: Columns in the ORDER BY clause can be sorted by index.

```
gaussdb=#EXPLAIN SELECT /*+ indexscan(test c1_idx) */ * FROM test ORDER BY c1;
                                QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..190456.74 rows=3000000 width=8)
   Merge Sort Key: c1
   Node/s: All datanodes
   ->  Index Scan using c1_idx on test  (cost=0.00..49831.74 rows=3000000 width=8)
(4 rows)
```

Example 3: Columns in the GROUP BY clause can be grouped by index.

```
gaussdb=# EXPLAIN SELECT /*+ indexscan(test c1_idx) */ c2 FROM test WHERE c1 = 10 GROUP BY c2;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 HashAggregate  (cost=8.33..8.34 rows=1 width=4)
   Group By Key: c2
   Skew Agg Optimized by Statistic
   ->  Streaming (type: GATHER)  (cost=8.33..8.34 rows=1 width=4)
         Node/s: datanode2
         ->  HashAggregate  (cost=8.27..8.28 rows=1 width=4)
               Group By Key: c2
               ->  Index Scan using c1_idx on test  (cost=0.00..8.27 rows=1 width=4)
                     Index Cond: (c1 = 10)
(9 rows)
```

Example 4: In the JOIN operation, indexes can be used for matching.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  EXPLAIN SELECT /*+ indexscan(t1 c1_idx) */ t1.*, t2.* FROM test t1 JOIN test t2 on t1.c1 = t2.c1;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..364718.08 rows=4933438 width=16)
   Node/s: All datanodes
   ->  Merge Join  (cost=0.00..133463.18 rows=4933438 width=16)
         Merge Cond: (t1.c1 = t2.c1)
         ->  Index Scan using c1_idx on test t1  (cost=0.00..46356.20 rows=3000000 width=8)
         ->  Materialize  (cost=0.00..50106.20 rows=3000000 width=8)
               ->  Index Scan using c1_idx on test t2  (cost=0.00..46356.20 rows=3000000 width=8)
(7 rows)

-- Drop.
gaussdb=# DROP TABLE test;
```

6.2.3.2.3 Index-only Scan

Description

Index-only scan is a query optimization technology in GaussDB. It can improve query performance by scanning only indexes without accessing table data. If the query condition involves only an index column of a table, you can use index-only scan to optimize the query. Index-only scan directly scans indexes, reducing I/O operations and CPU overhead and improving query performance.

Typical Scenarios

You only need to query the value of the index column without accessing other columns in the table. For example, query the maximum or minimum value of a column in a table, or query the number of different values in a column.

Examples

The target column contains only index columns.

```
-- Prepare data.
gaussdb=#CREATE TABLE test2 (a int, b int);
CREATE TABLE
gaussdb=#CREATE INDEX test2_idx ON test2 (a, b);
CREATE INDEX

-- Randomly insert 1,000 data records.
gaussdb=#INSERT INTO test2 VALUES(generate_series(1, 1000), generate_series(1, 1000));
INSERT 0 1000

-- Collect statistics.
gaussdb=#ANALYZE test2;

-- Execution result.
gaussdb=#EXPLAIN SELECT a, b FROM test2 WHERE a = 10 AND b = 20;
                              QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..8.36 rows=1 width=8)
   Node/s: datanode2
   ->  Index Only Scan using test2_idx on test2  (cost=0.00..8.27 rows=1 width=8)
         Index Cond: ((a = 10) AND (b = 20))
(4 rows)

-- Drop.
gaussdb=#DROP TABLE test2;
```

In the preceding example, the output of the index-only scan operator is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Index Only Scan	Operator name.
Index Cond	Filter predicate of the operator. In the example, the filter condition is that the value of column **a** is equal to **10** and the value of column **b** is equal to **20**. When a query is executed, rows that meet these conditions are included in the final result set.

6.2.3.2.4 Bitmap

Description

1. Bitmap index scan: This operator uses the index scan to form a bitmap based on the TIDs of tuples that meet the filter conditions and returns the bitmap to the upper layer. The BitmapAnd or BitmapOr operation can be executed on multiple result bitmaps scanned from multiple tables. Unlike index scans that require comparing filtered tuples across tables, BitmapAnd and BitmapOr operations decrease the filtering time.
2. Bitmap heap scan: The lower layer of this operator contains the bitmap index scan, which is used to scan the bitmap returned by the lower-layer operator to determine which tuples meet the certain conditions, obtain the tuples, and return them to the upper layer. The optimizer uses the bitmap index scan based on cost estimation and needs to return tuples that meet certain conditions. In this case, the upper layer usually uses the bitmap heap scan to filter tuples by scanning bitmaps and return the tuples.
3. BitmapOr: This operator performs the OR operation on the lower-layer bitmap and returns the bitmap after the operation.
4. BitmapAnd: This operator performs the AND operation on the lower-layer bitmap and returns the bitmap after the operation.

The prerequisite for using bitmap index scan and bitmap heap scan is that the GUC parameter **enable_bitmapscan** has been set to **on**.

Typical Scenarios

Multiple tables are joined, indexes are available on the joined columns of one or more tables, and there is enough data in some or all tables.

Examples

Join multiple tables with indexes.

```
-- Prepare data. Create three tables with data of the numeric type, randomly fill in data, and create indexes for each attribute of each table.
gaussdb=#SET enable_default_ustore_table = on;
SET
gaussdb=#CREATE TABLE t_btm_test_1(a numeric,b numeric,c numeric);

                     ->  BitmapAnd  (cost=37.02..37.02 rows=1 width=0)
                           ->  Bitmap Index Scan on idx_btm_test_22  (cost=0.00..12.26 rows=1 width=0)
                                 Index Cond: (b = 1::numeric)
                           ->  BitmapOr  (cost=24.52..24.52 rows=1 width=0)
                                 ->  Bitmap Index Scan on idx_btm_test_21  (cost=0.00..12.26 rows=1 width=0)
                                       Index Cond: (a = 1::numeric)
                                 ->  Bitmap Index Scan on idx_btm_test_21  (cost=0.00..12.26 rows=1 width=0)
                                       Index Cond: (a = 3::numeric)
               ->  Materialize  (cost=24.52..28.65 rows=1 width=13)
                     ->  Streaming(type: REDISTRIBUTE)  (cost=24.52..28.64 rows=1 width=13)
                           Spawn on: All datanodes
                           ->  Bitmap Heap Scan on t_btm_test_3  (cost=24.52..28.53 rows=1 width=13)
                                 Recheck Cond: ((a = 1::numeric) OR (a = 3::numeric))
                                 ->  BitmapOr  (cost=24.52..24.52 rows=1 width=0)
                                       ->  Bitmap Index Scan on idx_btm_test_31  (cost=0.00..12.26 rows=1 width=0)
                                             Index Cond: (a = 1::numeric)
                                       ->  Bitmap Index Scan on idx_btm_test_31  (cost=0.00..12.26 rows=1 width=0)
                                             Index Cond: (a = 3::numeric)
         ->  Hash  (cost=3.41..3.41 rows=2 width=13)
               ->  Streaming(type: BROADCAST)  (cost=0.00..3.41 rows=2 width=13)
                     Spawn on: datanode1
                     ->  Seq Scan on t_btm_test_1  (cost=0.00..3.25 rows=1 width=13)
                           Filter: (a = 1::numeric)
(31 rows)

-- Drop the table.
gaussdb=#DROP TABLE t_btm_test_1, t_btm_test_2, t_btm_test_3;
```

In the preceding example, the output of the bitmap heap scan operator is as follows.

Item	Description
Bitmap Heap Scan	Operator name.
Recheck Cond	After the index scan is performed, the database checks the filter predicate again. In the example, the filter condition of **Recheck Cond: ((a = 1::numeric) OR (a = 3::numeric))** is that the value of column **a** is equal to **1** or **3**. When a query is executed, rows that meet these conditions are included in the final result set.

In the preceding example, the output of the bitmap index scan operator is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Bitmap Index Scan	Operator name.
Index Cond	Filter predicate of the operator. When a query is executed, rows that meet these conditions are included in the final result set.

In the preceding example, the output of the BitmapOr and BitmapAnd operators is as follows.

Item	Description
BitmapOr	Operator name, indicating that the OR operation is performed on the bitmap returned by the lower layer to form a bitmap that matches more complex conditions.
BitmapAnd	Operator name, indicating that the AND operation is performed on the bitmap returned by the lower layer to form a bitmap that matches more complex conditions.

6.2.3.2.5 TID Scan

Description

This is a row number scan operator, which uses the row number (**ctid**) to filter and return the tuples. In the Astore scenario, data is stored in the heap page by row. In addition to the value of a storage column, the corresponding row number is also stored in the B-tree index. Therefore, GaussDB supports quick retrieval by row number.

The row number is in the following format:

```
(page_number, item_number)      -- page_number starts from 0, and the value of item_number starts from 1.
```

The corresponding tuple in the disk or cache is found based on the given **ctid** value.

Typical Scenarios

Prerequisites: The GUC parameter **enable_tidscan** has been set to **on**.

You can quickly search for data by specifying a valid row number if a table supports TID scan. Currently, GaussDB selects TID scan only when the WHERE condition is =. IN is not supported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Prepare data.
gaussdb=#CREATE TABLE t_tid_test(a numeric,b numeric,c numeric);
CREATE TABLE
gaussdb=#DECLARE
    n1 numeric := 10;
    n2 numeric := 0;
    n3 numeric := 100;
BEGIN
    WHILE n1 > 0 LOOP
        WHILE n2 < 100 LOOP
            WHILE n3 > 0 LOOP
                INSERT INTO t_tid_test VALUES(n1, n2, n3);
                n3 := n3 - 1;
            END LOOP;
            n2 := n2 + 1;
        END LOOP;
        n1 := n1 - 1;
    END LOOP;
END;
/
ANONYMOUS BLOCK EXECUTE

-- Collect statistics.
gaussdb=#ANALYZE t_tid_test;

-- Execution result.
gaussdb=#SET enable_tidscan = on;
SET
gaussdb=# SET max_datanode_for_plan = 2;
SET
gaussdb=# EXPLAIN SELECT * FROM t_tid_test WHERE ctid = '(0,10)'::tid;
                                QUERY PLAN
---------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes

 Remote SQL: SELECT a, b, c FROM public.t_tid_test WHERE ctid = '(0,10)'::tid
 Datanode Name: datanode1
   Seq Scan on t_tid_test  (cost=0.00..2.25 rows=1 width=13)
     Filter: (ctid = '(0,10)'::tid)

 Datanode Name: datanode2
   Tid Scan on t_tid_test  (cost=0.00..4.01 rows=1 width=96)
     TID Cond: (ctid = '(0,10)'::tid)

(12 rows)

-- Drop the table.
gaussdb=#DROP TABLE t_tid_test;
```

In the preceding example, the output of the TID scan operator is as follows.

Item	Description
TID Scan	Operator name.
TID Cond	Filter predicate of the operator. When a query is executed, rows that meet these conditions are included in the final result set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.2.3.2.6 CTE Scan

Description

Common table expression (CTE) is a temporary expression. CTE scan is used to scan temporary tables generated by CTEs.

In GaussDB, you can use the WITH keyword to specify one or more CTEs, which can be used multiple times in subsequent queries.

Typical Scenarios

When a query result set needs to be used for multiple times in subsequent queries, you can use CTE to avoid multiple calculations.

Examples

CTEs with the WITH statement cannot be rewritten as subqueries.

```
-- Prepare data.
gaussdb=#CREATE TABLE employees(deptid integer, salary number);
CREATE TABLE
gaussdb=#CREATE TABLE managers(deptid integer);
CREATE TABLE

gaussdb=# SET max_datanode_for_plan = 2;
SET
-- Execution result.
gaussdb=#EXPLAIN WITH table_b AS (SELECT deptid,sum(salary) dept_salary FROM employees GROUP BY
deptid)
SELECT m.deptid, b.dept_salary
FROM managers m,table_b b,table_b c
WHERE m.deptid = b.deptid AND  m.deptid = c.deptid;

                                                
```

```
     ->  HashAggregate  (cost=28.57..30.57 rows=200 width=36)
           Group By Key: employees.deptid
           ->  Seq Scan on employees  (cost=0.00..22.38 rows=1238 width=36)
   ->  Seq Scan on managers m  (cost=0.00..34.02 rows=2402 width=4)
   ->  Hash  (cost=13.25..13.25 rows=200 width=40)
         ->  Hash Join  (cost=6.50..13.25 rows=200 width=40)
               Hash Cond: (b.deptid = c.deptid)
               ->  CTE Scan on table_b b  (cost=0.00..4.00 rows=200 width=36)
               ->  Hash  (cost=4.00..4.00 rows=200 width=4)
                     ->  CTE Scan on table_b c  (cost=0.00..4.00 rows=200 width=4)

(34 rows)

-- Drop the table.
gaussdb=#DROP TABLE employees, managers;
```

In the preceding example, the output of the CTE scan operator is as follows.

Item	Description
CTE Scan	Operator name.
Hash	Operator for creating a hash table in an inner table.

6.2.3.2.7 Function Scan

Description

Function scan is used to execute a function and obtain tuples from the result set returned by the function.

Typical Scenarios

When a query needs to call a function and return a result set, the function scan operator can call the function and obtain tuples from the result set returned by the function.

Examples

Call a system function.

```
gaussdb=#EXPLAIN SELECT * FROM generate_series(2,4);
                            QUERY PLAN
------------------------------------------------------------------------------
 Function Scan on generate_series  (cost=0.00..10.00 rows=1000 width=4)
(1 row)
```

6.2.3.2.8 Sample Scan

Description

Sample scan is a method of scanning tables. It can randomly extract some data from a table for query instead of scanning the entire table. Sample scan is used together with the TABLESAMPLE keyword in [TABLESAMPLE sampling_method (argument [, ...]) [REPEATABLE (seed)]] mode. This technology is usually used

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

in a query scenario in which a large table or random sampling is required, to improve query efficiency.

Typical Scenarios

When the tablesample syntax is used for query, **sampling_method** is set to **system** or **bernoulli**.

Examples

Query the sampling data.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1 (c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,100), 2, 3);
INSERT 0 100

-- Execution result.
gaussdb=#EXPLAIN SELECT c1 FROM t1 tablesample system(10);
                        QUERY PLAN
------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..4.11 rows=2 width=32)
   Node/s: All datanodes
   ->  Sample Scan on t1  (cost=0.00..4.02 rows=2 width=32)
         Sampling: system (10::double precision)
(4 rows)

-- Drop.
gaussdb=#DROP TABLE t1;
```

In the preceding example, the output of the sample scan operator is as follows.

Item	Description
Sample Scan	Operator name.
Sampling	Operator sampling mode. In the example, system is used as the sampling method, and the sampling ratio is 10%.

6.2.3.2.9 Subquery Scan

Description

If the rule-based optimizer (RBO) does not optimize a statement that contains a subquery and is being executed, this operator executes the query plan tree of the subquery and then transfers the subquery result to the upper-layer query.

Typical Scenarios

If a statement contains a subquery, the subquery scan operator is generated to obtain tuples from the subquery.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

```
-- Prepare data.
gaussdb=#CREATE TABLE t_distinct(a int, b int, c int, d int, e regproc);

-- Execution result.
gaussdb=#EXPLAIN (costs off, nodes off) SELECT COUNT(DISTINCT(a)), COUNT(DISTINCT(b)), d FROM
t_distinct GROUP BY c, d;
                                        QUERY PLAN
-----------------------------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)
   ->  Hash Join
         Hash Cond: ((public.t_distinct.c = subquery."?column?") AND (public.t_distinct.d = subquery.d))
         ->  GroupAggregate
               Group By Key: public.t_distinct.c, public.t_distinct.d
               ->  Sort
                     Sort Key: public.t_distinct.c, public.t_distinct.d
                     ->  Streaming(type: REDISTRIBUTE)
                           ->  Seq Scan on t_distinct
         ->  Hash
               ->  Subquery Scan on subquery
                     ->  HashAggregate
                           Group By Key: public.t_distinct.c, public.t_distinct.d
                           ->  Streaming(type: REDISTRIBUTE)
                                 ->  HashAggregate
                                       Group By Key: public.t_distinct.c, public.t_distinct.d, public.t_distinct.a
                                       ->  Seq Scan on t_distinct
(17 rows)

-- Drop the table.
gaussdb=#DROP TABLE t_distinct;
```

In the preceding example, the output of the subquery scan operator is as follows.

Item	Description
Subquery Scan	Operator name.
HashAggregate	Operator name.

6.2.3.2.10 VALUES Scan

Description

Reads the list of values specified in the VALUES clause and returns it as a set of virtual rows to the query planner. These virtual rows can be used by other scanners or operators, such as hash join or merge join.

Typical Scenarios

This operator provides a quick and simple way to specify a set of values without reading data from a table. This is useful during testing or debugging, or when you need to insert a small amount of data.

Examples

The insert statement contains VALUES.

```
-- Prepare data.
gaussdb=#CREATE TABLE test_b (c1 number);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE TABLE

-- Execution result.
gaussdb=#EXPLAIN INSERT INTO test_b(c1) VALUES ('1'),('2');
                              QUERY PLAN
--------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.12..2.21 rows=1 width=32)
   Node/s: All datanodes
   ->  Insert on test_b  (cost=0.00..2.11 rows=4 width=32)
         ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..0.11 rows=4 width=32)
               Spawn on: datanode2
               ->  Values Scan on "*VALUES*"  (cost=0.00..0.03 rows=4 width=32)
(6 rows)

-- Drop the table.
gaussdb=#DROP TABLE test_b;
```

6.2.3.2.11 Worktable Scan

Description

Worktable scan is a memory-based query optimization technology. It can cache query results in the memory to improve query performance. When GaussDB executes a query statement, it stores the query result in a temporary table and uses worktable scan to scan the temporary table to obtain the query result. Worktable scan reduces disk I/O operations and improves query performance. However, it also has some disadvantages, for example, a large amount of memory space is consumed, and a problem such as memory overflow may be caused. Therefore, you need to adjust and optimize the worktable scan according to actual situations.

Typical Scenarios

- Recursive query: In the WITH RECURSIVE scenario, worktable scan can cache the query result of each recursion and use it as the data source input for the next recursion.

Examples

Example: Recursive Union tables without indexes

```
-- Prepare data.
gaussdb=#CREATE TABLE t9(a int);
CREATE TABLE
gaussdb=#INSERT INTO t9 VALUES(1);
INSERT 0 1

-- Execution result.
gaussdb=#EXPLAIN WITH RECURSIVE tt AS (
SELECT a FROM t9
UNION ALL
SELECT a + 1 FROM tt WHERE a < 10)
SELECT * FROM tt;
                              QUERY PLAN
--------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=48.89..85.84 rows=721 width=4)
   Node/s: All datanodes
   ->  CTE Scan on tt  (cost=0.00..7.20 rows=721 width=4)
         ->  Recursive Union  (cost=0.00..44.89 rows=721 width=4)
               ->  Seq Scan on t9  (cost=0.00..13.13 rows=20 width=4)
               ->  WorkTable Scan on tt  (cost=0.00..2.45 rows=70 width=4)
                     Filter: (a < 10)
(7 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop.
gaussdb=#DROP TABLE t9;
```

In the preceding example, the output of the worktable scan operator is as follows.

Item	Description
Worktable Scan	Operator name.
Filter	Filter condition of the operator. In the example, **a** is less than 10.

6.2.3.3 Table Join Modes

6.2.3.3.1 Nested-Loop Join

Description

A nested-loop join is the simplest join method, which is implemented in all relational database systems. It compares the data in two tables to check whether the join conditions are met.

In GaussDB, a nested-loop join scans the inner table for each row in the outer table searching for rows that meet the join conditions. This is similar to two nested loops. The outer loop traverses the outer table, and the inner loop traverses the inner table.

The time complexity of a nested-loop join is O(*n* x *m*), where *n* and *m* indicate the numbers of rows in the two tables. If the inner table can be scanned by using indexes, the time complexity can be reduced to O(*n* log *m*).

Typical Scenarios

- Any of the inner or outer table is very small.
- An inner table quickly locates the row that meets the condition (for example, an index has been created for the join column of the inner table) based on the join condition.
- A nested-loop join can be executed under any join conditions if it has no restrictions.

Examples

Example: Join two small tables.

```
-- Prepare data.
gaussdb=#CREATE TABLE employee(id int, deptid int);
CREATE TABLE
gaussdb=#INSERT INTO employee VALUES(1, 1), (2,1),(3,2),(4, 1), (5,2);
INSERT 0 5
gaussdb=#CREATE TABLE manager(id int, deptid int);
CREATE TABLE
gaussdb=#INSERT INTO manager VALUES(1,1), (2,2),(3,1),(4,2);
INSERT 0 4
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Collect statistics.
gaussdb=#ANALYZE employee;
gaussdb=#ANALYZE manager;

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM employee e JOIN manager m ON e.deptid < m.deptid;
                              QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..38.43 rows=133 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..32.24 rows=133 width=16)
         Join Filter: (e.deptid < m.deptid)
         ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=8)
               Spawn on: All datanodes
               ->  Seq Scan on employee e  (cost=0.00..13.13 rows=20 width=8)
         ->  Materialize  (cost=0.00..13.20 rows=20 width=8)
               ->  Seq Scan on manager m  (cost=0.00..13.13 rows=20 width=8)
(9 rows)

-- Drop.
gaussdb=#DROP TABLE employee,manager;
```

In the preceding example, the output of nested-loop join is as follows.

Item	Description
Nested Loop	Operator name.
Join Filter	Join predicate of the operator join. In the example, the condition is that **e.deptid** is less than **m.deptid**. During query execution, rows that meet these conditions are included in the final result set.

Example: An index has been created for join columns in an inner table.

```
-- Prepare data.
gaussdb=# CREATE TABLE t1(a int,b int);
CREATE TABLE
gaussdb=#  create index key_a on t1(a);
CREATE INDEX
gaussdb=# CREATE TABLE t2(a int,b int);
CREATE TABLE

-- Collect statistics.
gaussdb=# ANALYZE t1;
gaussdb=# ANALYZE t2;

-- Execution result.
gaussdb=# explain select t1.*,t2.* from t1 inner join t2 on t1.a < t2.b;
                              QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..38.43 rows=133 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..32.24 rows=133 width=16)
         Join Filter: (t1.a < t2.b)
         ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=8)
               Spawn on: All datanodes
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=8)
         ->  Materialize  (cost=0.00..13.20 rows=20 width=8)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=8)
(9 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

Example: any join condition

```
-- Prepare data.
gaussdb=# CREATE TABLE t1(a int,b int);
CREATE TABLE
gaussdb=#  create index key_a on t1(a);
CREATE INDEX
gaussdb=# CREATE TABLE t2(a int,b int);
CREATE TABLE

-- Collect statistics.
gaussdb=# ANALYZE t1;
gaussdb=# ANALYZE t2;

-- Execution result.
gaussdb=# explain select t1.*,t2.* from t1 inner join t2 on t1.a != t2.b and t1.a < t2.a;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..38.89 rows=127 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..32.89 rows=127 width=16)
         Join Filter: ((t1.a <> t2.b) AND (t1.a < t2.a))
         ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=8)
               Spawn on: All datanodes
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=8)
         ->  Materialize  (cost=0.00..13.20 rows=20 width=8)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=8)
(9 rows)

-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

6.2.3.3.2 Hash Join

Description

A hash join is an efficient join method that depends on the hash technology. During a hash join, GaussDB selects one of the two tables (usually small tables) and creates a hash table based on join conditions. The key of the hash table is the join column of the small table, and the other columns of the small table are the value. Then, the hash value of the join column is calculated for each row in the large table. After this, the hash table is searched for a matching row.

The time complexity of a hash join is O(n + m), where n and m indicate the numbers of rows in the two tables. However, the performance may degrade if the inner table is too large for the memory storage, as it will require additional disk I/O operations.

Typical Scenarios

- The number of rows in two tables differs greatly and the join operation is performed, and the join columns of the two tables are equi-join (for example, using the = operator).

Examples

Example: The number of rows in two tables differ significantly and the join operation is performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE t1(c1 number,c2 number,c3 number);
CREATE TABLE
gaussdb=#CREATE TABLE t2(c1 number,c2 number,c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,100000), 2 ,3);
INSERT 0 100000
gaussdb=#INSERT INTO t2 VALUES(generate_series(1,100), 2, 3);
INSERT 0 100

-- Collect statistics.
gaussdb=#ANALYZE t1;
gaussdb=#ANALYZE t2;

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 JOIN t2 ON t1.c1 = t2.c2;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=12.56..986.88 rows=100 width=31)
   Node/s: All datanodes
   ->  Hash Join  (cost=9.44..982.19 rows=100 width=31)
         Hash Cond: (t1.c1 = t2.c2)
         ->  Seq Scan on t1  (cost=0.00..816.00 rows=100000 width=16)
         ->  Hash  (cost=8.19..8.19 rows=100 width=15)
               ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..8.19 rows=100 width=15)
                     Spawn on: All datanodes
                     ->  Seq Scan on t2  (cost=0.00..2.50 rows=100 width=15)
(9 rows)

-- Drop the table.
gaussdb=#DROP TABLE t1,t2;
```

In the preceding example, the output of the hash join operator is as follows.

Item	Description
Hash Join	Operator name.
Hash Cond	Join predicate of the operator hash join. In the example, the condition is that **t1.c1** is equal to **t2.c2**. During query execution, rows that meet these conditions are included in the final result set.
Hash	Operator for creating a hash table in an inner table.

6.2.3.3.3 Merge Join

Description

A merge join is an efficient join method that depends on sorting operations. During a merge join, GaussDB sorts the join columns of the two tables and scans both tables at the same time to find matching rows. The time complexity of a merge join is O(n + m), where n and m indicate the numbers of rows in the two tables. However, if a sorting operation is required, the time complexity of the sorting operation may reach max(O(log n), O(log m)), which is usually more

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

time-consuming than a direct merge join operation. In GaussDB, the optimizer prefers hash join, even if the two tables to be joined have been sorted.

Typical Scenarios

- The two tables are similar in size.
- The join columns of two tables have been sorted, for example, by index.

Examples

Example: Two tables are joined and the sizes of the two tables are close.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE t1(id int,info text);
CREATE TABLE
gaussdb=#CREATE TABLE t2(id int,info text);
CREATE TABLE
gaussdb=#INSERT INTO t2 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000
gaussdb=#INSERT INTO t1 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000

-- Collect statistics.
gaussdb=#ANALYZE t1;
gaussdb=#ANALYZE t2;

-- Execution result.
gaussdb=#EXPLAIN SELECT /*+ MERGEJOIN(t2 t1) */ * FROM t2 JOIN t1 ON (t1.id=t2.id);
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=9352.82..15036.32 rows=100000 width=26)
   Node/s: All datanodes
   ->  Merge Join  (cost=9348.82..10348.82 rows=100000 width=26)
         Merge Cond: (t2.id = t1.id)
         ->  Sort  (cost=4674.41..4799.41 rows=100000 width=13)
               Sort Key: t2.id
               ->  Seq Scan on t2  (cost=0.00..772.00 rows=100000 width=13)
         ->  Sort  (cost=4674.41..4799.41 rows=100000 width=13)
               Sort Key: t1.id
               ->  Seq Scan on t1  (cost=0.00..772.00 rows=100000 width=13)
(10 rows)

-- Drop the table.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
```

In the preceding example, the output of the merge join operator is as follows.

Item	Description
Merge Join	Operator name.
Merge Cond	Join predicate of the operator merge join. In the example, the condition is that **t2.id** is equal to **t1.id**. During query execution, rows that meet these conditions are included in the final result set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example: The join columns of two tables have been sorted, for example, by index.

```
-- Prepare data.
gaussdb=# DROP TABLE IF EXISTS t1;
gaussdb=# DROP TABLE IF EXISTS t2;
gaussdb=# CREATE TABLE t1(id int,info text);
CREATE TABLE
gaussdb=# CREATE TABLE t2(id int,info text);
CREATE TABLE
gaussdb=# CREATE INDEX t1_k on t1(id);
CREATE INDEX
gaussdb=# INSERT INTO t2 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000
gaussdb=# INSERT INTO t1 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000
gaussdb=# SET enable_fast_query_shipping = off;
SET

-- Collect statistics.
gaussdb=# ANALYZE t1;
gaussdb=# ANALYZE t2;

-- Execution result.
gaussdb=#
EXPLAIN SELECT /*+ MERGEJOIN(t2 t1) */ * FROM t2 JOIN t1 ON (t1.id=t2.id);
                           QUERY PLAN
--------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=27.37..27.91 rows=20 width=72)
   Node/s: All datanodes
   ->  Merge Join  (cost=26.74..26.97 rows=20 width=72)
         Merge Cond: (t2.id = t1.id)
         ->  Sort  (cost=13.37..13.40 rows=21 width=36)
               Sort Key: t2.id
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=36)
         ->  Sort  (cost=13.37..13.40 rows=21 width=36)
               Sort Key: t1.id
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=36)
(10 rows)

-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

6.2.3.4 Operators

6.2.3.4.1 Sort

Description

Sorts the tuples returned by the bottom-layer node. The sort operator is used to sort query results based on specified sorting rules and return ordered result sets.

Typical Scenarios

- If a query statement contains the ORDER BY clause, GaussDB selects the sort operator in the execution plan to perform sorting.
- Merge join is used for join operations.

Examples

The query statement contains the ORDER BY clause.

```
-- Prepare data.
gaussdb=#CREATE TABLE student(id integer, class_id integer, grade number);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
CREATE TABLE
gaussdb=#INSERT INTO student VALUES(generate_series(1,50), 1, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(51,100), 2, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(101,150), 3, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(151,200), 3, floor(100 * random()));
INSERT 0 50

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM student ORDER BY grade;
                           QUERY PLAN
-----------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.18..14.62 rows=21 width=40)
   Merge Sort Key: grade
   Node/s: All datanodes
   ->  Sort  (cost=13.37..13.40 rows=21 width=40)
         Sort Key: grade
         ->  Seq Scan on student  (cost=0.00..13.13 rows=20 width=40)
(6 rows)

-- Drop.
gaussdb=#DROP TABLE student;
```

In the preceding example, the output of the sort operator is as follows.

Item	Description
Sort	Operator name.
Sort Key	Keyword based on which the sort operator uses for sorting. In the example, the value is **grade**.

Example: Merge join is used for join operations.

```
-- Prepare data.
gaussdb=# DROP TABLE IF EXISTS t1;
gaussdb=# DROP TABLE IF EXISTS t2;
gaussdb=# CREATE TABLE t1(id int,info text);
CREATE TABLE
gaussdb=# CREATE TABLE t2(id int,info text);
CREATE TABLE
gaussdb=# INSERT INTO t2 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000
gaussdb=# INSERT INTO t1 SELECT generate_series(1,100000),'bill'||generate_series(1,100000);
INSERT 0 100000

-- Collect statistics.
gaussdb=# ANALYZE t1;
gaussdb=# ANALYZE t2;

-- Execution result.
gaussdb=# EXPLAIN SELECT /*+ MERGEJOIN(t2 t1) */ * FROM t2 JOIN t1 ON (t1.id=t2.id);
                              QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=9352.82..15036.32 rows=100000 width=26)
   Node/s: All datanodes
   ->  Merge Join  (cost=9348.82..10348.82 rows=100000 width=26)
         Merge Cond: (t2.id = t1.id)
         ->  Sort  (cost=4674.41..4799.41 rows=100000 width=13)
               Sort Key: t2.id
               ->  Seq Scan on t2  (cost=0.00..772.00 rows=100000 width=13)
         ->  Sort  (cost=4674.41..4799.41 rows=100000 width=13)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            Sort Key: t1.id
            ->  Seq Scan on t1  (cost=0.00..772.00 rows=100000 width=13)
(10 rows)

-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

6.2.3.4.2 Limit

Description

The limit operator limits the number of output execution results. If a limit operator is added, not all rows are retrieved.

Typical Scenarios

Use a query statement containing the keyword limit.

Examples

Use a query statement containing the keyword limit.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1 ( id int, number int);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES (generate_series(1,50), 1);
INSERT 0 50
gaussdb=#EXPLAIN SELECT * FROM t1 LIMIT 10 OFFSET 20;
                           QUERY PLAN
---------------------------------------------------------------------------
 Limit  (cost=11.23..15.89 rows=9 width=8)
   ->  Streaming (type: GATHER)  (cost=0.88..15.89 rows=9 width=8)
         Node/s: All datanodes
         ->  Limit  (cost=0.00..14.14 rows=29 width=8)
               ->  Seq Scan on t1  (cost=0.00..14.14 rows=29 width=8)
(5 rows)

-- Drop.
gaussdb=#DROP TABLE t1;
```

In the preceding example, the output of the Limit operator is as follows.

Item	Description
Limit	Operator name.
Seq Scan	Name of an operator that scans the **t1** table in sequence.

6.2.3.4.3 Append

Description

Append is used to append multiple relationship sets and process the linked list that contains one or more subplans.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Typical Scenarios

- SQL statements with UNION.
- SQL statements with UNION ALL.

Examples

Example 1: SQL statement with UNION.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE t1(c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1, 100), 2, 3);
INSERT 0 100
gaussdb=#CREATE TABLE t2(c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t2 VALUES(generate_series(1, 100), 2, 3);
INSERT 0 100

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 UNION SELECT * FROM t2;
                           QUERY PLAN
--------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=28.03..28.94 rows=42 width=96)
   Node/s: All datanodes
   ->  HashAggregate  (cost=26.72..26.98 rows=42 width=96)
         Group By Key: t1.c1, t1.c2, t1.c3
         ->  Append  (cost=0.00..26.52 rows=42 width=96)
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=96)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=96)
(7 rows)
```

In the preceding example, the output of the append operator is as follows.

Item	Description
Append	Operator name.
Seq Scan on t1	Name of an operator that scans the **t1** table in sequence.
Seq Scan on t2	Name of an operator that scans the **t2** table in sequence.

Example 2: SQL statement with UNION ALL.

```
-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 UNION ALL SELECT * FROM t2;
                           QUERY PLAN
--------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=1.62..28.70 rows=40 width=96)
   Node/s: All datanodes
   ->  Result  (cost=0.00..26.26 rows=40 width=96)
         ->  Append  (cost=0.00..26.26 rows=40 width=96)
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=96)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=96)
(6 rows)

-- Drop the table.
gaussdb=#DROP TABLE t1,t2;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.2.3.4.4 Agg

Description

The agg operator is used to perform aggregation calculation. It supports three policies: common aggregation (without grouping), sort aggregation, and hash aggregation. Sort aggregation and hash aggregation must be used together with GROUP BY because they involve grouping. The difference between sort aggregation and hash aggregation is that the input of sort aggregation must be ordered, while hash aggregation does not depend on the input sequence. Even if the input is sorted, sort aggregation may not be selected because hash aggregation may have better execution performance.

Typical Scenarios

- Common aggregation: Only aggregation calculation is involved. It is used to collect statistics on the total number of tables, or the number of rows or features in a column. The keyword Aggregate is used in the execution plan.
- Sort aggregation: If the input tuples are sorted or the group keys are ordered, the sort aggregation may be selected. The GroupAggregate keyword is used in the execution plan.
- Hash aggregation: It is the aggregation calculation in most service scenarios and in the case of disordered data. The HashAggregate keyword is used in the execution plan.

Examples

Example 1: common aggregation.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS student;
gaussdb=#CREATE TABLE student(id integer, class_id integer, grade number);
CREATE TABLE
gaussdb=#INSERT INTO student VALUES(generate_series(1,50), 1, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(51,100), 2, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(101,150), 3, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(151,200), 3, floor(100 * random()));
INSERT 0 50

-- Execution result.
gaussdb=#EXPLAIN SELECT count(*) FROM student;
                            QUERY PLAN
------------------------------------------------------------------------------
 Aggregate  (cost=13.23..13.27 rows=1 width=8)
   ->  Streaming (type: GATHER)  (cost=13.23..13.27 rows=2 width=8)
         Node/s: All datanodes
         ->  Aggregate  (cost=13.16..13.17 rows=2 width=8)
               ->  Seq Scan on student  (cost=0.00..13.13 rows=20 width=0)
(5 rows)
```

Example 2: sort aggregation.

```
gaussdb=#SET enable_hashagg = off;
SET
gaussdb=#EXPLAIN SELECT id, count(class_id) FROM student GROUP BY id ORDER BY id;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.00..14.54 rows=21 width=16)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  Merge Sort Key: id
  Node/s: All datanodes
  ->  GroupAggregate  (cost=13.37..13.60 rows=21 width=16)
        Group By Key: id
        ->  Sort  (cost=13.37..13.40 rows=21 width=8)
              Sort Key: id
              ->  Seq Scan on student  (cost=0.00..13.13 rows=20 width=8)
(8 rows)
```

Example 3: hash aggregation.

```
gaussdb=#SET enable_hashagg = on;
gaussdb=#EXPLAIN SELECT id, avg(grade) FROM student GROUP BY id;
                          QUERY PLAN
------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.84..15.59 rows=30 width=68)
   Node/s: All datanodes
   ->  HashAggregate  (cost=14.21..14.34 rows=30 width=68)
         Group By Key: id
         ->  Seq Scan on student  (cost=0.00..14.14 rows=30 width=36)
(5 rows)

-- Drop.
gaussdb=#DROP TABLE student;
```

In the preceding example, the output of the agg operator is as follows.

Item	Description
Aggregate	Name of an operator for common aggregation, indicating that aggregation is performed without grouping.
GroupAggregate	Name of an operator for sort aggregation, indicating that the input tuples are sorted or the grouping keys are ordered.
HashAggregate	Name of an operator for hash aggregation, which is used for aggregation calculation in most scenarios and in the case of disordered data.

6.2.3.4.5 Group

Description

The group operator is used to process the GROUP BY clause and group the lower-layer sorted tuples. The result after grouping by group key is returned.

Typical Scenarios

Grouping: queries the number of different values in a column. The function of this operation is similar to that of DISTINCT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

The query statement contains the GROUP BY clause.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS student;
gaussdb=#CREATE TABLE student(id integer, class_id integer, grade number);
CREATE TABLE
gaussdb=#INSERT INTO student VALUES(generate_series(1,50), 1, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(51,100), 2, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(101,150), 3, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(151,200), 3, floor(100 * random()));
INSERT 0 50

-- Execution result.
gaussdb=#SET enable_hashagg = off;
SET
gaussdb=#EXPLAIN SELECT class_id FROM student GROUP BY class_id ORDER BY class_id;
                                QUERY PLAN
-----------------------------------------------------------------------------------------
 Group  (cost=13.37..13.44 rows=26 width=4)
   Group By Key: class_id
   ->  Sort  (cost=15.27..15.33 rows=26 width=4)
         Sort Key: class_id
         ->  Streaming (type: GATHER)  (cost=14.18..14.65 rows=26 width=4)
               Node/s: All datanodes
               ->  Group  (cost=13.37..13.44 rows=26 width=4)
                     Group By Key: class_id
                     ->  Sort  (cost=13.37..13.40 rows=21 width=4)
                           Sort Key: class_id
                           ->  Seq Scan on student  (cost=0.00..13.13 rows=20 width=4)
(11 rows)

-- Drop.
gaussdb=#DROP TABLE student;
```

In the preceding example, the output of the Group operator is as follows.

Item	Description
Group	Operator name.
Group By Key	Group key. In the example, **class_id** is used as the key.

6.2.3.4.6 MergeAppend

Description

MergeAppend is used to append multiple ordered relationship sets. The operation is similar to Append. The only difference is that MergeAppend accelerates the calculation of ordered relationship sets. MergeAppend merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition. Therefore, different from common Append, MergeAppend needs to ensure that the input **m_plan** is ordered before performing operations. Generally, a sort operator appears before the MergeAppend operation (that is, in the subtree of the execution plan).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Typical Scenarios

The partition scan path is index or index-only, the partition pruning result is greater than 1, and the following conditions are met:

All partition indexes are valid B-tree indexes. The SQL query contains the LIMIT clause. During partition scan, no partitioned table query statement with the filter exists.

The MergeAppend path is no longer generated when the GUC parameter **sql_beta_feature** is set to **'disable_merge_append_partition'**.

Examples

```
-- Prepare data.
gaussdb=#CREATE TABLE test_range_pt (a INT, b INT, c INT)
 DISTRIBUTE BY REPLICATION
 PARTITION BY RANGE(a)
 (
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN (3000),
    PARTITION p3 VALUES LESS THAN (4000),
    PARTITION p4 VALUES LESS THAN (5000),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
 )ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=#INSERT INTO test_range_pt VALUES
(generate_series(1,10000),generate_series(1,10000),generate_series(1,10000));
INSERT 0 10000
gaussdb=#CREATE INDEX idx_range_b ON test_range_pt(b) GLOBAL;
CREATE INDEX
gaussdb=#ANALYZE test_range_pt;
ANALYZE

-- Execution result.
gaussdb=# EXPLAIN SELECT * FROM test_range_pt UNION ALL SELECT * FROM test_range_pt order by b
limit 10;
                                                
```

Item	Description
Merge Append	Operator name.
Sort Key	Keyword based on which the sort operator uses for sorting. In the example, the value is **grade**.

6.2.3.4.7 SetOp

Description

A SetOp operator is used to combine two or more query results into a result set. SetOp operators include INTERSECT and EXCEPT.

Typical Scenarios

- **INTERSECT**: returns the intersection of two query results, that is, the rows that exist in both result sets.
- **INTERSECT ALL**: returns the intersection of two query results, including duplicate rows.
- **EXCEPT**: returns the rows that exist in the first query result but do not exist in the second query result.
- **EXCEPT ALL**: returns the rows that exist in the first query result but do not exist in the second query result, including duplicate rows.

Examples

Example 1: **INTERSECT**.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t;
gaussdb=#CREATE TABLE t(a int, b int, c int);
CREATE TABLE
gaussdb=#INSERT INTO t VALUES(generate_series(1, 10), generate_series(601, 610), generate_series(901,
910));
INSERT 0 10

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t INTERSECT SELECT * FROM t;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=27.94..28.61 rows=21 width=12)
   Node/s: All datanodes
   ->  SetOp Intersect  (cost=27.13..27.39 rows=21 width=12)
         ->  Sort  (cost=27.13..27.20 rows=42 width=12)
               Sort Key: "*SELECT* 1".a, "*SELECT* 1".b, "*SELECT* 1".c
               ->  Append  (cost=0.00..26.52 rows=42 width=12)
                     ->  Subquery Scan on "*SELECT* 1"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
                     ->  Subquery Scan on "*SELECT* 2"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
(10 rows)
```

In the preceding example, the output of the SetOp operator is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
SetOp	Operator name.
Intersect	Mode of merging result sets. In the example, **Intersect** indicates the intersection of two query results, that is, the rows that exist in both result sets.

Example 2: **INTERSECT ALL**.

```
gaussdb=#EXPLAIN SELECT * FROM t INTERSECT ALL SELECT * FROM t;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=27.94..28.61 rows=21 width=12)
   Node/s: All datanodes
   ->  SetOp Intersect All  (cost=27.13..27.39 rows=21 width=12)
         ->  Sort  (cost=27.13..27.20 rows=42 width=12)
               Sort Key: "*SELECT* 1".a, "*SELECT* 1".b, "*SELECT* 1".c
               ->  Append  (cost=0.00..26.52 rows=42 width=12)
                     ->  Subquery Scan on "*SELECT* 1"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
                     ->  Subquery Scan on "*SELECT* 2"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
(10 rows)
```

In the preceding example, the output of the SetOp operator is as follows.

Item	Description
SetOp	Operator name.
Intersect All	Mode of merging result sets. In the example, **Intersect All** indicates that the intersection of two query results is returned, including duplicate rows.

Example 3: **EXCEPT**.

```
gaussdb=#EXPLAIN SELECT * FROM t EXCEPT SELECT * FROM t;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=27.94..28.61 rows=21 width=12)
   Node/s: All datanodes
   ->  SetOp Except  (cost=27.13..27.39 rows=21 width=12)
         ->  Sort  (cost=27.13..27.20 rows=42 width=12)
               Sort Key: "*SELECT* 1".a, "*SELECT* 1".b, "*SELECT* 1".c
               ->  Append  (cost=0.00..26.52 rows=42 width=12)
                     ->  Subquery Scan on "*SELECT* 1"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
                     ->  Subquery Scan on "*SELECT* 2"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
(10 rows)
```

In the preceding example, the output of the SetOp operator is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
SetOp	Operator name.
Except	Mode of merging result sets. In the example, **Except** indicates that the rows that exist in the first query result but do not exist in the second query result are returned.

Example 4: **EXCEPT ALL**

```
gaussdb=#EXPLAIN SELECT * FROM t EXCEPT ALL SELECT * FROM t;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=27.94..28.61 rows=21 width=12)
   Node/s: All datanodes
   ->  SetOp Except All  (cost=27.13..27.39 rows=21 width=12)
         ->  Sort  (cost=27.13..27.20 rows=42 width=12)
               Sort Key: "*SELECT* 1".a, "*SELECT* 1".b, "*SELECT* 1".c
               ->  Append  (cost=0.00..26.52 rows=42 width=12)
                     ->  Subquery Scan on "*SELECT* 1"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
                     ->  Subquery Scan on "*SELECT* 2"  (cost=0.00..13.26 rows=21 width=12)
                           ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=12)
(10 rows)

-- Drop.
gaussdb=#DROP TABLE t;
```

In the preceding example, the output of the SetOp operator is as follows.

Item	Description
SetOp	Operator name.
Except All	Mode of merging result sets. In the example, **Except All** indicates the rows that exist in the first query result but do not exist in the second query result, including duplicate rows.

6.2.3.4.8 RecursiveUnion

Description

The RecursiveUnion operator is used to process UNION statements that are recursively called. Such statements are usually used in CTEs. Common syntax logic is as follows: An initial input set is used as the initial data of the recursive process, and then recursive calling is performed to obtain the output. Finally, the output of the current recursive calling is used as the input of the next recursive calling, and the final output is obtained through cyclic calling.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Typical Scenarios

Execute an SQL statement with RecursiveUnion.

Examples

Execute an SQL statement with RecursiveUnion.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1(c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1, 100), 2, 3);
INSERT 0 100

-- Execution result.
gaussdb=#EXPLAIN WITH RECURSIVE t1(n) AS (
VALUES(1)
UNION ALL
SELECT n+1 FROM t1 WHERE n < 100)
SELECT sum(n) FROM t1;
                            QUERY PLAN
------------------------------------------------------------------------------
 Aggregate  (cost=3.65..3.66 rows=1 width=12)
   CTE t1
     ->  Recursive Union  (cost=0.00..2.96 rows=31 width=4)
           ->  Values Scan on "*VALUES*"  (cost=0.00..0.01 rows=1 width=4)
           ->  WorkTable Scan on t1  (cost=0.00..0.23 rows=3 width=4)
                 Filter: (n < 100)
   ->  CTE Scan on t1  (cost=0.00..0.62 rows=31 width=4)
(7 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
```

In the preceding example, the output of the RecursiveUnion operator is as follows.

Item	Description
Recursive Union	Operator name.
Values Scan	Name of an operator which is used to scan values.
WorkTable Scan	Stores the filtered result in a temporary table.

6.2.3.4.9 Unique

Description

Deduplicates lower-layer data. During the execution, it traverses all input data, filters duplicate records, and retains only the unique record.

Typical Scenarios

Disable the **enable_hashagg** parameter and perform the query with DISTINCT.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

Perform the query with DISTINCT.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1 (id INT , number INT);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,50), 1);
INSERT 0 50
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,50), 2);
INSERT 0 50

-- Execution result.
gaussdb=#SET enable_hashagg = off;
SET
gaussdb=#EXPLAIN SELECT DISTINCT t1.id FROM t1;
                           QUERY PLAN
---------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.18..14.65 rows=26 width=4)
   Node/s: All datanodes
   ->  Unique  (cost=13.37..13.44 rows=26 width=4)
         ->  Sort  (cost=13.37..13.40 rows=21 width=4)
               Sort Key: id
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=4)
(6 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
```

In the preceding example, the output of the Unique operator is as follows.

Item	Description
Unique	Operator name.
Sort	Operator name.
Sort Key	Name of an operator which is the keyword used by the sort operator to sort data. In the example, the value is **grade**.

6.2.3.4.10 LockRows

Description

The LockRows operator is used to lock rows in a query result set to prevent other transactions from modifying or deleting these rows.

Typical Scenarios

- When SELECT ... FOR SHARE/UPDATE is used to lock rows in a transaction, other transactions cannot modify or delete these rows.
- When FOR SHARE is used to lock a row, the current transaction and other transactions cannot modify or delete the locked row.
- When FOR UPDATE is used to lock a row, no transaction can modify or delete the locked row except the current transaction.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

SELECT FOR UPDATE syntax.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t;
gaussdb=#CREATE TABLE t(a int, b int, c int);
CREATE TABLE
gaussdb=#INSERT INTO t VALUES(generate_series(1, 10), generate_series(601, 610), generate_series(901,
910));
INSERT 0 10

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t WHERE a = 1 FOR UPDATE;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=18)
   Node/s: All datanodes
   ->  LockRows  (cost=0.00..13.16 rows=1 width=18)
         ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..13.16 rows=1 width=18)
               Spawn on: datanode1
               ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=18)
                     Filter: (a = 1)
(7 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t;
```

Example: SELECT FOR SHARE syntax.

```
-- Prepare data.
gaussdb=# DROP TABLE IF EXISTS t;
gaussdb=# CREATE TABLE t(a int, b int, c int);
CREATE TABLE
gaussdb=# INSERT INTO t VALUES(generate_series(1, 10), generate_series(601, 610), generate_series(901,
910));
INSERT 0 10

-- Execution result.
gaussdb=# EXPLAIN SELECT * FROM t WHERE a = 1 FOR SHARE;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=18)
   Node/s: All datanodes
   ->  LockRows  (cost=0.00..13.16 rows=1 width=18)
         ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..13.16 rows=1 width=18)
               Spawn on: datanode1
               ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=18)
                     Filter: (a = 1)
(7 rows)

-- Drop.
gaussdb=# DROP TABLE t;
```

In the preceding example, the output of the LockRows operator is as follows.

Item	Description
LockRows	Operator name.
Streaming	Operator name.
Spawn on: datanode1	Indicates that data will be distributed to datanode1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.2.3.4.11 Materialize

Description

The Materialize operator is used to cache the results returned by subnodes and save the subquery results. For subnodes that need to be scanned repeatedly for multiple times (especially when the scanning results are the same each time), the execution cost can be reduced.

Typical Scenarios

- If a query statement involves subqueries and the same batch of data needs to be queried for multiple times, the optimizer selects the Materialize operator to cache the subquery results, greatly reducing the scan execution time. Subqueries often exist in clauses such as IN, ANY, ALL, and EXISTS.
- Nested loop is used as the join operator.

Examples

Perform subqueries with ALL.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS student;
gaussdb=#CREATE TABLE student(id integer, class_id integer, grade number);
CREATE TABLE
gaussdb=#CREATE TABLE class_table(class_id integer);
CREATE TABLE
gaussdb=#INSERT INTO student VALUES(generate_series(1,50), 1, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(51,100), 2, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(101,150), 3, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO student VALUES(generate_series(151,200), 3, floor(100 * random()));
INSERT 0 50
gaussdb=#INSERT INTO class_table VALUES(1),(2),(3),(4);
INSERT 0 4

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM student WHERE class_id >= all (SELECT class_id FROM class_table);
                                QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.38..100.67 rows=10 width=40)
   Node/s: All datanodes
   ->  Seq Scan on student  (cost=0.00..100.11 rows=10 width=40)
         Filter: (SubPlan 1)
         SubPlan 1
           ->  Materialize  (cost=0.00..13.28 rows=80 width=4)
                 ->  Streaming(type: BROADCAST)  (cost=0.00..13.18 rows=40 width=4)
                       Spawn on: All datanodes
                       ->  Seq Scan on class_table  (cost=0.00..13.13 rows=20 width=4)
(9 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS student,class_table;
```

In the preceding example, the output of the Materialize operator is as follows.

Item	Description
Materialize	Operator name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Streaming	Operator name.
Spawn on: datanode1	In the example, the data is distributed to all DNs.

Example: Nested loop is used as the join operator.

```
-- Prepare data.
gaussdb=# CREATE TABLE t1(a int,b int);
CREATE TABLE
gaussdb=#  create index key_a on t1(a);
CREATE INDEX
gaussdb=# CREATE TABLE t2(a int,b int);
CREATE TABLE

-- Collect statistics.
gaussdb=# ANALYZE t1;
gaussdb=# ANALYZE t2;

-- Execution result.
gaussdb=# explain select t1.*,t2.* from t1 inner join t2 on t1.a < t2.b;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..38.43 rows=133 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..32.24 rows=133 width=16)
         Join Filter: (t1.a < t2.b)
         ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=8)
               Spawn on: All datanodes
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=8)
         ->  Materialize  (cost=0.00..13.20 rows=20 width=8)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=8)
(9 rows)

-- Drop.
gaussdb=# DROP TABLE t1,t2;
```

In the preceding example, the output of the Materialize operator is as follows.

Item	Description
Materialize	Operator name.
Seq Scan	Operator name.

6.2.3.4.12 Result

Description

Result is used to process the condition expression (2 > 1) that needs to be calculated only once or the INSERT statement that contains only one VALUES clause. In this case, the process can be returned in advance and no subsequent operation is required.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Typical Scenarios

- The Result node is used to optimize the query of constant condition expressions. The condition expression does not depend on the scanned data, for example, **select * from t1 where 1 > 2**.
- If the SELECT statement does not contain the FROM clause or the INSERT statement contains only one VALUES clause, the executor directly calculates the projection attribute of SELECT or uses the VALUES clause to construct a tuple.

Examples

Example 1: The Result node is used to optimize the query of constant condition expressions.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1(c1 number, c2 number, c3 number);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES(generate_series(1, 100), 2, 3);
INSERT 0 100

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 WHERE 1 > 2;
                QUERY PLAN
------------------------------------------
 Result  (cost=0.00..0.01 rows=1 width=0)
   One-Time Filter: false
(2 rows)
```

In the preceding example, the output of the Result operator is as follows.

Item	Description
Result	Operator name.
One-Time Filter	The constant expression is always **false** during filtering. Therefore, the expression needs to be executed only once.

Example 2: SELECT does not contain the FROM clause.

```
gaussdb=#EXPLAIN SELECT dbe_raw.bit_and('1','2');
                QUERY PLAN
------------------------------------------
 Result  (cost=0.00..0.01 rows=1 width=0)
(1 row)
```

Example 3: The INSERT statement contains only one VALUES clause.

```
gaussdb=#EXPLAIN INSERT INTO t1 VALUES(1, 2, 3);
                  QUERY PLAN
-----------------------------------------------
 Insert on t1  (cost=0.00..0.01 rows=1 width=0)
   Node/s: All datanodes
   Node expr: c1
   ->  Result  (cost=0.00..0.01 rows=1 width=0)
(4 rows)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
```

6.2.3.4.13 WindowAgg

Description

The WindowAgg operator is used to process tuple window aggregation. The functions and implementation modes of the WindowAgg operator are similar to those of the aggregate operator. The main difference is that the tuples processed by the WindowAgg operator are restricted to the same window, while the tuples processed by the aggregate operator are the entire table (GROUP BY division).

Typical Scenarios

The query statement contains window functions, such as row_number() OVER (PARTITION BY xxx) and avg(xxx) OVER (PARTITION BY xxx).

Examples

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t;
gaussdb=#CREATE TABLE t(a int, b int, c int);
CREATE TABLE
gaussdb=#INSERT INTO t VALUES(generate_series(1, 10), generate_series(601, 610), generate_series(901,
910));
INSERT 0 10

-- Execution result.
gaussdb=#EXPLAIN SELECT a, avg(b) OVER(partition by a) FROM t;
                          QUERY PLAN
------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.18..14.82 rows=21 width=8)
   Node/s: All datanodes
   ->  WindowAgg  (cost=13.37..13.60 rows=21 width=8)
         ->  Sort  (cost=13.37..13.40 rows=21 width=8)
               Sort Key: a
               ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=8)
(6 rows)

gaussdb=# EXPLAIN SELECT a, row_number() OVER(partition by a) FROM t;
                          QUERY PLAN
------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=14.18..14.82 rows=21 width=8)
   Node/s: All datanodes
   ->  WindowAgg  (cost=13.37..13.60 rows=21 width=8)
         ->  Sort  (cost=13.37..13.40 rows=21 width=8)
               Sort Key: a
               ->  Seq Scan on t  (cost=0.00..13.13 rows=20 width=8)
(6 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t;
```

In the preceding example, the output of the WindowAgg operator is as follows.

Item	Description
WindowAgg	Operator name.
Sort	Operator name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Sort Key	Keyword based on which the sort operator uses for sorting. In the example, the value is **a**.

6.2.3.4.14 StartWith Operator

Description

The hierarchical query operator is used to perform recursive query operations. The hierarchical query process is as follows:

- Select the initial dataset based on the condition in the START WITH area and set the initial dataset as the working set.
- If the working set is not empty, use the data in the working set as the input for the next query. Specify the filter criteria in the CONNECT BY clause. The keyword PRIOR indicates the current record.
- Set the dataset filtered in step 2 as the working set and repeat the operation in step 2.

In addition, the database adds the following pseudocolumns to each selected data record so that you can learn about the location of the data in the recursive or tree structure. You can create indexes based on the conditions in the CONNECT BY clause to improve the performance of the START WITH clause.

Typical Scenarios

Perform hierarchical query.

Examples

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS area;
gaussdb=#CREATE TABLE area (id INT,name VARCHAR(25),parent_id INT);
CREATE TABLE
gaussdb=#INSERT INTO area VALUES (1,'China',NULL);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES (2,'Beijing',1);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES (3,'Chaoyang District',2);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES(4,'Shaanxi Province',1);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES(5,'Xi'an',4);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES (6,'Yanta District',5);
INSERT 0 1
gaussdb=#INSERT INTO area VALUES(7,'Weiyang District',5);
INSERT 0 1

-- Execution result.
gaussdb=#EXPLAIN SELECT level, name FROM area START WITH (id = 1) CONNECT BY PRIOR id = parent_id;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 CTE Scan on tmp_reuslt  (cost=294.67..295.55 rows=44 width=72)
   CTE tmp_reuslt
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
   ->  StartWith Operator  (cost=0.00..294.67 rows=44 width=76)
         Start With pseudo atts: array_key_1
         ->  Recursive Union  (cost=0.00..294.67 rows=44 width=76)
               ->  Seq Scan on area  (cost=0.00..19.64 rows=4 width=76)
                     Filter: (id = 1)
               ->  Hash Join  (cost=27.35..27.42 rows=4 width=76)
                     Hash Cond: (tmp_reuslt.id = public.area.parent_id)
                     ->  WorkTable Scan on tmp_reuslt  (cost=0.00..0.02 rows=1 width=4)
                     ->  Hash  (cost=17.71..17.71 rows=771 width=76)
                           ->  Seq Scan on area  (cost=0.00..17.71 rows=771 width=76)
(12 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS area;
```

In the preceding example, the output of the StartWith operator is as follows.

Item	Description
StartWith	Operator name.
Start With pseudo atts	Recursive key column number. **Start With pseudo atts: array_key_1** indicates that the condition marked by prior is the first column of the original table and recursion is performed based on this column.

6.2.3.4.15 Rownum

Description

The rownum operator generates a pseudocolumn that returns a number indicating the row number of the result obtained from the query. The rownum of the first row is 1. You can use the keyword ROWNUM to filter the row number in the query result. It usually appears in the ROWNUM clause.

The restrictions on using ROWNUM are as follows:

- Do not use ROWNUM as an alias to avoid ambiguity in SQL statements.
- Do not use ROWNUM when creating an index.
- Do not use ROWNUM as the default value when creating a table.
- Do not use ROWNUM as an alias in the WHERE clause.
- Do not use ROWNUM when inserting data.
- Do not use ROWNUM in a tableless query.
- Do not use ROWNUM in the LIMIT clause.
- Do not use ROWNUM as a parameter of the EXECUTE statement.
- Do not use ROWNUM to update a clause in the UPSERT statement.

Typical Scenarios

The filter condition statement contains ROWNUM.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Examples

The filter condition statement contains ROWNUM.

```
-- Prepare data.
gaussdb=#CREATE TABLE t1 ( id INT , number INT );
CREATE TABLE
gaussdb=#INSERT INTo t1 VALUES(generate_series(1,50), 1);
INSERT 0 50
gaussdb=#INSERT INTO t1 VALUES(generate_series(1,50), 2);
INSERT 0 50

-- Execution result.
gaussdb=#EXPLAIN SELECT t1.id FROM t1 WHERE rownum > 10;
                          QUERY PLAN
------------------------------------------------------------------------
 Rownum  (cost=0.81..14.35 rows=20 width=4)
   Filter: (ROWNUM > 10::numeric)
   ->  Streaming (type: GATHER)  (cost=0.81..14.35 rows=20 width=4)
         Node/s: All datanodes
         ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=4)
(5 rows)
-- Drop.
gaussdb=#DROP TABLE t1;
```

In the preceding example, the output of the rownum operator is as follows.

Item	Description
Rownum	Operator name.
Filter	ROWNUM predicate for filtering. In the example, **ROWNUM > 10** indicates that the filter condition is to display rows whose ROWNUM is greater than 10.

6.2.3.4.16 Unpivot

Description

Transpose operator, which is used to convert rows into columns. This operation can convert data in multiple columns in a table into two columns. One column is the column name in the original table, and the other column is the corresponding value.

Typical Scenarios

Query the table that uses unpivot for transposition.

Examples

Query the table that uses unpivot for transposition.

```
-- The UNPIVOT syntax can be used only in the O-compatible database.
gaussdb=#CREATE DATABASE ora_test WITH DBCOMPATIBILITY = 'ORA';
gaussdb=#\c ora_test
gaussdb=#SET enable_fast_query_shipping=off;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Prepare data.
ora_test=# DROP TABLE IF EXISTS t1;
ora_test=# CREATE TABLE t1 (id int, number int, grade int);
CREATE TABLE
ora_test=# INSERT INTO t1 VALUES(generate_series(1,100), 1, 2);
INSERT 0 100

-- Execution result.
ora_test=# EXPLAIN SELECT *  FROM t1 UNPIVOT (v1 FOR v2 in (id,number,grade));
                                  oracle
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=1.88..16.24 rows=60 width=36)
   Node/s: All datanodes
   ->  Subquery Scan on __unnamed_unpivot_subquery__  (cost=0.00..13.43 rows=60 width=36)
         Filter: (__unnamed_unpivot_subquery__.v1 IS NOT NULL)
         ->  Unpivot  (cost=0.00..13.13 rows=60 width=36)
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=12)
(6 rows)

-- Drop.
ora_test=# DROP TABLE t1;
ora_test=# \c gaussdb
gaussdb=#DROP DATABASE ora_test;
```

In the preceding example, the output of the unpivot operator is as follows.

Item	Description
Unpivot	Operator name.
Seq Scan	Seq scan operator.

6.2.3.5 Distributed Operators

6.2.3.5.1 Data Node Scan

Description

If the GUC parameter **enable_fast_query_shipping** is set to **on**, the optimizer attempts to push down the query statement from the CN to DNs for execution, and then returns the execution result to the DNs.

Typical Scenarios

Use query statements that can be pushed down.

Examples

Queries that can be pushed down

```
-- Prepare data.
gaussdb=#SET enable_fast_query_shipping=on;
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#CREATE TABLE t1 (id int, number int, grade int);

-- Execution result.
gaussdb=#EXPLAIN SELECT *  FROM t1 where id > 1;
                QUERY PLAN
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

The actual plan is generated on the DN. To view the execution plan on the DN, set the **max_datanode_for_plan** parameter.

```
-- Enable a parameter.
gaussdb=#SET max_datanode_for_plan = 1;
-- Execution result.
gaussdb=#EXPLAIN SELECT *  FROM t1 where id > 1;
                          QUERY PLAN
------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes

 Remote SQL: SELECT id, "number", grade FROM public.t1 WHERE id > 1
 Datanode Name: datanode1
   Seq Scan on t1  (cost=0.00..34.31 rows=648 width=12)
     Filter: (id > 1)
(8 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
```

Item	Description
Data Node Scan	Specifies the operator name.
Node/s: All datanodes	Delivers data to all DNs.

6.2.3.5.2 Streaming

Description

If an SQL statement cannot be pushed down, a distributed execution plan is generated first. Streaming has three forms, which correspond to different data shuffle functions in the distributed structure.

- Streaming (type: GATHER): The CN collects data from DNs.
- Streaming (type: REDISTRIBUTE): Data is redistributed to all the DNs based on selected columns.
- Streaming (type: BROADCAST): Data on the current DN is broadcast to other DNs.

Typical Scenarios

Distributed Execution Plan

Examples

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE t1(c1 int, c2 int);
gaussdb=#CREATE TABLE t2(c1 int, c2 int);

-- Execution result.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#EXPLAIN SELECT * FROM t1,t2 WHERE t1.c2 = t2.c2;
                              QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=13.92..29.57 rows=20 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=13.29..28.64 rows=20 width=16)
         Hash Cond: (t1.c2 = t2.c2)
         ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=8)
               Spawn on: All datanodes
               ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=8)
         ->  Hash  (cost=13.13..13.13 rows=21 width=8)
               ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=8)
(9 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
```

Item	Description
Streaming	Specifies the operator name.
Spawn on: All datanodes	Distributes data to all DNs.

6.2.3.5.3 Remote Query

Description

If an SQL statement cannot be pushed down and a distributed execution plan cannot be generated, an execution plan for sending statements is generated. Run the **EXPLAIN VERBOSE** command to view the SQL statements delivered to DNs.

Typical Scenarios

If an SQL statement cannot be pushed down, a distributed execution plan cannot be generated.

Examples

```
-- Prepare the environment.
gaussdb=#CREATE TABLE t1(c1 int,c2 int);

gaussdb=#EXPLAIN VERBOSE SELECT * FROM t1 limit 1;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Limit  (cost=0.00..0.00 rows=1 width=8)
   Output: t1.c1, t1.c2
   ->  Data Node Scan on "__REMOTE_LIMIT_QUERY__"  (cost=0.00..0.00 rows=1 width=8)
         Output: t1.c1, t1.c2
         Node/s: All datanodes
         Remote query: SELECT c1, c2 FROM ONLY public.t1 WHERE true LIMIT 1::bigint
(6 rows)

-- Drop.
gaussdb=#DROP TABLE t1;
```

Item	Description
Data Node Scan	Operator name.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Node/s: All datanodes	Delivers data to all DNs.
Remote Query	Operator name.

6.2.3.6 Partition Pruning

6.2.3.6.1 Partition Iterator

Description

Table partitioning logically divides a large table or index into smaller and easier-to-manage logical units (partitions), minimizing the impact on table query and modification statements. Users can quickly locate a partition where data is located by using a partition key. In this way, users do not need to scan all large tables in the database and can concurrently perform DDL and DML operations on different partitions. GaussDB supports three partitioning policies: range partitioning, hash partitioning, and list partitioning. Range partitioning is implemented based on binary-search, and the complexity is $O(\log N)$. Hash partitioning and list partitioning are implemented based on the key-partOid hash table, and the complexity is O(1).

Typical Scenarios

- Create a partitioned table using range partitioning.
- Create a partitioned table using hash partitioning.
- Create a partitioned table using list partitioning.

Examples

Example 1: Create a partitioned table using range partitioning.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=# SET max_datanode_for_plan = 1;
gaussdb=#CREATE TABLE t1 (c1 int, c2 int) PARTITION BY RANGE (c1)(
    PARTITION p1 VALUES LESS THAN(10) ,
    PARTITION p2 VALUES LESS THAN(20),
    PARTITION p3 VALUES LESS THAN(MAXVALUE)
);
CREATE TABLE

gaussdb=#INSERT INTO t1 VALUES(generate_series(1,100,2), 1);
INSERT 0 50
gaussdb=#INSERT INTO t1 VALUES(generate_series(2,101,2), 2);
INSERT 0 50

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM t1 WHERE c1 < 15 AND c2 <= 1;
                            QUERY PLAN
------------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes

 Remote SQL: SELECT c1, c2 FROM public.t1 WHERE c1 < 15 AND c2 <= 1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Datanode Name: datanode1
   Partition Iterator  (cost=0.00..33.23 rows=239 width=8)
     Iterations: 2
     ->  Partitioned Seq Scan on t1  (cost=0.00..33.23 rows=239 width=8)
           Filter: ((c1 < 15) AND (c2 <= 1))
           Selected Partitions:  1..2

(11 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS t1;
```

In the preceding example, the output of the Partition Iterator operator is as follows.

Item	Description
Partition Iterator	Operator name.
Iterations	Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used. For example, **Iterations: 2** in example 1 indicates that the iteration operator needs to traverse two level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.
Filter	Filter predicate of the operator. In the example, the filter condition is that the value in column **c1** is less than 15 and the value in column **c2** is less than or equal to 1. When a query is executed, rows that meet these conditions are included in the final result set.
Partitioned Seq Scan	Scan mode of a partitioned table.
Selected Partitions	Level-1 partition pruning result. In example 1, **Selected Partitions: 1..2** indicates that partitions 1 and 2 are selected.

Example 2: Create a level-2 partitioned table using hash partitioning.

```
-- Prepare data.
gaussdb=#CREATE TABLE sales (id INT, number INT) PARTITION BY HASH (number);
CREATE TABLE

gaussdb=#INSERT INTO sales VALUES(generate_series(1,50), generate_series(1,50));
INSERT 0 50

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM sales WHERE id < 15 AND number <= 50;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes

 Remote SQL: SELECT id, "number" FROM public.sales WHERE id < 15 AND "number" <= 50
 Datanode Name: datanode1
   Partition Iterator  (cost=0.00..42.23 rows=239 width=8)
     Iterations: 1
     ->  Partitioned Seq Scan on sales  (cost=0.00..42.23 rows=239 width=8)
           Filter: ((id < 15) AND ("number" <= 50))
           Selected Partitions:  1

(11 rows)

-- Drop.
DROP TABLE sales;
```

In the preceding example, the output of the Partition Iterator operator is as follows.

Item	Description
Partition Iterator	Operator name.
Iterations	Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used. For example, **Iterations: 2** in example 2 indicates that the iteration operator needs to traverse two level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.
Filter	Filter predicate of the operator. In the example 2, the filter condition is that the value in column **id** is less than 15 and the value in column **number** is less than or equal to 50. When a query is executed, rows that meet these conditions are included in the final result set.
Partitioned Seq Scan	Scan mode of a partitioned table.
Selected Partitions	Level-1 partition pruning result. In example 2, **Selected Partitions: 1..2** indicates that partitions 1 and 2 are selected.

Example 3: Create a partitioned table using list partitioning.

```
-- Prepare data.
gaussdb=#CREATE TABLE list_partitioned_table (id INT, category INT)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
PARTITION BY LIST (category)
(
    PARTITION p0 VALUES (1, 3, 5, 7),
    PARTITION p1 VALUES (2, 4, 6, 8)
);
CREATE TABLE

gaussdb=#INSERT INTO list_partitioned_table VALUES(0,generate_series(1,8,2));
INSERT 0 4
gaussdb=#INSERT INTO list_partitioned_table VALUES(1,generate_series(2,7,2));
INSERT 0 3

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM list_partitioned_table WHERE id = 0 AND category <= 5;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Data Node Scan  (cost=0.00..0.00 rows=0 width=0)
   Node/s: datanode1

 Remote SQL: SELECT id, category FROM public.list_partitioned_table WHERE id = 0 AND category <= 5
 Datanode Name: datanode1
   Partition Iterator  (cost=0.00..42.23 rows=4 width=8)
     Iterations: 2
     ->  Partitioned Seq Scan on list_partitioned_table  (cost=0.00..42.23 rows=4 width=8)
           Filter: ((category <= 5) AND (id = 0))
           Selected Partitions:  1..2

(11 rows)
-- Drop.
gaussdb=#DROP TABLE list_partitioned_table;
```

In the preceding example, the output of the Partition Iterator operator is as follows.

Item	Description
Partition Iterator	Operator name.
Iterations	Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used. For example, **Iterations: 2** in example 3 indicates that the iteration operator needs to traverse two level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.
Filter	Filter predicate of the operator. In the example 2, the filter condition is that the value in column **category** is less than or equal to 5 and the value in column **id** is equal to 0. When a query is executed, rows that meet these conditions are included in the final result set.
Partitioned Seq Scan	Scan mode of a partitioned table.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Item	Description
Selected Partitions	Level-1 partition pruning result. In example 3, **Selected Partitions: 1..2** indicates that partitions 1 and 2 are selected.

6.2.3.7 Other Keywords

6.2.3.7.1 Initplan and Subplan

Description

Initplan is a kind of GaussDB subplan. In GaussDB, subquery plans can be classified into correlated subplans and non-correlated subplans. A correlated subplan is a row that a subquery depends on an external query and cannot be executed independently of the foreign query. A non-correlated subplan is the opposite. In GaussDB, a subplan or initplan is a part that can be independently executed compared with the entire plan and is generally generated by a subplan that cannot be promoted. Subplans are generated based on correlated subplans, and initplans are generated based on non-correlated subplans. Subplan runs during the execution of the main query and is re-executed on each row of the main query. Initplan runs before the execution of the main query and the result is one-time. They are calculated at the beginning of the query and then cached for reuse during the entire query execution, therefore, initplan is more efficient.

Typical Scenarios

The SELECT subplan does not depend on foreign queries and cannot be pulled up.

Examples

Example: The SELECT subplan does not depend on foreign queries and cannot be pulled up.

```
-- Prepare data.
gaussdb=#DROP TABLE IF EXISTS init_table;
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
gaussdb=#CREATE TABLE init_table (id int, grade int, time int);
CREATE TABLE
gaussdb=#INSERT INTO init_table VALUES(generate_series(1,10000), (random() * 10)::integer,(random() *
10)::integer );
INSERT 0 10000
gaussdb=#CREATE TABLE t1(grade int);
CREATE TABLE
gaussdb=#INSERT INTO t1 VALUES( 10),( 11);
INSERT 0 2
gaussdb=#CREATE TABLE t2(a int, b int, c int);
CREATE TABLE
gaussdb=#INSERT INTO t2 VALUES(1, 2, 3 );
INSERT 0 1

-- Execution result.
gaussdb=#EXPLAIN SELECT * FROM init_table  WHERE init_table.grade  IN  (SELECT grade FROM t2) AND
init_table.grade != (SELECT * FROM t1);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                                QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=13.56..126.53 rows=9 width=12)
   Node/s: All datanodes
   InitPlan 2 (returns $2)
     ->  Streaming(type: BROADCAST)  (cost=0.00..13.18 rows=40 width=4)
           Spawn on: All datanodes
           ->  Seq Scan on t1  (cost=0.00..13.13 rows=20 width=4)
   ->  Seq Scan on init_table  (cost=0.00..112.79 rows=9 width=12)
         Filter: ((grade <> $2) AND (SubPlan 1))
         SubPlan 1
           ->  Result  (cost=0.00..15.28 rows=40 width=0)
                 ->  Materialize  (cost=0.00..15.28 rows=40 width=0)
                       ->  Streaming(type: BROADCAST)  (cost=0.00..15.18 rows=40 width=0)
                             Spawn on: All datanodes
                             ->  Seq Scan on t2  (cost=0.00..13.13 rows=20 width=0)
(14 rows)

-- Drop.
gaussdb=#DROP TABLE IF EXISTS init_table;
gaussdb=#DROP TABLE IF EXISTS t1;
gaussdb=#DROP TABLE IF EXISTS t2;
```

In the preceding example, the output is as follows.

Item	Description
InitPlan	Non-correlated subplan. In the example, **InitPlan 2** indicates that subplan 2 is a non-correlated subplan.
returns	Returned result. In the example, **returns $2** indicates that the result of initplan is stored in **$2**.
SubPlan	Correlated subplan. In the example, **SubPlan 1** indicates that subplan 1 is a non-correlated subplan.

6.3 Optimization Process

You can analyze slow SQL statements to optimize them.

Procedure

Step 1 Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by an optimizer. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10% performance problems occurred because no statistics are collected. For details, see **Updating Statistics**.

Step 2 View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute EXPLAIN ANALYZE or EXPLAIN PERFORMANCE to check the execution plan and information to locate the fault. For details about the execution plan, see **Introduction to the SQL Execution Plan**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Step 3 Review and modify a table definition. For details, see **Reviewing and Modifying a Table Definition**.

Step 4 For details about EXPLAIN or EXPLAIN PERFORMANCE, the reason why SQL statements are slowly located, and how to solve this problem, see **Typical SQL Optimization Methods**.

Step 5 Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. **Experience in Rewriting SQL Statements** describes several tuning methods by rewriting SQL statements.

----End

6.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by an optimizer. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

Context

The ANALYZE statement collects statistic about table contents in databases, which will be stored in the **PG_STATISTIC** system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan. For details about the ANALYZE statement, see **ANALYZE | ANALYSE**.

After executing batch insertions and deletions, you are advised to run the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default_statistics_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default_statistics_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the ANALYZE statement.

If there are multiple inter-related columns in a table and the conditions or grouping operations based on these columns are involved in the query, collect statistics about these columns so that the query optimizer can accurately estimate the number of rows and generate an effective execution plan.

If the table has a GSI, perform ANALYZE on the base table first and then on the GSI.

Procedure

Update the statistics about a table or the entire database.

```
ANALYZE tablename;                  -- Update statistics about a table.
ANALYZE;                            -- Update statistics about the entire database.
```

Update statistics about the GSI on the table.

```
ANALYZE GLOBAL INDEX indexname FOR TABLE tablename;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> To update the statistics about the GSI, perform ANALYZE on the base table first.

Perform statistics-related operations on multiple columns.

```
ANALYZE tablename ((column_1, column_2));                    -- Collect statistics about column_1 and column_2 of tablename.

ALTER TABLE tablename ADD STATISTICS ((column_1, column_2));    -- Declare statistics about column_1 and column_2 of tablename.
ANALYZE tablename;                                           -- Collect statistics about one or more columns.

ALTER TABLE tablename DELETE STATISTICS ((column_1, column_2)); -- Delete statistics about column_1 and column_2 of tablename or their statistics declaration.
```

NOTICE

After the statistics are declared for multiple columns by executing the ALTER TABLE tablename ADD STATISTICS statement, the system collects the statistics about these columns next time ANALYZE is performed on the table or the entire database.

To collect the statistics, run the **ANALYZE** command.

> **NOTE**
>
> Use EXPLAIN to show the execution plan of each SQL statement. If **rows** is set to **10** (the default value, probably indicating that the table has not been analyzed) is displayed in the **SEQ SCAN** output of a table, execute the ANALYZE statement for this table.

6.5 Reviewing and Modifying a Table Definition

6.5.1 Overview

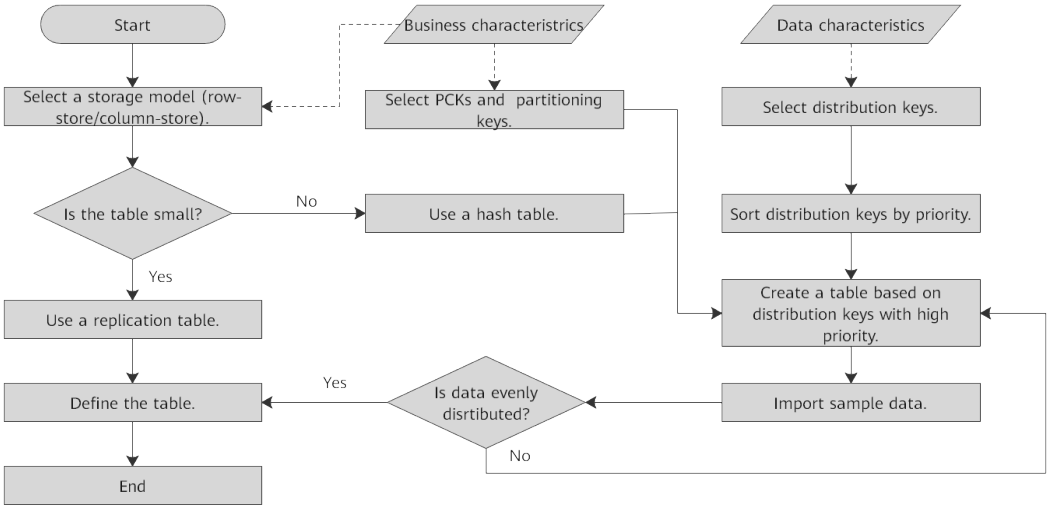
In a distributed framework, data is distributed on DNs. Data on one or more DNs is stored on a physical storage device. To properly define a table, you must:

1. Evenly distribute data on each DN to avoid the available capacity decrease of a cluster caused by insufficient storage space of the storage device associated with a DN. Select a proper distribution key to avoid data skew.
2. Evenly assign table scanning tasks on each DN to avoid that a single DN is overloaded by the table scanning tasks. Specifically, do not select columns in the equivalent filter of a base table as the distribution key.
3. Reduce the data volume scanned by using the partition pruning mechanism.
4. Minimize random I/Os by using clustering.
5. Avoid data shuffle and reduce the network pressure by selecting the **join-condition** or **group by** column as the distribution key.

The distribution key is the core for defining a table. **Figure 6-2** shows the procedure of defining a table. The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 6-2 Procedure of defining a table



6.5.2 Selecting a Distribution Mode

In replication mode, full data in a table is copied to each DN in the cluster. This mode is used for tables containing a small volume of data. The advantage of this storage mode is that each DN has full data of the table. During the join operation, data does not need to be redistributed, reducing network overheads and reducing plan segments (each plan segment starts a corresponding thread). The disadvantage is that each DN retains the complete data of the table, resulting in data redundancy. Generally, this mode is only used for small dimension tables.

In hash mode, hash values are generated for one or more columns. You can obtain the storage location of a tuple based on the mapping between DNs and the hash values. In a hash table, I/O resources on each node can be used during data read/write, which improves the read/write speed of a table. Generally, a table containing a large amount data is defined as a hash table.

Range distribution and list distribution are user-defined distribution policies. Values in a distribution key are within a certain range or fall into a specific value range of the corresponding target DN. The two distribution modes facilitate flexible data management, which, however, requires users equipped with certain data abstraction capability. For details, see **Table 6-4**.

Table 6-4 Policies and application scenarios

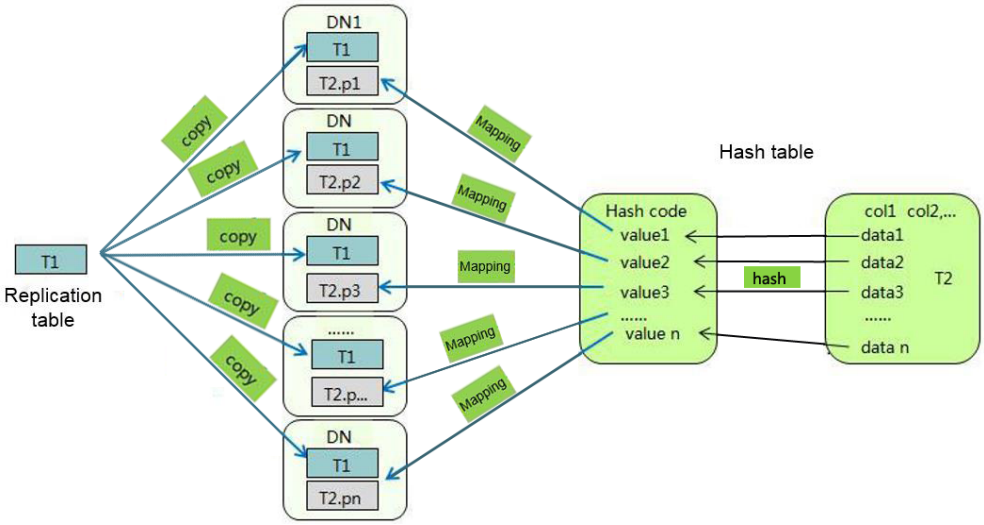
Policy	Description	Application Scenario
Hash	Table data is distributed on all DNs in the cluster.	Fact tables containing a large amount of data
Replication	Full data in a table is stored on every DN in the cluster.	Small tables and dimension tables
Range	Table data is mapped to specified columns based on the range and distributed to the corresponding DNs.	Users need to customize distribution rules.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Policy	Description	Application Scenario
List	Table data is mapped to specified columns based on specific values and distributed to corresponding DNs.	Users need to customize distribution rules.

As shown in **Figure 6-3**, **T1** is a replication table and **T2** is a hash table.

Figure 6-3 Replication tables and hash tables



NOTE

- When you insert, modify, or delete data in a replication table, if you use the shippable or immutable function to encapsulate components that cannot be pushed down, data on different DNs in the replication table may be inconsistent.
- If statements with unstable results, such as window functions, user-defined functions, and ROWNUM and limit clauses are used to insert or modify data in a replication table, data on different nodes may be different.

6.5.3 Selecting Distribution Keys

Selecting a distribution key for a hash table is essential. Details are as follows:

1. Ensure that the column values are discrete so that data can be evenly distributed to each DN. You can select the primary key of the table as the distribution key. For example, for a person information table, choose the ID card number column as the distribution key.
2. Do not select the column that has a constant filter. If a constant constraint (for example, **zqdh='000001'**) exists on the **zqdh** column in some queries on the **dwcjk** table, you are advised not to use **zqdh** as the distribution key.
3. Select the join condition as the distribution key, so that join tasks can be pushed down to DNs to execute, reducing the amount of data transferred between the DNs.

For a hash table, an improper distribution key may cause data skew or poor I/O performance on certain DNs. Therefore, you need to check the table to ensure that

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

data is evenly distributed on each DN. You can run the following SQL statements to check for data skew:

```
select
xc_node_id, count(1)
from tablename
group by xc_node_id
order by xc_node_id desc;
```

xc_node_id corresponds to a DN. Generally, over 5% difference between the amount of data on different DNs is regarded as data skew. If the difference is over 10%, choose another distribution key.

Multiple distribution keys can be selected in GaussDB to evenly distribute data.

You can select the distribution key of the range or list distributed table as required. In addition to selecting a proper distribution key, pay attention to the impact of distribution rules on data distribution.

6.5.4 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored on these physical partitions, instead of the logical partitioned table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

GaussDB supports range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

NOTE

If the same column definition is used for partitioning and distribution and the partitioning and distribution definition rules are the same or similar, some partitions on some DNs may have no data in some special cases, which may affect the accuracy of the query plan.

Typical scenario: The definitions of partitioning and distribution are the same, or both partitioning and distribution use the hash algorithm for mapping, and the number of partitions is a multiple of the number of distributed nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.5.5 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

   Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and GROUP BY) is more efficient than that of strings and floating point numbers.

2. **Select data types with a short length.**

   Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use SMALLINT instead of INT, and INT instead of BIGINT.

3. **Use the same data type for a join.**

   You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

6.6 Reviewing the Plan Change Scenario

The optimizer generates the optimal execution plan based on the cost model and statistics of related tables. Therefore, changes in statistics of related tables or parameter modifications of the cost model affect generation of the optimal plan. In addition, many operations of production services may cause the plan cache to become invalid and rebuild, such as operations related to statistics update (VACUUM, ANALYZE, AUTOVACUUM, and AUTOANALYZE), DDL operations such as index rebuilding, SQL patch application, and other scenarios that cause the cache to become invalid. If the optimal plan generated based on the cost during the period is different from the previous one, a plan change occurs. Therefore, plan change is a common phenomenon in production services.

Generally, positive plan changes do not need to be concerned. Pay special attention to the scenarios where the performance deteriorates and the CPU usage increases due to plan changes. This is usually accompanied by database environment variable changes, such as statistics update, table structure change, or database version upgrade.

In GaussDB, plan changes may occur in the following scenarios. Therefore, you need to review the scenarios and apply precise optimization methods (such as hints).

- Generic plan rebuilding: When the service is running stably, the generic plan is usually executed, indicating that the plan is stable and the optimizer does not need to optimize the SQL statement. In some cases, the generic plan may be invalid and needs to be rebuilt.
  - If you modify GUC parameters, the generic plan will be rebuilt. If you modify optimizer parameters, such as **query_dop**, plan changes will occur. Do not modify optimizer parameters unless there are special requirements for stable services.
  - DDL operations are performed on the base table involved in the query. The DDL operations on the table cause the rebuilding of the generic plan, and the addition, deletion, and modification of indexes affect the plan

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

selection. To optimize an index, ensure that the index is valid and update the index statistics in a timely manner to select a better plan.

  - Perform IUD operations on tables and manually or automatically collect statistics. Changes in statistics cause generic plan rebuilding. Generally, if statistics are collected in a timely manner, performance deterioration will not occur even if the plan changes. A common service scenario is that a large number of IUD operations are performed on the base table involved in the query but the statistics are not updated in a timely manner. In this case, you need to manually collect statistics or review the triggering of automatic statistics collection.

- Intelligent optimizer: The generic plan cannot meet service requirements in some scenarios. For example, in data skew scenarios, the optimal plan varies depending on data. The intelligent optimizer generates multiple alternative generic plans and selects the optimal plan for execution in real time based on the query feedback. The intelligent optimizer is related to the service execution sequence. If the intelligent optimizer cannot meet the requirements, you are advised to use hints or SQL patches to optimize key service statements.

6.7 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by **checking the execution plan** and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

6.7.1 Optimizing SQL Self-Diagnosis

Performance issues may occur when you query data or run the INSERT, DELETE, UPDATE, or CREATE TABLE AS statement.

Alarms that can trigger SQL self-diagnosis depend on the settings of the GUC parameter **resource_track_level**. If **resource_track_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource_track_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether an SQL plan will be diagnosed depends on the settings of the GUC parameter **resource_track_cost**. An SQL plan will be diagnosed only if its execution cost is greater than **resource_track_cost**. You can use the **EXPLAIN** keyword to check the plan execution cost.

The SQL self-diagnosis function is affected by the **enable_analyze_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr_unique_sql_count**.

Alarms

Currently, the following performance alarms will be reported:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Some column statistics are not collected.

  An alarm will be reported if some column statistics are not collected.

  Example alarms:

  No statistics about a table are not collected.

  ```
  Statistic Not Collect:
    schema_test.t1
  ```

  The statistics about a single column are not collected.

  ```
  Statistic Not Collect:
    schema_test.t2(c1,c2)
  ```

  The statistics about multiple columns are not collected.

  ```
  Statistic Not Collect:
    schema_test.t3((c1,c2))
  ```

  The statistics about a single column and multiple columns are not collected.

  ```
  Statistic Not Collect:
    schema_test.t4(c1,c2)    schema_test.t4((c1,c2))
  ```

- SQL statements are not pushed down.

  The cause details are displayed in the alarms. For details about the optimization method, see **Optimizing Statement Pushdown**.

  - If a function is not pushed down, an alarm is generated for the corresponding function.
  - If the pushdown failure is because of the syntax, the alarm indicates that the syntax does not support pushdown. For example, syntaxes whose return value is of record type, and syntaxes containing the **With Recursive**, **Distinct On**, or **Row** expression do not support pushdown.

  Example alarms:

  ```
  SQL is not plan-shipping, reason : "With Recursive" can not be shipped"
  SQL is not plan-shipping, reason : "Function now() can not be shipped"
  SQL is not plan-shipping, reason : "Function string_agg() can not be shipped"
  ```

- In a hash join, the larger table is used as the inner table.

  An alarm will be reported if the number of rows in the inner table reaches or exceeds 10 times of that in the outer table, more than 100 thousand of inner-table rows are processed on each DN in average, a hash join is used, and the join statement has spilled to disks. For details about the optimization, see **Hint-based Optimization**.

  Example alarms:

  ```
  PlanNode[7] Large Table is INNER in HashJoin "Vector Hash Aggregate"
  ```

- **nestloop** is used in a large-table equi-join.

  An alarm will be reported if **nestloop** is used in an equi-join where more than 100,000 larger-table rows are processed on each DN in average. For details about the optimization, see **Hint-based Optimization**.

  Example alarms:

  ```
  PlanNode[5] Large Table with Equal-Condition use Nestloop"Nested Loop"
  ```

- A large table is broadcasted.

  An alarm will be reported if more than 100 thousand of rows are broadcast on each DN in average. For details about the optimization, see **Hint-based Optimization**.

  Example alarms:

  ```
  PlanNode[5] Large Table in Broadcast "Streaming(type: BROADCAST dop: 1/2)"
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Data skew occurs.

  An alarm will be reported if the number of rows processed on any DN exceeds 100,000, and the number of rows processed on a DN reaches or exceeds 10 times of that processed on another DN.

  Example alarms:

  ```
  PlanNode[6] DataSkew:"Seq Scan", min_dn_tuples:0, max_dn_tuples:524288
  ```

- Estimation is inaccurate.

  An alarm will be reported if the maximum number or the estimated maximum number of rows processed on a DN is over 100,000, and the larger number reaches or exceeds 10 times of the smaller one. For details about the optimization, see **Hint-based Optimization**.

  Example alarms:

  ```
  PlanNode[5] Inaccurate Estimation-Rows: "Hash Join" A-Rows:0, E-Rows:52488
  ```

Restrictions

1. An alarm contains a maximum of 2048 characters. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.
   ```
   WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
   ```
2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.
3. For alarms about data skew and inaccurate estimation, only alarms on the lower-layer nodes in a plan tree will be reported. This is because the same alarms on the upper-level nodes may be triggered by problems on the lower-layer nodes. For example, if data skew occurs on the **Scan** node, data skew may also occur in operators (for example, **Hashagg**) at the upper layer.

6.7.2 Optimizing Statement Pushdown

Statement Pushdown

Currently, the GaussDB optimizer can use three methods to develop statement execution policies in the distributed framework: generating a statement pushdown plan, a distributed execution plan, or a distributed execution plan for sending statements.

- A statement pushdown plan pushes complete query statements from a CN down to DNs for execution and returns the execution results to the CN.
- In a distributed execution plan, a CN compiles and optimizes query statements, generates a plan tree, and then sends the plan tree to DNs for execution. After the statements have been executed, execution results will be returned to the CN.
- A distributed execution plan for sending statements pushes queries that can be pushed down (mostly base table scanning statements) to DNs for execution. Then, the plan obtains the intermediate results and sends them to the CN, on which the remaining queries are to be executed.

The third policy sends many intermediate results from DNs to the CN for further execution. In this case, the CN performance bottleneck (in bandwidth, storage, and

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

computing) is caused by statements that cannot be pushed down to DNs. Therefore, you are advised not to use the query statements where only the third policy applies.

Statements cannot be pushed down if they have **functions that do not support pushdown** or **syntax that does not support pushdown**. Generally, you can rewrite the execution statements to solve the problem.

Typical Scenarios of Statement Pushdown Plans

In the GaussDB optimizer, if you want to support statement pushdown, set the GUC parameter **enable_fast_query_shipping** to **on**. Generally, no execution plan operator is displayed after the EXPLAIN statement. If the keyword "Data Node Scan on" in the execution plan is displayed in the first line (excluding the plan format), the statement has been pushed down to DNs for execution. The following describes statement pushdown and its supported scope from multiple scenarios:

1. Pushdown of single-table query statements

   In a distributed database, to query a single table, whether the current statement can be pushed down depends on whether the CN needs to participate in calculation instead of simply collecting data. If the CN needs to further calculate the DN result, the statement cannot be pushed down. Generally, statements with keywords such as agg, windows function, limit/offset, sort, distinct cannot be pushed down.

   - Pushdown: Simple queries can be pushed down without further calculation on the CN.

     ```
     gaussdb=# explain select * from t where c1 > 1;
                                 QUERY PLAN
     ------------------------------------------------------------------------------
      Data Node Scan on "__REMOTE_FQS_QUERY__"  (cost=0.00..0.00 rows=0 width=0)
        Node/s: All datanodes
     (2 rows)
     ```

   - Non-pushdown: A CN with the limit clause cannot simply send statements to DNs and collect data, which is inconsistent with the semantics of the limit clause.

     ```
     gaussdb=# explain select * from t limit 1;
                                    QUERY PLAN
     ---------------------------------------------------------------------------------------
      Limit  (cost=0.00..0.00 rows=1 width=12)
        ->  Data Node Scan on "__REMOTE_LIMIT_QUERY__"  (cost=0.00..0.00 rows=1 width=12)
              Node/s: All datanodes
     (3 rows)
     ```

   - Non-pushdown: A CN with the aggregate function cannot simply push down statements. Instead, it needs to further aggregate the results collected from DNs.

     ```
     gaussdb=# explain select sum(c1), count(*) from t;
                                    QUERY PLAN
     ---------------------------------------------------------------------------------------
      Aggregate  (cost=0.10..0.11 rows=1 width=20)
        ->  Data Node Scan on "__REMOTE_GROUP_QUERY__"  (cost=0.00..0.00 rows=20 width=4)
              Node/s: All datanodes
     (3 rows)
     ```

2. Pushdown of multi-table query statements

   In the multi-table query scenario, whether a statement can be pushed down depends on the join condition and distribution keys. That is, if the join condition matches the distribution keys of the table, the statement can be

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

pushed down. Otherwise, the statement cannot be pushed down. Generally, a replication table can be pushed down.

- Create two hash distributed tables.

```
gaussdb=# create table t(c1 int, c2 int, c3 int)distribute by hash(c1);
CREATE TABLE
gaussdb=# create table t1(c1 int, c2 int, c3 int)distribute by hash(c1);
CREATE TABLE
```

- Pushdown: The join condition meets the hash distribution key attributes of two tables.

```
gaussdb=# explain select * from t1 join t on t.c1 = t1.c1;
                            QUERY PLAN
------------------------------------------------------------------------------
 Data Node Scan on "__REMOTE_FQS_QUERY__"  (cost=0.00..0.00 rows=0 width=0)
   Node/s: All datanodes
(2 rows)
```

- Non-pushdown: The join condition does not meet the hash distribution key attribute. That is, **t1.c2** is not the distribution key of **t1**.

```
gaussdb=# explain select * from t1 join t on t.c1 = t1.c2;
                                  QUERY PLAN
-------------------------------------------------------------------------------------------------
 Hash Join  (cost=0.25..0.53 rows=20 width=24)
   Hash Cond: (t1.c2 = t.c1)
   ->  Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=20 width=12)
         Node/s: All datanodes
   ->  Hash  (cost=0.00..0.00 rows=20 width=12)
         ->  Data Node Scan on t "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=20 width=12)
               Node/s: All datanodes
(7 rows)
```

- Delete two hash distributed tables.

```
gaussdb=# DROP TABLE t;
DROP TABLE
gaussdb=# DROP TABLE t1;
DROP TABLE
```

3. Set operation and CTE pushdown

   Whether statements in the set operation scenario can be pushed down depends on whether the left and right subqueries can be pushed down. The rules are as follows:

   - UNION ALL can be pushed down only when both the left and right branches can be pushed down and the DNs of the left and right branches are the same.
   - The set operation can be pushed down only when the left and right branches of UNION/INTERSECT/INTERSECT ALL/EXCEPT/EXCEPT ALL can be pushed down to the same single node.

```
-- The test environment contains one CN and six DNs.
-- Create a node group. You can run the SELECT node_name FROM PGXC_NODE WHERE node_type = 'D' command to query the DN name in the node group. In the query result, replace the DN name following WITH in the CREATE NODE GROUP statement as required.
gaussdb=# CREATE NODE GROUP ng WITH(datanode1, datanode2, datanode3, datanode4, datanode5, datanode6);
CREATE NODE GROUP
-- Create a table.
gaussdb=# CREATE TABLE t1(a int, b int, c int) DISTRIBUTE BY HASH(a) TO GROUP ng;
CREATE TABLE
gaussdb=# CREATE TABLE t2(a int, b int, c int) DISTRIBUTE BY HASH(a) TO GROUP ng;
CREATE TABLE
-- Both sides of UNION ALL can be pushed down. Therefore, UNION ALL can be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 UNION ALL SELECT * FROM t2;
      QUERY PLAN
-------------------------
 Data Node Scan
   Node/s: All datanodes
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(2 rows)

-- Both sides of UNION can be pushed down, but not to a single DN. Therefore, UNION cannot
be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 UNION SELECT * FROM t2;
              QUERY PLAN
---------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  HashAggregate
         Group By Key: t1.a, t1.b, t1.c
         ->  Append
               ->  Seq Scan on t1
               ->  Seq Scan on t2
(7 rows)

-- Both sides of UNION can be pushed down to the same DN. Therefore, UNION can be pushed
down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1 UNION SELECT * FROM t2
WHERE a = 1;
        QUERY PLAN
--------------------------
 Data Node Scan
   Node/s: (ng) datanode5
(2 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1;
        QUERY PLAN
-------------------------
 Data Node Scan
   Node/s: (ng) datanode5
(2 rows)

gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t2 WHERE a = 3;
        QUERY PLAN
--------------------------
 Data Node Scan
   Node/s: (ng) datanode4
(2 rows)

-- Both sides of UNION can be pushed down, but not to the same DN. Therefore, UNION
cannot be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) SELECT * FROM t1 WHERE a = 1 UNION SELECT * FROM t2
WHERE a = 3;
               QUERY PLAN
-----------------------------------------
 Streaming (type: GATHER)
   Node/s: (GenGroup) datanode4, datanode5
   ->  Unique
         ->  Sort
               Sort Key: t1.a, t1.b, t1.c
               ->  Append
                     ->  Seq Scan on t1
                           Filter: (a = 1)
                     ->  Seq Scan on t2
                           Filter: (a = 3)
(10 rows)
```

Whether statements in the CTE scenario can be pushed down depends on whether statements in the CTE scenario can be pushed down. The rules are as follows:

- The entire CTE can be pushed down only when statements in a CTE can be pushed down.
- For a recursive CTE, the recursive part references its CTE. When determining whether the recursive part can be pushed down, the pushdown information of the self-referenced CTE depends on the pushdown information of the non-recursive part. That is, the non-

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

recursive statement can be regarded as a subquery of the self-referenced CTE.

- An entire recursive CTE can be pushed down only when statements in the recursive CTE can be pushed down, and the recursive and non-recursive statements can be pushed down to the same DN.

```
-- Statements in the CTE can be pushed down. Therefore, the CTE can be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1) SELECT * FROM cte;
      QUERY PLAN
-------------------------
 Data Node Scan
   Node/s: All datanodes
(2 rows)

-- Statements in the CTE can be pushed down to a single DN. Therefore, the CTE can be pushed down to a single DN.
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1 WHERE a = 1) SELECT * FROM cte;
       QUERY PLAN
-------------------------
 Data Node Scan
   Node/s: (ng) datanode5
(2 rows)

-- Statements in the CTE cannot be pushed down. Therefore, the CTE cannot be pushed down.
gaussdb=# EXPLAIN (COSTS OFF) WITH cte AS (SELECT * FROM t1 ORDER BY a ) SELECT * FROM cte;
        QUERY PLAN
---------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Sort
         Sort Key: t1.a
         ->  Seq Scan on t1
(5 rows)

-- Statements in the recursive CTE can be pushed down, and the recursive and non-recursive parts can be pushed down to multiple same DNs. Therefore, the recursive CTE can be pushed down to multiple DNs.
gaussdb=# EXPLAIN (COSTS OFF)
WITH RECURSIVE cte AS (
SELECT * FROM t1
UNION ALL
SELECT t2.* FROM t2, cte WHERE cte.a = t2.a) SELECT * FROM cte;
      QUERY PLAN
-------------------------
 Data Node Scan
   Node/s: All datanodes
(2 rows)

-- Statements in the recursive CTE can be pushed down, and the recursive and non-recursive parts can be pushed down to a single DN. Therefore, the recursive CTE can be pushed down to the single DN.
gaussdb=# EXPLAIN (COSTS OFF)

gaussdb=# DROP NODE GROUP ng;
DROP NODE GROUP
```

4. Special scenarios

   The pushdown rules and restrictions in some special scenarios are as follows:

   - A statement cannot be pushed down if it is not a SELECT statement but contains WITH RECURSIVE CTE, common CTE, or set operation.
   - A statement cannot be pushed down if it contains elements that cannot be pushed down (such as volatile functions, not shippable functions, record types, agg functions, returning clauses, and triggers that cannot be pushed down).
   - If a CTE, recursive CTE, set operation, subquery, or sublink cannot tailor a DN based on constant conditions, you can rewrite the statement to write conditions to the CTE, recursive CTE, set operation, subquery, or sublink.
   - When a CTE, recursive CTE, or set operation is joined with the main query, the entire statement can be pushed down only when the distribution information of the CTE, recursive CTE, or set operation is the same as that of objects in the main query and the pushdown conditions are met.
   - In multi-table query scenarios, if a distributed table contains multiple distribution keys and the distribution keys in query conditions contain parameters, the gplan cannot be pushed down.

Checking Whether the Distributed Execution Plan Has Been Pushed Down

Perform the following procedure to quickly determine whether the execution plan can be pushed down:

Step 1 If the GUC parameter **enable_fast_query_shipping** is set to **off**, the query optimizer uses the distributed framework policy to ensure that a distributed execution plan is generated for the statement instead of a statement pushdown plan.

```
gaussdb=# SET enable_fast_query_shipping = off;
```

Step 2 View the execution plan.

If the execution plan contains Data Node Scan nodes, the execution plan is a distributed execution plan for sending statements and cannot be pushed down. If

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the execution plan contains Streaming nodes, the SQL statements can be pushed down to DNs.

For example:

```
gaussdb=# explain select
count(ss.ss_sold_date_sk order by ss.ss_sold_date_sk)c1
from store_sales ss, store_returns sr
where
sr.sr_customer_sk = ss.ss_customer_sk;
```

The execution plan is as follows, which indicates that the SQL statement cannot be pushed down.

```
                            QUERY PLAN
------------------------------------------------------------------------------
Aggregate
->  Hash Join
Hash Cond: (ss.ss_customer_sk = sr.sr_customer_sk)
->  Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
->  Hash
->  Data Node Scan on store_returns "_REMOTE_TABLE_QUERY_"
Node/s: All datanodes
(8 rows)
```

For example:

```
gaussdb=# CREATE TABLE t1(a int, b int);
gaussdb=# CREATE TABLE t2(a int, b int);
gaussdb=# EXPLAIN VERBOSE SELECT * FROM t1,t2 WHERE t1.b=t2.b;
```

The execution plan is as follows, which indicates that the SQL statement generates a distributed execution plan for pushdown:

```
                  QUERY PLAN
--------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         Join Filter: (t1.b = t2.b)
         ->  Streaming(type: REDISTRIBUTE)
               Spawn on: All datanodes
               ->  Seq Scan on t1
         ->  Materialize
               ->  Streaming(type: REDISTRIBUTE)
                     Spawn on: All datanodes
                     ->  Seq Scan on t2
(11 rows)
```

Drop tables.

```
gaussdb=# DROP TABLE t1;
gaussdb=# DROP TABLE t2;
```

----End

Syntax That Does Not Support Pushdown

SQL syntax that does not support pushdown is described using the following table definition examples:

```
gaussdb=# CREATE TABLE CUSTOMER1
(
    C_CUSTKEY     BIGINT NOT NULL
  , C_NAME        VARCHAR(25) NOT NULL
  , C_ADDRESS     VARCHAR(40) NOT NULL
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  , C_NATIONKEY   INT NOT NULL
  , C_PHONE       CHAR(15) NOT NULL
  , C_ACCTBAL     DECIMAL(15,2)   NOT NULL
  , C_MKTSEGMENT  CHAR(10) NOT NULL
  , C_COMMENT     VARCHAR(117) NOT NULL
)
DISTRIBUTE BY hash(C_CUSTKEY);
gaussdb=# CREATE TABLE test_stream(a int, b float); --float does not support redistribution.
gaussdb=# CREATE TABLE sal_emp ( c1 integer[] ) DISTRIBUTE BY replication;
```

- The RETURNING statement cannot be pushed down.

```
gaussdb=# explain update customer1 set C_NAME = 'a' returning c_name;
                            QUERY PLAN
------------------------------------------------------------------
 Update on customer1  (cost=0.00..0.00 rows=30 width=187)
   Node/s: All datanodes
   Node expr: c_custkey
   ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=187)
         Node/s: All datanodes
(5 rows)
```

- The ORDER BY statement cannot be pushed down in aggregate functions.

```
gaussdb=# explain verbose select count ( c_custkey order by c_custkey) from customer1;

                        QUERY PLAN
------------------------------------------------------------------
 Aggregate  (cost=2.50..2.51 rows=1 width=8)
   Output: count(customer1.c_custkey ORDER BY customer1.c_custkey)
   ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=8)
         Output: customer1.c_custkey
         Node/s: All datanodes
         Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(6 rows)
```

- If an SQL statement contains COUNT(DISTINCT expr) and columns in COUNT(DISTINCT expr) do not support redistribution, this statement cannot be pushed down.

```
gaussdb=# explain verbose select count(distinct b) from test_stream;
                                    QUERY PLAN
------------------------------------------------------------------
 Aggregate  (cost=2.50..2.51 rows=1 width=8)
   Output: count(DISTINCT test_stream.b)
   ->  Data Node Scan on test_stream "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30 width=8)
         Output: test_stream.b
         Node/s: All datanodes
         Remote query: SELECT b FROM ONLY public.test_stream WHERE true
(6 rows)
```

- A statement containing DISTINCT ON cannot be pushed down.

```
gaussdb=# explain verbose select distinct on (c_custkey) c_custkey from customer1 order by c_custkey;
                                    QUERY PLAN
------------------------------------------------------------------
 Unique  (cost=49.83..54.83 rows=30 width=8)
   Output: customer1.c_custkey
   ->  Sort  (cost=49.83..52.33 rows=30 width=8)
         Output: customer1.c_custkey
         Sort Key: customer1.c_custkey
         ->  Data Node Scan on customer1 "_REMOTE_TABLE_QUERY_"  (cost=0.00..0.00 rows=30
width=8)
               Output: customer1.c_custkey
               Node/s: All datanodes
               Remote query: SELECT c_custkey FROM ONLY public.customer1 WHERE true
(9 rows)
```

- A statement containing array expressions cannot be pushed down.

```
gaussdb=# explain verbose select array[c_custkey,1] from customer1 order by c_custkey;

                        QUERY PLAN
------------------------------------------------------------------
 Sort  (cost=49.83..52.33 rows=30 width=8)
   Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Sort Key: customer1.c_custkey
 ->  Data Node Scan on "__REMOTE_SORT_QUERY__"  (cost=0.00..0.00 rows=30 width=8)
       Output: (ARRAY[customer1.c_custkey, 1::bigint]), customer1.c_custkey
       Node/s: All datanodes
       Remote query: SELECT ARRAY[c_custkey, 1::bigint], c_custkey FROM ONLY public.customer1
WHERE true ORDER BY 2
(7 rows)
```

- **Table 1 Scenarios where a statement containing WITH RECURSIVE cannot be pushed down** describes scenarios where a statement containing WITH RECURSIVE cannot be pushed down in the current version, as well as the causes.

Table 6-5 Scenarios where a statement containing WITH RECURSIVE cannot be pushed down

No.	Scenario	Cause of Not Supporting Pushdown
1	The query contains foreign tables.	LOG: SQL can't be shipped, reason: RecursiveUnion contains ForeignScan is not shippable (In this table, **LOG** describes the cause of not supporting pushdown.) In the current version, queries containing foreign tables do not support pushdown.
2	Multiple node groups exist.	LOG: SQL can't be shipped, reason: With-Recursive under multi-nodegroup scenario is not shippable In the current version, pushdown is supported only when all base tables are stored and computed in the same node group.

3	UNION does not contain ALL, and deduplication is required.	LOG: SQL can't be shipped, reason: With-Recursive does not contain "ALL" to bind recursive & none-recursive branches
		For example:
		`WITH recursive t_result AS (`
		`SELECT dm,sj_dm,name,1 as level`
		`FROM test_rec_part`
		`WHERE sj_dm > 10`
		`UNION`
		`SELECT t2.dm,t2.sj_dm,t2.name||' > '||`
		`t1.name,t1.level+1`
		`FROM t_result t1`
		`JOIN test_rec_part t2 ON t2.sj_dm = t1.dm`
		`)`
		`SELECT * FROM t_result t;`

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Scenario	Cause of Not Supporting Pushdown
4	A base table contains a system catalog.	LOG: SQL can't be shipped, reason: With-Recursive contains system table is not shippable For example: WITH RECURSIVE x(id) AS (select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id < 5), y(id) AS (select count(1) from pg_class where oid=1247 UNION ALL SELECT id+1 FROM x WHERE id < 10) SELECT y.*, x.* FROM y LEFT JOIN x USING (id) ORDER BY 1;
5	Only the VALUES clause is used for scanning base tables. In this case, the statement need to be executed only on the CN.	LOG: SQL can't be shipped, reason: With-Recursive contains only values rte is not shippable For example: WITH RECURSIVE t(n) AS (VALUES (1) UNION ALL SELECT n+1 FROM t WHERE n < 100) SELECT sum(n) FROM t;
6	Only the recursion part has correlation conditions of correlated subqueries, and the non-recursion part has no correlation condition.	LOG: SQL can't be shipped, reason: With-Recursive recursive term correlated only is not shippable For example: select a.ID,a.Name, (with recursive cte as (select ID, PID, NAME from b where b.ID = 1 union all select parent.ID,parent.PID,parent.NAME from cte as child join b as parent on child.pid=parent.id where child.ID = a.ID) select NAME from cte limit 1) cName from (select id, name, count(*) as cnt from a group by id,name) a order by 1,2;

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Scenario	Cause of Not Supporting Pushdown

7	The **replicate** plan is used for limit in the non-recursion part but the **hash** plan is used in the recursion part, resulting in conflicts.	LOG: SQL can't be shipped, reason: With-Recursive contains conflict distribution in none-recursive(Replicate) recursive(Hash)
		For example:
		`WITH recursive t_result AS (`
		`select * from(`
		`SELECT dm,sj_dm,name,1 as level`
		`FROM test_rec_part`
		`WHERE sj_dm < 10 order by dm limit 6 offset 2)`
		`UNION all`
		`SELECT t2.dm,t2.sj_dm,t2.name||' > '|| t1.name,t1.level+1`
		`FROM t_result t1`
		`JOIN test_rec_part t2 ON t2.sj_dm = t1.dm`
		`)`
		`SELECT * FROM t_result t;`

8	**recursive** of multiple-layers are nested. That is, a **recursive** is nested in the recursion part of another **recursive**.	LOG: SQL can't be shipped, reason: Recursive CTE references recursive CTE "cte"
		For example:
		`with recursive cte as`
		`(`
		`select * from rec_tb4 where id<4`
		`union all`
		`select h.id,h.parentID,h.name from`
		`(`
		`with recursive cte as`
		`(`
		`select * from rec_tb4 where id<4`
		`union all`
		`select h.id,h.parentID,h.name from rec_tb4 h inner join cte c on h.id=c.parentID`
		`)`
		`SELECT id ,parentID,name from cte order by parentID`
		`) h`
		`inner join cte  c on h.id=c.parentID`
		`)`
		`SELECT id ,parentID,name from cte order by parentID,1,2,3;`

Drop tables.

```
gaussdb=# DROP TABLE CUSTOMER1;
DROP TABLE
gaussdb=# DROP TABLE test_stream;
DROP TABLE
gaussdb=# DROP TABLE sal_emp;
DROP TABLE
```

Functions That Do Not Support Pushdown

The following describes the volatility of functions. In GaussDB, every function has a volatility classification, with the possibilities being:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **IMMUTABLE**

  Indicates that the function always returns the same result if the parameter values are the same.

- **STABLE**

  Indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter value, but its result varies by SQL statements.

- **VOLATILE**

  Indicates that the function value can change in a single table scan and no optimization is performed.

The volatility of a function can be obtained by querying for its **provolatile** column in pg_proc. The value **i** indicates immutable, **s** indicates stable, and **v** indicates volatile. The valid values of the **proshippable** column in pg_proc are **t**, **f**, and **NULL**. This column and the **provolatile** column together describe whether a function is pushed down.

- If the **provolatile** of a function is **i**, the function can be pushed down regardless of the value of **proshippable**.
- If the **provolatile** of a function is **s** or **v**, the function can be pushed only if the value of **proshippable** is **t**.
- CTEs containing **random**, **exec_hadoop_sql**, or **exec_on_extension** are not pushed down, because pushdown may lead to incorrect results.

When creating a user-defined function, you can specify the values of **provolatile** and **proshippable**. For details, see **CREATE FUNCTION**.

In scenarios where a function does not support pushdown, perform one of the following as required:

- If it is a system function, replace it with a functionally equivalent one.
- If it is a user-defined function, check whether its **provolatile** and **proshippable** are correctly defined.

Example: User-defined Functions

Define a user-defined function that generates fixed output for a certain input as the immutable type.

Take the sales information of TPC Benchmark DS (TPC-DS) as an example. If you want to write a function to calculate the discount data of a product, you can define the function as follows:

```
CREATE FUNCTION func_percent_2 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
VOLATILE;
```

Run the following statements:

```
SELECT func_percent_2(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Data Node Scan on store_sales "_REMOTE_TABLE_QUERY_"
   Output: func_percent_2(store_sales.ss_sales_price, store_sales.ss_list_price)
   Remote query: SELECT ss_sales_price, ss_list_price FROM ONLY store_sales WHERE true
(3 rows)
```

func_percent_2 is not pushed down, and **ss_sales_price** and **ss_list_price** are executed on a CN. In this case, a large amount of resources on the CN is consumed, and the performance deteriorates as a result.

In this example, the function generates the same output when the same input is provided. Therefore, we can modify the function to the following one:

```
CREATE FUNCTION func_percent_1 (NUMERIC, NUMERIC) RETURNS NUMERIC
AS 'SELECT $1 / $2 WHERE $2 > 0.01'
LANGUAGE SQL
IMMUTABLE;
```

Run the following statements:

```
SELECT func_percent_1(ss_sales_price, ss_list_price)
FROM store_sales;
```

The execution plan is as follows.

```
 Data Node Scan
   Output: (func_percent_1(store_sales.ss_sales_price, store_sales.ss_list_price))
   Remote query: SELECT func_percent_1(ss_sales_price, ss_list_price) AS func_percent_1 FROM store_sales
(3 rows)
```

The func_percent_1 function is pushed down to DNs for execution.

6.7.3 Optimizing Subqueries

Context

When an application runs an SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a SELECT statement following immediately after the FROM keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the **WHERE** or **ON** clause or in the target list.

  In conclusion, a subquery is a range table and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:
  - exist_sublink: corresponds to the EXIST and NOT EXIST statements.
  - any_sublink: corresponds to the *op* ANY(SELECT…) statement. *op* can be the <, >, or = operator. IN/NOT IN (SELECT...) also belongs to this type.
  - all_sublink: corresponds to the *op* ALL(SELECT...) statement. *op* can be the <, >, or = operator.
  - rowcompare_sublink: corresponds to the RECORD *op* (SELECT...) statement.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- expr_sublink: corresponds to the (SELECT with a single target list item...) statement.
- array_sublink: corresponds to the ARRAY(SELECT...) statement.
- cte_sublink: corresponds to the WITH(...) query statement.

The exist_sublink and any_sublink are pulled up by the optimization engine of GaussDB. In addition, expr_sublink can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. If you do not want to pull up expr_sublink, set the GUC parameter **rewrite_rule**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- **Non-correlated subqueries**

  The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

  For example:

```
gaussdb=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
   select c2
   from t2
   where t2.c2 IN (2,3,4)
);
                        QUERY PLAN
------------------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Hash Right Semi Join
        Hash Cond: (t2.c2 = t1.c1)
        ->  Streaming(type: REDISTRIBUTE)
              Spawn on: All datanodes
              ->  Seq Scan on t2
                    Filter: (c2 = ANY ('{2,3,4}'::integer[]))
        ->  Hash
              ->  Seq Scan on t1
(10 rows)
```

- **Correlated subqueries**

  The execution of a subquery depends on some attributes (used as **AND** conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

  For example:

```
gaussdb=# explain select t1.c1,t1.c2
from t1
where t1.c1 in (
   select c2
   from t2
   where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);
                              QUERY PLAN
-----------------------------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Seq Scan on t1
        Filter: (SubPlan 1)
        SubPlan 1
          ->  Result
                Filter: (t2.c1 = t1.c1)
                ->  Materialize
                      ->  Streaming(type: BROADCAST)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                        Spawn on: All datanodes
                        ->  Seq Scan on t2
                              Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(12 rows)
```

Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries, preventing the subquery from being converted into a plan involving subplans and broadcast. You can run the EXPLAIN statement to check whether a sublink is converted into the combination of a subplan and broadcast.

Example

```
gaussdb=#  EXPLAIN (COSTS OFF) SELECT t1.c1, t1.c2 FROM t1 WHERE t1.c1 IN (SELECT c2 FROM t2
WHERE t2.c1 = t1.c1);
                  QUERY PLAN
-----------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on t1
         Filter: (SubPlan 1)
         SubPlan 1
           ->  Result
                 Filter: (t2.c1 = t1.c1)
                 ->  Materialize
                       ->  Streaming(type: BROADCAST)
                             Spawn on: All datanodes
                             ->  Seq Scan on t2
(11 rows)
```

- **Sublink-release scenarios supported by GaussDB**
  - Pulling up the **IN** sublink
    - The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
    - The subquery cannot contain volatile functions.

    Example:

    ```
    gaussdb=#  EXPLAIN (COSTS OFF) SELECT t1.c1, t1.c2 FROM t1 WHERE t1.c1 IN (SELECT c2
    FROM t2 WHERE t2.c1 = 1);
                      QUERY PLAN
    ---------------------------------------------------
     Streaming (type: GATHER)
       Node/s: All datanodes
       ->  Nested Loop Semi Join
             Join Filter: (t1.c1 = t2.c2)
             ->  Seq Scan on t1
             ->  Materialize
                   ->  Streaming(type: REDISTRIBUTE)
                         Spawn on: datanode1
                         ->  Seq Scan on t2
                               Filter: (c1 = 1)
    (10 rows)
    ```

  - Pulling up the **EXISTS** sublink

    The WHERE clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

    - The subquery must contain the FROM clause.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The subquery cannot contain the **WITH** clause.
- The subquery cannot contain aggregate functions.
- The subquery cannot contain a **SET**, **SORT**, **LIMIT**, **WindowAgg**, or **HAVING** operation.
- The subquery cannot contain volatile functions.

Example:

```
gaussdb=#  EXPLAIN (COSTS OFF) SELECT t1.c1, t1.c2 FROM t1 WHERE exists (SELECT c2
FROM t2 WHERE t2.c1 = t1.c1);
            QUERY PLAN
-----------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Semi Join
         Hash Cond: (t1.c1 = t2.c1)
         ->  Seq Scan on t1
         ->  Hash
               ->  Seq Scan on t2
(7 rows)
```

– Pulling up an equivalent correlated query containing aggregate functions

  The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

  - The columns in the expression in the WHERE condition of the subquery must exist in tables.
  - After the SELECT keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, **MAX**), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be COUNT.

    For example, the following subquery can be pulled up:

    ```
    select * from t1 where c1 >(
          select max(t2.c1) from t2 where t2.c1=t1.c1
    );
    ```

    The following subquery cannot be pulled up because the subquery has no aggregate function:

    ```
    select * from t1 where c1 >(
          select  t2.c1 from t2 where t2.c1=t1.c1
    );
    ```

    The following subquery cannot be pulled up because the subquery has two output columns:

    ```
    select * from t1 where (c1,c2) >(
          select  max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
    );
    ```

  - The subquery must be a FROM clause.
  - The subquery cannot contain a GROUP BY, HAVING, or SET operation.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The subquery can only be an inner join.

  For example, the following subquery cannot be pulled up:

  ```
  select * from t1 where c1 >(
      select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
  );
  ```

- The target list of the subquery cannot contain the function that returns a set.

- The **WHERE** condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using **AND**. Other parts of the subquery cannot contain the column. For example, the following subquery can be pulled up:

  ```
  select * from t3 where t3.c1=(
        select t1.c1
        from t1 where c1 >(
              select max(t2.c1) from t2 where t2.c1=t1.c1
  ));
  ```

  If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the innermost subquery references to the column in the outer and outer query. Example:

  ```
  select * from t3 where t3.c1=(
        select t1.c1
        from t1 where c1 >(
              select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2

  ));
  ```

– Pulling up a sublink in the **OR** clause

  If the WHERE condition contains an EXIST correlated sublink connected by OR, the following is an example:

  ```
  select a, c from t1
  where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
  exists (select * from t4 where t1.c = t4.c);
  ```

  The process of pulling up such a sublink is as follows:

  i. Extract **opExpr** from the OR clause in the WHERE condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.

  ii. The **opExpr** operation contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the NOT NULL condition **t3.b is not null**. **opExpr** is replaced by this NOT NULL condition. In this case, the SQL statement changes to:

  ```
  select a, c
  from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b)  as t3 on (t1.a = avg and t1.b = t3.b)
  where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
  ```

  iii. Extract the **EXISTS** sublink **exists (select * from t4 where t1.c = t4.c)** from the OR clause to check whether the sublink can be pulled up. If it can be pulled up, the subquery is converted into **select t4.c from t4 group by t4.c**, generating the NOT NULL condition **t4.c is not null**. In this case, the SQL statement changes to:

  ```
  select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c = t5.c) where t3.b is not null or t5.c is not null;
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **Sublink-release scenarios not supported by GaussDB**

  Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a correlated subquery is planned as the combination of subplans and broadcast. As a result, if inner tables have a large amount of data, query performance may be poor.

  If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the outer query into a WITH clause and then perform the join.

  For example:

  ```
  select distinct t1.a, t2.a
  from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
  test1.b=t2.a);
  ```

  The rewriting is as follows:

  ```
  with temp as
  (
        select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)

  )
  select distinct a,b
  from temp
  where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
  ```

  – The subquery (without COUNT) in the target list cannot be pulled up.

    For example:

    ```
    gaussdb=# explain (costs off)
    select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
    from t1
    where t1.c2 > 10;
    ```

    The execution plan is as follows:

    ```
    gaussdb=# explain (costs off)
    select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
    from t1
    where t1.c2 > 10;
                        QUERY PLAN
    ------------------------------------------------------
     Streaming (type: GATHER)
       Node/s: All datanodes
       ->  Seq Scan on t1
             Filter: (c2 > 10)
             SubPlan 1
               ->  Result
                     Filter: (t1.c1 = t2.c1)
                     ->  Materialize
                           ->  Streaming(type: BROADCAST)
                                 Spawn on: All datanodes
                                 ->  Seq Scan on t2
    (11 rows)
    ```

    The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use a right outer join to join **t2** and **t1** so that the SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

    > NOTE
    >
    > ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:
    >
    > - SSQ: a sublink that returns a scalar value of a single row with a single column
    > - CSSQ: an SSQ containing correlation conditions

    The preceding SQL statement can be changed into:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
with ssq as
(
   select * from t1 where t1.c2 > 10
)
select t2.c2,ssq.c2 from t2 right join ssq on ssq.c1 = t2.c1;
```

The execution plan after the change is as follows:

```
            QUERY PLAN
---------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Right Join
         Hash Cond: (t2.c1 = t1.c1)
         ->  Seq Scan on t2
         ->  Hash
               ->  Seq Scan on t1
                     Filter: (c2 > 10)
(8 rows)
```

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans and broadcast when the table (**t2**) in the subquery is too large.

- The subquery (with COUNT) in the target list cannot be pulled up.

  For example:

  ```
  select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
  from t1,t3
  where t1.c1=t3.c1 order by cnt, t1.c1;
  ```

  The execution plan is as follows:

  ```
                          QUERY PLAN
  ------------------------------------------------------------------
   Streaming (type: GATHER)
     Node/s: All datanodes
     ->  Sort
           Sort Key: ((SubPlan 1)), t1.c1
           ->  Hash Join
                 Hash Cond: (t1.c1 = t3.c1)
                 ->  Seq Scan on t1
                 ->  Hash
                       ->  Seq Scan on t3
                 SubPlan 1
                   ->  Aggregate
                         ->  Result
                               Filter: (t2.c1 = t1.c1)
                               ->  Materialize
                                     ->  Streaming(type: BROADCAST)
                                           Spawn on: All datanodes
                                           ->  Seq Scan on t2
  (17 rows)
  ```

  The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However, COUNT is used, which requires that **0** is returned when the condition is not met. Therefore, case-when NULL then 0 else count(*) can be used.

  The preceding SQL statement can be changed into:

  ```
  with ssq as
  (
     select count(*) cnt, c1 from t2 group by c1
  )
  select case when
            ssq.cnt is null then 0
            else ssq.cnt
         end cnt, t1.c1, t3.c1
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;
```

The execution plan after the change is as follows:

```
 QUERY PLAN
-----------------------------------------------------
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Sort
        Sort Key: (count(*)), t1.c1
        ->  Hash Join
              Hash Cond: (t1.c1 = t3.c1)
              ->  Hash Left Join
                    Hash Cond: (t1.c1 = t2.c1)
                    ->  Seq Scan on t1
                    ->  Hash
                          ->  HashAggregate
                                Group By Key: t2.c1
                                ->  Seq Scan on t2
              ->  Hash
                    ->  Seq Scan on t3
(15 rows)
```

– Non-equivalent correlated subqueries cannot be pulled up.

  For example:

```
select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);
```

  Non-equivalent correlated sublinks cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

  You can rewrite the statement in either of the following ways:

  - Subquery rewriting:

```
select t1.c1, t1.c2
from t1, (
   select t1.rowid, agg() aggref
   from t1,t2
   where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;
```

  - CTE rewriting:

```
WITH dt as
(
   select t1.rowid, agg() aggref
   from t1,t2
   where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, dt
where t1.rowid = dt.rowid AND
t1.c1 = dt.aggref;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Currently, GaussDB does not have an effective way to provide globally unique row IDs for tables and intermediate result sets. Therefore, the rewriting is difficult. It is recommended that this issue is avoided at the service layer or by using **t1.xc_nodeid + t1.ctid** to associate row IDs. However, the high repetition rate of **xc_nodeid** leads to low association efficiency, and **xc_node_id+ctid** cannot be used as the join condition of a hash join.
- If the AGG type is COUNT(*), **0** is used for data padding when **CASE-WHEN** is not matched. If the type is not COUNT(*), **NULL** is used.
- CTE rewriting works better by using sharescan.

More Optimization Examples

Example 1: Change the base table to a replication table and create an index on the filter column.

```
create table master_table (a int);
create table sub_table(a int, b int);
select a from master_table group by a having a in (select a from sub_table);
```

In this example, a correlated subquery is contained. To improve the query performance, you can change **sub_table** to a replication table when creating a table and create an index on the **a** column.

Example 2: Modify the SELECT statement to change the subquery to a join relationship between the main table and the parent query, or modify the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
gaussdb=# explain (costs off)select * from master_table as t1 where t1.a in (select t2.a from sub_table as t2
where t1.a = t2.b);
                        QUERY PLAN
------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on master_table t1
         Filter: (SubPlan 1)
         SubPlan 1
           ->  Result
                 Filter: (t1.a = t2.b)
                 ->  Materialize
                       ->  Streaming(type: BROADCAST)
                             Spawn on: All datanodes
                             ->  Seq Scan on sub_table t2
(11 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
gaussdb=# explain(costs off) select * from master_table as t1 where exists (select t2.a from sub_table as t2
where t1.a = t2.b and t1.a = t2.a);
                    QUERY PLAN
---------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Semi Join
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on master_table t1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
      ->  Hash
            ->  Streaming(type: REDISTRIBUTE)
                  Spawn on: All datanodes
                  ->  Seq Scan on sub_table t2
(9 rows)
```

In this way, the subplan is replaced by the semi-join between the two tables, greatly improving the execution efficiency.

6.7.4 Optimizing Statistics

Context

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using ANALYZE. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using ANALYZE: **relpages** and **reltuples** in the system catalog **PG_CLASS**; **stadistinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram_bounds** in the pg_statistic catalog.

Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
L_ORDERKEY        BIGINT        NOT NULL
, L_PARTKEY       BIGINT        NOT NULL
, L_SUPPKEY       BIGINT        NOT NULL
, L_LINENUMBER    BIGINT        NOT NULL
, L_QUANTITY      DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE  DECIMAL(15,2) NOT NULL
, L_DISCOUNT      DECIMAL(15,2) NOT NULL
, L_TAX           DECIMAL(15,2) NOT NULL
, L_RETURNFLAG    CHAR(1)       NOT NULL
, L_LINESTATUS    CHAR(1)       NOT NULL
, L_SHIPDATE      DATE          NOT NULL
, L_COMMITDATE    DATE          NOT NULL
, L_RECEIPTDATE   DATE          NOT NULL
, L_SHIPINSTRUCT  CHAR(25)      NOT NULL
, L_SHIPMODE      CHAR(10)      NOT NULL
, L_COMMENT       VARCHAR(44)   NOT NULL
) distribute by hash(L_ORDERKEY);

CREATE TABLE ORDERS
(
O_ORDERKEY        BIGINT        NOT NULL
, O_CUSTKEY       BIGINT        NOT NULL
, O_ORDERSTATUS   CHAR(1)       NOT NULL
, O_TOTALPRICE    DECIMAL(15,2) NOT NULL
, O_ORDERDATE     DATE NOT NULL
, O_ORDERPRIORITY CHAR(15)      NOT NULL
, O_CLERK         CHAR(15)      NOT NULL
, O_SHIPPRIORITY  BIGINT        NOT NULL
, O_COMMENT       VARCHAR(79)   NOT NULL
) distribute by hash(O_ORDERKEY);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using ANALYZE:

1. Execute EXPLAIN VERBOSE to analyze the execution plan and check the warning information:

   ```
   WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,
   public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,
   public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
   HINT:Do analyze for them in order to generate optimized plan.
   ```

2. Check whether the following information exists in the log file in the **gs_log** directory; if it does, the poor query performance was caused by the lack of statistics in some tables or columns:

   ```
   2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables
   or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey,
   public.linei
   tem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
   2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in
   order to generate optimized plan.
   ```

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using ANALYZE. You can execute ANALYZE to warnings or tables and columns recorded in logs to resolve the problem.

Example 2: Optimization is Not Accurate When Intermediate Results Exist in the Query Where JOIN Is Used for Multiple Tables

Symptom: Query the personnel who have registered in an Internet cafe within 15 minutes before and after the registration of a specified person.

```
SELECT
C.WBM,
C.DZQH,
C.DZ,
B.ZJHM,
B.SWKSSJ,
B.XWSJ
FROM
b_zyk_wbswxx A,
b_zyk_wbswxx B,
b_zyk_wbcs C
WHERE
A.ZJHM = '522522******3824'
AND A.WBDM = B.WBDM
AND A.WBDM = C.WBDM
AND abs(to_date(A.SWKSSJ,'yyyymmddHH24MISS') - to_date(B.SWKSSJ,'yyyymmddHH24MISS')) <
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
INTERVAL '15 MINUTES'
ORDER BY
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

Figure 6-4 shows the execution plan. This query takes about 12s.

Figure 6-4 Using an unlogged table (1)

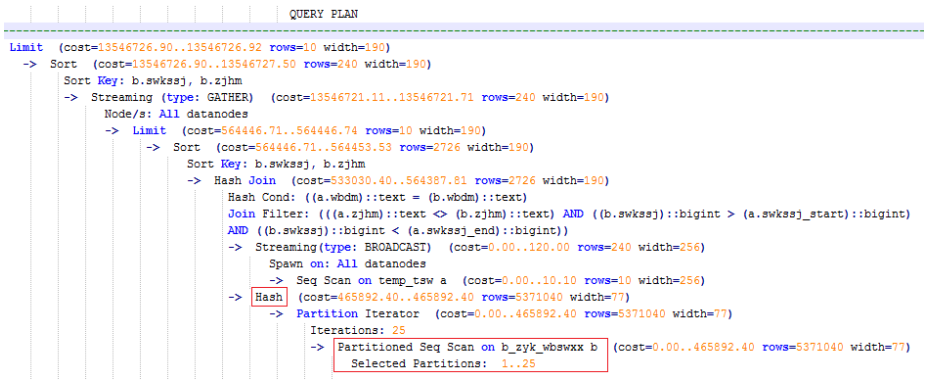
```
                                                
```

```
B.WBM,B.DZQH,B.DZ,B.IPDZ
FROM
b_zyk_wbswxx A,
b_zyk_wbcs B
WHERE
A.ZJHM='522522******3824' AND A.WBDM = B.WBDM
;

// Query the personnel who have registered in an Internet cafe before and after 15 minutes of the registration of the specified person. Convert their ID card number format to int8 in comparison.
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
order by
B.SWKSSJ,
B.ZJHM
limit 10 offset 0
;
```

The query takes about 7s. **Figure 6-5** shows the execution plan.

Figure 6-5 Using an unlogged table (2)



3. In the previous plan, a hash join has been executed, and a Hash table has been created for the large table b_zyk_wbswxx (Internet access information in the Internet cafe). The table contains large amounts of data, so the creation takes long time.

   temp_tsw (Internet access user information) contains only hundreds of records, and an equi-join is created between **temp_tsw** and **b_zyk_wbswxx** (Internet access information in the Internet cafe) using wbdm (an Internet cafe code). Therefore, if JOIN is changed to NEST LOOP JOIN, index scan can be used for node scanning, and the performance will be boosted.

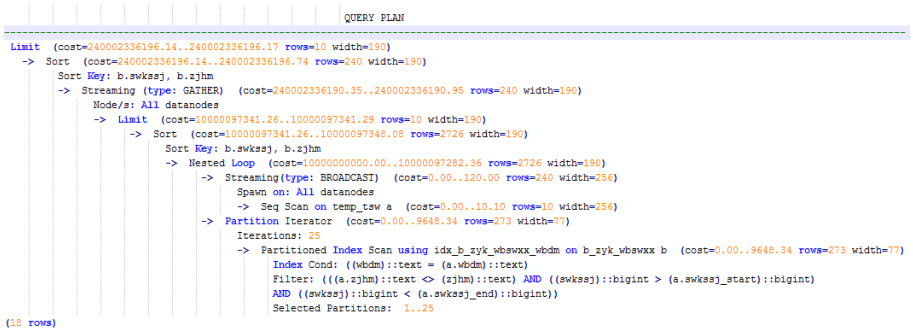
4. Change JOIN to NEST LOOP JOIN.

   ```
   SET enable_hashjoin = off;
   ```

   Figure 6-6 shows the execution plan. The query takes about 3s.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 6-6 Using an unlogged table (3)



5. Save the query result set in the unlogged table for paging display.

   If paging display needs to be achieved on the upper-layer application page, change the **offset** value to determine the result set on the target page. In this way, the previous query statement will be executed every time after a page turning operation, which causes long response latency.

   To resolve this problem, the unlogged table is recommended to save the result set.

```
// Create an unlogged table to save the result set.
CREATE UNLOGGED TABLE temp_result
(
WBM      NVARCHAR2(70),
DZQH     NVARCHAR2(6),
DZ       NVARCHAR2(70),
IPDZ     NVARCHAR2(39),
ZJHM     NVARCHAR2(18),
XM       NVARCHAR2(30),
SWKSSJ   date,
XWSJ     date,
SWZDH    NVARCHAR2(32)
);

// Insert the result set to the unlogged table. The insertion takes about 3s.
INSERT INTO
temp_result
SELECT
A.WBM,
A.DZQH,
A.DZ,
A.IPDZ,
B.ZJHM,
B.XM,
to_date(B.SWKSSJ,'yyyymmddHH24MISS') as SWKSSJ,
to_date(B.XWSJ,'yyyymmddHH24MISS') as XWSJ,
B.SWZDH
FROM temp_tsw A,
b_zyk_wbswxx B
WHERE
A.ZJHM <> B.ZJHM
AND A.WBDM = B.WBDM
AND (B.SWKSSJ)::int8 > (A.swkssj_start)::int8
AND (B.SWKSSJ)::int8 < (A.swkssj_end)::int8
;

// Perform paging query on the result set. The paging query takes about 10 ms.
SELECT
*
FROM
temp_result
ORDER BY
SWKSSJ,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
ZJHM
LIMIT 10 OFFSET 0;
```

CAUTION

Collecting more accurate statistics usually improves the query performance, but may also deteriorate the performance. If the performance deteriorates, you can:

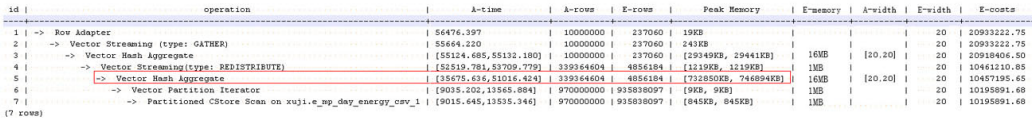
- Restore to the default statistics.
- Use plan hints to adjust the query plan to the previous one. For details, see **Hint-based Optimization**.

6.7.5 Optimizing Operators

Context

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the Hashagg operator accounts for about 66% [(51016-13535)/56476 ≈ 66%] of the total execution time. Therefore, the Hashagg operator is the bottleneck operator for this query. Optimize this operator first.



Example

Example 1: Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan for index scanning.

```
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
 id |          operation          |     A-time      | A-rows | Peak Memory | A-width
----+-----------------------------+-----------------+--------+-------------+---------
  1 | ->  Streaming (type: GATHER) | 20.040          |      5 | 85KB        |
  2 |    ->  Seq Scan on t1        | [17.239,17.376] |      5 | [18KB,18KB] |
(2 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Seq Scan on t1
         Filter: (c2 = 10004)
         Rows Removed by Filter: 90002
(3 rows)
gaussdb=# create index idx on t1(c2);
CREATE INDEX
gaussdb=# explain (analyze on,costs off) select * from t1 where c2=10004;
```

```
 id |            operation             |    A-time     | A-rows | Peak Memory | A-width
----+----------------------------------+---------------+--------+-------------+---------
  1 | ->  Streaming (type: GATHER)     | 3.206         |      5 | 85KB        |
  2 |    ->  Index Scan using idx on t1 | [0.122,0.146] |      5 | [73KB,73KB] |
(2 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Index Scan using idx on t1
         Index Cond: (c2 = 10004)
(2 rows)
```

In this example, the full table scan filters large amounts of data and returns 5 records. After an index has been created on the **c2** column, the scanning efficiency is significantly boosted and the duration of IndexScan is reduced from 20 ms to 3 ms.

Example 2: If NestLoop is used for joining tables with a large number of rows, the join may take a long time. In the following example, NestLoop takes 5s. If **enable_mergejoin** is set to **off** to disable merge join and **enable_nestloop** is set to **off** to disable NestLoop so that the optimizer selects hash join, the join duration is reduced to 86 ms.

```
gaussdb=#  explain analyze select count(*) from t2,t1 where t1.c1=t2.c2;
 id |                  operation                   |       A-time        |  A-rows  | E-rows | Peak Memory | A-width | E-
width | E-costs
----+----------------------------------------------+---------------------+----------+--------+-------------+---------
+---------+---------
  1 | ->  Aggregate                                | 5070.296            |        1 |      1 | 14KB        |         |       8 |
2148.49
  2 |    ->  Streaming (type: GATHER)              | 5070.219            |        2 |      2 | 81KB        |         |       8
| 2148.49
  3 |       ->  Aggregate                          | [4828.705,5062.289] |        2 |      2 | [11KB,11KB] |         |       8
| 2148.40
  4 |          ->  Nested Loop (5,6)               | [4828.565,5062.142] |      996 |     40 | [4KB,4KB]   |

6.7.6 Optimizing Data Skew

Data skew breaks the balance among nodes in the distributed MPP architecture. If the amount of data stored or processed by a node is much greater than that by other nodes, the following problems may occur:

- Storage skew severely limits the system capacity. The skew on a single node hinders system storage utilization.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Computing skew severely affects performance. The data to be processed on the skew node is much more than that on other nodes, deteriorating overall system performance.
- Data skew severely affects the scalability of the MPP architecture. During storage or computing, data with the same values is often placed on the same node. Therefore, even if we add nodes after a data skew occurs, the skew data (data with the same values) is still placed on the node and affects the system capacity or performance bottleneck.

GaussDB provides a complete solution to data skew, including storage and computing skew.

Data Skew in the Storage Layer

In GaussDB, data is distributed and stored on each DN. You can improve the query efficiency by using distributed execution. However, if data skew occurs, bottlenecks exist on some DNs during distribution execution, affecting the query performance. This is because the distribution key is not properly selected. This can be solved by adjusting the distribution key.

Example:

```
gaussdb=# explain performance select count(*) from inventory;
5 --Seq Scan on lmz.inventory
        dn_6001_6002 (actual time=0.444..83.127 rows=42000000 loops=1)
        dn_6003_6004 (actual time=0.512..63.554 rows=27000000 loops=1)
        dn_6005_6006 (actual time=0.722..99.033 rows=45000000 loops=1)
        dn_6007_6008 (actual time=0.529..100.379 rows=51000000 loops=1)
        dn_6009_6010 (actual time=0.382..71.341 rows=36000000 loops=1)
        dn_6011_6012 (actual time=0.547..100.274 rows=51000000 loops=1)
        dn_6013_6014 (actual time=0.596..118.289 rows=60000000 loops=1)
        dn_6015_6016 (actual time=1.057..132.346 rows=63000000 loops=1)
        dn_6017_6018 (actual time=0.940..110.310 rows=54000000 loops=1)
        dn_6019_6020 (actual time=0.231..41.198 rows=21000000 loops=1)
        dn_6021_6022 (actual time=0.927..114.538 rows=54000000 loops=1)
        dn_6023_6024 (actual time=0.637..118.385 rows=60000000 loops=1)
        dn_6025_6026 (actual time=0.288..32.240 rows=15000000 loops=1)
        dn_6027_6028 (actual time=0.566..118.096 rows=60000000 loops=1)
        dn_6029_6030 (actual time=0.423..82.913 rows=42000000 loops=1)
        dn_6031_6032 (actual time=0.395..78.103 rows=39000000 loops=1)
        dn_6033_6034 (actual time=0.376..51.052 rows=24000000 loops=1)
        dn_6035_6036 (actual time=0.569..79.463 rows=39000000 loops=1)
```

In the performance information, the number of scan lines on each DN in the inventory table is displayed. The maximum number of scan lines is 63,000,000, and the minimum number is 15,000,000, which is four times of the actual number. This value difference on the performance of data scan is acceptable, but if the join operator exists in the upper-layer, the impact on the performance cannot be ignored.

Generally, the data table is hash distributed on each DN; therefore, it is important to choose a proper distribution key. Run **table_skewness()** to view data skew of each DN in the inventory table. The query result is as follows:

```
gaussdb=# select table_skewness('inventory');
             table_skewness
-------------------------------------------
 ("dn_6015_6016        ",63000000,8.046%)
 ("dn_6013_6014        ",60000000,7.663%)
 ("dn_6023_6024        ",60000000,7.663%)
 ("dn_6027_6028        ",60000000,7.663%)
 ("dn_6017_6018        ",54000000,6.897%)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 ("dn_6021_6022       ",54000000,6.897%)
 ("dn_6007_6008       ",51000000,6.513%)
 ("dn_6011_6012       ",51000000,6.513%)
 ("dn_6005_6006       ",45000000,5.747%)
 ("dn_6001_6002       ",42000000,5.364%)
 ("dn_6029_6030       ",42000000,5.364%)
 ("dn_6031_6032       ",39000000,4.981%)
 ("dn_6035_6036       ",39000000,4.981%)
 ("dn_6009_6010       ",36000000,4.598%)
 ("dn_6003_6004       ",27000000,3.448%)
 ("dn_6033_6034       ",24000000,3.065%)
 ("dn_6019_6020       ",21000000,2.682%)
 ("dn_6025_6026       ",15000000,1.916%)
(18 rows)
```

The table definition indicates that the table uses the **inv_date_sk** column as the distribution key, which causes a data skew. Based on the data distribution of each column, change the distribution key to **inv_item_sk** when creating a table. The skew status is as follows:

```
gaussdb=# select table_skewness('inventory');
              table_skewness
-------------------------------------------
 ("dn_6001_6002       ",43934200,5.611%)
 ("dn_6007_6008       ",43829420,5.598%)
 ("dn_6003_6004       ",43781960,5.592%)
 ("dn_6031_6032       ",43773880,5.591%)
 ("dn_6033_6034       ",43763280,5.589%)
 ("dn_6011_6012       ",43683600,5.579%)
 ("dn_6013_6014       ",43551660,5.562%)
 ("dn_6027_6028       ",43546340,5.561%)
 ("dn_6009_6010       ",43508700,5.557%)

Data skew is solved.

In addition to the table_skewness() view, you can use the **table_distribution** function and the **PGXC_GET_TABLE_SKEWNESS** view to efficiently query the data skew status of each table.

Data Skew in the Computing Layer

Even if data is balanced across nodes after you change the distribution key of a table, data skew may still occur during a query. If data skew occurs in the result set of an operator on a DN, skew will also occur during the computing that involves the operator. Generally, this is caused by data redistribution during the execution.

During a query, JOIN keys and GROUP BY keys are not used as distribution keys. Data is redistributed among DNs based on the hash values of data on the keys. The redistribution is implemented using the Redistribute operator in an execution plan. Data skew in redistribution keys can lead to data skew during system operation. After the redistribution, some nodes will have much more data, process more data, and will have much lower performance than other nodes.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In the following example, the **s** and **t** tables are joined, and **s.x** and **t.x** columns in the join condition are not their distribution keys. Table data is redistributed using the REDISTRIBUTE operator. Data skew occurs in the **s.x** column and not in the **t.x** column. The result set of the Streaming operator (**id** being **6**) on datanode2 has data three times that of other DNs and causes a skew.

```
gaussdb=#  explain select * from skew s,test t where s.x = t.x order by s.a limit 1;
 id |                    operation                     |        A-time
----+--------------------------------------------------+----------------------
  1 | ->  Limit                                        | 52622.382
  2 |    ->  Streaming (type: GATHER)                  | 52622.374
  3 |       ->  Limit                                  | [30138.494,52598.994]
  4 |         ->  Sort                                 | [30138.486,52598.986]
  5 |           ->  Hash Join (6,8)                    | [30127.013,41483.275]
  6 |             ->  Streaming(type: REDISTRIBUTE)    | [11365.110,22024.845]

        datanode4 (rows=5219328)
```

Computing skew is more difficult to detect than storage skew. To solve computing skew, GaussDB provides the Runtime Load Balance Technology (RLBT) solution, controlled by the GUC parameter **skew_option**. The RLBT solution addresses how to detect and solve data skew.

1. Detect data skew.

   The solution first checks whether skew data exists in redistribution keys used for computing. RLBT provides three solutions: statistics, specified hints, and rules.

   - Detection based on statistics

     Execute the ANALYZE statement to collect statistics on tables. The optimizer will automatically identify skew data on redistribution keys based on the statistics and generate optimization plans for queries having potential skew. When the redistribution key has multiple columns, statistics information can be used for identification only when all columns belong to the same base table.

     The statistics information can only provide the skew of the base table. When a column in the base table is skewed, other columns have filter conditions, or after the join of other tables, the skewed data may still exist on the skewed column. If the GUC parameter **skew_option** is set to **normal**, the system considers that skew data still exists and optimizes the skew identified in the base table. If the GUC parameter **skew_option** is set to **lazy**, the system considers that skew data does not exist and does not perform optimization.

   - Detection based on specified hints

     The intermediate results of complex queries are difficult to estimate based on statistics. In this case, you can specify hints to provide the skew information based on which the optimizer optimizes queries. For details about the syntax of hints, see **Skew Hints**.

   - Detection based on rules

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In a business intelligence (BI) system, a large number of SQL statements having outer joins (including left joins, right joins, and full joins) are generated, and many NULL values will be generated in empty columns that have no match for outer joins. If JOIN or GROUP BY operations are performed on the columns, data skew will occur. RLBT can automatically identify this scenario and generate an optimization plan for NULL value skew.

2. Solve computing skew.

   Join and Aggregate operators are optimized to solve skew.

   – Join optimization

   Skew and non-skew data is separately processed. Details are as follows:

   a. When redistribution is required on both sides of a join:

      Use PART_REDISTRIBUTE_PART_ROUNDROBIN on the side with skew. Specifically, perform round-robin on skew data and redistribution on non-skew data.

      Use PART_REDISTRIBUTE_PART_BROADCAST on the side with no skew. Specifically, perform broadcast on skew data and redistribution on non-skew data.

   b. When redistribution is required on only one side of a join:

      Use PART_REDISTRIBUTE_PART_ROUNDROBIN on the side where redistribution is required.

      Use PART_LOCAL_PART_BROADCAST on the side where redistribution is not required. Specifically, perform broadcast on skew data and retain other data locally.

   c. When a table has NULL values padded:

      Use PART_REDISTERIBUTE_PART_LOCAL on the table. Specifically, retain the NULL values locally and perform redistribution on other data.

   In the example query, the **s.x** column contains skewed data and its value is **0**. The optimizer identifies the skew data in statistics and generates the following optimization plan:

```
 id |                            operation                            |        A-time
----+-----------------------------------------------------------------+-----------------------
  1 | ->  Limit                                                       | 23642.049
  2 |    ->  Streaming (type: GATHER)                                 | 23642.041
  3 |       ->  Limit                                                 | [23310.768,23618.021]
  4 |          ->  Sort                                               | [23310.761,23618.012]
  5 |             ->  Hash Join (6,8)                                 | [20898.341,21115.272]
  6 |                ->  Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)   |
[7125.834,7472.111]
  7 |                   ->  Seq Scan on public.skew s                 | [1837.079,1911.025]
  8 |                ->  Hash                                         | [2612.484,2640.572]
  9 |                   ->  Streaming(type: PART REDISTRIBUTE PART BROADCAST) | [1193.548,1297.894]
 10 |                      ->  Seq Scan on public.test t              | [314.343,328.707]
(10 rows)
   5 --Vector Hash Join (6,8)
       Hash Cond: s.x = t.x
       Skew Join Optimizated by Statistic
   6 --Streaming(type: PART REDISTRIBUTE PART ROUNDROBIN)
       datanode1 (rows=7635968)
       datanode2 (rows=7517184)
       datanode3 (rows=7748608)
       datanode4 (rows=7818240)
```

In the preceding execution plan, **Skew Join Optimizated by Statistic** indicates that this is an optimized plan used for handling data skew. The

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Statistic keyword indicates that the plan optimization is based on statistics. The hint keyword indicates that the optimization is based on hints. The Rule keyword indicates that the optimization is based on rules. In this plan, skew and non-skew data are separately processed. Non-skew data in the **s** table is redistributed based on its hash values, and skew data (whose value is **0**) is evenly distributed on all nodes in round-robin mode. In this way, data skew is solved.

To ensure result correctness, the **t** table also needs to be processed. In the **t** table, the data whose value is **0** (skew value in the **s.x** table) is broadcast and other data is redistributed based on its hash values.

In this way, data skew in JOIN operations is solved. The above result shows that the output of the **Streaming** operator (**id** being **6**) is balanced and the end-to-end performance of the query is doubled.

– Aggregate optimization

For aggregation, distribution keys on each DN are deduplicated based on the GROUP BY KEY and then redistributed. After the deduplication on DNs, each DN has only one value for each redistribution key. The global occurrences of each value will not be greater than the number of DNs. Therefore, no serious data skew will occur. Take the following query as an example:

```
select c1, c2, c3, c4, c5, c6, c7, c8, c9, count(*) from t group by c1, c2, c3, c4, c5, c6, c7, c8, c9 limit 10;
```

The command output is as follows:

```
 id |                operation                 |         A-time         | A-rows
----+------------------------------------------+------------------------+----------
  1 | ->  Streaming (type: GATHER)             | 130621.783             |      12
  2 |    ->  GroupAggregate                    | [85499.711,130432.341] |      12
  3 |       ->  Sort                           | [85499.509,103145.632] | 36679237
  4 |          ->  Streaming(type: REDISTRIBUTE) | [25668.897,85499.050]  | 36679237
  5 |             ->  Seq Scan on public.t     | [9835.069,10416.388]   | 36679237
(5 rows)

  4 --Streaming(type: REDISTRIBUTE)
       datanode1 (rows=36678837)
       datanode2 (rows=100)
       datanode3 (rows=100)
       datanode4 (rows=200)
```

A large amount of skew data exists. As a result, after data is redistributed based on its GROUP BY key, the data volume of datanode1 is hundreds of thousands of times that of others. After optimization, a GROUP BY operation is performed on the DN to deduplicate data. After redistribution, no data skew occurs.

```
 id |                operation                 |        A-time
----+------------------------------------------+-----------------------
  1 | ->  Streaming (type: GATHER)             | 10961.337
  2 |    ->  HashAggregate                     | [10953.014,10953.705]
  3 |       ->  HashAggregate                  | [10952.957,10953.632]
  4 |          ->  Streaming(type: REDISTRIBUTE) | [10952.859,10953.502]
  5 |             ->  HashAggregate            | [10084.280,10947.139]
  6 |                ->  Seq Scan on public.t  | [4757.031,5201.168]
(6 rows)

Applicability

- Join operator
  - The nested loop, merge join, and hash join are supported.
  - If skew data is on the left to the join, the inner join, left join, semi join, and anti join are supported. If skew data is on the right to the join, the inner join, right join, right semi join, and right anti join are supported.
  - For an optimization plan generated based on statistics, the optimizer checks whether it is optimal by estimating its cost. Optimization plans based on hints or rules are forcibly generated.
- Aggregate operator
  - Optimization is not supported in the array_agg, string_agg, and subplan in agg qual scenarios.
  - A plan generated based on statistics is affected by its cost, the **plan_mode_seed** parameter, and the **best_agg_plan** parameter. A plan generated based on hints or rules is not affected by them.

6.7.7 Long-running Query and Transaction Optimization

Long-running queries or transactions affect AUTOVACUUM's ability to clear earlier versions. As a result, earlier versions created during data updates may not be cleared promptly.

When accessing data, it is necessary to traverse earlier versions to determine which versions are visible to the current query snapshot. The longer a query or transaction continues, the more earlier versions will remain uncleared, which can increasingly affect access performance. In extreme scenarios, for example, when the throughput is queried based on index points with a small amount of data, an increase in earlier versions can significantly decrease the throughput, and the performance may deteriorate by more than 50%.

In addition, if the earlier version cannot be cleared in time, extra storage space is occupied, table bloat and index bloat occur, and extra I/Os increase during data access, affecting performance.

Astore indexes and table data are updated in non-in-place mode. If an index key or a non-index key is updated, an earlier index version and an earlier data version are generated. Ustore indexes are updated in non-in-place mode, and data is updated in-place mode. Updating index keys generates earlier index versions and earlier data versions. Updating non-index keys generates only earlier data versions.

Long-running queries and transactions affect the access performance of both Astore and Ustore.

In terms of service implementation, avoid long-running queries or transactions. You can access pg_stat_activity and pg_running_xacts to check whether long-running queries or transactions exist in the system, and then use

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

pg_cancel_backend(pid int) or pg_terminate_backend(pid int) function to cancel long-running queries or transactions.

6.8 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace UNION with UNION ALL.

  UNION eliminates duplicate rows while merging two result sets but UNION ALL merges the two result sets without deduplication. Therefore, replace UNION with UNION ALL if you are sure that the two result sets do not contain duplicate rows based on the service logic.

- Add not null to the join columns.

  If there are many NULL values in the join columns, you can add the filter criterion IS NOT NULL to filter data in advance to improve the join efficiency.

- Convert NOT IN to NOT EXISTS.

  Nested loop anti join must be used to implement NOT IN, and hash anti join is required for NOT EXISTS. If no NULL value exists in the join columns, NOT IN is equivalent to NOT EXISTS. Therefore, if you are sure that no NULL value exists, you can convert NOT IN to NOT EXISTS to generate hash join and to improve the query performance.

  As shown in the following statement, if the **t2.d2** column does not contain NULL values (it is set to **NOT NULL**), the query can be modified as follows:

  ```
  SELECT * FROM t1 WHERE  NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
  ```

  The generated execution plan is as follows:

  Figure 6-7 NOT EXISTS execution plan

  ```
   id |                  operation
  ----+-----------------------------------------------
    1 | ->  Streaming (type: GATHER)
    2 |     ->  Hash Anti Join (3, 4)
    3 |        ->  Seq Scan on t1
    4 |        ->  Hash
    5 |           ->  Streaming(type: REDISTRIBUTE)
    6 |              ->  Seq Scan on t2
  (6 rows)

   Predicate Information (identified by plan id)
  -----------------------------------------------
     2 --Hash Anti Join (3, 4)
           Hash Cond: (t1.c1 = t2.d2)
  (2 rows)
  ```

- Use **hashagg**.

  If a plan involving groupAgg and SORT operations generated by the GROUP BY statement is poor in performance, you can set **work_mem** to a larger value to generate a HashAgg plan, which does not require sorting and improves the performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Replace functions with CASE statements.

  The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can change the pushdown functions to CASE statements.

- Do not use functions or expressions for indexes.

  Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use the !=, <, or > operator, NULL, OR, or implicit parameter conversion in WHERE clauses.

- If the values of >= and <= are the same in WHERE condition, change the condition to = because range equivalence class derivation is not supported currently.

  ```
  SELECT * FROM t1 WHERE c1 >= 1 AND c1 <= 1
  ```

  Change the preceding content to the following:

  ```
  SELECT * FROM t1 WHERE c1 = 1
  ```

  For range queries, the optimizer has a larger error when calculating selectivity than equivalent queries. Therefore, change range queries to equivalent queries as much as possible.

- Split complex SQL statements.

  You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:

  – The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
  – Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
  – Functions such as substr and to_number cause incorrect measures for subqueries containing large amounts of data.
  – BROADCAST subqueries are performed on large tables in multi-DN environment.

6.9 Configuring Key Parameters for SQL Optimization

This section describes key CN configuration parameters that affect GaussDB SQL performance optimization. Contact an administrator to configure parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 6-6 CN parameters

Parameter/ Reference Value	Description
enable_nestloop=off	Specifies how the optimizer uses nested loop join. If the value is **on**, the optimizer preferentially uses nested loop Join. If it is set to **off**, the optimizer preferentially uses other methods, if any. **NOTE** If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: `SET enable_nestloop to off;` Disabling this parameter does not affect the index nested-loop join operator (corresponding to the **enable_index_nestloop** parameter). During real-world optimization, it is important to assess whether to disable this parameter based on the specific circumstances. Three types of joins are supported: nested loops, merge joins, and hash joins. Specifically, nested loops are best suited for scenarios with small data volumes or indexes, while hash joins are ideal for big data analysis.
enable_index_nestloop=on	Specifies whether to enable the index nested-loop join operator. **NOTE** If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: `SET enable_index_nestloop to off;` Differences between **enable_index_nestloop** and **enable_nestloop**: **enable_index_nestloop** helps manage scenarios where the inner table undergoes index scans, and the outer table supplies index condition parameters for the inner table.
enable_bitmapscan=on	Specifies whether the optimizer uses bitmap scan. If the value is **on**, bitmap scan is used. If the value is **off**, it is not used. **NOTE** If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: `SET enable_bitmapscan to off;` The bitmap scan applies only in the query condition **where a > 1 and b > 1** and indexes are created on columns **a** and **b**. However, the performance of bitmapscan is sometimes inferior to that of indexscan. During optimization, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to **off** and check whether the performance is improved.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter/ Reference Value	Description
enable_fast_query_shipping=on	Specifies whether the optimizer uses a distribution framework to execute quick execution plans. If the value is **on**, the execution plan is generated on both CNs and DNs. If the value is **off**, the distribution framework is used, that is, the execution plan is generated on the CN and then sent to the DN for execution. **NOTE** If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: `SET enable_fast_query_shipping to off;`
enable_hashagg=on	Specifies whether the optimizer uses hash aggregate plans.
enable_hashjoin=on	Specifies whether the optimizer uses hash join plans.
enable_mergejoin=on	Specifies whether the optimizer uses merge join plans.
enable_indexscan=on	Specifies whether the optimizer uses index scan plans.
enable_gsitablescan=on	Specifies whether the optimizer uses GSI scan plans.
gsi_fastpath_level=strict	Specifies whether the optimizer executes the determination system of simple query rules of GSI. The simple query rules of GSI are as follows: ● A single table, no subquery, no sublink, or the target table is not a view. ● The query statement cannot generate an execution plan for an ordinary index. ● The query statement cannot generate the IndexOnlyScan execution plan of GSI. ● Query statements do not contain scan hints, such as **tablescan** and **indexscan**. ● The WHERE condition contains an equivalent condition that contains the index key of the candidate GSI (unique and not a partial GSI index).
enable_indexonlyscan=on	Specifies whether the optimizer uses index-only scan plans.
enable_gsiscan=on	Specifies whether the optimizer uses GSI-only scan plans.
enable_seqscan=on	Specifies whether the optimizer uses sequential scan plans. It is impossible to suppress sequential scans entirely, but setting this variable to **off** encourages the optimizer to choose other methods if available.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter/ Reference Value	Description
enable_sort=on	Specifies the optimizer sorting order. It is impossible to fully suppress explicit sorting, but setting this variable to **off** encourages the optimizer to choose other methods if available.
enable_broadcast=on	Specifies whether the optimizer uses data broadcast. In data broadcast, a large amount of data is transferred on the network. When the number of transmission nodes (stream) is large and the estimation is inaccurate, set this parameter to **off** and check whether the performance is improved.
rewrite_rule	Specifies whether the optimizer enables the LAZYAGG, MAGICSET, PARTIALPUSH, DISABLEREP, UNIQUECHECK, INTARGETLIST, PREDPUSH, PREDPUSHFORCE, PREDPUSHNORMAL, DISABLE_PULLUP_EXPR_SUBLINK, ENABLE_SUBLINK_PULLUP_ENHANCED, DISABLE_PULLUP_NOT_IN_SUBLINK, DISABLE_ROWNUM_PUSHDOWN, DISABLE_WINDOWAGG_PUSHDOWN rewriting, or GROUPBY_PUSHDOWN_SUBQUERY rule.
sql_beta_feature	Specifies whether the optimizer enables the SEL_SEMI_POISSON, NO_UNIQUE_INDEX_FIRST, JOIN_SEL_WITH_CAST_FUNC, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, INDEX_COST_WITH_INDEX_COST_WITH_LEAF_PAGES_ONLY, PREDPUSH_SAME_LEVEL, PARTITION_FDW_ON, DISABLE_BITMAP_COST_WITH_LOSSY_PAGES, or ENABLE_UPSERT_EXECUTE_GPLAN beta feature.
enable_inner_unique_opt	Specifies whether the optimizer uses Inner Unique.

6.10 Hint-based Optimization

6.10.1 Plan Hint Optimization

In plan hints, you can specify a join order; join, stream, and scan operations, the number of rows in a result, and redistribution skew information to tune an execution plan, improving query performance.

GaussDB also provides the SQL patch function. You can create an SQL patch to make hints take effect without modifying service statements.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them with spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the SELECT of this subquery.

For example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, <*plan_hint1*> and <*plan_hint2*> are the hints of a query, and <*plan_hint3*> is the hint of its subquery.

You can use the EXPLAIN syntax to analyze the plan hint optimization effect. You can use EXPLAIN to view the plan of the target SQL statement after the plan hint is used and check whether the plan meets the requirements to verify the plan hint effect. EXPLAIN has multiple plan display modes, which are controlled by **explain_perf_mode**. In some examples in this section, **explain_perf_mode** is set to **pretty** to display complete plan information. In some examples, **explain_perf_mode** is set to **normal** to simplify the output information.

NOTICE

If a hint is specified in the CREATE VIEW statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan_mode_seed** is set to a value other than 0), the specified hint will not be used.

Scope

Currently, the following hints are supported:

- Join order hints (**leading**).
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints.
- Rows hints.
- Stream operation hints.
- Scan operation hints, supporting only the **tablescan**, **indexscan**, **index**, **indexonlyscan**, and **gsi** hints.
- Sublink name hints.
- Skew hints, supporting only the skew in the redistribution involving Join or HashAgg.
- Hints of GUC parameters, which take effect in a query and do not take effect in views.
- Hints that use the custom plan or generic plan and are valid only for query statements executed by PBE.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Hints specifying not to expand subqueries.
- Hints specifying that the current query statement does not enter the global plan cache. The hints are valid only when **enable_global_plancache** is enabled and the current statement is executed by PBE.
- Hints for internal table materialization.
- Bitmap scan hints.
- Hints of the Agg method

Precautions

- Hints do not support Sort, Setop, or Subplan.
- Hints do not support SMP or node groups.

Examples

Create tables and indexes.

```
create table t1(c1 int, c2 int, c3 int);
create table t2(c1 int, c2 int, c3 int);
create table t3(c1 int, c2 int, c3 int);
create index it1 on t1(c1,c2);
create index it2 on t2(c1,c2);
create index it3 on t1(c3,c2);
-- The following TPC-H data table needs to be inserted with 10 times of the data to match the provided
plan example:
create table store

                        ->  Index Scan using customer_address_pkey on customer_address ad2  (cost=0.00..3.35
rows=1 width=368)
                              Index Cond: (ca_address_sk = customer.c_current_addr_sk)
(34 rows)
```

6.10.2 Hint Specifying the Query Block Where the Hint Is Located

Description

This function allows users to use @queryblock in hints to implement block-level hint control. Users can specify the query block to which the hint takes effect. For example, you can specify the hint of an inner query block in the outer query block.

Syntax

Add **@queryblock** at the beginning of the hint parameter. **Hint_SEPC** is a specific hint.

```
Hint_SEPC([@queryblock])
```

Parameters

Hint_SEPC is the hint name, and **@queryblock** can be left empty. If **@queryblock** is left empty, the hint takes effect in the current query block declared by the hint. If **@queryblock** is left empty and **Hint_SPEC** has no parameter, use **Hint_SPEC** instead of **Hint_SPEC()**. Parentheses are unnecessary. The following describes how to name a query block and how to make a hint take effect. Some hints do not take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

- Query the name of a query block.

  Each query block must have a name for accurately specifying a hint. There are two naming methods: user-specified and system-specified.

  - You can use the blockname hint to specify the block to be queried. For details, see **Sublink Name Hints**.
  - If no alias is specified for a query block, the default block name is automatically generated based on the processing sequence. Generally, the default alias of each query block consists of the first three letters of the query block name, **$**, and the number of the query block. For example, the alias of the first SELECT query block is **sel$1**. In pretty mode, you can use the explain method with a specified block name to view the name of the query block where the processing operator of each table is located. In

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

distributed scenarios, only stream plans can be displayed in pretty mode. You can set **enable_fast_query_shipping** to generate stream plans.

```
gaussdb=# set explain_perf_mode = pretty;
SET
gaussdb=# set enable_fast_query_shipping = off;
SET
gaussdb=# explain (blockname on,costs off) select * from t1, (select c1 from t2 group by c1)
sub1 where t1.c1 = sub1.c1;
 id |              operation               | Query Block
----+--------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)         | sel$1
  2 |    ->  Hash Join (3,4)               | sel$1
  3 |       ->  Seq Scan on t1@"sel$1"     | sel$1
  4 |       ->  Hash                       |
  5 |          ->  HashAggregate           | sel$2
  6 |             ->  Seq Scan on t2@"sel$2" | sel$2
(6 rows)
```

You can see that Seq Scan of **t2** is located in the **sel$2** query block.

- **@queryblock** specifies the query block.

  For the preceding example, if you want to modify the indexscan mode in **t2**, run the following command:

  ```
  select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1, (select c1 from t2 group by c1) sub1 where
  t1.c1 = sub1.c1;
  ```

  Both indexscan and tablescan are scan hints. For details about scan hints, see **Scan Hints**. You can specify the hint of indexscan(**@sel$2 t2**) in the **sel$1** query block to move the hint to the **sel$2** query block. The hint takes effect for **t2**. If the **sel$2** query block is promoted to **sel$1** during subsequent rewriting, the hint is also promoted together to **sel$1** and continues to take effect for **t2**.

  ```
  gaussdb=# explain (blockname on,costs off) select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1,
  (select c1 from t2 group by c1) sub1 where t1.c1 = sub1.c1;
   id |                      operation                       | Query Block
  ----+------------------------------------------------------+-------------
    1 | ->  Streaming (type: GATHER)                         | sel$1
    2 |    ->  Hash Join (3,4)                               | sel$1
    3 |       ->  Seq Scan on t1@"sel$1"                     | sel$1
    4 |       ->  Hash                                       |
    5 |          ->  HashAggregate                           | sel$2
    6 |             ->  Index Only Scan using it2 on t2@"sel$2" | sel$2
  (6 rows)
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

CAUTION

Sometimes, query rewriting in the optimizer phase expands some query blocks. As a result, the plan does not display related query blocks in the explain method. The hint specifies a query block based on the name of the query block before the optimizer phase. If a query block to be queried may be expanded in the planning phase, you can add the no_expand hint (see **Hints Specifying Not to Expand Subqueries**) to prevent it from being expanded.

1. The **sel$2** query block is a simple query. The optimizer performs query rewriting during subsequent processing, and **t1** is promoted to **sel$1** for processing. Therefore, the operation in the **sel$2** query block is not displayed in the plan.

```
gaussdb=# explain (blockname on,costs off) select * from t2, (select c1 from t1 where t1.c3 = 2) sub1
where t2.c1 = sub1.c1;
 id |                operation                 | Query Block
----+------------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)             | sel$1
  2 |    ->  Nested Loop (3,4)                 | sel$1
  3 |       ->  Index Scan using it3 on t1@"sel$2" | sel$1
  4 |       ->  Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

2. The **sel$2** query block is a simple query. During subsequent processing, the optimizer skips query rewriting because of the no_expand hint, and **t1** is still processed in the original query block.

```
gaussdb=# explain (blockname on,costs off) select * from t2, (select /*+ no_expand*/ c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
 id |                operation                 | Query Block
----+------------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)             | sel$1
  2 |    ->  Nested Loop (3,4)                 | sel$1
  3 |       ->  Index Scan using it3 on t1@"sel$2" | sel$2
  4 |       ->  Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

3. Because **t1** is processed in the **sel$2** query block after the no_expand hint is added, you can use **@sel$2** to specify the query block for the hint.

```
explain (blockname on,costs off) select/*+ tablescan(@sel$2 t1)*/ * from t2, (select c1 from t1 where
t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
 id |                operation                 | Query Block
----+------------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)             | sel$1
  2 |    ->  Nested Loop (3,4)                 | sel$1
  3 |       ->  Seq Scan on t1@"sel$2"         | sel$1
  4 |       ->  Index Scan using it2 on t2@"sel$1" | sel$1
(4 rows)
```

4. The query block number in the view depends on the sequence of the statement using the view. Therefore, do not use hints to specify query blocks when creating a view. The behavior is uncontrollable.

```
gaussdb=# create view v1 as select/*+ no_expand */ c1 from t1 where c1 in (select /*+ no_expand */ c1
from t2 where t2.c3=4 );
CREATE VIEW
gaussdb=# explain (blockname on,costs off) select  * from v1;
 id |              operation               | Query Block
----+--------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)         | sel$1
  2 |    ->  Seq Scan on t1@"sel$2"        | sel$2
  3 |       ->  Materialize  [2, SubPlan 1]  |
  4 |          ->  Streaming(type: BROADCAST) |
  5 |             ->  Seq Scan on t2@"sel$3"  | sel$3
(5 rows)

 Predicate Information (identified by plan id)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------------------------------------
  2 --Seq Scan on t1@"sel$2"
        Filter: (hashed SubPlan 1)
  5 --Seq Scan on t2@"sel$3"
        Filter: (c3 = 4)
(4 rows)
```

In this case, the statements in **v1** belong to **sel$2** and **sel$3**.

5. Some hints take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

6.10.3 Hint Specifying the Query Block and Schema of a Table

Description

In a query, the table name can be duplicate in different query blocks and different schemas. Therefore, when specifying a table in a query, you can use a hint to specify the query block and schema where the table is located to avoid ambiguity. This function is applicable to all hints whose table names need to be specified.

Syntax

When specifying a table using a hint, specify a schema using a period (**schema.**) and a query block using the at sign (**@queryblock**). Both the schema and query block can be left empty.

```
[schema.]relname[@queryblock]
```

Parameters

- **relname** indicates the name of the table in the query. If the table has an alias, use the alias first. In this case, **relname** is set to the alias. If the table name contains special characters, such as at sign (@) and period (.), **relname** must be enclosed in double quotation marks ("") to avoid conflict with the declaration of the query block and schema names. For example, if the table name is **relnametest@1**, enter **"relnametest@1"**.
- **schema** indicates the schema where the table is located. It can be left empty. If no schema is specified, the hint searches all schemas for **relname**.
- **queryblock** indicates the query block where the table is located. It can be left empty. If no query block is specified, the hint searches all query blocks for **relname**.

Example

1. **t1** of **sel$2** is promoted to **sel$1** for processing, and **t1** is unclear.

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1)*/ * from t1, (select c2 from t1
where c1=1) tt1 where t1.c1 = tt1.c2;
WARNING:  Error hint: TableScan(t1), relation name "t1" is ambiguous.
...
```

2. **t1@sel$2** is specified to perform tablescan on **t1** of **sel$2** (Filter: (c1 = 1)).

```
gaussdb=# explain(blockname on,costs off) select /*+ tablescan(t1@sel$2)*/ * from t1, (select c2 from
t1 where c1=1) tt1 where t1.c1 = tt1.c2;
 id |                operation                 | Query Block
----+------------------------------------------+-------------
  1 | ->  Streaming (type: GATHER)             | sel$1
  2 |    ->  Nested Loop (3,5)                 | sel$1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 3 |       ->  Streaming(type: REDISTRIBUTE)       | sel$1
 4 |         ->  Seq Scan on t1@"sel$2"            | sel$1
 5 |       ->  Index Scan using it1 on t1@"sel$1" | sel$1
(5 rows)

 Predicate Information (identified by plan id)
------------------------------------------------
  4 --Seq Scan on t1@"sel$2"
        Filter: (c1 = 1)
  5 --Index Scan using it1 on t1@"sel$1"
        Index Cond: (c1 = public.t1.c2)
(4 rows)
```

6.10.4 Join Order Hints

Description

Specifies the join order and outer/inner tables.

Syntax

- Specify only the join order.

```
leading([@queryblock] join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading([@queryblock] (join_table_list))
```

Parameters

join_table_list specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.

NOTICE

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

To prevent semantic errors, tables specified by **join_table_list** must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

leading(t1 t2 t3 t4 t5): **t1**, **t2**, **t3**, **t4**, and **t5** are joined. The join sequence and outer/inner tables are not specified.

leading((t1 t2 t3 t4 t5)): **t1**, **t2**, **t3**, **t4**, and **t5** are joined in sequence. The table on the right is used as the inner table in each join.

leading(t1 (t2 t3 t4) t5): First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1** and **t5**, and the outer/inner tables are not specified.

leading((t1 (t2 t3 t4) t5)): First, **t2**, **t3**, and **t4** are joined and the outer/inner tables are not specified. Then, the result is joined with **t1**, and **(t2 t3 t4)** is used as the inner table. Finally, the result is joined with **t5**, and **t5** is used as the inner table.

leading((t1 (t2 t3) t4 t5)) leading((t3 t2)): First, **t2** and **t3** are joined and **t2** is used as the inner table. Then, the result is joined with **t1**, and **(t2 t3)** is used as the inner table. Finally, the result is joined with **t4** and then **t5**, and the table on the right in each join is used as the inner table.

Examples

Hint the query plan in **Examples** as follows:

```
explain
select /*+ leading((((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store store_sales))*/ i_product_name product_name ...
```

First, **store_sales** and **store** are joined and **store_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store_returns** in sequence. The optimized plan is as follows.

```
WARNING:  Duplicated or conflict hint: Leading(store_sales store), will be discarded.
 id |                                  operation                                  | E-rows | E-width | E-costs
----+-----------------------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                                |      2 |     880 | 78.79
  2 |    ->  HashAggregate                                                        |      2 |     880 | 78.15
  3 |       ->  Nested Loop (4,24)                                                |      2 |     776 | 78.11
  4 |          ->  Streaming(type: REDISTRIBUTE)                                  |      2 |     784 | 71.39
  5 |             ->  Nested Loop (6,23)                                          |      2 |     784 | 70.75
  6 |                ->  Streaming(type: REDISTRIBUTE)                            |      2 |     424 | 64.04
  7 |                   ->  Nested Loop (8,22)                                    |      2 |     424 | 63.67
  8 |                      ->  Streaming(type: REDISTRIBUTE)                      |      2 |     424 | 56.96
  9 |                         ->  Nested Loop (10,12)                             |      2 |     424 | 56.59
 10 |                            ->  Streaming(type: BROADCAST)                   |      2 |     208 | 13.67
 11 |                               ->  Seq Scan on item                          |      1 |     208 | 13.36
 12 |                            ->  Materialize                                  |     20 |     216 | 42.81
 13 |                               ->  Hash Join (14,20)                         |     20 |     216 | 42.79
 14 |                                  ->  Streaming(type: REDISTRIBUTE)          |     20 |     220 | 29.35
 15 |                                     ->  Hash Join (16,17)                   |     20 |     220 | 27.73
 16 |                                        ->  Seq Scan on store                |     20 |     166 | 13.13
 17 |                                        ->  Hash                             |     21 |      62 | 14.31
 18 |                                           ->  Streaming(type: REDISTRIBUTE) |     20 |      62 | 14.31
 19 |                                              ->  Seq Scan on store_sales    |     20 |      62 | 13.13
 20 |                                  ->  Hash                                   |     21 |       4 | 13.13
 21 |                                     ->  Seq Scan on promotion               |     20 |       4 | 13.13
 22 |                      ->  Index Scan using customer_pkey on customer         |      1 |       8 | 3.35
 23 |                ->  Index Scan using customer_address_pkey on customer_address ad2 |      1 |     368 | 3.35
 24 |          ->  Index Only Scan using store_returns_pkey on store_returns      |      1 |       8 | 3.35
(24 rows)
```

For details about the warning at the top of the plan, see **Hint Errors, Conflicts, and Other Warnings**.

6.10.5 Join Operation Hints

Description

Specifies the join method, which can be nested loop join, hash join, or merge join.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
[no] nestloop|hashjoin|mergejoin([@queryblock] table_list)
```

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **no** indicates that the specified hint will not be used for a join.
- **table_list** specifies the tables to be joined. The values are the same as those of **join_table_list** but contain no parentheses.

For example:

no nestloop(t1 t2 t3): **nestloop** is not used for joining **t1**, **t2**, and **t3**. The three tables may be joined in either of the two ways: Join **t2** and **t3**, and then **t1**; join **t1** and **t2**, and then **t3**. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add **no nestloop(t2 t3)** to join **t2** and **t3** first and to forbid the use of **nestloop**.

Example

Hint the query plan in **Examples** as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

nestloop is used for the last join between **store_sales**, **store_returns**, and **item**. The optimized plan is as follows.

```
 id |                                        operation                                        | E-rows | E-width | E-costs
----+-----------------------------------------------------------------------------------------+--------+---------+---------
  1 | ->  HashAggregate                                                                       |      1 |     880 | 53.76
  2 |    ->  Streaming (type: GATHER)                                                         |      2 |     880 | 53.76
  3 |       ->  HashAggregate                                                                 |      2 |     880 | 53.11
  4 |          ->  Nested Loop (5,20)                                                         |      2 |     776 | 53.07
  5 |             ->  Streaming(type: REDISTRIBUTE)                                           |      2 |     416 | 46.36
  6 |                ->  Nested Loop (7,19)                                                   |      2 |     416 | 45.99
  7 |                   ->  Streaming(type: REDISTRIBUTE)                                     |      2 |     258 | 39.27
  8 |                      ->  Nested Loop (9,18)                                             |      2 |     258 | 38.99
  9 |                         ->  Streaming(type: REDISTRIBUTE)                               |      2 |     262 | 32.28
 10 |                            ->  Nested Loop (11,17)                                      |      2 |     262 | 32.00
 11 |                               ->  Streaming(type: REDISTRIBUTE)                         |      2 |     262 | 25.28
 12 |                                  ->  Nested Loop (13,16)                                |      2 |     262 | 25.00
 13 |                                     ->  Nested Loop (14,15)                             |      2 |     270 | 21.64
 14 |                                        ->  Seq Scan on item                             |      1 |     208 | 13.36
 15 |                                        ->  Index Scan using store_sales_pkey on store_sales |      1 |      62 | 8.27
 16 |                                     ->  Index Only Scan using store_returns_pkey on store_returns |      1 |       8 | 3.35
 17 |                                  ->  Index Scan using customer_pkey on customer         |      1 |       8 | 3.35
 18 |                            ->  Index Only Scan using promotion_pkey on promotion       |      1 |       4 | 3.35
 19 |                      ->  Index Scan using store_pkey on store                           |      1 |     166 | 3.35
 20 |                ->  Index Scan using customer_address_pkey on customer_address ad2      |      1 |     368 | 3.35
(20 rows)
```

6.10.6 Rows Hints

Description

Specifies the number of rows in an intermediate result set. Both absolute values and relative values are supported.

Syntax

```
rows( [@queryblock] table_list #|+|-|* const)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- #, +, -, and * are operators used for hinting the estimation. # indicates that the original estimation is used without any calculation. +, -, and * indicate that the original estimation is calculated using these operators. The minimum calculation result is 1. **table_list** specifies the tables to be joined. The values are the same as those of **table_list** in **Join Operation Hints**.
- **const** can be any non-negative number and supports scientific notation.

For example:

rows(t1 #5): The result set of **t1** is five rows.

rows(t1 t2 t3 *1000): The result set of joined **t1**, **t2**, and **t3** is multiplied by 1000.

Suggestion

- The hint using * for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is **rows(t1 t2 * 3)**, the join result of **(t1 t3 t4)** and **(t2 t5 t6)** will be multiplied by 3 because **t1** and **t2** appear on both sides of the join.
- **rows** hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

Example

Hint the query plan in **Examples** as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined **store_sales** and **store_returns** by 50. The optimized plan is as follows.

```
 id |                                      operation                                       | E-rows | E-width | E-costs
----+--------------------------------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                                         |      4 |     880 | 58.44
  2 |    ->  HashAggregate                                                                 |      4 |     880 | 57.15
  3 |       ->  Nested Loop (4,20)                                                         |      5 |     776 | 57.07
  4 |          ->  Streaming(type: REDISTRIBUTE)                                           |      2 |     784 | 50.34
  5 |             ->  Nested Loop (6,19)                                                   |      2 |     784 | 49.71
  6 |                ->  Streaming(type: REDISTRIBUTE)                                     |      2 |     424 | 43.00
  7 |                   ->  Nested Loop (8,18)                                             |      2 |     424 | 42.63
  8 |                      ->  Streaming(type: REDISTRIBUTE)                               |      2 |     266 | 35.91
  9 |                         ->  Nested Loop (10,17)                                      |      2 |     266 | 35.63
 10 |                            ->  Streaming(type: REDISTRIBUTE)                         |      2 |     270 | 28.92
 11 |                               ->  Nested Loop (12,16)                                |      2 |     270 | 28.63
 12 |                                  ->  Streaming(type: REDISTRIBUTE)                   |      2 |     270 | 21.92
 13 |                                     ->  Nested Loop (14,15)                          |      2 |     270 | 21.64
 14 |                                        ->  Seq Scan on item                          |      1 |     208 | 13.36
 15 |                                        ->  Index Scan using store_sales_pkey on store_sales |      1 |      62 | 8.27
 16 |                                  ->  Index Scan using customer_pkey on customer      |      1 |       8 | 3.35
 17 |                            ->  Index Only Scan using promotion_pkey on promotion     |      1 |       4 | 3.35
 18 |                      ->  Index Scan using store_pkey on store                        |      1 |     166 | 3.35
 19 |                ->  Index Scan using customer_address_pkey on customer_address ad2    |      1 |     368 | 3.35
 20 |          ->  Index Only Scan using store_returns_pkey on store_returns               |      1 |       8 | 3.35
(20 rows)
```

The estimation value after the hint in row 11 is **360**, and the original value is rounded off to 7.

6.10.7 Stream Operation Hints

Description

Specifies a stream operation, which can be broadcast or redistribute. You can also directly generate a gather plan.

Syntax

```
[no] broadcast|redistribute|local_roundrobin( [@queryblock] table_list)
gather( [@queryblock] REL|JOIN|ALL)
```

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **broadcast**, **redistribute**, and **local_roundrobin** indicate data distribution methods.
  - **no** specifies that the specified hint will not be used for a stream operation.
  - **table_list** specifies the table on which a stream operation is to be performed or the tables to be joined. For details, see **Parameters**.
- gather

  The gather hint can specify the following plan generation modes:
  - **REL**: Only the gather path based on the base table is generated, and then the remaining plan is executed on the CN.
  - **JOIN**: A join-based gather path is generated as much as possible and is added to the join subplan that can be pushed down (the join subplan does not contain the redistribution node), and the remaining plan is executed on the CN. For a join plan that requires node redistribution, such a join-based gather path cannot be generated. Instead, a base table-based gather path is generated.

    CAUTION

    After **Hint(JOIN)** is specified, the plan expected by **Hint(JOIN)** cannot be generated if the distributed table and replication table are joined, because the optimizer has found a better plan for replacement.
  - **ALL**: The **Gather Rel** or **Gather Join** path is selected based on the optimal mode.

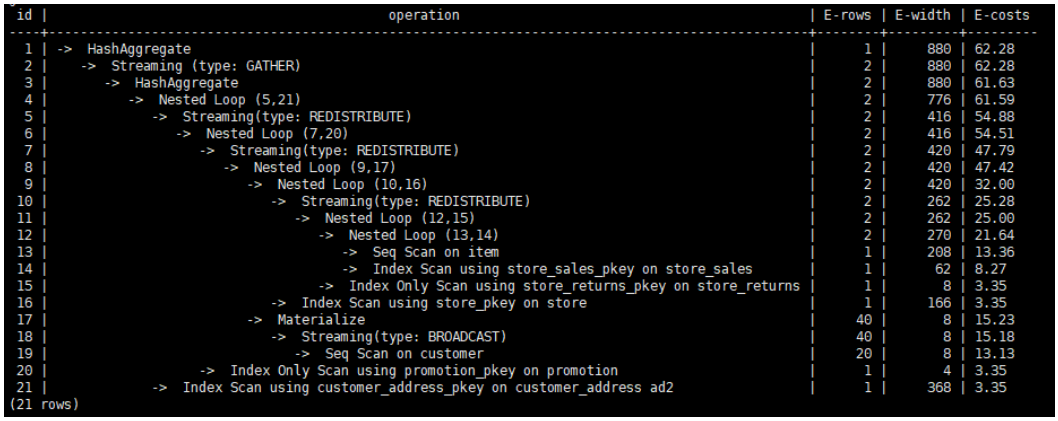
Examples

Hint the query plan in **Examples** as follows:

```
explain
select /*+ no redistribute(store_sales store_returns item store) leading(((store_sales store_returns item
store) customer)) */ i_product_name product_name ...
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

In the original plan, the join result of **store_sales**, **store_returns**, **item**, and **store** is redistributed before it is joined with **customer**. After the hinting, the redistribution is disabled and the join order is retained. The optimized plan is as follows.



```
 id |                                      operation                                       | E-rows | E-width | E-costs
----+--------------------------------------------------------------------------------------+--------+---------+---------
  1 | ->  HashAggregate                                                                    |      1 |     880 | 62.28
  2 |    ->  Streaming (type: GATHER)                                                      |      2 |     880 | 62.28
  3 |       ->  HashAggregate                                                              |      2 |     880 | 61.63
  4 |          ->  Nested Loop (5,21)                                                      |      2 |     776 | 61.59
  5 |             ->  Streaming(type: REDISTRIBUTE)                                        |      2 |     416 | 54.88
  6 |                ->  Nested Loop (7,20)                                                |      2 |     416 | 54.51
  7 |                   ->  Streaming(type: REDISTRIBUTE)                                  |      2 |     420 | 47.79
  8 |                      ->  Nested Loop (9,17)                                          |      2 |     420 | 47.42
  9 |                         ->  Nested Loop (10,16)                                      |      2 |     420 | 32.00
 10 |                            ->  Streaming(type: REDISTRIBUTE)                         |      2 |     262 | 25.28
 11 |                               ->  Nested Loop (12,15)                                |      2 |     262 | 25.00
 12 |                                  ->  Nested Loop (13,14)                             |      2 |     270 | 21.64
 13 |                                     ->  Seq Scan on item                             |      1 |     208 | 13.36
 14 |                                     ->  Index Scan using store_sales_pkey on store_sales |      1 |      62 | 8.27

```
      Hash Cond: (t1.c1 = t2.c1)
(4 rows)
```

3. Generate the gather plan **/*+ GATHER(ALL)*/** based on the optimal mode.

   The **GATHER(REL)** or **GATHER(JOIN)** path is selected based on the optimal mode and rules.

```
gaussdb=# explain select /*+ GATHER(ALL)*/* from t1, t2, t3 where t1.c1 = t2.c1 and t2.c2 = t3.c2;
 id |            operation             | E-rows | E-width | E-costs
----+----------------------------------+--------+---------+---------
  1 | ->  Hash Join (2,7)              |     20 |      36 | 42.37
  2 |   ->  Streaming (type: GATHER)   |     20 |      24 | 27.49
  3 |     ->  Hash Join (4,5)          |     20 |      24 | 26.56
  4 |       ->  Seq Scan on t1         |     20 |      12 | 13.13
  5 |       ->  Hash                   |     21 |      12 | 13.13
  6 |         ->  Seq Scan on t2       |     20 |      12 | 13.13
  7 |   ->  Hash                       |     20 |      12 | 14.35
  8 |     ->  Streaming (type: GATHER) |     20 |      12 | 14.35
  9 |       ->  Seq Scan on t3         |     20 |      12 | 13.13
(9 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   1 --Hash Join (2,7)
       Hash Cond: (t2.c2 = t3.c2)
   3 --Hash Join (4,5)
       Hash Cond: (t1.c1 = t2.c1)
(4 rows)
```

   local_roundrobin hint usage:

```
SET enable_fast_query_shipping=off; -- Disable FQS optimization.
SET query_dop=4; -- Set the degree of parallelism.
gaussdb=# EXPLAIN(costs off) SELECT /*+ local_roundrobin(t2) scandop(t2 1) scandop(t1 4)*/* FROM
t1, t2  WHERE t1.c1 = t2.c1;
 id |                      operation
----+-----------------------------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |   ->  Streaming(type: LOCAL GATHER dop: 1/4)
  3 |     ->  Nested Loop (4,6)
  4 |       ->  Streaming(type: LOCAL BROADCAST dop: 4/4)
  5 |         ->  Seq Scan on t1
  6 |       ->  Materialize
  7 |         ->  Streaming(type: LOCAL ROUNDROBIN dop: 4/1)
  8 |           ->  Seq Scan on t2
(8 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   3 --Nested Loop (4,6)
       Join Filter: (t1.c1 = t2.c1)
(2 rows)
```

   The local_roundrobin data distribution mode is successfully selected. However, you are advised not to use this mode because there are many restrictions (such as setting the degree of parallelism and disabling FQS optimization).

   NOTE

   The local_roundrobin hint takes effect only when the degree of parallelism for table scanning is 1. You are advised to use this hint with **scandop hint**.

6.10.8 Scan Hints

Description

Specifies a scan operation, which can be **tablescan**, **indexscan**, **index** (same as **indexscan**) **indexonlyscan**, **gsi** or **gsitable**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
[no] tablescan|indexscan|index|indexonlyscan|gsi|gsitable( [@queryblock] table [index])
```

Parameters

- **no** indicates that the specified hint will not be used for a join.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- **index** specifies only one index when an index scan, index, index-only scan, GSI, or GSI table hint is used.

NOTE

- Index scan, index, index-only scan, and GSI hints can be used only when the hint index belongs to the hint table.
- Scan operation hints can be used for row-store tables and subquery tables.
- The index-only scan plan can be generated by the index scan and index hints, but the index-only hint can generate only the index-only plan.
- When index scan and index are compatible with index-only scan, some plan changes may occur. For example, **cost_model_version** is added for escape. This parameter can be used to determine whether index scan and index are compatible with index-only scan. Index scan and index are compatible with index-only scan when the parameter value is greater than 2 or equal to 0.
- If a GSI can be used for a query, using the GSI hint will generate an index-only scan query plan that uses the GSI, but not a query plan that uses an ordinary index.
- If the GSI for TABLE ACCESS BY INDEX ROWID can be used for a query, using the GSI table hint will generate a plan that uses the GSI for TABLE ACCESS BY INDEX ROWID.
- If no query block, table, or index is specified for a GSI hint, the GSI hint takes effect across query blocks.
- To use the GSI table hint, enable the **enable_stream_operator** parameter. Otherwise, the hint does not take effect.
- Valid GSIs can be directly queried on DNs.

Example

To specify an index-based hint for a scan, create an index named **i** on the **i_item_sk** column of the **item** table.

```
create index i on item(i_item_sk);
```

Hint the query plan in **Examples** as follows:

```
explain
select /*+ indexscan(item i) */ i_product_name product_name ...
or
EXPLAIN
SELECT /*+ index(item i) */ i_product_name product_name ...
```

item is scanned based on an index. The optimized plan is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
WARNING:  Error hint: IndexScan(item i), index "i" doesn't exist.
 id |                                        operation                                        | E-rows | E-width | E-costs

 15 |                                        ->  Index Scan using store_sales_pkey on store_sales |      1 |      62 | 8.27
 16 |                                     ->  Index Only Scan using store_returns_pkey on store_returns |      1 |       8 | 3.35
 17 |                                  ->  Index Scan using customer_pkey on customer         |      1 |       8 | 3.35
 18 |                            ->  Index Only Scan using promotion_pkey on promotion       |      1 |       4 | 3.35
 19 |                         ->  Index Scan using store_pkey on store                        |      1 |     166 | 3.35
 20 |                   ->  Index Scan using customer_address_pkey on customer_address ad2    |      1 |     368 | 3.35
(20 rows)
```

6.10.9 Sublink Name Hints

Description

Specifies the name of a sublink block.

Syntax

```
blockname ( [@queryblock] table)
```

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the name you have specified for a sublink block.

NOTE

- The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
- The subquery after the FROM keyword is hinted by using the subquery alias. In this case, the blockname hint becomes invalid.
- If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, the hint also becomes invalid.

Examples

```
explain select /*+nestloop(store_sales tt) */ * from store_sales where ss_item_sk in (select /*
+blockname(tt)*/ i_item_sk from item group by 1);
```

tt indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store_sales** by using **nestloop**. The optimized plan is as follows.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# explain select /*+nestloop(store_sales tt) */ * from store_sales wh
 id |              operation               | E-rows | E-width | E-costs
----+--------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)         |     20 |     212 | 30.02
  2 |    ->  Nested Loop Semi Join (3, 4)  |     20 |     212 | 28.47
  3 |       ->  Seq Scan on store_sales    |     20 |     212 | 13.13
  4 |       ->  Materialize                |     20 |       4 | 13.41
  5 |          ->  HashAggregate           |     20 |       4 | 13.26
  6 |             ->  Seq Scan on item     |     20 |       4 | 13.13
(6 rows)
```

CAUTION

When the blockname hint is specified using **@queryblock** instead of taking effect in the current query block, for example, **blockname(@sel$2 new_qb_name)**, other hints cannot be specified using **@new_qb_name**. In this case, **new_qb_name** is only used as the name of the sublink and can be specified using hints.

- The block **bn2** is specified using **blockname(@sel$2 bn2)**. As a result, **TableScan(@bn2 t2)** cannot find the queryblock by using **@bn2**. The query block should be specified by using **@sel$2**. The block **bn3** is specified using the **blockname(bn3)** hint. The hint takes effect in the current query block and changes the name of the query block. Therefore, **tablescan(@bn3 t3@bn3)** can find the query block specified by using **@bn3**.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) tablescan(@bn2 t2) tablescan(@sel$2 t2@bn2) indexscan(@sel$2 t2@sel$2) tablescan(@bn3 t3@bn3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1 from t2 where t2.c2 = 1 group by 1) and c3 in ( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2 = 1 group by 1);
WARNING:  hint: TableScan(@bn2 t2) does not match any query block
WARNING:  Error hint: TableScan(@"sel$2" t2@bn2), relation name "t2@bn2" is not found.
```

- The following specifies the sublink block **bn2** by using **blockname(@sel$2 bn2)**. When the sublink is promoted, **hashjoin(t1 bn2)** can be used to specify the operation of the promoted sublink.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) hashjoin(t1 bn2) nestloop(t1 bn3) nestloop(t1 sel$3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1 from t2 where t2.c2 = 1 group by 1)  and c3 in ( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2 = 1 group by 1);
WARNING:  Duplicated or conflict hint: NestLoop(t1 "sel$3"), will be discarded.
```

6.10.10 Skew Hints

Description

Specifies redistribution keys containing skew data and skew values, and are used to optimize redistribution involving Join or HashAgg.

Syntax

- Specify single-table skew.

```
skew( [@queryblock] table (column) [(value)])
```

- Specify intermediate result skew.

```
skew( [@queryblock] (join_rel) (column) [(value)])
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table where skew occurs.
- **join_rel** specifies two or more joined tables. For example, **(t1 t2)** indicates that the result of joining **t1** and **t2** tables contains skew data.
- **column** specifies one or more columns where skew occurs.
- **value** specifies one or more skew values.

NOTE

- Skew hints are used only if redistribution is required and the specified skew information matches the redistribution information.
- Skew hints are controlled by the GUC parameter **skew_option**. If the parameter is disabled, skew hints cannot be used for solving skew.
- Currently, skew hints support only the table relationships of the ordinary table and subquery types. Hints can be specified for base tables, subqueries, and WITH ... AS clauses. Unlike other hints, a subquery can be used in skew hints regardless of whether it is pulled up.
- Use an alias (if any) to specify a table where data skew occurs.
- You can use a name or an alias to specify a skew column as long as it is not ambiguous. The columns in skew hints cannot be expressions. If data skew occurs in the redistribution that uses an expression as a redistribution key, set the redistribution key as a new column and specify the column in skew hints.
- The number of skew values must be an integer multiple of the number of columns. Skew values must be grouped based on the column sequence, with each group containing a maximum of 10 values. You can specify duplicate values to group skew columns having different number of skew values. For example, the **c1** and **c2** columns of the **t1** table contain skew data. The skew value of the **c1** column is **a1**, and the skew values of the **c2** column are **b1** and **b2**. In this case, the skew hint is **skew(t1 (c1 c2) ((a1 b1)(a1 b2)))**. **(a1 b1)** is a value group, where **NULL** is allowed as a skew value. Each hint can contain a maximum of 10 groups and the number of groups should be an integer multiple of the number of columns.
- In the redistribution optimization of Join, a skew value must be specified for skew hints. The skew value can be left empty for HashAgg.
- If multiple tables, columns, or values are specified, separate items of the same type with spaces.
- For skew values, forcible type conversion is not supported in hints. For the string type, single quotation marks are required.

Example:

- Specify single-table skew.

  Each skew hint describes the skew information of one table relationship. To describe the skews of multiple table relationships in a query, specify multiple skew hints.

  Skew hints have the following formats:

  – One skew value in one column: **skew(t (c1) (v1))**

    Description: The **v1** value in the **c1** column of the **t** table relationship causes skew in query execution.

  – Multiple skew values in one column: **skew(t (c1) (v1 v2 v3 ...))**

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Description: Values including **v1, v2**, and **v3** in the **c1** column of the **t** table relationship cause skew in query execution.

- Multiple columns, each having one skew value: **skew(t (c1 c2) (v1 v2))**

  Description: The **v1** value in the **c1** column and the **v2** value in the **c2** column of the **t** table relationship cause skew in query execution.

- Multiple columns, each having multiple skew values: **skew(t (c1 c2) ((v1 v2) (v3 v4) (v5 v6) ...))**

  Description: Values including **v1**, **v3**, and **v5** in the **c1** column and values including **v2**, **v4**, and **v6** in the **c2** column of the **t** table relationship cause skew in query execution.

NOTICE

In the last format, parentheses for skew value groups can be omitted, for example, **skew(t (c1 c2) (v1 v2 v3 v4 v5 v6 ...))**. In a skew hint, either use parentheses for all skew value groups or for none of them.

Otherwise, a syntax error will be generated. For example, **skew(t (c1 c2) (v1 v2 v3 v4 (v5 v6) ...))** will generate an error.

- Specify intermediate result skew.

  If data skew does not occur in base tables but in an intermediate result during query execution, specify skew hints of the intermediate result to solve the skew. skew((t1 t2) (c1) (v1))

  Description: Data skew occurs after the table relationships **t1** and **t2** are joined. The **c1** column of the **t1** table contains skew data and its skew value is **v1**.

  c1 can exist only in a table relationship of **join_rel**. If there is another column having the same name, use aliases to avoid ambiguity.

Suggestion

- For a multi-level query, write the hint on the layer where data skew occurs.
- For a listed subquery, you can specify the subquery name in a hint. If you know data skew occurs on which base table, directly specify the table.
- Aliases are preferred when you specify a table or column in a hint.

6.10.11 Parameterized Path Hint

Description

Specifies the parameterized path and the conditional predicate pushdown method.

Syntax

```
predpush( [@queryblock] src1 src2)
predpush( [@queryblock] src, dest)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **src**, **src1**, and **src2** indicate the set of candidates tables pushed down by **predpush**.
- **dest** indicates the specified destination table pushed down by **predpush**.
- If **predpush** does not contain commas (,), all tables are candidates table. If **predpush** contains commas (,), both candidates tables and destination tables are specified.

NOTE

Use the **predpush** hint to move the filter expression as close to the data source as possible to optimize the query.

- Before using the **predpush** hint, ensure that the **rewrite_rule** GUC parameter contains the **PREDPUSH|REDPUSHFORCE|PREDPUSHNORMAL** option.
- **subquery_block** can also be a view or materialized view.

Examples

Use the **predpush** hint to improve the statement execution efficiency. The following is an example:

```
CREATE TABLE pt2(a int, b int);
CREATE TABLE pt3(a int, b int);
CREATE TABLE pt4(a int, b int);
CREATE INDEX t4_a_idx on pt4(a);
CREATE INDEX t3_a_idx on pt3(a, b);
CREATE INDEX t2_a_idx on pt2(a);
SET rewrite_rule='predpushforce';
SET enable_fast_query_shipping = off;
SET explain_perf_mode=pretty;
gaussdb=# EXPLAIN (costs off) SELECT /*+PREDPUSH(pt2 st3) */ *
FROM pt2,
    (SELECT /*+ indexscan(pt3) indexscan(pt4)  */sum(pt3.b), pt3.a FROM pt3, pt4 where pt3.a = pt4.a
GROUP BY pt3.a) st3
WHERE st3.a = pt2.a;
 id |                      operation
----+-----------------------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  Nested Loop (3,4)
  3 |       ->  Seq Scan on pt2
  4 |       ->  HashAggregate
  5 |          ->  Nested Loop (6,7)
  6 |             ->  Index Only Scan using t3_a_idx on pt3
  7 |             ->  Index Only Scan using t4_a_idx on pt4
(7 rows)
 Predicate Information (identified by plan id)
-----------------------------------------------
   6 --Index Only Scan using t3_a_idx on pt3
         Index Cond: (a = pt2.a)
   7 --Index Only Scan using t4_a_idx on pt4
         Index Cond: (a = pt2.a)
(4 rows)
```

If the **predpush** hint is not used, pt3 and pt4 in the subquery are not processed outside the query block before being joined. As a result, the returned result set is large, causing performance waste.

However, as shown in the preceding plan, after the **predpush** hint is used, condition filtering is performed on pt3 and pt4 based on pt2 before they are

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

joined. The result set returned after joining is small, which effectively improves the performance.

6.10.12 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can use EXPLAIN to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an EXPLAIN statement are displayed as a warning on the interface. Hint errors in other statements will be recorded in debug1-level logs containing the PLANHINT keyword.

Hint error types are as follows:

- Syntax errors

  An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

  For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

  For example:

  ```
  leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
  ```

  The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.
- Semantic errors
  - An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.
  - An error will be reported if the index specified in a scan hint does not exist.
  - If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.
- Duplicated or conflicted hints

  If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.
  - Hint duplication indicates that a hint is used more than once in the same query. Example: **nestloop(t1 t2) nestloop(t1 t2)**.
  - A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

    For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

Duplicate hints are allowed. However, for duplicate hints, only the first one is used. For other unused hints, an unused hint warning is reported. Take **/*+ expand_sublink expand_sublink */** as an example, database uses only the first expand_sublink hint. Therefore, the unused hint warning is still displayed.

- A hint becomes invalid after a sublink is pulled up.

  In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.

- Unsupported column types
  - Skew hints are specified to optimize redistribution. They will be invalid if their corresponding columns do not support redistribution.

- Hints are not used.
  - If a **hashjoin** or **mergejoin** hint is specified for non-equivalent joins, it will not be used.
  - If an **indexscan**, **index** or **indexonlyscan** hint is specified for a table that does not have an index, it will not be used.
  - The GSI hint is used for tables that do not contain GSIs or GSI table hints.
  - If an IndexScan, Index, IndexOnlyScan or GSI hint is specified for a full-table scan, it will not be used. Generally, index paths are generated only when filter conditions are used on index columns. Indexes are not used during a full table scan.
  - The specified IndexOnlyScan hint is used only when the output column contains only indexes.
  - The GSI hint is used only when queries can be pushed down to GSIs.
  - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
  - When a stream plan is generated, if the distribution key of the table is the same as that of the **join** column, the redistribute plan is not generated. If they are different and the distribution key of another table is the same as that of the **join** column, only the redistribute plan can be generated, and the broadcast plan cannot be generated. If the corresponding hint is specified, the plan will not be used.
  - If no sublink is pulled up, the specified **blockname** hint will not be used.
  - Skew hints are not used possibly because:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- The plan does not require redistribution.
- The columns specified by hints contain distribution keys.
- Skew information specified in hints is incorrect or incomplete, for example, no value is specified for join optimization.
- Skew optimization is disabled by GUC parameters.

6.10.13 Plan Hint Cases

NOTE

The table creation statements and complete test set of TPC-DS can be downloaded from the TPC official website. The table creation statements are stored in the **tools** directory.

This section takes the statements in TPC-DS (Q24) decision support benchmark as an example to describe how to optimize an execution plan by using hints in an environment with 1000 datasets and 24 DNs. For example:

```
gaussdb=# explain analyze select avg(netpaid) from
(select c_last_name
,c_first_name
,s_store_name
,ca_state
,s_state
,i_color
,i_current_price
,i_manager_id
,i_units
,i_size
,sum(ss_sales_price) netpaid
from store_sales
,store_returns
,store
,item
,customer
,customer_address
where ss_ticket_number = sr_ticket_number
and ss_item_sk = sr_item_sk
and ss_customer_sk = c_customer_sk
and ss_item_sk = i_item_sk
and ss_store_sk = s_store_sk
and c_birth_country = upper(ca_country)
and s_zip = ca_zip
and s_market_id=7
group by c_last_name
,c_first_name
,s_store_name
,ca_state
,s_state
,i_color
,i_current_price
,i_manager_id
,i_units
,i_size);
```

1. The original plan of this statement is as follows and the statement execution takes 110s.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 id |                                   operation                                    |        A-time         |  A-rows   |  E-rows

 18 |                                        ->  Vector Partition Iterator           | [296.805,319.014]     |    287999764 |    287999764 |
 19 |                                           ->  Partitioned CStore Scan on public.store_returns | [292.938,314.787]     |    287999764 |    287999764 |
 20 |                                  ->  CStore Scan on public.customer            | [114.358,144.462]     |     12000000 |     12000000 |
 21 |                               ->  CStore Scan on public.customer_address       | [38.426,56.753]       |      6000000 |      6000000 |
 22 |                      ->  CStore Scan on public.item                            | [3.160,5.026]         |       300000 |       300000 |
(22 rows)
```

In this plan, the performance of the layer-10 **broadcast** is poor because the estimation result generated at layer 11 is 2140 rows, much less than the actual number of rows. The inaccurate estimation is mainly caused by the underestimated number of rows in layer-13 hash join. In this layer, **store_sales** and **store_returns** are joined (based on the **ss_ticket_number** and **ss_item_sk** columns in **store_sales** and the **sr_ticket_number** and **sr_item_sk** columns in **store_returns**) but the multi-column correlation is not considered.

2. After the **rows** hint is used for optimization, the plan is as follows and the statement execution takes 318s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns * 11270)*/ c_last_name ...
```

```
 id |                                   operation                                    |        A-time         |  A-rows   |  E-rows
----+--------------------------------------------------------------------------------+-----------------------+-----------+-----------+
  1 | ->  Row Adapter                                                                | 318585.246            |         1 |         1 |
  2 |    ->  Vector Aggregate                                                        | 318585.232            |         1 |         1 |

```

The execution takes a longer time because layer-9 **redistribute** is slow. Considering that data skew does not occur at layer-9 **redistribute**, the slow redistribution is caused by the slow layer-8 **hashjoin** due to data skew at layer-18 **redistribute**.

3. Data skew occurs because **customer_address** has a few different values in its two join keys. Therefore, plan **customer_address** as the last one to be joined. After the hint is used for optimization, the plan is as follows and the statement execution takes 116s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((store_sales store_returns store item customer) customer_address)*/
c_last_name ...
```

```

Most of the time is spent on layer-6 **redistribute**. The plan needs to be further optimized.

4. Most of the time is spent on **redistribute** at the last layer because of data skew. To avoid the data skew, plan the **item** table as the last one to be joined because the number of rows is not reduced after **item** is joined. After the hint is used for optimization, the plan is as follows and the statement execution takes 120s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((customer_address (store_sales store_returns store customer) item))
c_last_name ...
```

```

(23 rows)
```

Data skew occurs after the join of **item** and **customer_address** because **item** is broadcast at layer-22. As a result, **redistribute** is still slow.

5. Add a hint to disable **broadcast** for **item** or add a **redistribute** hint for the join result of **item** and **customer_address**. After the hint is used for optimization, the plan is as follows and the statement execution takes 105s:

```
select avg(netpaid) from
(select /*+rows(store_sales store_returns *11270)
leading((customer_address (store_sales store_returns store customer) item))
no broadcast(item)*/
c_last_name ...
```

6. The last layer uses single-layer **Agg** and the number of rows is greatly reduced. Set **best_agg_plan** to **3** and change the single-layer **Agg** to a double-layer **Agg**. The plan is as follows and the statement execution takes 94s. The optimization ends.

```

If the query performance deteriorates due to statistics changes, you can use hints to optimize the query plan. Take TPCH-Q17 as an example. The query performance deteriorates after the value of **default_statistics_target** is changed from the default one to **–2** for statistics collection.

```
gaussdb=# explain analyze select sum(l_extendedprice) / 7.0 as avg_yearly
from lineitem, part
where p_partkey = l_partkey
and p_brand = 'Brand#23'
and p_container = 'MED BOX'
and l_quantity < (
    select 0.2 * avg(l_quantity)
    from lineitem
    where l_partkey = p_partkey
);
```

1. If **default_statistics_target** is set to the default value **100**, the plan is as follows.

(24 rows)
```

3. After comparison, it is found that the deterioration is caused by the change of the stream type from **Broadcast** to **Redistribute** when the **lineitem** and **part** tables are joined and the **part** table is scanned. You can use a hint to change the stream type back to the previous one. The following is an example.

```
select /*+ no redistribute(part lineitem) */
    sum(l_extendedprice) / 7.0 as avg_yearly
from
    lineitem,
    part
where
    p_partkey = l_partkey
    and p_brand = 'Brand#23'
    and p_container = 'MED BOX'
    and l_quantity < (
        select
            0.2 * avg(l_quantity)
        from
            lineitem
        where
            l_partkey = p_partkey
    );
```

After the optimization, the plan is as follows.

6.10.14 GUC Parameter Hints

Description

Sets GUC parameters related to query optimization. The settings take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

Syntax

```
set( [@queryblock] param value)
```

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. This hint takes effect only when it specifies the outermost queryblock.
- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using hints:
  - Boolean type

    enable_bitmapscan, enable_hashagg, enable_hashjoin, enable_indexscan, enable_indexonlyscan, enable_gsiscan, enable_gsitablescan, enable_material, enable_mergejoin, enable_nestloop, enable_index_nestloop, enable_seqscan, enable_sort, enable_tidscan, enable_stream_operator, enable_stream_recursive, enable_broadcast, enable_fast_query_shipping, enable_trigger_shipping, enable_remotejoin, enable_remotegroup, enable_remotelimit, enable_remotesort, enable_inner_unique_opt, and enable_invisible_indexes
  - Integer type

    best_agg_plan, query_dop, join_collapse_limit, and from_collapse_limit
  - Floating point type

    cost_weight_index, default_limit_rows, seq_page_cost, random_page_cost, cpu_tuple_cost, cpu_index_tuple_cost, cpu_operator_cost, and effective_cache_size

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - Enumerated type

    try_vector_engine_strategy

  - Character string type

    node_name

    By setting **node_name**, you can deliver the current SQL statement to the DN corresponding to **node_name** for execution.

    Example:

    ```
    select /*+ set(node_name datanode1) */ from table_name;
    ```

    datanode1 indicates the name of the DN queried from the pgxc_node system catalog (without quotation marks), and **table_name** indicates the table name. This query is directly performed on **datanode1**.

    NOTICE

    - **node_name** can be set only by using the SELECT statement. If it is set by using other statements, it does not take effect.
    - **node_name** can only be set to the name of a DN and cannot be set to the name of a CN.
    - **node_name** cannot be modified by using the SET statement and can only be used in plan hints.
    - **node_name** cannot be modified by using **gs_guc**.
    - **node_name** supports only simple query statements and does not support complex query statements (such as UNION and UNION ALL), subqueries, and multi-table joins.
    - This operation can be performed by common users.
    - This operation cannot be performed together with row-level security. If they are performed together, an error will be reported.

NOTE

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- In the CREATE TABLE ... AS ... statement, the outermost GUC parameter hint takes effect.

6.10.15 Hints for Selecting the Custom Plan or Generic Plan

Description

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and parameters. You can use the hint of **use_cplan** or **use_gplan** to specify the plan to execute.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

- To select the custom plan, run the following statement:
  ```
  use_cplan
  ```
- To select the generic plan, run the following statement:
  ```
  use_gplan
  ```

  NOTE

  - For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
  - This hint has a higher priority than cost-based selection and the **plan_cache_mode** parameter. That is, this hint does not take effect for statements where **plan_cache_mode** cannot forcibly select an execution mode.

Examples

Forcibly use the custom plan:

```
set enable_fast_query_shipping = off;
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the actual value of the input parameter, that is, the plan is a custom plan.

```
                            QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=12)
   Node/s: datanode1
   ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=12)
         Filter: (a = 1)
(4 rows)
```

Forcibly use the generic plan:

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the input parameter to be added. That is, the plan is a generic plan.

```
                            QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.26 rows=1 width=12)
   Node/s: All datanodes
   ->  Seq Scan on t  (cost=0.00..13.16 rows=1 width=12)
         Filter: (a = $1)
(4 rows)
```

6.10.16 Hints Specifying Not to Expand Subqueries

Description

When the database optimizes the query logic, some subqueries can be pulled up to the upper layer to avoid nested execution. However, for some subqueries that have a low selectivity and can use indexes to filter pages, nested execution does

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

not cause too much performance deterioration, while after the pull-up, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the no_expand hint for debugging. This hint is not recommended in most cases.

Syntax

```
no_expand[(@queryblock)]
```

Parameters

For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, **no_expand** does not have parentheses (()).

Example

Normal query execution:

```
explain select * from t1 where t1.c1 in (select t2.c1 from t2);
```

Plan

```
                                QUERY PLAN
--------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=16.98..34.28 rows=40 width=12)
   Node/s: All datanodes
   ->  Hash Semi Join  (cost=16.36..32.72 rows=40 width=12)
         Hash Cond: (t1.c1 = t2.c1)
         ->  Seq Scan on t1  (cost=0.00..16.16 rows=40 width=12)
         ->  Hash  (cost=16.16..16.16 rows=40 width=4)
               ->  Seq Scan on t2  (cost=0.00..16.16 rows=40 width=4)
(7 rows)
```

After **no_expand** is added:

```
explain select * from t1 where t1.c1 in (select /*+ no_expand*/ t2.c1 from t2);
```

Plan

```
                                QUERY PLAN
--------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=17.38..34.33 rows=20 width=12)
   Node/s: All datanodes
   ->  Seq Scan on t1  (cost=16.88..33.08 rows=20 width=12)
         Filter: (hashed SubPlan 1)
         SubPlan 1
           ->  Materialize  (cost=0.00..16.48 rows=640 width=4)
                 ->  Streaming(type: BROADCAST)  (cost=0.00..16.29 rows=160 width=4)
                       Spawn on: All datanodes
                       ->  Seq Scan on t2  (cost=0.00..16.16 rows=40 width=4)
(9 rows)
```

6.10.17 Hints Specifying Not to Use Global Plan Cache

Function

When global plan cache is enabled, you can use the no_gpc hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Syntax

```
no_gpc
```

> NOTE
>
> This parameter takes effect only for statements executed by PBE when **enable_global_plancache** is set to **on**.

Example

```
gaussdb=#  deallocate all;
DEALLOCATE ALL
gaussdb=#  prepare p1 as insert /*+ no_gpc */ into t1 select c1,c2 from t2 where c1=$1;
PREPARE
gaussdb=#  execute p1(3);
INSERT 0 1
gaussdb=#  select * from dbe_perf.global_plancache_status where schema_name='public' order by 1,2;
 nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id | pkg_id | stmt_id
----------+-------+----------+-------+------------+-------------+------------+---------+--------+---------
(0 rows)
```

No result exists in the **dbe_perf.global_plancache_status** view, that is, no plan is cached globally.

6.10.18 Hints of Parameterized Paths at the Same Level

Description

The predpush_same_level and nestloop_index hints are used to specify the generation of parameterized paths between tables or materialized views at the same level.

For details about cross-layer parameterized path hints, see **Parameterized Path Hint**.

Syntax

```
predpush_same_level([@queryblock] src, dest)
predpush_same_level([@queryblock] src1 src2 ..., dest)
[no] nestloop_index([@queryblock] dest[, index_list]) -- With indexes
[no] nestloop_index([@queryblock] dest[,(src1 src2 ...)]) -- With tables
```

> NOTE
>
> The **predpush_same_level** parameter takes effect only when the **predpushforce** option in **rewrite_rule** is enabled.
>
> **nestloop_index** has no requirement on **rewrite_rule**.

Parameters

- **no** indicates that the parameterized path of hints is not used.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **dest** is the target table of the parameterized path, that is, the table where the indexes are located.
- **src** is the parameter table of the parameterized path.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **index_list** is the index sequence used by the parameterized path, which consists of character strings separated by spaces.

Examples

To view the following plan example, you need to set the following parameters:

```
set enable_fast_query_shipping = off;
set enable_stream_operator = on;
```

1. Examples of nestloop_index:

- Transfer **t2.c1** and **t3.c2** of **t2** and **t3** to the **t1** table for index scanning (parameterized path).

```
gaussdb=# explain (costs off) select /*+nestloop_index(t1,(t2 t3)) */* from t1,t2,t3 where t1.c1 = t2.c1
and t1.c2 = t3.c2;
                        QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Streaming(type: BROADCAST)
               Spawn on: All datanodes
               ->  Seq Scan on t3
         ->  Nested Loop
               ->  Seq Scan on t2
               ->  Index Scan using it1 on t1
                     Index Cond: ((c1 = t2.c1) AND (c2 = t3.c2))
(10 rows)
```

- Perform an index scan on **it1** of the **t1** table (parameterized path).

```
gaussdb=# explain (costs off) select /*+NestLoop_Index(t1,it1) */* from t1,t2 where t1.c1 = t2.c1;
              QUERY PLAN
---------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Seq Scan on t2
         ->  Index Scan using it1 on t1
               Index Cond: (c1 = t2.c1)
(6 rows)
```

2. Examples of predpush_same_level:

- Prepare parameters.

```
gaussdb=# set rewrite_rule = 'predpushforce';
SET
gaussdb=# set enable_fast_query_shipping=off;
SET
```

- View the plan.

```
gaussdb=# explain select * from t1, t2 where t1.c1 = t2.c1;
                            QUERY PLAN
------------------------------------------------------------------------------

 Streaming (type: GATHER)  (cost=16.98..34.22 rows=40 width=24)
   Node/s: All datanodes
   ->  Hash Join  (cost=16.36..32.66 rows=40 width=24)
         Hash Cond: (t1.c1 = t2.c1)
         ->  Seq Scan on t1  (cost=0.00..16.16 rows=40 width=12)
         ->  Hash  (cost=16.16..16.16 rows=40 width=12)
               ->  Seq Scan on t2  (cost=0.00..16.16 rows=40 width=12)

(7 rows)
```

- The filter condition **t1.c1 = t2.c2** is displayed on **Join**. In this case, **predpush_same_level(t1, t2)** can be used to push the condition down to the scan operator of **t2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.c1 = t2.c1;
                              QUERY PLAN
------------------------------------------------------------------------------

 Streaming (type: GATHER)  (cost=0.62..70.20 rows=40 width=24)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..68.64 rows=40 width=24)
         ->  Seq Scan on t1  (cost=0.00..16.16 rows=40 width=12)
         ->  Index Scan using it2 on t2  (cost=0.00..3.27 rows=1 width=12)
               Index Cond: (c1 = t1.c1)

(6 rows)
```

NOTICE

- You can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.
- If a stream operator exists on the **dest** scanning operator, this hint does not take effect.

6.10.19 Hints for Setting Slow SQL Control Rules

Description

Users can set the execution time, maximum execution time, and maximum IOPS for SQL statements marked as slow SQL statements.

Syntax

```
wlmrule("time_limit,max_execute_time,max_iops")
```

NOTE

This parameter is valid only for SELECT statements executed by non-sysadmin or non-monitoradmin users when **enable_thread_pool** is set to **on**.

- **time_limit**: execution time of an SQL statement marked as a slow statement. The value ranges from **0** to *INT_MAX*. This parameter takes effect on both CNs and DNs.
- **max_execute_time**: maximum execution time of an SQL statement. If the execution time exceeds the value of this parameter, the SQL statement is forcibly canceled and exits. The value ranges from **0** to *INT_MAX*. This parameter takes effect only on DNs. If the value of **max_execute_time** is less than or equal to the value of **time_limit**, the rule does not take effect.
- **max_iops**: maximum IOPS of an SQL statement marked as a slow SQL statement. This parameter is valid only when **use_workload_manager** is set to **on**. The IOPS limit applies logical I/O control. For details about the definition of IOPS, see the definition of **io_control_unit**. The value can be **Low**, **Medium**, **High**, **None**, or **0** to *INT_MAX*. This parameter takes effect only on DNs.

Examples

```
select /*+ wlmrule("100,500,1") */ * from t2 order by b limit 1;
```

It indicates that the execution time of the current statement marked as a slow SQL statement is 100 ms, the maximum execution time is 500 ms, and the maximum IOPS is 1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.10.20 Bitmap Scan Hints

Description

These hints generate a bitmap scan path by using the specified index on the target table. The path that meets the hint requirement is selected from the paths that can be generated by the optimizer.

Syntax

```
[no] bitmapscan([@queryblock] table [index_list])
```

Parameters

- **no** indicates that the scan of hints is not used.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** indicates the target table of the bitmap scan.
- **index_list** indicates the index used by the bitmap scan.

Example

```
gaussdb=# explain(costs off)  select /*+ BitmapScan(t1 it1 it3)*/* from t1 where  (t1.c1 = 5 or t1.c2=6) or (t1.c3=3 or t1.c2=7);
                          QUERY PLAN
---------------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Bitmap Heap Scan on t1
         Recheck Cond: ((c1 = 5) OR (c2 = 6) OR (c3 = 3) OR (c2 = 7))
         ->  BitmapOr
               ->  Bitmap Index Scan on it1
                     Index Cond: (c1 = 5)
               ->  Bitmap Index Scan on it3
                     Index Cond: (c2 = 6)
               ->  Bitmap Index Scan on it3
                     Index Cond: (c3 = 3)
               ->  Bitmap Index Scan on it3
                     Index Cond: (c2 = 7)
(13 rows)
```

NOTE

The path that meets the bitmap scan hint is selected from the existing index paths. Because the index path construction space is large and the optimizer prunes the paths, if any index path is not generated, the path cannot be constructed.

6.10.21 Hint for Inner Table Materialization During Join

Description

These hints materialize inner tables when specifying the inner tables to be joined.

Syntax

```
[no] materialize_inner([@queryblock] inner_table_list)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters

- **no** indicates that the materialization of hints is not used.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **inner_table_list**: a list of inner tables to be materialized during the join operation. The value is a character string separated by spaces.

Example

Table **t1** is an inner table to be materialized, and the result of (t1 t2) is materialized as a joined inner table.

```
gaussdb=# explain (costs off) select /*+materialize_inner(t1) materialize_inner(t1 t2)*/ * from t1,t2,t3
where  t1.c3 = t2.c3 and t2.c2=t3.c2 and t1.c2=5;
                          QUERY PLAN
------------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
        Join Filter: (t2.c2 = t3.c2)
        ->  Seq Scan on t3
        ->  Materialize
             ->  Streaming(type: BROADCAST)
                  Spawn on: All datanodes
                  ->  Nested Loop
                       Join Filter: (t1.c3 = t2.c3)
                       ->  Seq Scan on t2
                       ->  Materialize
                            ->  Streaming(type: BROADCAST)
                                 Spawn on: All datanodes
                                 ->  Index Scan using it3 on t1
                                      Index Cond: (c2 = 5)
(16 rows)
```

6.10.22 AGG Hint

Description

You can specify the AGG method when performing the AGG algorithm.

Syntax

```
use_hash_agg[(@queryblock)], use_sort_agg[(@queryblock)]
```

Parameters

For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, the hint does not have parentheses (()).

Example

1. Use hash aggregation.

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_hash_agg */ t1.c1 from
t1,t3 where t1.c1=t3.c1 group by 1);
                    QUERY PLAN
-----------------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Join
         Hash Cond: (t2.c1 = t1.c1)
         ->  Seq Scan on t2
         ->  Hash
               ->  HashAggregate
                     Group By Key: t1.c1
                     ->  Hash Join
                           Hash Cond: (t1.c1 = t3.c1)
                           ->  Seq Scan on t1
                           ->  Hash
                                 ->  Seq Scan on t3
(13 rows)
```

2. Use use_sort_agg for aggregation and then perform merge join.

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_sort_agg */ t1.c1 from t1,t3
where t1.c1=t3.c1 group by 1);
                      QUERY PLAN
------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Join
         Hash Cond: (t2.c1 = t1.c1)
         ->  Seq Scan on t2
         ->  Hash
               ->  Group
                     Group By Key: t1.c1
                     ->  Sort
                           Sort Key: t1.c1
                           ->  Hash Join
                                 Hash Cond: (t1.c1 = t3.c1)
                                 ->  Seq Scan on t1
                                 ->  Hash
                                       ->  Seq Scan on t3
(15 rows)
```

6.10.23 Query Rewriting Hints

Description

The optimizer supports a series of query rewriting rules and can perform equivalent logical rewriting on SQL statements to generate a better execution plan. If you do not want to perform SQL statement rewriting or the optimizer rewriting results in plan changes, you need to use hints to control the rewriting rules so that the optimizer performs rewriting in the way you want. Currently, the database supports hint control for SQL statements in various scenarios, such as ANY/EXISTS sublinks, simple subqueries, ORDER BY removal, HAVING clause pushdown, and delayed aggregation. For details, see **Hint Usage Description**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

- Some query rewriting rules are controlled by both query rewriting hints and GUC parameters. Generally, query rewriting hints have a higher priority than GUC parameters. Rewriting rules controlled by GUC parameters are described in **Hint Usage Description**.
- Each query rewriting rule is controlled by a pair of mutually exclusive hints, for example: The subquery expansion rule is controlled by both EXPAND_SUBQUERY and NO_EXPAND_SUBQUERY. The EXPAND_SUBQUERY hint indicates that the rule can be used to rewrite SQL statements, and NO_EXPAND_SUBQUERY indicates that the rule cannot be used to rewrite SQL statements. If two mutually exclusive hints exist in the same query block, the first obtained hint prevails. For example, if **/*+ EXPAND_SUBQUERY NO_EXPAND_SUBQUERY */** is obtained, the EXPAND_SUBQUERY hint takes effect.
- Duplicate hints are allowed. However, for duplicate hints, only the first one is used. For other unused hints, an unused hint warning is reported. Take **/*+ EXPAND_SUBLINK EXPAND_SUBLINK */** as an example, database uses only the first EXPAND_SUBLINK hint. Therefore, the unused hint warning is still displayed.

Syntax

```
hintname[(@queryblock)]
```

Parameters

- **hintname**: name of the hint that controls the query rewriting rule. For details about the supported query rewriting hints, see **Table 6-7**.
- For details about **@queryblock**, see **Hint for Specifying the Query Block Where the Hint Is Located**. This parameter can be omitted, indicating that it takes effect in the current query block. If it is not specified, the hint does not have parentheses (()).

Query Rewriting Hint List

Table 6-7 Query rewriting hints

No.	Hint Name	Description
1	EXPAND_SUBLINK_HAVING	Sublinks in the HAVING clause can be pulled up.
2	NO_EXPAND_SUBLINK_HAVING	Sublinks in the HAVING clause cannot be pulled up.
3	EXPAND_SUBLINK	Sublinks of the ANY/EXISTS type can be pulled up.
4	NO_EXPAND_SUBLINK	Sublinks of the ANY/EXISTS type cannot be pulled up.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Hint Name	Description
5	EXPAND_SUBLINK_TARGET	Sublinks in the TargetList can be pulled up.
6	NO_EXPAND_SUBLINK_TARGET	Sublinks in the TargetList cannot be pulled up.
7	USE_MAGIC_SET	When conditions are pushed down from the main query to the subquery, the join columns of the subquery are grouped and aggregated, and then the subquery is joined with the main query. This reduces repeated scanning of related sublinks and improves query efficiency.
8	NO_USE_MAGIC_SET	Conditions cannot be pushed down from the main query to the subquery. The subquery with an aggregate operator is joined with the main query in advance.
9	EXPAND_SUBLINK_UNIQUE_CHECK	Sublinks without aggregation can be pulled up on the premise that only one line is displayed for each condition.
10	NO_EXPAND_SUBLINK_UNIQUE_CHECK	Sublinks without aggregation cannot be pulled up.
11	NO_SUBLINK_DISABLE_REPLICATED	Expression sublinks can be pulled up in the fast query shipping plan or stream scenario with a replication table.
12	SUBLINK_DISABLE_REPLICATED	Expression sublinks cannot be pulled up in the fast query shipping plan or stream scenario with a replication table.
13	NO_SUBLINK_DISABLE_EXPR	Expressions in sublinks can be pulled up.
14	SUBLINK_DISABLE_EXPR	Expressions in sublinks cannot be pulled up.
15	ENABLE_SUBLINK_ENHANCED	Pulling up sublinks can be enhanced. Related or non-related sublinks such as OR expressions can be pulled up.
16	NO_ENABLE_SUBLINK_ENHANCED	Pulling up sublinks cannot be enhanced. Related or non-related sublinks such as OR expressions cannot be pulled up.
17	PARTIAL_PUSH	In the stream scenario, the gather operator can be added to listagg and arrayagg.
18	NO_PARTIAL_PUSH	In the stream scenario, the gather operator cannot be added to listagg and arrayagg.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Hint Name	Description
19	REDUCE_ORDER_BY	Redundant ORDER BY can be reduced. If the outer query does not have sorting requirements on the inner query result, unnecessary ORDER BY can be reduced to improve the query efficiency.
20	NO_REDUCE_ORDER_BY	Unnecessary ORDER BY cannot be reduced.
21	REMOVE_NOT_NULL	The unnecessary NOT NULL condition can be deleted. When the column attribute is **NOT NULL**, the IS NOT NULL judgment in the query condition can be deleted.
22	NO_REMOVE_NOT_NULL	The IS NOT NULL conditions cannot be deleted.
23	LAZY_AGG	The subquery and outer query have the same GROUP BY condition. The two-layer aggregation operation may cause low query efficiency. The aggregation operation in the subquery can be eliminated to improve query efficiency.
24	NO_LAZY_AGG	The aggregation operation rules in the subquery cannot be eliminated.
25	EXPAND_SUBQUERY	The subquery is pulled up and joined with the upper layer to optimize the query efficiency.
26	NO_EXPAND_SUBQUERY	The subquery cannot be pulled up.
27	PUSHDOWN_HAVING	The HAVING condition expression can be pushed down.
28	NO_PUSHDOWN_HAVING	The HAVING expression cannot be pushed down.
29	INLIST_TO_JOIN	The inlist-to-join can be used to rewrite SQL statements.
30	NO_INLIST_TO_JOIN	The inlist-to-join cannot be used to rewrite SQL statements.
31	ROWNUM_PUSHDOWN	Row numbers can be pushed down.
32	NO_ROWNUM_PUSHDOWN	Row numbers cannot be pushed down.
33	WINDOWAGG_PUSHDOWN	The filter criterion of the window function in the parent query can be pushed down to the subquery.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

No.	Hint Name	Description
34	NO_WINDOWAGG_PUSHDOWN	The filter criterion of the window function in the parent query cannot be pushed down to the subquery.
35	CSE_REWRITE_OPT	The common subexpression (CSE) can be used to rewrite a HAVING clause with a common subquery as a window aggregate function.
36	NO_CSE_REWRITE_OPT	The CSE cannot be used to rewrite a HAVING clause with a common subquery as a window aggregate function.
37	GROUPBY_PUSHDOWN_SUBQUERY	The GROUP BY aggregate function can be pushed down to a subquery using **groupby-pushdown-subquery**.
38	NO_GROUPBY_PUSHDOWN_SUBQUERY	The GROUP BY aggregate function cannot be pushed down to a subquery using **groupby-pushdown-subquery**.

Preparations for Using Hints

To help you understand the application scenarios of hints, this document provides all application examples of query rewriting hints. For details, see **Hint Usage Description**. The table creation statements and environment preparation are as follows:

- Session settings:

```
SET client_encoding = 'UTF8';
CREATE SCHEMA rewrite_rule_test;
SET current_schema = rewrite_rule_test;
SET enable_codegen= off;
```

- Table creation statements:

```
CREATE TABLE rewrite_rule_hint_t1 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t2 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t3 (a INT, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t4 (a INT NOT NULL, b INT, c INT, d INT);
CREATE TABLE rewrite_rule_hint_t5 (slot INTEGER NOT NULL,cid BIGINT NOT NULL,name
CHARACTER VARYING NOT NULL) WITH (ORIENTATION = row);
INSERT INTO rewrite_rule_hint_t5 (slot, cid, name) values(generate_series(1, 10),generate_series(1,
10),'records.storage.state');
ANALYZE rewrite_rule_hint_t5;
CREATE TABLE rewrite_rule_hint_customer (
    c_custkey INTEGER NOT NULL,
    c_name CHARACTER VARYING(25) NOT NULL,
    c_address CHARACTER VARYING(40) NOT NULL,
    c_nationkey INTEGER NOT NULL,
    c_phone CHARACTER(15) NOT NULL,
    c_acctbal NUMERIC(15, 2) NOT NULL,
    c_mktsegment CHARACTER(10) NOT NULL,
    c_comment CHARACTER VARYING(117) NOT NULL
);
CREATE TABLE rewrite_rule_hint_orders (
    o_orderkey INTEGER NOT NULL,
    o_custkey INTEGER NOT NULL,
    o_orderstatus CHARACTER(1) NOT NULL,
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    o_totalprice NUMERIC(15, 2) NOT NULL,
    o_orderdate DATE NOT NULL,
    o_orderpriority CHARACTER(15) NOT NULL,
    o_clerk CHARACTER(15) NOT NULL,
    o_shippriority INTEGER NOT NULL,
    o_comment CHARACTER VARYING(79) NOT NULL
);
```

Hint Usage Description

1. EXPAND_SUBLINK_HAVING

   Sublinks in the HAVING clause can be pulled up. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **enable_sublink_pullup_enhanced**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_EXPAND_SUBLINK_HAVING are mutually exclusive.

   ```
   gaussdb=# EXPLAIN(costs off)SELECT /*+EXPAND_SUBLINK_HAVING*/ a,sum(b) AS value FROM
   rewrite_rule_hint_t1 GROUP BY a HAVING sum(a) >= (SELECT avg(b) FROM rewrite_rule_hint_t1)
   ORDER BY value DESC;
                                       QUERY PLAN
   ------------------------------------------------------------------------------------------------
    Streaming (type: GATHER)
      Merge Sort Key: inner_subquery.value DESC
      Node/s: All datanodes
      InitPlan 1 (returns $0)
        ->  Aggregate
              ->  Streaming(type: BROADCAST)
                    Spawn on: All datanodes
                    ->  Aggregate
                          ->  Seq Scan on rewrite_rule_hint_t1
      ->  Sort
            Sort Key: inner_subquery.value DESC
            ->  Subquery Scan on inner_subquery
                  ->  HashAggregate
                        Group By Key: rewrite_rule_test.rewrite_rule_hint_t1.a
                        Filter: ((sum(rewrite_rule_test.rewrite_rule_hint_t1.a))::numeric >= $0)
                        ->  Seq Scan on rewrite_rule_hint_t1
   (16 rows)
   ```

2. NO_EXPAND_SUBLINK_HAVING

   Sublinks in the HAVING clause cannot be pulled up. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is not **enable_sublink_pullup_enhanced**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and EXPAND_SUBLINK_HAVING are mutually exclusive.

   ```
   gaussdb=# EXPLAIN(costs off)SELECT /*+NO_EXPAND_SUBLINK_HAVING*/ a,sum(b) AS value FROM
   rewrite_rule_hint_t1 GROUP BY a HAVING sum(a) >= (SELECT avg(b) FROM rewrite_rule_hint_t1)
   ORDER BY value DESC;
                                       QUERY PLAN
   ------------------------------------------------------------------------------------------
    Streaming (type: GATHER)
      Merge Sort Key: (sum(rewrite_rule_test.rewrite_rule_hint_t1.b)) DESC
      Node/s: All datanodes
      InitPlan 1 (returns $0)
        ->  Aggregate
              ->  Streaming(type: BROADCAST)

                                         Spawn on: All datanodes
                                         ->  Seq Scan on rewrite_rule_hint_t1
(15 rows)
```

7. USE_MAGIC_SET

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When conditions are pushed down from the main query to the subquery, the join columns of the subquery are grouped and aggregated, and then the subquery is joined with the main query. This reduces repeated scanning of related sublinks and improves query efficiency. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **magicset**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_USE_MAGIC_SET are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off) SELECT rewrite_rule_hint_t1 FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.b = 10 AND rewrite_rule_hint_t1.c < (SELECT /*+USE_MAGIC_SET*/ sum(c) FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a);
                                                                QUERY PLAN
------------------------------------------------------------------------------------------------------------------------------------------------
 Nested Loop
   Join Filter: ((rewrite_rule_test.rewrite_rule_hint_t1.c < (sum(rewrite_rule_hint_t2.c))) AND
(rewrite_rule_test.rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a))
   ->  Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
         Node/s: All datanodes
   ->  HashAggregate
         Group By Key: rewrite_rule_hint_t2.a
         ->  Hash Semi Join
               Hash Cond: (rewrite_rule_hint_t2.a = rewrite_rule_test.rewrite_rule_hint_t1.a)
               ->  Data Node Scan on rewrite_rule_hint_t2 "_REMOTE_TABLE_QUERY_"
                     Node/s: All datanodes
               ->  Hash
                     ->  Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
                           Node/s: All datanodes
(13 rows)
```

8. NO_USE_MAGIC_SET

   Conditions cannot be pushed down from the main query to the subquery. The subquery with an aggregate operator is joined with the main query in advance. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is not **magicset**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and USE_MAGIC_SET are mutually exclusive.

   ```
   gaussdb=# EXPLAIN(costs off) SELECT rewrite_rule_hint_t1 FROM rewrite_rule_hint_t1 WHERE
   rewrite_rule_hint_t1.b = 10 AND rewrite_rule_hint_t1.c < (SELECT /*+NO_USE_MAGIC_SET*/ sum(c)
   FROM rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a);
                              QUERY PLAN
   ------------------------------------------------------------------------------
    Hash Join
      Hash Cond: (rewrite_rule_hint_t2.a = rewrite_rule_hint_t1.a)
      Join Filter: (rewrite_rule_hint_t1.c < (sum(rewrite_rule_hint_t2.c)))
      ->  Data Node Scan on "__REMOTE_GROUP_QUERY__"
            Node/s: All datanodes
      ->  Hash
            ->  Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
                  Node/s: All datanodes
   (8 rows)
   ```

9. EXPAND_SUBLINK_UNIQUE_CHECK

   Sublinks without aggregation can be pulled up if only one line is output for each condition. Sublinks with aggregation can be automatically pulled up. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **uniquecheck**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_EXPAND_SUBLINK_UNIQUE_CHECK are mutually exclusive.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1 WHERE
rewrite_rule_hint_t1.a = (SELECT /*+EXPAND_SUBLINK_UNIQUE_CHECK*/ rewrite_rule_hint_t2.a FROM
rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.b);
                              QUERY PLAN

               ->  Data Node Scan on rewrite_rule_hint_t1 "_REMOTE_TABLE_QUERY_"
                     Node/s: All datanodes
               ->  Hash
                     ->  Subquery Scan on subquery
                           Filter: (subquery."?column?" OPERATOR(pg_catalog.=) 1::bigint)
                           ->  WindowAgg
                                 ->  Sort
                                       Sort Key: rewrite_rule_hint_t2.b, rewrite_rule_hint_t2.c
                                       ->  Data Node Scan on rewrite_rule_hint_t2 "_REMOTE_TABLE_QUERY_"
                                             Node/s: All datanodes
(15 rows)
```

19. REDUCE_ORDER_BY

    Unnecessary ORDER BY can be reduced. If the outer query does not have sorting requirements on the inner query result, unnecessary ORDER BY can be reduced to improve the query efficiency. This hint and NO_REDUCE_ORDER_BY are mutually exclusive.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The rules for the optimization solution to take effect are as follows:

- The optimization solution does not take effect if the main query contains limitoffset, limit, rownum, or window functions, or the subquery contains limitoffset, limit, rownum, or distinct on.
- If the JOIN condition is met, the optimization solution takes effect at the current layer.
- If FROM has only one query table, the current layer takes effect based on whether the upper layer takes effect. If FROM has multiple query tables, the optimization solution takes effect at the current layer.
- If there is an aggregate function and the aggregation conditions do not depend on the result sequence, the optimization solution takes effect at the current layer. If UNION ALL is available in the centralized system, whether the current layer takes effect depends on whether the upper layer takes effect.
- If the current layer is not SELECT, the optimization solution takes effect.
- If no rule takes effect, the optimization solution does not take effect.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+REDUCE_ORDER_BY*/ *
FROM rewrite_rule_hint_t2 ORDER BY a DESC);
                    QUERY PLAN
-----------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Streaming(type: BROADCAST)
               Spawn on: All datanodes
               ->  Seq Scan on rewrite_rule_hint_t1
         ->  Materialize
               ->  Seq Scan on rewrite_rule_hint_t2
(8 rows)
```

20. NO_REDUCE_ORDER_BY

    Unnecessary ORDER BY cannot be reduced. This hint and REDUCE_ORDER_BY are mutually exclusive. The effective rules are the same as those of **19. REDUCE_ORDER_BY**.

```
gaussdb=# EXPLAIN(costs off)SELECT * FROM rewrite_rule_hint_t1,(SELECT /*
+NO_REDUCE_ORDER_BY*/ * FROM rewrite_rule_hint_t2 ORDER BY a DESC);
                      QUERY PLAN
-------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Streaming(type: BROADCAST)
               Spawn on: All datanodes
               ->  Seq Scan on rewrite_rule_hint_t1
         ->  Materialize
               ->  Sort
                     Sort Key: rewrite_rule_hint_t2.a DESC
                     ->  Seq Scan on rewrite_rule_hint_t2
(10 rows)
```

21. REMOVE_NOT_NULL

    Unnecessary IS NOT NULL conditions can be deleted. When the column attribute is **NOT NULL**, the IS NOT NULL judgment in the query condition can be deleted. This scenario is also controlled by the GUC parameter **enable_constraint_optimization**. If the hint of this rule is not used and the value of **enable_constraint_optimization** is **on**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_REMOVE_NOT_NULL are mutually exclusive.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off)SELECT /*+REMOVE_NOT_NULL*/ * FROM rewrite_rule_hint_t4 WHERE b > 10 OR a
IS NOT NULL;
              QUERY PLAN
---------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on rewrite_rule_hint_t4
(3 rows)
```

22. NO_REMOVE_NOT_NULL

    Unnecessary IS NOT NULL conditions cannot be deleted. This scenario is also controlled by the GUC parameter **enable_constraint_optimization**. If the hint of this rule is not used and the value of **enable_constraint_optimization** is **off**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and REMOVE_NOT_NULL are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off)SELECT /*+NO_REMOVE_NOT_NULL*/ * FROM rewrite_rule_hint_t4 WHERE b > 10
OR a IS NOT NULL;
               QUERY PLAN
------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on rewrite_rule_hint_t4
         Filter: ((b > 10) OR (a IS NOT NULL))
(4 rows)
```

23. LAZY_AGG

    The subquery and outer query have the same GROUP BY condition. The two-layer aggregation operation may cause low query efficiency. The aggregation operation in the subquery can be eliminated to improve query efficiency. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **lazyagg**, this rule also takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_LAZY_AGG are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT rewrite_rule_hint_t1.b,sum(cc) FROM (SELECT /*+LAZY_AGG*/
b,sum(c) AS cc FROM rewrite_rule_hint_t2 GROUP BY b) s1,rewrite_rule_hint_t1 WHERE s1.b =
rewrite_rule_hint_t1.b GROUP BY rewrite_rule_hint_t1.b ORDER BY 1,2;
                                QUERY PLAN
-------------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Merge Sort Key: rewrite_rule_hint_t1.b, (sum((rewrite_rule_hint_t2.c)::bigint))
   Node/s: All datanodes
   ->  Sort
         Sort Key: rewrite_rule_hint_t1.b, (sum((rewrite_rule_hint_t2.c)::bigint))
         ->  HashAggregate

                     ->  Hash
                           ->  Subquery Scan on s1
                                 ->  HashAggregate
                                       Group By Key: rewrite_rule_hint_t2.b
                                       ->  Streaming(type: REDISTRIBUTE)
                                             Spawn on: All datanodes
                                             ->  Seq Scan on rewrite_rule_hint_t2
(19 rows)
```

25. EXPAND_SUBQUERY

    The subquery is pulled up and joined with the upper layer to optimize the query efficiency. The hint of this rule and the NO_EXPAND hint are mutually exclusive. When both this hint and NO_EXPAND are used, this hint has a higher priority. This hint and NO_EXPAND_SUBQUERY are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off) SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+EXPAND_SUBQUERY*/ * FROM
rewrite_rule_hint_t2 WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;
                          QUERY PLAN
-----------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Join
         Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
         ->  Seq Scan on rewrite_rule_hint_t1
               Filter: (a > 1)
         ->  Hash
               ->  Seq Scan on rewrite_rule_hint_t2
                     Filter: (a > 1)
(9 rows)
```

26. NO_EXPAND_SUBQUERY

    The subquery cannot be pulled up. This hint is equivalent to the NO_EXPAND hint, but this hint has a higher priority. This hint and EXPAND_SUBQUERY are mutually exclusive.

```
gaussdb=# SET enable_fast_query_shipping=off;
EXPLAIN(costs off) SELECT * FROM rewrite_rule_hint_t1,(SELECT /*+NO_EXPAND_SUBQUERY*/ *
FROM rewrite_rule_hint_t2 WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;
                          QUERY PLAN
-----------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Join
         Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
         ->  Seq Scan on rewrite_rule_hint_t1
         ->  Hash
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            ->  Seq Scan on rewrite_rule_hint_t2
                  Filter: (a > 1)
(8 rows)
```

27. PUSHDOWN_HAVING

    The HAVING condition expression can be pushed down. This hint and NO_PUSHDOWN_HAVING are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+PUSHDOWN_HAVING*/ sum(a),b,c FROM
rewrite_rule_hint_t1 WHERE b > 0 GROUP BY b,c HAVING sum(a) > 100 AND c > 0;
                  QUERY PLAN
------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  HashAggregate
         Group By Key: b, c
         Filter: (sum(a) > 100)
         ->  Streaming(type: REDISTRIBUTE)
               Spawn on: All datanodes
               ->  Seq Scan on rewrite_rule_hint_t1
                     Filter: ((b > 0) AND (c > 0))
(9 rows)
```

28. NO_PUSHDOWN_HAVING

    The HAVING expression cannot be pushed down. This hint and PUSHDOWN_HAVING are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off)SELECT /*+NO_PUSHDOWN_HAVING*/ sum(a),b,c FROM
rewrite_rule_hint_t1 WHERE b > 0 GROUP BY b,c HAVING sum(a) > 100 AND c > 0;
                  QUERY PLAN

         Group By Key: b, c
         Filter: ((sum(a) > 100) AND (c > 0))
         ->  Streaming(type: REDISTRIBUTE)
               Spawn on: All datanodes
               ->  Seq Scan on rewrite_rule_hint_t1
                     Filter: (b > 0)
(9 rows)
```

29. INLIST_TO_JOIN

    The inlist-to-join can be used to rewrite SQL statements. This scenario is also controlled by the GUC parameter **qrw_inlist2join_optmode**. If the hint of this rule is not used and the value of **qrw_inlist2join_optmode** is **rule_base**, this rule takes effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_INLIST_TO_JOIN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off)SELECT * FROM rewrite_rule_hint_t5 WHERE slot = '5' AND (name) IN
(SELECT /*+INLIST_TO_JOIN*/ name FROM rewrite_rule_hint_t5 WHERE slot = '5'AND cid IN

                ->  Limit
                     ->  Streaming(type: BROADCAST)
                          Spawn on: datanode2
                          ->  Limit
                               ->  Hash Right Semi Join
                                    Hash Cond: ("*VALUES*".column1 =
rewrite_rule_test.rewrite_rule_hint_t5.cid)
                                    ->  Values Scan on "*VALUES*"
                                    ->  Hash
                                         ->  Seq Scan on rewrite_rule_hint_t5
                                              Filter: (slot = 5)
(22 rows)
```

NOTE

INLIST_TO_JOIN[(@queryblock threshold)]: supports no parameter or any integer greater than or equal to 0. It is compatible with the value of the GUC parameter **qrw_inlist2join_optmode**. The default value is recommended.

Parameter description:

- **threshold**: specifies the query rewriting threshold. This parameter is optional. For details, see the value range part.

Default value: **1** (Optional. If it is not set, the default value is used.)

Value range:

- **0**: cost_base
- **1**: rule_base
- Any other positive integer: specifies the query rewriting threshold. If the number of elements in the list is greater than the threshold, the inlist2join query rewriting is performed.

30. NO_INLIST_TO_JOIN

The inlist-to-join cannot be used to rewrite SQL statements. This scenario is also controlled by the GUC parameter **qrw_inlist2join_optmode**. If the hint of this rule is not used and the value of **qrw_inlist2join_optmode** is **disable**, this rule does not take effect. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and INLIST_TO_JOIN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off)SELECT * FROM rewrite_rule_hint_t5 WHERE slot = '5' AND (name) IN
(SELECT /*+NO_INLIST_TO_JOIN*/ name FROM rewrite_rule_hint_t5 WHERE slot = '5'AND cid IN
(5,1000,1001,1002,1003,1004,1005,1006,1007,2000,4000,10781986,10880002)LIMIT 50);
                                                
```

31. ROWNUM_PUSHDOWN

    Row numbers can be pushed down. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **disable_rownum_pushdown**, pushdown is allowed. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and NO_ROWNUM_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+ROWNUM_PUSHDOWN*/rownum rn, a
FROM rewrite_rule_hint_t1) WHERE rn BETWEEN 5 AND 10;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Subquery Scan on __unnamed_subquery__
         Filter: ((__unnamed_subquery__.rn >= 5::numeric) AND (__unnamed_subquery__.rn <=
10::numeric))
         ->  Rownum
               StopKey: (ROWNUM <= 10::numeric)
               ->  Streaming(type: BROADCAST)
                     Spawn on: All datanodes
                     ->  Rownum
                           StopKey: (ROWNUM <= 10::numeric)
                           ->  Seq Scan on rewrite_rule_hint_t1
(11 rows)
```

32. NO_ROWNUM_PUSHDOWN

    Row numbers cannot be pushed down. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **disable_rownum_pushdown**, pushdown is not allowed. However, when both the hint and GUC parameter of this rule are used, the hint precedes the GUC parameter. This hint and ROWNUM_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+NO_ROWNUM_PUSHDOWN*/rownum rn,
a FROM rewrite_rule_hint_t1) WHERE rn BETWEEN 5 AND 10;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Subquery Scan on __unnamed_subquery__
         Filter: ((__unnamed_subquery__.rn >= 5::numeric) AND (__unnamed_subquery__.rn <=
10::numeric))
         ->  Rownum
               ->  Streaming(type: BROADCAST)

                     ->  Seq Scan on rewrite_rule_hint_t1
(8 rows)
```

33. WINDOWAGG_PUSHDOWN

    The filter criterion of the window function in the parent query can be pushed down to the subquery. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is not used and the value of **rewrite_rule** is **disable_windowagg_pushdown**, the filter criterion of the window function in the parent query cannot be pushed down to the subquery. If the hint of this rule is used and the value of **rewrite_rule** is **disable_windowagg_pushdown**, the hint precedes the GUC parameter, and the filter criterion of the window function in the parent query can be pushed down to the subquery. This hint and NO_WINDOWAGG_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+WINDOWAGG_PUSHDOWN*/
row_number() over() rid, rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1) WHERE rid BETWEEN 5
AND 10;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
Streaming (type: GATHER)
  Node/s: All datanodes
  ->  Subquery Scan on __unnamed_subquery__
        Filter: (__unnamed_subquery__.rid >= 5)
        ->  WindowAgg
              row_number_filter: (row_number() OVER () <= 10)
              ->  Streaming(type: BROADCAST)

                          ->  Seq Scan on rewrite_rule_hint_t1
(11 rows)
```

34. NO_WINDOWAGG_PUSHDOWN

    The filter criterion of the window function in the parent query cannot be pushed down to the subquery. This scenario is also controlled by the GUC parameter **rewrite_rule**. If the hint of this rule is used or the value of **rewrite_rule** is **disable_windowagg_pushdown**, the filter criterion of the window function in the parent query cannot be pushed down to the subquery. This hint and WINDOWAGG_PUSHDOWN are mutually exclusive.

```
gaussdb=# EXPLAIN (costs off) SELECT * FROM (SELECT /*+NO_WINDOWAGG_PUSHDOWN*/
row_number() over() rid, rewrite_rule_hint_t1.a FROM rewrite_rule_hint_t1) WHERE rid BETWEEN 5
AND 10;
                                        QUERY PLAN
-------------------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Subquery Scan on __unnamed_subquery__
         Filter: ((__unnamed_subquery__.rid >= 5) AND (__unnamed_subquery__.rid <= 10))
         ->  WindowAgg
               ->  Streaming(type: BROADCAST)
                     Spawn on: All datanodes
                     ->  Seq Scan on rewrite_rule_hint_t1
(8 rows)
```

35. CSE_REWRITE_OPT

    The HAVING clause with a common subquery, that is, the query whose number of subquery tables and join mode are the same as those of the parent query, can be promoted to WindowAgg. Currently, only one HAVING clause with a common subquery is supported. This hint and NO_CSE_REWRITE_OPT are mutually exclusive.

```
gaussdb=# EXPLAIN(costs off) SELECT /*+ CSE_REWRITE_OPT */ rewrite_rule_hint_t1.a,
sum(rewrite_rule_hint_t1.c * rewrite_rule_hint_t1.d) AS VALUE FROM
rewrite_rule_hint_t1,rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.b = rewrite_rule_hint_t2.b
GROUP BY rewrite_rule_hint_t1.a HAVING sum(rewrite_rule_hint_t1.c * rewrite_rule_hint_t1.d) >
(SELECT sum(rewrite_rule_hint_t1.c * rewrite_rule_hint_t1.d ) * (0.001 / 500) FROM
rewrite_rule_hint_t1,rewrite_rule_hint_t2 WHERE rewrite_rule_hint_t1.b = rewrite_rule_hint_t2.b)

               Hash Cond: (t3.c = t4.b)
               ->  Hash Join
                     Hash Cond: (t2.b = t1.a)
                     ->  Hash Join
                           Hash Cond: (t3.b = t2.a)
                           ->  Seq Scan on rewrite_rule_hint_t3 t3
                           ->  Hash
                                 ->  Seq Scan on rewrite_rule_hint_t2 t2
                     ->  Hash
                           ->  Seq Scan on rewrite_rule_hint_t1 t1
               ->  Hash
                     ->  Seq Scan on rewrite_rule_hint_t4 t4
                           Filter: (c > 2)
(18 rows)
```

6.10.24 Hints for Specifying ANY Sublink Pullup

Description

A method of optimizing operators is specified when an ANY sublink is pulled up.

Syntax

```
[no] hashed_sublink[(@queryblock)]
```

Parameters

- **no** indicates that the optimization is not used.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block. If it is not specified, the hint does not have parentheses (()).
- **hashed_sublink** uses hash table optimization for specified sublinks.

Examples

Table creation and preparation:

```
set work_mem='64kB';  -- Reduce the work memory to reproduce the scenario.
set explain_perf_mode = pretty;   -- Open the explain pretty option to view a detailed plan.
CREATE TABLE nt1 (a int);
CREATE TABLE nt2 (a int);
INSERT INTO nt1 VALUES(generate_series(1, 50000));
INSERT INTO nt2 VALUES(generate_series(1, 50000));
ANALYZE nt1;
ANALYZE nt2;
```

Example:

```
-- Do not use hashed_sublink hints.
gaussdb=# EXPLAIN SELECT * FROM nt1 WHERE nt1.a NOT IN (SELECT /*+ no_expand*/ a FROM nt2);
 id |               operation               | E-rows  | E-memory | E-width |  E-costs
----+---------------------------------------+---------+----------+---------+------------
  1 | ->  Streaming (type: GATHER)          |   25000 |          |       4 | 5079922.80
  2 |    ->  Seq Scan on nt1                |   25000 | 1MB      |       4 | 5079011.27
  3 |       ->  Materialize  [2, SubPlan 1] | 1800000 | 32MB     |       4 | 468.98
  4 |          ->  Streaming(type: BROADCAST) |  300000 | 2MB      |       4 | 218.98
  5 |             ->  Seq Scan on nt2       |   50000 | 1MB      |       4 | 121.33
(5 rows)

 Predicate Information (identified by plan id)
-----------------------------------------------
   2 --Seq Scan on nt1
       Filter: (NOT (SubPlan 1))
(2 rows)

-- Use hashed_sublink hints.
gaussdb=# EXPLAIN SELECT * FROM nt1 WHERE nt1.a NOT IN (SELECT /*+ hashed_sublink no_expand*/ a
FROM nt2);
 id |               operation               | E-rows  | E-memory | E-width | E-costs
----+---------------------------------------+---------+----------+---------+----------
  1 | ->  Streaming (type: GATHER)          |   25000 |          |       4 | 2272.68
  2 |    ->  Seq Scan on nt1                |   25000 | 1MB      |       4 | 1361.14
  3 |       ->  Materialize  [2, SubPlan 1] | 1800000 | 32MB     |       4 | 468.98
  4 |          ->  Streaming(type: BROADCAST) |  300000 | 2MB      |       4 | 218.98
  5 |             ->  Seq Scan on nt2       |   50000 | 1MB      |       4 | 121.33
(5 rows)

 Predicate Information (identified by plan id)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
------------------------------------------------
  2 --Seq Scan on nt1
        Filter: (NOT (hashed SubPlan 1))
(2 rows)
-- work_mem affects plan generation and execution. If you perform other operations, you need to reset it.
reset work_mem;  -- Roll back the memory settings.
```

The hashed operation is performed on the sublink. If the hint is not used, a common plan is used.

6.10.25 Hints for Specifying the Degree of Parallelism for Scans

Description

The degree of parallelism (DOP) is specified for table scans in a parallel execution plan.

Syntax

```
scandop([@queryblock] table dop_num)
```

Parameters

- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table** specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- **dop_num** specifies the DOP for table scans.
- **scandop** specifies a hint for specifying the DOP for scans.

Examples

```
-- Preparation
CREATE TABLE cst1(a int, b int, c int, d bigint);
set explain_perf_mode = pretty;  -- Open the explain pretty option to view a detailed plan.
set enable_fast_query_shipping = off;  -- Disable FQS optimization.
-- Usage
gaussdb=# EXPLAIN (costs off) SELECT /*+ Set(query_dop 2) scandop(cst1 2)*/ * FROM cst1;
 id |                  operation
----+-----------------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  Streaming(type: LOCAL GATHER dop: 1/2)
  3 |       ->  Seq Scan on cst1
(3 rows)
```

In a parallel plan, you can use scandop hints to specify the degree of parallelism.

NOTE

The hint takes effect only when **dop_num** is the same as the current degree of parallelism (**query_dop**) or is set to **1**.

```
gaussdb=# EXPLAIN (costs off) SELECT /*+ Set(query_dop 2) scandop(cst1 4)*/ * FROM cst1;
 id |      operation
----+----------------------
  1 | ->  Seq Scan on cst1
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.10.26 Hints for Specifying Whether to Use Semi-Join

Description

Specifies whether to select semi-join.

Syntax

```
[no] semijoin([@queryblock] table_list)
```

Parameters

- **no** indicates that semi-join is not used.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **table_list** specifies the tables to be joined. The values are the same as those of **join_table_list** but contain no parentheses.
- **semijoin** specifies whether semi-join is used for table join.

Examples

```
-- Preparation
CREATE TABLE se_t1 (a int, b int);
CREATE TABLE se_t2 (a int, b int);
CREATE TABLE se_t3 (a int, b int);
set explain_perf_mode = pretty;  -- Open the explain pretty option to view a detailed plan.
-- Scenarios where hints are not used
gaussdb=# EXPLAIN(costs off) SELECT a FROM se_t2 WHERE a IN( SELECT  se_t1.a FROM se_t1,se_t3
WHERE se_t1.a=se_t3.a GROUP BY 1);
 id |              operation
----+----------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  Hash Join (3,4)
  3 |      ->  Seq Scan on se_t2
  4 |      ->  Hash
  5 |        ->  HashAggregate
  6 |          ->  Hash Join (7,8)
  7 |            ->  Seq Scan on se_t1
  8 |            ->  Hash
  9 |              ->  Seq Scan on se_t3
(9 rows)

 Predicate Information (identified by plan id)
------------------------------------------------
   2 --Hash Join (3,4)
       Hash Cond: (se_t2.a = se_t1.a)
   6 --Hash Join (7,8)
       Hash Cond: (se_t1.a = se_t3.a)
(4 rows)

-- Scenarios where hints are used
gaussdb=# EXPLAIN(costs off) SELECT /*+ SemiJoin(se_t2@"sel$1" "sel$2") */ a FROM se_t2 WHERE a
IN( SELECT  se_t1.a FROM se_t1,se_t3 WHERE se_t1.a=se_t3.a GROUP BY 1);
 id |              operation
----+----------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  Hash Semi Join (3, 4)
  3 |      ->  Seq Scan on se_t2
  4 |      ->  Hash
  5 |        ->  HashAggregate
  6 |          ->  Hash Join (7,8)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 7 |              ->  Seq Scan on se_t1
 8 |              ->  Hash
 9 |                 ->  Seq Scan on se_t3
(9 rows)

 Predicate Information (identified by plan id)
------------------------------------------------
  2 --Hash Semi Join (3, 4)
       Hash Cond: (se_t2.a = se_t1.a)
  6 --Hash Join (7,8)
       Hash Cond: (se_t1.a = se_t3.a)
(4 rows)
```

You can see that the semijoin hint can determine whether to use semi-join.

6.10.27 Hints for Specifying Whether to Use Minmax Optimization

Description

Specifies whether a statement is rewritten using minmax.

Syntax

```
[no] use_minmax[(@queryblock)]
```

Parameters

- **no** indicates that minmax is not used for query rewriting.
- For details about **@queryblock**, see **Hint Specifying the Query Block Where the Hint Is Located**. **@queryblock** can be omitted, indicating that the hint takes effect in the current query block.
- **use_minmax** uses minmax optimization for statement query rewriting.

Examples

```
-- Preparation
create table minmaxtest(f1 int);
create index minmaxtesti on minmaxtest(f1);
insert into minmaxtest values(11), (12);
set explain_perf_mode=pretty;  -- Open the explain pretty option to view a detailed plan.

-- Common scenario
gaussdb=# explain (costs off) select min(f1), max(f1) from minmaxtest;
 id |                           operation
----+-----------------------------------------------------------------------------
  1 | ->  Result
  2 |    ->  Aggregate  [1, InitPlan 1 (returns $0)]
  3 |       ->  Streaming (type: GATHER)
  4 |          ->  Limit
  5 |             ->  Index Only Scan using minmaxtesti on minmaxtest
  6 |    ->  Aggregate  [1, InitPlan 2 (returns $1)]
  7 |       ->  Streaming (type: GATHER)
  8 |          ->  Limit
  9 |             ->  Index Only Scan Backward using minmaxtesti on minmaxtest
(9 rows)

       Predicate Information (identified by plan id)
-------------------------------------------------------------
  5 --Index Only Scan using minmaxtesti on minmaxtest
       Index Cond: (f1 IS NOT NULL)
  9 --Index Only Scan Backward using minmaxtesti on minmaxtest
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
       Index Cond: (f1 IS NOT NULL)
(4 rows)

-- Use hints to disable minmax rewriting.
gaussdb=# explain (costs off)select /*+ no use_minmax*/ min(f1), max(f1) from minmaxtest;
id |             operation
----+-----------------------------------
 1 | ->  Aggregate
 2 |    ->  Streaming (type: GATHER)
 3 |       ->  Aggregate
 4 |          ->  Seq Scan on minmaxtest
(4 rows)
```

After the no use_minmax hint is used, the SQL statement does not use minmax optimization.

```
-- Use minmax hints.
analyze;  -- Collect statistics.
gaussdb=# explain (costs off) select min(f1), max(f1) from minmaxtest;
id |             operation
----+-----------------------------------
 1 | ->  Aggregate
 2 |    ->  Streaming (type: GATHER)
 3 |       ->  Aggregate
 4 |          ->  Seq Scan on minmaxtest
(4 rows)

-- Use the use_minmax hint to select minmax rewriting.
gaussdb=# explain (costs off) select  /*+ indexonlyscan(minmaxtest) use_minmax*/ min(f1), max(f1) from
minmaxtest;
 id |                            operation
----+-------------------------------------------------------------------------
 1 | ->  Result
 2 |    ->  Aggregate  [1, InitPlan 1 (returns $0)]
 3 |       ->  Streaming (type: GATHER)
 4 |          ->  Limit
 5 |             ->  Index Only Scan using minmaxtesti on minmaxtest
 6 |    ->  Aggregate  [1, InitPlan 2 (returns $1)]
 7 |       ->  Streaming (type: GATHER)
 8 |          ->  Limit
 9 |             ->  Index Only Scan Backward using minmaxtesti on minmaxtest
(9 rows)
```

The use_minmax hint takes effect.

NOTE

The use_minmax optimization takes effect only when index scan is used for table scanning.

6.10.28 Hints for Specifying Whether to Use Partition-wise Scan Optimization

In the SMP scenario, partitioned tables can be concurrently scanned in either of the following modes:

- Each thread traverses all partitions, but reads only a part of data in the partitions. Since the data read by threads does not overlap, the data read by all threads combined is the whole data.
- Each thread is bound to only some partitions and the partitions bound to threads do not overlap. Each thread reads all data from its bound partitions. This mode is called Partition-wise Scan.

In some scenarios, Partition-wise Scan can read data more evenly and has higher concurrent read performance.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

You can enable Partition-wise Scan in either of the following ways:

- Set GUC parameter **force_smp_partitionwise_scan**.
- Set the **partitionwisescan** hint.

Description

Specifies whether the statement uses Partition-wise Scan in partitioned tables in SMP scenarios.

Syntax

```
[no] partitionwisescan[(@tablename)]
```

Parameters

- **no**

  Does not use Partition-wise Scan to query rewriting.

- **@tablename**

  Partitioned table for Partition-wise Scan, which cannot be omitted.

- **partitionwisescan**

  Uses Partition-wise Scan to concurrently scan partitioned tables.

Example

```
-- Create a partitioned table.
gaussdb=# CREATE TABLE partition_3_part
(
    a INTEGER,
    b INTEGER,
    c INTEGER
) PARTITION BY HASH(a) (
    PARTITION p1,
    PARTITION p2,
    PARTITION p3
);

-- Enable SMP and Partition-wise Join.
gaussdb=# SET query_dop = 5;
SET
gaussdb=# SET enable_smp_partitionwise = on;
SET

-- Use the partitionwisescan hint.
gaussdb=# EXPLAIN SELECT /*+ partitionwisescan(partition_3_part)*/ count(*) FROM partition_3_part;
                                      QUERY PLAN
---------------------------------------------------------------------------------------------------
 Aggregate  (cost=14.24..14.31 rows=1 width=8)
   ->  Streaming (type: GATHER)  (cost=14.24..14.31 rows=3 width=8)
         Node/s: All datanodes
         ->  Aggregate  (cost=14.18..14.19 rows=3 width=8)
               ->  Partition Iterator  (cost=0.00..14.14 rows=30 width=0)
                     Iterations: 3
                     ->  Partitioned Seq Scan on partition_3_part  (cost=0.00..14.14 rows=30 width=0)
                           Selected Partitions:  1..3
(8 rows)

-- Drop the partitioned table.
gaussdb=# DROP TABLE partition_3_part;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

6.11 Checking the Implicit Conversion Performance

In some scenarios, implicit data type conversion may cause performance problems. See the following scenario:

```
SET enable_fast_query_shipping = off;
CREATE TABLE t1(c1 VARCHAR, c2 VARCHAR);
CREATE INDEX on t1(c1);
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10;
```

The execution plan of the preceding query is as follows.

```
                            QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..13.29 rows=1 width=64)
   Output: c1, c2
   Node/s: All datanodes
   ->  Seq Scan on public.t1  (cost=0.00..13.20 rows=1 width=64)
         Output: c1, c2
         Distribute Key: c1
         Filter: ((t1.c1)::bigint = 10)
(7 rows)
```

The data type of **c1** is **varchar**. When the filter criterion is **c1 = 10**, the optimizer implicitly converts the data type of **c1** to **bigint** by default. As a result, the following two consequences occur:

- DN tailoring is not allowed. The plan is delivered to all DNs for execution.
- The Index Scan mode cannot be used to scan data in the plan.

These may cause performance problems.

After knowing the causes, you can rewrite the SQL statements. In the preceding scenario, you only need to convert the constant display in the filter criteria to the varchar type. The result is as follows:

```
EXPLAIN verbose SELECT * FROM t1 WHERE c1 = 10::varchar;
```

```
                                  QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..8.36 rows=1 width=64)
   Output: c1, c2
   Node/s: datanode2
   ->  Index Scan using t1_c1_idx on public.t1  (cost=0.00..8.27 rows=1 width=64)
         Output: c1, c2
         Distribute Key: c1
         Index Cond: ((t1.c1)::text = '10'::text)
(7 rows)
```

To identify the performance impact of implicit type conversion in advance, GaussDB provides a GUC option: **check_implicit_conversions**. After this parameter is enabled, the system checks the index columns that are implicitly converted in the query in the path generation phase. If no candidate index scan path is generated for the index columns, an error message is displayed. For example:

```
SET check_implicit_conversions = on;
SELECT * FROM t1 WHERE c1 = 10;
ERROR:  There is no optional index path for index column: "t1"."c1".
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- The **check_implicit_conversions** parameter is used only to check for potential performance problems caused by implicit type conversion. In the formal production environment, set this parameter to **off** (default value) to disable it.
- When enabling **check_implicit_conversions**, you must disable **enable_fast_query_shipping**. Otherwise, you cannot view the result of restoring the implicit type conversion.
- A candidate path of a table may include multiple possible data scan modes such as sequential scan and index scan. A table scan mode used in the final execution plan is determined by the cost of the execution plan. Therefore, even if a candidate path for index scan is generated, other scan modes may also be used in the final execution plan.

6.12 Using the Vectorized Executor for Tuning

GaussDB supports the row executor and vectorized executor. Vectorized executors have the following advantages:

- More data is read in one batch at a time, saving I/O resources.
- There are a large number of records in a batch, and the CPU cache hit rate increases.
- In pipeline mode, the number of function calls is small.
- A batch of data is processed at a time, which is efficient.

GaussDB can achieve better query performance for complex analytical queries.

To improve the query performance of row-store tables in complex analytical queries, GaussDB provides the vectorized executor for processing row-store tables. You can set the GUC parameter **try_vector_engine_strategy** to convert query statements containing row-store tables into vectorized execution plans for execution.

This conversion is not applicable to all query scenarios. If a query statement contains operations such as expression calculation, multi-table join, and aggregation, the performance can be improved by converting the statement to a vectorized execution plan. Theoretically, converting a row-store table to a vectorized execution plan causes conversion overheads and performance deterioration. After the foregoing expression calculation, join operation, and aggregation operations are converted into vectorized execution plans, performance can be improved. The performance improvement must be higher than the overheads generated by the conversion. This determines whether the conversion is required.

Take TPCH Q1 as an example. When the row execution engine is used, the execution time of the scan operator is 405,210 ms, and the execution time of the aggregation operation is 2,618,964 ms. After the vectorized execution engine is used, the execution time of the scanning operator (SeqScan + VectorAdapter) is 470,840 ms, and the execution time of the aggregation operation is 212,384 ms. Therefore, the query performance can be improved.

Example:

The default value of **try_vector_engine_strategy** is **off**. You can run the **SHOW try_vector_engine_strategy;** command to view the current value.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  SHOW try_vector_engine_strategy;
 try_vector_engine_strategy
----------------------------
 off
(1 row)
```

For row-store tables, if the value of **try_vector_engine_strategy** is **off**, no vectorized plan is generated.

Execution plan of the TPCH Q1 row executor:

```
                                                
```

6.13 Performing Optimization with SQL Patches

SQL patches are designed for database administrators (DBAs), O&M personnel, and other roles who need to optimize SQL statements. If performance problems caused by poor plans of service statements are identified through other O&M views or fault locating methods, you can create SQL patches to optimize service statements based on hints. Currently, the following hints are supported: number of rows, scanning mode, join mode, join sequence, PBE custom/generic plan selection, statement-level parameter setting, and parameterized path. In addition, in case that services are unavailable due to internal system errors that are triggered by specific statements, you can create SQL patches to rectify single-point failures without changing service statements. In this way, errors can be reported in advance to avoid greater loss.

Limitations

1. Patches can be created only by unique SQL ID. If unique SQL IDs conflict, SQL patches that are used for hint-based optimization may affect performance but do not affect semantic correctness.
2. Only hints that do not change SQL semantics can be used as patches. SQL rewriting is not supported.
3. This tool is not applicable to logical backup and restoration.
4. SQL patches cannot be created on DNs.
5. Only the initial user, OPRADMIN, MONADMIN, and SYSADMIN have the permission to perform this operation.
6. Patches are not shared between databases. When creating SQL patches, you need to connect to the target database. If the CN where the SQL PATCH is created is removed and a full build is triggered, the SQL PATCH in the target CN of the full build is inherited. Therefore, you are advised to create the corresponding SQL PATCH on each CN.
7. CNs do not share SQL patches because their unique SQL IDs are different. You need to manually create SQL patches on different CNs.
8. SQL patches in a stored procedure and global SQL patches cannot coexist.
9. SQL patches cannot be used for prepared statement that are executed using the PREPARE + EXECUTE syntax. There are special cases. For details, see **Special Cases**.
10. It is not recommended that the SQL patches be used in the database for a long time. It should be used only as a workaround. If the database service is unavailable due to a kernel fault triggered by a specific statement or SQL hints are used for performance optimization, you must rectify the service fault or upgrade the kernel as soon as possible. After the upgrade, the method of generating unique SQL IDs may change. Therefore, the workaround may become invalid.
11. Currently, except DML statements, unique SQL IDs of SQL statements (such as CREATE TABLE) are generated by hashing the statement text. Therefore, SQL patches are sensitive to uppercase and lowercase letters, spaces, and linefeeds. That is, even statements of different texts have the same semantics, you still need to create different SQL patches for them. For DML operations,

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

an SQL patch can take effect for the same statement with different input parameters, regardless of uppercase letters, lowercase letters, and spaces.

Example

The SQL patch is implemented based on the unique SQL ID. Therefore, you need to enable related O&M parameters (**enable_resource_track = on**, **instr_unique_sql_count > 0**) for the SQL patch to take effect. The unique SQL ID can be obtained from the slow SQL view. You need to specify the unique SQL ID when creating the SQL patch. For SQL statements in a stored procedure, you need to set **instr_unique_sql_track_type** to **'all'** and query unique SQL ID in the dbe_perf.statement_history view.

The following provides simple examples:

Scenario 1: Use an SQL patch to optimize specific statements based on hints.

```
gaussdb=#  create table hint_t1(a int, b int, c int);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# create index on hint_t1(a);
CREATE INDEX

 b
---
 2
(1 row)

gaussdb=# call mypro();
ERROR:  Statement 2859505004 canceled by abort patch patch1
CONTEXT:  SQL statement "select b          from test_proc_patch where a = 1"
PL/SQL function mypro() line 3 at SQL statement
```

Scenario 4: Install the SQL patch for the same slow SQL statement on each CN.

```
-- Find the slow SQL statement and plan on each node. (This function requires the MONADMIN
permission.)
select node_name, unique_query_id, start_time, query, query_plan from
dbe_perf.get_global_full_sql_by_timestamp(<start_time>, <end_time>);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Observe and analyze the returned slow SQL statement and plan, and perform local optimization and verification to obtain a proper hint_str.

-- Run the following statement on any CN to create an SQL patch, where node_name and unique_query_id are obtained from step 1:
select * from dbe_sql_util.create_remote_hint_sql_patch(<node_name>, <patch_name>, <unique_query_id>, <hint_str>);
```

Special Cases

According to the example, SQL patches can be used only when the correct unique SQL IDs are used. Therefore, SQL patches do not support prepared statement executed by the PREPARE + EXECUTE syntax.

```
-- Generally, an SQL ID with PREPARE is obtained. Therefore, the SQL patch cannot be used.
unique_query_id |                          query
-----------------+------------------------------------------------------------
      658407023 | prepare p1 as                                              +
                | SELECT /*+ tablescan(rewrite_rule_hint_t1)*/*          +
                | FROM rewrite_rule_hint_t1,                             +
                |      (SELECT * FROM rewrite_rule_hint_t2 WHERE a > 1) tt+
                | WHERE rewrite_rule_hint_t1.a = tt.a;
```

However, if the plan cache becomes invalid, the plan cache uses the statement in PREPARE to generate a unique SQL ID again. If the unique SQL ID is used to apply the SQL patch, the SQL patch can be used normally.

```
-- Example
-- Create a table.
gaussdb=# DROP TABLE rewrite_rule_hint_t1;
gaussdb=# DROP TABLE rewrite_rule_hint_t2;
gaussdb=# CREATE TABLE rewrite_rule_hint_t1 (a int, b int, c int, d int);
gaussdb=# CREATE TABLE rewrite_rule_hint_t2 (a int, b int, c int, d int);

-- Enable FullSQL statistics.
gaussdb=# SET track_stmt_stat_level = 'L1,L1';

-- Clear the sql_patch and environment.
gaussdb=# SELECT dbe_sql_util.drop_sql_patch('patch1');
gaussdb=# DEALLOCATE all;

-- Disable FQS.
gaussdb=# SET enable_fast_query_shipping=off;

-- PRARARE
gaussdb=# PREPARE p1 AS SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;

-- View the unique SQL ID.
gaussdb=# SELECT unique_query_id,QUERY FROM dbe_perf.statement_history WHERE QUERY LIKE
'%rewrite_rule_hint%' ORDER BY finish_time DESC LIMIT 1;
 unique_query_id |
query
-----------------
+-----------------------------------------------------------------------------------------------------------------------------
---------------
       25719777 | prepare p1 as SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > 1) tt WHERE rewrite_rule_hint_t1.a = tt.a;

-- In this case, the unique SQL ID cannot make the SQL patch take effect.

-- Insert and analyze data to invalidate the cache.
gaussdb=# INSERT INTO rewrite_rule_hint_t1 VALUES(generate_series(1, 10000), generate_series(1, 10000),
generate_series(1, 10000),generate_series(1, 10000));
gaussdb=# ANALYZE rewrite_rule_hint_t1;

-- Generate a unique SQL ID again.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# EXPLAIN EXECUTE p1(1);
                                  QUERY PLAN
-------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=13.47..116.77 rows=7 width=32)
   Node/s: All datanodes
   ->  Hash Join  (cost=13.22..116.40 rows=7 width=32)
         Hash Cond: (rewrite_rule_hint_t1.a = rewrite_rule_hint_t2.a)
         ->  Seq Scan on rewrite_rule_hint_t1  (cost=0.01..90.50 rows=9999 width=16)
               Filter: (a > 1)
         ->  Hash  (cost=13.16..13.16 rows=6 width=16)
               ->  Seq Scan on rewrite_rule_hint_t2  (cost=0.00..13.16 rows=7 width=16)
                     Filter: (a > 1)
(9 rows)

-- Check the new unique SQL ID.
gaussdb=# SELECT unique_query_id,QUERY FROM dbe_perf.statement_history WHERE QUERY LIKE
'%rewrite_rule_hint%' ORDER BY finish_time DESC LIMIT 1;
 unique_query_id |
query
-----------------
+-------------------------------------------------------------------------------------------------------------------------------------------
---------------
     2936377667 | prepare p1 as SELECT * FROM rewrite_rule_hint_t1,(SELECT * FROM rewrite_rule_hint_t2
WHERE a > ?) tt WHERE rewrite_rule_hint_t1.a = tt.a;

The unique SQL ID changes and is generated using the SQL statement in PREPARE. In this case, the unique
SQL ID is available.

-- Use SQL_PATCH.
gaussdb=# SELECT * FROM dbe_sql_util.create_hint_sql_patch('patch1', 2936377667 , 'set(enable_hashjoin

         ->  Materialize  (cost=0.00..13.22 rows=7 width=16)
               ->  Seq Scan on rewrite_rule_hint_t2  (cost=0.00..13.16 rows=7 width=16)
                     Filter: (a > 1)
(8 rows)

-- The SQL patch takes effect and the corresponding plan is generated.
```

Helpful Links

For details about the system functions, system catalogs, system views, and functions related to the SQL patch, see **Table 1 System functions, system catalogs, system views, and functions related to SQL PATCH**.

Table 6-8 System functions, system catalogs, system views, and functions related to SQL PATCH

Category	Name	Description
System function	global_sql_patch_func()	SQL patch information on each global node, which is used to return the result of the global_sql_patch view.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Name	Description
System catalog	GS_SQL_PATCH	GS_SQL_PATCH records the status information about all SQL patches.
System view	GLOBAL_SQL_PATCH	GLOBAL_SQL_PATCH stores information about all SQL patches. This view is available only in the PG_CATALOG schema.
Function DBE_SQL_UTIL Schema	DBE_SQL_UTIL.create_hint_sql_patch	create_hint_sql_patch creates hint SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.create_abort_sql_patch	create_abort_sql_patch creates abort SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.drop_sql_patch	drop_sql_patch deletes SQL patches from the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.enable_sql_patch	enable_sql_patch enables SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.disable_sql_patch	disable_sql_patch disables SQL patches on the connected CN and returns whether the execution is successful.
	DBE_SQL_UTIL.show_sql_patch	show_sql_patch displays the SQL patch corresponding to a specified patch name and return the running result.
	DBE_SQL_UTIL.create_hint_sql_patch	create_hint_sql_patch creates hint SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of **parent_unique_sql_id** can be used to limit the effective range of the hint patch.
	DBE_SQL_UTIL.create_abort_sql_patch	create_abort_sql_patch creates abort SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of **parent_unique_sql_id** can be used to limit the effective range of the abort patch.

	DBE_SQL_UTIL.create_remote_hint_sql_patch	create_remote_hint_sql_patch creates hint SQL patches on a specified CN and returns whether the execution is successful.
	DBE_SQL_UTIL.create_remote_abort_sql_patch	create_remote_abort_sql_patch creates abort SQL patches on a specified CN and returns whether the execution is successful.
	DBE_SQL_UTIL.drop_remote_sql_patch	drop_remote_sql_patch deletes SQL patches from a specified CN and returns whether the execution is successful.
	DBE_SQL_UTIL.enable_remote_sql_patch	enable_remote_sql_patch enables SQL patches on a specified CN and returns whether the execution is successful.
	DBE_SQL_UTIL.disable_remote_sql_patch	disable_remote_sql_patch disables SQL patches on a specified CN and returns whether the execution is successful.

6.14 Optimization Cases

6.14.1 Case: Selecting an Appropriate Distribution Key

Symptom

Tables are defined as follows:

```
CREATE TABLE t1 (a int, b int);
CREATE TABLE t2 (a int, b int);
```

The following query is executed:

```
SELECT * FROM t1, t2 WHERE t1.a = t2.b;
```

Optimization Analysis

If **a** is the distribution key of **t1** and **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (a);
```

Then **Streaming** exists in the execution plan and the data volume is heavy among DNs, as shown in **Figure 6-8**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Figure 6-8 Selecting an appropriate distribution key (1)

```
openGauss => explain select * from t1, t2 where t1.a = t2.b;
                                  QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=245.40..582.15 rows=240 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=10.22..24.26 rows=10 width=16)
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on t1  (cost=0.00..10.10 rows=10 width=8)
         ->  Hash  (cost=3.79..3.79 rows=10 width=8)
               ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..3.79 rows=10 width=8)
                     Spawn on: All datanodes
                     ->  Seq Scan on t2  (cost=0.00..10.10 rows=10 width=8)
(9 rows)
```

If **a** is the distribution key of **t1** and **b** is the distribution key of **t2**:

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH (a);
CREATE TABLE t2 (a int, b int) DISTRIBUTE BY HASH (b);
```

Then **Streaming** does not exist in the execution plan, and the data volume among DNs is decreasing and the query performance is increasing, as shown in **Figure 6-9**.

Figure 6-9 Selecting an appropriate distribution key (2)

```
openGauss=> explain select * from t1, t2 where t1.a = t2.b;
                                  QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=245.40..491.10 rows=240 width=16)
   Node/s: All datanodes
   ->  Hash Join  (cost=10.22..20.46 rows=10 width=16)
         Hash Cond: (t1.a = t2.b)
         ->  Seq Scan on t1  (cost=0.00..10.10 rows=10 width=8)
         ->  Hash  (cost=10.10..10.10 rows=10 width=8)
               ->  Seq Scan on t2  (cost=0.00..10.10 rows=10 width=8)
(7 rows)
```

6.14.2 Case: Creating an Appropriate Index

Symptom

Query the information about all personnel in the sales department.

```
-- Create tables.
CREATE TABLE staffs (staff_id NUMBER(6) NOT NULL, first_name VARCHAR2(20), last_name
VARCHAR2(25), employment_id VARCHAR2(10), section_id NUMBER(4), state_name VARCHAR2(10), city
VARCHAR2(10));
CREATE TABLE sections(section_id NUMBER(4), place_id NUMBER(4), section_name VARCHAR2(20));
CREATE TABLE states(state_id NUMBER(4));
CREATE TABLE places(place_id NUMBER(4), state_id  NUMBER(4));
-- Query before optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
-- Create indexes.
CREATE INDEX loc_id_pk ON places(place_id);
CREATE INDEX state_c_id_pk ON states(state_id);
-- Query after optimization.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
```

Optimization Analysis

The original execution plan is as follows before creating the **places.place_id** and **states.state_id** indexes:

```
 id |                          operation                          | E-rows | E-width | E-costs
----+-------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                |      2 |     254 | 54.08
  2 |    ->  Sort                                                 |      2 |     254 | 53.90
  3 |       ->  Nested Loop (4,5)                                 |      2 |     254 | 53.88
  4 |          ->  Seq Scan on staffs                             |     20 |     266 | 13.13
  5 |          ->  Materialize                                    |      4 |      12 | 40.37
  6 |             ->  Streaming(type: BROADCAST)                  |      4 |      12 | 40.36
  7 |                ->  Nested Loop (8,9)                        |      2 |      12 | 40.20
  8 |                   ->  Seq Scan on states                    |     20 |      12 | 13.13
  9 |                   ->  Materialize                           |      2 |      24 | 26.69
 10 |                      ->  Streaming(type: REDISTRIBUTE)      |      2 |      24 | 26.68
 11 |                         ->  Nested Loop (12,14)             |      2 |      24 | 26.57
 12 |                            ->  Streaming(type: REDISTRIBUTE)|      1 |      24 | 13.28
 13 |                               ->  Seq Scan on sections      |      1 |      24 | 13.16
 14 |                            ->  Seq Scan on places           |     20 |      24 | 13.13
(14 rows)

        Predicate Information (identified by plan id)
-------------------------------------------------------------------
  3 --Nested Loop (4,5)
        Join Filter: (sections.section_id = staffs.section_id)
  7 --Nested Loop (8,9)
        Join Filter: (places.state_id = states.state_id)
 11 --Nested Loop (12,14)
        Join Filter: (sections.place_id = places.place_id)
 13 --Seq Scan on sections
        Filter: ((section_name)::text = 'Sales'::text)
(8 rows)
```

The optimized execution plan is as follows (two indexes have been created on the **places.place_id** and **states.state_id** columns in **Symptom**):

```
 id |                          operation                          | E-rows | E-width | E-costs
----+-------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                |      2 |     254 | 42.26
  2 |    ->  Sort                                                 |      2 |     254 | 42.08
  3 |       ->  Nested Loop (4,5)                                 |      2 |     254 | 42.06
  4 |          ->  Seq Scan on staffs                             |     20 |     266 | 13.13
  5 |          ->  Materialize                                    |      4 |      12 | 28.55
  6 |             ->  Streaming(type: BROADCAST)                  |      4 |      12 | 28.54
  7 |                ->  Nested Loop (8,13)                       |      2 |      12 | 28.38
  8 |                   ->  Streaming(type: REDISTRIBUTE)         |      2 |      24 | 21.66
  9 |                      ->  Nested Loop (10,12)                |      2 |      24 | 21.56
 10 |                         ->  Streaming(type: REDISTRIBUTE)   |      1 |      24 | 13.28
 11 |                            ->  Seq Scan on sections         |      1 |      24 | 13.16
 12 |                         ->  Index Scan using loc_id_pk on places |  1 |      24 | 8.27
 13 |                   ->  Index Only Scan using state_c_id_pk on states |  1 |  12 | 3.35
(13 rows)

        Predicate Information (identified by plan id)
-------------------------------------------------------------------
  3 --Nested Loop (4,5)
        Join Filter: (sections.section_id = staffs.section_id)
 11 --Seq Scan on sections
```

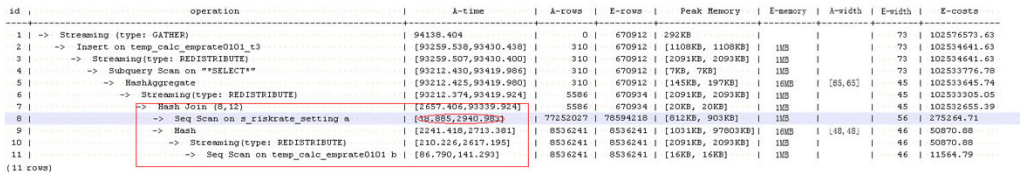
 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
      Filter: ((section_name)::text = 'Sales'::text)
 12 --Index Scan using loc_id_pk on places
      Index Cond: (place_id = sections.place_id)
 13 --Index Only Scan using state_c_id_pk on states
      Index Cond: (state_id = places.state_id)
(8 rows)
```

6.14.3 Case: Adjusting Distribution Keys

Symptom

During a site test, the information is displayed after **EXPLAIN ANALYZE** is run:



id	operation	A-time	A-rows	E-rows	Peak Memory	E-memory	A-width	E-width	E-costs
1	-> Streaming (type: GATHER)	94138.404	0	670912	292KB			73	102576573.63
2	-> Insert on temp_calc_emprate0101_t3	[93259.538,93430.438]	310	670912	[1108KB, 1108KB]	1MB		73	102534641.63
3	-> Streaming(type: REDISTRIBUTE)	[93259.507,93430.400]	310	670912	[2091KB, 2093KB]	1MB		73	102534641.63
4	-> Subquery Scan on "*SELECT*"	[93212.430,93419.986]	310	670912	[7KB, 7KB]	1MB		73	102533776.78
5	-> HashAggregate	[93212.425,93419.980]	310	670912	[145KB, 197KB]	16MB	[65,65]	45	102533645.74
6	-> Streaming(type: REDISTRIBUTE)	[93212.374,93419.924]	5586	670934	[2091KB, 2093KB]	1MB		45	102533305.05
7	-> Hash Join (8,12)	[2657.406,93339.924]	5586	670934	[20KB, 20KB]	1MB		45	102532655.39
8	-> Seq Scan on s_riskrate_setting a	[38.885,2940.983]	77252027	78594218	[812KB, 903KB]	1MB		56	275264.71
9	-> Hash	[2241.418,2713.381]	8536241	8536241	[1031KB, 97803KB]	16MB	[48,48]	46	50870.88
10	-> Streaming(type: REDISTRIBUTE)	[210.226,2617.195]	8536241	8536241	[2091KB, 2093KB]	1MB		46	50870.88
11	-> Seq Scan on temp_calc_emprate0101 b	[86.790,141.293]	8536241	8536241	[16KB, 16KB]	1MB		46	11564.79

(11 rows)

According to the execution information, Hash Join becomes the performance bottleneck of the whole plan. Based on the execution time of Hash Join [2657.406,93339.924] (for details about the values, see **Execution Plan Details**), it can be seen that severe skew occurs on different DNs during the Hash Join operation.

In the memory information (as shown in the following figure), it can be seen that the data skew occurs in the memory usage of each node.

```
Memory Information (identified by plan id)
------------------------------------------------------------------------
Coordinator:
  Query Peak Memory: 4MB
Datanode:
  Max Query Peak Memory: 118MB
  Min Query Peak Memory: 24MB
 12 --Hash
      Max Buckets: 131072  Max Batches: 1  Max Memory Usage: 91857kB
      Min Buckets: 131072  Min Batches: 1  Min Memory Usage: 0kB
(8 rows)
```

Optimization Analysis

The preceding two features indicate that this SQL statement has extremely serious computing unbalance. The further lower-layer analysis on the Hash Join operator shows that serious computing skew **[38.885,2940.983]** occurs in **Seq Scan on s_riskrate_setting**. Based on the description of the Scan, we can infer that the performance problems of this plan lie in data skew occurred in the **s_riskrate_setting** table. Later, it is proved that serious data skew occurred in the **s_riskrate_setting** table. After performance optimization, the execution time is reduced from 94s to 50s.

6.14.4 Case: Adjusting the GUC Parameter best_agg_plan

Symptom

The **agg_t1** table is defined as follows:

```
create table agg_t1(a int, b int, c int) distribute by hash(a);
```

Assume that the distribution key of the result set provided by the agg lower-layer operator is **setA**, and the **group by** column of the agg operation is **setB**, the agg operations can be performed in two scenarios in the Stream framework.

1. **setA** is a subset of **setB**.

   In this scenario, the aggregation result of the lower-layer is correct and can be directly used by upper-level operators. Example:

   ```
   gaussdb=# explain select a, count(1) from agg_t1 group by a;
    id |          operation          | E-rows | E-width | E-costs
   ----+-----------------------------+--------+---------+---------
     1 | ->  Streaming (type: GATHER) |     20 |      12 | 14.23
     2 |    ->  HashAggregate        |     20 |      12 | 13.30
     3 |       ->  Seq Scan on agg_t1 |     20 |       4 | 13.13
   (3 rows)
   ```

2. **setA** is not a subset of **setB**.

   In this scenario, the Stream execution framework is classified into the following three plans:

   - hashagg + gather(redistribute) + hashagg;
   - redistribute + hashagg(+ gather);
   - hashagg + redistribute + hashagg(+ gather).

   GaussDB provides the GUC parameter **best_agg_plan** to intervene the execution plan, and forces the plan to generate the corresponding execution plan. This parameter can be set to **0**, **1**, **2**, or **3**.

   - When the parameter is set to **1**, the first plan is forcibly generated.
   - When the parameter is set to **2** and if the **group by** column can be redistributed, the second plan is forcibly generated. Otherwise, the first plan is generated.
   - When the parameter is set to **3** and if the **group by** column can be redistributed, the third plan is generated. Otherwise, the first plan is generated.
   - When the parameter is set to **0**, the query optimizer chooses the most optimal plan by the three preceding plans' evaluation cost.

   The impact is as follows:

   ```
   gaussdb=# set best_agg_plan to 1;
   SET
   gaussdb=# explain select b,count(1) from agg_t1 group by b;
    id |           operation           | E-rows | E-width | E-costs
   ----+-------------------------------+--------+---------+---------
     1 | ->  HashAggregate             |     10 |      12 | 14.23
     2 |    ->  Streaming (type: GATHER) |     20 |      12 | 14.23
     3 |       ->  HashAggregate       |     20 |      12 | 13.30
     4 |          ->  Seq Scan on agg_t1 |     20 |       4 | 13.13
   (4 rows)
   gaussdb=# set best_agg_plan to 2;
   SET
   gaussdb=# explain select b,count(1) from agg_t1 group by b;
    id |              operation              | E-rows | E-width | E-costs
   ----+-------------------------------------+--------+---------+---------
     1 | ->  Streaming (type: GATHER)        |     20 |      12 | 14.52
     2 |    ->  HashAggregate                |     20 |      12 | 13.58
     3 |       ->  Streaming(type: REDISTRIBUTE) |     20 |       4 | 13.42
     4 |          ->  Seq Scan on agg_t1     |     20 |       4 | 13.13
   (4 rows)
   gaussdb=# set best_agg_plan to 3;
   SET
   gaussdb=# explain select b,count(1) from agg_t1 group by b;
    id |              operation              | E-rows | E-width | E-costs
   ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----+-----------------------------------------+--------+---------+---------
 1 | ->  Streaming (type: GATHER)            |     20 |      12 | 14.97
 2 |    ->  HashAggregate                    |     20 |      12 | 13.76
 3 |       ->  Streaming(type: REDISTRIBUTE) |     20 |      12 | 13.56
 4 |         ->  HashAggregate               |     20 |      12 | 13.30
 5 |           ->  Seq Scan on agg_t1        |     20 |       4 | 13.13
(5 rows)
```

Optimization

Generally, the optimizer chooses an optimal execution plan, but the cost estimation, especially that of the intermediate result set, has large deviations, which may result in large deviations in agg calculation. In this case, you need to use **best_agg_plan** to adjust the agg calculation model.

When the aggregation convergence ratio is very small, that is, the number of result sets does not become small obviously after the agg operation (5 times is a critical point), you can select the redistribute+hashagg or hashagg+redistribute +hashagg execution mode.

6.14.5 Case: Rewriting SQL Statements to Eliminate Subqueries

Symptom

```
select
   1,
   (select count(*) from customer_address_001 a4 where a4.ca_address_sk = a.ca_address_sk) as GZCS
from customer_address_001 a;
```

This SQL performance is poor. SubPlan exists in the execution plan as follows.

```
openGauss=# explain select 1,(select count(*)
openGauss(#           from customer_address_001 a4
openGauss(#          where a4.ca_address_sk = a.ca_address_sk
openGauss(#         ) as GZCS from customer_address_001 a;
 id |                          operation                          | E-rows | E-width | E-costs
----+-------------------------------------------------------------+--------+---------+---------
  1 | ->  Streaming (type: GATHER)                                |    320 |       4 | 4529.27
  2 |    ->  Seq Scan on customer_address_001 a                   |    320 |       4 | 4496.27
  3 |       ->  Aggregate  [2, SubPlan 1]                         |     32 |       4 | 139.50
  4 |          ->  Result                                         |  10240 |       4 | 138.69
  5 |             ->  Materialize                                 |  10240 |       4 | 138.69
  6 |                ->  Streaming(type: BROADCAST)               |  10240 |       4 | 137.09
  7 |                   ->  Seq Scan on customer_address_001 a4   |    320 |       4 | 32.32
(7 rows)
```

Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, **a.ca_address_sk** is not **NULL**. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```
select
count(*)
from customer_address_001 a4, customer_address_001 a
where a4.ca_address_sk = a.ca_address_sk
group by  a.ca_address_sk;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

To ensure that the modified statements have the same functions, NOT NULL is added to **customer_address_001. ca_address_sk**.

6.14.6 Case: Rewriting SQL Statements to Eliminate Pruning Interference

Symptom

In a test at a site, **ddw_f10_op_cust_asset_mon** is a partitioned table and the partitioning key is **year_mth** whose value is a combined string of month and year values.

The tested SQL statements are displayed as follows:

```
select
   count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between to_char(add_months(to_date(''20170222'','yyyymmdd'), -11),'yyyymm') and
substr(''20170222'',1 ,6 );
```

The test result shows the Scan operation on the tables in the SQL statement takes 135s. This may be the performance bottleneck.

NOTE

add_months is a local adaptation function.

```
CREATE OR REPLACE FUNCTION ADD_MONTHS(date, integer) RETURNS date
   AS $$
   SELECT
   CASE
   WHEN (EXTRACT(day FROM $1) = EXTRACT(day FROM (date_trunc('month', $1) + INTERVAL '1
month - 1 day'))) THEN
       date_trunc('month', $1) + CAST($2 + 1 || ' month - 1 day' as interval)
   ELSE
       $1 + CAST($2 || ' month' as interval)
   END
   $$
   LANGUAGE SQL
   IMMUTABLE;
```

Optimization

According to the statement execution plan, the base table filter is displayed as follows:

```
Filter: (((year_mth)::text <= '201702'::text) AND ((year_mth)::text >=
to_char(add_months(to_date('20170222'::text, 'YYYYMMDD'::text), (-11)), 'YYYYMM'::text)))
```

The filter condition contains a non-constant expression to_char(add_months(to_date(''20170222'','yyyymmdd'), -11),'yyyymm'), which cannot be used for pruning. Therefore, the query statement scans all data in the partitioned table.

to_date and to_char are stable functions as queried in pg_proc. According to the function behavior described in the database, this type of functions cannot be converted to Const values in the preprocessing phase, which is the root cause why partition pruning cannot be performed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Based on the preceding analysis, the optimization expression can be used for partition pruning, which is the key to performance optimization. The original SQL statements can be written to as follows:

```
select
   count(1)
from t_ddw_f10_op_cust_asset_mon b1
where b1.year_mth between(substr(ADD_MONTHS('20170222'::date, -11), 1, 4)||
substr(ADD_MONTHS('20170222'::date, -11), 6, 2)) and substr(''20170222'',1 ,6 );
```

The execution time of modified SQL statements is reduced from 135s to 18s.

6.14.7 Case: Rewriting SQL Statements and Deleting in-clause

Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in ('20120405', '20130405');
```

Or:

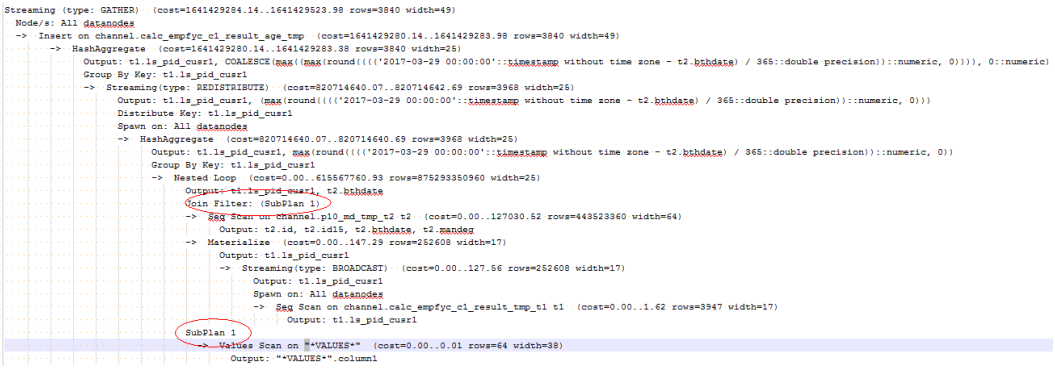
```
select
count(1)
from calc_empfyc_c1_result_tmp_t1
where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT
ls_pid_cusr1,COALESCE(max(round((current_date-bthdate)/365)),0)
FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
WHERE t1.ls_pid_cusr1 = any(values(id),(id15))
GROUP BY ls_pid_cusr1;
```

id and **id15** are columns in **p10_md_tmp_t2**, and **t1.ls_pid_cusr1 = any(values(id),(id15))** is equivalent to **t1.ls_pid_cusr1 = id or t1.ls_pid_cusr1 = id15**.

Therefore, join-condition is essentially an inequality, and nestloop must be used for this unequal join operation. The corresponding execution plan is as follows.



Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to

performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```
select
ls_pid_cusr1,COALESCE(max(round(ym/365)),0)
from
(
	(
		SELECT
			ls_pid_cusr1,(current_date-bthdate) as ym
		FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
		WHERE t1.ls_pid_cusr1 = t2.id and t1.ls_pid_cusr1 != t2.id15
	)
	union all
	(
		SELECT
			ls_pid_cusr1,(current_date-bthdate) as ym
		FROM calc_empfyc_c1_result_tmp_t1 t1,p10_md_tmp_t2 t2
		WHERE t1.ls_pid_cusr1 = id15
	)
)
GROUP BY ls_pid_cusr1;
```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows.

```
 id |                                operation                                 |        A-time         | A-rows  | E-rows  |   Peak Memory   | E-memory | A-width
----+--------------------------------------------------------------------------+-----------------------+---------+---------+-----------------+----------+---------
  1 | ->  Streaming (type: GATHER)                                             | 6737.281              |       0 |     192 | 292KB           |          |

Before the optimization, no result is returned for more than 1 hour. After the optimization, the result is returned within 7s.

6.14.8 Case: Modifying the GUC Parameter rewrite_rule

rewrite_rule contains multiple query rewriting rules: magicset, partialpush, uniquecheck, disablerep, intargetlist, and predpush. The following describes the application scenarios of some important rules.

Preparing the Case Environment

To demonstrate rule application scenarios, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS rewrite_rule_guc_test CASCADE;
CREATE SCHEMA rewrite_rule_guc_test;
SET current_schema=rewrite_rule_guc_test;
-- Create a test table.
CREATE TABLE t(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t1(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t2(c1 INT, c2 INT, c3 INT, c4 INT);
```

partialpush: Partial Pushdown

Queries are pushed down to DNs for distributed execution, greatly accelerating queries. If a query statement contains a factor that cannot be pushed down, the entire statement cannot be pushed down. As a result, a stream plan cannot be generated and executed on DNs for the distributed execution, and the performance is poor.

The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off)  select group_concat(tt.c1, tt.c2) from (select t1.c1,t2.c2 from
t1,t2 where t1.c1=t2.c2) tt(c1,c2);
                            QUERY PLAN
------------------------------------------------------------------------------
 Aggregate
   Output: group_concat(t1.c1, t2.c2 SEPARATOR ',')
   ->  Hash Join
         Output: t1.c1, t2.c2
         Hash Cond: (t1.c1 = t2.c2)
         ->  Data Node Scan on t1 "_REMOTE_TABLE_QUERY_"
               Output: t1.c1
               Node/s: All datanodes
               Remote query: SELECT c1 FROM ONLY public.t1 WHERE true
         ->  Hash
               Output: t2.c2
               ->  Data Node Scan on t2 "_REMOTE_TABLE_QUERY_"
                     Output: t2.c2
                     Node/s: All datanodes
                     Remote query: SELECT c2 FROM ONLY public.t2 WHERE true
```

The group_concat() function cannot be pushed down. As a result, the remote query plan is executed:

1. Deliver the **select c1 from t1 where true** statement to DNs to read all data in the **t1** table.
2. Deliver the **select c2 from t2 where true** statement to DNs to read all data in the **t2** table.
3. Perform HASH JOIN on the CN.
4. Perform the group_concat calculation and return the final result.

This plan is slow because a large amount of data is transmitted over the network and then HASH JOIN is executed on the CN. As a result, cluster resources cannot be fully used.

partialpush is added to push the preceding 1, 2, and 3 operations down to DNs for distributed execution, greatly improving statement performance.

```
gaussdb=# set rewrite_rule='partialpush';
SET
gaussdb=# explain (verbose on, costs off) select group_concat(tt.c1, tt.c2) from (select t1.c1,t2.c2 from t1,t2
where t1.c1=t2.c2) tt(c1,c2);
                    QUERY PLAN
-----------------------------------------------------
 Aggregate
   Output: group_concat(t1.c1, t2.c2 SEPARATOR ',')
   ->  Streaming (type: GATHER) -- The Gather plan is executed on DNs in a distributed manner.
         Output: t1.c1, t2.c2
         Node/s: All datanodes
         ->  Hash Join
               Output: t1.c1, t2.c2
               Hash Cond: (t2.c2 = t1.c1)
               ->  Streaming(type: REDISTRIBUTE)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                  Output: t2.c2
                  Distribute Key: t2.c2
                  Spawn on: All datanodes
                  Consumer Nodes: All datanodes
                  ->  Seq Scan on public.t2
                        Output: t2.c2
                        Distribute Key: t2.c2
            ->  Hash
                  Output: t1.c1
                  ->  Seq Scan on public.t1
                        Output: t1.c1
                        Distribute Key: t1.c1
(21 rows)
```

intargetlist: Target Column Subquery Performance Improvement

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
                          QUERY PLAN
------------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1, ((SubPlan 1)), t1.c2
   Merge Sort Key: t1.c2
   Node/s: All datanodes
   ->  Sort
         Output: t1.c1, ((SubPlan 1)), t1.c2
         Sort Key: t1.c2
         ->  Seq Scan on public.t1
               Output: t1.c1, (SubPlan 1), t1.c2
               Distribute Key: t1.c1
               Filter: (t1.c1 < 100)
               SubPlan 1
                 ->  Aggregate
                       Output: avg(t2.c2)
                       ->  Result
                             Output: t2.c2
                             Filter: (t2.c2 = t1.c2)
                             ->  Materialize
                                   Output: t2.c2
                                   ->  Streaming(type: BROADCAST)
                                         Output: t2.c2
                                         Spawn on: All datanodes
                                         Consumer Nodes: All datanodes
                                         ->  Seq Scan on public.t2
                                               Output: t2.c2
                                               Distribute Key: t2.c1
(26 rows)
```

Because the subquery (select avg(c2) from t2 where t2.c2=t1.c2) in the target column cannot be pulled up, the subquery is executed once each time a data row of **t1** is scanned, and the query efficiency is low. If the **intargetlist** parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```
gaussdb=# set rewrite_rule='intargetlist';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
                      QUERY PLAN
---------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1, (avg(t2.c2)), t1.c2
   Merge Sort Key: t1.c2
   Node/s: All datanodes
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
  ->  Sort
        Output: t1.c1, (avg(t2.c2)), t1.c2
        Sort Key: t1.c2
        ->  Hash Right Join
              Output: t1.c1, (avg(t2.c2)), t1.c2
              Hash Cond: (t2.c2 = t1.c2)
              ->  Streaming(type: BROADCAST)
                    Output: (avg(t2.c2)), t2.c2
                    Spawn on: All datanodes
                    Consumer Nodes: All datanodes
                    ->  HashAggregate
                          Output: avg(t2.c2), t2.c2
                          Group By Key: t2.c2
                          ->  Streaming(type: REDISTRIBUTE)
                                Output: t2.c2
                                Distribute Key: t2.c2
                                Spawn on: All datanodes
                                Consumer Nodes: All datanodes
                                ->  Seq Scan on public.t2
                                      Output: t2.c2
                                      Distribute Key: t2.c1
              ->  Hash
                    Output: t1.c1, t1.c2
                    ->  Seq Scan on public.t1
                          Output: t1.c1, t1.c2
                          Distribute Key: t1.c1
                          Filter: (t1.c1 < 100)
(31 rows)
```

uniquecheck: Performance Improvement of Subqueries Without Aggregate Functions

To ensure subquery pullup, each condition must have only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, as shown in the following example:

```
select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2);
```

Rewrite as follows:

```
select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by t2.c1(unique check)) tt(c1) on tt.c1=t1.c1;
```

Note that unique check in the preceding SQL statement indicates that **t2.c1** needs to be checked. If the SQL statement is abnormal, the SQL statement cannot be directly executed. To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```
gaussdb=# set rewrite_rule='uniquecheck';
SET
gaussdb=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1) ;
                            QUERY PLAN
------------------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c1
   Node/s: All datanodes
   ->  Nested Loop
         Output: t1.c1
         Join Filter: (t1.c1 = subquery."?column?")
         ->  Seq Scan on public.t1
               Output: t1.c1, t1.c2, t1.c3
               Distribute Key: t1.c1
         ->  Materialize
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            Output: subquery."?column?", subquery.c1
            ->  Subquery Scan on subquery
                  Output: subquery."?column?", subquery.c1
                  ->  HashAggregate
                        Output: t2.c1, t2.c1
                        Group By Key: t2.c1
                        Filter: (t2.c1 IS NOT NULL)
                        Unique Check Required   -- If more than one row of data is output during running, an
error is reported.
                        ->  Index Only Scan using t2idx on public.t2
                              Output: t2.c1
                              Distribute Key: t2.c1
(21 rows)
```

Note: Because **group by t2.c1 unique check** occurs before the filter condition **tt.c1=t1.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```
gaussdb=# select * from t1 order by c2;
 c1 | c2 | c3
----+----+----

```

predpush, predpushnormal, and predpushforce: Condition Pushdown to Subqueries

Generally, the optimizer performs optimization by query block, and different query blocks are independently optimized. If a predicate condition involving cross-query blocks exists, it is difficult to consider the location of a predicate application from a global perspective. The predpush may push down the predicate to the subquery block, so that performance can be improved in a scenario in which the data volume in the parent query block is relatively small and an index can be used in the subquery. There are three rewriting rules related to predpush:

- predpushnormal: attempts to push down predicates to subqueries. The STREAM operators, such as BROADCAST, are used to implement distributed plans.
- predpushforce: attempts to push down predicates to subqueries and uses the index of the parameterized path for scanning as much as possible.
- predpush: selects an optimal distributed plan from predpushnormal and predpushforce at a cost, but increases optimization time.

The following is an example of a plan for disabling and enabling the query rewriting rule:

```
gaussdb=# set enable_fast_query_shipping = off; -- Disable FQS optimization.
SET
gaussdb=# show rewrite_rule;
 rewrite_rule
--------------
 magicset
(1 row)

gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
             QUERY PLAN
------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         Join Filter: (t1.c1 = t2.c1)
         ->  HashAggregate
               Group By Key: t2.c1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            ->  Seq Scan on t2
      ->  Seq Scan on t1
(8 rows)

gaussdb=# set rewrite_rule='predpushnormal';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
              QUERY PLAN
---------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Seq Scan on t1
         ->  HashAggregate
               Group By Key: t2.c1
               ->  Result
                     Filter: (t1.c1 = t2.c1)
                     ->  Seq Scan on t2
(9 rows)

-- You can see that the filter criteria are pushed to the subquery for execution.

gaussdb=# set rewrite_rule='predpushforce';
SET

gaussdb=# explain (costs off) select /*+predpush(t1 st2)*/ * from t1, (select sum(c2), c1 from t2 group by
c1) st2 where st2.c1 = t1.c1;
                  QUERY PLAN
-----------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Seq Scan on t1
         ->  HashAggregate
               Group By Key: t2.c1
               ->  Index Scan using t2_c1_idx on t2
                     Index Cond: (t1.c1 = c1)
(8 rows)

-- When used together with predpush hints, you can see that parameterized paths are used.

gaussdb=# set rewrite_rule = 'predpush';
SET
gaussdb=# explain (costs off) select * from t1, (select sum(c2), c1 from t2 group by c1) st2 where st2.c1 =
t1.c1;
                  QUERY PLAN
-----------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Nested Loop
         ->  Seq Scan on t1
         ->  HashAggregate
               Group By Key: t2.c1
               ->  Index Scan using t2_c1_idx on t2
                     Index Cond: (t1.c1 = c1)
(8 rows)
```

Forbidding Pullup of Subquery Parameter disablerep for Replication Tables

When querying a replication table, the query actually takes effect on a DN only. Pulling up the subquery parameter **disablerep** may deteriorate the performance. The following is an example:

```
gaussdb=# create table t_rep(a int) distribute by replication;
CREATE TABLE
gaussdb=# create table t_dis(a int);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'a' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# set rewrite_rule = '';
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
                        QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Hash Left Join
         Hash Cond: (t_dis.a = subquery.a)
         Filter: ((subquery.a IS NOT NULL) OR (t_dis.a > 100))
         ->  Seq Scan on t_dis
         ->  Hash
               ->  Subquery Scan on subquery
                     Filter: (Hash By subquery.a)
                     ->  HashAggregate
                           Group By Key: t_rep.a
                           ->  Seq Scan on t_rep
(12 rows)
```

For a replication table, the data stored on all DNs is the same. Therefore, you do not need to scan the replication table on all nodes.

```
gaussdb=# set rewrite_rule = disablerep;
SET
gaussdb=# explain (costs off) select * from t_dis where a = any(select a from t_rep) or a > 100;
                   QUERY PLAN
-------------------------------------------------
 Streaming (type: GATHER)
   Node/s: All datanodes
   ->  Seq Scan on t_dis
         Filter: ((hashed SubPlan 1) OR (a > 100))
         SubPlan 1
           ->  Seq Scan on t_rep
(6 rows
```

6.14.9 Case: Adjusting the GUC Parameter costbased_rewrite_rule for Cost-based Query Rewriting

Query rewriting allows the optimizer to select different execution paths. However, performance will not be improved after some rules rewrite the SQL statements. A rewriting error may result in a 1,000-fold performance difference. Therefore, in the query rewriting phase, the cost-based evaluation policy needs to be supported for such rules to determine whether to apply the rules to rewrite SQL statements. These rules are controlled by the GUC parameter **costbased_rewrite_rule**. For details about the controlled rules, see **Table 6-9**.

Table 6-9 Control rules supported by GUC costbased_rewrite_rule

Parameter	Description
none	Does not use any cost-based query rewriting policy.
pullup_subquery	The cost-based query rewriting policy is enabled for the rewriting rules of simple subquery expansion.
pullup_sublink_any_exists	The cost-based query rewriting policy is enabled for the rewriting rules of non-correlated sublinks of the ANY type and related sublinks of the [NOT] EXISTS type in a single or AND condition.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description
pullup_not_in_sublink	The cost-based query rewriting policy is enabled for the rewriting rules of non-correlated sublinks of the NOT IN type in a single or AND condition. This parameter is mutually exclusive with the **disable_pullup_not_in_sublink** parameter of the GUC parameter **rewrite_rule**. When this parameter is enabled, the **disable_pullup_not_in_sublink** parameter of the GUC parameter **rewrite_rule** does not take effect.
pullup_expr_sublink	This parameter takes effect in the rewriting scenarios of expression sublinks, non-correlated sublinks of the ANY type, and related sublinks of [NOT] the EXISTS type in the OR condition. This parameter is mutually exclusive with the **disable_pullup_expr_sublink**, **enable_sublink_pullup_enhanced**, and **magicset** parameters of the GUC parameter **rewrite_rule**. When this parameter is enabled, the related parameters of the GUC parameter **rewrite_rule** do not take effect.
intargetlist	The cost-based query rewriting policy is enabled for the rewriting rules of the sublinks of related expression in the TargetList. This parameter is mutually exclusive with the **intargetlist** and **magicset** parameters of the GUC parameter **rewrite_rule**. When this parameter is enabled, the **intargetlist** and **magicset** parameters of the GUC parameter **rewrite_rule** do not take effect.
enable_sublink_pullup_enhanced	The cost-based query rewriting policy is enabled for the rewriting rules of expression sublinks in the enhanced scenario. This parameter is affected by the **pullup_expr_sublink** parameter. This parameter takes effect only when the **pullup_expr_sublink** parameter is enabled for the expression sublink rewriting scenario in the AND condition. This parameter is mutually exclusive with the **enable_sublink_pullup_enhanced** parameter of the GUC parameter **rewrite_rule**. When this parameter is enabled, the **enable_sublink_pullup_enhanced** parameter of the GUC parameter **rewrite_rule** does not take effect.

The following uses typical cases to describe the application scenarios of the query rewriting rules controlled by the preceding parameters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTICE

In distributed scenarios, the cost-based rewriting policy preferentially selects the STREAM plan. If the STREAM plan cannot be generated before and after the rewriting, the STREAM plan is degraded to the PGXC plan. However, if the generated PGXC plan is pushed down to DNs, the cost information on the CNs is inaccurate. Therefore, when a plan is generated in this scenario, query rewriting is performed based on rules. See an example in **Using Rule-based Query Rewriting when PGXC Plans Are Generated**.

Preparing the Case Environment

To demonstrate rule application scenarios, you need to prepare the following table creation statements:

```
SET client_min_messages = warning;
SET CLIENT_ENCODING = 'UTF8';
-- Clean the environment.
DROP SCHEMA IF EXISTS costbased_rule_test cascade;
CREATE SCHEMA costbased_rule_test;
SET current_schema = costbased_rule_test;
SET enable_codegen = off;
DROP TABLE IF EXISTS costbased_rule_test.ct1;
DROP TABLE IF EXISTS costbased_rule_test.ct2;
DROP TABLE IF EXISTS costbased_rule_test.ct3;
DROP TABLE IF EXISTS costbased_rule_test.ct4;
-- Create a test table.
CREATE TABLE ct1 (a INT, b INT, c INT, d INT);
CREATE TABLE ct2 (a INT, b INT, c INT, d INT);
CREATE TABLE ct3 (a INT, b INT, c INT, d INT);
CREATE TABLE ct4 (a INT, b INT, c INT, d INT);
CREATE INDEX idx_ct1_b ON ct1(b);
CREATE INDEX idx_ct2_c ON ct2(c);
CREATE INDEX idx_ct3_c ON ct3(c);
-- Insert data.
INSERT INTO ct1 (a, b, c) VALUES (generate_series(1, 100), generate_series(200, 300), left(random()::int,
100));
INSERT INTO ct2 VALUES(1,2,3,4),(3,4,5,6);
INSERT INTO ct3 (a, b, c, d) VALUES (generate_series(1, 10), generate_series(20, 30), left(random()::int, 10),
left(random()::int, 10));
-- Update statistics.
ANALYZE ct1;
ANALYZE ct2;
ANALYZE ct3;
```

Rewriting Rules of Non-correlated Sublinks in the Having Condition

SQL statements can be rewritten when the Having condition contains non-correlated expression sublinks with AGG. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=enable_sublink_pullup_enhanced;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=#  EXPLAIN SELECT ct2.a, SUM(ct2.b) AS value FROM ct2,ct1 WHERE ct2.a = ct1.b GROUP BY ct2.a
HAVING SUM(ct2.b) >= (SELECT AVG(ct2.b) FROM ct2,ct1 WHERE ct2.a = ct1.b) ORDER BY value DESC;
                                                 QUERY PLAN

-------------------------------------------------------------------------------------------------------------------------
-------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------------
 Streaming (type: GATHER)  (cost=5.31..5.37 rows=3 width=12)
   Merge Sort Key: (pg_catalog.sum((sum(costbased_rule_test.ct2.b)))) DESC
   Node/s: All datanodes
   ->  Sort  (cost=5.24..5.25 rows=3 width=12)
         Sort Key: (pg_catalog.sum((sum(costbased_rule_test.ct2.b)))) DESC
         ->  Nested Loop  (cost=5.13..5.23 rows=1 width=12)
               Join Filter: (((pg_catalog.sum((sum(costbased_rule_test.ct2.b))))::numeric >=
(pg_catalog.avg((avg(costbased_rule_tes
t.ct2.b)))))
               ->  HashAggregate  (cost=2.79..2.80 rows=2 width=24)

                                                   Spawn on: All datanodes
                                                   ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
               ->  Materialize  (cost=2.33..2.41 rows=3 width=32)
                     ->  Aggregate  (cost=2.33..2.40 rows=3 width=36)
                           ->  Streaming(type: BROADCAST)  (cost=2.33..2.40 rows=9 width=36)
                                 Spawn on: All datanodes
                                 ->  Aggregate  (cost=2.33..2.34 rows=3 width=36)
                                       ->  Merge Join  (cost=1.46..2.16 rows=200 width=4)
                                             Merge Cond: (costbased_rule_test.ct1.b = costbased_rule_test.ct2.a)
                                             ->  Index Only Scan using idx_ct1_b on ct1  (cost=0.00..90.75 rows=10100
width=4)
                                             ->  Sort  (cost=1.29..1.30 rows=6 width=8)
                                                   Sort Key: costbased_rule_test.ct2.a
                                                   ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=8)
                                                         Spawn on: All datanodes
                                                         ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
(34 rows)
```

When **costbased_rewrite_rule** is set to **pullup_expr_sublink,enable_sublink_pullup_enhanced**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting SQL statements is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=enable_sublink_pullup_enhanced;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_expr_sublink,enable_sublink_pullup_enhanced;
SET
gaussdb=# EXPLAIN SELECT ct2.a, SUM(ct2.b) AS value FROM ct2,ct1 WHERE ct2.a = ct1.b GROUP BY ct2.a
HAVING SUM(ct2.b) >= (SELECT AVG(ct2.b) FROM ct2,ct1 WHERE ct2.a = ct1.b) ORDER BY value DESC;
                                        QUERY PLAN

-----------------------------------------------------------------------------------------------------------------------
---
 Sort  (cost=5.35..5.35 rows=2 width=24)
   Sort Key: (pg_catalog.sum((sum(costbased_rule_test.ct2.b)))) DESC
   InitPlan 1 (returns $0)
     ->  Streaming (type: GATHER)  (cost=2.52..2.58 rows=3 width=36)
           Node/s: All datanodes
           ->  Aggregate  (cost=2.33..2.40 rows=3 width=36)
                 ->  Streaming(type: BROADCAST)  (cost=2.33..2.40 rows=9 width=36)
                       Spawn on: All datanodes
                       ->  Aggregate  (cost=2.33..2.34 rows=3 width=36)
                             ->  Merge Join  (cost=1.46..2.16 rows=200 width=4)
                                   Merge Cond: (costbased_rule_test.ct1.b = costbased_rule_test.ct2.a)
                                   ->  Index Only Scan using idx_ct1_b on ct1  (cost=0.00..90.75 rows=10100 width=
4)
```

```
                          ->  Sort  (cost=1.29..1.30 rows=6 width=8)
                                Sort Key: costbased_rule_test.ct2.a
                                ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=8)
                                      Spawn on: All datanodes
                                      ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
  ->  HashAggregate  (cost=2.79..2.94 rows=2 width=24)
        Group By Key: costbased_rule_test.ct2.a
        Filter: ((pg_catalog.sum((sum(costbased_rule_test.ct2.b))))::numeric >= $0)
        ->  Streaming (type: GATHER)  (cost=2.79..2.94 rows=6 width=24)
              Node/s: All datanodes
              ->  HashAggregate  (cost=2.66..2.69 rows=6 width=24)
                    Group By Key: costbased_rule_test.ct2.a
                    ->  Merge Join  (cost=1.46..2.16 rows=200 width=8)
                          Merge Cond: (costbased_rule_test.ct1.b = costbased_rule_test.ct2.a)
                          ->  Index Only Scan using idx_ct1_b on ct1  (cost=0.00..90.75 rows=10100 width=4)
                          ->  Sort  (cost=1.29..1.30 rows=6 width=8)
                                Sort Key: costbased_rule_test.ct2.a
                                ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=8)
                                      Spawn on: All datanodes
                                      ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
(32 rows)
```

CAUTION

costbased_rewrite_rule=pullup_expr_sublink,enable_sublink_pullup_enhanced is mutually exclusive with **rewrite_rule=disable_pullup_expr_sublink** and **rewrite_rule=enable_sublink_pullup_enhanced**, and the value of **costbased_rewrite_rule** precedes that of **rewrite_rule**.

Pulling Up Non-correlated Sublinks of ANY/IN Type in the AND Condition

SQL statements can be rewritten when a single or AND condition contains non-correlated sublinks of ANY/IN type. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE ct2.a IN (SELECT a FROM ct1 WHERE ct1.c > 500 AND
ct1.a = 10);
                        QUERY PLAN
------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.19..66.72 rows=3 width=16)
   Node/s: datanode2
   ->  Nested Loop Semi Join  (cost=0.00..66.53 rows=3 width=16)
         ->  Seq Scan on ct2  (cost=0.00..1.01 rows=1 width=16)
               Filter: (a = 10)
         ->  Seq Scan on ct1  (cost=0.00..65.50 rows=1 width=4)
               Filter: ((c > 500) AND (a = 10))
(7 rows)
```

When **costbased_rewrite_rule** is set to **pullup_sublink_any_exists**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting SQL statements is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_sublink_any_exists;
SET
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE ct2.a IN (SELECT a FROM ct1 WHERE ct1.c > 500 AND
ct1.a = 10);
                                QUERY PLAN
-------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=65.59..66.66 rows=1 width=16)
   Node/s: All datanodes
   ->  Seq Scan on ct2  (cost=65.52..66.54 rows=1 width=16)
         Filter: (hashed SubPlan 1)
         SubPlan 1
           ->  Materialize  (cost=0.00..65.52 rows=9 width=4)
                 ->  Streaming(type: BROADCAST)  (cost=0.00..65.51 rows=3 width=4)
                       Spawn on: datanode2
                       ->  Seq Scan on ct1  (cost=0.00..65.50 rows=1 width=4)
                             Filter: ((c > 500) AND (a = 10))
(10 rows)
```

NOTE

This scenario is controlled only by the GUC parameter **costbased_rewrite_rule=pullup_sublink_any_exists**. The GUC parameter **rewrite_rule** does not have related control parameters.

Pulling Up Related Sublinks of [NOT]EXISTS Type in the AND Condition

SQL statements can be rewritten when a single or AND condition contains related sublinks of [NOT]EXISTS type. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE EXISTS (SELECT 1 FROM ct3 WHERE ct3.b = ct2.c AND
ct3.c < 1000);
                                   QUERY PLAN
--------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.66..5.95 rows=2 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=4.60..5.82 rows=2 width=16)
         Join Filter: (ct2.c = ct3.b)
         ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..1.13 rows=2 width=16)
               Spawn on: All datanodes
               ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=16)
         ->  Materialize  (cost=4.60..4.65 rows=11 width=4)
               ->  HashAggregate  (cost=4.60..4.64 rows=11 width=4)
                     Group By Key: ct3.b
                     ->  Streaming(type: REDISTRIBUTE)  (cost=3.55..4.57 rows=33 width=4)
                           Spawn on: All datanodes
                           ->  HashAggregate  (cost=3.55..3.66 rows=33 width=4)
                                 Group By Key: ct3.b
                                 ->  Seq Scan on ct3  (cost=0.00..3.46 rows=110 width=4)
                                       Filter: (c < 1000)
(16 rows)
```

When **costbased_rewrite_rule** is set to **pullup_sublink_any_exists**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting SQL statements is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_sublink_any_exists;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE EXISTS (SELECT 1 FROM ct3 WHERE ct3.b = ct2.c AND
ct3.c < 1000);
```

```
                                QUERY PLAN
-------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=0.06..1.26 rows=1 width=16)
   Node/s: All datanodes
   ->  Seq Scan on ct2  (cost=0.00..1.14 rows=1 width=16)
         Filter: (SubPlan 1)
         SubPlan 1
           ->  Result  (cost=0.00..14.02 rows=330 width=4)
                 Filter: (ct3.b = ct2.c)
                 ->  Materialize  (cost=0.00..14.02 rows=330 width=4)
                       ->  Streaming(type: BROADCAST)  (cost=0.00..13.47 rows=330 width=4)
                             Spawn on: All datanodes
                             ->  Seq Scan on ct3  (cost=0.00..3.46 rows=110 width=4)
                                   Filter: (c < 1000)
(12 rows)
```

NOTE

This scenario is controlled only by the GUC parameter **costbased_rewrite_rule=pullup_sublink_any_exists**. The GUC parameter **rewrite_rule** does not have related control parameters.

Pulling Up Non-correlated Sublinks of NOT IN Type in the AND Condition

SQL statements can be rewritten when a single or AND condition contains non-correlated sublinks of NOT IN type. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE ct1.b NOT IN (SELECT a FROM ct3);
                              QUERY PLAN
-----------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..5681.51 rows=9100 width=16)
   Node/s: All datanodes
   ->  Nested Loop Anti Join  (cost=0.00..5302.39 rows=9100 width=16)
         Join Filter: ((ct1.b = ct3.a) OR (ct1.b IS NULL) OR (ct3.a IS NULL))
         ->  Seq Scan on ct1  (cost=0.00..48.67 rows=10100 width=16)
         ->  Materialize  (cost=0.00..13.93 rows=330 width=4)
               ->  Streaming(type: BROADCAST)  (cost=0.00..13.38 rows=330 width=4)
                     Spawn on: All datanodes
                     ->  Seq Scan on ct3  (cost=0.00..3.37 rows=110 width=4)
(9 rows)
```

When **costbased_rewrite_rule** is set to **pullup_not_in_sublink**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting SQL statements is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_not_in_sublink;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE ct1.b NOT IN (SELECT a FROM ct3);
                              QUERY PLAN
-----------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=8.96..272.42 rows=5050 width=16)
   Node/s: All datanodes
   ->  Seq Scan on ct1  (cost=4.96..62.05 rows=5050 width=16)
         Filter: (NOT (hashed SubPlan 1))
         SubPlan 1
           ->  Materialize  (cost=0.00..4.14 rows=990 width=4)
                 ->  Streaming(type: BROADCAST)  (cost=0.00..3.59 rows=330 width=4)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                  Spawn on: All datanodes
                  ->  Seq Scan on ct3  (cost=0.00..3.37 rows=110 width=4)
(9 rows)
```

CAUTION

costbased_rewrite_rule=pullup_not_in_sublink is mutually exclusive with **rewrite_rule=disable_pullup_not_in_sublink**, and **costbased_rewrite_rule** precedes **rewrite_rule**.

Pulling Up Expression Sublinks in the AND Condition

SQL statements can be rewritten when a single or AND condition contains related sublinks of expression type. If both the rule-based and cost-based query rewriting evaluation policies are disabled, sublinks are not rewritten. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=disable_pullup_expr_sublink;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT 1)
AND ct1.b > 50;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=1.07..4454.57 rows=50 width=16)
   Node/s: All datanodes
   ->  Seq Scan on ct1  (cost=0.01..4452.44 rows=50 width=16)
         Filter: ((b > 50) AND (a = (SubPlan 1)))
         SubPlan 1
           ->  Limit  (cost=1.30..1.30 rows=3 width=8)
                 ->  Sort  (cost=1.30..1.31 rows=3 width=8)
                       Sort Key: ct2.a
                       ->  Result  (cost=0.00..1.29 rows=6 width=8)
                             Filter: (ct2.b = ct1.b)
                             ->  Materialize  (cost=0.00..1.29 rows=6 width=8)
                                   ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=8)
                                         Spawn on: All datanodes
                                         ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
(14 rows)
```

When **costbased_rewrite_rule** is set to **pullup_expr_sublink**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated after SQL statements are rewritten is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=disable_pullup_expr_sublink;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_expr_sublink;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT 1)
AND ct1.b > 50;
                                                QUERY PLAN
-----------------------------------------------------------------------------------------------------------------------------------------
-
 Streaming (type: GATHER)  (cost=1.31..1.83 rows=3 width=16)
   Node/s: All datanodes
   ->  Merge Join  (cost=1.25..1.71 rows=3 width=16)
         Merge Cond: (subquery."?column?" = ct1.b)
         Join Filter: (ct1.a = subquery.a)
         ->  Sort  (cost=1.24..1.24 rows=1 width=8)
               Sort Key: subquery."?column?"
               ->  Streaming(type: REDISTRIBUTE)  (cost=1.05..1.23 rows=1 width=8)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                Spawn on: All datanodes
                ->  Subquery Scan on subquery  (cost=1.05..1.08 rows=1 width=8)
                      Filter: (subquery."?column?" OPERATOR(pg_catalog.=) 1::bigint)
                      ->  WindowAgg  (cost=1.05..1.07 rows=1 width=8)
                            row_number_filter: (row_number() OVER (PARTITION BY ct2.b)
OPERATOR(pg_catalog.<=) 1::bigint)
                            ->  Sort  (cost=1.05..1.06 rows=1 width=8)
                                  Sort Key: ct2.b
                                  ->  Streaming(type: REDISTRIBUTE)  (cost=1.01..1.04 rows=1 width=8)
                                        Spawn on: All datanodes
                                        ->  Seq Scan on ct2  (cost=1.01..1.01 rows=1 width=8)
                                              Filter: (b > 50)
      ->  Index Scan using idx_ct1_b on ct1  (cost=0.00..159.16 rows=10099 width=16)
            Index Cond: (b > 50)
(21 rows)
```

CAUTION

costbased_rewrite_rule=pullup_expr_sublink is mutually exclusive with **rewrite_rule=disable_pullup_expr_sublink**, **rewrite_rule=enable_sublink_pullup_enhanced**, and **rewrite_rule=magicset**, and **costbased_rewrite_rule** precedes **rewrite_rule**.

Rewriting SQL Statements when the Expression Sublinks in the AND Condition Meet the MAGICSET Pushdown Rules

SQL statements can be rewritten when a single or AND condition contains related sublinks of expression type and MagicSet pushdown rules can push down some filter criteria to the sublinks. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=magicset;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE  ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT 1)
AND ct1.c=10;
                                                QUERY PLAN
-----------------------------------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=62.95..78.78 rows=3 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=62.89..78.66 rows=3 width=16)
         ->  Streaming(type: REDISTRIBUTE)  (cost=58.39..58.57 rows=1 width=8)
               Spawn on: All datanodes
               ->  Subquery Scan on subquery  (cost=58.39..58.43 rows=1 width=8)
                     Filter: (subquery."?column?" OPERATOR(pg_catalog.=) 1::bigint)
                     ->  WindowAgg  (cost=58.39..58.42 rows=3 width=8)
                           row_number_filter: (row_number() OVER (PARTITION BY ct2.b)
OPERATOR(pg_catalog.<=) 1::bigint)
                           ->  Sort  (cost=58.39..58.40 rows=3 width=8)
                                 Sort Key: ct2.b
                                 ->  Nested Loop Semi Join  (cost=0.00..58.38 rows=3 width=8)
                                       Join Filter: (ct2.b = costbased_rule_test.ct1.b)
                                       ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..1.13 rows=2 width=8)
                                             Spawn on: All datanodes
                                             ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
                                       ->  Materialize  (cost=0.00..57.24 rows=1 width=4)
                                             ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..57.23 rows=1 width=4)
                                                   Spawn on: All datanodes
                                                   ->  Seq Scan on ct1  (cost=0.00..57.09 rows=1 width=4)
                                                         Filter: (c = 10)
         ->  Bitmap Heap Scan on ct1  (cost=4.50..20.08 rows=1 width=16)
               Recheck Cond: (b = subquery."?column?")
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            Filter: ((c = 10) AND (subquery.a = a))
            ->  Bitmap Index Scan on idx_ct1_b  (cost=0.00..4.50 rows=100 width=0)
                  Index Cond: (b = subquery."?column?")
(26 rows)
```

When **costbased_rewrite_rule** is set to **pullup_expr_sublink**, the optimizer evaluates whether to rewrite the MagicSet pushdown conditions of sublinks based on the cost. In this scenario, the plan generated without rewriting MagicSet is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=magicset;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_expr_sublink;
SET
gaussdb=# EXPLAIN SELECT * FROM ct1 WHERE  ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT
1)  AND ct1.c=10;
                                                 QUERY PLAN
------------------------------------------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=5.61..21.43 rows=3 width=16)
   Node/s: All datanodes
   ->  Nested Loop  (cost=5.54..21.31 rows=3 width=16)
         ->  Streaming(type: REDISTRIBUTE)  (cost=1.05..1.22 rows=1 width=8)
               Spawn on: All datanodes
               ->  Subquery Scan on subquery  (cost=1.05..1.08 rows=1 width=8)
                     Filter: (subquery."?column?" OPERATOR(pg_catalog.=) 1::bigint)
                     ->  WindowAgg  (cost=1.05..1.07 rows=1 width=8)
                           row_number_filter: (row_number() OVER (PARTITION BY ct2.b)
OPERATOR(pg_catalog.<=) 1::bigint)
                           ->  Sort  (cost=1.05..1.05 rows=1 width=8)
                                 Sort Key: ct2.b
                                 ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..1.04 rows=2 width=8)
                                       Spawn on: All datanodes
                                       ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
         ->  Bitmap Heap Scan on ct1  (cost=4.50..20.08 rows=1 width=16)
               Recheck Cond: (b = subquery."?column?")

Pulling Up Expression Sublinks in the OR Condition

SQL statements can be rewritten when an OR condition contains related sublinks of expression type. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE ct2.a = (SELECT min(b) FROM ct1 WHERE ct1.b = ct2.c)
OR ct2.b = (SELECT sum(a) FROM ct3 WHERE ct3.a = ct2.c);
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=73.05..75.50 rows=3 width=16)
   Node/s: All datanodes
   ->  Nested Loop Left Join  (cost=72.99..75.38 rows=3 width=16)
         Join Filter: (ct3.a = ct2.c)
         Filter: ((ct2.a = (min((min(ct1.b)))))) OR (ct2.b = (sum(ct3.a))))
         ->  Nested Loop Left Join  (cost=69.43..71.67 rows=2 width=20)
               Join Filter: (ct1.b = ct2.c)
               ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..1.13 rows=2 width=16)
                     Spawn on: All datanodes
                     ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=16)
               ->  Materialize  (cost=69.43..70.20 rows=101 width=8)
                     ->  HashAggregate  (cost=69.43..69.77 rows=101 width=8)
                           Group By Key: ct1.b
                           ->  Streaming(type: REDISTRIBUTE)  (cost=65.51..68.93 rows=303 width=8)
                                 Spawn on: All datanodes
                                 ->  HashAggregate  (cost=65.51..66.52 rows=303 width=8)
                                       Group By Key: ct1.b
                                       ->  Seq Scan on ct1  (cost=0.00..48.67 rows=10100 width=4)
         ->  HashAggregate  (cost=3.55..3.59 rows=12 width=12)
               Group By Key: ct3.a
               ->  Seq Scan on ct3  (cost=0.00..3.37 rows=110 width=4)
(21 rows)
```

When **costbased_rewrite_rule** is set to **pullup_expr_sublink**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_expr_sublink;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2 WHERE ct2.a = (SELECT min(b) FROM ct1 WHERE ct1.b = ct2.c)
OR ct2.b = (SELECT sum(a) FROM ct3 WHERE ct3.a = ct2.c);

CAUTION

costbased_rewrite_rule=pullup_expr_sublink is mutually exclusive with **rewrite_rule=disable_pullup_expr_sublink**, **rewrite_rule=enable_sublink_pullup_enhanced**, and **rewrite_rule=magicset**, and **costbased_rewrite_rule** precedes **rewrite_rule**.

Pulling Up the Related Sublinks of the Expression Type in TargetList

SQL statements can be rewritten when TargetList contains related sublinks of expression type. If both the rule-based and cost-based query rewriting evaluation policies are disabled, sublinks are not rewritten. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT *, ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT 1)  FROM ct1
WHERE ct1.b >50;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..4871.89 rows=10099 width=16)
   Node/s: All datanodes
   ->  Seq Scan on ct1  (cost=0.00..4451.14 rows=10099 width=16)
       Filter: (b > 50)
       SubPlan 1
         ->  Limit  (cost=1.30..1.30 rows=3 width=8)
             ->  Sort  (cost=1.30..1.31 rows=3 width=8)
                 Sort Key: ct2.a
                 ->  Result  (cost=0.00..1.29 rows=6 width=8)
                     Filter: (ct2.b = ct1.b)
                     ->  Materialize  (cost=0.00..1.29 rows=6 width=8)
                         ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=8)
                             Spawn on: All datanodes
                             ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
(14 rows)
```

When **costbased_rewrite_rule** is set to **intargetlist**, the optimizer evaluates whether to rewrite sublinks based on the cost. In this scenario, the plan generated without rewriting is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=intargetlist;
SET
gaussdb=# EXPLAIN SELECT *, ct1.a = (SELECT a FROM ct2 WHERE ct2.b = ct1.b LIMIT 1)  FROM ct1
WHERE ct1.b >50;
                                        QUERY PLAN
-----------------------------------------------------------------------------------------------------------------------
-
 Streaming (type: GATHER)  (cost=5.36..496.38 rows=10099 width=20)

rows=
100 width=0)
                                                                Index Cond: (b = 10)
(33 rows)
```

When **costbased_rewrite_rule** is set to **intargetlist**, the optimizer evaluates whether to rewrite the MagicSet pushdown conditions of sublinks based on the cost. In this scenario, the plan generated without rewriting MagicSet is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=intargetlist,magicset;
SET
gaussdb=# SET costbased_rewrite_rule=intargetlist;
SET
gaussdb=# EXPLAIN SELECT *,ct1.a = (SELECT a FROM ct2 WHERE ct2.c = ct1.c LIMIT 1) FROM ct1 WHERE
ct1.b=10;
                                                 QUERY PLAN
------------------------------------------------------------------------------------------------------------------------------------------
-
 Streaming (type: GATHER)  (cost=7.93..25.74 rows=100 width=20)
   Node/s: All datanodes
   ->  Hash Left Join  (cost=5.87..21.62 rows=100 width=20)
        Hash Cond: (ct1.c = subquery."?column?")
        ->  Bitmap Heap Scan on ct1  (cost=4.51..19.92 rows=100 width=16)
             Recheck Cond: (b = 10)
             ->  Bitmap Index Scan on idx_ct1_b  (cost=0.00..4.50 rows=100 width=0)
                  Index Cond: (b = 10)
        ->  Hash  (cost=1.35..1.35 rows=3 width=8)
             ->  Streaming(type: BROADCAST)  (cost=1.05..1.35 rows=3 width=8)
                  Spawn on: All datanodes
                  ->  Subquery Scan on subquery  (cost=1.05..1.08 rows=1 width=8)
                       Filter: (subquery."?column?" OPERATOR(pg_catalog.=) 1::bigint)
                       ->  WindowAgg  (cost=1.05..1.07 rows=1 width=8)
                            row_number_filter: (row_number() OVER (PARTITION BY ct2.c)
OPERATOR(pg_catalog.<=) 1::bigint)
                            ->  Sort  (cost=1.05..1.05 rows=1 width=8)
                                 Sort Key: ct2.c
                                 ->  Streaming(type: REDISTRIBUTE)  (cost=0.00..1.04 rows=2 width=8)
                                      Spawn on: All datanodes
                                      ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=8)
(20 rows)
```

CAUTION

costbased_rewrite_rule=intargetlist is mutually exclusive with **rewrite_rule=intargetlist** and **rewrite_rule=magicset**, and **costbased_rewrite_rule** precedes **rewrite_rule**.

Rewriting SQL Statements when Simple Subqueries Exist

SQL statements can be rewritten when simple subqueries exist. If the cost-based query rewriting evaluation policy is disabled, sublinks are rewritten based on rules. The generation plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=none;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2,(SELECT ct1.* FROM ct1,ct2,ct3 WHERE ct1.c > 10 AND ct1.a = 10)
ct WHERE ct.a = ct2.d;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=4.00..100.52 rows=660 width=32)
   Node/s: All datanodes
   ->  Nested Loop  (cost=0.00..73.02 rows=660 width=32)
         ->  Nested Loop  (cost=0.00..69.52 rows=110 width=16)
               ->  Streaming(type: BROADCAST)  (cost=0.00..65.78 rows=3 width=16)
                     Spawn on: datanode2
                     ->  Seq Scan on ct1  (cost=0.00..65.50 rows=1 width=16)
                           Filter: ((c > 10) AND (a = 10))
               ->  Seq Scan on ct3  (cost=0.00..3.37 rows=110 width=0)
         ->  Materialize  (cost=0.00..2.58 rows=6 width=16)
               ->  Streaming(type: BROADCAST)  (cost=0.00..2.57 rows=6 width=16)
                     Spawn on: All datanodes
                     ->  Nested Loop  (cost=0.00..2.30 rows=2 width=16)
                           ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=0)
                           ->  Materialize  (cost=0.00..1.29 rows=3 width=16)
                                 ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=3 width=16)
                                       Spawn on: All datanodes
                                       ->  Seq Scan on ct2  (cost=0.00..1.01 rows=1 width=16)
                                             Filter: (d = 10)
(19 rows)
```

When **costbased_rewrite_rule** is set to **pullup_subquery**, the optimizer evaluates whether to rewrite simple subqueries based on the cost. In this scenario, the plan generated without rewriting simple subqueries is better. The generated plan is as follows:

```
gaussdb=# SET rewrite_rule=none;
SET
gaussdb=# SET costbased_rewrite_rule=pullup_subquery;
SET
gaussdb=# EXPLAIN SELECT * FROM ct2,(SELECT ct1.* FROM ct1,ct2,ct3 WHERE ct1.c > 10 AND ct1.a = 10)
ct WHERE ct.a = ct2.d;
                                    QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Streaming (type: GATHER)  (cost=1.37..73.72 rows=4 width=32)
   Node/s: All datanodes
   ->  Hash Join  (cost=1.31..73.60 rows=4 width=32)
         Hash Cond: (ct1.a = costbased_rule_test.ct2.d)
         ->  Nested Loop  (cost=0.00..71.37 rows=220 width=16)
               ->  Seq Scan on ct3  (cost=0.00..3.37 rows=110 width=0)
               ->  Materialize  (cost=0.00..67.08 rows=6 width=16)
                     ->  Streaming(type: BROADCAST)  (cost=0.00..67.07 rows=6 width=16)
                           Spawn on: All datanodes
                           ->  Nested Loop  (cost=0.00..66.80 rows=2 width=16)
                                 ->  Streaming(type: BROADCAST)  (cost=0.00..65.78 rows=3 width=16)
                                       Spawn on: datanode2
                                       ->  Seq Scan on ct1  (cost=0.00..65.50 rows=1 width=16)
                                             Filter: ((c > 10) AND (a = 10))
                                 ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=0)
         ->  Hash  (cost=1.28..1.28 rows=6 width=16)
               ->  Streaming(type: BROADCAST)  (cost=0.00..1.28 rows=6 width=16)
                     Spawn on: All datanodes
                     ->  Seq Scan on ct2  (cost=0.00..1.01 rows=2 width=16)
(19 rows)
```

Using Rule-based Query Rewriting when PGXC Plans Are Generated

When a PGXC plan is generated, the cost of the DN execution plan is incorrectly calculated. As a result, the result of cost-based plan comparison is inaccurate, and cost-based query rewriting is degraded to rule-based query rewriting.

The following plan is better because EXISTS sublinks are pulled up after rule-based rewriting:

```
gaussdb=# SET enable_stream_operator=off;
SET
gaussdb=# SET costbased_rewrite_rule= pullup_sublink_any_exists;
SET
gaussdb=# EXPLAIN ANALYZE  SELECT * FROM ct3 WHERE EXISTS (SELECT 1 from ct1 WHERE ct1.a = ct3.a
AND ct1.c < 1000);
                                                
```

6.14.10 Case: Using Global Secondary Indexes to Accelerate Query

Index-only Scanning of Global Secondary Indexes

When non-distribution keys in the base table are queried, DN pushdown query or index scanning cannot be performed, deteriorating performance problems.

- Scenario 1: common query

```
gaussdb=# CREATE TABLE t (a INT, b INT, c INT) DISTRIBUTE BY HASH(a);
CREATE TABLE
gaussdb=# INSERT INTO t VALUES(generate_series(1,1000), generate_series(1,1000),
generate_series(1,1000));
INSERT 0 1000
gaussdb=# CREATE INDEX i ON t(b);
CREATE INDEX
gaussdb=# SET MAX_DATANODE_FOR_PLAN = 1;
SET
gaussdb=# SET ENABLE_FAST_QUERY_SHIPPING = TRUE;
SET
gaussdb=# SET ENABLE_LIGHT_PROXY = TRUE;
SET
gaussdb=# SET ENABLE_STREAM_OPERATOR = FALSE;
SET
gaussdb=# -- Point query. The query condition is not a distribution key. Push down all DNs and use
ordinary indexes for query on DNs.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF)  SELECT b FROM t WHERE b = 1;
                    QUERY PLAN
-----------------------------------------------------
 Data Node Scan
   Output: t.b
   Node/s: All datanodes
   Remote query: SELECT b FROM public.t WHERE b = 1

 Remote SQL: SELECT b FROM public.t WHERE b = 1
 Datanode Name: datanode1
   [Bypass]
   Index Only Scan using i on public.t
     Output: b
     Index Cond: (t.b = 1)

(12 rows)

gaussdb=#  -- Sequentially scan all DNs in a range query.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF)  SELECT b FROM t WHERE b <= 10;
                     QUERY PLAN
-----------------------------------------------------
 Data Node Scan
   Output: t.b
   Node/s: All datanodes
   Remote query: SELECT b FROM public.t WHERE b <= 10

 Remote SQL: SELECT b FROM public.t WHERE b <= 10
 Datanode Name: datanode1
   Seq Scan on public.t
     Output: b
     Filter: (t.b <= 10)

(11 rows)
```

  You can create a global secondary index to push down the preceding query to DNs and use index scanning to accelerate the query. (To use the GSI to optimize query, enable **ENABLE_GSISCAN** parameter and **ENABLE_FAST_QUERY_SHIPPING** parameter.)

```
gaussdb=# DROP INDEX i;
DROP INDEX
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# -- Create a global secondary index.
gaussdb=# CREATE GLOBAL INDEX gsi_t ON t(b);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'b' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE GLOBAL INDEX
gaussdb=#  -- Point query. The query condition falls on the distribution key of the global secondary index. A single DN is pushed down and the index is used to scan the query.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT b FROM t WHERE b = 1;
                        QUERY PLAN
------------------------------------------------------------------
 Data Node Scan
   Output: gsi_t.b
   Node/s: datanode1
   Remote query: SELECT b FROM ONLY public.gsi_t WHERE b = 1

 Remote SQL: SELECT b FROM ONLY public.gsi_t WHERE b = 1
 Datanode Name: datanode1
   [Bypass]
   Index Only Scan using gsi_t on public.gsi_t
     Output: b
     Index Cond: (gsi_t.b = 1)

(12 rows)

gaussdb=#  -- Range query. All DNs are pushed down and the index is used to scan the query.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT b FROM t WHERE b <= 10;
                        QUERY PLAN
------------------------------------------------------------------
 Data Node Scan
   Output: gsi_t.b
   Node/s: All datanodes
   Remote query: SELECT b FROM ONLY public.gsi_t WHERE b <= 10

 Remote SQL: SELECT b FROM ONLY public.gsi_t WHERE b <= 10
 Datanode Name: datanode1
   [Bypass]
   Index Only Scan using gsi_t on public.gsi_t
     Output: b
     Index Cond: (gsi_t.b <= 10)

(12 rows)
```

- Scenario 2: Multi-table join query.

```
gaussdb=# DCREATE TABLE t1(c1 INT, c2 INT, c3 INT, c4 INT, c5 INT) DISTRIBUTE BY HASH(c1);
CREATE TABLE
gaussdb=# DINSERT INTO t1 VALUES (GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10));
INSERT 0 10
gaussdb=# DCREATE TABLE t2(c1 INT, c2 INT, c3 INT, c4 INT, c5 INT) DISTRIBUTE BY HASH(c1);
CREATE TABLE
gaussdb=# DINSERT INTO t2 VALUES (3, GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10));
INSERT 0 10
gaussdb=#  -- Create an ordinary index.
gaussdb=# CREATE INDEX i_t1 ON t1(c2);
CREATE INDEX
gaussdb=#  -- Join two tables. The STREAM plan is used for query and no DN is pushed down.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT t1.c2 FROM t1, t2 WHERE t1.c2 = t2.c1;
                          QUERY PLAN
---------------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t1.c2
   Node/s: All datanodes
   ->  Hash Join
         Output: t1.c2
         Hash Cond: (t2.c1 = t1.c2)
         ->  Seq Scan on public.t2
               Output: t2.c1, t2.c2, t2.c3, t2.c4, t2.c5
               Distribute Key: t2.c1
         ->  Hash
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
            Output: t1.c2
            ->  Streaming(type: REDISTRIBUTE)
                  Output: t1.c2
                  Distribute Key: t1.c2
                  Spawn on: All datanodes
                  Consumer Nodes: All datanodes
                  ->  Index Only Scan using i_t1 on public.t1
                        Output: t1.c2
                        Distribute Key: t1.c1
(19 rows)
```

You can create a global secondary index on the associated column to push down the query to a DN.

```
gaussdb=# : Create a GSI.
gaussdb=# CREATE GLOBAL INDEX gsi_t1 ON t1(c2);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c2' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE GLOBAL INDEX
gaussdb=#  -- Join two tables and use the GSI to push down all DNs.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT t1.c2 FROM t1, t2 WHERE t1.c2 = t2.c1;
                                 QUERY PLAN
-----------------------------------------------------------------------------------------------
 Data Node Scan
   Output: gsi_t1.c2
   Node/s: All datanodes
   Remote query: SELECT gsi_t1.c2 FROM ONLY public.gsi_t1, public.t2 WHERE gsi_t1.c2 = t2.c1

 Remote SQL: SELECT gsi_t1.c2 FROM ONLY public.gsi_t1, public.t2 WHERE gsi_t1.c2 = t2.c1
 Datanode Name: datanode1
   Hash Join
     Output: gsi_t1.c2
     Hash Cond: (t2.c1 = gsi_t1.c2)
     ->  Seq Scan on public.t2
           Output: t2.c1, t2.c2, t2.c3, t2.c4, t2.c5
     ->  Hash
           Output: gsi_t1.c2
           ->  Index Only Scan using gsi_t1 on public.gsi_t1
                 Output: gsi_t1.c2

(17 rows)
```

- Scenario 3: Subquery.

```
gaussdb=# CREATE TABLE t3(c1 INT, c2 INT, c3 INT, c4 INT, c5 INT) DISTRIBUTE BY HASH(c1);
CREATE TABLE
gaussdb=# INSERT INTO t3 VALUES (GENERATE_SERIES(1,10), GENERATE_SERIES(1,10),
GENERATE_SERIES(1,10), GENERATE_SERIES(1,10), GENERATE_SERIES(1,10));
INSERT 0 10
gaussdb=# CREATE TABLE t4(c1 INT, c2 INT, c3 INT, c4 INT, c5 INT) DISTRIBUTE BY HASH(c1);
CREATE TABLE
gaussdb=# INSERT INTO t4 VALUES (3, GENERATE_SERIES(1,10), GENERATE_SERIES(1,10),
GENERATE_SERIES(1,10), GENERATE_SERIES(1,10));
INSERT 0 10
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT t4.c2 FROM t4, (SELECT c2 FROM t3) aa
WHERE aa.c2 = t4.c1;
               QUERY PLAN
-------------------------------------------
 Streaming (type: GATHER)
   Output: t4.c2
   Node/s: All datanodes
   ->  Hash Join
         Output: t4.c2
         Hash Cond: (t3.c2 = t4.c1)
         ->  Streaming(type: REDISTRIBUTE)
               Output: t3.c2
               Distribute Key: t3.c2
               Spawn on: All datanodes
               Consumer Nodes: All datanodes
               ->  Seq Scan on public.t3
                     Output: t3.c2
                     Distribute Key: t3.c1
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
      ->  Hash
            Output: t4.c2, t4.c1
            ->  Seq Scan on public.t4
                  Output: t4.c2, t4.c1
                  Distribute Key: t4.c1
(19 rows)
```

You can create a global secondary index to push down the query to a DN. In this case, GSI force hint may be increased in the query to use the global secondary index.

```
gaussdb=# CREATE GLOBAL INDEX gsi_t3 ON t3(c2) CONTAINING(c3, c4) DISTRIBUTE BY HASH(c2);
CREATE GLOBAL INDEX
gaussdb=#  -- Use GSI force hint to push down all DNs.
gaussdb=# -- GSI force hint is not applicable and pushdown cannot be performed.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT t4.c2 FROM t4, (SELECT c2 FROM t3) aa
WHERE aa.c2 = t4.c1;
                      QUERY PLAN
-------------------------------------------------------------
 Streaming (type: GATHER)
   Output: t4.c2
   Node/s: All datanodes
   ->  Hash Join
         Output: t4.c2
         Hash Cond: (t4.c1 = t3.c2)
         ->  Seq Scan on public.t4
               Output: t4.c1, t4.c2, t4.c3, t4.c4, t4.c5
               Distribute Key: t4.c1
         ->  Hash
               Output: t3.c2
               ->  Index Only Scan using gsi_t3 on public.t3
                     Output: t3.c2
                     Distribute Key: t3.c2
(14 rows)

gaussdb=#  -- Use GSI force hint to push down all DNs.
gaussdb=# EXPLAIN (VERBOSE ON, COSTS OFF) SELECT /*+gsi()*/ t4.c2 FROM t4, (SELECT c2 FROM
t3) aa WHERE aa.c2 = t4.c1;
                                          QUERY PLAN
-----------------------------------------------------------------------------------------------------------------------
----
 Data Node Scan
   Output: t4.c2
   Node/s: All datanodes
   Remote query: SELECT/*+ gsi()*/ t4.c2 FROM public.t4, (SELECT gsi_t3.c2 FROM ONLY public.gsi_t3)
aa WHERE aa.c2 = t4.c1

 Remote SQL: SELECT/*+ gsi()*/ t4.c2 FROM public.t4, (SELECT gsi_t3.c2 FROM ONLY public.gsi_t3) aa
WHERE aa.c2 = t4.c1
 Datanode Name: datanode1
   Hash Join
     Output: t4.c2
     Hash Cond: (t4.c1 = gsi_t3.c2)

           Output: gsi_t3.c2
           ->  Index Only Scan using gsi_t3 on public.gsi_t3
                 Output: gsi_t3.c2

(17 rows)
```

Global Secondary Index Scanning for Table Access by Index Row ID

- STREAM distributed plan: Create a base table of the global secondary index. During query, the global secondary index needs to be returned to the table. If the predicate hits a large number of rows (for example, range query), the STREAM distributed plan is preferred. Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=#  -- Enable the STEAM mode.
gaussdb=#  SET ENABLE_STREAM_OPERATOR = ON;
SET
gaussdb=#  SET EXPLAIN_PERF_MODE=PRETTY;
SET
gaussdb=#  CREATE TABLE test(c1 INT, c2 INT, c3 INT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# -- Create a global secondary index on column c2 for the test table.
gaussdb=#  CREATE GLOBAL INDEX gsi_test ON test(c2);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c2' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE GLOBAL INDEX
gaussdb=#  -- Use the global secondary index for STREAM distributed plan.
gaussdb=#  EXPLAIN(VERBOSE ON, COSTS OFF) SELECT /*+ gsitable(test gsi_test)*/ * FROM test
WHERE c2 > 1;
WARNING:  Statistics in some tables or columns(public.test.c1, public.test.c2) are not collected.
HINT:  Do analyze for them in order to generate optimized plan.
 id |                       operation
----+-------------------------------------------------------------
  1 | ->  Streaming (type: GATHER)
  2 |    ->  GSI Tid Scan on public.test
  3 |       ->  Streaming(type: REDISTRIBUTE GSI)
  4 |          ->  GSI Only Scan using gsi_test on public.test
(4 rows)
   Predicate Information (identified by plan id)
-----------------------------------------------------
  4 --GSI Only Scan using gsi_test on public.test
        Index Cond: (test.c2 > 1)
(2 rows)
 Targetlist Information (identified by plan id)
-----------------------------------------------------
  1 --Streaming (type: GATHER)
        Output: c1, c2, c3
        Node/s: All datanodes
  2 --GSI Tid Scan on public.test
        Output: c1, c2, c3
        Distribute Key: c1
  3 --Streaming(type: REDISTRIBUTE GSI)
        Output: xc_node_hash, ctid
        Spawn on: All datanodes
        Consumer Nodes: All datanodes
  4 --GSI Only Scan using gsi_test on public.test
        Output: xc_node_hash, ctid
        Distribute Key: c2
(13 rows)
```

- Non-STREAM distributed plan: Create a base table of the global secondary index. During query, the global secondary index needs to be returned to the table. If the predicate hits a few rows (for example, point query), the non-STREAM distributed plan is preferred. Example:

```
gaussdb=#  -- Disable the STEAM mode.
gaussdb=#  SET ENABLE_STREAM_OPERATOR = OFF;
SET
gaussdb=#  CREATE TABLE test(c1 INT, c2 INT, c3 INT);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c1' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
gaussdb=# -- Create a global secondary index on column c2 for the test table.
gaussdb=#  CREATE GLOBAL INDEX gsi_test ON test(c2);
NOTICE:  The 'DISTRIBUTE BY' clause is not specified. Using 'c2' as the distribution column by default.
HINT:  Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE GLOBAL INDEX
gaussdb=#  -- Use the global secondary index for non-STREAM distributed plan.
gaussdb=#  EXPLAIN(VERBOSE ON, COSTS OFF) SELECT /*+ gsitable(test gsi_test)*/ * FROM test
WHERE c2 = 1;
                              QUERY PLAN
-------------------------------------------------------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
Select on public.test
  Output: test.c1, test.c2, test.c3
  Node/s: All datanodes
  Remote query: SELECT c1, c2, c3 FROM ONLY public.test WHERE ctid = $2
  ->  Data Node Scan on gsi_test "REMOTE_TABLE_QUERY"
        Output: gsi_test.xc_node_hash, gsi_test.ctid
        Node/s: datanode1
        Remote query: SELECT xc_node_hash, ctid FROM public.gsi_test WHERE c2 = 1
(8 rows)
```

7 SQL Reference

7.1 GaussDB SQL

What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. This language can also forcibly implement the rules for data types, expressions, and texts. Therefore, **SQL Reference** describes data types, expressions, functions, and operators in addition to SQL syntax.

Development of SQL Standards

Released SQL standards are as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92
- 1999: ISO/IEC 9075:1999, SQL:1999
- 2003: ISO/IEC 9075:2003, SQL:2003
- 2011: ISO/IEC 9075:2011, SQL:2011
- 2016: ISO/IEC 9075:2016, SQL:2016
- 2019: ISO/IEC 9075:2019, SQL:2019

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL:2016.

7.2 Keywords

SQL statements are classified into reserved keywords and non-reserved keywords. For details about common SQL keywords, see **Table 7-1**. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

NOTICE

- Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
  - It cannot be directly used as a column alias. That is, usage similar to SELECT 1 ABORT may cause errors.
  - Keywords ENTITYESCAPING, NOENTITYESCAPING, and WELLFORMED cannot be used as identifiers of table names, column names, table aliases, column aliases, and function names if they are not enclosed in double quotation marks.
  - The RAW keyword without double quotation marks cannot be used as the identifier of a table name or function name.
  - The SET keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to SELECT * FROM T1 SET may cause errors.
  - Keywords such as BEGIN, BY, CLOSE, CURSOR, DECLARE, DELETE, EXECUTE, FUNCTION, IF, IMMEDIATE, INSERT, LOOP, MOVE, OF, REF, RELEASE, RETURN, SAVEPOINT, STRICT, TYPE, and UPDATE without double quotation marks cannot be used as variable names.
  - When the SYS_REFCURSOR keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS_REFCURSOR** is created.
- Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
- The reserved keyword CURRENT_TIMESTAMP with double quotation marks cannot be used as a function name.
- CONVERT, TIMESTAMPADD, ADDDATE, DATE_ADD, SUBDATE, DATE_SUB, and GET_FORMAT are used as keywords only in MySQL-compatible and M-compatible modes. JSON_OBJECT, LAST_DAY, and IFNULL are used as keywords only in MySQL-compatible mode.

Identifier Naming Conventions

Identifier naming must comply with the following rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- An identifier name can only contain letters, digits (0–9), underscores (_), and dollar signs ($).
- An identifier name must start with a letter or an underscore (_).

  NOTE

  - The naming rules are recommended but not required.
  - In special cases, double quotation marks (") can be used to avoid special character errors.

Columns listed in the following table cannot be used as column names during table creation.

CTID	XMIN	CMIN	XMAX	CMAX
TABLEOID	XC_NODE_ID	XC_NODE_HASH	TABLEBUCKETID	GS_TUPLE_UID

7.3 Data Types

A data type is a basic data attribute. Occupied storage space and allowed operations vary according to data types. Data is stored in tables in a database. Each column of a data table specifies a data type and data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see **PG_CAST**.

7.3.1 Numeric Types

Table 7-2 lists all available types. For arithmetic operators and related built-in functions, see **Arithmetic Functions and Operators**.

Table 7-2 Integer types

Name	Description	Storage Space	Range
TINYINT [UNSIGNED]	Tiny integer. The signed alias is INT1, and the unsigned alias is UINT1.	1 byte	• The signed value ranges from 0 to +255. • The unsigned value ranges from 0 to +255. • When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the signed value ranges from –128 to +127.
SMALLINT [UNSIGNED]	Small integer. The signed alias is INT2, and the unsigned alias is UINT2.	2 bytes	• The signed value ranges from –32,768 to +32,767. • The unsigned value ranges from 0 to +65,535.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
MEDIUMINT [UNSIGNED]	Medium-sized integer. The signed alias is INT4, and the unsigned alias is UINT4.	4 bytes	• The signed value ranges from –2147483648 to +2147483647. • The unsigned value ranges from 0 to +4294967295.
INTEGER [UNSIGNED]	Common integer. The signed alias is INT4, and the unsigned alias is UINT4.	4 bytes	• The signed value ranges from –2147483648 to +2147483647. • The unsigned value ranges from 0 to +4294967295.
BINARY_INTEGER	Common integer. The signed alias is INTEGER.	4 bytes	–2,147,483,648 to +2,147,483,647.
BIGINT [UNSIGNED]	Large integer. The signed alias is INT8, and the unsigned alias is UINT8.	8 bytes	• The signed value ranges from –9,223,372,036,854,775,808 to +9,223,372,036,854,775,807. • The unsigned value ranges from 0 to +18,446,744,073,709,551,615.
INT16 [SIGNED]	A 16-byte integer cannot be used to create tables.	16 bytes	–170,141,183,460,469,231,731,687,303,715,884,105,728 to +170,141,183,460,469,231,731,687,303,715,884,105,727

NOTE

- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, integers support the display width and **ZEROFILL** attributes.
- The display width does not limit the range of values that can be stored in a column, nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as SMALLINT(3) has the usual SMALLINT range of –32768 to 32767, and values outside the range permitted by three digits are displayed in full using more than three digits.
- When the display width is used in conjunction with the **ZEROFILL** attribute, zeros are padded in front of the numeric value to achieve the display width. For example, for a column declared as **INT(4) ZEROFILL**, a value of **5** is retrieved as 0005.
- If you specify **ZEROFILL** for a numeric column, the **UNSIGNED** attribute is automatically added.
- If **ZEROFILL** is not specified for a numeric column and only the width information is specified, the width information is not displayed in the table structure description.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a database.
gaussdb=# CREATE DATABASE b_database dbcompatibility = 'MYSQL';
gaussdb=# \c b_database
-- Create a table containing TINYINT data.
b_database=# CREATE TABLE int_type_t1
          (
           IT_COL1 TINYINT,
           IT_COL2 TINYINT UNSIGNED
          );

-- Insert data.
b_database=# INSERT INTO int_type_t1 VALUES(10,20);

-- View data.
b_database=# SELECT * FROM int_type_t1;
it_col1 | it_col2
--------+---------
     10 |      20
(1 row)

-- Drop the table.
b_database=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
b_database=# CREATE TABLE int_type_t2
(
    a TINYINT,
    b TINYINT,
    c INTEGER,
    d INTEGER UNSIGNED,
    e BIGINT,
    f BIGINT UNSIGNED
);

-- Insert data.
b_database=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000, 200, 2000);

-- View data.
b_database=# SELECT * FROM int_type_t2;
  a  | b  |  c   |   d    | e  |  f
-----+----+------+--------+----+------
 100 | 10 | 1000 |  10000 | 200 | 2000
(1 row)

-- Drop the table.
b_database=# DROP TABLE int_type_t2;

-- Delete the database.
b_database=# \c postgres
gaussdb=# DROP DATABASE b_database;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- If **UNSIGNED** is specified, negative values are not allowed.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.
- The unsigned numeric type can be used only in the row storage engine when **sql_compatibility** is set to **'MYSQL'**.
- When a minus sign, plus sign, or multiplication sign is used between integer values (one of which is of the UNSIGNED type), the result is unsigned.
- The return value of the addition (+), subtraction (–), and multiplication (x) operations of the INT1, UINT1, UINT2, UINT4, or UINT8 type can exceed the range of the corresponding type. The return value of the addition (+), subtraction (–), and multiplication (x) operations of the INT2, INT4, or INT8 type cannot exceed the range of the corresponding type.
- The UNSIGNED type cannot be converted to the SET type. Do not calculate or compare the UNSIGNED type with the SET type.
- When **sql_compatibility** is set to **'MYSQL'**, non-numeric characters are automatically truncated or the value **0** is returned.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-3 Arbitrary precision types

Name	Description	Storage Space	Range
NUMERIC[(p[,s])], DECIMAL[(p[,s])]	• The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. • When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, if the precision and scale are not specified, the default precision **p** is **10** and the scale **s** is **0**. If a numeric type is not attached with parentheses, it is set to numeric (10,0) only when being applied to table columns. In other scenarios, the numeric type is used based on the original range by default. **NOTE** **p** indicates the total digits, and **s** indicates the decimal digit.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
NUMBER[(p[,s])]	Alias of the NUMERIC type.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE decimal_type_t1
(
    DT_COL1 DECIMAL(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
gaussdb=# SELECT * FROM decimal_type_t1;
   dt_col1
-------------
 123456.1223
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE decimal_type_t1;
-- Create a table.
gaussdb=# CREATE TABLE numeric_type_t1
(
    NT_COL1 NUMERIC(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
   nt_col1
-------------
 123456.1235
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE numeric_type_t1;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The INTEGER type is the common choice when number types are defined. Arbitrary precision numbers are used when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.
- When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output range specifications of the NUMERIC[(p[,s])] and DECIMAL[(p[,s])] types are different.
  - Input format: The value can be a number or a numeric string.
    - If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the input value is invalid or exceeds the range.
    - If the value of **sql_mode** does not contain **strict_trans_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
  - Output format: The output format of the DECIMAL[(p[,s])] type is different from that of the NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DECIMAL has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

Table 7-4 Sequence integer

Name	Description	Storage Space	Range
SMALLSERIAL	Two-byte serial integer	2 bytes.	–32,768 to +32,767.
SERIAL	Four-byte serial integer	4 bytes.	–2,147,483,648 to +2,147,483,647.
BIGSERIAL	Eight-byte serial integer	8 bytes.	–9,223,372,036,854,775,808 to +9,223,372,036,854,775,807.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM smallserial_type_tab;
 a
---
 1
 2
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM serial_type_tab;
 b
---
 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);

-- Insert data.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM bigserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE smallserial_type_tab;

gaussdb=# DROP TABLE serial_type_tab;

gaussdb=# DROP TABLE bigserial_type_tab;
```

NOTE

SMALLSERIAL, SERIAL, and BIGSERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value is set to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases, you may also want to attach a UNIQUE or PRIMARY KEY constraint to prevent duplicate values from being inserted unexpectedly. Finally, the sequencer belongs to the column. When the column or table is deleted, the sequencer is deleted at the same time. Currently, the **SERIAL** column can be specified only when you create a table. You cannot add the **SERIAL** column in an existing table. In addition, **SERIAL** columns cannot be created in temporary tables because **SERIAL** is not a real type. Therefore, column types in temporary tables cannot be converted to **SERIAL**.

Table 7-5 shows the floating point type.

NOTE

- The REAL(p,s), DOUBLE, DOUBLE(p,s), and FLOAT(p,s) floating-point types can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. For the behavior of the REAL, FLOAT, and DEC[(p[,s])] data types when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, see **Table 7-5**.
- In **Table 7-5**, **p** is the precision, indicating the minimum acceptable total number of integral places, and **s** indicates the decimal digit.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-5 Floating point types

Name	Description	Storage Space	Range
REAL, FLOAT4	Single precision floating points, inexact The REAL data type is mapped to the double-precision floating-point number FLOAT8 when the scenario described in **Description** is met. For details about the application scenario, see FLOAT8.	4 bytes.	–3.402E+38 to +3.402E+38, round to six decimal places.
REAL(p,s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
DOUBLE PRECISION, FLOAT8	Double precision floating points, inexact	8 bytes.	–1.79E+308 to +1.79E+308, 15-bit decimal digits.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
DOUBLE	Double precision floating points, inexact This type maps to double-precision floating-point number FLOAT8. For details about the application scenario, see FLOAT8.	8 bytes.	–1.79E+308 to +1.79E +308, 15-bit decimal digits.
DOUBLE(p, s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
FLOAT[(p)]	Floating points, inexact The value range of precision (p) is [1,53]. The type is selected based on the precision **p**. When **p** is less than or equal to 24, the mapping type is REAL. When **p** is greater than 24 or not specified, the mapping type is DOUBLE PRECISION. In the scenario described in **NOTE**, if the precision **p** is less than or equal to 24, or it is not specified, the mapping type is FLOAT4. If **p** is greater than 24, the mapping type is DOUBLE PRECISION.	4 bytes or 8 bytes.	N/A
FLOAT(p,s)	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space	Range
BINARY_DOUBLE	DOUBLE PRECISION alias, compatible with Oracle Database.	8 bytes.	–1.79E+308 to +1.79E+308, 15-bit decimal digits.
DEC[(p[,s])]	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the scenario in **Note** is met and the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. This type maps to NUMERIC. For details about the application scenario, see NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
INTEGER[(p[,s])]	The value range of **p** is [1,1000], and the value range of **s** is [0,*p*]. If the precision and scale are not specified, the precision **p** is **10** and the scale **s** is **0** by default. If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum. If the precision and scale are not specified, the value ranges from –2,147,483,648 to +2,147,483,647.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

For the precision of the floating-point type, only the number of precision bits can be ensured when the data is directly read. When distributed computing is involved, the computation is executed on each DN and is finally aggregated to a CN. Therefore, the error may be amplified as the number of compute nodes increases.

When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output ranges of the FLOAT[(p[,s])], DOUBLE[(p[,s])], DEC[(p[,s])] and REAL[(p[,s])] types are different.

- Input format: The value can be a number or a numeric string.
  - If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the input value is invalid or exceeds the range.
  - If the value of **sql_mode** does not contain **strict_trans_tables** and the input value is invalid or exceeds the range, a warning message is reported and **0** or the truncated value is returned.
- Output format: The output format of the DEC[(p[,s])] type is different from that of the mapping NUMERIC[(p[,s])] type when the precision and scale are not specified. If NUMERIC has no precision or scale, the decimal part is retained during type conversion. For details, see the output format in the scenario where no parameter is set. If DEC has no precision or scale, the precision is **10** and the scale is **0** during type conversion.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE float_type_t2
(
    FT_COL1 INTEGER,
    FT_COL2 FLOAT4,
    FT_COL3 FLOAT8,
    FT_COL4 FLOAT(3),
    FT_COL5 BINARY_DOUBLE,
    FT_COL6 DECIMAL(10,4),
    FT_COL7 INTEGER(6,3)
)DISTRIBUTE BY HASH ( ft_col1);

-- Insert data.
gaussdb=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
gaussdb=# SELECT * FROM float_type_t2 ;
 ft_col1 | ft_col2 |   ft_col3   | ft_col4 | ft_col5 | ft_col6  | ft_col7
---------+---------+-------------+---------+---------+----------+---------
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE float_type_t2;

-- Example: REAL(p,s), FLOAT(p,s), DOUBLE, and DOUBLE(p,s).
gaussdb=# CREATE DATABASE gaussdb_m  WITH dbcompatibility  'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(a real(10,2), b float(10,2), c double, d double(10,2));
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1000.12, 2000.23, 3000.34, 4000.45);
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
   a    |    b    |    c    |    d
--------+---------+---------+---------
 1000.12 | 2000.23 | 3000.34 | 4000.45
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

-- Delete the table and database.
gaussdb_m=# DROP TABLE t1;
gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;

-- Reset parameters.
gaussdb=# RESET ALL;
```

7.3.2 Monetary Types

The monetary type stores a currency amount with fixed fractional precision.

The range shown in **Table 7-6** assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "$1,000.00". Output is generally in the last format but depends on the locale.

Table 7-6 Monetary type

Name	Description	Storage Space	Range
money	Currency amount	8 bytes	-92233720368547758.08 ~ +92233720368547758.07

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real or double precision data type to a money value can be done by casting to numeric type first, for example:

```
gaussdb=# SELECT '12.34'::float8::numeric::money;
 money
--------
 $12.34
(1 row)
```

However, this is not recommended. Floating-point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
gaussdb=# SELECT '52093.89'::money::numeric::float8;
  float8
----------
 52093.89
(1 row)
```

When a money value is divided by another money value, the result is of the double precision type (that is, the digit type instead of the money type); the currency units cancel each other out in the division.

7.3.3 Boolean Types

Table 7-7 lists the Boolean types supported by GaussDB.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-7 Boolean Types

Name	Description	Storage Space	Value
BOOLEAN	Boolean Types	1 byte	• **true** • **false** • **null**: unknown

- Valid literal values for the "true" state are:
  TRUE, **'t'**, **'true'**, **'y'**, **'yes'**, **'1'**, **'TRUE'**, **true**, **on**, and all non-zero values.
- Valid literal values for the "false" state include:
  FALSE, **'f'**, **'false'**, **'n'**, **'no'**, **'0'**, **0**, **'FALSE'**, **false**, and **off**.

TRUE and **FALSE** are standard expressions, compatible with SQL statements.

Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.
gaussdb=# CREATE TABLE bool_type_t1
(
    BT_COL1 BOOLEAN,
    BT_COL2 TEXT
)DISTRIBUTE BY HASH(BT_COL2);

-- Insert data.
gaussdb=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

gaussdb=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
gaussdb=# SELECT * FROM bool_type_t1;
 bt_col1 | bt_col2
---------+---------
 t       | sic est
 f       | non est
(2 rows)

gaussdb=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
 bt_col1 | bt_col2
---------+---------
 t       | sic est
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE bool_type_t1;
```

7.3.4 Character Types

Table 7-8 lists the character types supported by GaussDB. For string operators and related built-in functions, see **Character Processing Functions and Operators**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-8 Character types

Name	Description	Storage Space
CHAR(n) CHARACTER(n) NCHAR(n)	Fixed-length character string, blank padded. **n** indicates the byte length. If it is not specified, the default precision **1** is used.	The maximum value of **n** is **10485760** (10 MB).
	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**: ● Type: **n** indicates the character length. The value range is [0,10485760]. If the precision **n** is not specified, the default precision **1** is used. Fixed-length character string, blank padded. ● Input: – Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of **sql_mode** contains **strict_trans_tables**, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by **n** and an alarm is generated. ● Output: – Data type of table columns and temporary variables: If the value of **sql_mode** contains **pad_char_to_full_length**, the character string containing spaces at the end is output. Otherwise, the character string without spaces at the end is output. – Function parameter and return value or stored procedure parameter: The length cannot be verified. For example, if the input parameter of a user-defined function is of the CHAR(5) type and a string **'123456'** is input, the parameter can be directly transferred without length verification.	The value contains a maximum of 10M characters.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
VARCHAR(n) CHARACTER VARYING(n)	Variable-length string. In PG-compatible mode, **n** indicates the string length. In other compatibility modes, **n** indicates the byte length.	The maximum value of **n** is **10485760** (10 MB). If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar, c int), the maximum length for the varchar column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**: ● **n** indicates the string length. The value range is [0,10485760]. If the precision **n** is not specified, there is no length limit by default. The length is the same as that of the TEXT type. ● Input – Data type of table columns and temporary variables: If the number of characters in an input string is within the range, the string can be entered normally. If the value of **sql_mode** contains **strict_trans_tables**, an error is reported. Otherwise, the string is truncated based on the maximum string length specified by **n** and an alarm is generated. ● Output: The original character string is output.	The maximum value of **n** is **10485760** (10 MB). If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar, c int), the maximum length for the varchar column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
VARCHAR2(n)	Variable-length string. It is the alias of the VARCHAR(n) type.	The maximum value of **n** is **10485760** (10 MB). If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b varchar2, c int), the maximum length for the varchar2 column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
NVARCHAR2(n)	Variable-length string. In the SQL_ASCII character set, **n** indicates bytes. In the non-SQL_ASCII character set, **n** indicates characters.	The maximum value of **n** is **10485760** (10 MB). If **n** is not specified, the maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b nvarchar2, c int), the maximum length for the nvarchar2 column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TEXT	Variable-length string.	The maximum storage length is 1 GB – 85 – 4 (space for storing length parameter) – Length of other columns. For example, in a table with columns (a int, b text, c int), the maximum length for the text column is 1 GB – 85 – 4 (space for storing length parameter) – 4 (length of column **a** int) – 4 (length of column **c** int) = 1,073,741,727.
CLOB	Big text object.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 1 GB minus 1 byte.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TINYTEXT MEDIUMTEXT LONGTEXT	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, these types can be used. Converts a data type to the TEXT type. The application scenario is the same as that of the TEXT type.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.

NOTE

1. In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
3. In ORA-compatible mode, the received empty string is converted to null by default.

Table 7-9 lists the two other fixed-length character types supported by GaussDB. The name type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The char type uses only one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

Table 7-9 Special character types

Name	Description	Storage Space
name	Internal type for object names	64 bytes
"char"	Single-byte internal type	1 byte

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

7.3.5 Binary Types

Table 7-10 lists the binary types supported by GaussDB.

Table 7-10 Binary types

Name	Description	Storage Space
BLOB	Binary large object (BLOB). Currently, BLOB only supports the following external access APIs: • DBE_LOB.GET_LENGTH • DBE_LOB.READ • DBE_LOB.WRITE • DBE_LOB.WRITE_APPEND • DBE_LOB.COPY • DBE_LOB.ERASE For details about the APIs, see DBE_LOB.	The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 1 GB minus 1 byte.
	When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the BLOB type is mapped to the BYTEA type, and the alias is BYTEA.	For details about the storage specifications, see the BYTEA type.
TINYBLOB MEDIUMBLOB LONGBLOB	Binary large object (BLOB). This type can be used only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. The type is mapped to the BYTEA type, and the alias is BYTEA.	For details about the storage specifications, see the BYTEA type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
RAW	Variable-length hexadecimal string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEA	Variable-length binary string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITHEQUALCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
BYTEAWITHOUTORDERCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
_BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).
_BYTEAWITHOUTORDERCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

NOTE

- In addition to the size limit of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte.
- BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, _BYTEAWITHOUTORDERWITHEQUALCOL, and _BYTEAWITHOUTORDERCOL cannot be directly used to create a table.
- RAW(*n*), where *n* indicates the recommended byte length and is not used to verify the byte length of the input raw type.
- When **sql_compatibility** is set to **'MYSQL'**, if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB types are displayed as BYTEA. For example, when the table structure is queried, the TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB types are displayed as BYTEA.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BLOB,
    BT_COL3 RAW,
    BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\\xDEADBEEF');

-- Query data in the table.
gaussdb=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3  |  bt_col4
---------+---------+----------+------------
      10 |         | DEADBEEF | \xdeadbeef
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE blob_type_t1;

-- Example: TINYBLOB, MEDIUMBLOB, and LONGBLOB types
gaussdb=# CREATE DATABASE gaussdb_m WITH dbcompatibility  'MYSQL';
gaussdb=# \c gaussdb_m
-- Set compatible version control parameters.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s1';
-- Create a table.
gaussdb_m=# CREATE TABLE t1(num int, a tinyblob, b blob, m mediumblob, l longblob);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Insert data.
gaussdb_m=# INSERT INTO t1 VALUES (1, 'tinyblobtest', 'blobtest', 'mediumblobtest', 'longblobtest');
-- Query data in the table.
gaussdb_m=# SELECT * FROM t1;
 num |      a       |    b     |       m        |      l
-----+--------------+----------+----------------+--------------
   1 | tinyblobtest | blobtest | mediumblobtest | longblobtest
(1 row)

-- Delete the table and database.
gaussdb_m=# DROP TABLE t1;
gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;
-- Reset parameters.
gaussdb=# RESET ALL;
```

7.3.6 Date/Time Types

Table 7-11 lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see **Date and Time Processing Functions and Operators**.

NOTE

- If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.
- The current date is expressed according to the ISO standard. The year consists of four digits. For example, 1 A.D. is 0001, 1 B.C. is 0000, and 2 B.C. is -0001. The rest may be deduced by analogy.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-11 Date/Time types

Name	Description	Storage Space
DATE	Date and time. Minimum value: **4714-11-24 BC** (4713 B.C.). Maximum value: **5874897-12-31AD** (5874897 A.D.) After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, the input and output formats and ranges are different. • Input format: YYYY-MM-DD with separators and YYYYMMDD without separators are supported. – In the scenario where separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day of a date. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. Example: **date'2020-12?12'**.) The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used, the output result may be incorrect though no error is reported. • Output format: Only YYYY-MM-DD is supported and the format is not affected by the **DateStyle** parameter. • Value range: 4713-01-01 BC to 5874897-12-31 AD. – If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the value is invalid or exceeds the range. – If the value of **sql_mode** does not contain	4 bytes (8 bytes in ORA-compatible mode)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	strict_trans_tables, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10' will be converted to 0002-12-10 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. **NOTE** For ORA compatibility, the database treats empty strings as **NULL** and replaces **DATE** with **TIMESTAMP(0) WITHOUT TIME ZONE**.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIME [(p)] [WITHOUT TIME ZONE]	Time within one day (without a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **00:00:00**. Maximum value: **24:00:00**. After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, they are not limited to the time in a day. For example, they can indicate concepts such as duration and relative time, and the format, range, and precision are different. ● Input format: [D] hh:mm:ss.ffffff with separators and hhmmss.ffffff without separators are supported. **D** indicates the number of days. The value is an integer (negative numbers are supported). This parameter is optional. The value is converted into the number of hours on the basis of 24 hours in a day. The value is displayed after hh is added. Only colons (:) can be used as separators. ● Output format: hh:mm:ss.ffffff. All zeros at the end of the decimal part are automatically ignored during display. ● Value range: –838:59:59.000000 to +838:59:59.000000. – If the value of **sql_mode** contains **strict_trans_tables**, **00:00:00** is returned for invalid input. If the value exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, **00:00:00** is returned for invalid input. If the input is valid but	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	exceeds the range, the nearest boundary value is returned. For example, inputting 838:59:59.000001 returns 838:59:59, and inputting –838:59:59.000001 returns –838:59:59. • Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If **p** is set to a value greater than 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example, time '10:10:10.123456'), the default precision is **6**.	
TIME [(p)] [WITH TIME ZONE]	Time within one day (with a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **00:00:00+15:59**. Maximum value: **24:00:00–15:59**.	12 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIMESTAMP[(p)] [WITHOUT TIME ZONE]	Date and time (without a time zone). **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **4714-11-24 BC 00:00:00.000000** (4713 B.C.). Maximum value: **294277-01-09 AD 04:00:54.775807** (294277 A.D.), representing infinity After **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, they will be replaced with the TIMESTAMP[(p)] [WITH TIME ZONE] type. However, the format, range, and precision specifications are different. • Input format: YYYY-MM-DD hh:mm:ss.ffffff+timezone with separators and YYYYMMDDhhmmss.ffffff without separators are supported. – If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, timestamp '2020-12?12 00:00:00'.) Only colons (:) can be used as separators in the time part. The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported. – If the year has only two digits, 00–69 corresponds to	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	2000–2069, and 70–99 corresponds to 1970–1999. – If the year contains only one digit, for example, timestamp '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'. ● Output format: Only YYYY-MM-DD hh:mm:ss.ffffff is supported and the format is not affected by the **DateStyle** parameter. All zeros at the end of the decimal part of the time are automatically ignored. ● Range – If the value of **sql_mode** contains **strict_trans_tables**, the value range is the same as that of TIMESTAMP[(p)] WITH TIME ZONE. If the value is invalid or exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. ● Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If **p** is set to a value greater than 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example,	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	timestamp '2000-01-01 00:00:00.123456'), the default precision is **6**. • Time zone: The value ranges from –15:59 to +15:59. You can also use the time zone name (see the system view **PG_TIMEZONE_NAMES**). The time zone specifications are the same as those of the TIMESTAMP[(p)] WITH TIME ZONE type. Converts the time value of a specified time zone to the time of the UTC-0 time zone. When it is displayed, the time in the UTC-0 time zone is converted to the time in the current time zone of the server. You can run **SHOW TIME ZONE** to view the time zone of the server. Therefore, when you use the SET TIME ZONE statement to change the time zone of the server, the displayed result also changes.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
TIMESTAMP[(p)] [WITH TIME ZONE]	Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ. **p** indicates the precision after the decimal point. The value ranges from **0** to **6**. Minimum value: **4714-11-24 BC 00:00:00.000000 +0** (4713 B.C.). Maximum value: **294277-01-09 AD 04:00:54.775807 +0** (294277 A.D.), representing infinity. Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system needs to modify the time zone file to ensure that the time is correct. Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information.	8 bytes
SMALLDATETIME	Date and time (without a time zone). The precision level is minute. 30s to 59s are rounded into one minute. Minimum value: **4713-11-24BC 00:00:00.000000** (4713 B.C.). Maximum value: **294277-01-09AD 00:00:00.000000** (294277 A.D.).	8 bytes
INTERVAL DAY (l) TO SECOND (p)	Specifies the time interval (*X* days *X* hours *X* minutes *X* seconds). • **l**: indicates the precision of days. The value ranges from 0 to 6. For compatibility, the precision functions are not supported. • **p**: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed.	16 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
INTERVAL [FIELDS] [(p)]	Time interval. • **FIELDS**: **YEAR**, **MONTH**, **DAY**, **HOUR**, **MINUTE**, **SECOND**, **DAY TO HOUR**, **DAY TO MINUTE**, **DAY TO SECOND**, **HOUR TO MINUTE**, **HOUR TO SECOND**, or **MINUTE TO SECOND**. • **p**: indicates the precision of seconds. The value ranges from 0 to 6. **p** takes effect only when **FIELDS** is set to **SECOND**, **DAY TO SECOND**, **HOUR TO SECOND**, or **MINUTE TO SECOND**. The digit 0 at the end of a decimal number is not displayed.	12 bytes
reltime	Relative time interval. • The format is as follows: X years X mons X days XX:XX:XX. • The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.	4 bytes
abstime	Date and time. • Format: YYYY-MM-DD hh:mm:ss +timezone. • The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second. If the inserted data exceeds the range, the data is converted to an invalid value for storage.	4 bytes

Name	Description	Storage Space
datetime[(p)]	Date and time. This parameter takes effect only when **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**. The datetime[(p)] type is replaced by the TIMESTAMP[(p)] WITHOUT TIME ZONE type, but the format, range, precision, and time zone processing specifications are different. • Input format: YYYY-MM-DD hh:mm:ss.ffffff+timezone with separators and YYYYMMDDhhmmss.ffffff without separators are supported. – If separators are used, the plus sign (+) and colon (:) cannot be used as separators between the year, month, and day. (Some separators are not supported when they are used together. The specifications inherit the existing implementation. For example, **datetime '2020-12?12 00:00:00'**.) Only colons (:) can be used as separators in the time part. The input format is not affected by the **DateStyle** parameter. – In the scenario where separators are not used and the input is incomplete, the output result may be incorrect though no error is reported. – If the year has only two digits, 00–69 corresponds to 2000–2069, and 70–99 corresponds to 1970–1999. – If the year contains only one digit, for example, datetime '1-1-1 00:00:00', the result is '0001-01-01 00:00:00'.	8 bytes

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	• Output format: Only YYYY-MM-DD hh:mm:ss.ffffff is supported and the format is not affected by the **DateStyle** parameter. All zeros at the end of the decimal part of the time are automatically ignored. • Range – If the value of **sql_mode** contains **strict_trans_tables**, the value range is the same as that of TIMESTAMP[(p)] WITHOUT TIME ZONE. If the value is invalid or exceeds the range, an error is reported. – If the value of **sql_mode** does not contain **strict_trans_tables**, the values of year, month, and day can be 0. However, the values will be converted to valid values in the sequence of year, month, and day. For example, '0000-00-10 00:00:00' will be converted to 0002-12-10 00:00:00 BC. If the input is invalid or exceeds the range, a warning message is reported and the value **0000-00-00 00:00:00** is returned. • Precision: **p** indicates the precision after the decimal point. The value ranges from 0 to 6. If the specified precision exceeds 6, the value **6** is used. – When it is used as the data type of a table column, the default precision is **0**. – When it is used as an expression (for example, datetime '2000-01-01 00:00:00.123456'), the default precision is **6**. • Time zone: The value ranges from –15:59 to +15:59. You can also use the time zone name (see the system view	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	PG_TIMEZONE_NAMES). The time zone specifications are the same as those of the TIMESTAMP[(p)] WITH TIME ZONE type. It converts the time value of a specified time zone to the time of the current time zone of the server. You can run **SHOW TIME ZONE** to view the time zone of the server. If the converted date and time are saved to the table, the time zone is not converted when the time zone of the server changes.	

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
year[(w)]	Year. It takes effect only after **sql_compatibility** is set to **'MYSQL'**. ● Input formats: – A string of four digits, ranging from '1901' to '2155' (that is, the years from 1901 to 2155). – Four digits, ranging from 1901 to 2155 (that is, the years from 1901 to 2155). – A string of one or two digits, ranging from '0' to '99'. The values '0' to '69' indicate the years from 2000 to 2069, and the values '70' to '99' indicate the years from 1970 to 1999. **'0'** and **'00'** indicate the year 2000. – One or two digits, ranging from **0** to **99**. The values **1** to **69** indicate the years from 2001 to 2069, and **70** to **99** indicate the years from 1970 to 1999. The value **0** indicates 0000. – Return values of other time functions, for example, now(). ● Output format: Only the YYYY format is supported. **w** indicates the number of digits in the output format. Only four digits are supported. If not specified, the default value is **4**. ● Value range: **1901** to **2155**. – If the value of **sql_mode** contains **strict_trans_tables**, an error is reported if the value is invalid or exceeds the range. – If the value of **sql_mode** does not contain **strict_trans_tables**, the invalid value is converted to	1 byte

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Name	Description	Storage Space
	0000 and inserted, and an alarm is generated.	

NOTE

- The data of the time type automatically ignores all zeros at the end of the data when it is displayed.
- The default value of **p** is **6**.
- For the INTERVAL type, the date and time are stored in the int32 and double types in the system. Therefore, the value ranges of the two types are the same as those of the corresponding data type.
- If the insertion time is out of the range, the system may not report an error, but may not ensure that the operation is normal.

If the values of **a_format_version** and **a_format_dev_version** are **10c** and **s1**, the default DATE value is determined by the following:

- Year: returned through SYSDATE
- Month: returned through SYSDATE
- Day: 01 (first day of the month)
- Hour, minute, and second: all 0

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.

gaussdb_m=# \c postgres;
gaussdb=# DROP DATABASE gaussdb_m;

-- Reset parameters.
gaussdb=# RESET ALL;
```

Date Inputs

Date and time input is accepted in almost any reasonable formats, including ISO 8601 and SQL-compatible. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks (''), and the syntax is as follows:

```
type [ ( p ) ] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. Table 7-12 shows the input formats of the date type.

Table 7-12 Date input formats

Example	Description
1999-01-08	ISO 8601 (recommended format). January 8, 1999 in any format.
January 8, 1999	Unambiguous in any **datestyle** input mode
1/8/1999	January 8 in MDY format. August 1 in DMY format.
1/18/1999	January 18 in MDY format, rejected in other formats.
01/02/03	• January 2, 2003 in MDY format. • February 1, 2003 in DMY format. • February 3, 2001 in YMD format.
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in **YMD** mode, else error
08-Jan-99	January 8, except error in YMD format.
Jan-08-99	January 8, except error in YMD format.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example	Description
19990108	ISO 8601. January 8, 1999 in any format.
990108	ISO 8601. January 8, 1999 in any format.
1999.008	Year and day of year.
J2451187	Julian date.
January 8, 99 BC	Year 99 B.C.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
(1 row)

-- View the date format.
gaussdb=# SHOW datestyle;
 DateStyle
-----------
 ISO, MDY
(1 row)

-- Set the date format.
gaussdb=# SET datestyle='YMD';
SET

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
        coll
---------------------
 2010-12-10
 2010-12-11
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE date_type_tab;
```

Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see **Table 7-13**. For details about time zone input types, see **Table 7-14**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-13 Time input types

Example	Description
05:06.8	ISO 8601
4:05:06	ISO 8601
4:05	ISO 8601
040506	ISO 8601
4:05 AM	Same as 04:05. Input hours must be less than or equal to 12.
4:05 PM	Same as 16:05. Input hours must be less than or equal to 12.
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by abbreviation
2003-04-12 04:05:06 America/New_York	Time zone specified by full name

Table 7-14 Time zone input types

Example	Description
PST	Abbreviation (for Pacific Standard Time)
America/New_York	Full time zone name
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST

Example:

```
gaussdb=# SELECT time '04:05:06';
   time
----------
 04:05:06
(1 row)

gaussdb=# SELECT time '04:05:06 PST';
   time
----------
 04:05:06
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT time with time zone '04:05:06 PST';
   timetz
-------------
 04:05:06-08
(1 row)
```

Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see **Table 7-15**.

Table 7-15 Special values

Input String	Applicable Type	Description
epoch	date and timestamp	1970-01-01 00:00:00+00 (Unix system time zero)
infinity	timestamp	Later than any other timestamps
-infinity	timestamp	Earlier than any other timestamps
now	date, time, and timestamp	Start time of the current transaction
today	date and timestamp	Midnight today
tomorrow	date and timestamp	Midnight tomorrow
yesterday	date and timestamp	Midnight yesterday
allballs	time	00:00:00.00 UTC

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE realtime_type_special(col1 varchar(20), col2 date, col3 timestamp, col4 time);

-- Insert data.
gaussdb=# INSERT INTO realtime_type_special VALUES('epoch', 'epoch', 'epoch', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('now', 'now', 'now', 'now');
gaussdb=# INSERT INTO realtime_type_special VALUES('today', 'today', 'today', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('tomorrow', 'tomorrow', 'tomorrow', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('yesterday', 'yesterday', 'yesterday', NULL);

-- View data.
gaussdb=# SELECT * FROM realtime_type_special;
   col1    |        col2         |            col3             |      col4

-- Drop the table.
gaussdb=# DROP TABLE realtime_type_special;
```

Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format or ISO-8601 format. In addition, the text input needs to be enclosed with single quotation marks ('').

For details about interval input, see **Table 7-16**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-16 Interval input types

Input	Output	Description
60	2 mons	Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before.
31.25	1 mons 1 days 06:00:00	
-365	-12 mons -5 days	
1 years 1 mons 8 days 12:00:00	1 years 1 mons 8 days 12:00:00	Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-13 months -10 hours	-1 years -25 days -04:00:00	
-2 YEARS +5 MONTHS 10 DAYS	-1 years -6 mons -25 days -06:00:00	
P-1.1Y10M	-3 mons -5 days -06:00:00	Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-12H	-12:00:00	

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
gaussdb=# INSERT INTO reltime_type_tab VALUES ('90', '90');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5
MONTHS 10 DAYS');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
gaussdb=# SELECT * FROM reltime_type_tab;
              col1              |                col2
--------------------------------+-------------------------------------
 90                             | 3 mons
 -366                           | -1 years -18:00:00
 1975.25                        | 5 years 4 mons 29 days
 -2 YEARS +5 MONTHS 10 DAYS     | -1 years -6 mons -25 days -06:00:00
 30 DAYS 12:00:00               | 1 mon 12:00:00
 P-1.1Y10M                      | -3 mons -5 days -06:00:00
(6 rows)

-- Drop the table.
gaussdb=# DROP TABLE reltime_type_tab;
```

7.3.7 Geometric Types

Table 7-17 lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

Table 7-17 Geometric types

Name	Storage Space	Description	Representation
point	16 bytes	Point on a plane	(x,y)
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Rectangle	((x1,y1),(x2,y2))
path	16 + 16*n* bytes	Closed path (similar to polygon)	((x1,y1),...)
path	16 + 16*n* bytes	Open path	[(x1,y1),...]
polygon	40 + 16*n* bytes	Polygon (similar to closed paths)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center point and radius)

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see **Geometric Functions and Operators**.

Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
( x , y )
x , y
```

x and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
gaussdb=# SELECT point(1.1, 2.2);
   point
-----------
 (1.1,2.2)
(1 row)
```

Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntaxes:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

(x1,y1) and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
gaussdb=# SELECT lseg(point(1.1, 2.2), point(3.3, 4.4));
        lseg
-----------------------
 [(1.1,2.2),(3.3,4.4)]
(1 row)
```

Rectangles

Rectangles are represented by pairs of points that are opposite corners of a rectangle. Values of the **box** type are specified using any of the following syntaxes:

```
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1   ,   x2 , y2
```

(x1,y1) and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
gaussdb=# SELECT box(point(1.1, 2.2), point(3.3, 4.4));
        box
---------------------
 (3.3,4.4),(1.1,2.2)
(1 row)
```

Paths

Paths are represented by lists of connected points. The path may be open, that is, the first and last points in the list are not connected. The path may also be closed, that is, the first point in the list is connected to the last point in sequence.

Values of the **path** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0))');
       path
--------------------
 ((0,0),(1,1),(2,0))
(1 row)
```

Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntaxes:

```
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1   , ... ,   xn , yn )
x1 , y1   , ... ,   xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1))');
         polygon
--------------------------
 ((0,0),(0,1),(1,1),(1,0))
(1 row)
```

Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using the following syntax:

```
< ( x , y ) , r >
( ( x , y ) , r )
( x , y ) , r
x , y   , r
```

(x,y) is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
gaussdb=# SELECT circle(point(0,0),1);
  circle
-----------
 <(0,0),1>
(1 row)
```

7.3.8 Network Address Types

GaussDB offers data types to store IPv4, IPv6, and MAC addresses. For details, see **Table 7-18**.

It is better to use these types instead of plain-text types to store network addresses, because these types offer input error checking and specialized operators and functions (see **Network Address Functions and Operators**).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-18 Network address types

Name	Storage Space	Description
cidr	7 or 19 bytes	IPv4 or IPv6 networks
inet	7 or 19 bytes	IPv4 or IPv6 hosts and networks
macaddr	6 bytes	MAC address

When sorting **inet** or **cidr** data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped to IPv6 addresses, such as ::10.2.3.4 or ::ffff:10.4.3.2.

cidr

The cidr type (Classless Inter-Domain Routing) holds an IPv4 or IPv6 network address, as described in **Table 7-19**. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 or IPv6 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

Table 7-19 cidr type input examples

cidr Input	cidr Output	abbrev(cidr)
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32
2001:4f8:3:ba::/64	2001:4f8:3:ba::/64	2001:4f8:3:ba::/64
2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1/128	2001:4f8:3:ba:2e0:81ff:fe22:d1f1
::ffff:127.0.0.0/120	::ffff:127.0.0.0/120	::ffff:127.0.0.0/120
::ffff:127.0.0.0/128	::ffff:127.0.0.0/128	::ffff:127.0.0.0/128

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

inet

The **inet** type holds an IPv4 or IPv6 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host. In IPv6, because the address length is 128 bits, 128 bits specify a unique host address.

The input format for this type is **address/y** where **address** is an IPv4 or IPv6 address and **y** is the number of bits in the netmask. If the **/y** portion is omitted, the netmask is 32 for an IPv4 address and 128 for an IPv6 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'
'08-00-2b-01-02-03'
'08002b:010203'
'08002b-010203'
'0800.2b01.0203'
'08002b010203'
```

These examples specify the same address. Data bits **a** to **f** are case-insensitive and are displayed in the first format.

7.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: bit(*n*) and bit varying(*n*). Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The bit type data must match the length *n* exactly. An error will be reported if the data length of the storage is not matched. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while bit varying without a length specification means unlimited length.

NOTE

- If you convert a bit string value to bit(*n*), the content that exceeds *n* digits on the right of the bit string value will be truncated, or the bit string value will be padded with zeros to *n* digits on the right if the bit string value is less than *n* digits. In this case, no error message is displayed.
- Similarly, if one explicitly casts a bit-string value to **bit varying(n)**, the bit-string value will be truncated on the right if it is more than *n* bits.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create a table.
gaussdb=# CREATE TABLE bit_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BIT(3),
    BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;

-- Insert data.
gaussdb=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');

-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR:  bit string length 2 does not match type bit(3)
CONTEXT:  referenced column: bt_col2

-- Specify the type length. Data is converted if it exceeds this length.
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');

-- View data.
gaussdb=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
---------+---------+---------
       1 | 101     | 00
       2 | 100     | 101
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE bit_type_t1;
```

7.3.10 UUID Type

The data type UUID stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity (16 bytes in size) that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

Therefore, for distributed systems, these identifiers provide a better uniqueness guarantee than sequence generators, which are only unique within a single database.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

Example

```
-- Generate a UUID sequence number.
gaussdb=# SELECT uuid();
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
                uuid
--------------------------------------
 846b9d00-172d-c63d-4a03-e8b4700370e0
(1 row)

-- Create a table.
gaussdb=# CREATE TABLE uuid_test(id int, test uuid) DISTRIBUTE BY HASH(test);

-- Use the UUID generated by the system to insert data.
gaussdb=# INSERT INTO uuid_test VALUES(1, uuid()::uuid);

-- Insert data in the example format.
gaussdb=# INSERT INTO uuid_test VALUES(2, 'A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11');
gaussdb=# INSERT INTO uuid_test VALUES(3, '{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}');
gaussdb=# INSERT INTO uuid_test VALUES(4, 'a0eebc999c0b4ef8bb6d6bb9bd380a11');
gaussdb=# INSERT INTO uuid_test VALUES(5, 'a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11');

-- View data and output the data in the standard format.
gaussdb=# SELECT * FROM uuid_test;
 id |                 test
----+--------------------------------------
  1 | 1b52051c-1731-c63d-4a03-e8b4700370e0
  2 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
  3 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
  4 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
  5 | a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
(5 rows)

-- Drop the table.
gaussdb=# DROP TABLE uuid_test;
```

7.3.11 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets ([]), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces ({}), in which objects are stored in the format of key:value. Each key must be a string enclosed by a pair of double quotation marks (""), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence. The JSONB data type stores data in a decomposed binary form, removing semantic-irrelevant details and duplicate keys, and sorting key-values. Therefore, the JSONB data does not need to be parsed.

It can be found that both are of JSON type, and the same strings can be entered as input. The main difference between them is the efficiency. Because JSON data type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in its parsed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks ('').

null (null-json): The value can only be **null** in lowercase.

```
gaussdb=# SELECT 'null'::json;   -- suc
 json
------
 null
(1 row)

gaussdb=# SELECT 'NULL'::jsonb;  -- err
ERROR:  invalid input syntax for type json
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
gaussdb=# SELECT '1'::json;
 json
------
 1
(1 row)

gaussdb=# SELECT '-1.5'::json;
 json
------
 -1.5
(1 row)

gaussdb=# SELECT '-1.5e-5'::jsonb, '-1.5e+2'::jsonb;
   jsonb   | jsonb
-----------+-------
 -0.000015 | -150
(1 row)

gaussdb=# SELECT '001'::json, '+15'::json, 'NaN'::json;  -- Redundant leading zeros, plus signs (+), NaN, and infinity are not supported.
ERROR:  invalid input syntax for type json
```

Boolean (bool-json): The value can only be **true** or **false** in lowercase.

```
gaussdb=# SELECT 'true'::json;
 json
------
 true
(1 row)

gaussdb=# select 'false'::jsonb;
 jsonb
-------
 false
(1 row)
```

String (str-json): The value must be a string enclosed in double quotation marks ("").

```
gaussdb=# SELECT '"a"'::json;
 json
------
 "a"
(1 row)

gaussdb=# select '"abc"'::jsonb;
 jsonb
-------
 "abc"
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
gaussdb=# SELECT '[1, 2, "foo", null]'::json;
       json
--------------------
 [1, 2, "foo", null]
(1 row)

gaussdb=# SELECT '[]'::json;
 json
------
 []
(1 row)

gaussdb=# SELECT '[1, 2, "foo", null, [[]], {}]'::jsonb;
            jsonb
------------------------------
 [1, 2, "foo", null, [[]], {}]
(1 row)
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
gaussdb=# SELECT '{}'::json; json
------
 {}
(1 row)

gaussdb=# SELECT '{"a": 1, "b": {"a": 2,  "b": null}}'::json;
               json
-------------------------------------
 {"a": 1, "b": {"a": 2,  "b": null}}
(1 row)

gaussdb=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}'::jsonb;
                       jsonb
-----------------------------------------------------
 {"foo": [true, "bar"], "tags": {"a": 1, "b": null}}
(1 row)
```

NOTICE

- Note that **'null'::json** and **null::json** are different, which are similar to the strings **str="null"** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

JSONB Advanced Features

- Precautions
  - It cannot be used as a partition key.
  - Foreign tables are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

  - After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:

```
gaussdb=# SELECT '    [1, " a ", {"a"    :1     }]  '::jsonb;
        jsonb
----------------------
 [1, " a ", {"a": 1}]
(1 row)
```

  - For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:

```
gaussdb=# SELECT '{"a" : 1, "a" : 2}'::jsonb;
  jsonb
----------
 {"a": 2}
(1 row)
```

  - For object-json, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:

```
gaussdb=# SELECT '{"aa" : 1, "b" : 2, "a" : 3}'::jsonb;
           jsonb
----------------------------
{"a": 3, "b": 2, "aa": 1}
(1 row)
```

- Size comparison

  Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

  - First, type comparison: object-jsonb > array-jsonb > bool-jsonb > num-jsonb > str-jsonb > null-jsonb
  - Content comparison if the data type is the same:
    - str-jsonb: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.
    - num-jsonb: numeric comparison
    - bool-jsonb: **true** > **false**
    - array-jsonb: long elements > short elements. If the lengths are the same, compare each element in sequence.
    - object-jsonb: If the length of a key-value pair is longer than that of a short key-value pair, the keys are compared first, and then the values are compared.

      NOTE

      For comparison within the object-jsonb type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

- Creating indexes and primary keys
  - B-tree index

    B-tree indexes and primary keys can be created for the JSONB type.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Inclusion and existence

  Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

```
-- Simple scalar/primitive values contain only the identical value.
gaussdb=# SELECT '"foo"'::jsonb @> '"foo"'::jsonb;
 ?column?
----------
 t
(1 row)

-- The array on the left contains the character string on the right.
gaussdb=# SELECT '[1, "aa", 3]'::jsonb ? 'aa';
 ?column?
----------
 t
(1 row)

-- The array on the left contains all elements of the array on the right, regardless of the sequence and repetition.
gaussdb=# SELECT '[1, 2, 3]'::jsonb @> '[1, 3, 1]'::jsonb;
 ?column?
----------
 t
(1 row)

-- The object-json on the left contains all key-value pairs of object-json on the right.
gaussdb=# SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @>
'{"version":9.4}'::jsonb;
 ?column?
----------
 t
(1 row)

-- The array on the left does not contain all elements of the array on the right. The three elements on the left are 1, 2, and [1,3], but the elements on the right are 1 and 3.
gaussdb=# SELECT '[1, 2, [1, 3]]'::jsonb @> '[1, 3]'::jsonb;
 ?column?
----------
 f
(1 row)

gaussdb=# SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"bar": "baz"}'::jsonb;
 ?column?
----------
 f
(1 row)
```

  For details about the operators, see **JSON/JSONB Functions and Operators**.

- Functions and operators

  For details about the functions and operators supported by the JSON/JSONB type, see **JSON/JSONB Functions and Operators**.

7.3.12 HLL Type

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

Table 7-20 compares HLL with other algorithms.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-20 Comparison between HLL and other algorithms

Item	Sorting Algorithm	Hash Algorithm	HLL
Time complexity	O(nlogn)	O(n)	O(n)
Space complexity	O(n)	O(n)	log(logn)
Error rate	0	0	≈0.8%
Storage space requirement	Size of original data	Size of original data	The maximum size is 16 KB by default.

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs O(nlogn) time for sorting, and the hash algorithm and HLL need O(n) time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of about 16 KB.

NOTICE

- In the current default specifications, the maximum number of distinct values that can be calculated is about 1.1e + 15, and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the distinct value is 1.1e + 15. If the distinct value is NaN, you need to adjust log2m or use another algorithm to calculate the distinct value.
  - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

Table 7-21 describes main HLL data structures.

Table 7-21 Main HLL data structures

Data Type	Description
hll	The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the hll_empty function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **–1**, the default value of the HLL parameter is used. You can run the **\d** or **\d+** command to view the parameters of the HLL type.

NOTE

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **–1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
gaussdb=# CREATE TABLE t1 (id integer, set hll);
gaussdb=# \d t1
      Table "public.t1"
 Column |  Type   | Modifiers
--------+---------+-----------
 id     | integer |
 set    | hll     |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two input parameters.
gaussdb=# CREATE TABLE t2 (id integer, set hll(12,4));
gaussdb=# \d t2
          Table "public.t2"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
gaussdb=# CREATE TABLE t3(id int, set hll(-1,-1,8,-1));
gaussdb=# \d t3
          Table "public.t3"
 Column |      Type      | Modifiers
--------+----------------+-----------
 id     | integer        |
 set    | hll(14,10,8,0) |

-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
gaussdb=# CREATE TABLE t4(id int, set hll(5,-1));
ERROR:  log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
gaussdb=# DROP TABLE t1,t2,t3;
DROP TABLE
```

NOTE

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- Create an HLL table.
gaussdb=# CREATE TABLE t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
gaussdb=# INSERT INTO t1 VALUES (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
gaussdb=# INSERT INTO t1(id, set) VALUES (1, hll_empty(14,5));
ERROR:  log2explicit does not match: source is 5 and dest is 10

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

  The following example shows how to use the HLL data type:

  ```
  -- Create an HLL table.
  gaussdb=# CREATE TABLE helloworld (id integer, set hll);

  -- Insert an empty HLL to the table.
  gaussdb=# INSERT INTO helloworld(id, set) VALUES (1, hll_empty());

  -- Add a hashed integer to the HLL.
  gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_integer(12345)) WHERE id = 1;

  -- Add a hashed string to the HLL.
  gaussdb=# UPDATE helloworld SET set = hll_add(set, hll_hash_text('hello world')) WHERE id = 1;

  -- Obtain the number of distinct values of the HLL.
  gaussdb=# SELECT hll_cardinality(set) FROM helloworld WHERE id = 1;
   hll_cardinality
  -----------------
                2
  (1 row)

  -- Drop the table.
  gaussdb=# DROP TABLE helloworld;
  ```

- Scenario 2: Collect statistics about website visitors.

  The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

  ```
  -- Create a raw data table to show that a user has visited the website at a certain time.
  gaussdb=# CREATE TABLE facts (
          date            date,
          user_id         integer
  );

  -- Create a raw data table to show that a user has visited the website at a certain time.
  gaussdb=# INSERT INTO facts VALUES ('2019-02-20', generate_series(1,100));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-21', generate_series(1,200));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-22', generate_series(1,300));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-23', generate_series(1,400));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-24', generate_series(1,500));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-25', generate_series(1,600));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-26', generate_series(1,700));
  gaussdb=# INSERT INTO facts VALUES ('2019-02-27', generate_series(1,800));

  -- Create another table and specify an HLL column:
  gaussdb=# CREATE TABLE daily_uniques (
     date            date UNIQUE,
     users           hll
  );

  -- Group data by date and insert the data into the HLL.
  gaussdb=# INSERT INTO daily_uniques(date, users)
     SELECT date, hll_add_agg(hll_hash_integer(user_id))
  ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    FROM facts
    GROUP BY 1;

-- Calculate the numbers of users visiting the website every day.
gaussdb=# SELECT date, hll_cardinality(users) FROM daily_uniques ORDER BY date;
    date    | hll_cardinality
------------+------------------
 2019-02-20 |              100
 2019-02-21 | 200.217913059312
 2019-02-22 |  301.76494508014
 2019-02-23 | 400.862858326446
 2019-02-24 | 502.626933349694
 2019-02-25 | 601.922606454213
 2019-02-26 | 696.602316769498
 2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019.
gaussdb=# SELECT hll_cardinality(hll_union_agg(users)) FROM daily_uniques WHERE date >=
'2019-02-20'::date AND date <= '2019-02-26'::date;
 hll_cardinality
------------------
 696.602316769498
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
gaussdb=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1 PRECEDING);  -- The default
compatibility details (M-compatibility) are listed as
follows:
    date    | lost_uniques
------------+--------------
 2019-02-20 |            0
 2019-02-21 |            0
 2019-02-22 |            0
 2019-02-23 |            0
 2019-02-24 |            0
 2019-02-25 |            0
 2019-02-26 |            0
 2019-02-27 |            0
(8 rows)

-- Drop the table.
gaussdb=# DROP TABLE facts;
gaussdb=# DROP TABLE daily_uniques;
```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

  When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, **'E\\1234'** to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
gaussdb=# CREATE TABLE test(id integer, set hll);
gaussdb=# INSERT INTO test VALUES(1, 'E\\1234');
ERROR:  not a hll type, size=6 is not enough
gaussdb=# DROP TABLE test;
```

7.3.13 Range Types

A range type is a data type that represents the range of a value of an element type (called the subtype of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is tsrange (short for timestamp range), and timestamp is the

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping (time and date ranges for time arrangement, price ranges, and instrument ranges).

Built-in Range

The following built-in ranges are available:

- int4range: integer range.
- int8range: bigint range.
- numrange: numeric range.
- tsrange: range of timestamp without the time zone.
- tstzrange: range of timestamp with the time zone
- daterange: date range.

In addition, you can customize range types. For details, see **CREATE TYPE**.

Example

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE reservation (room int, during tsrange);
gaussdb=# INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
-- Inclusion
gaussdb=# SELECT int4range(10, 20) @> 3;
 ?column?
----------
 f
(1 row)

-- Determine whether the two ranges overlap.
gaussdb=# SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
 ?column?
----------
 t
(1 row)

-- Extract the upper bound.
gaussdb=# SELECT upper(int8range(15, 25));
 upper
-------
    25
(1 row)
-- Calculate the intersection.
gaussdb=# SELECT int4range(10, 20) * int4range(15, 25);
 ?column?
----------
 [15,20)
(1 row)
-- Determine whether the range is empty.
gaussdb=# SELECT isempty(numrange(1, 5));
 isempty
---------
 f
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE reservation;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

See the complete list of operators and functions on a range type in **Range Functions and Operators**.

Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In the textual form of a range, the inclusion lower bound is expressed as "[", and the exclusion lower bound is expressed as "("; the inclusion upper bound is expressed as "]", and the exclusion upper bound is expressed as ").

The lower_inc and upper_inc functions test the upper and lower bounds of a range value, respectively.

Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. When the upper bound and the lower bound of the range are not set, that is, the upper bound is positive infinity and the lower bound is negative infinity, the range is an infinite (unbounded) range.

Element types with the **infinity** values can be used as explicit bound values. For example, in the timestamp range [**today**, **infinity**) and [**today**, **infinity**], [**today**, **infinity**) indicates that the special timestamp values **infinity** is not included, and [**today**, **infinity**] indicates that the special timestamp value **infinity** is included.

The lower_inf and upper_inf functions test the infinite upper and lower bounds of a range, respectively.

Range Input/Output

Range input mode:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

Range output mode:

```
[lower-bound, upper-bound)
Empty
```

() or [] specifies whether the upper and lower bounds are excluded or included, respectively. **empty** specifies an empty range (a range that does not contain vertices).

The value of *lower-bound* can be a valid input string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input string of the subtype or null, indicating that there is no upper bound.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Each bound value can be referenced using the quotation marks("") character. This is necessary if a bound value contains parentheses (), square brackets [], commas (,), quotation marks (""), or backslashes (\), because otherwise those characters will be considered part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing or use backslash escapes to protect all data characters. Otherwise, the data characters will be used as part of the range syntax. If you want to write a bound value that is an empty string, write "", indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses or square brackets is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples:

```
-- All values between 3 (included) and 7 (excluded) are included.
gaussdb=# SELECT '[3,7)'::int4range;
 int4range
-----------
 [3,7)
(1 row)
-- All values between 3 (excluded) and 7 (excluded) are included.
gaussdb=# SELECT '(3,7)'::int4range;
 int4range
-----------
 [4,7)
(1 row)
-- Only value 4 is included.
gaussdb=# SELECT '[4,4]'::int4range;
 int4range
-----------
 [4,5)
(1 row)
-- No value is included (and will be normalized to null).
gaussdb=# SELECT '[4,4)'::int4range;
 int4range
-----------
Empty
(1 row)
```

Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions receive two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third parameter. The third parameter must be one of the following character strings: (), (], [), or [].

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/
exclusion of bounds.
gaussdb=# SELECT numrange(1.0, 14.0, '(]');
  numrange
------------
 (1.0,14.0]
(1 row)
-- If the third parameter is ignored, it is assumed to be '[)'.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT numrange(1.0, 14.0);
  numrange
------------
 [1.0,14.0)
(1 row)
-- Although '(]' is specified here, the value will be converted to the standard format when displayed,
because int8range is a discrete range type.
gaussdb=# SELECT int8range(1, 14, '(]');
 int8range
-----------
 [2,15)
(1 row)
-- Using NULL for a bound causes the range to be unbounded on that side.
gaussdb=# SELECT numrange(NULL, 2.2);
 numrange
----------
 (,2.2)
(1 row)
```

Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values can always be identified between two given values. For example, a range above the numeric type is continuous, and the range of timestamp is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it can be considered as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. You can switch between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a regularization function that knows the specified step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types int4range, int8range, and daterange use a regularized form that includes the lower bound and excludes the upper bound, that is, [). However, user-defined range types can use other conventions.

Index

In addition, B-tree indexes can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding < and > operators, there is a B-tree sort order for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree support for range types is primarily designed to allow sorting within a query, rather than creating an index.

7.3.14 Object Identifier Types

Object identifiers (OIDs) are used internally by GaussDB as primary keys for various system catalogs. The system does not automatically add an OID column to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

a table created by a user. The OID type indicates an object identifier. **Table 7-22** describes the OID types.

The OID type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

Table 7-22 Object identifier types

Name	Reference	Description	Example
OID	N/A	Numeric object identifier	564182
CID	N/A	Command identifier. This is the data type of the system columns **cmin** and **cmax**. Command identifiers are 32-bit quantities.	N/A
XID	N/A	A transaction identifier. This is the data type of the system columns **xmin** and **xmax**. Transaction identifiers are 64-bit quantities.	N/A
TID	N/A	Row identifier. This is the data type of the system column **ctid**. A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.	N/A
REGCONFIG	pg_ts_config	Text search configuration	english
REGDICTIONARY	pg_ts_dict	Text search dictionary	simple
REGOPER	pg_operator	Operator name	N/A
REGOPERATOR	pg_operator	Operator with argument types	*(integer,integer) or -(NONE,integer)
REGPROC	pg_proc	Function name	sum
REGPROCEDURE	pg_proc	Function with argument types	sum(int4)
REGCLASS	pg_class	Relation name	pg_type
REGTYPE	pg_type	Data type name	integer

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The OID type is used for a column in the database system catalog.

Example:

```
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
 oid
------
 1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
gaussdb=# SELECT attrelid,attname,atttypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
 attrelid |  attname   | atttypid | attstattarget
----------+------------+----------+---------------
     1247 | xc_node_id     |       23 |             0
     1247 | tableoid       |       26 |             0
     1247 | cmax           |       29 |             0
     1247 | xmax           |       28 |             0
     1247 | cmin           |       29 |             0
     1247 | xmin           |       28 |             0
     1247 | oid            |       26 |             0
     1247 | ctid           |       27 |             0
     1247 | typname        |       19 |            -1
     1247 | typnamespace   |       26 |            -1
     1247 | typowner       |       26 |            -1
     1247 | typlen         |       21 |            -1
     1247 | typbyval       |       16 |            -1
     1247 | typtype        |       18 |            -1
     1247 | typcategory    |       18 |            -1
     1247 | typispreferred |       16 |            -1

(39 rows)
```

7.3.15 Pseudo-Types

GaussDB type system contains a number of special-purpose types that are collectively called pseudo-types, as shown in **Table 7-23**. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Pseudo-types are useful when a function not only simply accepts or returns a certain SQL data type. **Table 7-23** lists all pseudo-types.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-23 Pseudo-types

Name	Description
any	Indicates that a function accepts any input data type.
anyelement	Indicates that a function accepts any data type.
anyarray	Indicates that a function accepts any array data type.
anynonarray	Indicates that a function accepts any non-array data type.
anyenum	Indicates that a function accepts any enum data type.
anyrange	Indicates that a function accepts any range data type.
cstring	Indicates that a function accepts or returns a null-terminated C string.
internal	Indicates that a function accepts or returns a server-internal data type.
language_handler	Indicates that a procedural language call handler is declared to return **language_handler**.
fdw_handler	Indicates that a foreign data wrapper handler is declared to return **fdw_handler**.
record	Identifies a function returning an unspecified row type.
trigger	Indicates that a trigger function is declared to return **trigger**.
void	Indicates that a function returns no value.
opaque	Indicates an obsolete type name that formerly served all the above purposes.

Functions coded in C language (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the anyelement, anyarray, anynonarray, anyenum, and anyrange types.

Each location (parameter or return value) declared as the anyelement type is allowed to have any specific actual data type, but they must all be of the same actual type in any given query.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct calling in an SQL query. If a function has at least one internal-type argument, then it cannot be called

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

from SQL. You are advised not to create any function that is declared to return internal unless it has at least one internal argument.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (a int);

-- Insert two data records.
gaussdb=# INSERT INTO t1 values(1),(2);

-- Create the showall() function.
gaussdb=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
gaussdb=# SELECT showall();
 showall
---------
 (2)
(1 row)

-- Delete the function.
gaussdb=# DROP FUNCTION showall();

-- Drop the table.
gaussdb=# DROP TABLE t1;
```

7.3.16 Data Types Used by the Ledger Database

The ledger database uses the hash16 data type to store row-level hash digests or table-level hash digests, and uses the hash32 data type to store global hash digests or history table verification hashes.

Table 7-24 Hash types of the ledger database

Name	Description	Storage Space	Range
HASH16	Stored as an unsigned 64-bit integer.	8 bytes	0 to +18446744073709551615
HASH32	Stored as an unsigned integer array of 16 elements.	16 bytes	Value range of an unsigned integer array of 16 elements

The hash16 data type is used to store row-level or table-level hash digests in the ledger database. After obtaining the hash sequence of a 16-character hexadecimal string, the system calls the hash16in function to convert the sequence into an unsigned 64-bit integer and stores the integer in a hash16 variable. For example:

```
Hexadecimal string: e697da2eaa3a775b; 64-bit unsigned integer: 16615989244166043483
Hexadecimal string: ffffffffffffffff; 64-bit unsigned integer: 18446744073709551615
```

The hash32 data type is used to store the global hash digest or history table verification hash in the ledger database. After obtaining the hash sequence of a

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

32-character hexadecimal string, the system calls the hash32in function to convert the sequence to an unsigned integer array of 16 elements. For example:

```
Hexadecimal string: 685847ed1fe38e18f6b0e2b18c00edee
Hash32 array: [104,88,71,237,31,227,142,24,246,176,226,177,140,0,237,238]
```

7.3.17 XML Types

The XML data type can be used to store Extensible Markup Language (XML) data. The internal format of XML is the same as that of the TEXT data type. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check. For details about functions related to XML types, see **Functions of the XML Type**.

The XML type can store well-formed "documents" and "content" fragments that comply with the XML standard. It is defined by referencing the broader "DOCUMENT NODE" XQUERY and XPATH data models. In general, this means that a content fragment can contain multiple top-level elements or character nodes. The expression XMLVALUE IS DOCUMENT can be used to evaluate whether a particular XML value is a complete document or just a document fragment.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. An element, the text of the element, and the attributes of the element are all considered as nodes.

The XML bottom layer uses the same data structure as the TEXT type for storage. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltest ( id int, data xml );
gaussdb=# INSERT INTO xmltest VALUES (1, 'one');
gaussdb=# INSERT INTO xmltest VALUES (2, 'two');
gaussdb=# SELECT * FROM xmltest ORDER BY 1;
 id | data
----+--------------------
1 | one
2 | two
(2 rows)
gaussdb=# SELECT xmlconcat(xmlcomment('hello'),
                           xmlelement(NAME qux, 'xml'),
                           xmlcomment('world'));
              xmlconcat
----------------------------------------
 <!--hello--><qux>xml</qux><!--world-->
(1 row)
gaussdb=# DROP TABLE xmltest;
```

The XML type does not support the following operations:

- Logical expressions AND, OR, and NOT.
- Input parameter of a system function that is used as a non-XML operation function.
- Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Implicit conversion related to XML, including the conversion between strings and the XML data type.
- Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX.
- Use columns of the XML data format as ordinary indexes, unique indexes, global indexes, local indexes, and partial indexes.
- Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM.
- Condition expressions DECODE, NULLIF, GREATEST, and LEAST.
- Used as DISTINCT, GROUP BY, or ORDER BY parameters.
- Aggregate functions, including sum, max, min, avg, list_agg, corr, covar_pop, covar_samp, stddev, stddev_pop, stddev_samp, var_pop, var_samp, variance, bit_and, bit_or, bool_and, bool_or, every, regr_avgx, regr_avgy, regr_count, regr_intercept, regr_r2, regr_slope, regr_sxx, regr_sxy, regr_syy, rank, and spread.
- ODBC-related APIs with binding parameters.

The XML type supports the following operations:

- Physical backup and restoration.
- Comparison expressions IS NULL and IS NOT NULL.
- Condition expressions CASE and COALESCE.
- Global temporary tables and local temporary tables.
- Forcible type conversion.
- Expression indexes.
- Input XML values that comply with the XML standard.
- gs_dump and gs_restore.
- Parallel query, supporting Astore and Ustore.
- Input parameters, output parameters, customized variables, and return values of a user-defined function.
- Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
- Character processing functions quote_literal(string text) (explicitly converted to the character type) and quote_nullable(string text) (explicitly converted to the character type).
- Aggregate functions count, array_agg, and checksum (explicitly converted to the character type), and string_agg (explicitly converted to the character type).
- If addition, deletion, modification, and query of user-defined composite types involve XML types that are similar to XML columns in ordinary tables, the composite types must be inserted and modified based on the XML syntax.
- JDBC and ODBC operations on XML data types are supported. The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XML column. You can enter an XML value using the SQL syntax and use the getSQLXML method of the ResultSet class to obtain the XML value. JDBC-related APIs with binding parameters are supported. For example, you can use

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

the setSQLXML method in the PreparedStatement API and the getSQLXML(int columnIndex) method in the ResultSet execution result set API.

In the calling process, use the java.sql.SQLXML API class to construct an XML object, set the specified object type to Oid.XML, and send the type ID and XML value to the server. After obtaining the result returned from the server, call ResultSet.getString. Then, use the java.sql.SQLXML API class to construct an XML object based on the obtained character string. In this case, the system checks whether the content complies with the XML standard again. Therefore, you can also use ResultSet.getString to directly obtain the XML string object.

7.3.18 XMLType

The XMLType data type is used to store XMLType data. Currently, data is stored in character strings. Its advantage over storing XML data in a TEXT field is that, XMLType data supports standard XML operation functions based on LIBXML2 and XML standardization check. For details about functions related to XMLType, see **Functions of the XMLType Type**.

The XMLType type can store well-formed "documents" that comply with the XML standard.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. An element, the text of the element, and the attributes of the element are all considered as nodes. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltypetest(id int, data xmltype);
gaussdb=# INSERT INTO xmltypetest VALUES (1, '<ss/>');
gaussdb=# INSERT INTO xmltypetest VALUES (2, '<xx/>');
gaussdb=# SELECT * FROM xmltypetest ORDER BY 1;
 id | data
----+-------
  1 | <ss/>
  2 | <xx/>
(2 rows)
gaussdb=# DROP TABLE xmltypetest;
```

The XMLType type does not support the following operations:

- Logical expressions AND, OR, and NOT.
- Input parameter of a system function that is used as a non-XMLType operation function.
- Used as a distribution key, partition key, level-2 partition key, primary key, or unique constraint.
- Implicit conversion related to XMLType, including the conversion between strings and the XMLType data type.
- Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX.
- Column of the XMLType data format that is used as an ordinary index, unique index, global index, local index, or partial index.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM.
- Condition expressions DECODE, NULLIF, GREATEST, and LEAST.
- Used as DISTINCT, GROUP BY, or ORDER BY parameters.
- Aggregate functions, including sum, max, min, avg, list_agg, corr, covar_pop, covar_samp, stddev, stddev_pop, stddev_samp, var_pop, var_samp, variance, bit_and, bit_or, bool_and, bool_or, every, regr_avgx, regr_avgy, regr_count, regr_intercept, regr_r2, regr_slope, regr_sxx, regr_sxy, regr_syy, rank, and spread.
- ODBC-related APIs with binding parameters.

The XMLType type supports the following operations:

- Physical backup and restoration.
- Comparison expressions IS NULL and IS NOT NULL.
- Condition expressions CASE and COALESCE.
- Global temporary tables and local temporary tables.
- Forcible type conversion.
- Expression indexes.
- Input XMLType values that comply with the XML standard.
- gs_dump and gs_restore.
- Parallel query, supporting Astore and Ustore.
- Input parameters, output parameters, customized variables, and return values of a user-defined function.
- Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
- Character processing functions quote_literal(string text) (explicitly converted to the character type) and quote_nullable(string text) (explicitly converted to the character type).
- Aggregate functions count, array_agg, and checksum (explicitly converted to the character type), and string_agg (explicitly converted to the character type).
- If addition, deletion, modification, and query of user-defined composite types involve XMLType types that are similar to XMLType columns in ordinary tables, the composite types must be inserted and modified based on the XMLType syntax.
- You can perform the SELECT, UPDATE, INSERT, or DELETE operation on the column and use the SQL syntax to enter the XMLTYPE value.

You can create a schema named **xmltype**. In the schema, you can create functions, but cannot use schema.func() to call functions defined in the schema.

7.3.19 ACLItem Type

The aclitem data type is used to store object permission information. The internal implementation is of the int type, and the supported format is '*user1*=*privs*|*user2*'.

The aclitem[] data type is an array consisting of ACL items. The supported format is {*user1* = *privs1*|*user3*, *user2* = *privs2*|*user3*}.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

user1, *user2*, and *user3* indicate the existing users or roles in the database, and *privs* indicates the permissions supported by the database. For details, see **Table 12-94**.

Example:

```
-- Create a user.
gaussdb=# CREATE USER user1 WITH PASSWORD '**********';
gaussdb=# CREATE USER user2 WITH PASSWORD '**********';
gaussdb=# CREATE USER omm WITH PASSWORD '**********';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
gaussdb=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);

-- Insert a data record whose content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');

-- Insert a data record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (2,'user1=aw/omm','{omm=d/user2}');
gaussdb=# SELECT * FROM  table_acl;
 id |     priv      |          privs
----+---------------+-------------------------
  1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
  2 | user1=aw/omm  | {omm=d/user2}
(2 rows)

-- Delete the table and user.
gaussdb=# DROP USER user1;
gaussdb=# DROP USER user2;
gaussdb=# DROP USER omm;
gaussdb=# DROP TABLE table_acl;
```

7.3.20 Array Types

Array types can be used to store several elements of the same type. For details about how to use array types and related functions, see **Arrays**.

Array Type Definition

Generally, an array data type is named by adding square brackets ([]) to the end of the data type name of an array element.

Example 1:

```
-- Create a table named sal_emp. The table contains the following columns: name of the text type, indicating employee names; pay_by_quarter of the integer element type, indicating an array of quarterly salaries; phone_numbers of the varchar(11) element type, indicating an array of mobile numbers.
gaussdb=# CREATE TABLE sal_emp (
 name            text,
 pay_by_quarter  integer[],
 phone_numbers   varchar(11)[]
);
gaussdb=# DROP TABLE sal_emp;
```

Example 2: Define an array type in other ways. For details about the definition method and behavior, see the comments in the example.

```
gaussdb=# CREATE TABLE sal_emp (
 name            text,
pay_by_quarter1  integer[][],      -- Two-dimensional array of the int type.
 pay_by_quarter2  integer[3],       -- One-dimensional array of the int type. The size is 3.
pay_by_quarter3  integer[3][3],    -- Two-dimensional array of the int type. The size of each dimension is 3.
 pay_by_quarter4  integer ARRAY,    -- One-dimensional array of the int type.
pay_by_quarter5  integer ARRAY[3]  -- One-dimensional array of the int type. The size is 3.
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
);
gaussdb=# DROP TABLE sal_emp;
```

NOTE

- The definition of the number of dimensions of an array does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type and do not use multidimensional array data.
- The definition of the array size does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type.
- The maximum number of dimensions of an array is 6.
- The restrictions on the number of array elements are as follows:
  - The maximum number of elements is 134217727.
  - The maximum storage space of all elements cannot exceed 1 GB minus 1 byte, that is, 1073741823 bytes.

Array Constructor

An array constructor is an expression that can build array values. A simple array constructor consists of the keyword ARRAY and an expression list of array element values which are separated by commas and enclosed (,) by square brackets ([]). For example:

```
gaussdb=# SELECT ARRAY[1, 2, 3 + 4];
  array
---------
 {1,2,7}
(1 row)
```

By default, the element type of an array is the common type of member expressions and is determined by the same rules as the UNION or CASE structure (for details, see **UNION, CASE, and Related Constructs**). You can construct an array to the desired data type through explicit type conversion. The following is an example:

```
gaussdb=# SELECT ARRAY[1, 2, 3]::varchar[];
  array
---------
 {1,2,3}
(1 row)

gaussdb=# SELECT ARRAY['a', 'b', 'c']::varchar[];
  array
---------
 {a,b,c}
(1 row)
```

In addition to the preset basic types, the record type and table type can also be defined as array types. The following is an example:

```
gaussdb=# CREATE TYPE rec IS (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::rec[];
       array
-------------------
 {"(1,1)","(2,2)"}
(1 row)

gaussdb=# CREATE TABLE tab (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)]::tab[];
       array
-------------------
 {"(1,1)","(2,2)"}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

gaussdb=# DROP TYPE rec;
gaussdb=# DROP TABLE tab;
```

An array must have a type. Therefore, when constructing an empty array, you must construct it as the required type. For example:

```
gaussdb=# SELECT ARRAY[]::int[];
 array
-------
 {}
(1 row)
```

You can also construct an array from the result of a subquery. In this case, the array constructor consists of the keyword ARRAY and a subquery enclosed in parentheses. The subquery must return only one separate column. The generated one-dimensional array generates an element for each row of the result in the subquery. The element type matches the output column of the subquery. For example:

```
gaussdb=# SELECT ARRAY(SELECT generate_series(1, 6));
    array
---------------
 {1,2,3,4,5,6}
(1 row)
```

Multidimensional array values can be made by nesting array constructors. The ARRAY keyword in the inner constructor can be omitted. For example, the following two examples show the same result:

```
gaussdb=# SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
    array
---------------
 {{1,2},{3,4}}
(1 row)

gaussdb=# SELECT ARRAY[[1,2], [3,4]];
    array
---------------
 {{1,2},{3,4}}
(1 row)
```

NOTE

- Inner constructors at the same layer must generate subarrays of the same dimension.
- Any type conversion applied to the outer ARRAY constructor is automatically applied to all inner constructors.

String Inputs of the Array Type

To write an array value as a literal constant (constant input), enclose the element values with braces and separate them with commas. The general format of an array constant is as follows:

```
'{ val1 delim val2 delim ... }'
```

In the preceding format, **delim** indicates the delimiter of the element type and is recorded in the **typdelim** column in the pg_type catalog of the type. Each **val** can be a constant of the array element type or a subarray. For example:

```
gaussdb=# SELECT '{1, 2, 3}'::int[] AS RESULT;
 result
---------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 {1,2,3}
(1 row)

gaussdb=# SELECT '{{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}'::int[] AS RESULT;
     result
---------------------------
 {{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

Double quotation marks can be used around any element value, and double quotation marks must be used when the element value contains special characters such as commas or braces.

For example:

-- This example indicates that there is an array of the varchar type and there are seven varchar elements in total. The elements are as follows:

- Character string containing a space
- Character string whose value is **NULL**
- **NULL**
- Character string with a backslash (\)
- Character string with a left brace ({)
- Character string with a right brace (}) and a comma (,).

```
gaussdb=# SELECT '{" ", "NULL", null, "\\", "{", "}", ","}'::varchar[] AS RESULT;
            result
-----------------------------------
 {" ","NULL",NULL,"\\","{","}",","}
(1 row)
```

NOTE

- For array string constant inputs, if the array element value is an empty string, contains braces, delimiters, double quotation marks, backslashes, or spaces, or matches the keyword NULL, then element inputs are enclosed in double quotation marks. An additional backslash is input if the element value contains double quotation marks or backslashes.
- The keyword NULL is case-insensitive.
- The input spaces not enclosed in double quotation marks are automatically skipped.
- You are advised to use the array constructor instead of character constants to construct array data.

String Outputs of the Array Type

The output of an array value consists of the output of the array element type plus some modifiers indicating the array structure. These modifiers consist of braces ({}) around array values plus delimiters between adjacent items. In a multidimensional array, each dimension has its own level of braces and contains delimiters between adjacent braces at the same level.

The data of the array type contains special characters (in the following description). The following is an example of character string output:

```
gaussdb=# SELECT ARRAY['{', '}', 'hello, world', '"', '\', '  ', NULL] AS RESULT;
                  array
-------------------------------------------------
 {"{","}","hello, world","\"","\\","  ",NULL}
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

For array string constant outputs, if the array element value is an empty string or contains braces, delimiters, double quotation marks, backslashes, or spaces, or the element is NULL, then element outputs are enclosed in double quotation marks. An additional backslash is output if the element value contains double quotation marks or backslashes. This parameter corresponds to the string constant inputs.

Use of Array Types

The following is an example of using the array type:

```
-- Create a table with array columns and insert some data.
gaussdb=# CREATE TABLE orders (
 name  varchar,
 items varchar[]
);
gaussdb=# INSERT INTO orders VALUES('a', ARRAY['Apple', 'Orange', 'Pear']);
gaussdb=# INSERT INTO orders VALUES('b', ARRAY['Mineral water', 'Coke', 'Sprite']);
gaussdb=# INSERT INTO orders VALUES('c', ARRAY['Mouse', 'Keyboard', 'Earphone']);
gaussdb=# INSERT INTO orders VALUES('d', '{Cabbage, Potato, Eggplant}');

-- Query data.
gaussdb=# SELECT * FROM orders ORDER BY name;
 name |       items
------+--------------------
 a    | {Apple,Orange,Pear}
 b    | {Mineral water,Coke,Sprite}
 c    | {Mouse,Keyboard,Earphone}
 d    | {Cabbage,Potato,Eggplant}
(4 rows)

-- Access array elements.
gaussdb=# SELECT items[1] FROM orders ORDER BY name;
 items
--------
 Apple
 Mineral water
 Mouse
 Cabbage
(4 rows)

-- If the accessed element exceeds the range or the accessed index is NULL, NULL is returned.
gaussdb=# SELECT items[4] FROM orders ORDER BY name;
 items
-------

(4 rows)

gaussdb=# SELECT items[null] FROM orders ORDER BY name;
 items
-------

(4 rows)

-- Access a subarray.
gaussdb=# SELECT items[1:2] FROM orders ORDER BY name;
     items
---------------
 {Apple,Orange}
 {Mineral water,Coke}
 {Mouse,Keyboard}
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 {Cabbage,Potato}
(4 rows)

-- Updates the entire array.
gaussdb=# UPDATE orders SET items = ARRAY['Banana', 'Watermelon', 'Strawberry'] WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
      items
------------------
 {Banana,Watermelon,Strawberry}
(1 row)

-- Updates the elements of an array.
gaussdb=# UPDATE orders SET items[1] = 'Mango' WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
      items
------------------
 {Mango,Watermelon,Strawberry}
(1 row)

-- Updates the element fragment of an array.
gaussdb=# UPDATE ORDERS SET items[1:2] = ARRAY['Computer', 'Mobile phone'] WHERE name = 'c';
gaussdb=# SELECT items FROM ORDERS WHERE name = 'c';
      items
------------------
 {Computer,Mobile phone,Earphone}
(1 row)

-- Add an array element. All unassigned elements between the last element of the original array and the
new element are set to NULL.
gaussdb=# UPDATE orders SET items[4] = 'Display' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
          items
-------------------------
 {Computer,Mobile phone,Earphone,Display}
(1 row)

gaussdb=# UPDATE orders SET items[6] = 'Display 2' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
                items
--------------------------------------
 {Computer,Mobile phone,Earphone,Display,NULL,Display 2}
(1 row)
```

7.3.21 Vector Data Types

Vector data types include floatvector and boolvector.

- The floatvector data type indicates that multidimensional data contains data of the float type, for example, [1.0,3.0,11.0,110.0,62.0,22.0,4.0].

  NOTE

  - The floatvector member supports only single precision. Single-precision range: -3.402E+38 to +3.402E+38, 6-digit decimal digits.
  - The floatvector does not support NULL, Nan, or Inf as elements. If a vector contains NULL values, the database reports an error.
  - The floatvector cannot be NULL. The database reports an error when a NULL value is inserted, updated, or converted as vector data.
  - In some scenarios (when the execution plan is a streaming plan), the precision of numeric values stored in the floatvector member is influenced by the GUC parameter **extra_float_digits**. As a result, the calculation results of the same data may be inconsistent. To mitigate this issue, set **extra_float_digits** to **3**.

- The boolvector data type indicates that the multidimensional data contains data of the Boolean type, for example, [0,0,0,0,0,1,0,0,1,0,0,0].

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Members of the boolvector data type can express Boolean data in **t(T)**/**f(F)**, **y(Y)**/**n(N)**, **1**/**0**, **true**/**false**, **yes**/**no**, or **on**/**off** mode.
- The boolvector does not support NULL, Nan, or Inf as elements. If a vector contains NULL values, the database reports an error.
- The boolvector cannot be NULL. The database reports an error when a NULL value is inserted, updated, or converted as vector data.

Usage of Vector Types

An example of using the vector type is as follows:

```
-- Create a table that contains vector types and set data dimensions. Dimensions must be specified for vector types during table creation.
gaussdb=# CREATE TABLE t1(id int unique, repr floatvector(4));
gaussdb=# CREATE TABLE t2(id int unique, repr boolvector(3));
-- Insert data.
gaussdb=# INSERT INTO t1 VALUES(0, '[30,12,12,25]');
gaussdb=# INSERT INTO t2 VALUES(1, '[1, 0, 1]');
```

7.3.22 Data Types Supported by the Vectorized Executor

Table 7-25 lists the data types supported by the vectorized executor.

Table 7-25 Data types supported by the vectorized executor

Category	Data Type	Length	Supported or Not
Numeric Types	tinyint [unsigned]	1	Supported
	smallint [unsigned]	2	Supported
	mediumint [unsigned]	3	Supported
	integer [unsigned]	4	Supported
	bigint [unsigned]	8	Supported
	decimal	-1	Supported
	numeric	-1	Supported
	real	4	Supported
	double precision	8	Supported
	smallserial	2	Supported
	serial	4	Supported
	bigserial	8	Supported
	largeserial	-1	Supported
Monetary Types	money	8	Supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Category	Data Type	Length	Supported or Not
Boolean Types	boolean	1	Supported
Character Types	character varying(n), varchar(n)	-1	Supported
	character(n), char(n),nchar(n)	n	Supported
	character, char	1	Supported
	text	-1	Supported
	varchar2(n)	-1	Supported
	nvarchar2(n)	-1	Supported
	clob	-1	Supported
Binary Types	raw	-1	Supported
	bytea	-1	Supported
Bit String Types	bit(n)	n	Supported
	bit varying(n)	-1	Supported
Date/Time Types	timestamp with time zone	8	Supported
	timestamp without time zone	8	Supported
	date	4	Supported
	time without time zone	8	Supported
	time with time zone	12	Supported
	interval	16	Supported
Network Address Types	cidr	7 or 19	Supported
	inet	7 or 19	Supported
XML Types	xml	-1	Supported
Other Types	enum	An enumerated type is a list of one or more quoted labels, each of which must be 1 to 63 bytes long.	Supported

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

Currently, the enumerated type can be created only in the following mode. For details, see **CREATE TYPE**.

```
CREATE TYPE name AS ENUM (['label' [, ...]]);
```

7.4 Character Sets and Collations

A character set provides character encoding rules, and a collation provides character sorting rules. This section describes the character sets and collations in MySQL-compatible GaussDB (**sql_compatibility = 'MYSQL'**). The following character sets, collation rules, and syntax are supported only in MySQL-compatible mode:

For details about the character sets supported by GaussDB, see "ENCODING" in **CREATE DATABASE**. For details about the supported collations, see the PG_COLLATION system catalog.

Some character sets have default collations in MySQL-compatible mode. For details, see **Table 7-269**.

The character set and collations are described as follows:

- Each character set has one or more collations and has only one default collation.
- Each collation has only one associated character set.
- The sorting results of the same data using different collations may be different.
- In GaussDB, utf8mb4 and utf8 are the same character set.
- When **sql_compatibility** is set to **'MYSQL'**, the binary and SQL_ASCII character sets are the same.
- You are advised to select the same character set for table columns and server_encoding to avoid performance loss caused by transcoding.

GaussDB supports the following functions:

- Multiple character sets can be used to store character strings.
- Collations can be used to compare character strings.
- Database-level, schema-level, table-level, and column-level character sets and collations are supported.

  NOTE

  Character strings with different character sets and collations cannot be used in the same server, database, table, or SQL statement.

7.4.1 Character Sets and Collations of the Client Connection

When data containing character set attributes is transmitted between the server and client, encoding conversion is automatically performed. After receiving an SQL statement from a client, the server converts the character set of the SQL statement from the client character set client_encoding to the database character set server_encoding. Before the query result data is sent to the client, the data is encoded and converted to the client_encoding character set of the client.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

System parameters:

- server_encoding

  Character set specified during database creation. For details, see **CREATE DATABASE**.

- client_encoding

  Character set of the client, which can be modified using the SET NAMES statement. For details, see **SET**.

- character_set_connection

  Default character set of string constants for which no character sets are specified in SQL statements.

- collation_connection

  Default collation of string constants for which no collations are specified in SQL statements.

- character_set_results

  Character set of the returned result.

  NOTE

  - For an expression that converts a non-character type object to a character type, the result character set and collation are **character_set_connection** and **collation_connection**, respectively.
  - By default, the character set and collation number of a bound parameter of the character type are the values of **character_set_connection** and **collation_connection**, respectively.
  - During character data conversion, the character encoding is verified. If the character encoding does not meet the requirements, an error message is displayed.

7.4.2 Database-level Character Sets and Collations

When creating a database, you can specify the character set sequence of the database. For details about how to create a database, see **CREATE DATABASE**.

```
CREATE DATABASE [IF NOT EXISTS] database_name
            [ ENCODING [=] encoding ] |
            [ LC_COLLATE [=] lc_collate ] |
            [ LC_CTYPE [=] lc_ctype ] |;
```

Parameters:

- **database_name**

  Specifies the database name.

  Value range: a string. It must comply with the naming convention.

- **ENCODING [=] encoding**

  Specifies the character encoding used by the database. The value can be a string (for example, **'SQL_ASCII'**) or an integer.

- **LC_COLLATE [=] lc_collate**

  Specifies the character set used by the new database. For example, set this parameter by using **lc_collate = 'zh_CN.gbk'**.

  The use of this parameter affects the sort order of strings (for example, the order of using ORDER BY for execution and the order of using indexes on text columns). By default, the sorting order of the template database is used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Value range: character sets supported by the OS.

- **LC_CTYPE [=] lc_ctype**

  Specifies the character class used by the new database. For example, set this parameter by using **lc_ctype = 'zh_CN.gbk'**. The use of this parameter affects the character class, such as uppercase letters, lowercase letters, and digits. By default, the character class of the template database is used.

  Value range: character classes supported by the OS.

  NOTE

  - The database-level character set and collation syntax can be used in all modes. For details about the syntax, see **CREATE DATABASE**.
  - The LC_COLLATE/LC_CTYPE syntax does not support the collations specific to MySQL-compatible mode. The parameter value range depends on the character sets supported by the local environment. You can run the **locale -a** command to view the parameter value range.

7.4.3 Schema-level Character Sets and Collations

Create a schema and specify the default character set and collation. For details about how to create a schema, see **CREATE SCHEMA**.

```
CREATE SCHEMA schema_name
 [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
 [ [DEFAULT] COLLATE [ = ] default_collation ];
```

Modify the default character set and collation attributes of a schema. For details about how to modify a schema, see **ALTER SCHEMA**.

```
ALTER SCHEMA schema_name
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ] [ [DEFAULT] COLLATE [ = ]
default_collation ];
```

Parameter description:

- **schema_name**

  Specifies the schema name.

  Value range: a string. It must comply with the **naming convention**.

- **default_charset**

  Specifies the default character set of a schema. If you specify a character set separately, the default collation of the schema is set to the default collation of the specified character set.

- **default_collation**

  Specifies the default collation of a schema. If you specify a collation separately, the default character set of the schema is set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a schema in the following ways:

- If both **default_charset** and **default_collation** are set, the character set **default_charset** and collation **default_collation** are used. In addition, **default_charset** and **default_collation** must correspond to each other. Otherwise, an error is reported.
- If only **default_charset** is set, the character set **default_charset** and its default collation are used.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If only **default_collation** is set, the collation **default_collation** and its corresponding character set are used.
- If neither **default_charset** nor **default_collation** is specified, the schema has no default character set or default collation.

NOTE

- Only character sets with a default collation support **default_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode (**sql_compatibility = 'MYSQL'**) support **default_collation**. If another collation is specified, an error is reported.
- The character set and collation of the new schema must be server_encoding of the database.

Example:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE SCHEMA test CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE SCHEMA test COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE SCHEMA test CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of test to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER SCHEMA test CHARSET utf8mb4 COLLATE utf8mb4_bin;
```

7.4.4 Table-level Character Sets and Collations

Set the default character set and collation for a table. For details about how to create a table, see **CREATE TABLE**.

```
CREATE TABLE table_name (column_list)
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
    [ [DEFAULT] COLLATE [ = ] default_collation ]
```

Modify the default character set and collation of a table. The modification does not affect the existing columns in the table. For details about how to modify a table, see **ALTER TABLE**.

```
ALTER TABLE table_name
    [ [DEFAULT] CHARACTER SET | CHARSET [ = ] default_charset ]
    [ [DEFAULT] COLLATE [ = ] default_collation ]
```

NOTE

Currently, you cannot modify the default character set and collation of a table to the specified values, set the character set and collation of all columns with character type to the specified value, or convert the data in the column to new character set encoding. The syntax is as follows:

```
ALTER TABLE table_name
    CONVERT TO CHARACTER SET | CHARSET charset [ COLLATE collation ]
```

Parameters

- **table_name**

  Specifies the name of the table.

- **default_charset**

  Specifies the default character set of a table. If you specify a character set separately, the default collation of the table is set to the default collation of the specified character set.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **default_collation**

  Specifies the default collation of a table. If you specify a collation separately, the default character set of the table is set to the character set corresponding to the specified collation.

GaussDB selects a character set and collation of a table in the following ways:

- If both **default_charset** and **default_collation** are set, the character set **default_charset** and collation **default_collation** are used. In addition, **default_charset** and **default_collation** must correspond to each other. Otherwise, an error is reported.
- If only **default_charset** is set, the character set **default_charset** and its default collation are used.
- If only **default_collation** is set, the collation **default_collation** and its corresponding character set are used.
- If neither **default_charset** nor **default_collation** is set, the default character set and collation of the schema where the table is located are used as the default character set and collation of the table.

NOTE

- Only character sets with a default collation support **default_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode (**sql_compatibility = 'MYSQL'**) support **default_collation**. If another collation is specified, an error is reported.
- If the default collation of a table is binary, the text types whose collation is not specified in the table are converted to the corresponding binary type, and the collation is set to binary.
- Currently, the default character set and collation of a table must be server_encoding of the database.
- Currently, the data of columns of the character type in the table cannot be converted into encoding.

Example:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text) CHARSET utf8;

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text) COLLATE utf8_bin;

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text)  CHARSET utf8 COLLATE utf8_bin;

-- Change the default character set of the table to utf8mb4 and the default collation to utf8mb4_bin.
gaussdb=# ALTER TABLE test CHARSET utf8mb4 COLLATE utf8mb4_bin;
```

7.4.5 Column-level Character Sets and Collations

You can set the character set and collation for each column of the string type (CHAR, VARCHAR, or TEXT).

```
CREATE TABLE table_name (
    column_name data_type
    [ CHARACTER SET | CHARSET charset ]
    [ COLLATE collation ]
);
```

Syntax description:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **table_name**

  Specifies the name of the table.

- **data_type**

  Specifies the data type of a column. The value can be character set or collation syntax.

- **CHARACTER SET | CHARSET charset**

  Specifies the character set of a table column. If this parameter is specified separately, the collation of the table column is set to the default collation of the specified character set.

- **COLLATE collation**

  The COLLATE clause specifies the collation of a column (the data type of the column must support collation). If no collation is specified, the default collation is used.

GaussDB selects a character set and collation of a table column in the following ways:

- If both **charset** and **collation** are specified, **charset** and **collation** are used. **charset** and **collation** must correspond to each other. Otherwise, an error is reported.
- If only **charset** is specified, the character set **charset** and its default collation are used.
- If only **collation** is specified, the character set associated with collation and the specified collation are used.
- If neither **charset** nor **collation** is specified, the default character set and collation of the table are used.

NOTE

- Only character sets with a default collation support **default_charset**. If the specified character set does not have a default collation, an error is reported.
- Only the collations in MySQL-compatible mode support **default_collation**. If another collation is specified, an error is reported.
- If a table column is of the text type and the specified collation is binary, the text type is converted to the corresponding binary type and the collation is the specified binary collation.
- The character set of the partition key of the partitioned table must be the same as that of the database.
- Currently, the default character set and collation of a table column must be server_encoding of the database.

Example:

```
-- Set only the character set. The collation is the default collation of the character set.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8);

-- Set only the collation. The character set is the character set associated with the collation.
gaussdb=# CREATE TABLE test(c1 text COLLATE utf8_bin);

-- Set both the character set and collation. The character set and collation must correspond to each other.
gaussdb=# CREATE TABLE test(c1 text CHARSET utf8 COLLATE utf8_bin);
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

7.4.6 Character Sets and Collations of Expressions of the String Type

Each expression of the string type contains character sets and collation attributes.

In MySQL-compatible mode (**sql_compatibility** is set to **'MYSQL'**), if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, the default character sets and collations of string constants are determined by the system parameters **character_set_connection** and **collation_connection**. Otherwise, the default character set is the same as server_encoding of the database, and the default collation is **default**.

Character set syntax:

GaussDB does not support the character set of string constants specified by the following syntax:

```
[_charset_name]'string'
```

Collation syntax:

You can also specify the collation for expressions of other character string types.

```
EXPRESSION [COLLATE collation_name]
```

Parameters:

COLLATE collation_name

Collation name, which is the collation attribute of the string.

- The data type of the expression must be a data type that supports collations.
- The specified collation must be supported by the character set of the expression.

Example:

```
-- Use the COLLATE statement to specify the collation.
gaussdb=# SELECT 'a' COLLATE utf8mb4_general_ci = 'A';
```

7.4.7 Rules for Combining Character Sets and Collations

In MySQL-compatible database (**sql_compatibility = 'MYSQL'**), if **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, expressions with different character sets and collations are processed based on certain priorities to determine the collations used for character string comparison and the character sets of the expressions.

Collation priority

The priorities of different expressions in descending order are as follows:

- The COLLATE syntax has the highest priority.
- Expressions with collation conflicts (for example, two character strings with different collations).
- Columns of data types that support collation, user-defined variables, stored procedure parameters, and CASE expressions.
- Specific system functions (such as version() and opengauss_version() function expressions).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- String constants and bound parameters.
- NULL expression.
- If a data type of an expression does not support collation, the expression has the lowest priority.

When the collations of two expressions are different, the collation of the expression with the highest priority is used.

Example:

```
gaussdb=# CREATE TABLE t_utf8(c1 varchar(16) character set utf8mb4 collate utf8mb4_bin);
gaussdb=# INSERT INTO t_utf8 VALUES('STRING');

-- If the utf8mb4_bin collation is used for comparison, the result is false.
gaussdb=# SELECT c1 = 'string' AS result FROM t_utf8;
 result
--------
 f
(1 row)

-- If the utf8mb4_general_ci collation is used for comparison, the result is true.
gaussdb=# SELECT c1 = 'string' COLLATE utf8mb4_general_ci AS result FROM t_utf8;
 result
--------
 t
(1 row)

-- Define the collation of the bound parameter $1 as collation_connection.
gaussdb=# PREPARE test_collation(text) AS SELECT c1 = $1 AS result FROM t_utf8;

-- The collation of the bound parameter is at the same level as that of the string constant. Even if the input expression contains an explicit collation, the collation of c1 is still used for comparison.
gaussdb=# EXECUTE test_collation('string' COLLATE utf8mb4_general_ci);
 result
--------
 f
(1 row)

-- The CASE expression is at the same level as the c1 column. Even if the expression contains an explicit collation, the collation of the c1 column is still used for comparison. The two collations are different. "same level" is displayed.
gaussdb=# SELECT CASE 'string' COLLATE utf8mb4_general_ci WHEN c1 THEN 'different level' ELSE 'same level' END AS result FROM t_utf8;
   result
------------
 same level
(1 row)

-- The IN subquery has the same level as the c1 column. Even if the expression contains an explicit collation, the collation of c1 is still used for comparison. The two collations are different.
gaussdb=# SELECT c1 FROM t_utf8 WHERE c1 in (SELECT 'string' COLLATE utf8mb4_general_ci);
 c1
----
(0 rows)
```

If the collations of two expressions with the same priority are different, the following processing method is used:

- If the two character sets are the same, the collation suffixed with **_bin** is preferred.
- If the two character sets are the same, the default collation is not preferred.
- If the preceding conditions are not met, the two expressions are marked as a collation conflict, and the collations are marked as invalid.
  - If a conflict occurs because the COLLATE syntax specifies different collations for the same character set, an exception is displayed.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- If the two conflicting collations are supported in MySQL-compatible mode (**sql_compatibility = 'MYSQL'**), an exception occurs.
- If the conflicting character set is different from server_encoding of the database, an exception occurs.
- If an invalid collation is used for sorting operations (such as > and <), an exception occurs.
- During equivalent comparison of character strings, if the collation is invalid, the character strings are compared as binary values.

Example:

```
gaussdb=# CREATE TABLE t_utf8mb4_charset(
    c_utf8_bin varchar(16) character set utf8mb4 collate utf8mb4_bin,
    c_utf8_uni varchar(16) character set utf8mb4 collate utf8mb4_unicode_ci,
    c_utf8_gen varchar(16) character set utf8mb4 collate utf8mb4_general_ci);
gaussdb=# INSERT INTO t_utf8mb4_charset VALUES('STRING', 'String', 'string');

-- The utf8mb4_bin collation is preferentially used for comparison. The result is false.
gaussdb=# SELECT c_utf8_bin = c_utf8_uni FROM t_utf8mb4_charset;

-- Collation conflict. Binary comparison is performed, and the result is false.
gaussdb=# SELECT c_utf8_uni = c_utf8_gen FROM t_utf8mb4_charset;

-- Conflict of the explicitly specified collation. An exception is reported.
gaussdb=# SELECT c_utf8_uni COLLATE utf8mb4_unicode_ci = c_utf8_gen COLLATE utf8mb4_general_ci
FROM t_utf8mb4_charset;
```

NOTE

- Only the character sets of objects and expressions of the string type (excluding "char", name, and clob) can be different from those of the database.
- Data types such as ARRAY, XML, JSON, and TSVECTOR contain text data. The character sets in the text data of the objects and expressions of these data types must be the character sets of the database.
- According to the rules for combining character sets and collations, the character sets corresponding to C, POSIX, and DEFAULT collations are server_encoding.

7.5 Constant and Macro

Table 7-26 lists the constants and macros that can be used in GaussDB.

Table 7-26 Constant and macro

Parameter	Description	Example
CURRENT_CATALOG	Specifies the current database.	testdb=# SELECT CURRENT_CATALOG; current_database ------------------ testdb (1 row)
CURRENT_ROLE	Specifies the current user.	gaussdb=# SELECT CURRENT_ROLE; current_user -------------- omm (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Description	Example
CURRENT_SCHEMA	Specifies the current database mode.	gaussdb=# SELECT CURRENT_SCHEMA; current_schema ---------------- public (1 row)
CURRENT_USER	Specifies the current user.	gaussdb=# SELECT CURRENT_USER; current_user -------------- omm (1 row)
LOCALTIMESTAMP	Specifies the current session time (without time zone).	gaussdb=# SELECT LOCALTIMESTAMP; timestamp ---------------------------- 2015-10-10 15:37:30.968538 (1 row)
NULL	This parameter is left blank.	N/A
SESSION_USER	Specifies the current system user.	gaussdb=# SELECT SESSION_USER; session_user -------------- omm (1 row)
SYSDATE	Specifies the current system date.	gaussdb=# SELECT SYSDATE; sysdate --------------------- 2015-10-10 15:48:53 (1 row)
USER	Specifies the current user, also called **CURRENT_USER**.	gaussdb=# SELECT USER; current_user -------------- omm (1 row)

7.6 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

NOTE

When the GUC parameter **behavior_compat_options** contains the **'enable_funcname_with_argsname'** option, the projection alias displays the complete function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

7.6.1 Logical Operators

Common logical operators include AND, OR, and NOT. The operation result has three values: **TRUE**, **FALSE**, and **NULL**. NULL indicates unknown. Their priorities are NOT > AND > OR.

Table 7-27 lists the calculation rules, where a and b represent logical expressions.

Table 7-27 Operation rules

a	b	a AND b Result	a OR b Result	NOT a Result
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	TRUE	FALSE
TRUE	NULL	NULL	TRUE	FALSE
FALSE	FALSE	FALSE	FALSE	TRUE
FALSE	NULL	FALSE	NULL	TRUE
NULL	NULL	NULL	NULL	NULL

NOTE

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.
- Operations on XML data are not supported.

7.6.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

Table 7-28 describes comparison operators provided by GaussDB.

Table 7-28 Comparison operations

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator	Description
<>, !=, or ^=	Not equal to

- For comparison operators <=, <>, >=, and ^=, if there is a space between two symbols, it does not affect normal operations. For !=, if there is a space between the exclamation mark (!) and an equal sign (=), the exclamation mark will be identified as factorial, which may cause the result to be inconsistent with the expected result.
- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type. The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as **1 < 2 < 3** is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Besides, each comparison operator has a corresponding function in the pg_proc system catalog. If the value of the **proleakproof** attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.
- This operator does not support data of the XML type.

7.6.3 Character Processing Functions and Operators

7.6.3.1 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Note: Except length-related functions, other functions and operators of string processing functions do not support parameters greater than 1 GB.

bin(number)

Description: Returns a binary string of a given number.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
number	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Given number.

Return type: text.

Example:

```
gaussdb=# SELECT bin(5);
  bin
--------
  101
(1 row)
```

NOTE

- The bin function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the value of the input parameter **number** is a decimal, round it down.
- If the absolute value of the input parameter **number** exceeds the maximum value of the bigint unsigned type, convert the input parameter **number** to the maximum value of the bigint unsigned type.

bit_length(string)

Description: Specifies the number of bits occupied by a string.

Return type: int.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT bit_length('world');
 bit_length
------------
         40
(1 row)
```

btrim(string text [, characters text])

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT btrim('sring' , 'ing');
 btrim
-------
 sr
(1 row)
```

char_length(string) or character_length(string)

Description: Specifies the number of characters in a string.

Return type: int.

Example:

```
gaussdb=# SELECT char_length('hello');
 char_length
-------------
           5
(1 row)
```

dump(expr[, return_fmt [, start_position [, length]]])

Description: Returns the data type code, byte length, and internal representation of the input expression. **return_fmt** specifies the number system of the internal representation, **start_position** specifies the byte from which the internal representation starts, and **length** indicates the length of the data to be read.

Return type: text.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

elt(pos,str1,str2,...)

Description: Returns the *pos*th string.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
pos	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Specified position of the parameter.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
str1,str2,...	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	List of character strings.

Return type: text.

Example:

```
gaussdb=# SELECT elt(3, 'a', 'b', 'c');
 elt
-------
   c
(1 row)
```

NOTE

- The elt function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the input parameter **pos** is less than 1 or exceeds the number of parameters, **NULL** is returned.

field(str,str1,str2,str3,...)

Description: The field function returns the position of **str** in the *str1,str2,str3,...,strN* list. The position increases from 1. If **0** is returned, **str** is not found. If **str** is **NULL**, **0** is returned. If the input parameters of a function are all digits, the comparison is

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

performed based on digits. If the input parameters are all non-digits, the comparison is performed based on character strings. If the input parameters contain both digits and non-digits, the comparison is performed based on the double type.

Parameter	Type	Description
str,str1,str2,str3,...	• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Boolean types: true and false. • Floating-point types: float(p), float, real, double, float(m, d), double(m, d), and real(m, d). • Fixed-point types: numeric, decimal, and dec. • Text types: tinytext, text, mediumtext, and longtext. • Character string types: char and varchar. • Large object types: tinyblob, blob, mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	List of character strings.

Return type: bigint.

Example:

```
gaussdb=# SELECT field( 'abc','1',1,'abc','abcd' );
 field
-------
     3
(1 row)
```

NOTE

- The field function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the sql_mode parameter **pad_char_to_full_length** specifies whether to add spaces at the end of the char type, which affects the field comparison result. For details, see **Table 7-8**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the behavior of the character, binary, numeric, and date and time types is M-compatible, which affects the field comparison result. For details, see **Data Types**. For the floating-point type in the numeric type, the precision may be different from that in MySQL due to different connection parameter settings. Therefore, this scenario is not recommended, or the numeric type is used instead. For details, see **Connection Parameters**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, characters can be escaped and constant character strings can obtain collations. The collations affect the field comparison result. For details, see the SET NAMES syntax in **SET**. For details about the rules for combining different collations of the character types, see **Rules for Combining Character Sets and Collations**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

insert(str1, pos, len, str2)

Description: Returns the processing result of *str1*. The substring starts from *pos* and the number of *len* characters in the character string is replaced with *str2*. If any input parameter is **NULL**, the return value is **NULL**.

Parameter	Type	Description
pos, len	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec.	**pos** indicates the parameter in the specified position, and **len** indicates the replacement length.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
str1, str2	• NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference is an inherent difference between GaussDB and MySQL and is not caused by this function. • Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in M* are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function. • Character string types: char and varchar. • Text types: tinytext, text, mediumtext, and longtext. • Large object types: tinyblob, blob,	String.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
	mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	

Return value type: The return value of the function is of the text type (both **s1** and **s2** are of the text type) or bytea type (any of **s1** or **s2** is of the bytea type).

Example:

```
gaussdb=# SELECT INSERT('abcdef',2,3,'gg');
 insert
--------
 aggef
(1 row)
```

NOTE

- The insert function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- The value range of the input parameter of the Int64 type is limited. If the value exceeds the value range of –9223372036854775808 to 9223372036854775807, an error is reported. MySQL has no restriction on the range of input parameters of the numeric type. If an exception occurs, an alarm is generated and the upper or lower limit is used. Input parameters of the character string are restricted. The maximum length of the input parameter of the text type is 2^30 – 5 bytes, and the maximum length of the input parameter of the bytea type is 2^30 – 512 bytes.

instr(text,text,int,int)

Description: **instr(string1,string2,int1,int2)** returns the position matching *string2* in *string1* for the *int2*th time from the position specified by *int1*. *int1* indicates the start position for matching, and *int2* indicates the number of matching times.

Return type: int.

Example:

```
gaussdb=# SELECT instr( 'abcdabcdabcd', 'bcd', 2, 2 );
 instr
-------
     6
(1 row)
```

instrb(text,text,int,int)

Description: **instrb(string1,string2,int1,int2)** returns the position matching *string2* in *string1* for the *int2*th time from the position specified by *int1*. *int1* indicates the start position for matching, and *int2* indicates the number of matching times. Different from the instr function, instrb is calculated in bytes and is not affected by the character set in use.

Return type: int.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT instrb( 'abcdabcdabcd', 'bcd', 2, 2 );
 instrb
-------
     6
(1 row)
```

NOTE

- This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database.
- If the values of *int1* and *int2* are decimals, the values are truncated instead of being rounded off.

lengthb(text/bpchar)

Description: Obtains the number of bytes of a specified string.

Return type: int.

Example:

```
gaussdb=# SELECT lengthb('hello');
 lengthb
---------
       5
(1 row)
```

lengthc(text/bpchar)

Description: Returns the length of a specified string, calculated according to Unicode character encoding rules.

Return type: int.

Example:

```
gaussdb=# SELECT lengthc('hello');
 lengthc
---------
       5
(1 row)
```

left(str text, n int)

Description: Returns the first *n* characters in a string. When *n* is negative, all but the last */n/* characters are returned.

Return type: text.

Example:

```
gaussdb=# SELECT left('abcde', 2);
 left
------
 ab
(1 row)
```

length(string bytea, encoding name)

Description: Specifies the number of characters in **string** in the given **encoding**. The **string** must be valid in this encoding.

Return type: int.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT length('jose', 'UTF8');
 length
--------
      4
(1 row)
```

NOTE

If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

locate(substr, str[, pos])

Description: Returns the position where *substr* appears for the first time in *str*, starting from *pos* (**1** by default). If *substr* cannot be found in *str*, this function returns **0**.

Parameter	Type	Description
substr, str	• Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Floating-point types: float and double. • Arbitrary precision type: numeric. • Character types: char, varchar, and text. • Binary types: bytea and blob. • Date/Time types: date, time, datetime, and timestamp.	1. **substr** (required): substring to be searched for. 2. **str** (required): character string to be searched for.
pos	• Integer types: tinyint, smallint, mediumint, int, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. • Floating-point types: float and double. • Arbitrary precision type: numeric. • Character types: char, varchar, and text. • Boolean types: true and false.	(Optional) Start position of the search.

Return type: int.

Example:

```
gaussdb=# SELECT locate( 'b','abcabc');
 locate
-------
     2
(1 row)

gaussdb=# SELECT locate( 'b','abcabc',3);
 locate
-------
     5
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

The locate function takes effect only when **sql_compatibility** is set to **'MYSQL'**.

lpad_s(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If the length of **string** is longer than **length**, an error is reported.

Return type: text.

NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
- If the value of **length** is a decimal, the value is rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

lpad(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text.

NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on ORA-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of **length** is a decimal, the value is rounded down instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
- If the value of **length** is a decimal, the value is rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

make_set(bits,str1,str2...)

Description: **str1** corresponds to bit 0 of the bits input parameter in the bit format, **str2** corresponds to bit 1, and so on. If the lower bit of the corresponding bit form is **1**, the corresponding **str** parameter is appended to the result and returned with a comma as the separator.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
make_set	• The input parameter **bits** supports the following types: – NULL. – Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. – Floating-point and fixed-point types: float, real, and double; numeric, decimal, and dec. – Bit type: bit. GaussDB does not fully support the bit type. In the code design, when input parameter **1** is a hexadecimal number, for example, "x'FFF'", and the length is an odd number, MySQL reports an error. – Character string types: char and varchar. Only integer strings are supported. For strings containing decimals, the returned results are different because the rounding rule is different from that of M*. The character string consisting of digits and letters is not supported. The value range of an integer string is in the value range of a value of the bigint type. – Text types: tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. If the integer range is exceeded, the returned result is different from that in M*. The returned results of character strings with decimal places are different from those of M* due to different rounding rules. The text type combined by digits and letters is not supported. The value range of an integer string is in the value range of a value of the bigint type. – Large object types: tinyblob, blob, mediumblob, and longblob.	The returned result consists of some character strings selected from *str1,str2,...,strN* and separated by commas (,).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
	• The input parameter **str** supports the following types: – NULL. – Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of M*. This difference is an inherent difference between Gauss and M* and is not caused by this function. – Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in Gauss are displayed, and those in MySQL are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function. – Character string types: char and varchar. – Text types: tinytext, text, mediumtext, and longtext. – Large object types: tinyblob, blob, mediumblob, and longblob. – Date types: datetime, timestamp, date, and time.	

Return type: text.

Example:

```
gaussdb=# SELECT make_set(7,'a','b','c','d');
 make_set
----------
 a,b,c
(1 row)
gaussdb=# SELECT
make_set(b'10101010101011010101010101101010101010110101010101011010101010','1','2','3','4','5','6','
7','8','9','10','11','12','13','14','15','16','17','18','19','20','21','22','23','24','25','26','27','28','29','30','31','32','33','34','3
5','36','37','38','39','40','41','42','43','44','45','46','47','48','49','50','51','52','53','54','55','56','57','58','59','60','61','62'
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
,'63','64','65','66','67','68','69');
                                        make_set
-----------------------------------------------------------------------------------------------------------
 2,4,6,8,10,12,13,15,17,19,21,23,25,26,28,30,32,34,36,38,39,41,43,45,47,49,51,52,54,56,58,60,62,64
(1 row)
```

NOTE

- The make_set function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- When the **bits** parameter is an integer, the maximum range is int128, which is smaller than the MySQL range.
- When the **bits** parameter is of the date type (datetime, timestamp, date, or time), it is not supported because the conversion from the date type to the integer type is different from that in MySQL, which is not caused by this function.
- GaussDB and MySQL are inherently different in the bit and Boolean types, causing different returned results, which is not caused by this function. When the **bits** input parameter is of the Boolean type, the **str** input parameter of the bit and Boolean types is not supported.

notlike(x bytea name text, y bytea text)

Description: Compares **x** and **y** to check whether they are inconsistent.

Return type: Boolean.

Example:

```
gaussdb=# SELECT notlike(1,2);
   notlike
--------------
          t
(1 row)
gaussdb=# SELECT notlike(1,1);
   notlike
--------------
          f
(1 row)
```

octet_length(string)

Description: Specifies the number of bytes in a string.

Return type: int.

Example:

```
gaussdb=# SELECT octet_length('jose');
 octet_length
--------------
          4
(1 row)
```

overlay(string placing string FROM int [for int])

Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

Return type: text.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT overlay('hello' placing 'world' from 2 for 3 );
 overlay
---------
 hworldo
(1 row)
```

position(substring in string)

Description: Specifies the position of a substring. Parameters are case-sensitive.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
gaussdb=# SELECT position('ing' in 'string');
 position
----------
        4
(1 row)
```

pg_client_encoding()

Description: Specifies the current client-side encoding name.

Return type: name

Example:

```
gaussdb=# SELECT pg_client_encoding();
 pg_client_encoding
--------------------
 UTF8
(1 row)
```

quote(str)

Description: Returns a string enclosed in single quotation marks and adds a backslash (\) before the instances of backslashes (\), single quotation marks ('), ASCII NUL (\0), and Control+Z (\Z). If the parameter is **NULL**, the return value is **NULL** without single quotation marks.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
quote	• NULL. • Integer types: tinyint, smallint, mediumint, int, bigint, tinyint unsigned, smallint unsigned, int unsigned, and bigint unsigned. However, the integer value exceeds the range from 81 negative nines to 81 positive nines, and the return value is different from that of MySQL. This difference is an inherent difference between GaussDB and MySQL and is not caused by this function. • Floating-point and fixed-point types: float, real, and double for floating-point types; numeric, decimal, and dec for fixed-point types. However, when the value is expressed in scientific notation, the trailing zeros in GaussDB are displayed, and those in MySQL are not displayed. The value is printed in scientific notation. This is an inherent display difference and is not caused by this function. • Character string types: char and varchar. • Text types: tinytext, text, mediumtext, and longtext. • Large object types: tinyblob, blob,	Adds quotation marks to the input string and adds a backslash (\) before the backslash (\) and single quotation mark (').

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter	Type	Description
	mediumblob, and longblob. • Date types: datetime, timestamp, date, and time.	

Return type: text.

Example:

```
gaussdb=# SELECT quote('hello\' world');
   quote
--------------
 'hello\' world'
(1 row)
```

NOTE

1. The function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
2. To enable the GUC parameters, run the following commands:
   ```
   SET standard_conforming_strings=off;
   SET escape_string_warning=off;
   SET backslash_quote=on;
   ```
3. If the **str** character string contains \Z, \r, \%, or _, GaussDB does not escape it, which is different from MySQL. The slash followed by digits may also cause differences, for example, \563. This function difference is the escape character difference between GaussDB and MySQL, which is not caused by this function.
4. The output format of \b in the **str** character string is different from that in MySQL. This is an inherent difference between GaussDB and MySQL and is not caused by this function.
5. If the **str** character string contains \0, GaussDB cannot identify the character because the UTF-8 character set cannot identify the character. As a result, the input fails. This is an inherent difference between GaussDB and MySQL and is not caused by this function.
6. If **str** is of the bit or Boolean type, these types are not supported because they are different in GaussDB and MySQL.
7. GaussDB supports a maximum of 1 GB data transfer. The maximum length of the **str** input parameter is 536870908, and the maximum size of the result string returned by the function is 1 GB.

quote_ident(string text)

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

Return type: text.

Example:

```
gaussdb=# SELECT quote_ident('hello world');
 quote_ident
--------------
 "hello world"
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

quote_literal(string text)

Description: Returns the given string suitably quoted to be used as text in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text.

Example:

```
gaussdb=# SELECT quote_literal('hello');
 quote_literal
---------------
 'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
gaussdb=# SELECT quote_literal(E'O\'hello');
 quote_literal
---------------
 'O''hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_literal('O\hello');
 quote_literal
---------------
 E'O\\hello'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned. If the parameter may be null, you are advised to use **quote_nullable**.

```
gaussdb=# SELECT quote_literal(NULL);
 quote_literal
---------------

(1 row)
```

quote_literal(value anyelement)

Description: Converts the given value to text and then quotes it as a literal.

Return type: text.

Example:

```
gaussdb=# SELECT quote_literal(42.5);
 quote_literal
---------------
 '42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_literal(E'O\'42.5');
 quote_literal
---------------
 '0''42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT quote_literal('O\42.5');
 quote_literal
---------------
 E'O\\42.5'
(1 row)
```

quote_nullable(string text)

Description: Returns the given string suitably quoted to be used as a string in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text.

Example:

```
gaussdb=# SELECT quote_nullable('hello');
 quote_nullable
----------------
 'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O\'hello');
 quote_nullable
----------------
 'O''hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\hello');
 quote_nullable
----------------
 E'O\\hello'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
 quote_nullable
----------------
 NULL
(1 row)
```

quote_nullable(value anyelement)

Description: Converts the given value to text and then quotes it as a literal.

Return type: text.

Example:

```
gaussdb=# SELECT quote_nullable(42.5);
 quote_nullable
----------------
 '42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O\'42.5');
 quote_nullable
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------
 'O''42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\42.5');
 quote_nullable
----------------
 E'O\\42.5'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
 quote_nullable
----------------
 NULL
(1 row)
```

space(count)

Description: Returns a string consisting of a specified number of spaces.

Parameter	Type	Description
count	• Integer types: tinyint, smallint, mediumint, int, and bigint. • Unsigned integer types: tinyint unsigned, smallint unsigned, and int unsigned. • Character and text types: char, varchar, tinytext, text, mediumtext, and longtext. Only numeric integer strings are supported, and the integer range is within the bigint range. • Floating-point types: float, real, and double. • Fixed-point types: numeric, decimal, and dec. • Boolean type.	Number of spaces.

Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT space(5);
 space
--------

(1 row)
```

NOTE

- The space function takes effect only when **sql_compatibility** is set to **'MYSQL'**.
- If the input parameter **count** is less than **1073741819** and greater than **0**, a string of *count* spaces is returned. Otherwise, an empty string is returned.

substring_inner(string [from int] [for int])

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

Return type: text.

Example:

```
gaussdb=# SELECT substring_inner('adcde', 2,3);
 substring_inner
-----------------
 dcd
(1 row)
```

substring(string [from int] [for int])

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of bytes truncated.

Return type: text.

Example:

```
gaussdb=# SELECT substring('Thomas' from 2 for 3);
 substring
-----------
 hom
(1 row)
```

NOTE

This function is in the MySQL database. When the GUC parameter **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, **[from int]** can be a negative number, indicating the sequence number of the character counted from back to front. If this parameter is not set, **[from int]** is a negative number and the result is empty.

substring(string, pos, len)

Description: Extracts a substring. **pos** indicates the start position of the truncation. **len** indicates the number of bytes truncated.

Parameters: See **Table 1 Parameters**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-29 Parameters

Parameter	Type	Description	Value Range
string	text	Character string to be truncated.	-
pos	int	Start position of the character string to be truncated.	The absolute value is less than the string length.
len	int	Length of the character string to be truncated.	The value is greater than 0.

Return type: text.

Example:

```
gaussdb=# SELECT substring('substrteststring', -5, 5);
 substring
-----------
 tring
(1 row)
```

NOTE

This function is in the MySQL database. When the GUC parameter **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, **pos** can be a negative number, indicating the sequence number of the character counted from back to front. If this parameter is not set, **pos** is a negative number and the result is empty.

substring_index(str,split,index)

Description: **str** is a string, **split** is a separator string, and **index** is the position from which the string is split. This function returns all contents on the left or right (left if the value of **index** is positive and right if the value of **index** is negative) of the **str** string that is split by **split** from the position specified by **index**.

Parameters: See **Table 2 substring_index parameters**.

Table 7-30 substring_index parameters

Parameter	Type	Description
str	text	Character string to be truncated.
split	text	Target character string to be split.
index	int	Position from which the string is split. If the value of **index** is a positive number, all contents on the left of the position are obtained. If the value of **index** is a negative number, all contents on the right are obtained.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: text.

Example:

```
gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', 2);
 substring_index
-----------------
 Test1splitTest2
(1 row)

gaussdb=# SELECT substring_index('Test1splitTest2splitTest3splitTest4', 'split', -2);
 substring_index
-----------------
 Test3splitTest4
(1 row)
```

substring(string from *pattern*)

Description: Extracts substrings matching the POSIX-style regular expression. It returns the text that matches the pattern. If no match record is found, a null value is returned.

Return type: text.

Example:

```
gaussdb=# SELECT substring('Thomas' from '...$');
 substring
-----------
 mas
(1 row)
gaussdb=# SELECT substring('foobar' from 'o(.)b');
 result
--------
 o
(1 row)
gaussdb=# SELECT substring('foobar' from '(o(.)b)');
 result
--------
 oob
(1 row)
```

NOTE

- If the POSIX regular expression contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception.
- When **sql_compatibility** is set to **'MYSQL'**, the GUC parameter **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, this function is used in the same way as the **substr(str FROM pos)** function. The output result and behavior of this function are the same as those of the **substr(str FROM pos)** function.

substring(string from *pattern* for *escape*)

Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function fails and returns a null value. To indicate the part of the schema that should be returned on success, the schema must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT substring('Thomas' from '%#"o_a#"_' for '#');
 substring
-----------
 oma
(1 row)
```

NOTE

When **sql_compatibility** is set to **'MYSQL'**, the GUC parameter **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, this function is used in the same way as the **substr(str FROM pos FOR len)** function. The output result and behavior of this function are the same as those of the **substr(str FROM pos FOR len)** function.

rawcat(raw,raw)

Description: Indicates the string concatenation function.

Return type: raw.

Example:

```
gaussdb=# SELECT rawcat('ab','cd');
 rawcat
--------
 ABCD
(1 row)
```

regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])

Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in **Table 7-31**.

Table 7-31 Options supported by flags

Option	Description
'b'	Indicates the BRE matching without extension.
'c'	Indicates the case-sensitive matching.
'e'	Indicates the ERE matching with extension.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description
'i'	Indicates the case-insensitive matching.
'm'	Indicates the multi-line matching. If **flags** contains "m", use the multi-line matching. Otherwise, use the single-line matching.
'n'	The option meanings of "n" are related to the GUC parameter **behavior_compat_options** and the compatibility mode of the current database. ● If the SQL syntax is ORA- and MySQL-compatible and the value of the GUC parameter **behavior_compat_options** contains **aformat_regexp_match**, the **n** option indicates that "." matches the linefeed **'\n'**. If **'n'** is not specified, "." does not match the linefeed. ● In other cases, the **'n'** option has the same meaning as the **'m'** option.
'p'	Indicates partial linefeed-sensitive matching, which is similar to the linefeed-sensitive matching (**'m'** or **'n'**) and affects "." and square bracket expression, but does not affect ^ and $.
'q'	Indicates common character matching.
's'	Indicates the single-line matching. The meaning is opposite to those of **'m'** and **'n'**.
't'	Indicates the compact matching. The whitespace characters match themselves.
'w'	Indicates the reverse partial linefeed-sensitive matching. The meaning is opposite to that of **'p'**.
'x'	Indicates the loose matching. The whitespace characters are ignored.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_substr('str','[ac]');
 regexp_substr
---------------

(1 row)

gaussdb=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
 result
--------
 baz
(1 row)
```

regexp_count(string text, pattern text [, position int [, flags text]])

Description: obtains the number of substrings used for matching.

Parameter description:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in **Table 7-31**.

NOTE

When the function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and the value of **a_format_dev_version** is **s1**, the **pattern** parameter ending with a backslash (\) is valid.

Return type: int.

Example:

```
gaussdb=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result
--------
1
(1 row)
```

regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])

Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be obtained. This parameter is optional. The default value is **1**.
- **return_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in **Table 7-31**.

Return type: int.

Example:

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
result
--------
4
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
result
--------
7
(1 row)
```

regexp_matches(string text, pattern text [, flags text])

Description: Returns all captured substrings resulting from matching a POSIX-style regular expression against **string**. If the pattern does not match, the function returns no rows. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The optional **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matched substring is replaced, instead of replacing only the first one.

NOTICE

If the last parameter is provided but the parameter value is an empty string ('') and the SQL compatibility mode of the database is set to ORA, the returned result is an empty set. This is because the ORA compatible mode treats the empty string ('') as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to TD.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[].

Example:

```
gaussdb=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
 regexp_matches
----------------
 {bar,beque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
 regexp_matches
----------------
 {barbeque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
 regexp_matches
----------------
 {bar,beque}
 {bazil,barf}
(2 rows)
```

regexp_match(string text, pattern text [, flags text])

Description: Returns a string array, which is the first substring obtained by matching the POSIX regular expression with the specified string. If the pattern

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

does not match, the function returns a blank line. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The **flags** parameter is optional. If **flags** is not specified, tight syntax matching is used by default. The **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. **Table 7-32** lists the supported flags.

Table 7-32 Parameters of flags

Option	Description
'b'	Converts the POSIX regular expression to a BRE.
'c'	Indicates the case-sensitive matching.
'e'	Converts the POSIX regular expression to an ERE.
'i'	Indicates the case-insensitive matching.
'n'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign ($) match the beginning and end of each line. Periods (.) do not match linefeed.
'm'	Indicates newline-sensitive matching. A character string is regarded as multiple lines. Caret (^) and dollar sign ($) match the beginning and end of each line. Periods (.) do not match linefeed. The matching mode of *n* is the same.
'p'	Indicates partial newline-sensitive matching. Periods (.) do not match linefeed. Caret (^) can only match the beginning of the first line and dollar sign ($) can only match the end of the last line.
'q'	Represents the regular expression is a text string, all of which are common characters.
's'	Indicates non-newline-sensitive matching. That is, a character string is regarded as a single line, and caret (^) and dollar sign ($) match the beginning and end of the line, respectively. In this mode, periods (.) in the regular expression can match any character, including the linefeed character.
't'	Indicates the tight syntax matching.
'w'	Indicates inverse partial newline-sensitive matching. In the regular expression, caret (^) matches the beginning of each line, and dollar sign ($) matches only the end of the last line. Period (.) can match any character, including the linefeed character.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Option	Description
'x'	Indicates the extended syntax matching, ignoring whitespace characters and comments in regular expressions. The following three scenarios are excluded: • The whitespace characters or comments starting with the number sign (#) that are prefixed with slashes (\) will be retained. • The whitespace characters or comments starting with the number sign (#) in square brackets will be retained. • The whitespace characters and comments are not allowed in multi-character symbols, such as, left parenthesis ((), question mark (?), and colon (:).

NOTICE

If the parameter contains an empty string ('') and the compatibility mode of the database is set to **ORA**, the returned result is **NULL**. This is because the empty string is processed as **NULL** in ORA-compatible mode.

Return type: SETOF text[].

Example:

```
gaussdb=# SELECT regexp_match('foobarbequebaz', '(bar)(beque)');
 regexp_match
--------------
 {bar,beque}
(1 row)
gaussdb=# SELECT (regexp_match('foobarbequebaz', 'bar.*que'))[1];
 regexp_match
--------------
 barbeque
(1 row)
gaussdb=# SELECT regexp_match('Learning #PostgreSQL', 'R', 'c');
 regexp_match
--------------

(1 row)
gaussdb=# SELECT regexp_match('hello world', 'h e l l o', 'x');
 regexp_match
--------------
 {hello}
(1 row)
```

regexp_split_to_array(string text, pattern text [, flags text])

Description: Splits **string** using a POSIX-style regular expression as the delimiter. The regexp_split_to_array function behaves the same as regexp_split_to_table, except that regexp_split_to_array returns its result as an array of text.

Return type: text[].

Example:

```
gaussdb=# SELECT regexp_split_to_array('hello world', E'\\s+');
 regexp_split_to_array
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------------------
 {hello,world}
(1 row)
```

regexp_split_to_table(string text, pattern text [, flags text])

Description: Splits **string** using a POSIX-style regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

The **flags** parameter contains zero or multiple single-letter flags that change the behavior of a function. **i** indicates that the matching is not related to uppercase and lowercase. By default, each matching substring is replaced, instead of replacing only the first one.

Return type: SETOF text.

Example:

```
gaussdb=# SELECT regexp_split_to_table('hello world', E'\\s+');
 regexp_split_to_table
-----------------------
 hello
 world
(2 rows)
```

repeat(string text, number int)

Description: Repeats **string** the specified number of times.

Return type: text.

Example:

```
gaussdb=# SELECT repeat('Pg', 4);
  repeat
----------
 PgPgPgPg
(1 row)
```

NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed (1 GB – **x**)/**lengthb** (**string**) – 1. **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

replace(string text, from text, to text)

Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

Return type: text.

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
    replace
----------------
 abXXXefabXXXef
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

replace(string, substring)

Description: Deletes all substrings in a string.

String type: text.

Substring type: text.

Return type: text.

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd');
    replace
----------------
 abefabef
(1 row)
```

reverse(str)

Description: Returns a reversed string (by character).

Return type: text.

Example:

```
gaussdb=# SELECT reverse('abcde');
 reverse
---------
 edcba
(1 row)
```

right(str text, n int)

Description: Returns the last *n* characters in a string. When *n* is negative, all but the first */n/* characters are returned.

Return type: text.

Example:

```
gaussdb=# SELECT right('abcde', 2);
 right
-------
 de
(1 row)

gaussdb=# SELECT right('abcde', -2);
 right
-------
 cde
(1 row)
```

rpad(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

In the scenario where this function is in an ORA-compatible database, the value of **a_format_version** is **10c**, and that of **a_format_dev_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on O-compatible requirements.
- During the function execution, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string.
- If the value of *length* is a decimal, the value is truncated instead of being rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.
- If the length of the **string** parameter exceeds 1 GB after padding, an error is reported.

In other cases:

- The **length** parameter indicates the total length of characters in a character string. The length of a single character is fixed to 1.
- If the value of **length** is a decimal, the value is rounded off.
- The **string** and **fill** parameters do not comply with the encoding specifications.
- If the length of the **string** parameter exceeds 1 GB after padding, an error is reported.

substrb(text,int,int)

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('string',2,3);
 substrb
---------
 tri
(1 row)
```

substrb(text,int)

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('string',2);
 substrb
---------
 tring
(1 row)
```

substr(text,int)/substr(str FROM pos)

Description: **str** is the target string, and **pos** is the position in the string. The string of **str** from the **pos** position is output to the end of the character.

Return type: text.

Example:

```
gaussdb=# SELECT substr('stringtest' from 4);
 substr
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------
 ingtest
(1 row)

gaussdb=# SELECT substr('stringtest', 4);
 substr
---------
 ingtest
(1 row)
```

substr(str FROM pos FOR len)

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted. The value of **pos** can be a negative number. If the value is a negative number, the value is extracted from back to front.

Return type: text.

Example:

```
gaussdb=# SELECT substr('teststring' from 5 for 2);
 substr
--------
 st
(1 row)
```

substr(bytea,from,count)

Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

Return type: text.

Example:

```
gaussdb=# SELECT substr('string',2,3);
 substr
--------
 tri
(1 row)
```

string || string

Description: Concatenates strings.

Return type: text.

Example:

```
gaussdb=# SELECT 'MPP'||'DB' AS RESULT;
 result
--------
 MPPDB
(1 row)
```

string || non-string or non-string || string

Description: Concatenates strings and non-strings.

Return type: text.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT 'Value: '||42 AS RESULT;
  result
-----------
 Value: 42
(1 row)
```

split_part(string text, delimiter text, field int)

Description: Splits **string** on **delimiter** and returns the *field*th column (counting from text of the first appeared delimiter).

Return type: text.

Example:

```
gaussdb=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
 split_part
------------
 def
(1 row)
```

strpos(string, substring)

Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.

Return type: int.

Example:

```
gaussdb=# SELECT strpos('source', 'rc');
 strpos
--------
      4
(1 row)
```

to_hex(number int or bigint)

Description: Converts a number to a hexadecimal expression.

Return type: text.

Example:

```
gaussdb=# SELECT to_hex(2147483647);
  to_hex
----------
 7fffffff
(1 row)
```

translate(string text, from text, to text)

Description: Any character in **string** that matches a character in **from** is replaced by the corresponding character in **to**. If **from** is longer than **to**, extra characters occurred in **from** are removed.

Return type: text.

Example:

```
gaussdb=# SELECT translate('12345', '143', 'ax');
 translate
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----------
 a2x5
(1 row)
```

length(string)

Description: Obtains the number of characters in a string. When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **'5.7'**, and **b_format_dev_version** is set to **'s1'**, if the string is of the string or text type, the number of bytes of the string is returned.

Return type: integer.

lengthb(string)

Description: Obtains the number of bytes in a string. The value depends on character sets (GBK and UTF8).

Return type: integer.

Example:

```
gaussdb=# SELECT lengthb('Chinese');
 lengthb
---------
       7
(1 row)
```

substr(string,from)

Description:

Extracts substrings from a string.

from indicates the start position of the extraction.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, all characters from **from** to the end are extracted.
- If the value of **from** is negative, the last *n* characters in the string are extracted, and *n* indicates the absolute value of **from**.

Return type: text.

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2);
 substr
--------
 BCDEF
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-2);
 substr
--------
 EF
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

substr(string,from,count)

Description:

Extracts substrings from a string.

from indicates the start position of the extraction.

count indicates the length of the extracted substring.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, extract **count** characters starting from **from**.
- If the value of **from** is negative, extract the last *n* **count** characters in the string, in which *n* indicates the absolute value of **from**.
- If the value of **count** is smaller than **1**, **null** is returned.

Return type: text.

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2,2);
 substr
--------
 BC
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-3,2);
 substr
--------
 DE
(1 row)
```

substrb(string,from)

Description: The functionality of this function is the same as that of SUBSTR(string,from). However, the calculation unit is byte.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('ABCDEF',-2);
 substrb
---------
 EF
(1 row)
```

substrb(string,from,count)

Description: The functionality of this function is the same as that of SUBSTR(string,from,count). However, the calculation unit is byte.

Return type: text.

Example:

```
gaussdb=# SELECT substrb('ABCDEF',2,2);
 substrb
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------
 BC
(1 row)
```

to_single_byte(char)

Description: Converts all multi-byte characters in a string to single-byte characters.

Return type: text.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

to_multi_byte(char)

Description: Converts all single-byte characters in a string to multi-byte characters.

Return type: text.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

trim([leading |trailing |both] [characters] from string)

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start, end, or both sides of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT trim(BOTH 'x' FROM 'xTomxx');
 btrim
-------
 Tom
(1 row)
gaussdb=# SELECT trim(LEADING 'x' FROM 'xTomxx');
 ltrim
-------
 Tomxx
(1 row)
gaussdb=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
 rtrim
-------
 xTom
(1 row)
```

rtrim(string [, characters])

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the end of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT rtrim('TRIMxxxx','x');
 rtrim
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-------
 TRIM
(1 row)
```

ltrim(string [, characters])

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start of **string**.

Return type: text.

Example:

```
gaussdb=# SELECT ltrim('xxxxTRIM','x');
 ltrim
-------
 TRIM
(1 row)
```

upper(string)

Description: Converts the string into the uppercase.

Return type: text.

Example:

```
gaussdb=# SELECT upper('tom');
 upper
-------
 TOM
(1 row)
```

lower(string)

Description: Converts the string into the lowercase.

Return type: text.

Example:

```
gaussdb=# SELECT lower('TOM');
 lower
-------
 tom
(1 row)
```

nls_upper(string [, nlsparam])

Description: Converts a character string to uppercase letters. You can specify a sorting rule to process special uppercase conversion rules in some languages. The format of **nlsparam** is **'nls_sort=sort_name'**, where **sort_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **upper**.

Return type: text.

Example:

```
gaussdb=# SELECT nls_upper('große');
 nls_upper
-----------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 GROßE
(1 row)
gaussdb=# SELECT nls_upper('große', 'nls_sort = XGerman');
 nls_upper
-----------
 GROSSE
(1 row)
```

NOTE

This function can be used only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

nls_lower(string [, nlsparam])

Description: Converts a character string to lowercase letters. You can specify a sorting rule to process special lowercase conversion rules in some languages. The format of **nlsparam** is **'nls_sort=sort_name'**, where **sort_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **lower**.

Return type: text.

Example:

```
gaussdb=# SELECT nls_lower('INDIVISIBILITY');
   nls_lower
----------------
 indivisibility
(1 row)
gaussdb=# SELECT nls_lower('INDIVISIBILITY', 'nls_sort = XTurkish');
   nls_lower
----------------
 ındıvısıbılity
(1 row)
```

NOTE

This function can be used only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

instr(string,substring[,position,occurrence])

Description: Queries and returns the value of the substring position that occurs the *occurrence* (**1** by default) times from the *position* (**1** by default) in the string.

- If the value of *position* is **0**, **0** is returned.
- If the value of *position* is a negative number, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of *position*.

In this function, the calculation unit is character. One Chinese character is one character.

Return type: integer.

Example:

```
gaussdb=# SELECT instr('corporate floor','or', 3);
 instr
-------
     5
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT instr('corporate floor','or',-3,2);
 instr
-------
     2
(1 row)
```

initcap(string)

Description: Capitalizes the first letter of each word in a string.

Return type: text.

Example:

```
gaussdb=# SELECT initcap('hi THOMAS');
  initcap
------------
 Hi Thomas
(1 row)
```

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2**, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a_format_version** to **10c** and **a_format_dev_version** to **s2**.

ascii(string)

Description: Indicates the ASCII code of the first character in the string.

Return type: integer.

Example:

```
gaussdb=# SELECT ascii('xyz');
 ascii
-------
   120
(1 row)
```

ascii2(string)

Description: Returns the decimal code of the first character of the input string in the database character set.

Return type: bigint.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

asciistr(string)

Description: Converts non-ASCII characters in the input string to *\XXXX*, where *XXXX* indicates the UTF-16 code unit.

Return type: text.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

unistr(string)

Description: Converts the coding sequence in a string into the corresponding character. Other characters remain unchanged.

Return type: text.

NOTE

- This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.
- The backslash (\) must be followed by four hexadecimal characters to indicate the coding sequence, or another backslash (\) indicates that a single backslash (\) is entered.
- If the input parameter is of the time type, the time type is implicitly converted to the character string type.

vsize(expr)

Description: Returns the number of bytes of the input expression.

Return type: int.

NOTE

This function is valid only when the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s2** in an ORA-compatible database.

replace(string varchar, search_string varchar, replacement_string varchar)

Description: Replaces all **search_string** in the string with **replacement_string**.

Return type: text.

Example:

```
gaussdb=# SELECT replace('jack and jue','j','bl');
    replace
----------------
 black and blue
(1 row)
```

concat(str1,str2)

Description: Connects str1 and str2 and returns the string. Note: **concat** calls the output function of the data type and the return value is uncertain. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator **||**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- If **sql_compatibility** is set to **'MYSQL'** and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
- The return value of the concat function is of the variable-length type. When the concat function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

Return type: text.

Example:

```
gaussdb=# SELECT concat('Hello', ' World!');
   concat
--------------
 Hello World!
(1 row)
gaussdb=# SELECT concat('Hello', NULL);
 concat
--------

(1 row)
gaussdb=# CREATE TABLE test_space(c char(10));
CREATE TABLE
gaussdb=# INSERT INTO test_space values('a');
INSERT 0 1
-- After spaces are padded, the character string is still a fixed-length character string. It is expected that the result can be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a ';
     c
------------
 a
(1 row)
-- The combination result is a variable-length character string. The comparison fails and the result cannot be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a' || ' ';
 c
---
(0 rows)
```

chr(integer)

Description: For the UTF-8 character set, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

Return type: text.

NOTE

- When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the value is truncated instead of being rounded off if the value of *integer* is a decimal.
- For details about how to set and modify the character set and collation, see **Character Sets and Collations**.

Example:

```
gaussdb=# SELECT chr(65);
 chr
-----
 A
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-- In the case of UTF-8 character set
gaussdb=# select chr(19968);
 chr
-----
 一
(1 row)
```

chr(cvalue int|bigint)

Description: Converts *cvalue* to the character of the corresponding byte order and returns the character.

cvalue can be converted into a value of the int or bigint type. The value range is [0,2^32 – 1], corresponding to the range of unsigned int. A character array consisting of one to four bytes is returned based on the value of *n*. The byte arrays returned in different character sets are the same. However, due to different encoding rules, the result of the returned character string varies depending on the character set encoding.

If the character set is a single-byte character set, an ASCII character is returned after *cvalue* mod 256.

Precautions:

- If a byte in the input *cvalue* is **0**, the output is truncated.
- If the input does not comply with the encoding rule of the current character set, an error is reported.
- If the input is **NULL** or **0**, **NULL** is returned.

Return type: text.

Example:

```
gaussdb=# SELECT chr(65);
 chr
-----
 A
(1 row)
gaussdb=# CREATE DATABASE gaussdb_o WITH DBCOMPATIBILITY 'ORA';
gaussdb=# \c gaussdb_o
gaussdb_o=# SET a_format_version='10c';
gaussdb_o=# SET a_format_dev_version = 's1';
gaussdb_o=# SELECT chr(16705);
 chr
-----
 AA
(1 row)

-- The output is truncated.
gaussdb_o=# SELECT chr(4259905);
 chr
-----
 A
(1 row)
gaussdb_o=# \c postgres
gaussdb=#  DROP DATABASE gaussdb_o;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the chr function returns a character in the collation based on the input value. If the current character set for database encoding is a multi-byte character set, the return value contains one to four bytes. If the current character set for database encoding is a single-byte character set, the return value is a single byte obtained by performing the mod 256 operation on the input value. Otherwise, if the current character set for database encoding is UTF-8, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

nchr(cvalue int|bigint)

Description: Returns the characters corresponding to the input parameter in the national character set. The GUC parameter **nls_nchar_characterset** specifies the country character set. Only AL16UTF16 and UTF8 are supported. This function is valid only when the value of the GUC parameter **a_format_version** is **10c** and that of **a_format_dev_version** is **s4** in an ORA-compatible database. If **nls_nchar_characterset** is set to **AL16UTF16** and the input parameter exceeds two bytes, the input parameter will be truncated and the lowest two bytes will be retained. If **nls_nchar_characterset** is set to **UTF8** and the input parameter exceeds three bytes, the value **0** is used.

Parameter: cvalue. **cvalue** can be converted to the int or bigint type. The value range is [0, 2^32 – 1], corresponding to the range of unsigned int. If the input parameter contains the decimal part, the decimal part will be deleted.

Return type: NVARCHAR2.

CAUTION

- The byte length of the return value of the function is different from that in database ORA.
- The return value of the function is restricted by the database character set. In different database character sets, if there is no mapping table for converting UTF8 to the database character set or the mapping table does not contain the UTF8 code, the current database character set does not support the UTF8 character corresponding to the input parameter. As a result, the result returned by the nchr(cvalue int|bigint) function is inconsistent with that in database ORA.
- If the current database character set does not support the UTF8 character corresponding to the input parameter, or the national character set is UTF8 but the input parameter does not comply with the UTF8 format, the byte array corresponding to the input parameter is returned. If a single byte is in the range of [0x00,0x7F], an ASCII character is returned. If a single byte is in the range of [0x80,0xFF], a question mark (?) is returned.
- For details about how to set and modify the character set and collation, see **Character Sets and Collations**.

regexp_substr(source_char, pattern)

Description: Extracts substrings from a regular expression. If the SQL syntax is ORA- and MySQL-compatible and the value of the GUC parameter

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

behavior_compat_options contains **aformat_regexp_match**, the period (.) cannot match the **'\n'** character. If **aformat_regexp_match** is not contained, the period (.) matches the **'\n'** character by default.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', ',[^,]+,') "REGEXPR_SUBSTR";
  REGEXPR_SUBSTR
-------------------
 , Redwood Shores,
(1 row)
```

regexp_replace(string, pattern, replacement [,flags])

Description: Replaces substrings matching the POSIX-style regular expression. If no pattern is matched, the original string is returned. When a match exists, the matched substring in the returned string is replaced with the string specified by **replacement**. The replacement string can contain **\n**, where **\n** ranges from 1 to 9, to indicate that the source substring matching the *n*th parenthesized subexpression of the pattern should be inserted, and it can contain **\&** to indicate that the substring matching the entire pattern should be inserted.

Parameters:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. **g** indicates that all matched substrings are replaced with the specified content, instead of only the first matching item. Other options supported by **flags** and description are described in **Table 7-31**.

Return type: text

Example:

```
gaussdb=# SELECT regexp_replace('Thomas', '.[mN]a.', 'M');
 regexp_replace
----------------
 ThM
(1 row)
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\\1Y', 'g') AS
RESULT;
   result
-------------
 fooXarYXazY
(1 row)
```

regexp_replace(string text, pattern text [, replacement text [, position int [, occurrence int [, flags text]]]])

Description: Replaces substrings matching the POSIX-style regular expression. If no pattern is matched, the original string is returned. When a match exists, the matched substring in the returned string is replaced with the string specified by **replacement**.

Parameters:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **replacement**: character string used to replace the matched substring. This parameter is optional. If no parameter value is specified or the parameter value is null, an empty string is used for replacement.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**, indicating that the first matched substring is replaced.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are described in **Table 7-31**.

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1** in an ORA-compatible database, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced and the pattern parameter ending with a backslash (\) is valid.

Return type: text.

Example:

```
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\\1Y', 2, 2, 'n') AS RESULT;
result
------------
foobarXazY
(1 row)
```

concat_ws(sep text, str"any" [, str"any" [, ...]])

Description: Uses the first parameter as the separator, which is associated with all following parameters. The **NULL** parameter is ignored.

NOTICE

- If the first parameter value is **NULL**, the returned result is **NULL**.
- If the first parameter is provided but the parameter value is an empty string (''') and the SQL compatibility mode of the database is set to ORA, the returned result is **NULL**. This is because the ORA-compatible mode treats the empty string (''') as **NULL**. To resolve this problem, you can change the SQL compatibility mode of the database to MySQL, TD, or PG.

Return type: text.

Example:

```
gaussdb=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
 concat_ws
------------
 ABCDE,2,22
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

nlssort(string text, sort_method text)

Description: Returns the encoding value of a string in the sorting mode specified by **sort_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort_method** can be set to **nls_sort=schinese_pinyin_m** or **nls_sort=generic_m_ci**. **nls_sort=generic_m_ci** supports only the case-insensitive order for English characters.

String type: text.

sort_method type: text

Return type: text.

Example:

convert(string bytea, src_encoding name, dest_encoding name)

Description: Converts the string to **dest_encoding**. **src_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: bytea.

Example:

```
gaussdb=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
         convert
-----------------------------
 \x746578745f696e5f75746638
(1 row)
```

NOTE

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the pg_conversion system catalog for details. **server_encoding** is specified during database initialization.

Example:

```
gaussdb=# SHOW server_encoding;
 server_encoding
-----------------
 LATIN1
(1 row)

gaussdb=# SELECT convert_from('some text', 'GBK');
 convert_from
--------------
 some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
      convert_to
----------------------
 \x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
       convert
----------------------
 \x736f6d652074657874
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

convert(expr, USING transcoding_name)

Description: Converts a parameter, which can be a character or a number, into a character string of the transcoding_name type, and returns the character string.

Return type: text.

Example:

```
gaussdb=# SELECT convert('asdas' using 'gbk');
 convert
---------
 asdas
(1 row)
```

NOTE

This function takes effect only in databases in MySQL-compatible mode.

convert_from(string bytea, src_encoding name)

Description: Converts a string using the coding mode of the database.

src_encoding specifies the source code encoding. The string must be valid in this encoding.

Return type: text.

Example:

```
gaussdb=# SELECT convert_from('text_in_utf8', 'UTF8');
 convert_from
--------------
 text_in_utf8
(1 row)
```

convert_to(string text, dest_encoding name)

Description: Converts a string to **dest_encoding**.

Return type: bytea.

Example:

```
gaussdb=# SELECT convert_to('some text', 'UTF8');
     convert_to
----------------------
 \x736f6d652074657874
(1 row)
```

string [NOT] LIKE pattern [ESCAPE escape-character]

Description: Specifies the pattern matching function.

If the pattern does not include a percentage sign (%) or an underscore (_), this mode represents itself only. In this case, the behavior of LIKE is the same as the equal operator. The underscore (_) in the pattern matches any single character while one percentage sign (%) matches no or multiple characters.

To match with underscores (_) or percent signs (%), corresponding characters in **pattern** must lead escape characters. The default escape character is a backward

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

slash (\) and can be specified using the ESCAPE clause. To match with escape characters, enter two escape characters.

Return type: Boolean.

Example:

```
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 f
(1 row)
gaussdb=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
 result
--------
 t
(1 row)
```

REGEXP_LIKE(source_string, pattern [, match_parameter])

Description: Indicates the mode matching function of a regular expression.

source_string indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match_parameter** indicates the matching items and the values are as follows:

- 'i': case-insensitive
- 'c': case-sensitive
- 'n': allowing the metacharacter "." in a regular expression to be matched with a linefeed.
- 'm': allows **source_string** to be regarded as multiple rows.

If **match_parameter** is ignored, **case-sensitive** is enabled by default, "." is not matched with a linefeed, and **source_string** is regarded as a single row.

Return type: Boolean.

Example:

```
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[D-Z]');
 regexp_like
-------------
 f
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]','i');
 regexp_like
-------------
 t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
 regexp_like
-------------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

format(formatstr text [, str"any" [, ...]])

Description: Formats a string.

Return type: text.

Example:

```
gaussdb=# SELECT format('Hello %s, %1$s', 'World');
      format
-------------------
 Hello World, World
(1 row)
```

md5(string)

Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

NOTE

The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

Return type: text.

Example:

```
gaussdb=# SELECT md5('ABC');
              md5
----------------------------------
 902fbdd2b1df0c4f70b4a5d23525e932
(1 row)
```

sha(string) / sha1(string)

Description: Encrypts a string using SHA1 and returns a hexadecimal number. The sha and sha1 functions are the same.

NOTE

- The SHA-1 encryption algorithm is not recommended because it has lower security and poses security risks.
- This function is valid only when GaussDB is compatible with the MY type (that is, **sql_compatibility** is set to **'MYSQL'**).

Return type: text.

Example:

```
gaussdb=# SELECT sha('ABC');
                 sha
------------------------------------------
 3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
gaussdb=# SELECT sha1('ABC');
                 sha1
------------------------------------------
 3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

sha2(string, hash_length)

Description: Encrypts a string in SHA-2 mode and returns a value in hexadecimal form.

hash_length: corresponds to an SHA-2 algorithm. The value can be **0** (SHA-256), **224** (SHA-224), **256** (SHA-256), **384** (SHA-384), or **512** (SHA-512). For other values, **NULL** is returned.

NOTE

- The SHA-224 encryption algorithm is not recommended because it has lower security and poses security risks.
- The SHA2 function records hash plaintext in logs. Therefore, you are advised not to use this function to encrypt sensitive information such as keys.
- This function is valid only when GaussDB is compatible with the MY type (that is, **sql_compatibility** is set to **'MYSQL'**).

Return type: text.

Example:

```
gaussdb=# SELECT sha2('ABC',224);
                            sha2
------------------------------------------------------------
 107c5072b799c4771f328304cfe1ebb375eb6ea7f35a3aa753836fad
(1 row)
gaussdb=# SELECT sha2('ABC',256);
                              sha2
----------------------------------------------------------------
 b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
gaussdb=# SELECT sha2('ABC',0);
                              sha2
----------------------------------------------------------------
 b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
```

decode(string text, format text)

Description: Decodes binary data from textual representation.

Return type: bytea.

Example:

```
gaussdb=# SELECT decode('MTIzAAE=', 'base64');
   decode
--------------
 \x3132330001
(1 row)
```

similar_escape(pat text, esc text)

Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

Return type: text.

Example:

```
gaussdb=# SELECT similar_escape('\s+ab','2');
 similar_escape
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
----------------
 ^(?:\\s+ab)$
(1 row)
```

find_in_set(text, set)

Description: Finds the position of a given member in a set, counting from 1. If no record is found, 0 is returned. The distributed system does not support the SET data type. An error will be reported when this function is executed.

Return type: int2

find_in_set(str, strlist)

Description: Queries whether the **strlist** column contains **str**. If the **strlist** column contains **str**, the position of **str** in the **strlist** field is returned. The inputs are **str** and **strlist**. **str** indicates the character string to be queried. **strlist** is a set of character strings separated by commas (,). If **str** is not in **strlist** or **strlist** is an empty string, the return value is **0**.

The parameters are described as follows.

Table 7-33 Parameter

Parameter	Type	Description
str	text	Target string
strlist	text	A set of character strings

Return type: int.

Example:

```
gaussdb=# SELECT find_in_set('ee','a,ee,c');
 find_in_set
-------------
           2
(1 row)
```

encode(data bytea, format text)

Description: Encodes binary data into a textual representation.

Return type: text.

Example:

```
gaussdb=# SELECT encode(E'123\\000\\001', 'base64');
  encode
----------
 MTIzAAE=
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

strcmp(expr1,expr2)

Description: Compares two input strings based on the current character order. If the strings are the same, **0** is returned. If the first string is smaller than the second string, **–1** is returned. Otherwise, **1** is returned.

The parameters are described as follows.

Parameter	Type	Description
expr1/expr2	• Character types: CHAR, VARCHAR, NVARCHAR2, and TEXT. • Binary type: BYTEA. • Numeral types: TINYINT [UNSIGNED], SMALLINT [UNSIGNED], INTEGER [UNSIGNED], BIGINT [UNSIGNED], FLOAT4, FLOAT8, and NUMERIC. • Date and time types: DATE, TIME WITHOUT TIME ZONE, DATETIME, and TIMESTAMPTZ.	Character string involved in comparison.

Return type: integer.

Example:

```
-- Switch to the MySQL-compatible database.
gaussdb=# CREATE DATABASE gaussdb_m dbcompatibility='MYSQL';
gaussdb=# \c gaussdb_m

-- Set the compatible version control parameter to enable the function of specifying the collation for
constant character strings.
gaussdb_m=# SET b_format_version='5.7';
gaussdb_m=# SET b_format_dev_version='s2';

gaussdb_m=# SELECT strcmp('abc', 'ABC');
 strcmp
--------
      0
(1 row)

gaussdb_m=# SELECT strcmp('abc     ', 'abc');
 strcmp
--------
      0
(1 row)

gaussdb_m=# SELECT strcmp('1', 1);
 strcmp
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
     0
(1 row)

gaussdb_m=# SELECT strcmp(123, 2);
 strcmp
--------
    -1
(1 row)
```

NOTE

- The strcmp function is valid only when **sql_compatibility** is set to **'MYSQL'**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the sql_mode parameter **pad_char_to_full_length** specifies whether to add spaces at the end of the char type, which affects the strcmp comparison result. For details, see **Table 7-8**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s1'**, the behavior of the character, binary, numeric, and date and time types is M-compatible, which affects the strcmp comparison result. For details, see **Data Types**. For the floating-point type in the numeric type, the precision may be different from that in MySQL due to different connection parameter settings. Therefore, this scenario is not recommended, or the numeric type is used instead. For details, see **Connection Parameters**.
- Since the version whose **b_format_version** is set to **'5.7'** and **b_format_dev_version** is set to **'s2'**, character escape and constant character string obtaining collation are supported. The collation affects the strcmp comparison result. For details, see the SET NAMES syntax in **SET**. For details about the rules for combining different collations of the character types, see **Rules for Combining Character Sets and Collations**.

NOTE

- For a string containing linefeed characters, for example, a string consisting of a linefeed character and a space, the value of **LENGTH** and **LENGTHB** in GaussDB is 2.
- In GaussDB, *n* in the CHAR(n) type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the LENGTHB function may be longer than *n*.
- GaussDB supports multiple types of databases, including ORA, MySQL, TD, and PG. The lexical analyzer of ORA-compatible database is different from that of the other three databases. In an ORA-compatible database, an empty string is considered as **NULL**. Therefore, when an ORA-compatible database is used, if an empty string is used as a parameter in the preceding character operation function, no output is displayed. For example:

  ```
  gaussdb=# SELECT translate('12345','123','');
  translate
  -----------

  (1 row)
  ```

  This is because the kernel checks whether the input parameter contains **NULL** before calling the corresponding function. If the input parameter contains **NULL**, the kernel does not call the corresponding function. As a result, no output is displayed. In PG-compatible mode, the processing of character strings is the same as that of PG. Therefore, the preceding problem does not occur.

7.6.3.2 Extension Functions and Operators

pkg_bpchar_opc()

Description: Serves as an extension API to add the comparison operator between bpchar and text or between text and bpchar policies, so as to solve the problem

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

that indexes cannot be matched when data of the bpchar and text types is compared. Only a system administrator can install extensions.

Example:

Compare the bpchar type with the text type (initial state, forward compatibility).

```
/*
Create a table and initialize data.
*/
gaussdb=# CREATE TABLE logs_nchar(log_id nchar(16), log_message text);
gaussdb=# INSERT INTO logs_nchar SELECT GENERATE_SERIES(1,100000),MD5(RANDOM());
gaussdb=# INSERT INTO logs_nchar VALUES ('FE306991300002  ','002');
gaussdb=# CREATE INDEX idx_nchar_logid on logs_nchar(log_id);
gaussdb=# VACUUM ANALYZE logs_nchar;

/*
The purpose is to obtain the detailed execution plan of all nodes.
*/
gaussdb=# SET max_datanode_for_plan = 1;
SET

/*
If no extension is installed, when nchar and text are compared, nchar is implicitly converted to text because there is no bpchar or text index operator. That is, the fixed-length character type is converted to the variable-length character type. As a result, the execution plan changes and the index cannot be matched.
*/
gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002  '),16,' ');
                                                
```

```
text types and index-related content are added to the database.
*/
gaussdb=# CREATE EXTENSION pkg_bpchar_opc;

NOTE

- This solves the problem that data and indexes cannot be properly matched when equality matching is performed between the bpchar type (containing multiple spaces) and the text type.
- The UB-tree and B-tree are involved. The comparison symbols include >, >=, <, <=, and <>.
- The impact scope involves implicit conversion between character types. For example, when a variable-length data type is compared with a fixed-length data type, the variable-length data type is preferentially converted to the text type instead of the original bpchar type.
- The pkg_bpchar_opc extension is disabled by default. You can check whether the extension is enabled in the pg_extension system catalog. If the extension data exists, the extension is enabled. If the extension data does not exist, the extension is disabled. When extension is disabled, forward compatibility is maintained. When extension is enabled, compatibility with database ORA is maintained. After the pkg_bpchar_opc extension is enabled, you need to set the **max_datanode_for_plan** parameter as required. This parameter specifies the number of execution plans displayed on DNs when the FQS plan is generated. For example, to set **max_datanode_for_plan** to **64**, run the following command:
  ```
  set max_datanode_for_plan = 64
  ```
  The extended function is for internal use only. You are advised not to use it.
- In the example, the table structure uses **log_id** as the index and has two columns: **log_id** and **log_message**. The table name is followed by the **log_id** column type. For example, if the table name is **logs_text**, the **log_id** column type is text.

Table 7-34 Functions supported by pkg_bpchar_opc

API	Description
pg_catalog.bpchar_text_lt	Compares the bpchar type with the text type to check whether the value on the left is less than the value on the right.
pg_catalog.bpchar_text_le	Compares the bpchar type with the text type to check whether the value on the left is less than or equal to the value on the right.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

API	Description
pg_catalog.bpchar_text_eq	Compares the bpchar type with the text type to check whether the value on the left is equal to the value on the right.
pg_catalog.bpchar_text_ge	Compares the bpchar type with the text type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.bpchar_text_gt	Compares the bpchar type with the text type to check whether the value on the left is greater than the value on the right.
pg_catalog.bpchar_text_ne	Compares the bpchar type with the text type to check whether the value on the left is different from the value on the right.
pg_catalog.bpchar_text_cmp	Specifies that the index of the bpchar and text types supports comparison functions.
pg_catalog.text_bpchar_lt	Compares the text type with the bpchar type to check whether the value on the left is less than the value on the right.
pg_catalog.text_bpchar_le	Compares the text type with the bpchar type to check whether the value on the left is less than or equal to the value on the right.
pg_catalog.text_bpchar_eq	Compares the text type with the bpchar type to check whether the value on the left is equal to the value on the right.
pg_catalog.text_bpchar_ge	Compares the text type with the bpchar type to check whether the value on the left is greater than or equal to the value on the right.
pg_catalog.text_bpchar_gt	Compares the text type with the bpchar type to check whether the value on the left is greater than the value on the right.
pg_catalog.text_bpchar_ne	Compares the text type with the bpchar type to check whether the value on the left is different from the value on the right.
pg_catalog.text_bpchar_cmp	Specifies that the index of the text and bpchar types supports comparison functions.
pg_catalog.hashbpchartext	Specifies that the hash of the bpchar and text types supports comparison functions.
pg_catalog.hashtextbpchar	Specifies that the hash of the text and bpchar types supports comparison functions.

bpcharlikebpchar(BPCHAR, BPCHAR)

Description: Determines whether the BPCHAR character string of the first input parameter is LIKE and whether the BPCHAR character string of the second input parameter is LIKE. It is used to add the BPCHAR type and the LIKE operator of the BPCHAR type. To enable the ~~ operator, ensure that the value of the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** configuration item.

Return type: Boolean.

Value range:

- **t**: Two parameters of the BPCHAR type are matched.
- **f**: Two parameters of the BPCHAR type are not matched.

Example:

```
gaussdb=#  SELECT bpcharlikebpchar('455'::BPCHAR(10), '455  '::BPCHAR);
 bpcharlikebpchar
------------------
 f
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR(10));
 bpcharlikebpchar
------------------
 t
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(10));
 bpcharlikebpchar
------------------
 t
(1 row)
gaussdb=#  SELECT bpcharlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(11));
 bpcharlikebpchar
------------------
 f
(1 row)
gaussdb=#  CREATE TABLE op_test (

```

NOTE

- bpcharlikebpchar can be used only when the database compatibility parameter **SQL_COMPATIBILITY** is set to **ORA** and the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column.
- If this feature is enabled, the result set and execution plan for the LIKE pattern matching of the BPCHAR types are affected.
- **SET behavior_compat_options='';** indicates that this feature is disabled, and **SET behavior_compat_options='enable_bpcharlikebpchar_compare'** indicates that this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (bpchar matches bpchar). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

bpcharnlikebpchar(BPCHAR, BPCHAR)

Description: Determines whether the BPCHAR character string of the first input parameter is NOT LIKE and whether the BPCHAR character string of the second input parameter is NOT LIKE. It is used to add the BPCHAR type and the NOT LIKE operator of the BPCHAR type. To enable the !~~ operator, ensure that the value of **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** configuration item.

Return type: Boolean.

Value range:

- **t**: Two parameters of the BPCHAR type are matched.
- **f**: Two parameters of the BPCHAR type are not matched.

Example:

```
gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(11));
 bpcharnlikebpchar
-------------------
 t
(1 row)

gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455'::BPCHAR(10));
 bpcharnlikebpchar
-------------------
 f
(1 row)

gaussdb=#  SELECT bpcharnlikebpchar('455 '::BPCHAR(10), '455 '::BPCHAR);
 bpcharnlikebpchar
-------------------
 t
(1 row)
gaussdb=#  CREATE TABLE op_test (
 col BPCHAR(2) DEFAULT NULL
);
CREATE TABLE
gaussdb=#  CREATE INDEX op_index ON op_test(col);
CREATE INDEX
gaussdb=#  INSERT INTO op_test VALUES ('a');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('1');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('11');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('12');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('sd');
INSERT 0 1
gaussdb=#  INSERT INTO op_test VALUES ('aa');
INSERT 0 1
gaussdb=#  SHOW behavior_compat_options;
 behavior_compat_options
-------------------------
(1 row)
-- If behavior_compat_options does not contain enable_bpcharlikebpchar_compare, the latest bpcharnlikebpchar operator is not enabled and the result set returned by the matching between bpchars is not the same as expected (no data record is returned in normal cases).
gaussdb=#  SELECT * FROM op_test WHERE col NOT LIKE col::BPCHAR ORDER BY col;

NOTE

- bpcharlikebpchar can be used only when the database compatibility parameter **SQL_COMPATIBILITY** is set to **ORA** and the GUC parameter **behavior_compat_options** contains the **enable_bpcharlikebpchar_compare** column.
- If this feature is enabled, the result set and execution plan for the NOT LIKE pattern matching of the BPCHAR types are affected.
- **SET behavior_compat_options='';** indicates that this feature is disabled, and **SET behavior_compat_options='enable_bpcharlikebpchar_compare'** indicates that this feature is enabled.
- After the new feature is enabled, fixed-length matching is used (bpchar matches bpchar). The parameter lengths on the left and right sides must be the same. During pattern matching, ensure that the length of the pattern column is the same as the forcible conversion length to avoid the difference between the result and the expected result caused by filling spaces after the length is too long.

7.6.4 Binary String Functions and Operators

7.6.4.1 String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

octet_length(string)

Description: Specifies the number of bytes in a binary string.

Return type: int

Example:

```
gaussdb=# SELECT octet_length(E'jo\\000se'::bytea) AS RESULT;
 result
--------
      5
(1 row)
```

overlay(string placing string from int [for int])

Description: Replaces substrings.

Return type: bytea

Example:

```
gaussdb=# SELECT overlay(E'Th\\000omas'::bytea placing E'\\002\\003'::bytea from 2 for 3) AS RESULT;
     result
----------------
 \x5402036d6173
(1 row)
```

position(substring in string)

Description: Specifies the position of a substring.

Return type: int

Example:

```
gaussdb=# SELECT position(E'\\000om'::bytea in E'Th\\000omas'::bytea) AS RESULT;
 result
--------
      3
(1 row)
```

substring(string [from int] [for int])

Description: Truncates a substring.

Return type: bytea

Example:

```
gaussdb=# SELECT substring(E'Th\\000omas'::bytea from 2 for 3) AS RESULT;
  result
----------
 \x68006f
(1 row)
```

substr(bytea [from int] [for int])

Description: Truncates a substring.

Return type: bytea

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT substr(E'Th\\000omas'::bytea,2, 3) as result;
  result
----------
 \x68006f
(1 row)
```

trim([both] bytes from string)

Description: Removes the longest string containing only **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
gaussdb=# SELECT trim(E'\\000'::bytea from E'\\000Tom\\000'::bytea) AS RESULT;
  result
----------
 \x546f6d
(1 row)
```

7.6.4.2 Other Binary String Functions

GaussDB provides common syntax used for calling functions.

btrim(string bytea,bytes bytea)

Description: Removes the longest string containing only **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
gaussdb=# SELECT btrim(E'\\000trim\\000'::bytea, E'\\000'::bytea) AS RESULT;
   result
------------
 \x7472696d
(1 row)
```

get_bit(string, offset)

Description: Extracts bits from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_bit(E'Th\\000omas'::bytea, 45) AS RESULT;
 result
--------
      1
(1 row)
```

get_byte(string, offset)

Description: Extracts bytes from a string.

Return type: int

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT get_byte(E'Th\\000omas'::bytea, 4) AS RESULT;
 result
--------
    109
(1 row)
```

set_bit(string,offset, newvalue)

Description: Sets bits in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_bit(E'Th\\000omas'::bytea, 45, 0) AS RESULT;
      result
------------------
 \x5468006f6d4173
(1 row)
```

set_byte(string,offset, newvalue)

Description: Sets bytes in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_byte(E'Th\\000omas'::bytea, 4, 64) AS RESULT;
      result
------------------
 \x5468006f406173
(1 row)
```

rawcmp(raw, raw)

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: integer

raweq(raw, raw)

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: Boolean

rawge(raw, raw)

Description: Specifies the raw data type comparison function.

Parameters: raw, raw

Return type: Boolean

rawgt(raw, raw)

Description: Specifies the raw data type comparison function.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: raw, raw

Return type: Boolean

rawin(cstring)

Description: Specifies the raw data type parsing function.

Parameter: cstring

Return type: bytea

rawle(raw, raw)

Description: Specifies the raw data type parsing function.

Parameters: raw, raw

Return type: Boolean

rawlike(raw, raw)

Description: Specifies the raw data type parsing function.

Parameters: raw, raw

Return type: Boolean

rawlt(raw, raw)

Description: Specifies the raw data type parsing function.

Parameters: raw, raw

Return type: Boolean

rawne(raw, raw)

Description: Compares whether the raw types are the same.

Parameters: raw, raw

Return type: Boolean

rawnlike(raw, raw)

Description: Checks whether the raw type matches the pattern.

Parameters: raw, raw

Return type: Boolean

rawout(bytea)

Description: Specifies the RAW output API.

Parameter: bytea

Return type: cstring

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

rawsend(raw)

Description: Converts the bytea type to the binary type.

Parameter: raw

Return type: bytea

rawtohex(text)

Description: Converts the raw format to the hexadecimal format.

Parameter: text

Return type: text

7.6.5 Bit String Functions and Operators

7.6.5.1 Bit String Operators

Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

||

Description: Connects bit strings.

Example:

```
gaussdb=# SELECT B'10001' || B'011' AS RESULT;
  result
----------
 10001011
(1 row)
```

NOTE

- A field can have a maximum of 180 consecutive internal joins. A field with excessive joins will be split into joined consecutive strings.

  Example: **str1||str2||str3||str4** is split into **(str1||str2)||(str3||str4)**.
- In ORA-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned.

  Take **str1||NULL||str2** as an example. **str1str2** is returned in ORA-compatible mode and **NULL** is returned in other compatibility modes.

&

Description: Specifies the AND operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' & B'01101' AS RESULT;
 result
--------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 00001
(1 row)
```

|

Description: Specifies the OR operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' | B'01101' AS RESULT;
 result
--------
 11101
(1 row)
```

#

Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

Example:

```
gaussdb=# SELECT B'10001' # B'01101' AS RESULT;
 result
--------
 11100
(1 row)
```

~

Description: Specifies the NOT operation between bit strings.

Example:

```
gaussdb=# SELECT ~B'10001'AS RESULT;
 result
----------
 01110
(1 row)
```

<<

Description: Shifts left in a bit string.

Example:

```
gaussdb=# SELECT B'10001' << 3 AS RESULT;
 result
----------
 01000
(1 row)
```

>>

Description: Shifts right in a bit string.

Example:

```
gaussdb=# SELECT B'10001' >> 2 AS RESULT;
 result
----------
 00100
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

The following SQL-standard functions work on bit strings as well as strings: length, bit_length, octet_length, position, substring, and overlay.

The following functions work on bit strings as well as binary strings: get_bit and set_bit. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type bit. Example:

```
gaussdb=# SELECT 44::bit(10) AS RESULT;
   result
------------
 0000101100
(1 row)

gaussdb=# SELECT 44::bit(3) AS RESULT;
 result
--------
 100
(1 row)

gaussdb=# SELECT cast(-44 as bit(12)) AS RESULT;
    result
--------------
 111111010100
(1 row)

gaussdb=# SELECT '1110'::bit(4)::integer AS RESULT;
 result
--------
     14
(1 row)

gaussdb=# SELECT substring('10101111'::bit(8), 2);
 substring
-----------
 0101111
(1 row)
```

NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

7.6.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

LIKE

Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

Matching rules:

1. This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2. An underscore (_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.
3. To match a literal underscore or percent sign, the respective character in pattern must be preceded by the escape character. The default escape character is one backslash but a different one can be selected by using the ESCAPE clause.
4. To match with escape characters, enter two escape characters. For example, to write a pattern constant containing a backslash (\), you need to enter two backslashes in SQL statements.

   NOTE

   When **standard_conforming_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement. You can avoid this by selecting a different escape character by using ESCAPE, so that the backslash is no longer a special character of LIKE. But the backslash is still the special character of the character text analyzer. In this case, two backslashes are required. You can also select no escape character by writing **"ESCAPE"**. This effectively disables the escape mechanism, but it does not eliminate the special meaning of underscore and percent signs in the pattern.
5. The keyword ILIKE can be used instead of LIKE to make the match case-insensitive.
6. Operator **~~** is equivalent to LIKE, and operator **~~*** corresponds to ILIKE.

Example:

```
gaussdb=# SELECT 'abc' LIKE 'abc' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'a%' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE '_b_' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'c' AS RESULT;
 result
------------
 f
(1 row)
```

SIMILAR TO

Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that it uses the regular expression understanding pattern defined by the SQL standard.

Matching rules:

1. Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

2. An underscore (_) represents (matches) any single character. A percent sign (%) represents the wildcard character of any string.
3. SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX-style regular expressions:

Metacharacter	Description
|	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly *m* times.
{m,}	Specifies repetition of the previous item *m* or more times.
{m,n}	Specifies repetition of the previous item at least *m* times and does not exceed *n* times.
()	Specifies that parentheses () can be used to group items into a single logical item.
[...]	Specifies a character class, just as in POSIX-style regular expressions.

4. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

Regular expressions:

The **substring(string from pattern for escape)** function can be used to intercept a substring that matches an SQL regular expression.

Example:

```
gaussdb=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
 result
------------
 t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
 result
------------
 f
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
 result
------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '(b|c)%'  AS RESULT;
 result
------------
 f
(1 row)
```

POSIX-style regular expressions

Description: A regular expression is a collation that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular set described by a regular expression, the string matches the regular expression. POSIX-style regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. **Table 1 Regular expression match operators** lists all available operators for pattern matching using POSIX-style regular expressions.

Table 7-35 Regular expression match operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

Matching rules:

1. Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
2. Besides the metacharacters mentioned above, POSIX-style regular expressions also support the following pattern matching metacharacters:

Metacharacter	Description
^	Specifies the match starting with a string.
$	Specifies the match at the end of a string.
.	Matches any single character.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Regular expressions:

POSIX-style regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp_count(string text, pattern text [, position int [, flags text]])** function counts the number of substrings that match the POSIX-style regular expression pattern.
- The **regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])** function obtains the position of a substring that matches the POSIX-style regular expression pattern.
- The **regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp_replace(string, pattern, replacement [,flags])** function provides the function of replacing the substring matching the POSIX-style regular expression pattern with the new text.
- The **regexp_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.
- The **regexp_split_to_table(string text, pattern text [, flags text])** function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The **regexp_split_to_array(string text, pattern text [, flags text])** function behaves the same as regexp_split_to_table, except that its result is returned as an array of text.

  NOTE

  The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
gaussdb=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
--------
 f
(1 row)
gaussdb=# SELECT 'abc' ~* 'Abc' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc' !~ 'Abc' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc'!~* 'Abc' AS RESULT;
 result
--------
 f
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT 'abc' ~ '^a' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc' ~ '(b|d)'AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'abc' ~ '^(b|c)'AS RESULT;
 result
--------
 f
(1 row)
```

Although most regular expression searches can be executed quickly, they can still be artificially processed to require any length of time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO pattern has the same security risks, as SIMILAR TO provides many capabilities that are the same as those of the POSIX-style regular expression. The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

[NOT] REGEXP/ [NOT] RLIKE

Description: The REGEXP operator is used for regular expression matching and complies with POSIX-style regular expression matching rules. True or false is returned based on whether the pattern matches the given string.

The following table describes the regular expression operators.

Operator Name	Description	Syntax
REGEXP	Specifies whether a string matches the regular expression.	expr REGEXP pat
RLIKE	Specifies whether a string matches the regular expression (same as REGEXP).	expr RLIKE pat
NOT REGEXP	Specifies whether a string does not match the regular expression.	expr NOT REGEXP pat
NOT RLIKE	Specifies whether the character string does not match the regular expression (same as NOT REGEXP).	expr NOT RLIKE pat

Matching rules:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

1. A regular expression allows you to match any position in a string unless the regular expression is explicitly concatenated at the beginning or end of the string.
2. The pattern matching metacharacters supported by the REGEXP operator are the same as those supported by POSIX-style regular expressions.
3. The operator supports the following escape character matching.

Escape Character	Description
\b	Backspace key.
\f	Form feed character, for example, C language.
\n	Newline character, for example, C language.
\r	Carriage return character, for example, C language.
\t	Horizontal tab character, for example, C language.
\uwxyz	Character whose hexadecimal value is **0xwxyz**, where **wxyz** is four hexadecimal digits.
\xhhh	Character whose hexadecimal value is **0xhhh**, where **hhh** is any sequence of hexadecimal digits.
\xy	Character whose octal value is **0xy**, where **xy** is two octal digits.
\xyz	Character whose octal value is **0xyz**, where **xyz** is three octal digits.

4. Ranges for matching a pattern string: [a-dX] and [^a-dX].

   [a-dX] matches any characters of a, b, c, d, and X. [^a-dX] matches characters other than a, b, c, d, or X.

   The hyphen (-) between two characters forms a range, indicating that all characters in the range are matched. To include a right square bracket (]), it must follow the left square bracket ([). To include a hyphen (-), it must be after the left square bracket ([) or before the right square bracket (]). Any character that does not have any special meaning enclosed in square brackets ([]) matches itself.

   Example:

```
gaussdb=# SELECT 'abd' REGEXP 'a[bc]d' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'aed' REGEXP 'a[^bc]d' AS RESULT;
 result
--------
 t
(1 row)
gaussdb=# SELECT 'a-' REGEXP 'a[-b]' AS RESULT;
 result
--------
 t
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT 'aX]bc' REGEXP '^[]a-dXYZ]*$' AS RESULT;
 result
--------
 t
(1 row)
```

5. [.characters.] in the pattern string pat matches the collation of the element. In bracket expressions using quare brackets ([]), the collation used to proofread elements is matched. The character is a single character or a character name such as **space**. A complete list of character names can be found in the **regex/regc_locale** file.

   Example:

   ```
   gaussdb=# SELECT ' ' REGEXP '[[.space.]]' AS RESULT;
    result
   --------
    t
   (1 row)
   ```

6. Character class matching the **[=character_class=]** character in the pattern string pat. It is written in the square bracket expression. **[=character_class=]** indicates the equivalence class. A character matches all characters with the same sort proofreading value, including itself. For example, if o and (+) are of the same class, [[=o=]], [[=(+)=]], and [o(+)] are synonyms. The same class cannot be used as an endpoint of a range.
7. Character class matching the **[:character_class:]** character in the pattern string pat. It is written in square brackets ([]). **[:character_class:]** is used to match the characters that match the character class. Other class names may be provided for specific regions. The character class cannot be used as an endpoint of a range. The following table lists the standard class names. If the backslash (\) is involved, set the parameters according to the description.

Character Class	Description	Character Range
alnum	Alphanumeric numeric character.	[0-9a-zA-Z]
alpha	Alphanumeric character.	[a-zA-Z]
blank	Blank character.	[\t], indicating a blank character
cntrl	Control character.	[\x01-\x1F]
digit	Digit character.	[0-9]
graph	Graphic character.	[^\x01-\x20]
lower	Lowercase character.	[a-z]
print	Graphic character.	[^\x01-\x20]
punct	Punctuation character.	[-!"#$%&'( )*+,./:;<=>?@[\ \]^_`{|}~]
space	Spaces, tabs, new lines, and carriage returns.	[\n\r\t\x0B]

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Character Class	Description	Character Range
upper	Uppercase character.	[A-Z]
xdigit	Hexadecimal numeric character.	[0-9a-fA-F]

Example:

```
gaussdb=# SELECT '\n' REGEXP '[[:space:]]' AS RESULT;
 result
--------
 t
(1 row)
```

8. Start and end matching of the [[:<:]], [[:>:]] matching string in the pattern string pat.

   Example:

   ```
   gaussdb=# SELECT 'a word a' REGEXP '[[:<:]]word[[:>:]]' AS RESULT;
    result
   --------
    t
   (1 row)
   ```

9. To match a text instance with special characters, you need to add two backslashes (\\) before the following special characters: ( ) " ^ + ? To match single quotation marks, you need to write **\'** in the source string to match **\\\'** in the pattern string. If the backslash (\) is involved, set the parameters according to the description.

   Example:

   ```
   gaussdb=# SELECT 'a+b' REGEXP 'a\\+b' AS RESULT;
    result
   --------
    t
   (1 row)
   gaussdb=# SELECT '\" REGEXP '\\\" AS RESULT;
    result
   --------
    t
   (1 row)
   gaussdb=# SELECT '\\' REGEXP '\\\\' AS RESULT;
    result
   --------
    t
   (1 row)
   ```

10. When the case-sensitive character set and collation are set, regular expression matching is also case-sensitive.

    Example:

    ```
    gaussdb=# SELECT 'abc' REGEXP 'ABC' COLLATE utf8mb4_bin AS RESULT;
     result
    --------
     f
    (1 row)
    ```

11. If the input parameter **Expr** or pat is **NULL**, an empty value is returned.

    ```
    gaussdb=# SELECT NULL REGEXP '*' AS RESULT;
     result
    --------
    ```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)
gaussdb=# SELECT '-' REGEXP NULL AS RESULT;
 result
--------

(1 row)
```

NOTE

This operator is supported only in MySQL-compatible databases and is valid only when **sql_compatibility** is set to **'MYSQL'**. **b_format_version** is set to **'5.7'**. In this case, the REGEXP operator is equivalent to the ~* operator, and the NOT REGEXP operator is equivalent to the !~* operator.

- When **b_format_dev_version** is set to **s2**, **standard_conforming_strings** is set to **off** and **escape_string_warning** is set to **off** by default. In this case, any backslash written in the string constant must be written repeatedly. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement.
- This operator supports only the string type, text type, and other data types that can be implicitly converted to the string type and text type. The bytea type is not supported.

7.6.7 Arithmetic Functions and Operators

7.6.7.1 Arithmetic Operators

+

Description: Addition

Example:

```
gaussdb=# SELECT 2+3 AS RESULT;
 result
--------
      5
(1 row)
```

-

Description: Subtraction

Example:

```
gaussdb=# SELECT 2-3 AS RESULT;
 result
--------
     -1
(1 row)
```

*****

Description: Multiplication

Example:

```
gaussdb=# SELECT 2*3 AS RESULT;
 result
--------
      6
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

/

Description: Division (The result is not rounded.)

Example:

```
gaussdb=# SELECT 4/2 AS RESULT;
 result
--------
      2
(1 row)
gaussdb=# SELECT 4/3 AS RESULT;
       result
------------------
 1.33333333333333
(1 row)
```

+/-

Description: Positive/Negative

Example:

```
gaussdb=# SELECT -2 AS RESULT;
 result
--------
     -2
(1 row)
```

%

Description: Model (to obtain the remainder)

Example:

```
gaussdb=# SELECT 5%4 AS RESULT;
 result
--------
      1
(1 row)
```

@

Description: Absolute value

Example:

```
gaussdb=# SELECT @ -5.0 AS RESULT;
 result
--------
    5.0
(1 row)
```

^

Description: Power (exponent calculation)

Example:

```
gaussdb=# SELECT 2.0^3.0 AS RESULT;
       result
--------------------
 8.0000000000000000
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

|/

Description: Square root

Example:

```
gaussdb=# SELECT |/ 25.0 AS RESULT;
 result
--------
      5
(1 row)
```

||/

Description: Cubic root

Example:

```
gaussdb=# SELECT ||/ 27.0 AS RESULT;
 result
--------
      3
(1 row)
```

!

Description: Factorial

Example:

```
gaussdb=# SELECT 5! AS RESULT;
 result
--------
    120
(1 row)
```

!!

Description: Factorial (prefix operator)

Example:

```
gaussdb=# SELECT !!5 AS RESULT;
 result
--------
    120
(1 row)
```

&

Description: Binary AND

Example:

```
gaussdb=# SELECT 91&15  AS RESULT;
 result
--------
     11
(1 row)
```

|

Description: Binary OR

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT 32|3  AS RESULT;
 result
--------
     35
(1 row)
```

#

Description: Binary XOR

Example:

```
gaussdb=# SELECT 17#5  AS RESULT;
 result
--------
     20
(1 row)
```

~

Description: Binary NOT

Example:

```
gaussdb=# SELECT ~1 AS RESULT;
 result
--------
     -2
(1 row)
```

<<

Description: Binary shift left

Example:

```
gaussdb=# SELECT 1<<4 AS RESULT;
 result
--------
     16
(1 row)
```

>>

Description: Binary shift right

Example:

```
gaussdb=# SELECT 8>>2 AS RESULT;
 result
--------
      2
(1 row)
```

7.6.7.2 Arithmetic Functions

abs(x)

Description: Absolute value

Return type: same as the input.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT abs(-17.4);
 abs
------
 17.4
(1 row)
```

acos(x)

Description: Arc cosine

Return type: double precision

Example:

```
gaussdb=# SELECT acos(-1);
       acos
------------------
 3.14159265358979
(1 row)
```

asin(x)

Description: Arc sine

Return type: double precision

Example:

```
gaussdb=# SELECT asin(0.5);
       asin
------------------
 .523598775598299
(1 row)
```

atan(x)

Description: Arc tangent

Return type: double precision

Example:

```
gaussdb=# SELECT atan(1);
       atan
------------------
 .785398163397448
(1 row)
```

atan2(y, x)

Description: Arc tangent of y/x

Return type: double precision

Example:

```
gaussdb=# SELECT atan2(2, 1);
      atan2
------------------
 1.10714871779409
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

bitand(integer, integer)

Description: Performs the AND (&) operation on two integers.

Return type: bigint

Example:

```
gaussdb=# SELECT bitand(127, 63);
 bitand
--------
     63
(1 row)
```

cbrt(dp)

Description: Cubic root

Return type: double precision

Example:

```
gaussdb=# SELECT cbrt(27.0);
 cbrt
------
    3
(1 row)
```

ceil(x)

Description: Minimum integer greater than or equal to the parameter

Return type: integer

Example:

```
gaussdb=# SELECT ceil(-42.8);
 ceil
------
  -42
(1 row)
```

ceiling(dp or numeric)

Description: Minimum integer (alias of ceil) greater than or equal to the parameter

Return type: same as the input.

Example:

```
gaussdb=# SELECT ceiling(-95.3);
 ceiling
---------
     -95
(1 row)
```

cos(x)

Description: Cosine

Return type: double precision

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT cos(-3.1415927);
        cos
-------------------
 -.999999999999999
(1 row)
```

cosh(x)

Description: Hyperbolic cosine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT cosh(4);
        cosh
-------------------
 27.3082328360165
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

cot(x)

Description: Cotangent

Return type: double precision

Example:

```
gaussdb=# SELECT cot(1);
       cot
-------------------
 .642092615934331
(1 row)
```

degrees(dp)

Description: Converts a radian into an angle.

Return type: double precision

Example:

```
gaussdb=# SELECT degrees(0.5);
     degrees
-------------------
 28.6478897565412
(1 row)
```

div(y numeric, x numeric)

Description: Integer part of y/x

Return type: numeric

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT div(9,4);
 div
-----
   2
(1 row)
```

exp(x)

Description: Natural exponent

Return type: same as the input.

Example:

```
gaussdb=# SELECT exp(1.0);
        exp
--------------------
 2.7182818284590452
(1 row)
```

floor(x)

Description: Not larger than the maximum integer of the parameter

Return type: same as the input.

Example:

```
gaussdb=# SELECT floor(-42.8);
 floor
-------
   -43
(1 row)
```

int1(in)

Description: Converts the input parameter **text** into the int1 type and returns the result.

Return type: int1

Example:

```
gaussdb=# SELECT int1('123');
 int1
------
 123
(1 row)
gaussdb=# SELECT int1('1.1');
 int1
------
   1
(1 row)
```

int2(in)

Description: Converts the input parameter into the int2 type and returns the result. The input parameter can be of the bigint, float4, float8, int16, integer, numeric, real, or text type.

Return type: int2

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT int2('1234');
 int2
------
 1234
(1 row)
gaussdb=# SELECT int2(25.3);
 int2
------
   25
(1 row)
```

int4(in)

Description: Converts the input parameter into the int4 type and returns the result. The input parameter can be of the bit, Boolean, char, double precision, int16, numeric, real, smallint, or text type.

Return type: int4

Example:

```
gaussdb=# SELECT int4('789');
 int4
------
 789
(1 row)
gaussdb=# SELECT int4(99.9);
 int4
------
  100
(1 row)
```

int8(in)

Description: Converts the input parameter into the int8 type and returns the result. The input parameter can be of the bit, double precision, int16, integer, numeric, oid, real, smallint, or text type.

Return type: int8

Example:

```
gaussdb=# SELECT int8('789');
 int8
------
 789
(1 row)
gaussdb=# SELECT int8(99.9);
 int8
------
   99
(1 row)
```

float4(in)

Description: Converts the input parameter into the float4 type and returns the result. The input parameter can be of the bigint, double precision, int16, integer, numeric, smallint, or text type.

Return type: float4

Example:

```
gaussdb=# SELECT float4('789');
 float4
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
--------
   789
(1 row)

gaussdb=# SELECT float4(99.9);
 float4
--------
  99.9
(1 row)
```

float8(in)

Description: Converts the input parameter into the float8 type and returns the result. The input parameter can be of the bigint, int16, integer, numeric, real, smallint, or text type.

Return type: float8

Example:

```
gaussdb=# SELECT float8('789');
 float8
--------
   789
(1 row)

gaussdb=# SELECT float8(99.9);
 float8
--------
  99.9
(1 row)
```

int16(in)

Description: Converts the input parameter into the int16 type and returns the result. The input parameter can be of the bigint, Boolean, double precision, integer, numeric, oid, real, smallint, or tinyint type.

Return type: int16

Example:

```
gaussdb=# SELECT int16('789');
 int16
--------
   789
(1 row)

gaussdb=# SELECT int16(99.9);
 int16
--------
  100
(1 row)
```

numeric(in)

Description: Converts the input parameter into the numeric type and returns the result. The input parameter can be of the bigint, Boolean, double precision, int16, integer, money, real, or smallint type.

Return type: numeric

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT "numeric"('789');
 numeric
---------
     789
(1 row)

gaussdb=# SELECT "numeric"(99.9);
 numeric
---------
    99.9
(1 row)
```

oid(in)

Description: Converts the input parameter into the oid type and returns the result. The input parameter can be of the bigint or int16 type.

Return type: oid

radians(dp)

Description: Converts an angle into a radian.

Return type: double precision

Example:

```
gaussdb=# SELECT radians(45.0);
     radians
------------------
 .785398163397448
(1 row)
```

random()

Description: Random number between 0.0 and 1.0.

Return type: double precision

Example:

```
gaussdb=# SELECT random();
      random
------------------
 .824823560658842
(1 row)
```

rand([seed])

Description: The input can be without any parameters or only include a **seed** parameter of the bigint type. Typically, this function returns a random number from 0 to 1. If **seed** is specified, this function will return a random value for **seed**.

Parameter: a random number seed of the bigint type.

Return type: double

Example:

```
b_compatible_db=# SELECT rand();
       rand
------------------
 .327476012520492
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
(1 row)

b_compatible_db=# SELECT rand(12321);
       rand
------------------
 .326073104515672
(1 row)
```

NOTE

This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.

multiply(x double precision or text, y double precision or text)

Description: product of x and y.

Return type: double precision

Example:

```
gaussdb=# SELECT multiply(9.0, '3.0');
    multiply
--------------------
                27
(1 row)
gaussdb=# SELECT multiply('9.0', 3.0);
    multiply
--------------------
                27
(1 row)
```

ln(x)

Description: Natural logarithm.

Return type: same as the input.

Example:

```
gaussdb=# SELECT ln(2.0);
        ln
--------------------
 .6931471805599453
(1 row)
```

log(x)

Description: Logarithm with 10 as the base.

Return type: same as the input.

Example:

```
gaussdb=# SELECT log(100.0);
        log
--------------------
 2.0000000000000000
(1 row)
```

log(b numeric, x numeric)

Description: Logarithm with b as the base.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: numeric

Example:

```
gaussdb=# SELECT log(2.0, 64.0);
       log
--------------------
 6.0000000000000000
(1 row)
```

log2(x)

Description: Logarithm with 2 as the base.

Return type: double precision

Example:

```
gaussdb=# SELECT log2(2);
 log2
------
    1
(1 row)
```

NOTE

This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.

log10(x)

Description: Logarithm with 10 as the base.

Return type: double precision

Example:

```
gaussdb=# SELECT log10(10);
 log10
-------
     1
(1 row)
```

NOTE

This function takes effect when the database parameter **sql_compatibility** is set to **'MYSQL'**.

mod(x,y)

Description:

Remainder of x/y (model).

If x equals to 0, y is returned.

Return type: If the input parameter is of the (text, int) type, the return value is of the NUMERIC type. If the input parameter is of other types, the return type is the same as the parameter type.

Example:

```
gaussdb=# SELECT mod(9,4);
 mod
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
-----
   1
(1 row)
gaussdb=# SELECT mod(9,0);
 mod
-----
   9
(1 row)
```

NOTE

In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s6**, the mod function supports overloading with mod(text, int). When the mod function is called with (text, int) as the input type, mod(text, int) will take precedence.

```
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s6';
SET
gaussdb=# SELECT mod('170141183460469231731687303715884105728', 7);
 mod
-----
   2
(1 row)
```

pi()

Description: π constant value.

Return type: double precision

Example:

```
gaussdb=# SELECT pi();
        pi
------------------
 3.14159265358979
(1 row)
```

power(a double precision, b double precision)

Description: b power of a.

Return type: double precision

Example:

```
gaussdb=# SELECT power(9.0, 3.0);
        power
----------------------
 729.0000000000000000
(1 row)
```

remainder(x,y)

Description: Remainder of x/y. If y is 0, an error is reported.

Return type: same as the input (float4, float8, or numeric)

Example:

```
gaussdb=# SELECT remainder(11,4);
 remainder
-----------
        -1
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT remainder(9,0);
ERROR: division by zero
CONTEXT:  referenced column: remainder
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

round(x)

Description: Integer closest to the input parameter.

Return type: same as the input (double precision or numeric).

Example:

```
gaussdb=# SELECT round(42.4);
 round
-------
    42
(1 row)

gaussdb=# SELECT round(42.6);
 round
-------
    43
(1 row)
```

CAUTION

The output of the float/double type may be **-0**. (This also occurs in functions such as trunc and ceil. In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, the output will be **0**.) Below is an example:

```
gaussdb=# SELECT round(-0.2::float8);
 round
-------
    -0
(1 row)
```

round(v numeric, s int)

Description: The number of *s* digits are kept after the decimal point, and the number is rounded off.

Return type: numeric

Example:

```
gaussdb=# SELECT round(42.4382, 2);
 round
-------
 42.44
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- When the value of **a_format_version** is **10c** and that of **a_format_dev_version** is **s1** in an ORA-compatible database, **s** is truncated to an integer. Otherwise, **s** is rounded off to an integer.
- If the value of **a_format_version** is **10c** and the value of **a_format_dev_version** is **s1**, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, '')** is used as the input parameter to call the round function, round (timestamp, text) is preferred.

setseed(dp)

Description: Sets seed for the following random() calling (from –1.0 to 1.0, inclusive).

Return type: void

Example:

```
gaussdb=# SELECT setseed(0.54823);
 setseed
---------

(1 row)
```

sign(x)

Description: Returns symbols of this parameter.

Return type: **–1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

Example:

```
gaussdb=# SELECT sign(-8.4);
 sign
------
   -1
(1 row)
```

sin(x)

Description: Sine

Return type: double precision

Example:

```
gaussdb=# SELECT sin(1.57079);
       sin
------------------
 .999999999979986
(1 row)
```

sinh(x)

Description: Hyperbolic sine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT sinh(4);
      sinh
------------------
 27.2899171971277
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

sqrt(x)

Description: Square root

Return type: same as the input.

Example:

```
gaussdb=# SELECT sqrt(2.0);
      sqrt
-------------------
 1.414213562373095
(1 row)
```

NOTE

This function uses the Karatsuba sqrt square root algorithm when the GUC parameter **gs_format_behavior_compat_options** is set to **sqrt_karatsuba**. Otherwise, this function uses the Newton iteration algorithm. The performance of the Karatsuba sqrt square root algorithm is better. In a few scenarios, the precision of the Karatsuba sqrt square root algorithm is different from that of the Newton iteration algorithm.

tan(x)

Description: Tangent

Return type: double precision

Example:

```
gaussdb=# SELECT tan(20);
      tan
------------------
 2.23716094422474
(1 row)
```

tanh(x)

Description: Hyperbolic tangent

Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT tanh(0.1);
                        tanh
-----------------------------------------
0.099667994624955817118305083678352183538 9
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

> **NOTE**
>
> This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

trunc(x)

Description: Truncation (the integer part is retained).

Return type: same as the input.

Example:

```
gaussdb=# SELECT trunc(42.8);
 trunc
-------
    42
(1 row)
```

trunc(v numeric, s int)

Description: Truncates the last *s* digits after a decimal point.

Return type: numeric

Example:

```
gaussdb=# SELECT trunc(42.4382, 2);
 trunc
-------
 42.43
(1 row)
```

> **NOTE**
>
> This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**. If the input parameter **s** is a decimal, it will be truncated rather than rounded off.

width_bucket(op numeric, b1 numeric, b2 numeric, count int)

Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
 width_bucket
--------------
            3
(1 row)
```

width_bucket(op dp, b1 dp, b2 dp, count int)

Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.

Return type: int

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
 width_bucket
--------------
            3
(1 row)
```

smgrne(a smgr, b smgr)

Description: Checks whether two smgr integers are not equal.

Return type: Boolean

smgreq(a smgr, b smgr)

Description: Checks whether two smgr integers are equal.

Return type: Boolean

int1abs(tinyint)

Description: Returns the absolute value of data of the uint8 type.

Parameter: tinyint

Return type: tinyint

int1and(tinyint, tinyint)

Description: Returns the bitwise AND result of two data records of the uint8 type.

Parameter: tinyint, tinyint

Return type: tinyint

int1cmp(tinyint, tinyint)

Description: Compares two uint8 parameters. If the first parameter is greater, the function will return **1**. If the second parameter is greater, the function will return **-1**. If they are equal, the function will return **0**.

Parameter: tinyint, tinyint

Return type: integer

int1div(tinyint, tinyint)

Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.

Parameter: tinyint, tinyint

Return type: tinyint

int1eq(tinyint, tinyint)

Description: Compares two pieces of data of the uint8 type to check whether they are the same.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: tinyint, tinyint

Return type: Boolean

int1ge(tinyint, tinyint)

Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.

Parameter: tinyint, tinyint

Return type: Boolean

int1gt(tinyint, tinyint)

Description: Performs a greater-than operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: Boolean

int1larger(tinyint, tinyint)

Description: Returns the larger value of unsigned one-byte integers.

Parameter: tinyint, tinyint

Return type: tinyint

int1le(tinyint, tinyint)

Description: Determines whether the unsigned 1-byte integer is less than or equal to.

Parameter: tinyint, tinyint

Return type: Boolean

int1lt(tinyint, tinyint)

Description: Determines whether the unsigned 1-byte integer is less than.

Parameter: tinyint, tinyint

Return type: Boolean

int1smaller(tinyint, tinyint)

Description: Returns the smaller of two unsigned one-byte integers.

Parameter: tinyint, tinyint

Return type: tinyint

int1inc(tinyint)

Description: Unsigned 1-byte integer plus 1.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameter: tinyint

Return type: tinyint

int1mi(tinyint, tinyint)

Description: Performs a minus operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

int1mod(tinyint, tinyint)

Description: Performs a reminder operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

int1mul(tinyint, tinyint)

Description: Performs a multiplication operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

int1ne(tinyint, tinyint)

Description: Performs a not-equal-to operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: Boolean

int1pl(tinyint, tinyint)

Description: Performs an addition operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

int1um(tinyint)

Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.

Parameter: tinyint

Return type: smallint

int1xor(tinyint, tinyint)

Description: Performs an exclusive OR operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: tinyint

cash_div_int1(money, tinyint)

Description: Performs a division operation on the money type.

Parameter: money, tinyint

Return type: money

cash_mul_int1(money, tinyint)

Description: Performs a multiplication operation on the money type.

Parameter: money, tinyint

Return type: money

int1not(tinyint)

Description: Reverts binary bits of an unsigned 1-byte integer.

Parameter: tinyint

Return type: tinyint

int1or(tinyint, tinyint)

Description: Performs an OR operation on an unsigned 1-byte integer.

Parameter: tinyint, tinyint

Return type: tinyint

int1shl(tinyint, integer)

Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.

Parameter: tinyint, integer

Return type: tinyint

int1shr(tinyint, integer)

Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.

Parameter: tinyint, integer

Return type: tinyint

analyze_tgtype_for_type(n smallint)

Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one of **before each row**, **after each row**, **before statement**, **after statement**, and **instead of**.

Return type: varchar2(16)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

analyze_tgtype_for_event(n smallint)

Description: Parses **pg_trigger.tgtype**, parses *n* by bit, and returns one or more of **insert**, **update**, **delete**, and **truncate**.

Return type: varchar2(246)

nanvl(n2, n1)

Description: The input includes two parameters. These parameters must be either numeric or a non-numeric type that can be implicitly converted into the numeric type. If the first parameter, **n2**, is NaN, the function will return **n1**. Otherwise, it will return **n2**.

Return type: double precision > float4 > numeric, depending on the input parameters

Example:

```
gaussdb=# SELECT nanvl('NaN', 1.1);
 nanvl
-------
   1.1
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

numeric_eq_text(numeric, text)

Description: Checks whether a numeric variable is equal to the numeric value converted from a text variable.

Return type: Boolean

Example:

```
gaussdb=# SELECT numeric_eq_text(1, '1');
 numeric_eq_text
-----------------
 t
(1 row)
```

numeric_ne_text(numeric, text)

Description: Checks whether a numeric variable is not equal to the numeric value converted from a text variable.

Return type: Boolean

numeric_gt_text(numeric, text)

Description: Checks whether a numeric variable is greater than the numeric value converted from a text variable.

Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

numeric_ge_text(numeric, text)

Description: Checks whether a numeric variable is greater than or equal to the numeric value converted from a text variable.

Return type: Boolean

numeric_lt_text(numeric, text)

Description: Checks whether a numeric variable is less than the numeric value converted from a text variable.

Return type: Boolean

numeric_le_text(numeric, text)

Description: Checks whether a numeric variable is less than or equal to the numeric value converted from a text variable.

Return type: Boolean

text_eq_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is equal to a numeric variable.

Return type: Boolean

Example:

```
gaussdb=# SELECT text_eq_numeric('1', 1);
 text_eq_numeric
-----------------
 t
(1 row)
```

text_ne_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is not equal to a numeric variable.

Return type: Boolean

text_gt_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is greater than a numeric variable.

Return type: Boolean

text_ge_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is greater than or equal to a numeric variable.

Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

text_lt_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is less than a numeric variable.

Return type: Boolean

text_le_numeric(text, numeric)

Description: Checks whether the numeric value converted from a text variable is less than or equal to a numeric variable.

Return type: Boolean

bigint_eq_text(bigint, text)

Description: Checks whether a bigint variable is equal to the bigint value converted from a text variable.

Return type: Boolean

```
gaussdb=# SELECT bigint_eq_text(1, '1');
 bigint_eq_text
----------------
 t
(1 row)
```

bigint_ne_text(bigint, text)

Description: Checks whether a bigint variable is not equal to the bigint value converted from a text variable.

Return type: Boolean

bigint_gt_text(bigint, text)

Description: Checks whether a bigint variable is greater than the bigint value converted from a text variable.

Return type: Boolean

bigint_ge_text(bigint, text)

Description: Checks whether a bigint variable is greater than or equal to the bigint value converted from a text variable.

Return type: Boolean

bigint_lt_text(bigint, text)

Description: Checks whether a bigint variable is less than the bigint value converted from a text variable.

Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

bigint_le_text(bigint, text)

Description: Checks whether a bigint variable is less than or equal to the bigint value converted from a text variable.

Return type: Boolean

text_eq_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is equal to a bigint variable.

Return type: Boolean

Example:

```
gaussdb=# SELECT text_eq_bigint('1', 1);
 text_eq_bigint
----------------
 t
(1 row)
```

text_ne_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is not equal to a bigint variable.

Return type: Boolean

text_gt_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is greater than a bigint variable.

Return type: Boolean

text_ge_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is greater than or equal to a bigint variable.

Return type: Boolean

text_lt_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is less than a bigint variable.

Return type: Boolean

text_le_bigint(text, bigint)

Description: Checks whether the bigint value converted from a text variable is less than or equal to a bigint variable.

Return type: Boolean

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

7.6.8 Date and Time Processing Functions and Operators

7.6.8.1 Time and Date Operators

Table 7-36 describes the time and date operators.

NOTE

When using time and date operators, use explicit type prefixes to modify the corresponding operands to ensure that the operands parsed by the database are consistent with user expectations and avoid unexpected results.

Example: Not specifying a data type results in an error.

```
gaussdb=# SELECT date '2001-10-01' - '7' AS RESULT;
ERROR:
GAUSS-10416: invalid input syntax for type timestamp: "7"
SQLSTATE: 22007
LINE 1: SELECT date '2001-10-01' - '7' AS RESULT;
                                   ^
CONTEXT:  referenced column: result
```

Table 7-36 Time and date operators

Operator	Example
+	gaussdb=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ------------ 2001-10-05 (1 row) **NOTE** In ORA-compatible mode, the query result is 2001-10-05 00:00:00.
	gaussdb=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result --------------------- 2001-09-28 01:00:00 (1 row)
	gaussdb=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result --------------------- 2001-09-28 03:00:00 (1 row)
	gaussdb=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ---------------- 1 day 01:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result --------------------- 2001-09-29 00:00:00 (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator	Example
	gaussdb=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ---------- 04:00:00 (1 row)
-	gaussdb=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result -------- 3 (1 row)
	gaussdb=# SELECT date '2001-10-01' - integer '7' AS RESULT; result --------------------- 2001-09-24 00:00:00 (1 row)
	gaussdb=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result --------------------- 2001-09-27 23:00:00 (1 row)
	gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ---------- 02:00:00 (1 row)
	gaussdb=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ---------- 03:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result --------------------- 2001-09-28 00:00:00 (1 row)
	gaussdb=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ---------- 23:00:00 (1 row)
	gaussdb=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ---------------- 1 day 15:00:00 (1 row)
*	gaussdb=# SELECT 900 * interval '1 second' AS RESULT; result ---------- 00:15:00 (1 row)
	gaussdb=# SELECT 21 * interval '1 day' AS RESULT; result --------- 21 days (1 row)

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Operator	Example
*	gaussdb=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ---------- 03:30:00 (1 row)
/	gaussdb=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ---------- 00:40:00 (1 row)

7.6.8.2 Time and Date Functions

age(timestamp, timestamp)

Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters may or may not contain a time zone.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
          age
--------------------------
 43 years 9 mons 27 days
(1 row)
```

age(timestamp)

Description: Subtracts the parameter value from the system time when the current SQL statement starts to be executed. The input parameter may or may not contain a time zone.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '1957-06-13');
          age
--------------------------
 60 years 2 mons 18 days
(1 row)
```

clock_timestamp()

Description: Returns the timestamp of the system time when the current function is called. This volatile function obtains the latest timestamp for each scan. Therefore, the result of each function call in a query is different.

Return type: timestamp with time zone

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT clock_timestamp();
       clock_timestamp
-------------------------------
 2017-09-01 16:57:36.636205+08
(1 row)
```

current_date

Description: Returns the system date indicating the initiation of the current SQL statement.

Return type: date

Example:

```
gaussdb=# SELECT current_date;
    date
------------
 2017-09-01
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_date;
    current_date
---------------------
 2023-11-24 11:25:09
(1 row)
```

NOTE

- When **sql_compatibility** is **'ORA'** and the GUC parameter **a_format_date_timestamp** is **on**, this function operates as follows:
  - It returns a timestamp for the system time indicating the initiation of the current SQL statement.
  - The return type is timestamp without time zone, accurate to seconds. The column name is **current_date**.
  - The return type is timestamp when **a_format_version** is **10c** and **a_format_dev_version** is **s2**.
  - It returns a date for the system time indicating the initiation of the transaction, if the GUC parameter **a_format_date_timestamp** is disabled.
- When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function operates as follows:
  - current_date can be called with parentheses.
  - The current_date function works by calling the curdate function. To view the detailed input parameters and output values of curdate, run the **\df curdate** command.

current_time()

Description: Returns the system time indicating the initiation of the current transaction. When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function returns the system time indicating the initiation of the current SQL statement.

Return type: time with time zone (or time without time zone when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**).

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT current_time;
      timetz
-------------------
 16:58:07.086215+08
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT current_time;
 current_time
--------------
 15:14:00
(1 row)
```

current_time([precision])

Description: Returns the system time indicating the initiation of the current SQL statement.

Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Using an invalid precision will trigger an error.

Return type: time without time zone

Implementation method: This function is mapped to the system function curtime.

Example:

```
gaussdb_m=# SELECT current_time();
 current_time
--------------
 15:14:05
(1 row)
gaussdb_m=# SELECT current_time(3);
 current_time
--------------
 15:14:08.433
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**. The curent_time function works by calling the curtime function. To view the detailed input parameters and output values of curtime, run the **\df curtime** command.

current_timestamp

Description: Specifies the current date and time. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

Return type: timestamp without time zone (when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **'5.7'**, and **b_format_dev_version** is **'s1'**) or timestamp with time zone (for other setups).

Example:

```
gaussdb=# SELECT current_timestamp;
      pg_systimestamp
-------------------------------
 2017-09-01 16:58:19.22173+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp;
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
    timestamp
---------------------
 2023-08-21 15:08:24
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp;
      current_timestamp
-------------------------------
 2023-11-24 11:31:04.895312+08
(1 row)
```

NOTE

When **sql_compatibility** is set to **'ORA'**, or **sql_compatibility** is set to **'MYSQL'** and the **b_format_version** and **b_format_dev_version** parameters are not set, the return result is the timestamp of the system time when the latest SQL statement is started, and the return type is timestamp with time zone. If the GUC parameter **a_format_date_timestamp** is set to **on**, the column name is **current_timestamp**.

In PL/SQL, a simple assignment statement, such as time1 := current_timestamp, is considered as an expression. Therefore, the return result is the timestamp of the system time when the latest SQL statement is started.

When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function operates as follows:

- The return type is timestamp without time zone.
- The precision of the returned result is 0.
- It returns a timestamp for the system time indicating the initiation of the current SQL statement.
- This function is not registered but is implemented through TYPE conversion. Therefore, running the gsql command **\df+** retrieves the function information in modes other than MySQL-compatible (version 5.7).
- When the function is called multiple times in an anonymous block, the entire anonymous block is considered as a statement. Therefore, the same result is returned each time the function is called.

current_timestamp()

Description: Returns the system time when the current SQL statement starts.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT current_timestamp();
    timestamp
---------------------
 2023-08-21 14:34:30
(1 row)
```

NOTE

This function is available only when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**. It operates as follows:

- The return type is timestamp without time zone.
- The precision of the returned result is 0.
- It returns a timestamp for the system time indicating the initiation of the current SQL statement.
- This function is not registered but is implemented through TYPE conversion. Therefore, running the gsql command **\df+** retrieves the function information in modes other than MySQL-compatible (version 5.7).

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

current_timestamp(precision)

Description: Obtains the current date and time, and rounds the microseconds of the result to the specified decimal place.

Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than **6** will trigger an alarm and return a time value with a precision of 6. Using any other invalid precision will trigger an error.

Return type: timestamp without time zone (when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **'5.7'**, and **b_format_dev_version** is **'s1'**) or timestamp with time zone (for other setups).

Example:

```
gaussdb=# SELECT current_timestamp(1);
       timestamptz
-----------------------------
 2017-09-01 16:58:19.2+08
(1 row)

-- When the version is 5.7 in MySQL-compatible database:
gaussdb_m=# SELECT current_timestamp(1);
       timestamp
-----------------------
 2023-08-21 15:09:35.3
(1 row)

-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT current_timestamp(6);
       current_timestamp
-------------------------------
 2023-11-24 11:35:57.268592+08
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT current_timestamp(6.0);
      current_timestamp
-------------------------------
 2023-11-25 11:14:48.74763+08
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function operates as follows:
  - The return type is timestamp without time zone.
  - It returns a timestamp for the system time indicating the initiation of the current SQL statement.
  - This function is not registered but is implemented through TYPE conversion. Therefore, running the gsql command **\df+** retrieves the function information in modes other than MySQL-compatible (version 5.7).
- When **sql_compatibility** is **'ORA'** and the GUC parameter **a_format_date_timestamp** is **on**, this function operates as follows:
  - The return type is timestamp with time zone, and the column name is **current_timestamp**.
  - It returns a timestamp for the system time indicating the initiation of the current SQL statement.
  - When **a_format_version** is **10c** and **a_format_dev_version** is **s2**, the **precision** parameter accepts either the numeric type (integers) or the int type.
  - If the GUC parameter **a_format_date_timestamp** is disabled, when the input parameter is an integer without a decimal point, the returned result is the date and time of the system where the transaction is started; when the input parameter is an integer with a decimal point, the returned result is the timestamp of the system time when the current SQL statement starts.

pg_systimestamp()

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_systimestamp();
       pg_systimestamp
-------------------------------
 2015-10-14 11:21:28.317367+08
(1 row)
```

systimestamp()

Description: Gets the date and time of the current system.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT systimestamp();
        systimestamp
-------------------------------
 2024-04-16 15:55:21.614342+08
(1 row)
-- After the behavior_compat_options parameter is set to sys_function_without_brackets, calling without parentheses is supported.
gaussdb=# SET behavior_compat_options='sys_function_without_brackets';
gaussdb=# SELECT systimestamp;
        systimestamp
-------------------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 2024-04-16 15:55:21.614342+08
(1 row)
```

NOTE

This function takes effect only when **sql_compatibility** is **'ORA'**.

systimestamp(precision)

Description: Obtains the date and time of the current system and displays the microsecond part of the result based on the specified precision.

Parameter: **precision** (number of decimal places after the second). INT type. Range: [0,6]. The default value is **6**. When the value exceeds 6, a warning message is displayed, the time value is output with precision of 6.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT systimestamp(6);
         systimestamp
-------------------------------
 2024-04-16 15:55:21.614342+08
(1 row)
gaussdb=# SELECT systimestamp(9);
WARNING:  TIMESTAMP(9) WITH TIME ZONE precision reduced to maximum allowed, 6
CONTEXT:  referenced column: systimestamp
         systimestamp
-------------------------------
 2024-04-16 15:59:49.492505+08
(1 row)
gaussdb=# SELECT systimestamp(5.0);
         systimestamp
-------------------------------
 2024-04-16 16:00:23.48079+08
(1 row)
```

NOTE

This function takes effect only when **sql_compatibility** is **'ORA'**.

date_part(text, timestamp)

Description: Obtains fields such as year or hour from date/time values. It is equivalent to **extract(field from timestamp)**.

Parameter: The timestamp type can be abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, or timestamp without time zone.

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
 date_part
-----------
        20
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

date_part(text, interval)

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('month', interval '2 years 3 months');
 date_part
-----------
         3
(1 row)
```

date_trunc(text, timestamp)

Description: Truncates to the precision specified by **text**.

Return type: interval, timestamp with time zone, timestamp without time zone.

Example:

```
gaussdb=# SELECT date_trunc('hour', timestamp  '2001-02-16 20:38:40');
     date_trunc
---------------------
 2001-02-16 20:00:00
(1 row)
```

trunc(timestamp)

Description: Truncates to day by default.

Parameter type: timestamp with time zone, timestamp without time zone.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT trunc(TIMESTAMP  '2001-02-16
20:38:40');
                   trunc
---------------------
2001-02-16 00:00:00
(1 row)

gaussdb=# SELECT trunc(TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40');
        trunc
---------------------
 2001-02-16 00:00:00
(1 row)
```

trunc(arg1, arg2)

Description: Truncates to the precision specified by **arg2**.

Parameters:

- Type of **arg1**: interval, timestamp with time zone, timestamp without time zone
- Type of **arg2**: text. **Table 7-37** lists the units supported by **arg2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-37 Units supported by arg2

Unit	Description
mil, mils, millennia, millennium	Millennium
c, cc, cent, centuries, century	Century
dec, decade, decades, decs	Decade
y, year, years, yr, yrs, yyyy	Year
q, qtr, quarter	Quarter
mm, mon, mons, month, months	Month
w, week, weeks	Week
j, d, day, days, dd, ddd	Day
h, hh, hour, hours, hr, hrs	Hour
m, mi, min, mins, minute, minutes	Minute
s, sec, second, seconds, secs	Second
millisecon, ms, msec, msecond, mseconds, msecs	Millisecond
microsecon, us, usec, usecond, useconds, usecs	Microsecond

Return type: interval, timestamp with time zone, timestamp without time zone.

Example:

```
gaussdb=# SELECT trunc(timestamp  '2001-02-16 20:38:40',
'hour');
            trunc
---------------------
2001-02-16 20:00:00
(1 row)
```

round(arg1, arg2)

Description: Rounds off to the precision specified by **arg2**.

Parameters:

- Type of **arg1**: timestamp without time zone
- Type of **arg2**: text

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT round(timestamp  '2001-02-16 20:38:40',
'hour');
            round
---------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
2001-02-16 21:00:00
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**.

daterange(arg1, arg2)

Description: Obtains time boundary information.

Parameters: The type of **arg1** and **arg2** is date.

Return type: daterange

Example:

```
gaussdb=# SELECT daterange('2000-05-06','2000-08-08');
       daterange
-------------------------
 [2000-05-06,2000-08-08)
(1 row)
```

daterange(arg1, arg2, text)

Description: Obtains time boundary information.

Parameters: The type of **arg1** and **arg2** is date, and the type of **text** is text.

Return type: daterange

Example:

```
gaussdb=# SELECT daterange('2000-05-06','2000-08-08','[]');
       daterange
-------------------------
 [2000-05-06,2000-08-09)
(1 row)
```

isfinite(date)

Description: Checks whether a date is a finite value. If so, the function will return **t**. If not, the function will return **f**.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(date '2001-02-16');
 isfinite
----------
 t
(1 row)
gaussdb=# SELECT isfinite(date 'infinity');
 isfinite
----------
 f
(1 row)
```

isfinite(timestamp)

Description: Checks whether a timestamp is a finite value. If so, the function will return **t**. If not, the function will return **f**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
 isfinite
----------
 t
(1 row)
gaussdb=# SELECT isfinite(timestamp 'infinity');
 isfinite
----------
 f
(1 row)
```

isfinite(interval)

Description: Checks whether the interval is a finite value. If the interval is a finite value, **t** is returned. Currently, **f** cannot be returned. If **'infinity'** is entered, an error is reported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(interval '4 hours');
 isfinite
----------
 t
(1 row)
```

justify_days(interval)

Description: Adjusts an interval, converting 30-day time periods to months.

Return type: interval

Example:

```
gaussdb=# SELECT justify_days(interval '35 days');
 justify_days
--------------
 1 mon 5 days
(1 row)
```

justify_hours(interval)

Description: Adjusts an interval, converting 24-hour time periods to days.

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
 justify_hours
----------------
 1 day 03:00:00
(1 row)
```

justify_interval(interval)

Description: Adjusts **interval** using **justify_days** and **justify_hours**.

Return type: interval

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
 justify_interval
------------------
 29 days 23:00:00
(1 row)
```

localtime()

Description: Returns the system time indicating the initiation of the current transaction. When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function returns the system date and time indicating the initiation of the current SQL statement.

Return type: time (or timestamp without time zone when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**).

Example:

```
gaussdb=# SELECT localtime AS RESULT;
     result
----------------
 16:05:55.664681
(1 row)
-- When the parameter is enabled in MySQL-compatible mode:
gaussdb_m=# SELECT localtime;
      localtime
---------------------
 2023-08-21 15:21:57
(1 row)
```

localtime[([precision])]

Description: Returns the system date and time indicating the initiation of the current SQL statement.

Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Using an invalid precision will trigger an error.

Return type: timestamp without time zone

Implementation method: Register the system function localtime.

Example:

```
gaussdb_m=# SELECT localtime();
      localtime
---------------------
 2023-08-21 15:23:49
(1 row)
gaussdb_m=# SELECT localtime(3);
       localtime
-------------------------
 2023-08-21 15:23:51.965
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

localtimestamp

Description: Specifies the current date and time.

Return type: timestamp

Example:

```
gaussdb=# SELECT localtimestamp;
         timestamp
---------------------------
 2017-09-01 17:03:30.781902
(1 row)
-- In MySQL-compatible mode:
gaussdb_m=# SELECT localtimestamp;
      timestamp
--------------------
 2023-08-21 15:27:55
(1 row)
-- Enable the GUC parameter a_format_date_timestamp in ORA-compatible mode.
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp;
       localtimestamp
----------------------------
 2023-11-24 11:38:25.633231
(1 row)
```

NOTE

When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function operates as follows:

- The system date and time indicating the initiation of the current SQL statement are returned.
- The return type is timestamp without time zone, and the column name is **timestamp**.

When **sql_compatibility** is **'ORA'** and the GUC parameter **a_format_date_timestamp** is **on**, this function operates as follows:

- The return type is timestamp without time zone, and the column name is **localtimestamp**.
- It returns a timestamp for the system time indicating the initiation of the current SQL statement.
- This prevents the optimizer from obtaining the constant time in advance. As a result, the obtained time is incorrect in the gplan scenario.
- It returns the system date and time indicating the initiation of the transaction, if the GUC parameter **a_format_date_timestamp** is disabled.

localtimestamp[([precision])]

Description: Specifies the current date and time.

Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than **6** will trigger an alarm and return a time value with a precision of 6. Using any other invalid precision will trigger an error.

Return type: timestamp without time zone

Example:

```
-- Calls with parentheses and without input parameters are supported only in MySQL-compatible mode.
gaussdb_m=# SELECT localtimestamp();
      timestamp
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
---------------------
 2023-08-21 15:27:59
(1 row)
gaussdb_m=# SELECT localtimestamp(3);
       timestamp
-------------------------
 2023-08-21 15:28:02.445
(1 row)
-- When the GUC parameter a_format_date_timestamp is enabled in ORA-compatible mode:
gaussdb=# SET a_format_date_timestamp=on;
SET
gaussdb=# SELECT localtimestamp(6);
      localtimestamp
----------------------------
 2023-11-24 11:41:14.086227
(1 row)
-- If a_format_version is set to 10c and a_format_dev_version is set to s2 in an ORA-compatible database, precision can be an integer of the numeric type.
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT localtimestamp(6.0);
      localtimestamp
----------------------------
 2023-11-24 11:42:45.642167
(1 row)
```

NOTE

- Zeros at the end of microseconds are not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.
- When **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**, this function returns the system date and time indicating the initiation of the current SQL statement. It can be called with parentheses and without input parameters.
- When **sql_compatibility** is **'ORA'** and the GUC parameter **a_format_date_timestamp** is **on**, this function operates as follows:
  - It returns a timestamp for the system time indicating the initiation of the current SQL statement.
  - The return type is timestamp without time zone, and the column name is **localtimestamp**.
  - When **a_format_version** is **10c** and **a_format_dev_version** is **s2**, the **precision** parameter accepts either the numeric type (integers) or the int type.
  - It returns the system date and time indicating the initiation of the transaction, if the GUC parameter **a_format_date_timestamp** is disabled.

maketime(hour, minute, second)

Description: Generates a value of the time type based on the input parameters **hour**, **minute**, and **second**, which are of the bigint, bigint, and numeric types, respectively.

Return type: time

Example:

```
gaussdb=# SELECT maketime(8, 15, 26.53);
  maketime
-------------
 08:15:26.53
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT maketime(-888, 15, 26.53);
  maketime
------------
 -838:59:59
(1 row)
```

NOTE

This function is available only when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **'5.7'**, and **b_format_dev_version** is **'s1'**. It operates as follows:

- It returns **NULL** if any of the following conditions is met:
  - The input parameter **minute** is less than **0** or greater than or equal to **60**.
  - The input parameter **second** is less than **0** or greater than or equal to **60**.
  - Any parameter is **NULL**.
- The returned value of the time type contains six decimal places. If **second** contains more than six decimal places, it will be rounded off.
- The returned value of the time type is in the range [–838:59:59,838:59:59]. If the value is out of the range, the specified boundary value will be returned based on the positive and negative values of **hour**.
- **maketime** does not support self-nesting.

now()

Description: Returns the system date and time indicating the initiation of the current transaction. The results remain consistent within the same transaction. This function returns the system date and time indicating the initiation of the current SQL statement, but only when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

Return type: timestamp with time zone (or timestamp without time zone when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**).

Example:

```
gaussdb=# SELECT now();
              now
-------------------------------
 2017-09-01 17:03:42.549426+08
(1 row)
-- In MySQL-compatible mode:
gaussdb_m=# SELECT now();
      timestamp
---------------------
 2023-08-21 17:17:42
(1 row)
```

now(precision)

Description: Returns the system date and time indicating the initiation of the current SQL statement.

Parameter: **precision** (number of decimal places after the second). The precision is of the int type, within the range of [0,6] and with a default value of **0**. Setting a value greater than **6** will trigger an integer value alarm and return a time value with a precision of 6. Using any other invalid precision will trigger an error.

Return type: timestamp without time zone

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Implementation mode: Obtain the value using a 'now' :: text :: timestamp without time zone expression.

Example:

```
gaussdb_m=# SELECT now(3);
        timestamp
-------------------------
 2023-08-21 17:17:48.819
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

timenow()

Description: Returns the system date and time indicating the initiation of the current SQL statement.

Return type: abstime

Example:

```
gaussdb=# SELECT timenow();
        timenow
------------------------
 2020-06-23 20:36:56+08
(1 row)
```

dbtimezone

Description: Time zone of the current database.

Return type: text

Example:

```
gaussdb=# SELECT dbtimezone;
        dbtimezone
------------------------
 PRC
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

numtodsinterval(num, interval_unit)

Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

You can set the GUC parameter **intervalstyle** to **oracle** to maintain compatibility with the output format interval.

Return type: interval

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
 numtodsinterval
-----------------
 100:00:00
(1 row)

gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
       numtodsinterval
------------------------------
 +000000004 04:00:00.000000000
(1 row)
```

NOTE

When **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s2** in an ORA-compatible database, an error is reported if **interval_unit** is set to **'DAY'** and **num** is set to a value greater than **1000000000**.

numtoyminterval(num, interval_unit)

Description: Converts a number to the interval type. **num** is a number of the numeric type, and **interval_unit** is a string of the fixed format ('YEAR'|'MONTH').

You can set the GUC parameter **intervalstyle** to **oracle** to maintain compatibility with the output format interval.

Return type: interval

Example:

```
gaussdb=# \c gaussdb_o;
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "gaussdb_o" as user "omm".
gaussdb_o=# SET a_format_version='10c';
SET
gaussdb_o=# SET a_format_dev_version='s2';
SET
gaussdb=# SELECT numtoyminterval(100, 'MONTH');
 numtoyminterval
-----------------
 8 years 4 mons
(1 row)
gaussdb_o=# SET intervalstyle = oracle;
SET
gaussdb_o=# SELECT numtoyminterval(100, 'MONTH');
 numtoyminterval
-----------------
 8-4
(1 row)

gaussdb_o=# \c postgres
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "postgres" as user "omm".
gaussdb=# DROP DATEBASE gaussdb_o;
DROP DATABASE
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

new_time(date, timezone1,timezone2)

Description: Returns the date and time of the time zone specified by **timezone2** when the date and time of the time zone specified by **timezone1** are date.

Return type: timestamp

Example:

```
gaussdb=# SELECT new_time('1997-10-10','AST','EST');
     new_time
---------------------
 1997-10-09 23:00:00
(1 row)
gaussdb=# SELECT NEW_TIME(TO_TIMESTAMP ('10-Sep-02 14:10:10.123000','DD-Mon-RR HH24:MI:SS.FF'),
'AST', 'PST');
        new_time
-------------------------
 2002-09-10 10:10:10.123
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

sessiontimezone()

Description: Returns the time zone of the current session. There is no input parameter.

Return type: text

Example:

```
gaussdb=# SELECT SESSIONTIMEZONE;
 session_time_zone
-------------------
 PST8PDT
(1 row)
gaussdb=# SELECT LOWER(SESSIONTIMEZONE);
   lower
-----------
 @ 8 hours
(1 row)
```

NOTE

- This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.
- If the value of **session time zone** is **GMT+08:00** or **GMT-08:00**, the offset of the positive value is used as the position west of Greenwich Mean Time (GMT). For example, **GMT +08:00** indicates GMT–08:00 and **GMT-08:00** indicates GMT+08:00.

sys_extract_utc(timestamp| timestamptz)

Description: Extracts Coordinated Universal Time (UTC, also formerly known as Greenwich Mean Time) from a date-time value with a time zone offset or time zone region name. If no time zone is specified, the date and time are associated with the session time zone. The input parameter can be in timestamp or timestamptz format.

Return type: timestamp

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Example:

```
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00');
  sys_extract_utc
---------------------
 2000-03-28 03:30:00
(1 row)
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMPTZ '2000-03-28 11:30:00.00 -08:00');
  sys_extract_utc
---------------------
 2000-03-28 19:30:00
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

tz_offset('time_zone_name' | '(+/-)hh:mi' | SESSIONTIMEZONE | DBTIMEZONE)

Description: Returns the UTC offset of the time zone indicated by the input parameter. The input parameter has the preceding four formats.

Return type: text

Example:

```
gaussdb=# SELECT TZ_OFFSET('US/Pacific');
 tz_offset
-----------
 -08:00
(1 row)
gaussdb=# SELECT TZ_OFFSET(sessiontimezone);
 tz_offset
-----------
 +08:00
(1 row)
```

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s2**.

pg_sleep(seconds)

Description: Specifies the delay time of the server thread in unit of second. Note that when the database calls this function, the corresponding transaction snapshot is obtained, which is equivalent to a long transaction. If the input parameter time is too long, the database **oldestxmin** may fail to be executed, affecting the table recycling and query performance.

Return type: void

Example:

```
gaussdb=# SELECT pg_sleep(10);
 pg_sleep
----------

(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

statement_timestamp()

Description: Current date and time (start of the current statement).

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT statement_timestamp();
     statement_timestamp
-------------------------------
 2017-09-01 17:04:39.119267+08
(1 row)
```

sysdate

Description: Returns the system date and time indicating the initiation of the current SQL statement.

Return type: timestamp

Example:

```
gaussdb=# SELECT sysdate;
       sysdate
---------------------
 2017-09-01 17:04:49
(1 row)
```

sysdate([precision])

Description: Returns the system date and time when a function is executed.

Parameter: Indicates the time precision. The value is of the int type and in the range [0,6]. The default value is **0**.

Return type: timestamp without time zone

Example:

```
gaussdb_m=# SELECT sysdate();
      sysdate()
---------------------
 2023-08-21 17:17:42
(1 row)
gaussdb_m=# SELECT sysdate(3);
        sysdate(3)
-------------------------
 2023-08-21 17:17:48.819
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

current_sysdate()

Description: Returns the system date and time indicating the initiation of the current SQL statement.

Return type: timestamp

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT current_sysdate();
  current_sysdate
---------------------
 2023-06-20 20:09:02
(1 row)
```

timeofday()

Description: Returns the timestamp of the system time when the current function is called. It is similar to the clock_timestamp function, but the return type is text.

Return type: text

Example:

```
gaussdb=# SELECT timeofday();
              timeofday
--------------------------------------
 Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

transaction_timestamp()

Description: Returns the system date and time indicating the initiation of the current transaction.

Return type: timestamp with time zone (or timestamp without time zone when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**).

Example:

```
gaussdb=# SELECT transaction_timestamp();
    transaction_timestamp
-------------------------------
 2017-09-01 17:05:13.534454+08
(1 row)
-- In MySQL-compatible mode:
gaussdb=#  SELECT transaction_timestamp();
  transaction_timestamp
----------------------------
 2023-09-07 09:32:09.728998
(1 row)
```

add_months(d,n)

Description: Returns the time point *d* plus *n* months.

Parameters:

- **d**: indicates a value of the timestamp type or a value that can be implicitly converted into the timestamp type.
- **n**: indicates a value of the INTEGER type or a value that can be implicitly converted into the INTEGER type.

Return type: timestamp

Example:

```
gaussdb=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
    add_months
---------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 2018-04-29 00:00:00
(1 row)
```

NOTE

In ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**, this function operates as follows:

- If the calculation result is greater than 9999, an error will be reported.
- If the input parameter **n** is a decimal, it will be truncated rather than rounded off.

last_day(d)

Description: Returns the date of the last day of the month that contains time point *d*.

Return type: timestamp

Example:

```
gaussdb=# SELECT last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
    cal_result
---------------------
 2017-01-31 00:00:00
(1 row)
```

NOTE

When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, the last_day function calls the built-in function b_db_last_day. The input parameter type can be TEXT, DATE, DATETIME, or TIME. The return value is of the date type and can be a number in the datetime format.

months_between(d1, d2)

Description: Calculates the month difference between time points **d1** and **d2**. If both dates are the end of a month or are the same day, an integer is returned. Otherwise, the return value is a decimal and is calculated as 31 days per month.

Return type: numeric

Example:

```
gaussdb=# SELECT months_between(to_date('2022-10-31', 'yyyy-mm-dd'), to_date('2022-09-30', 'yyyy-mm-dd'));
 months_between
----------------
              1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-30', 'yyyy-mm-dd'), to_date('2022-09-30', 'yyyy-mm-dd'));
 months_between
----------------
              1
(1 row)

gaussdb=# SELECT months_between(to_date('2022-10-29', 'yyyy-mm-dd'), to_date('2022-09-30', 'yyyy-mm-dd'));
    months_between
-----------------------
 .96774193548387096774
(1 row)
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

This function takes effect in ORA-compatible databases where **a_format_version** is **10c** and **a_format_dev_version** is **s1**.

next_day(x,y)

Description: Calculates the time of the next week y started from x.

Return type: timestamp

Example:

```
gaussdb=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
    cal_result
---------------------
 2017-05-28 00:00:00
(1 row)
gaussdb=# SELECT next_day(timestamp '2024-01-17 00:00:00', 7.9999999);
ERROR:  Week day out of range, the range is 1 ... 7
CONTEXT:  referenced column: next_day
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SELECT next_day(timestamp '2024-01-17 00:00:00', 7.9999999);
     next_day
---------------------
 2024-01-20 00:00:00
(1 row)
```

NOTE

- If **a_format_version** is set to **10c**, **a_format_dev_version** is set to **s1**, and the second parameter is a floating-point number, this function discards the decimal part in the ORA-compatible database. Otherwise, this function rounds off the decimal part.
- In an ORA-compatible database, the first parameter can be of TIMESTAMP WITH TIME ZONE type only when **a_format_version** is set to **10c** and **a_format_dev_version** is set to **s1**.
- The second parameter of **next_day** supports abbreviations (case-insensitive), including **SUN**, **MON**, **TUE**, **WED**, **THU**, **THUR**, **FRI**, and **SAT**.

tinterval(abstime, abstime)

Description: Creates a time interval with two pieces of absolute time.

Return type: tinterval

Example:

```
gaussdb=# CALL tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May  1 00:30:30 1995');
                    tinterval
----------------------------------------------------
 ["1947-05-10 23:59:12+08" "1995-05-01 00:30:30+08"]
(1 row)
```

tintervalend(tinterval)

Description: Returns the end time of tinterval.

Return type: abstime

Example:

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
gaussdb=# SELECT tintervalend('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
      tintervalend
------------------------
 1983-10-04 23:59:12+08
(1 row)
```

tintervalrel(tinterval)

Description: Calculates and returns the relative time of **tinterval**.

Return type: reltime

Example:

```
gaussdb=# SELECT tintervalrel('["Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"]');
 tintervalrel
--------------
 1 mon
(1 row)
```

smalldatetime_ge(smalldatetime, smalldatetime)

Description: Checks whether the first parameter is greater than the second.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_cmp(smalldatetime, smalldatetime)

Description: Compares two smalldatetime values to check whether they are the same.

Parameter: smalldatetime, smalldatetime

Return type: integer

smalldatetime_eq(smalldatetime, smalldatetime)

Description: Compares two smalldatetime values to check whether they are the same.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_gt(smalldatetime, smalldatetime)

Description: Checks whether the first parameter is less than the second.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_hash(smalldatetime)

Description: Calculates the hash value corresponding to a timestamp.

Parameter: smalldatetime

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Return type: integer

smalldatetime_in(cstring, oid, integer)

Description: Inputs a timestamp.

Parameters: **cstring**, **oid**, and **integer**

Return type: smalldatetime

smalldatetime_larger(smalldatetime, smalldatetime)

Description: Returns a larger timestamp.

Parameter: smalldatetime, smalldatetime

Return type: smalldatetime

smalldatetime_le(smalldatetime, smalldatetime)

Description: Checks whether the first parameter is less than the second.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_lt(smalldatetime, smalldatetime)

Description: Checks whether the first parameter is greater than the second.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_ne(smalldatetime, smalldatetime)

Description: Compares two timestamps to check whether they are different.

Parameter: smalldatetime, smalldatetime

Return type: Boolean

smalldatetime_out(smalldatetime)

Description: Converts a timestamp into the external form.

Parameter: smalldatetime

Return type: cstring

smalldatetime_send(smalldatetime)

Description: Converts a timestamp into the binary format.

Parameter: smalldatetime

Return type: bytea

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

smalldatetime_smaller(smalldatetime, smalldatetime)

Description: Returns a smaller smalldatetime.

Parameter: smalldatetime, smalldatetime

Return type: smalldatetime

smalldatetime_to_abstime(smalldatetime)

Description: Converts smalldatetime into abstime.

Parameter: smalldatetime

Return type: abstime

smalldatetime_to_time(smalldatetime)

Description: Converts smalldatetime into time.

Parameter: smalldatetime

Return type: time without time zone

smalldatetime_to_timestamp(smalldatetime)

Description: Converts smalldatetime into timestamp.

Parameter: smalldatetime

Return type: timestamp without time zone

smalldatetime_to_timestamptz(smalldatetime)

Description: Converts smalldatetime into timestamptz.

Parameter: smalldatetime

Return type: timestamp with time zone

smalldatetime_to_varchar2(smalldatetime)

Description: Converts smalldatetime into varchar2.

Parameter: smalldatetime

Return type: character varying

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

1. The following APIs return values based on the start time of the current transaction:

```
CURRENT_DATE CURRENT_TIME
CURRENT_TIME(precision)
CURRENT_TIMESTAMP(precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME(precision)
LOCALTIMESTAMP(precision)
transaction_timestamp()
now()
```

   The values of **CURRENT_TIME** and **CURRENT_TIMESTAMP(precision)** contain time zone information. The values of **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. CURRENT_TIME, LOCALTIME, and LOCALTIMESTAMP can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result provides the full precision that can be obtained.

   These functions maintain consistent values throughout the transaction by returning results based on the start time of the current transaction. This ensures that the transaction can maintain consistency at the "current" moment and that multiple modifications within the same transaction retain the same timestamp. **transaction_timestamp()** is equivalent to **CURRENT_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction_timestamp()**.

   Note that when a transaction starts, **sql_compatibility** is set to **'ORA'**, and the GUC parameter **a_format_date_timestamp** is set to **on**, the CURRENT_DATE, CURRENT_TIMESTAMP(precision), LOCALTIMESTAMP, and LOCALTIMESTAMP (precision) functions return the timestamp when the current SQL statement starts. If the GUC parameter **a_format_date_timestamp** is disabled, these functions return the transaction start date or date and time.

   When **sql_compatibility** is set to **'MYSQL'**, **b_format_version** is set to **5.7**, and **b_format_dev_version** is set to **s1**, CURDATE, CURRENT_DATE, CURTIME, CURRENT_TIME, CURRENT_TIMESTAMP, NOW, LOCALTIME, LOCALTIMESTAMP, UTC_TIME and UTC_TIMESTAMP all return the start time of SQL statement execution, and SYSDATE returns the start time of function calling. In addition, transaction_timestamp() still indicates the transaction start time, but its return value type is changed to timestamp without time zone.

2. The following APIs return the start time of the current statement:

```
statement_timestamp()
```

   statement_timestamp() returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). During the execution of the first command of a transaction, the return values of statement_timestamp() and transaction_timestamp() are the same. However, in subsequent commands, the return values of statement_timestamp() and transaction_timestamp() may be different.

3. The following APIs return the actual current time when the function is called:

```
clock_timestamp()
timeofday()
```

   clock_timestamp() returns the actual current time. Therefore, its value changes even in the same SQL statement. Similar to clock_timestamp(), timeofday() also returns the actual current time. However, the result is a formatted text string instead of a timestamp with time zone value.

convert_tz(dt, from_tz, to_tz)

Description: Converts the date and time value **dt** from the **from_tz** time zone to the **to_tz** time zone.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Parameters: See **Table 7-38**.

Table 7-38 Parameters

Parameter	Type	Description	Value Range
dt	datetime, date, text, and numeric	Time and date value.	[0000-01-01 00:00:00.000000,9999-12-31 23:59:59.999999].
from_tz/ to_tz	A character string in the format of ±hh:mm	Offset compared with the UTC time, for example, '+08:00'.	[–15:59,15:00]
	Named time zone	For example, 'MET' and 'UTC'.	See the system view **PG_TIMEZONE_NAMES**.

Return type: datetime

Example:

```
gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT convert_tz(cast('2023-01-01 10:10:10' as datetime), '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(cast('2023-01-01' as date), '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01', '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz(20230101101010, '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 11:10:10
(1 row)
gaussdb=# SELECT convert_tz(20230101, '+00:00', '+01:00');
    convert_tz
---------------------
 2023-01-01 01:00:00
(1 row)
gaussdb=# SELECT convert_tz('2023-01-01 10:10:10', 'UTC', 'PRC');
    convert_tz
---------------------
```

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

```
 2023-01-01 18:10:10
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

sec_to_time(seconds)

Description: Converts the number of seconds into a time of the time type.

Parameters: See **Table 7-39**.

Table 7-39 Parameters

Parameter	Type	Description	Value Range
seconds	numeric and text	Number of seconds	[–3020399,+3020399], corresponding to the range of the time type [–838:59:59,838:59:59]. An out-of-bounds input will be truncated to the corresponding boundary value.

Return type: time without time zone

Example:

```
gaussdb=# SET b_format_dev_version = 's1';
SET
gaussdb=# SET b_format_version = '5.7';
SET
gaussdb=# SELECT sec_to_time(2000);
 sec_to_time
-------------
 00:33:20
(1 row)
gaussdb=# SELECT sec_to_time('-2000');
 sec_to_time
-------------
 -00:33:20
(1 row)
```

NOTE

This function takes effect when **sql_compatibility** is **'MYSQL'**, **b_format_version** is **5.7**, and **b_format_dev_version** is **s1**.

adddate(date, INTERVAL val unit)

Description: Returns a new date by adding a certain interval to a date.

Parameters: See **Table 7-40**.

 Copyright © Huawei Cloud Computing Technologies Co., Ltd.

Table 7-40 Parameters

Parameter	Type	Description	Value Range
date	A time expression, or a type such as text, datetime, date, or time.	Date to which a time interval needs to be added.	See the value ranges of the corresponding types.
val	Integer, floating-point number, or character string	Time interval to be added.	See the value ranges of the corresponding types.
unit	Keyword	Unit of the time interval.	YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, MICROSECOND, etc. For details, see **Time Interval Expressions**.

Return type: TEXT, DATE, DATETIME, or TIME WITHOUT TIMEZONE

Example:

```
