| pn_id | Integer | plan_node_id of the query executed by the stream |
| send_smp | Integer | smpid of the sender of the query executed by the stream |
| recv_smp | Integer | smpid of the receiver of the query executed by the stream |
| recv_bytes | Bigint | Total data volume received from the stream. The unit is byte. |
| time | Bigint | Current life cycle service duration of the stream. The unit is ms. |
| speed | Bigint | Average receiving rate of the stream. The unit is byte/s. |
| quota | Bigint | Current communication quota value of the stream. The unit is Byte. |
| buff_useize | Bigint | Current size of the data cache of the stream. The unit is byte. |

18.3.104 PG_COMM_SEND_STREAM

PG_COMM_SEND_STREAM displays the sending stream status of all the communication libraries for a single DN.

Table 18-175 PG_COMM_SEND_STREAM columns

| Column | Type | Description |
|-----------|------|-------------|
| node_name | Text | Node name |

| Column | Type | Description |
|-------------|---------|---|
| local_tid | Bigint | ID of the thread using this stream |
| remote_name | Text | Name of the peer node |
| remote_tid | Bigint | Peer thread ID |
| idx | Integer | Peer DN ID in the local DN |
| sid | Integer | Stream ID in the physical connection |
| tcp_sock | Integer | TCP socket used in the stream |
| state | Text | Current status of the stream <ul style="list-style-type: none">• UNKNOWN: The logical connection is unknown.• READY: The logical connection is ready.• RUN: The logical connection sends packets normally.• HOLD: The logical connection is waiting to send packets.• CLOSED: The logical connection is closed.• TO_CLOSED: The logical connection is to be closed.• WRITING: Data is being written. |
| query_id | Bigint | debug_query_id corresponding to the stream |
| pn_id | Integer | plan_node_id of the query executed by the stream |
| send_smp | Integer | smpid of the sender of the query executed by the stream |
| recv_smp | Integer | smpid of the receiver of the query executed by the stream |
| send_bytes | Bigint | Total data volume sent by the stream. The unit is Byte. |
| time | Bigint | Current life cycle service duration of the stream. The unit is ms. |
| speed | Bigint | Average sending rate of the stream. The unit is Byte/s. |
| quota | Bigint | Current communication quota value of the stream. The unit is Byte. |
| wait_quota | Bigint | Extra time generated when the stream waits the quota value. The unit is ms. |

18.3.105 PG_COMM_QUERY_SPEED

PG_COMM_QUERY_SPEED displays traffic information about all queries on a single node.

Table 18-176 PG_COMM_QUERY_SPEED columns

| Column | Type | Description |
|-----------|--------|--|
| node_name | Text | Node name |
| query_id | Bigint | debug_query_id corresponding to the stream |
| rxkB/s | Bigint | Receiving rate of the query stream (unit: byte/s) |
| txkB/s | Bigint | Sending rate of the query stream (unit: byte/s) |
| rxkB | Bigint | Total received data of the query stream (unit: byte) |
| txkB | Bigint | Total sent data of the query stream (unit: byte) |
| rxpck/s | Bigint | Packet receiving rate of the query (unit: packets/s) |
| txpck/s | Bigint | Packet sending rate of the query (unit: packets/s) |
| rxpck | Bigint | Total number of received packets of the query |
| txpck | Bigint | Total number of sent packets of the query |

18.3.106 PG_CONTROL_GROUP_CONFIG

PG_CONTROL_GROUP_CONFIG displays the Cgroup configuration information in the system.

Table 18-177 PG_CONTROL_GROUP_CONFIG columns

| Column | Type | Description |
|-------------------------|------|---|
| pg_control_group_config | Text | Configuration information of the Cgroup |

18.3.107 PG_CURSORS

PG_CURSORS displays available cursors.

Table 18-178 PG_CURSORS columns

| Column | Type | Description |
|---------------|--------------------------|---|
| Name | Text | Cursor name. |
| statement | Text | Query statement when the cursor is declared to change |
| is_holdable | boolean | Whether the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed). If it is, its value is true . |
| is_binary | boolean | Whether the cursor was declared BINARY. If it was, its value is true . |
| is_scrollable | boolean | Whether the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner). If it is, its value is true . |
| creation_time | Timestamp with time zone | Timestamp of the cursor. |

18.3.108 PG_EXT_STATS

PG_EXT_STATS displays extension statistics stored in the [PG_STATISTIC_EXT](#) table. The extension statistics means multiple columns of statistics.

Table 18-179 PG_EXT_STATS columns

| Column | Type | Reference | Description |
|------------|------------|---|--|
| schemaname | Name | PG_NAMESPACE.nspname | Name of the schema that contains a table |
| tablename | Name | PG_CLASS.relname | Name of a table |
| attname | int2vector | PG_STATISTIC_EXT.stakey | Indicates the columns to be combined for collecting statistics. |
| inherited | boolean | - | Includes inherited sub-columns if the value is true ; otherwise, indicates the column in a specified table. |
| null_frac | Real | - | Percentage of column combinations that are null to all records |
| avg_width | Integer | - | Average width of column combinations. The unit is byte. |

| Column | Type | Reference | Description |
|------------------|----------|-----------|--|
| n_distinct | Real | - | <ul style="list-style-type: none">Estimated number of distinct values in a column combination if the value is greater than 0Negative of the number of distinct values divided by the number of rows if the value is less than 0The number of distinct values is unknown if the value is 0. NOTE
The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows.
The positive form is used when the column seems to have a fixed number of possible values. For example, -1 indicates that the number of distinct values is the same as the number of rows for a column combination. |
| n_dndistinct | Real | - | <p>Number of unique not-null data values in the dn1 column combination</p> <ul style="list-style-type: none">Exact number of distinct values if the value is greater than 0Negative of the number of distinct values divided by the number of rows if the value is less than 0 For example, if a value in a column combination appears twice in average, n_dndistinct equals -0.5.The number of distinct values is unknown if the value is 0. |
| most_common_vals | anyarray | - | <p>List of the most common values in a column combination. If this combination does not have the most common values, most_common_vals_null will be NULL. None of the most common values in most_common_vals is NULL.</p> |

| Column | Type | Reference | Description |
|------------------------|----------|-----------|---|
| most_common_freqs | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals is NULL) |
| most_common_vals_null | anyarray | - | List of the most common values in a column combination. If this combination does not have the most common values, most_common_vals_null will be NULL. At least one of the common values in most_common_vals_null is NULL. |
| most_common_freqs_null | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals_null is NULL) |

18.3.109 PG_GET_INVALID_BACKENDS

PG_GET_INVALID_BACKENDS displays the information about backend threads on the CN that are connected to the current standby DN.

Table 18-180 PG_GET_INVALID_BACKENDS columns

| Column | Type | Description |
|---------------|--------------------------|--|
| pid | Bigint | Thread ID |
| node_name | Text | Node information connected to the backend thread |
| dbname | Name | Name of the connected database |
| backend_start | Timestamp with time zone | Backend thread startup time |
| query | Text | Query statement performed by the backend thread |

18.3.110 PG_GET_SENDERS_CATCHUP_TIME

PG_GET_SENDERS_CATCHUP_TIME displays the catchup information of the currently active primary/standby instance sending thread on a single DN.

Table 18-181 PG_GET_SENDERS_CATCHUP_TIME columns

| Column | Type | Description |
|------------------------|--------------------------|--|
| pid | Bigint | Current sender thread ID |
| lwpid | Integer | Current sender lwpid |
| local_role | Text | Local role |
| peer_role | Text | Peer role |
| state | Text | Current sender's replication status |
| type | Text | Current sender type |
| catchup_start | Timestamp with time zone | Startup time of a catchup task |
| catchup_end | Timestamp with time zone | End time of a catchup task |
| catchup_type | Text | Catchup task type, full or incremental |
| catchup_bcm_filename | Text | BCM file executed by the current catchup task |
| catchup_bcm_finished | Integer | Number of BCM files completed by a catchup task |
| catchup_bcm_total | Integer | Total number of BCM files to be operated by a catchup task |
| catchup_percent | Text | Completion percentage of a catchup task |
| catchup_remaining_time | Text | Estimated remaining time of a catchup task |

18.3.111 PG_GLOBAL_TEMP_ATTACHED_PIDS

This view displays information about sessions of resources occupied by global temporary tables on the current node. This view is supported only by clusters of 8.2.1.220 and later versions.

Table 18-182 PG_GLOBAL_TEMP_ATTACHED_PIDS columns

| Column | Type | Description |
|------------|------|-------------|
| schemaname | Name | Schema name |

| Column | Type | Description |
|-----------|--------|------------------|
| tablename | Name | Table name |
| pid | Bigint | PID of a session |

18.3.112 PG_GROUP

PG_GROUP displays the database role authentication and the relationship between roles.

Table 18-183 PG_GROUP columns

| Column | Type | Description |
|----------|-------|--|
| groname | Name | Group name |
| grosysid | OID | Group ID |
| grolist | oid[] | An array, including all the role IDs in this group |

18.3.113 PG_INDEXES

PG_INDEXES displays access to useful information about each index in the database.

Table 18-184 PG_INDEXES columns

| Column | Type | Reference | Description |
|------------|------|---------------------------------------|--|
| schemaname | Name | PG_NAMESPACE.nspname | Name of the schema that contains tables and indexes |
| tablename | Name | PG_CLASS.relname | Name of the table for which the index serves |
| indexname | Name | PG_CLASS.relname | Index name |
| tablespace | Name | PG_TABLESPACE.spcname | Name of the tablespace that contains the index |
| indexdef | Text | N/A | Index definition (a reconstructed CREATE INDEX command) |

Example

Query the index information about a specified table.

```
SELECT * FROM pg_indexes WHERE tablename = 'mytable';
schemaname | tablename | indexname | tablespace | indexdef
```

```
-----+-----+-----+-----+
+-----+-----+-----+-----+
public | mytable | idx_mytable_id | | CREATE INDEX idx_mytable_id ON mytable USING btree
(id) TABLESPACE pg_default
(1 row)
```

Query information about indexes of all tables in a specified schema in the current database.

```
SELECT tablename, indexname, indexdef FROM pg_indexes WHERE schemaname = 'public' ORDER BY
tablename,indexname;
tablename | indexname | indexdef
-----+-----+-----+
books | books_pkey | CREATE UNIQUE INDEX books_pkey ON books USING btree (id) TABLESPACE
pg_default
books | idx_books_tags_gin | CREATE INDEX idx_books_tags_gin ON books USING gin (tags)
TABLESPACE pg_default
customer | c_custkey_key | CREATE UNIQUE INDEX c_custkey_key ON customer USING btree
(c_custkey, c_name) TABLESPACE pg_default
mytable | idx_mytable_id | CREATE INDEX idx_mytable_id ON mytable USING btree (id) TABLESPACE
pg_default
test1 | idx_test_id | CREATE INDEX idx_test_id ON test1 USING btree (id) TABLESPACE pg_default
v0 | v0_pkey | CREATE UNIQUE INDEX v0_pkey ON v0 USING btree (c) TABLESPACE pg_default
(6 rows)
```

18.3.114 PG_JOB

PG_JOB displays detailed information about scheduled tasks created by users.

The **PG_JOB** view replaces the **PG_JOB** system catalog in earlier versions and provides forward compatibility with earlier versions. The original **PG_JOB** system catalog is changed to the **PG_JOBS** system catalog. For details about **PG_JOBS**, see [PG_JOBS](#).

Table 18-185 PG_JOB columns

| Column | Type | Description |
|----------------------|--------|---|
| job_id | Bigint | Job ID |
| current_postgres_pid | Bigint | If the current job has been executed, the PostgreSQL thread ID of this job is recorded. The default value is -1 , indicating that the task is not executed or has been executed. |
| log_user | Name | User name of the job creator |
| priv_user | Name | User name of the job executor |
| dbname | Name | Name of the database where the job is executed |
| node_name | Name | CN node on which the job will be created and executed |

| Column | Type | Description |
|-----------------|-----------------------------|--|
| job_status | Text | <p>Status of the current job. The value range is r, s, f, d, p, w, or l. The default value is s. The indications are as follows:</p> <ul style="list-style-type: none">• r=running• s=successfully finished• f=job failed• d=disable• p=pending• w=waiting• l=launching <p>NOTE</p> <ul style="list-style-type: none">• Note: When you disable a scheduled task (by setting job_queue_processes to 0), the thread monitor the job execution is not started, and the job_status will not be updated. You can ignore the job_status.• Only when the scheduled task function is enabled (that is, when job_queue_processes is not 0), the system updates the value of job_status based on the real-time job status. |
| start_date | Timestamp without time zone | Start time of the first job execution, precise to millisecond |
| next_run_date | Timestamp without time zone | Scheduled time of the next job execution, accurate to millisecond |
| failure_count | Smallint | Number of consecutive failures |
| interval | Text | Job execution interval |
| last_start_date | Timestamp without time zone | Start time of the last job execution, accurate to millisecond |
| last_end_date | Timestamp without time zone | End time of the last job execution, accurate to millisecond |
| last_suc_date | Timestamp without time zone | Start time of the last successful job execution, accurate to millisecond |
| this_run_date | Timestamp without time zone | Start time of the ongoing job execution, accurate to millisecond |
| nspname | Name | Name of the namespace where a job is running |

| Column | Type | Description |
|--------|------|-------------|
| what | Text | Job content |

18.3.115 PG_JOB_PROC

The **PG_JOB_PROC** view replaces the **PG_JOB_PROC** system catalog in earlier versions and provides forward compatibility with earlier versions. The original **PG_JOB_PROC** and **PG_JOB** system catalogs are merged into the **PG_JOBS** system catalog in the current version. For details about the **PG_JOBS** system catalog, see [PG_JOBS](#).

Table 18-186 PG_JOB_PROC columns

| Column | Type | Description |
|--------|--------|-------------|
| job_id | Bigint | Job ID |
| what | Text | Job content |

18.3.116 PG_JOB_SINGLE

PG_JOB_SINGLE displays job information about the current node.

Table 18-187 PG_JOB_SINGLE columns

| Column | Type | Description |
|----------------------|--------|---|
| job_id | Bigint | Job ID |
| current_postgres_pid | Bigint | If the current job has been executed, the PostgreSQL thread ID of this job is recorded. The default value is -1, indicating that the task is not executed or has been executed. |
| log_user | Name | User name of the job creator |
| priv_user | Name | User name of the job executor |
| dbname | Name | Name of the database where the job is executed |
| node_name | Name | CN node on which the job will be created and executed |

| Column | Type | Description |
|-----------------|-----------------------------|--|
| job_status | Text | <p>Status of the current job. The value range is r, s, f, d, p, w, or l. The default value is s. The indications are as follows:</p> <ul style="list-style-type: none">• r=running• s=successfully finished• f=job failed• d=disable• p=pending• w=waiting• l=launching <p>NOTE</p> <ul style="list-style-type: none">• Note: When you disable a scheduled task (by setting job_queue_processes to 0), the thread monitor the job execution is not started, and the job_status will not be updated. You can ignore the job_status.• Only when the scheduled task function is enabled (that is, when job_queue_processes is not 0), the system updates the value of job_status based on the real-time job status. |
| start_date | Timestamp without time zone | Start time of the first job execution, precise to millisecond |
| next_run_date | Timestamp without time zone | Scheduled time of the next job execution, accurate to millisecond |
| failure_count | Smallint | Number of consecutive failures. |
| interval | Text | Job execution interval |
| last_start_date | Timestamp without time zone | Start time of the last job execution, accurate to millisecond |
| last_end_date | Timestamp without time zone | End time of the last job execution, accurate to millisecond |
| last_suc_date | Timestamp without time zone | Start time of the last successful job execution, accurate to millisecond |
| this_run_date | Timestamp without time zone | Start time of the ongoing job execution, accurate to millisecond |
| nspname | Name | Name of the namespace where a job is running |

| Column | Type | Description |
|--------|------|-------------|
| what | Text | Job content |

18.3.117 PG_LIFECYCLE_DATA_DISTRIBUTE

PG_LIFECYCLE_DATA_DISTRIBUTE displays the distribution of cold and hot data in a multi-temperature table of OBS.

Table 18-188 PG_LIFECYCLE_DATA_DISTRIBUTE columns

| Column | Type | Description |
|---------------------|------|---|
| schemaname | Name | Schema name |
| tablename | Name | Current table name |
| nodename | Name | Node name |
| hotpartition | Text | Hot partition on the DN |
| coldpartition | Text | Cold partition on the DN |
| switchablepartition | Text | Switchable partition on the DN |
| hotdatasize | Text | Data size of the hot partition on the DN |
| colddatasize | Text | Data size of the cold partition on the DN |
| switchabledatasize | Text | Data size of the switchable partition on the DN |

18.3.118 PG_LOCKS

PG_LOCKS displays information about the locks held by open transactions.

Table 18-189 PG_LOCKS columns

| Column | Type | Reference | Description |
|----------|------|-----------|---|
| locktype | Text | N/A | Type of the locked object: relation, extend, page, tuple, transactionid, virtualxid, object, userlock, and advisory |

| Column | Type | Reference | Description |
|--------------------|----------|---------------------------------|---|
| database | OID | PG_DATABASE.oid | OID of the database in which the locked target exists <ul style="list-style-type: none">The OID is 0 if the target is a shared object.The OID is NULL if the locked target is a transaction. |
| relation | OID | PG_CLASS.oid | OID of the relationship targeted by the lock. The value is NULL if the object is neither a relationship nor part of a relationship. |
| page | Integer | N/A | Page number targeted by the lock within the relationship. If the object is neither a relation page nor row page, the value is NULL . |
| tuple | Smallint | N/A | Row number targeted by the lock within the page. If the object is not a row, the value is NULL . |
| virtualxid | Text | N/A | Virtual ID of the transaction targeted by the lock. If the object is not a virtual transaction ID, the value is NULL . |
| transactionid | Xid | N/A | ID of the transaction targeted by the lock. If the object is not a transaction ID, the value is NULL . |
| classid | OID | PG_CLASS.oid | OID of the system table that contains the object. If the object is not a general database object, the value is NULL . |
| objid | OID | N/A | OID of the lock target within its system table. If the target is not a general database object, the value is NULL . |
| objsubid | Smallint | N/A | Column number for a column in the table. The value is 0 if the target is some other object type. If the object is not a general database object, the value is NULL . |
| virtualtransaction | Text | N/A | Virtual ID of the transaction holding or awaiting this lock |

| Column | Type | Reference | Description |
|----------|--------------------------|-----------|--|
| pid | Bigint | N/A | Logical ID of the server thread holding or awaiting this lock. This is NULL if the lock is held by a prepared transaction. |
| mode | Text | N/A | Lock mode held or desired by this thread For more information about lock modes, see "LOCK" in <i>Data Warehouse Service (DWS) SQL Syntax Reference</i> . |
| granted | boolean | N/A | <ul style="list-style-type: none">The value is true if the lock is a held lock.The value is false if the lock is an awaited lock. |
| fastpath | boolean | N/A | Whether the lock is obtained through fast-path (true) or main lock table (false) |
| waittime | Timestamp with time zone | N/A | Timestamp when the lock wait starts.
This column is available only in clusters of version 9.1.0.200 or later. |
| holdtime | Timestamp with time zone | N/A | Timestamp when the lock starts to be held. This column is available only in clusters of version 9.1.0.200 or later. |

18.3.119 PG_LWLOCKS

PG_LWLOCKS provides information on lightweight locks currently held or being waited for by the current instance. This view is supported only by 9.1.0.200 and later cluster versions.

Table 18-190 PG_LWLOCKS columns

| Column | Type | Description |
|-----------|---------|---|
| pid | Bigint | ID of the backend thread. |
| query_id | Bigint | ID of a query. |
| lwtid | Integer | Lightweight thread ID of the backend thread. |
| reqlockid | Integer | ID of the lightweight lock that is being requested by the current thread. |

| Column | Type | Description |
|--------------|---------|---|
| reqlock | Text | Name of the lightweight lock corresponding to reqlockid . |
| heldlocknums | Integer | Number of lightweight locks obtained by the current thread. |
| heldlockid | Integer | Lightweight lock ID obtained by the current thread. |
| heldlock | Text | Name of the lightweight lock corresponding to heldlockid . |
| heldlockmode | Text | Lightweight lock mode corresponding to heldlockid . |

Example

Use the **PG_LWLOCKS** view to query information about lightweight locks that are being held or waiting for the current instance.

```
SELECT * FROM pg_lwlocks;
```

| | | | | | | | | |
|---|-------------------|-------|-----------|---------|--------------|------------|--------------|--------------|
| pid | query_id | lwtid | reqlockid | reqlock | heldlocknums | heldlockid | heldlock | heldlockmode |
| -----+-----+-----+-----+-----+-----+-----+----- | | | | | | | | |
| +-----+ | | | | | | | | |
| 139810224192480 | | 0 | 54842 | | 1 | 7 | WALWriteLock | Exclusive |
| 139810224199520 | 78250043526306022 | 54963 | | | 1 | 193860 | | |
| BUFFER_POOL_LWLOCK Exclusive | | | | | | | | |
| (2 rows) | | | | | | | | |

18.3.120 PG_NODE_ENV

PG_NODE_ENV displays the environmental variable information about the current node.

Table 18-191 PG_NODE_ENV columns

| Column | Type | Description |
|---------------|---------|--|
| node_name | Text | Name of the node |
| host | Text | Host name of the node |
| process | Integer | Number of the node process |
| port | Integer | Port ID of the node |
| installpath | Text | Installation directory of current node |
| datapath | Text | Data directory of the node |
| log_directory | Text | Log directory of the node |

18.3.121 PG_OS_THREADS

PG_OS_THREADS displays the status information about all the threads under the current node.

Table 18-192 PG_OS_THREADS columns

| Column | Type | Description |
|---------------|--------------------------|--|
| node_name | Text | Name of the node |
| pid | Bigint | Thread number running under the current node process |
| lwpid | Integer | Lightweight thread IDs corresponding to the PIDs |
| thread_name | Text | Thread names corresponding to the PIDs |
| creation_time | Timestamp with time zone | Creation time of the threads corresponding to the PIDs |

18.3.122 PG_POOLER_STATUS

PG_POOLER_STATUS displays the cache connection status in the pooler.
PG_POOLER_STATUS can only query on the CN, and displays the connection cache information about the pooler module.

Table 18-193 PG_POOLER_STATUS columns

| Column | Type | Description |
|------------|---------|---|
| database | Text | Database name |
| user_name | Text | Username |
| tid | Bigint | ID of the thread used for the connection to the CN |
| node_oid | Bigint | OID of the node connected |
| node_name | Name | Name of the node connected |
| in_use | boolean | Whether the connection is in use. The options are: <ul style="list-style-type: none">• t (true): The connection is in use.• f (false): The connection is not in use. |
| fdsock | Bigint | Peer socket |
| remote_pid | Bigint | Peer thread ID |

| Column | Type | Description |
|----------------|------|---|
| session_params | Text | GUC session parameter delivered by the connection |

Example

View information about the connection pool **pooler**:

```
select database,user_name,node_name,in_use,count(*) from pg_pooler_status group by 1, 2, 3,4 order by 5
desc limit 50;
database | user_name | node_name | in_use | count
-----+-----+-----+-----+-----
mydbdemo | user3     | cn_5001   | f      | 2
mydbdemo | user3     | dn_6005_6006 | t      | 2
mydbdemo | user3     | dn_6001_6002 | t      | 2
mydbdemo | user3     | dn_6003_6004 | f      | 2
mydbdemo | user3     | dn_6003_6004 | t      | 2
mydbdemo | user3     | dn_6005_6006 | f      | 2
mydbdemo | user3     | dn_6001_6002 | f      | 2
mydbdemo | user3     | cn_5002   | f      | 2
gaussdb  | user3     | dn_6003_6004 | f      | 1
mydbdemo | user3     | cn_5001   | t      | 1
music    | user2     | dn_6003_6004 | f      | 1
music    | user2     | dn_6005_6006 | f      | 1
gaussdb  | user1     | dn_6005_6006 | f      | 1
(13 rows)
```

18.3.123 PG_PREPARED_STATEMENTS

PG_PREPARED_STATEMENTS displays all prepared statements that are available in the current session.

Table 18-194 PG_PREPARED_STATEMENTS columns

| Column | Type | Description |
|-----------------|--------------------------|---|
| Name | Text | Identifier of a prepared statement. |
| statement | Text | Query string for creating this prepared statement. For prepared statements created through SQL, this is the PREPARE statement submitted by the client. For prepared statements created through the frontend/backend protocol, this is the text of the prepared statement itself. |
| prepare_time | Timestamp with time zone | Timestamp when the prepared statement is created. |
| parameter_types | regtype[] | Expected parameter types for the prepared statement in the form of an array of regtype . The OID corresponding to an element of this array can be obtained by casting the regtype value to oid. |

| Column | Type | Description |
|----------|---------|---|
| from_sql | boolean | <ul style="list-style-type: none">The value is true if the prepared statement is created using the PREPARE statement.The value is false if the instance is created using the frontend/backend protocol. |

18.3.124 PG_PREPARED_XACTS

PG_PREPARED_XACTS displays information about transactions that are currently prepared for two-phase commit.

Table 18-195 PG_PREPARED_XACTS columns

| Column | Type | Reference | Description |
|-------------|--------------------------|-------------------------------------|--|
| transaction | Xid | N/A | Numeric transaction identifier of the prepared transaction |
| gid | Text | N/A | Global transaction identifier that was assigned to the transaction |
| prepared | Timestamp with time zone | N/A | Time at which the transaction is prepared for commit |
| owner | Name | PG_AUTHID .rolname | Name of the user that executes the transaction |
| database | Name | PG_DATABASE .dbname | Name of the database in which the transaction is executed |

18.3.125 PG_PUBLICATION_TABLES

PG_PUBLICATION_TABLES displays the mapping between a publication and its published tables. Unlike the underlying system catalog [PG_PUBLICATION_REL](#), this view expands the publications defined as **FOR ALL TABLES** and **FOR ALL TABLES IN SCHEMA**, in which each publishable table has a row. This view is supported only by clusters of version 8.2.0.100 or later.

Table 18-196 PG_PUBLICATION_TABLES columns

| Column | Type | Description |
|---------|------|------------------|
| pubname | Name | Publication name |

| Column | Type | Description |
|------------|------|-------------------------------|
| schemaname | Name | Name of the schema of a table |
| tablename | Name | Table name |

Examples

Query all published tables.

```
SELECT * FROM PG_PUBLICATION_TABLES;  
pubname | schemaname | tablename  
-----+-----+-----  
mypub   | public    | t1  
mypub   | public    | t2  
(2 rows)
```

18.3.126 PG_QUERYBAND_ACTION

PG_QUERYBAND_ACTION displays information about the object associated with **query_band** and the **query_band** query order.

Table 18-197 PG_QUERYBAND_ACTION columns

| Column | Type | Description |
|------------|---------|---|
| qband | Text | query_band key-value pairs |
| respool_id | OID | OID of the resource pool associated with query_band |
| respool | Text | Name of the resource pool associated with query_band |
| priority | Text | Intra-queue priority associated with query_band |
| qborder | Integer | query_band query order |

18.3.127 PG_REPLICATION_SLOTS

PG_REPLICATION_SLOTS displays the replication node information.

Table 18-198 PG_REPLICATION_SLOTS columns

| Column | Type | Description |
|-----------|------|--|
| slot_name | Text | Name of a replication node |
| plugin | Name | Name of the output plug-in of the logical replication slot |
| slot_type | Text | Type of a replication node |

| Column | Type | Description |
|---------------|---------|--|
| datoid | OID | OID of the database on the replication node |
| database | Name | Name of the database on the replication node |
| active | boolean | Whether the replication node is active |
| xmin | Xid | Transaction ID of the replication node |
| catalog_xmin | Text | ID of the earliest-decoded transaction corresponding to the logical replication slot |
| restart_lsn | Text | Xlog file information on the replication node |
| dummy_standby | boolean | Whether the replication node is the dummy standby node |

18.3.128 PG_ROLES

PG_ROLES displays information about database roles.

Table 18-199 PG_ROLES columns

| Column | Type | Reference | Description |
|----------------|---------|-----------|--|
| rolname | Name | N/A | Role name |
| rolsuper | boolean | N/A | Whether the role is the initial system administrator with the highest permission |
| rolinherit | boolean | N/A | Whether the role inherits permissions for this type of roles |
| rolcreatorole | boolean | N/A | Whether the role can create other roles |
| rolcreatedb | boolean | N/A | Whether the role can create databases |
| rolcatupdate | boolean | N/A | Whether the role can update system tables directly. Only the initial system administrator whose usesysid is 10 has this permission. It is not available for other users. |
| rolcanlogin | boolean | N/A | Whether the role can log in to the database |
| rolreplication | boolean | N/A | Whether the role can be replicated |
| rolauditadmin | boolean | N/A | Whether the role is an audit system administrator |

| Column | Type | Reference | Description |
|----------------|--------------------------|---------------------------------------|---|
| rolsystemadmin | boolean | N/A | Whether the role is a system administrator |
| rolconlimit | Integer | N/A | Limits the maximum number of concurrent connections of a user on a CN. -1 indicates no limit. |
| rolpassword | Text | N/A | Not the password (always reads as *****) |
| rolvalidbegin | Timestamp with time zone | N/A | Account validity start time; null if no start time |
| rolvaliduntil | Timestamp with time zone | N/A | Password expiry time; null if no expiration |
| rolrespool | Name | N/A | Resource pool that a user can use |
| rolparentid | OID | PG_AUTHID.rolparentid | OID of a group user to which the user belongs |
| roltabspace | Text | N/A | The storage space of the user permanent table. |
| roltemp space | Text | N/A | The storage space of the user temporary table. |
| rolspillspace | Text | N/A | The operator disk flushing space of the user. |
| rolconfig | Text[] | N/A | Session defaults for runtime configuration variables |
| OID | OID | PG_AUTHID.oid | ID of the role |
| roluseft | boolean | PG_AUTHID.roluseft | Whether the role can perform operations on foreign tables |
| nodegroup | Name | N/A | Name of the logical cluster associated with the role. If no logical cluster is associated, this column is left empty. |

18.3.129 PG_RULES

PG_RULES displays information about rewrite rules.

Table 18-200 PG_RULES columns

| Column | Type | Description |
|------------|------|--|
| schemaname | Name | Name of the schema that contains the table |
| tablename | Name | Name of the table the rule is for |
| rulename | Name | Rule name |
| definition | Text | Rule definition (a reconstructed creation command) |

18.3.130 PG_RUNNING_XACTS

PG_RUNNING_XACTS displays information about running transactions on the current node.

Table 18-201 PG_RUNNING_XACTS columns

| Column | Type | Description |
|-------------|---------|--|
| handle | Integer | Handle corresponding to the transaction in GTM |
| gxid | Xid | Transaction ID |
| state | tinyint | Transaction status (3 : prepared or 0 : starting) |
| node | Text | Node name |
| xmin | Xid | Minimum transaction ID xmin on the node |
| vacuum | boolean | Whether the current transaction is lazy vacuum |
| timeline | Bigint | Number of database restarts |
| prepare_xid | Xid | Transaction ID in the prepared status. If the status is not prepared , the value is 0 . |
| pid | Bigint | Thread ID corresponding to the transaction |
| next_xid | Xid | Transaction ID sent from a CN to a DN |

18.3.131 PG_SECLABELS

PG_SECLABELS displays information about security labels.

Table 18-202 PG_SECLABELS columns

| Column | Type | Reference | Description |
|--------------|---------|---------------------------------------|--|
| objoid | OID | Any OID column | OID of the object this security label pertains to |
| classoid | OID | PG_CLASS .oid | OID of the system table that contains the object |
| objsubid | Integer | N/A | For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is 0 . |
| objtype | Text | N/A | Type of the object to which this label applies |
| objnamespace | OID | PG_NAMESPACE .oid | OID of the namespace for this object, if applicable; otherwise NULL. |
| objname | Text | N/A | Name of the object to which the label applies |
| provider | Text | PG_SECLABEL .provider | Label provider associated with this label |
| label | Text | PG_SECLABEL .label | Security label applied to this object |

18.3.132 PG_SEQUENCES

PG_SEQUENCES displays the sequence attributes on which the current user has permissions. This view is supported only by clusters of version 9.1.0 or later.

Table 18-203 PG_SEQUENCES columns

| Column | Type | Description |
|---------------|--------|--|
| schemaname | Name | Name of the namespace. |
| sequencename | Name | Name of the sequence |
| sequenceowner | Name | Owner of the sequence |
| start_value | Bigint | Start value of the sequence. |
| min_value | Bigint | Minimum value generated by the sequence. |
| max_value | Bigint | Maximum value generated by the sequence. |

| Column | Type | Description |
|--------------|---------|---|
| increment_by | Bigint | Amount by which the generated value increases each time in a sequence. |
| cycle | Boolean | If set to true , the sequence value restarts from the minimum value after reaching the maximum value. If set to false , the sequence value stops generating after reaching the maximum value. |
| cache_size | Bigint | Size of the sequence cache value. |
| last_value | Bigint | Most recently generated value of the sequence. |

18.3.133 PG_SESSION_WLMSTAT

PG_SESSION_WLMSTAT displays the corresponding load management information about the task currently executed by the user.

Table 18-204 PG_SESSION_WLMSTAT columns

| Column | Type | Description |
|------------|---------|--|
| datid | OID | OID of the database this backend is connected to |
| datname | Name | Name of the database the backend is connected to |
| threadid | Bigint | ID of the backend thread |
| processid | Integer | Thread PID of the backend |
| usesysid | OID | OID of the user who logged in to the backend |
| appname | Text | Name of the application that is connected to the backend |
| username | Name | Name of the user logged in to the backend |
| priority | Bigint | Priority of Cgroup where the statement is located |
| attribute | Text | Statement attributes <ul style="list-style-type: none">● Ordinary: default attribute of a statement before it is parsed by the database● Simple: simple statements● Complicated: complicated statements● Internal: internal statement of the database |
| block_time | Bigint | Pending duration of the statements by now (unit: s) |

| Column | Type | Description |
|------------------|---------|---|
| elapsed_time | Bigint | Actual execution duration of the statements by now (unit: s) |
| total_cpu_time | Bigint | Total CPU usage duration of the statement on the DN in the last period (unit: s) |
| cpu_skew_percent | Integer | CPU usage inclination ratio of the statement on the DN in the last period |
| statement_mem | Integer | Estimated memory required for statement execution. This column is reserved. |
| active_points | Integer | Number of concurrently active points occupied by the statement in the resource pool |
| dop_value | Integer | DOP value obtained by the statement from the resource pool |
| control_group | Text | Cgroup currently used by the statement |
| status | Text | Status of a statement, including: <ul style="list-style-type: none">• pending• running• finished (If enqueue is set to StoredProc or Transaction, this state indicates that only some of the jobs in the statement have been executed. This state persists until the finish of this statement.)• aborted: terminated unexpectedly• active: normal status except for those above• unknown: unknown status |
| enqueue | Text | Current queuing status of the statements, including: <ul style="list-style-type: none">• Global: global queuing.• Respool: resource pool queuing.• CentralQueue: queuing on the CCN• Transaction: being in a transaction block• StoredProc: being in a stored procedure• None: not in a queue• Forced None: being forcibly executed (transaction block statement or stored procedure statement are) because the statement waiting time exceeds the specified value |
| resource_pool | Name | Current resource pool where the statements are located. |

| Column | Type | Description |
|------------|------|--|
| query | Text | Text of this backend's most recent query. If state is active , this column shows the executing query. In all other states, it shows the last query that was executed. |
| isplana | Bool | In logical cluster mode, indicates whether a statement occupies the resources of other logical clusters. The default value is f , indicating that resources of other logical clusters are not occupied. |
| node_group | Text | Logical cluster of the user running the statement |
| lane | Text | Fast or slow lane for statement queries. <ul style="list-style-type: none">• fast: fast lane• slow: slow lane• none: not controlled |

18.3.134 PG_SESSION_IOSTAT

PG_SESSION_IOSTAT has been discarded in version 8.1.2 and is reserved for compatibility with earlier versions. This view is invalid in the current version. You can use [PGXC_WLM_SESSION_STATISTICS](#) to view load management information about jobs being executed on all CNs.

Table 18-205 PG_SESSION_IOSTAT columns

| Column | Type | Description |
|-------------|---------|---|
| query_id | Bigint | Job ID |
| mincurriops | Integer | Minimum I/O of the current job across DN |
| maxcurriops | Integer | Maximum I/O of the current job across DN |
| minpeakops | Integer | Minimum peak I/O of the current job across DN |
| maxpeakops | Integer | Maximum peak I/O of the current job across DN |
| io_limits | Integer | io_limits set for the job |
| io_priority | Text | io_priority set for the job |
| query | Text | Job |
| node_group | Text | Logical cluster of the user running the job |

18.3.135 PG_SETTINGS

PG_SETTINGS displays information about parameters of the running database.

Table 18-206 PG_SETTINGS columns

| Column | Type | Description |
|------------|---------|---|
| Name | Text | Parameter name |
| setting | Text | Current value of the parameter |
| unit | Text | Implicit unit of the parameter |
| category | Text | Logical group of the parameter |
| short_desc | Text | Brief description of the parameter |
| extra_desc | Text | Detailed description of the parameter |
| context | Text | Context of parameter values including internal, postmaster, sighup, backend, superuser, and user |
| vartype | Text | Parameter type. It can be bool , enum , integer , real , or string . |
| source | Text | Method of assigning the parameter value |
| min_val | Text | Minimum value of the parameter. If the parameter type is not numeric data, the value of this column is null. |
| max_val | Text | Maximum value of the parameter. If the parameter type is not numeric data, the value of this column is null. |
| enumvals | Text[] | Valid values of an enum-typed parameter. If the parameter type is not enum, the value of this column is null. |
| boot_val | Text | Default parameter value used upon the database startup |
| reset_val | Text | Default parameter value used upon the database reset |
| sourcefile | Text | Configuration file used to set parameter values. If parameter values are not configured using the configuration file, the value of this column is null. |
| sourceline | Integer | Row number of the configuration file for setting parameter values. If parameter values are not configured using the configuration file, the value of this column is null. |

18.3.136 PG_SHADOW

PG_SHADOW displays properties of all roles that are marked as **rolcanlogin** in **PG_AUTHID**.

This view is not readable to all users because it contains passwords. **PG_USER** is a publicly readable view on **PG_SHADOW** that blanks out the password column.

Table 18-207 PG_SHADOW columns

| Column | Type | Reference | Description |
|-------------|--------------------------|------------------------------------|--|
| username | Name | PG_AUTHID .rolname | User name |
| usesysid | OID | PG_AUTHID .oid | ID of a user |
| usecreatedb | boolean | - | Indicates that the user can create databases. |
| usesuper | boolean | - | Indicates that the user is an administrator. |
| usecatupd | boolean | - | Indicates that the user can update system catalogs. Even the system administrator cannot do this unless this column is true . |
| userepl | boolean | - | User can initiate streaming replication and put the system in and out of backup mode. |
| passwd | Text | - | Password (possibly encrypted); null if none. See PG_AUTHID for details about how encrypted passwords are stored. |
| valbegin | Timestamp with time zone | - | Account validity start time; null if no start time |
| valuntil | Timestamp with time zone | - | Password expiry time; null if no expiration |
| respool | Name | - | Resource pool used by the user |
| parent | OID | - | Parent resource pool |
| spacelimit | Text | - | The storage space of the permanent table. |

| Column | Type | Reference | Description |
|-----------------|---------|-----------|--|
| tempspacelimit | Text | - | The storage space of the temporary table. |
| spillspacelimit | Text | - | The operator disk flushing space. |
| useconfig | text[] | - | Session defaults for runtime configuration variables |

18.3.137 PG_SHARED_MEMORY_DETAIL

PG_SHARED_MEMORY_DETAIL displays usage information about all the shared memory contexts.

Table 18-208 PG_SHARED_MEMORY_DETAIL columns

| Column | Type | Description |
|-------------|----------|--|
| contextname | Text | Name of the memory context. |
| level | Smallint | Hierarchy of the memory context. |
| parent | Text | Parent memory context. |
| totalsize | Bigint | Total size of the shared memory, in bytes. |
| freesize | Bigint | Remaining size of the shared memory, in bytes. |
| usedsize | Bigint | Used size of the shared memory, in bytes. |

18.3.138 PG_STATS

PG_STATS displays the single-column statistics stored in the **pg_statistic** table.

Table 18-209 PG_STATS columns

| Column | Type | Reference | Description |
|------------|------|---------------------------------------|--|
| schemaname | Name | PG_NAMESPACE .nspname | Name of the schema that contains the table |
| tablename | Name | PG_CLASS .relname | Name of the table |
| attname | Name | PG_ATTRIBUTE .attname | Column name |

| Column | Type | Reference | Description |
|----------------------|----------|-----------|--|
| inherited | boolean | - | Includes inherited sub-columns if the value is true ; otherwise, indicates the column in a specified table. |
| null_frac | Real | - | Percentage of column entries that are null |
| avg_width | Integer | - | Average width in bytes of column's entries |
| n_distinct | Real | - | <ul style="list-style-type: none">Estimated number of distinct values in the column if the value is greater than 0Negative of the number of distinct values divided by the number of rows if the value is less than 0 <p>The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows.</p> <p>The positive form is used when the column seems to have a fixed number of possible values. For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</p> |
| n_dndistinct | Real | - | <p>Number of unique non-null data values in the dn1 column</p> <ul style="list-style-type: none">Exact number of distinct values if the value is greater than 0Negative of the number of distinct values divided by the number of rows if the value is less than 0 (For example, if the value of a column appears twice in average, set n_dndistinct=-0.5.)The number of distinct values is unknown if the value is 0. |
| most_commo
n_vals | anyarray | - | List of the most common values in a column. If this combination does not have the most common values, it will be NULL . |

| Column | Type | Reference | Description |
|------------------------|----------|-----------|---|
| most_common_freqs | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals is NULL) |
| histogram_bounds | anyarray | - | List of values that divide the column's values into groups of equal proportion. The values in most_common_vals , if present, are omitted from this histogram calculation. This field is null if the field data type does not have a < operator or if the most_common_vals list accounts for the entire population. |
| correlation | Real | - | Statistical correlation between physical row ordering and logical ordering of the column values. It ranges from -1 to +1. When the value is near to -1 or +1, an index scan on the column is estimated to be cheaper than when it is near to zero, due to reduction of random access to the disk. This column is null if the column data type does not have a < operator. |
| most_common_elems | anyarray | - | Specifies a list of non-null element values most often appearing. |
| most_common_elem_freqs | real[] | - | Specifies a list of the frequencies of the most common element values. |
| elem_count_histogram | real[] | - | Histogram of the counts of distinct non-null element values. |
| partname | Name | - | Partition name. This column is available only in clusters of version 8.2.1.200 or later. |

18.3.139 PG_STAT_ACTIVITY

PG_STAT_ACTIVITY displays information about the current user's queries. If you have the rights of an administrator or the preset role, you can view all information about user queries.

Table 18-210 PG_STAT_ACTIVITY columns

| Column | Type | Description |
|------------------|--------------------------|---|
| datid | OID | OID of the database that the user session connects to in the backend |
| datname | Name | Name of the database that the user session connects to in the backend |
| pid | Bigint | Backend thread ID |
| lwtid | Integer | Lightweight thread ID |
| usesysid | OID | OID of the user logging in to the backend |
| username | Name | Username for logging in to the backend. |
| application_name | Text | Name of the application connected to the backend |
| client_addr | inet | IP address of the client connected to the backend. If this column is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| client_hostname | Text | Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will only be non-null for IP connections, and only when log_hostname is enabled. |
| client_port | Integer | TCP port number that the client uses for communication with this backend, or -1 if a Unix socket is used |
| backend_start | Timestamp with time zone | Startup time of the backend process, that is, the time when the client connects to the server. |
| xact_start | Timestamp with time zone | Time when the current transaction was started, or NULL if no transaction is active. If the current query is the first of its transaction, this column is equal to the query_start column. |
| query_start | Timestamp with time zone | Time when the currently active query was started, or if state is not active , when the last query was started |

| Column | Type | Description |
|--------------|--------------------------|---|
| state_change | Timestamp with time zone | Time for the last status change |
| waiting | boolean | The value is t if the backend is waiting for a lock or node. Otherwise, the value is f . |
| enqueue | Text | <p>Queuing status of a statement. Its value can be:</p> <ul style="list-style-type: none">• waiting in global queue: The statement is queuing in the global concurrent queue. The number of concurrent statements exceeds the value of max_active_statements configured for a single CN.• waiting in respool queue: The statement is queuing in the resource pool and the concurrency of simple jobs is limited. The main reason is that the concurrency of simple jobs exceeds the upper limit max_dop of the fast track.• waiting in ccn queue: The job is in the CCN queue, which may be global memory queuing, slow lane memory queuing, or concurrent queuing. The scenarios are:<ol style="list-style-type: none">1. The available global memory exceeds the upper limit, the job is queuing in the global memory queue.2. Concurrent requests on the slow lane in the resource pool exceed the upper limit, which is specified by active_statements.3. The slow lane memory of the resource pool exceeds the upper limit, that is, the estimated memory of concurrent jobs in the resource pool exceeds the upper limit specified by mem_percent.• Empty or no waiting queue: The statement is running. |

| Column | Type | Description |
|-----------------|--------|--|
| state | Text | <p>Current overall state of this backend. Its value can be:</p> <ul style="list-style-type: none">• active: The backend is executing queries.• idle: The backend is waiting for new client commands.• idle in transaction: The backend is in a transaction, but there is no statement being executed in the transaction.• idle in transaction (aborted): The backend is in a transaction, but there are statements failed in the transaction.• fastpath function call: The backend is executing a fast-path function.• disabled: This state is reported if track_activities is disabled in this backend. <p>NOTE
Common users can view only their own session status. The state information of other accounts is empty.</p> |
| resource_pool | Name | Resource pool used by the user |
| stmt_type | Text | Statement type |
| query_id | Bigint | ID of a query |
| query | Text | Text of the most recent query in this backend. If state is active , this column shows the running query. In all other states, it shows the last query that was executed. |
| connection_info | Text | A string in JSON format recording the driver type, driver version, driver deployment path, and process owner of the connected database (for details, see connection_info). |

18.3.140 PG_STAT_ALL_INDEXES

PG_STAT_ALL_INDEXES displays statistics about all accesses to a specific index in the current database.

Indexes can be used via either simple index scans or "bitmap" index scans. Bitmap scans can combine the output of multiple indexes using AND or OR rules, but

combining independent row fetching with specific indexes is challenging. Consequently, a bitmap scan increases the index count in **pg_stat_all_indexes.idx_tup_read** and the table count in **pg_stat_all_tables.idx_tup_fetch**, while having no effect on **pg_stat_all_indexes.idx_tup_fetch**.

Table 18-211 PG_STAT_ALL_INDEXES columns

| Column | Type | Description |
|---------------|--------|---|
| relid | OID | OID of the table for this index. |
| indexrelid | OID | OID of this index. |
| schemaname | Name | Name of the schema this index is in. |
| relname | Name | Name of the table for this index. |
| indexrelname | Name | Name of this index. |
| idx_scan | Bigint | Number of index scans initiated on this index. |
| idx_tup_read | Bigint | Number of index entries returned by scans on this index. |
| idx_tup_fetch | Bigint | Number of live table rows fetched by simple index scans using this index. |

18.3.141 PG_STAT_ALL_TABLES

PG_STAT_ALL_TABLES displays statistics about accesses to tables in the current database, including TOAST tables.

Table 18-212 PG_STAT_ALL_TABLES columns

| Column | Type | Description |
|---------------|--------|--|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of the table |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of rows that have live data fetched by sequential scans |
| idx_scan | Bigint | Number of index scans |
| idx_tup_fetch | Bigint | Number of rows that have live data fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |

| Column | Type | Description |
|-------------------|--------------------------|--|
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd | Bigint | Number of rows updated by HOT (no separate index update is required) |
| n_live_tup | Bigint | Estimated number of live rows |
| n_dead_tup | Bigint | Estimated number of dead rows |
| last_vacuum | Timestamp with time zone | Last time at which this table was manually vacuumed (excluding VACUUM FULL) |
| last_autovacuum | Timestamp with time zone | Last time at which this table was automatically vacuumed |
| last_analyze | Timestamp with time zone | Time when the last non-automatic rolling analysis is performed. |
| last_autoanalyze | Timestamp with time zone | Time when the last automatic rolling analysis is performed. |
| vacuum_count | Bigint | Number of vacuum operations (excluding VACUUM FULL) |
| autovacuum_count | Bigint | Number of autovacuum operations |
| analyze_count | Bigint | Number of ANALYZE operations |
| autoanalyze_count | Bigint | Number of autoanalyze operations |
| last_data_changed | Timestamp with time zone | Last time at which this table was updated (by INSERT/UPDATE/DELETE or EXCHANGE/TRUNCATE/DROP <i>partition</i>). This column is recorded only on the local CN. |

Example

Query the last data change time in the **table_test** table:

```
SELECT last_data_changed FROM PG_STAT_ALL_TABLES WHERE relname ='table_test';
      last_data_changed
-----
2024-03-27 10:28:16.277136+08
(1 row)
```

18.3.142 PG_STAT_BAD_BLOCK

PG_STAT_BAD_BLOCK displays statistics about page or CU verification failures after a node is started.

Table 18-213 PG_STAT_BAD_BLOCK columns

| Column | Type | Description |
|--------------|--------------------------|----------------------------------|
| nodename | Text | Node name. |
| databaseid | Integer | Database OID. |
| tablespaceid | Integer | Tablespace OID. |
| relfilenode | Integer | File object ID. |
| forknum | Integer | File type. |
| error_count | Integer | Number of verification failures. |
| first_time | Timestamp with time zone | Time of the first occurrence. |
| last_time | Timestamp with time zone | Time of the latest occurrence. |

18.3.143 PG_STAT_BGWRITER

PG_STAT_BGWRITER displays statistics about the background writer process's activity.

Table 18-214 PG_STAT_BGWRITER columns

| Column | Type | Description |
|-----------------------|------------------|---|
| checkpoints_timed | Bigint | Number of scheduled checkpoints that have been performed. |
| checkpoints_req | Bigint | Number of requested checkpoints that have been performed. |
| checkpoint_write_time | Double precision | Time spent on writing files to the disk during checkpoints, in milliseconds. |
| checkpoint_sync_time | Double precision | Time spent on synchronizing data to the disk during checkpoints, in milliseconds. |
| buffers_checkpoint | Bigint | Number of buffers written during checkpoints. |

| Column | Type | Description |
|-----------------------|--------------------------|--|
| buffers_clean | Bigint | Number of buffers written by the background writer. |
| maxwritten_clean | Bigint | Number of times the background writer stopped a cleaning scan because too many buffers were written. |
| buffers_backend | Bigint | Number of buffers written directly by a backend |
| buffers_backend_fsync | Bigint | Number of times that the backend has to execute fsync . |
| buffers_alloc | Bigint | Number of buffers allocated. |
| stats_reset | Timestamp with time zone | Time at which these statistics were reset. |

18.3.144 PG_STAT_DATABASE

PG_STAT_DATABASE displays the status and statistics of each database on the current node.

Table 18-215 PG_STAT_DATABASE columns

| Column | Type | Description |
|---------------|---------|---|
| datid | OID | Database OID |
| datname | Name | Database name |
| numbackends | Integer | Number of backends currently connected to this database on the current node. This is the only column in this view that reflects the current state value. All columns return the accumulated value since the last reset. |
| xact_commit | Bigint | Number of transactions in this database that have been committed on the current node |
| xact_rollback | Bigint | Number of transactions in this database that have been rolled back on the current node |
| blks_read | Bigint | Number of disk blocks read in this database on the current node |
| blks_hit | Bigint | Number of disk blocks found in the buffer cache on the current node, that is, the number of blocks hit in the cache. (This only includes hits in the DWS buffer cache, not in the file system cache.) |

| Column | Type | Description |
|----------------|--------------------------|---|
| tup_returned | Bigint | Number of rows returned by queries in this database on the current node |
| tup_fetched | Bigint | Number of rows fetched by queries in this database on the current node |
| tup_inserted | Bigint | Number of rows inserted in this database on the current node |
| tup_updated | Bigint | Number of rows updated in this database on the current node |
| tup_deleted | Bigint | Number of rows deleted from this database on the current node |
| conflicts | Bigint | Number of queries canceled due to database recovery conflicts on the current node (conflicts occurring only on the standby server). For details, see PG_STAT_DATABASE_CONFLICTS . |
| temp_files | Bigint | Number of temporary files created by this database on the current node. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the log_temp_files setting. |
| temp_bytes | Bigint | Size of temporary files written to this database on the current node. All temporary files are counted, regardless of why the temporary file was created, and regardless of the log_temp_files setting. |
| deadlocks | Bigint | Number of deadlocks in this database on the current node |
| blk_read_time | Double precision | Time spent reading data file blocks by backends in this database on the current node, in milliseconds |
| blk_write_time | Double precision | Time spent writing into data file blocks by backends in this database on the current node, in milliseconds |
| stats_reset | Timestamp with time zone | Time when the database statistics are reset on the current node |

18.3.145 PG_STAT_DATABASE_CONFLICTS

PG_STAT_DATABASE_CONFLICTS displays statistics about database conflicts.

Table 18-216 PG_STAT_DATABASE_CONFLICTS columns

| Column | Type | Description |
|------------------|--------|------------------------------------|
| datid | OID | Database OID. |
| datname | Name | Database name. |
| confl_tablespace | Bigint | Number of conflicting tablespaces. |
| confl_lock | Bigint | Number of conflicting locks. |
| confl_snapshot | Bigint | Number of conflicting snapshots. |
| confl_bufferpin | Bigint | Number of conflicting buffers. |
| confl_deadlock | Bigint | Number of conflicting deadlocks. |

18.3.146 PG_STATS_EXT_EXPRS

PG_STATS_EXT_EXPRS provides statistics about expressions stored in the **PG_STATISTIC_DATA** table. This view is supported only by clusters of version 8.2.1.200 or later.

Table 18-217 PG_STATS_EXT_EXPRS columns

| Column | Type | Reference | Description |
|---------------------------|---------|--|---|
| schemaname | Name | PG_NAMESP
ACE .nspname | Name of the schema that contains the table |
| tablename | Name | PG_CLASS .rel
name | Table name |
| statistics_sche
maname | Name | - | Name of the schema where expression objects whose statistics are collected is located |
| statistics_name | Name | - | Name of the expression object whose statistics are collected |
| statistics_owner | Name | - | Owner of the expression object whose statistics are collected |
| expr | Text | - | Expression |
| inherited | boolean | - | If the value is true , the inherited subcolumns are included. If the value is false , only the columns in a specified table are included. |

| Column | Type | Reference | Description |
|-----------------------|----------|-----------|---|
| null_frac | Real | - | Percentage of column entries that are null |
| avg_width | Integer | - | Average width in bytes of column's entries |
| n_distinct | Real | - | <ul style="list-style-type: none">• If the value is greater than 0, it indicates the estimated number of distinct values in the column.• If the value is less than 0, it indicates that the number of distinct values divided by the number of rows. <p>The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows.</p> <p>The positive form is used when the column seems to have a fixed number of possible values. For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</p> |
| n_dndistinct | Real | - | <p>Number of unique non-null data values in the dn1 column</p> <ul style="list-style-type: none">• Exact number of distinct values if the value is greater than 0• Negative of the number of distinct values divided by the number of rows if the value is less than 0 (For example, if the value of a column appears twice in average, set n_dndistinct=-0.5.)• The number of distinct values is unknown if the value is 0. |
| most_commo
n_vals | anyarray | - | List of the most common values in a column. If this combination does not have the most common values, it will be NULL . |
| most_commo
n_freqs | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals is NULL) |

| Column | Type | Reference | Description |
|------------------------|----------|-----------|---|
| histogram_bounds | anyarray | - | List of values that divide the column's values into groups of equal proportion. The values in most_common_vals , if present, are omitted from this histogram calculation. This field is null if the field data type does not have a < operator or if the most_common_vals list accounts for the entire population. |
| correlation | Real | - | Statistical correlation between physical row ordering and logical ordering of the column values. It ranges from -1 to +1. When the value is near to -1 or +1, an index scan on the column is estimated to be cheaper than when it is near to zero, due to reduction of random access to the disk. This column is null if the column data type does not have a < operator. |
| most_common_elems | anyarray | - | Specifies a list of non-null element values most often appearing. |
| most_common_elem_freqs | real[] | - | Specifies a list of the frequencies of the most common element values. |
| elem_count_histogram | real[] | - | Specifies a histogram of the counts of distinct non-null element values. |

18.3.147 PG_STAT_GET_MEM_MBYTES_RESERVED

PG_STAT_GET_MEM_MBYTES_RESERVED displays the current activity information of a thread stored in memory. You need to specify the thread ID (pid in [PG_STAT_ACTIVITY](#)) for query. If the thread ID is set to 0, the current thread ID is used. For example:

```
SELECT pg_stat_get_mem_mbytes_reserved(0);
```

Table 18-218 PG_STAT_GET_MEM_MBYTES_RESERVED columns

| Column | Description |
|---------------|-------------------------------------|
| ConnectInfo | Connection information. |
| ParctlManager | Concurrency management information. |

| Column | Description |
|----------------------|-----------------------------------|
| GeneralParams | Basic parameter information. |
| GeneralParams RPDATA | Basic resource pool information. |
| ExceptionManager | Exception management information. |
| CollectInfo | Collection information. |
| GeneralInfo | Basic information. |
| ParctlState | Concurrency status information. |
| CPU INFO | CPU information. |
| ControlGroup | Cgroup information. |
| IOWSTATE | I/O status information. |

18.3.148 PG_STAT_USER_FUNCTIONS

PG_STAT_USER_FUNCTIONS displays user-defined function status information in the namespace. (The language of the function is non-internal language.)

Table 18-219 PG_STAT_USER_FUNCTIONS columns

| Column | Type | Description |
|------------|------------------|--|
| funcid | OID | Function OID |
| schemaname | Name | Schema name |
| funcname | Name | Name of the function |
| calls | Bigint | Number of times this function has been called |
| total_time | Double precision | Total time spent in this function and all other functions called by it |
| self_time | Double precision | Total time spent in this function itself, excluding other functions called by it |

18.3.149 PG_STAT_USER_INDEXES

PG_STAT_USER_INDEXES displays information about the index status of user-defined ordinary tables and TOAST tables.

Table 18-220 PG_STAT_USER_INDEXES columns

| Column | Type | Description |
|---------------|--------|---|
| relid | OID | Table OID for the index |
| indexrelid | OID | OID of this index |
| schemaname | Name | Name of the schema this index is in |
| relname | Name | Name of the table for this index |
| indexrelname | Name | Name of this index |
| idx_scan | Bigint | Number of index scans |
| idx_tup_read | Bigint | Number of index entries returned by scans on this index |
| idx_tup_fetch | Bigint | Number of rows that have live data fetched by index scans |

18.3.150 PG_STAT_USER_TABLES

PG_STAT_USER_TABLES displays status information about user-defined ordinary tables and TOAST tables in all namespaces.

Table 18-221 PG_STAT_USER_TABLES columns

| Column | Type | Description |
|---------------|--------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of rows that have live data fetched by sequential scans |
| idx_scan | Bigint | Number of index scans |
| idx_tup_fetch | Bigint | Number of rows that have live data fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd | Bigint | Number of rows updated by HOT (no separate index update is required) |

| Column | Type | Description |
|-------------------|--------------------------|---|
| n_live_tup | Bigint | Estimated number of live rows |
| n_dead_tup | Bigint | Estimated number of dead rows |
| last_vacuum | Timestamp with time zone | Last time at which this table was manually vacuumed (excluding VACUUM FULL) |
| last_autovacuum | Timestamp with time zone | Time of the last AUTOVACUUM |
| last_analyze | Timestamp with time zone | Time when the last non-automatic rolling analysis is performed. |
| last_autoanalyze | Timestamp with time zone | Time when the last automatic rolling analysis is performed. |
| vacuum_count | Bigint | Number of vacuum operations (excluding VACUUM FULL) |
| autovacuum_count | Bigint | Number of autovacuum operations |
| analyze_count | Bigint | Number of analyze operations |
| autoanalyze_count | Bigint | Number of autoanalyze operations |

18.3.151 PG_STAT_REPLICATION

PG_STAT_REPLICATION displays information about log synchronization status, such as the locations of the sender sending logs and the receiver receiving logs.

Table 18-222 PG_STAT_REPLICATION columns

| Column | Type | Description |
|------------------|--------|--------------------|
| pid | Bigint | PID of the thread. |
| usesysid | OID | User system ID. |
| username | Name | Username. |
| application_name | Text | Program name. |
| client_addr | inet | Client address. |
| client_hostname | Text | Client name. |

| Column | Type | Description |
|--------------------------|--------------------------|--|
| client_port | Integer | Client port number. |
| backend_start | Timestamp with time zone | Program start time. |
| state | Text | Log replication state (catch-up or consistent streaming). |
| sender_sent_location | Text | Location where the sender sends logs. |
| receiver_write_location | Text | Location where the receiver writes logs. |
| receiver_flush_location | Text | Location where the receiver flushes logs. |
| receiver_replay_location | Text | Location where the receiver replays logs. |
| sync_priority | Integer | Priority of synchronous duplication (0 indicates asynchronization). |
| sync_state | Text | Synchronization state (asynchronous duplication, synchronous duplication, or potential synchronization). |

18.3.152 PG_STAT_SYS_INDEXES

PG_STAT_SYS_INDEXES displays the index status information about all the system catalogs in the **pg_catalog** and **information_schema** schemas.

Table 18-223 PG_STAT_SYS_INDEXES columns

| Column | Type | Description |
|--------------|--------|--|
| relid | OID | Table OID for the index. |
| indexrelid | OID | OID of this index. |
| schemaname | Name | Name of the schema this index is in. |
| relname | Name | Name of the table for this index. |
| indexrelname | Name | Name of this index. |
| idx_scan | Bigint | Number of index scans. |
| idx_tup_read | Bigint | Number of index entries returned by scans on this index. |

| Column | Type | Description |
|---------------|--------|--|
| idx_tup_fetch | Bigint | Number of rows that have live data fetched by index scans. |

18.3.153 PG_STAT_SYS_TABLES

PG_STAT_SYS_TABLES displays the statistics about the system catalogs of all the namespaces in **pg_catalog** and **information_schema** schemas.

Table 18-224 PG_STAT_SYS_TABLES columns

| Column | Type | Description |
|-----------------|--------------------------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of rows that have live data fetched by sequential scans |
| idx_scan | Bigint | Number of index scans |
| idx_tup_fetch | Bigint | Number of rows that have live data fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd | Bigint | Number of rows updated by HOT (no separate index update is required) |
| n_live_tup | Bigint | Estimated number of live rows |
| n_dead_tup | Bigint | Estimated number of dead rows |
| last_vacuum | Timestamp with time zone | Last time at which this table was manually vacuumed (excluding VACUUM FULL) |
| last_autovacuum | Timestamp with time zone | Last time at which this table was automatically vacuumed |
| last_analyze | Timestamp with time zone | Last time at which this table was analyzed |

| Column | Type | Description |
|-------------------|--------------------------|---|
| last_autoanalyze | Timestamp with time zone | Last time at which this table was automatically analyzed |
| vacuum_count | Bigint | Number of vacuum operations (excluding VACUUM FULL) |
| autovacuum_count | Bigint | Number of autovacuum operations |
| analyze_count | Bigint | Number of analyze operations |
| autoanalyze_count | Bigint | Number of autoanalyze operations |

18.3.154 PG_STAT_XACT_ALL_TABLES

PG_STAT_XACT_ALL_TABLES displays the transaction status information about all ordinary tables and TOAST tables in the namespaces.

Table 18-225 PG_STAT_XACT_ALL_TABLES columns

| Column | Type | Description |
|---------------|--------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of live rows fetched by sequential scans |
| idx_scan | Bigint | Number of index scans started on the table |
| idx_tup_fetch | Bigint | Number of live rows fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd | Bigint | Number of rows with HOT updates (no separate index update is required). |

18.3.155 PG_STAT_XACT_SYS_TABLES

PG_STAT_XACT_SYS_TABLES displays the transaction status information of the system catalog in the namespace.

Table 18-226 PG_STAT_XACT_SYS_TABLES columns

| Column | Type | Description |
|--------------------|--------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Table name |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of live rows fetched by sequential scans |
| idx_scan | Bigint | Number of index scans started on the table |
| idx_tup_fetch | Bigint | Number of live rows fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd
d | Bigint | Number of rows with HOT updates (no separate index update is required). |

18.3.156 PG_STAT_XACT_USER_FUNCTIONS

PG_STAT_XACT_USER_FUNCTIONS displays statistics about function execution.

Table 18-227 PG_STAT_XACT_USER_FUNCTIONS columns

| Column | Type | Description |
|------------|------------------|--|
| funcid | OID | Function OID |
| schemaname | Name | Schema name |
| funcname | Name | Name of the function |
| calls | Bigint | Number of times this function has been called |
| total_time | Double precision | Total time spent in this function and all other functions called by it |
| self_time | Double precision | Total time spent in this function itself, excluding other functions called by it |

18.3.157 PG_STAT_XACT_USER_TABLES

PG_STAT_XACT_USER_TABLES displays the transaction status information of the user table in the namespace.

Table 18-228 PG_STAT_XACT_USER_TABLES columns

| Column | Type | Description |
|--------------------|--------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| seq_scan | Bigint | Number of sequential scans started on the table |
| seq_tup_read | Bigint | Number of live rows fetched by sequential scans |
| idx_scan | Bigint | Number of index scans started on the table |
| idx_tup_fetch | Bigint | Number of live rows fetched by index scans |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd
d | Bigint | Number of rows with HOT updates (no separate index update is required). |

18.3.158 PG_STATIO_ALL_INDEXES

PG_STATIO_ALL_INDEXES displays I/O statistics of all indexes in the current database.

Table 18-229 PG_STATIO_ALL_INDEXES columns

| Column | Type | Description |
|---------------|--------|---|
| relid | OID | OID of the index table |
| indexrelid | OID | OID of this index |
| schemaname | Name | Name of the schema this index is in |
| relname | Name | Name of the table for this index |
| indexrelname | Name | Name of this index |
| idx_blks_read | Bigint | Number of disk blocks read from the index |
| idx_blks_hit | Bigint | Number of buffer hits in this index |

18.3.159 PG_STATIO_ALL_SEQUENCES

PG_STATIO_ALL_SEQUENCES displays the sequence information in the current database and the I/O statistics of a specified sequence.

Table 18-230 PG_STATIO_ALL_SEQUENCES columns

| Column | Type | Description |
|------------|--------|--|
| relid | OID | OID of this sequence |
| schemaname | Name | Name of the schema this sequence is in |
| relname | Name | Name of this sequence |
| blks_read | Bigint | Number of disk blocks read from the sequence |
| blks_hit | Bigint | Number of buffer hits in this sequence |

18.3.160 PG_STATIO_ALL_TABLES

PG_STATIO_ALL_TABLES displays I/O statistics about all tables (including TOAST tables) in the current database.

Table 18-231 PG_STATIO_ALL_TABLES columns

| Column | Type | Description |
|-----------------|--------|--|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| heap_blks_read | Bigint | Number of disks read from this table |
| heap_blks_hit | Bigint | Number of buffer hits in this table |
| idx_blks_read | Bigint | Number of disk blocks read from the index in this table |
| idx_blks_hit | Bigint | Number of buffer hits in all indexes on this table |
| toast_blks_read | Bigint | Number of disk blocks read from the TOAST table (if any) in this table |
| toast_blks_hit | Bigint | Number of buffer hits in the TOAST table (if any) in this table |

| Column | Type | Description |
|----------------|--------|--|
| tidx_blks_read | Bigint | Number of disk blocks read from the TOAST table index (if any) in this table |
| tidx_blks_hit | Bigint | Number of buffer hits in the TOAST table index (if any) in this table |

18.3.161 PG_STATIO_SYS_INDEXES

PG_STATIO_SYS_INDEXES displays the I/O status information about all system catalog indexes in the namespace.

Table 18-232 PG_STATIO_SYS_INDEXES columns

| Column | Type | Description |
|---------------|--------|--|
| relid | OID | Table OID for the index. |
| indexrelid | OID | OID of this index. |
| schemaname | Name | Name of the schema of the index. |
| relname | Name | Name of the table for this index. |
| indexrelname | Name | Name of this index. |
| idx_blks_read | Bigint | Number of disk blocks read from the index. |
| idx_blks_hit | Bigint | Number of buffer hits in this index. |

18.3.162 PG_STATIO_SYS_SEQUENCES

PG_STATIO_SYS_SEQUENCES displays the I/O status information about all the system sequences in the namespace.

Table 18-233 PG_STATIO_SYS_SEQUENCES columns

| Column | Type | Description |
|------------|--------|--|
| relid | OID | OID of this sequence |
| schemaname | Name | Name of the schema this sequence is in |
| relname | Name | Name of this sequence |
| blks_read | Bigint | Number of disk blocks read from the sequence |
| blks_hit | Bigint | Number of buffer hits in this sequence |

18.3.163 PG_STATIO_SYS_TABLES

PG_STATIO_SYS_TABLES displays the I/O status information about all the system catalogs in the namespace.

Table 18-234 PG_STATIO_SYS_TABLES columns

| Column | Type | Description |
|-----------------|--------|--|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| heap_blks_read | Bigint | Number of disk blocks read from this table |
| heap_blks_hit | Bigint | Number of buffer hits in this table |
| idx_blks_read | Bigint | Number of disk blocks read from the index in this table |
| idx_blks_hit | Bigint | Number of buffer hits in all indexes on this table |
| toast_blks_read | Bigint | Number of disk blocks read from the TOAST table (if any) in this table |
| toast_blks_hit | Bigint | Number of buffer hits in the TOAST table (if any) in this table |
| tidx_blks_read | Bigint | Number of disk blocks read from the TOAST table index (if any) in this table |
| tidx_blks_hit | Bigint | Number of buffer hits in the TOAST table index (if any) in this table |

18.3.164 PG_STATIO_USER_INDEXES

PG_STATIO_USER_INDEXES displays the I/O status information about all the user relationship table indexes in the namespace.

Table 18-235 PG_STATIO_USER_INDEXES columns

| Column | Type | Description |
|------------|------|-------------------------------------|
| relid | OID | OID of the table for this index |
| indexrelid | OID | OID of this index |
| schemaname | Name | Name of the schema this index is in |
| relname | Name | Name of the table for this index |

| Column | Type | Description |
|---------------|--------|---|
| indexrelname | Name | Name of this index |
| idx_blks_read | Bigint | Number of disk blocks read from the index |
| idx_blks_hit | Bigint | Number of buffer hits in this index |

18.3.165 PG_STATIO_USER_SEQUENCES

PG_STATIO_USER_SEQUENCES displays the I/O status information about all the user relation table sequences in the namespace.

Table 18-236 PG_STATIO_USER_SEQUENCES columns

| Column | Type | Description |
|------------|--------|--|
| relid | OID | OID of this sequence |
| schemaname | Name | Name of the schema this sequence is in |
| relname | Name | Name of this sequence |
| blks_read | Bigint | Number of disk blocks read from the sequence |
| blks_hit | Bigint | Cache hits in the sequence |

18.3.166 PG_STATIO_USER_TABLES

PG_STATIO_USER_TABLES displays the I/O status information about all the user relation tables in the namespace.

Table 18-237 PG_STATIO_USER_TABLES columns

| Column | Type | Description |
|----------------|--------|---|
| relid | OID | Table OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Name of a table |
| heap_blks_read | Bigint | Number of disk blocks read from this table |
| heap_blks_hit | Bigint | Number of buffer hits in this table |
| idx_blks_read | Bigint | Number of disk blocks read from the index in this table |

| Column | Type | Description |
|-----------------|--------|--|
| idx_blks_hit | Bigint | Number of buffer hits in all indexes on this table |
| toast_blks_read | Bigint | Number of disk blocks read from the TOAST table (if any) in this table |
| toast_blks_hit | Bigint | Number of buffer hits in the TOAST table (if any) in this table |
| tidx_blks_read | Bigint | Number of disk blocks read from the TOAST table index (if any) in this table |
| tidx_blks_hit | Bigint | Number of buffer hits in the TOAST table index (if any) in this table |

18.3.167 PG_THREAD_WAIT_STATUS

PG_THREAD_WAIT_STATUS allows you to test the block waiting status about the backend thread and auxiliary thread of the current instance.

Table 18-238 PG_THREAD_WAIT_STATUS columns

| Column | Type | Description |
|-------------|---------|---|
| node_name | Text | Current node name |
| db_name | Text | Database name |
| thread_name | Text | Thread name |
| query_id | Bigint | Query ID. It is equivalent to debug_query_id . |
| tid | Bigint | Thread ID of the current thread |
| lwtid | Integer | Lightweight thread ID of the current thread |
| ptid | Integer | Parent thread of the streaming thread |
| tlevel | Integer | Level of the streaming thread |
| smpid | Integer | Concurrent thread ID |
| wait_status | Text | Waiting status of the current thread. For details about the waiting status, see Table 18-239 . |
| wait_event | Text | If wait_status is acquire lock , acquire lwlock , or wait io , this column describes the lock, lightweight lock, and I/O information, respectively. If wait_status is not any of the three values, this column is empty. |

The waiting statuses in the **wait_status** column are as follows:

Table 18-239 Waiting status list

| Value | Description |
|---|---|
| none | Waiting for no event |
| acquire lock | Waiting for locking until the locking succeeds or times out |
| acquire lwlock | Waiting for a lightweight lock |
| wait io | Waiting for I/O completion |
| wait cmd | Waiting for network communication packet read to complete |
| wait pooler get conn | Waiting for pooler to obtain the connection |
| wait pooler abort conn | Waiting for pooler to terminate the connection |
| wait pooler clean conn | Waiting for pooler to clear connections |
| pooler create conn: [nodename], total N | Waiting for the pooler to set up a connection. The connection is being established with the node specified by <i>nodename</i> , and there are <i>N</i> connections waiting to be set up. |
| get conn | Obtaining the connection to other nodes |
| set cmd: [nodename] | Waiting for running the SET , RESET , TRANSACTION BLOCK LEVEL PARA SET , or SESSION LEVEL PARA SET statement on the connection. The statement is being executed on the node specified by <i>nodename</i> . |
| cancel query | Canceling the SQL statement that is being executed through the connection |
| stop query | Stopping the query that is being executed through the connection |
| wait node: [nodename](plevel), total N, [phase] | <p>Waiting for receiving the data from a connected node. The thread is waiting for the data from the plevel thread of the node specified by <i>nodename</i>. The data of <i>N</i> connections is waiting to be returned. If <i>phase</i> is included, the possible phases are as follows:</p> <ul style="list-style-type: none">• begin: The transaction is being started.• commit: The transaction is being committed.• rollback: The transaction is being rolled back. |

| Value | Description |
|---|--|
| wait transaction sync: xid | Waiting for synchronizing the transaction specified by <i>xid</i> |
| wait wal sync | Waiting for the completion of wal log of synchronization from the specified LSN to the standby instance |
| wait data sync | Waiting for the completion of data page synchronization to the standby instance |
| wait data sync queue | Waiting for putting the data pages that are in the row storage or the CU in the column storage into the synchronization queue |
| flush data: [nodename](plevel), [phase] | Waiting for sending data to the plevel thread of the node specified by <i>nodename</i> . If <i>phase</i> is included, the possible phase is wait quota , indicating that the current communication flow is waiting for the quota value. |
| stream get conn: [nodename], total N | Waiting for connecting to the consumer object of the node specified by <i>nodename</i> when the stream flow is initialized. There are <i>N</i> consumers waiting to be connected. |
| wait producer ready: [nodename] (plevel), total N | Waiting for each producer to be ready when the stream flow is initialized. The thread is waiting for the procedure of the plevel thread on the <i>nodename</i> node to be ready. There are <i>N</i> producers waiting to be ready. |
| synchronize quit | Waiting for the threads in the stream thread group to quit when the stream plan ends |
| nodegroup destroy | Waiting for destroying the stream node group when the stream plan ends |
| wait active statement | Waiting for job execution under resource and load control. |
| wait global queue | Waiting for job execution. The job is queuing in the global queue. |
| wait respool queue | Waiting for job execution. The job is queuing in the resource pool. |
| wait ccn queue | Waiting for job execution. The job is queuing on the central coordinator node (CCN). |
| gtm connect | Waiting for connecting to GTM. |
| gtm get gxid | Wait for obtaining xids from GTM. |

| Value | Description |
|--|---|
| gtm get snapshot | Wait for obtaining transaction snapshots from GTM. |
| gtm begin trans | Waiting for GTM to start a transaction. |
| gtm commit trans | Waiting for GTM to commit a transaction. |
| gtm rollback trans | Waiting for GTM to roll back a transaction. |
| gtm create sequence | Waiting for GTM to create a sequence. |
| gtm alter sequence | Waiting for GTM to modify a sequence. |
| gtm get sequence val | Waiting for obtaining the next value of a sequence from GTM. |
| gtm set sequence val | Waiting for GTM to set a sequence value. |
| gtm drop sequence | Waiting for GTM to delete a sequence. |
| gtm rename sequence | Waiting for GTM to rename a sequence. |
| analyze: [relname], [phase] | The thread is doing ANALYZE to the <i>relname</i> table. If <i>phase</i> is included, the possible phase is autovacuum , indicating that the database automatically enables the AutoVacuum thread to execute ANALYZE . |
| vacuum: [relname], [phase] | The thread is doing VACUUM to the <i>relname</i> table. If <i>phase</i> is included, the possible phase is autovacuum , indicating that the database automatically enables the AutoVacuum thread to execute VACUUM . |
| vacuum full: [relname] | The thread is doing VACUUM FULL to the <i>relname</i> table. |
| create index | An index is being created. |
| HashJoin - [build hash write file] | The HashJoin operator is being executed. In this phase, you need to pay attention to the execution time-consuming. <ul style="list-style-type: none">• build hash: The HashJoin operator is creating a hash table.• write file: The HashJoin operator is writing data to disks. |
| HashAgg - [build hash write file] | The HashAgg operator is being executed. In this phase, you need to pay attention to the execution time-consuming. <ul style="list-style-type: none">• build hash: The HashAgg operator is creating a hash table.• write file: The HashAgg operator is writing data to disks. |

| Value | Description |
|--|--|
| HashSetop - [build hash write file] | The HashSetop operator is being executed. In this phase, you need to pay attention to the execution time-consuming. <ul style="list-style-type: none">• build hash: The HashSetop operator is creating a hash table.• write file: The HashSetop operator is writing data to disks. |
| Sort Sort - write file | The Sort operator is being executed. write file indicates that the Sort operator is writing data to disks. |
| Material Material - write file | The Material operator is being executed. write file indicates that the Material operator is writing data to disks. |
| wait sync consumer next step | The consumer (receive end) synchronously waits for the next iteration. |
| wait sync producer next step | The producer (transmit end) synchronously waits for the next iteration. |
| wait agent release | The current agent is being released (supported by 8.1.2 and later versions). |
| wait stream task | The stream thread is waiting for being reused (supported by 8.1.2 and later versions). |

If **wait_status** is **acquire lwlock**, **acquire lock**, or **wait io**, there is an event performing I/O operations or waiting for obtaining the corresponding lightweight lock or transaction lock.

The following table describes the corresponding wait events when **wait_status** is **acquire lwlock**. (If **wait_event** is **extension**, the lightweight lock is dynamically allocated and is not monitored.)

Table 18-240 List of wait events corresponding to lightweight locks

| wait_event | Description |
|----------------|---|
| ShmemIndexLock | Used to protect the primary index table, a hash table, in shared memory |
| OidGenLock | Used to prevent different threads from generating the same OID |
| XidGenLock | Used to prevent two transactions from obtaining the same XID |

| wait_event | Description |
|-----------------------------|---|
| ProcArrayLock | Used to prevent concurrent access to or concurrent modification on the ProcArray shared array |
| SInvalReadLock | Used to prevent concurrent execution with invalid message deletion |
| SInvalWriteLock | Used to prevent concurrent execution with invalid message write and deletion |
| WALInsertLock | Used to prevent concurrent execution with WAL insertion |
| WALWriteLock | Used to prevent concurrent write from a WAL buffer to a disk |
| ControlFileLock | Used to prevent concurrent read/write or concurrent write/write on the pg_control file |
| CheckpointLock | Used to prevent multi-checkpoint concurrent execution |
| CLogControlLock | Used to prevent concurrent access to or concurrent modification on the Clog control data structure |
| MultiXactGenLock | Used to allocate a unique MultiXact ID in serial mode |
| MultiXactOffsetControl-Lock | Used to prevent concurrent read/write or concurrent write/write on pg_multixact/offset |
| MultiXactMemberControl-Lock | Used to prevent concurrent read/write or concurrent write/write on pg_multixact/members |
| RelCacheInitLock | Used to add a lock before any operations are performed on the init file when messages are invalid |
| CheckpointInterCommLock | Used to send file flush requests to a checkpoint. The request structure needs to be inserted to a request queue in serial mode. |
| TwoPhaseStateLock | Used to prevent concurrent access to or modification on two-phase information sharing arrays |
| TablespaceCreateLock | Used to check whether a tablespace already exists |
| BtreeVacuumLock | Used to prevent VACUUM from clearing pages that are being used by B-tree indexes |
| AutovacuumLock | Used to access the autovacuum worker array in serial mode |
| AutovacuumScheduleLock | Used to distribute tables requiring VACUUM in serial mode |

| wait_event | Description |
|------------------------------------|---|
| SyncScanLock | Used to determine the start position of a relfilenode during heap scanning |
| NodeTableLock | Used to protect a shared structure that stores CN and DN information |
| PoolerLock | Used to prevent two threads from simultaneously obtaining the same connection from a connection pool |
| RelationMappingLock | Used to wait for the mapping file between system catalogs and storage locations to be updated |
| AsyncCtlLock | Used to prevent concurrent access to or concurrent modification on the sharing notification status |
| AsyncQueueLock | Used to prevent concurrent access to or concurrent modification on the sharing notification queue |
| SerializableXactHashLock | Used to prevent concurrent read/write or concurrent write/write on a sharing structure for serializable transactions |
| SerializableFinishedList-Lock | Used to prevent concurrent read/write or concurrent write/write on a shared linked list for completed serial transactions |
| SerializablePredicateLock-ListLock | Used to protect a linked list of serializable transactions that have locks |
| OldSerXidLock | Used to protect a structure that records serializable transactions that have conflicts |
| FileStatLock | Used to protect a data structure that stores statistics file information |
| SyncRepLock | Used to protect Xlog synchronization information during primary-standby replication |
| DataSyncRepLock | Used to protect data page synchronization information during primary-standby replication |
| CStoreColspaceCacheLock | Used to add a lock when CU space is allocated for a column-store table |
| CStoreCUCacheSweep-Lock | Used to add a lock when CU caches used by a column-store table are cyclically washed out |
| MetaCacheSweepLock | Used to add a lock when metadata is cyclically washed out |
| DfsConnectorCacheLock | Used to protect a global hash table where HDFS connection handles are cached |

| wait_event | Description |
|--------------------------------|--|
| dummyServerInfoCache-Lock | Used to protect a global hash table where the information about computing Node Group connections is cached |
| ExtensionConnectorLibLock | Used to add a lock when a specific dynamic library is loaded or uninstalled in ODBC connection initialization scenarios |
| SearchServerLibLock | Used to add a lock on the file read operation when a specific dynamic library is initially loaded in GPU-accelerated scenarios |
| DfsUserLoginLock | Used to protect a global linked table where HDFS user information is stored |
| DfsSpaceCacheLock | Used to ensure that the IDs of files to be imported to an HDFS table increase monotonically |
| LsnXlogChkFileLock | Used to serially update the Xlog flush points for primary and standby servers recorded in a specific structure |
| GTMHostInfoLock | Used to prevent concurrent access to or concurrent modification on GTM host information |
| ReplicationSlotAllocation-Lock | Used to add a lock when a primary server allocates stream replication slots during primary-standby replication |
| ReplicationSlotControl-Lock | Used to prevent concurrent update of replication slot status during primary-standby replication |
| ResourcePoolHashLock | Used to prevent concurrent access to or concurrent modification on a resource pool table, a hash table |
| WorkloadStatHashLock | Used to prevent concurrent access to or concurrent modification on a hash table that contains SQL requests from the CN side |
| WorkloadIoStatHashLock | Used to prevent concurrent access to or concurrent modification on a hash table that contains the I/O information of the current DN |
| WorkloadCGroupHash-Lock | Used to prevent concurrent access to or concurrent modification on a hash table that contains Cgroup information |
| OBSGetPathLock | Used to prevent concurrent read/write or concurrent write/write on an OBS path |
| WorkloadUserInfoLock | Used to prevent concurrent access to or concurrent modification on a hash table that contains user information about load management |

| wait_event | Description |
|------------------------|--|
| WorkloadRecordLock | Used to prevent concurrent access to or concurrent modification on a hash table that contains requests received by CNs during adaptive memory management |
| WorkloadIOUtilLock | Used to protect a structure that records iostat and CPU load information |
| WorkloadNodeGroupLock | Used to prevent concurrent access to or concurrent modification on a hash table that contains Node Group information in memory |
| JobShmemLock | Used to protect global variables in the shared memory that is periodically read during a scheduled task where MPP is compatible with Oracle |
| OBSRuntimeLock | Used to obtain environment variables, for example, <i>GAUSSHOME</i> . |
| LLVMDumpIRLock | Used to export the assembly language for dynamically generating functions |
| LLVMParseIRLock | Used to compile and parse a finished IR function from the IR file at the start position of a query |
| RPNNumberLock | Used by a DN on a computing Node Group to count the number of threads for a task where plans are being executed |
| ClusterRPLock | Used to control concurrent access on cluster load data maintained in a CCN of the cluster |
| CriticalCacheBuildLock | Used to load caches from a shared or local cache initialization file |
| WaitCountHashLock | Used to protect a shared structure in user statement counting scenarios |
| BufMappingLock | Used to protect operations on a table mapped to shared buffer |
| LockMgrLock | It is used to protect a common lock structure. |
| PredicateLockMgrLock | Used to protect a lock structure that has serializable transactions |
| OperatorRealTLock | Used to prevent concurrent access to or concurrent modification on a global structure that contains real-time data at the operator level |
| OperatorHistLock | Used to prevent concurrent access to or concurrent modification on a global structure that contains historical data at the operator level |

| wait_event | Description |
|----------------------|--|
| SessionRealTLock | Used to prevent concurrent access to or concurrent modification on a global structure that contains real-time data at the query level |
| SessionHistLock | Used to prevent concurrent access to or concurrent modification on a global structure that contains historical data at the query level |
| CacheSlotMappingLock | Used to protect global CU cache information |
| BarrierLock | Used to ensure that only one thread is creating a barrier at a time |

The following table describes the corresponding wait events when **wait_status** is **wait io**.

Table 18-241 List of wait events corresponding to I/Os

| wait_event | Description |
|------------------------|---|
| BufFileRead | Reads data from a temporary file to a specified buffer. |
| BufFileWrite | Writes the content of a specified buffer to a temporary file. |
| ControlFileRead | Reads the pg_control file, mainly during database startup, checkpoint execution, and primary/standby verification. |
| ControlFileSync | Flushes the pg_control file to a disk, mainly during database initialization. |
| ControlFileSyncUpdate | Flushes the pg_control file to a disk, mainly during database startup, checkpoint execution, and primary/standby verification. |
| ControlFileWrite | Writes to the pg_control file, mainly during database initialization. |
| ControlFileWriteUpdate | Updates the pg_control file, mainly during database startup, checkpoint execution, and primary/standby verification. |
| CopyFileRead | Reads a file during file copying. |
| CopyFileWrite | Writes a file during file copying. |
| DataFileExtend | Writes a file during file extension. |
| DataFileFlush | Flushes a table data file to a disk. |
| DataFileImmediateSync | Flushes a table data file to a disk immediately. |

| wait_event | Description |
|-----------------------------|---|
| DataFilePrefetch | Reads a table data file asynchronously. |
| DataFileRead | Reads a table data file synchronously. |
| DataFileSync | Flushes table data file modifications to a disk. |
| DataFileTruncate | Truncates a table data file. |
| DataFileWrite | Writes a table data file. |
| LockFileAddToDataDir-Read | Reads the postmaster.pid file. |
| LockFileAddToDataDir-Sync | Flushes the postmaster.pid file to a disk. |
| LockFileAddToDataDir-Write | Writes the PID information into the postmaster.pid file. |
| LockFileCreateRead | Read the LockFile file %s.lock . |
| LockFileCreateSync | Flushes the LockFile file %s.lock to a disk. |
| LockFileCreateWRITE | Writes the PID information into the LockFile file %s.lock . |
| RelationMapRead | Reads the mapping file between system catalogs and storage locations. |
| RelationMapSync | Flushes the mapping file between system catalogs and storage locations to a disk. |
| RelationMapWrite | Writes the mapping file between system catalogs and storage locations. |
| ReplicationSlotRead | Reads a stream replication slot file during a restart. |
| ReplicationSlotRestore-Sync | Flushes a stream replication slot file to a disk during a restart. |
| ReplicationSlotSync | Flushes a temporary stream replication slot file to a disk during checkpoint execution. |
| ReplicationSlotWrite | Writes a temporary stream replication slot file during checkpoint execution. |
| SLRUFlushSync | Flushes the pg_clog , pg_subtrans , and pg_multixact files to a disk, mainly during checkpoint execution and database shutdown. |
| SLRURead | Reads the pg_clog , pg_subtrans , and pg_multixact files. |
| SLRUSync | Writes dirty pages into the pg_clog , pg_subtrans , and pg_multixact files, and flushes the files to a disk, mainly during checkpoint execution and database shutdown. |

| wait_event | Description |
|----------------------|--|
| SLRUWrite | Writes the pg_clog , pg_subtrans , and pg_multixact files. |
| TimelineHistoryRead | Reads the timeline history file during database startup. |
| TimelineHistorySync | Flushes the timeline history file to a disk during database startup. |
| TimelineHistoryWrite | Writes to the timeline history file during database startup. |
| TwophaseFileRead | Reads the pg_twophase file, mainly during two-phase transaction submission and restoration. |
| TwophaseFileSync | Flushes the pg_twophase file to a disk, mainly during two-phase transaction submission and restoration. |
| TwophaseFileWrite | Writes the pg_twophase file, mainly during two-phase transaction submission and restoration. |
| WALBootstrapSync | Flushes an initialized WAL file to a disk during database initialization. |
| WALBootstrapWrite | Writes an initialized WAL file during database initialization. |
| WALCopyRead | Read operation generated when an existing WAL file is read for replication after archiving and restoration. |
| WALCopySync | Flushes a replicated WAL file to a disk after archiving and restoration. |
| WALCopyWrite | Write operation generated when an existing WAL file is read for replication after archiving and restoration. |
| WALInitSync | Flushes a newly initialized WAL file to a disk during log reclaiming or writing. |
| WALInitWrite | Initializes a newly created WAL file to 0 during log reclaiming or writing. |
| WALRead | Reads data from Xlogs during redo operations on two-phase files. |
| WALSyncMethodAssign | Flushes all open WAL files to a disk. |
| WALWrite | Writes a WAL file. |

The following table describes the corresponding wait events when **wait_status** is **acquire lock**.

Table 18-242 List of wait events corresponding to transaction locks

| wait_event | Description |
|------------------|--|
| relation | Adds a lock to a table. |
| extend | Adds a lock to a table being scaled out. |
| partition | Adds a lock to a partitioned table. |
| partition_seq | Adds a lock to a partition of a partitioned table. |
| page | Adds a lock to a table page. |
| tuple | Adds a lock to a tuple on a page. |
| transactionid | Adds a lock to a transaction ID. |
| virtualxid | Adds a lock to a virtual transaction ID. |
| object | Adds a lock to an object. |
| cstore_freespace | Adds a lock to idle column-store space. |
| userlock | Adds a lock to a user. |
| advisory | Adds an advisory lock. |

18.3.168 PG_TABLES

PG_TABLES displays access to each table in the database.

Table 18-243 PG_TABLES columns

| Column | Type | Reference | Description |
|------------|---------|--|---|
| schemaname | Name | PG_NAMESPACE .nspname | Name of the schema that contains the table |
| tablename | Name | PG_CLASS .relname | Name of the table |
| tableowner | Name | pg_get_userbyid(PG_CLASS .relowner) | Owner of the table |
| tablespace | Name | PG_TABLESPACE .spcname | Tablespace that contains the table. The default value is null |
| hasindexes | boolean | PG_CLASS .relhasindex | Whether the table has (or recently had) an index. If it does, its value is true . Otherwise, its value is false . |

| Column | Type | Reference | Description |
|---------------|--------------------------|--|---|
| hasrules | boolean | PG_CLASS .relhasrules | Whether the table has rules. If it does, its value is true . Otherwise, its value is false . |
| hastriggers | boolean | PG_CLASS .RELHASTRIGGERS | Whether the table has triggers. If it does, its value is true . Otherwise, its value is false . |
| tablecreator | Name | pg_get_userbyid(PG_OBJECT .creator) | Table creator. If the creator has been deleted, no value is returned. |
| created | Timestamp with time zone | PG_OBJECT .ctime | Time when the table was created. |
| last_ddl_time | Timestamp with time zone | PG_OBJECT .mtime | Last time when the cluster was modified. |

Example

Query all tables in a specified schema.

```
SELECT tablename FROM PG_TABLES WHERE schemaname = 'myschema';
-----
inventory
product
sales_info
test1
mytable
product_info
customer_info
newproducts
customer_t1
(9 rows)
```

18.3.169 PG_TDE_INFO

PG_TDE_INFO displays the encryption information about the current cluster.

Table 18-244 PG_TDE_INFO columns

| Column | Type | Description |
|------------|------|--|
| is_encrypt | Text | Whether the cluster is an encryption cluster <ul style="list-style-type: none">f: Non-encryption clustert: Encryption cluster |

| Column | Type | Description |
|------------|------|--|
| g_tde_algo | Text | Encryption algorithm <ul style="list-style-type: none">AES-CTR-128 |
| remain | Text | Reserved columns |

Examples

Check whether the current cluster is encrypted, and check the encryption algorithm (if any) used by the current cluster.

```
SELECT * FROM PG_TDE_INFO;  
is_encrypt | g_tde_algo | remain  
-----+-----+-----  
f          | AES-CTR-128 | remain  
(1 row)
```

18.3.170 PG_TIMEZONE_ABBREVS

PG_TIMEZONE_ABBREVS displays all time zone abbreviations that can be recognized by the input routines.

Table 18-245 PG_TIMEZONE_ABBREVS columns

| Column | Type | Description |
|------------|----------|---|
| abbrev | Text | Time zone abbreviation |
| utc_offset | interval | Offset from UTC |
| is_dst | boolean | Whether the abbreviation indicates a daylight saving time (DST) zone. If it does, its value is true . Otherwise, its value is false . |

18.3.171 PG_TIMEZONE_NAMES

PG_TIMEZONE_NAMES displays all time zone names that can be recognized by **SET TIMEZONE**, along with their associated abbreviations, UTC offsets, and daylight saving time statuses.

Table 18-246 PG_TIMEZONE_NAMES columns

| Column | Type | Description |
|------------|----------|-----------------------------|
| Name | Text | Name of the time zone |
| abbrev | Text | Time zone name abbreviation |
| utc_offset | interval | Offset from UTC |

| Column | Type | Description |
|--------|---------|--|
| is_dst | boolean | Whether DST is used. If it is, its value is true . Otherwise, its value is false . |

18.3.172 PG_TOTAL_MEMORY_DETAIL

PG_TOTAL_MEMORY_DETAIL displays the memory usage of a certain node in the database.

Table 18-247 PG_TOTAL_MEMORY_DETAIL columns

| Column | Type | Description |
|----------|------|-------------|
| nodename | Text | Node name |

| Column | Type | Description |
|------------|------|--|
| memorytype | Text | <p>It can be set to any of the following values:</p> <ul style="list-style-type: none">• max_process_memory: memory used by a DWS cluster instance• process_used_memory: memory used by a DWS process• max_dynamic_memory: maximum dynamic memory• dynamic_used_memory: used dynamic memory• dynamic_peak_memory: dynamic peak value of the memory• dynamic_used_shrctx: maximum dynamic shared memory context• dynamic_peak_shrctx: dynamic peak value of the shared memory context• max_shared_memory: maximum shared memory• shared_used_memory: used shared memory• max_cstore_memory: maximum memory allowed for column store• cstore_used_memory: memory used for column store• max_sctpcomm_memory: maximum memory allowed for the communication library• sctpcomm_used_memory: memory used for the communication library• sctpcomm_peak_memory: memory peak of the communication library• max_topsql_memory: maximum memory that can be used by top SQL to record historical job monitoring information• topsql_used_memory: memory used by top SQL to record historical job monitoring information• topsql_peak_memory: memory peak of top SQL to record historical job monitoring information• other_used_memory: other used memory• gpu_max_dynamic_memory: maximum GPU memory |

| Column | Type | Description |
|-------------|---------|---|
| | | <ul style="list-style-type: none">• gpu_dynamic_used_memory: sum of the available GPU memory and temporary GPU memory• gpu_dynamic_peak_memory: maximum memory used for GPU• pooler_conn_memory: memory used for pooler connections• pooler_freeconn_memory: memory used for idle pooler connections• storage_compress_memory: memory used for column-store compression and decompression• udf_reserved_memory: memory reserved for the UDF Worker process• mmap_used_memory: memory used for mmap |
| memorybytes | Integer | Size of the used memory (MB) |

18.3.173 PG_TOTAL_SCHEMA_INFO

PG_TOTAL_SCHEMA_INFO displays the storage usage of all schemas in each database. This view is valid only if use_workload_manager is set to **on**.

| Column | Type | Description |
|--------------|--------|---|
| schemaid | OID | Schema OID |
| schemaname | Text | Schema name |
| databaseid | OID | Database OID |
| databasename | Name | Database name |
| usedspace | Bigint | Size of the permanent table storage space used by the schema, in bytes. |
| permspace | Bigint | Upper limit of the permanent table storage space of the schema, in bytes. |

18.3.174 PG_TOTAL_USER_RESOURCE_INFO

PG_TOTAL_USER_RESOURCE_INFO displays the resource usage of all users. Only administrators can query this view. This view is valid only if `use_workload_manager` is set to **on**.

Table 18-248 PG_TOTAL_USER_RESOURCE_INFO columns

| Column | Type | Description |
|------------------|------------------|--|
| username | Name | Username |
| used_memory | Integer | Memory used by a user, in MB. <ul style="list-style-type: none">On a DN, it indicates the memory used by users on the current DN.On a CN, it indicates the total memory used by users on all DNs. |
| total_memory | Integer | Memory used by the resource pool, in MB. 0 indicates that the maximum available memory is not limited and depends on the maximum available memory of the database (max_dynamic_memory). The calculation formula is as follows:
$\text{total_memory} = \text{max_dynamic_memory} * \text{parent_percent} * \text{user_percent}$
On a CN, it indicates the total maximum available memory on all DNs. |
| used_cpu | Double precision | Number of CPU cores in use. Only the CPU usage of complex jobs in the non-default resource pool is collected, and the value is the CPU usage of the related cgroup. |
| total_cpu | Integer | Total number of CPU cores of the Cgroup associated with a user on the node |
| used_space | Bigint | Used permanent table storage space (unit: KB) |
| total_space | Bigint | Available storage space (unit: KB). -1 indicates that the storage space is not limited. |
| used_temp_space | Bigint | Used temporary table storage space (unit: KB) |
| total_temp_space | Bigint | Available temporary table storage space (unit: KB). -1 indicates that the storage space is not limited. |
| used_spill_space | Bigint | Size of the used operator flushing space, in KB |

| Column | Type | Description |
|-------------------|------------------|--|
| total_spill_space | Bigint | Size of the available operator flushing space, in KB. The value -1 indicates that the operator flushing space is not limited. |
| read_kbytes | Bigint | On a CN, it indicates the total number of bytes logically read by a user on all DNs in the last 5 seconds, in KB.
On a DN, it indicates the total number of bytes logically read by a user from the instance startup time to the current time, in KB. |
| write_kbytes | Bigint | On a CN, it indicates the total number of bytes logically written by a user on all DNs in the last 5 seconds, in KB.
On a DN, it indicates the total number of bytes logically written by a user from the instance startup time to the current time, in KB. |
| read_counts | Bigint | On a CN, it indicates the total number of logical reads performed by a user on all DNs in the last 5 seconds.
On a DN, it indicates the total number of logical reads performed by a user from the instance startup time to the current time. |
| write_counts | Bigint | On a CN, it indicates the total number of logical writes performed by a user on all DNs in the last 5 seconds.
On a DN, it indicates the total number of logical writes performed by a user from the instance startup time to the current time. |
| read_speed | Double precision | On a CN, it indicates the sum of average logical read rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average logical read rate of a user on the DN in the last 5 seconds, in KB/s. |
| write_speed | Double precision | On a CN, it indicates the sum of average logical write rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average logical write rate of a user on the DN in the last 5 seconds, in KB/s. |

| Column | Type | Description |
|------------|------------------|---|
| send_speed | Double precision | On a CN, it indicates the sum of the average network sending rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average network sending rate of a user on the DN in the last 5 seconds, in KB/s. |
| recv_speed | Double precision | On a CN, it indicates the sum of the average network receiving rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average network receiving rate of a user on the DN in the last 5 seconds, in KB/s. |

18.3.175 PG_USER

PG_USER displays information about users who can access the database.

Table 18-249 PG_USER columns

| Column | Type | Description |
|-------------|--------------------------|--|
| username | Name | User name |
| usesysid | OID | ID of this user |
| usecreatedb | boolean | Whether the user has the permission to create databases |
| usesuper | boolean | whether the user is the initial system administrator with the highest rights. |
| usecatupd | boolean | whether the user can directly update system tables. Only the initial system administrator whose usesysid is 10 has this permission. It is not available for other users. |
| userepl | boolean | Whether the user has the permission to duplicate data streams |
| passwd | Text | Encrypted user password. The value is displayed as *****. |
| valbegin | Timestamp with time zone | Account validity start time; null if no start time |
| valuntil | Timestamp with time zone | Password expiry time; null if no expiration |

| Column | Type | Description |
|-----------------|--------|---|
| respool | Name | Resource pool where the user is in |
| parent | OID | Parent user OID |
| spacelimit | Text | The storage space of the permanent table. |
| tempspacelimit | Text | The storage space of the temporary table. |
| spillspacelimit | Text | The operator disk flushing space. |
| useconfig | Text[] | Session defaults for run-time configuration variables |
| nodegroup | Name | Name of the logical cluster associated with the user. If no logical cluster is associated, this column is left blank. |

Example

Query the current database user list.

```
SELECT username FROM pg_user;  
username  
-----  
dbadmin  
u1  
u2  
u3  
(4 rows)
```

18.3.176 PG_USER_MAPPINGS

PG_USER_MAPPINGS displays information about user mappings.

This is essentially a publicly readable view of **PG_USER_MAPPING** that leaves out the options column if the user has no rights to use it.

Table 18-250 PG_USER_MAPPINGS columns

| Column | Type | Reference | Description |
|---------|------|---|---|
| umid | OID | PG_USER_MAPPING.oid | OID of the user mapping |
| srvid | OID | PG_FOREIGN_SERVER.oid | OID of the foreign server that contains this mapping |
| srvname | Name | PG_FOREIGN_SERVER.srvname | Name of the foreign server |
| umuser | OID | PG_AUTHID.oid | OID of the local role being mapped, 0 if the user mapping is public |

| Column | Type | Reference | Description |
|-----------|--------|-----------|--|
| username | Name | - | Name of the local user to be mapped |
| umoptions | text[] | - | User mapping specific options. If the current user is the owner of the foreign server, its value is keyword=value strings. Otherwise, its value is null. |

18.3.177 PG_VIEWS

PG_VIEWS displays basic information about each view in the database.

Table 18-251 PG_VIEWS columns

| Column | Type | Reference | Description |
|------------|------|---------------------------------------|---|
| schemaname | Name | PG_NAMESPACE .nspname | Name of the schema that contains the view |
| viewname | Name | PG_CLASS .relname | View name |
| viewowner | Name | PG_AUTHID .rolname | Owner of the view |
| definition | Text | - | Definition of the view |

Example

Query all the views in a specified schema.

```
SELECT * FROM pg_views WHERE schemaname = 'myschema';
schemaname | viewname | viewowner | definition
-----+-----+-----+-----
myschema   | myview   | dbadmin   | SELECT * FROM pg_tablespace WHERE (pg_tablespace.spcname =
pg_default::name);
myschema   | v1       | dbadmin   | SELECT * FROM t1 WHERE (t1.c1 > 200);
(2 rows)
```

18.3.178 PG_WLM_STATISTICS

PG_WLM_STATISTICS displays information about workload management after the task is complete or the exception has been handled. This view has been discarded in 8.1.2. You can use [PGXC_WLM_SESSION_INFO](#) to view load management records of completed jobs executed on all CNs.

Table 18-252 PG_WLM_STATISTICS columns

| Column | Type | Description |
|--------------------|---------|--|
| statement | Text | Statement executed for exception handling |
| block_time | Bigint | Block time before the statement is executed |
| elapsed_time | Bigint | Elapsed time when the statement is executed |
| total_cpu_time | Bigint | Total time used by the CPU on the DN when the statement is executed for exception handling |
| qualification_time | Bigint | Period when the statement checks the inclination ratio |
| cpu_skew_percent | Integer | CPU usage skew on the DN when the statement is executed for exception handling |
| control_group | Text | Cgroup used when the statement is executed for exception handling |
| status | Text | Statement status after it is executed for exception handling <ul style="list-style-type: none">• pending: The statement is waiting to be executed.• running: The statement is being executed.• finished: The execution is finished normally.• abort: The execution is unexpectedly terminated. |
| action | Text | Actions when statements are executed for exception handling <ul style="list-style-type: none">• abort indicates terminating the operation.• adjust indicates executing the Cgroup adjustment operations. Currently, you can only perform the demotion operation.• finish indicates that the operation is normally finished. |
| queryid | Bigint | Internal query ID used for statement execution |
| threadid | Bigint | ID of the backend thread |

18.3.179 PGXC_BULKLOAD_PROGRESS

PGXC_BULKLOAD_PROGRESS displays the progress of the service import. Only GDS common files can be imported. This view is accessible only to users with system administrators rights.

Table 18-253 PGXC_BULKLOAD_PROGRESS columns

| Column | Type | Description |
|------------|--------|---|
| session_id | Bigint | GDS session ID |
| query_id | Bigint | Query ID. It is equivalent to debug_query_id . |
| query | Text | Query statement |
| progress | Text | Progress percentage |

18.3.180 PGXC_BULKLOAD_INFO

By querying the **PGXC_BULKLOAD_INFO** view on CNs, you can obtain historical statistics information for interconnection, GDS, COPY, and \COPY business executions after they have completed. This view summarizes the historical execution information of import and export business that have already completed on each node of the current cluster (including the interconnection cluster address, import and export business type, maximum, minimum, and total number of rows and bytes written to disk on DNs, etc.), to obtain historical information on import and export business execution and assist in performance troubleshooting.

This view does not record abnormal interruptions of import and export jobs. The data is directly obtained from the system catalog **GS_WLM_SESSION_INFO**, and the **loader_status** field is parsed to obtain import and export service information.

System administrator rights are required to access this view.

Table 18-254 PGXC_BULKLOAD_INFO columns

| Column | Type | Description |
|------------------|------|---|
| datid | OID | OID of the database the backend is connected to. |
| dbname | Text | Name of the database the backend is connected to. |
| schemaname | Text | Schema name. |
| nodename | Text | Name of the CN where the statement is run. |
| username | Text | Username for connecting to the backend. |
| application_name | Text | Name of the application that is connected to the backend. |

| Column | Type | Description |
|-----------------|--------------------------|---|
| client_addr | inet | IP address of the client connected to the backend. If this column is null, it indicates that the client is connected via a Unix socket on the server machine or that it is an internal process, such as autovacuum. |
| client_hostname | Text | Host name of the client, which is obtained by reverse DNS lookup of client_addr . This column is only non-null when log_hostname is enabled and IP connection is used. |
| client_port | Integer | TCP port number used by the client to communicate with the backend. If a Unix socket is used, it is -1 . |
| query_band | Text | Job type, which can be set using the GUC parameter query_band and is a null string by default. |
| block_time | Bigint | Blocking time before statement execution, including statement parsing and optimization time, in milliseconds. |
| start_time | Timestamp with time zone | Start time of statement execution. |
| finish_time | Timestamp with time zone | End time of statement execution. |
| status | Text | End status of statement execution: finished for normal and aborted for abnormal. The statement status recorded here should be the database server execution status. When the server-side execution is successful and an error occurs when the result set is returned, the statement should be finished . |
| queryid | Bigint | Internal query ID used for statement execution. |
| query | Text | Executed statement. |
| session_id | Text | A session uniquely identified in the database system, in the format of session_start_time.tid.node_name . |
| address | Text | Server address of the interconnection peer cluster. When not empty, it indicates an interconnection service, and the source cluster will additionally obtain the remote cluster port number. |

| Column | Type | Description |
|------------------|------|--|
| direction | Text | Type of import and export service, including gds to file , gds from file , gds to pipe , gds from pipe , copy from , and copy to . |
| min_done_lines | json | Minimum number of rows of a statement across all DNs. |
| max_done_lines | json | Maximum number of rows of a statement across all DNs. |
| total_done_lines | json | Total number of rows of a statement across all DNs. |
| min_done_bytes | json | Minimum number of bytes of a statement across all DNs. |
| max_done_bytes | json | Maximum number of bytes of a statement across all DNs. |
| total_done_bytes | json | Total number of bytes of a statement across all DNs. |

 NOTE

- Abnormal interruptions of import and export jobs are not recorded in the view.
- The implementation mechanism of GDS foreign tables and interconnection foreign tables is different. When querying, GDS records the full amount, while interconnection records the actual amount.
- For non-full import and export foreign tables with a limit, due to the special execution plan of limit, the data displayed is collected from one DN, which appears as a maximum value of all and a minimum value of 0.
- If the import and export table is a non-partitioned table:
 - When the GDS partitioned table is small, if one DN has finished collecting data and the other DNs have not started collecting data, they will not collect data. Therefore, when the data volume of GDS from non-partitioned tables is small, the minimum value may be 0, but it is not 0 when the table data volume is large.
 - When exporting non-partitioned tables from the interconnection source cluster, all DNs will be recorded, and only one DN's data will be collected, so the minimum value is 0.
 - When exporting replication tables from the interconnection remote cluster, only one DN will be recorded, so it is equivalent to having only one DN, and the minimum and maximum values are the same.
- Historical monitoring of import and export is implemented by reusing the historical TopSQL function, which follows the precautions, prerequisites, and operation steps of TopSQL. For details, refer to [Historical Top SQL](#).
- Due to the large amount of data recorded by TopSQL, you are advised to query and use it as needed by combining fields such as **start_time** and **finish_time** to improve query performance, or to reduce query frequency.

| Name | Type | Description |
|-------------|--------------------------|--|
| db_name | Text | Database name |
| query_id | Bigint | Query ID. It is equivalent to debug_query_id . |
| tid | Bigint | ID of the current thread |
| lwtid | Integer | Lightweight thread ID |
| session_id | Bigint | GDS session ID |
| direction | Text | Service type. The options are gds to file , gds from file , gds to pipe , gds from pipe , copy from , and copy to . |
| query | Text | Query statement |
| address | Text | Location of the foreign table used for data import and export |
| query_start | Timestamp with time zone | Start time of data import or export |
| total_bytes | Bigint | Total size of data to be processed
This parameter is specified only when a GDS common file is to be imported and the record in the row comes from a CN. Otherwise, left this parameter unspecified. |
| phase | Text | Current phase. The options are INITIALIZING , TRANSFER_DATA , and RELEASE_RESOURCE . |
| done_lines | Bigint | Number of lines that have been transferred |
| done_bytes | Bigint | Number of bytes that have been transferred |

18.3.182 PGXC_COLUMN_TABLE_IO_STAT

PGXC_COLUMN_TABLE_IO_STAT provides I/O statistics of all column-store tables of the database on all CNs and DN in the cluster. Except the **nodename** column of the name type added in front of each row, the names, types, and sequences of other columns are the same as those in the **GS_COLUMN_TABLE_IO_STAT** view. For details about the columns, see [Table 18-256](#).

Table 18-256 GS_COLUMN_TABLE_IO_STAT columns

| Column | Type | Description |
|------------|--------|--|
| schemaname | Name | Namespace of a table |
| relname | Name | Table name |
| heap_read | Bigint | Number of blocks logically read in the heap |
| heap_hit | Bigint | Number of block hits in the heap |
| idx_read | Bigint | Number of blocks logically read in the index |
| idx_hit | Bigint | Number of block hits in the index |
| cu_read | Bigint | Number of logical reads in the Compression Unit |
| cu_hit | Bigint | Number of hits in the Compression Unit |
| cidx_read | Bigint | Number of indexes logically read in the Compression Unit |
| cidx_hit | Bigint | Number of index hits in the Compression Unit |

18.3.183 PGXC_COMM_CLIENT_INFO

PGXC_COMM_CLIENT_INFO stores the client connection information of all nodes. (You can query this view on a DN to view the information about the connection between the CN and DN.)

Table 18-257 PGXC_COMM_CLIENT_INFO columns

| Column | Type | Description |
|-------------|---------|---|
| node_name | Text | Current node name. |
| app | Text | Client application name. |
| tid | Bigint | Thread ID of the current thread. |
| lwtid | Integer | Lightweight thread ID of the current thread. |
| query_id | Bigint | Query ID. It is equivalent to debug_query_id . |
| socket | Integer | It is displayed if the connection is a physical connection. |
| remote_ip | Text | Peer node IP address. |
| remote_port | Text | Peer node port. |

| Column | Type | Description |
|----------|---------|---|
| logic_id | Integer | If the connection is a logical connection, sid is displayed. If -1 is displayed, the current connection is a physical connection. |

18.3.184 PGXC_COMM_DELAY

PGXC_COMM_DELAY displays the communication library delay status for all the DNs.

Table 18-258 PGXC_COMM_DELAY columns

| Column | Type | Description |
|-------------|---------|---|
| node_name | Text | Node name |
| remote_name | Text | Name of the peer node with the maximum connection latency. |
| remote_host | Text | IP address of the peer |
| stream_num | Integer | Number of logical stream connections used by the current physical connection |
| min_delay | Integer | Minimum delay of the current physical connection. The unit is microsecond. |
| average | Integer | Average delay of the current physical connection. The unit is microsecond. |
| max_delay | Integer | Maximum delay of the current physical connection. The unit is microsecond.
NOTE
If its value is -1 , the latency detection has timed out. In this case, re-establish the connection between nodes and then perform the query. |

18.3.185 PGXC_COMM_RECV_STREAM

PG_COMM_RECV_STREAM displays the receiving stream status of the communication libraries for all the DNs.

Table 18-259 PGXC_COMM_RECV_STREAM columns

| Column | Type | Description |
|-----------|--------|------------------------------------|
| node_name | Text | Node name |
| local_tid | Bigint | ID of the thread using this stream |

| Column | Type | Description |
|-------------|---------|---|
| remote_name | Text | Name of the peer node |
| remote_tid | Bigint | Peer thread ID |
| idx | Integer | Peer DN ID in the local DN |
| sid | Integer | Stream ID in the physical connection |
| tcp_sock | Integer | TCP socket used in the stream |
| state | Text | Current status of the stream <ul style="list-style-type: none">• UNKNOWN: The logical connection is unknown.• READY: The logical connection is ready.• RUN: The logical connection receives packets normally.• HOLD: The logical connection is waiting to receive packets.• CLOSED: The logical connection is closed.• TO_CLOSED: The logical connection is to be closed.• WRITING: Data is being written. |
| query_id | Bigint | debug_query_id corresponding to the stream |
| pn_id | Integer | plan_node_id of the query executed by the stream |
| send_smp | Integer | smpid of the sender of the query executed by the stream |
| recv_smp | Integer | smpid of the receiver of the query executed by the stream |
| recv_bytes | Bigint | Total data volume received from the stream. The unit is byte. |
| time | Bigint | Current life cycle service duration of the stream. The unit is ms. |
| speed | Bigint | Average receiving rate of the stream. The unit is byte/s. |
| quota | Bigint | Current communication quota value of the stream. The unit is Byte. |
| buff_usize | Bigint | Current size of the data cache of the stream. The unit is byte. |

18.3.186 PGXC_COMM_SEND_STREAM

PGXC_COMM_SEND_STREAM displays the sending stream status of the communication libraries for all the DNs.

Table 18-260 PGXC_COMM_SEND_STREAM columns

| Column | Type | Description |
|-------------|---------|--|
| node_name | Text | Node name |
| local_tid | Bigint | ID of the thread using this stream |
| remote_name | Text | Name of the peer node |
| remote_tid | Bigint | Peer thread ID |
| idx | Integer | Peer DN ID in the local DN |
| sid | Integer | Stream ID in the physical connection |
| tcp_sock | Integer | TCP socket used in the stream |
| state | Text | Current status of the stream. <ul style="list-style-type: none">• UNKNOWN: The logical connection is unknown.• READY: The logical connection is ready.• RUN: The logical connection sends packets normally.• HOLD: The logical connection is waiting to send packets.• CLOSED: The logical connection is closed.• TO_CLOSED: The logical connection is to be closed.• WRITING: Data is being written. |
| query_id | Bigint | debug_query_id corresponding to the stream |
| pn_id | Integer | plan_node_id of the query executed by the stream |
| send_smp | Integer | smpid of the sender of the query executed by the stream |
| recv_smp | Integer | smpid of the receiver of the query executed by the stream |
| send_bytes | Bigint | Total data volume sent by the stream. The unit is Byte. |
| time | Bigint | Current life cycle service duration of the stream. The unit is ms. |
| speed | Bigint | Average sending rate of the stream. The unit is Byte/s. |

| Column | Type | Description |
|------------|--------|---|
| quota | Bigint | Current communication quota value of the stream. The unit is Byte. |
| wait_quota | Bigint | Extra time generated when the stream waits the quota value. The unit is ms. |

18.3.187 PGXC_COMM_STATUS

PGXC_COMM_STATUS displays the communication library status for all the DNs.

Table 18-261 PGXC_COMM_STATUS columns

| Column | Type | Description |
|----------------|---------|--|
| node_name | Text | Node name. |
| rxpck/s | Integer | Receiving rate of the communication library on a node. The unit is byte/s. |
| txpck/s | Integer | Sending rate of the communication library on a node. The unit is byte/s. |
| rxkB/s | Bigint | Receiving rate of the communication library on a node. The unit is KB/s. |
| txkB/s | Bigint | Sending rate of the communication library on a node. The unit is KB/s. |
| buffer | Bigint | Size of the buffer of the Cmailbox. |
| memKB(libcomm) | Bigint | Communication memory size of the libcomm process, in KB. |
| memKB(libpq) | Bigint | Communication memory size of the libpq process, in KB. |
| %USED(PM) | Integer | Real-time usage of the postmaster thread. |
| %USED (sflow) | Integer | Real-time usage of the gs_sender_flow_controller thread. |
| %USED (rflow) | Integer | Real-time usage of the gs_receiver_flow_controller thread. |
| %USED (rloop) | Integer | Highest real-time usage among multiple gs_receivers_loop threads. |
| stream | Integer | Total number of used logical connections. |

18.3.188 PGXC_COMM_QUERY_SPEED

PGXC_COMM_QUERY_SPEED displays traffic information about all queries on all nodes.

Table 18-262 PGXC_COMM_QUERY_SPEED columns

| Column | Type | Description |
|-----------|--------|--|
| node_name | Text | Node name |
| query_id | Bigint | debug_query_id corresponding to the stream |
| rxkB/s | Bigint | Receiving rate of the query stream (unit: byte/s) |
| txkB/s | Bigint | Sending rate of the query stream (unit: byte/s) |
| rxkB | Bigint | Total received data of the query stream (unit: byte) |
| txkB | Bigint | Total sent data of the query stream (unit: byte) |
| rxpck/s | Bigint | Packet receiving rate of the query (unit: packets/s) |
| txpck/s | Bigint | Packet sending rate of the query (Unit: packets/s) |
| rxpck | Bigint | Total number of received packets of the query |
| txpck | Bigint | Total number of sent packets of the query |

18.3.189 PGXC_DEADLOCK

PGXC_DEADLOCK displays lock wait information generated due to distributed deadlocks.

Currently, **PGXC_DEADLOCK** collects only lock wait information about locks whose **locktype** is **relation**, **partition**, **page**, **tuple**, or **transactionid**.

Table 18-263 PGXC_DEADLOCK columns

| Column | Type | Description |
|----------|------|--|
| locktype | Text | Type of the locked object |
| nodename | Name | Name of the node where the locked object resides |

| Column | Type | Description |
|---------------|--------------------------|--|
| dbname | Name | Name of the database where the locked object resides. The value is NULL if the locked object is a transaction. |
| nspname | Name | Name of the namespace of the locked object |
| relname | Name | Name of the relation targeted by the lock. The value is NULL if the object is not a relation or part of a relation. |
| partname | Name | Name of the partition targeted by the lock. The value is NULL if the locked object is not a partition. |
| page | Integer | Number of the page targeted by the lock. The value is NULL if the locked object is neither a page nor a tuple. |
| tuple | Smallint | Number of the tuple targeted by the lock. The value is NULL if the locked object is not a tuple. |
| transactionid | Xid | ID of the transaction targeted by the lock. The value is NULL if the locked object is not a transaction. |
| waitusername | Name | Name of the user who waits for the lock |
| waitgxid | Xid | ID of the transaction that waits for the lock |
| waitxactstart | Timestamp with time zone | Start time of the transaction that waits for the lock |
| waitqueryid | Bigint | Latest query ID of the thread that waits for the lock |
| waitquery | Text | Latest query statement of the thread that waits for the lock |
| waitpid | Bigint | ID of the thread that waits for the lock |
| waitmode | Text | Mode of the waited lock |
| holdusername | Name | Name of the user who holds the lock |
| holdgxid | Xid | ID of the transaction that holds the lock |
| holdxactstart | Timestamp with time zone | Start time of the transaction that holds the lock |
| holdqueryid | Bigint | Latest query ID of the thread that holds the lock |

| Column | Type | Description |
|-----------|--------------------------|--|
| holdquery | Text | Latest query statement of the thread that holds the lock |
| holdpid | Bigint | ID of the thread that holds the lock |
| holdmode | Text | Mode of the held lock |
| waittime | Timestamp with time zone | Timestamp when the lock wait starts.
This column is available only in clusters of version 9.1.0.200 or later. |
| holdtime | Timestamp with time zone | Timestamp when the lock starts to be held.
This column is available only in clusters of version 9.1.0.200 or later. |

18.3.190 PGXC_DISK_CACHE_STATS

PGXC_DISK_CACHE_STATS records the usage of file cache. This system view is supported only by clusters of version 9.1.0 or later.

Table 18-264 PGXC_DISK_CACHE_STATS columns

| Column | Type | Description |
|-------------|--------------|---|
| node_name | Text | Node name. |
| total_read | Bigint | Total number of accesses to disk cache. |
| local_read | Bigint | Total number of times disk cache reads from local disk. |
| remote_read | Bigint | Total number of times disk cache reads from remote storage. |
| hit_rate | numeric(5,2) | Hit rate of disk cache. |
| cache_size | Bigint | Total size of data saved in disk cache, in KB. |
| fill_rate | numeric(5,2) | Fill rate of disk cache. |

Example

Query the hit rate of disk cache on each node.

```
SELECT hit_rate FROM pgxc_disk_cache_stats;  
hit_rate  
-----
```

| |
|----------|
| 56.91 |
| 56.85 |
| NaN |
| NaN |
| NaN |
| NaN |
| (6 rows) |

18.3.191 PGXC_DISK_CACHE_ALL_STATS

PGXC_DISK_CACHE_ALL_STATS records all usage of file cache. This system view is supported only by clusters of version 9.1.0 or later.

Table 18-265 PGXC_DISK_CACHE_ALL_STATS columns

| Column | Type | Description |
|-----------------|--------------|--|
| node_name | Text | Node name. |
| total_read | Bigint | Total number of accesses to disk cache. |
| local_read | Bigint | Total number of times disk cache accesses local disk. |
| remote_read | Bigint | Total number of times disk cache accesses remote storage. |
| hit_rate | numeric(5,2) | Hit rate of disk cache. |
| cache_size | Bigint | Total size of data saved in disk cache, in KB. |
| fill_rate | numeric(5,2) | Fill rate of disk cache. |
| temp_file_size | Bigint | Total size of temporary/cold cache files, in KB. |
| a1in_size | Bigint | Total size of data saved in the a1in queue of disk cache, in KB. |
| a1out_size | Bigint | Total size of data saved in the a1out queue of disk cache, in KB. |
| am_size | Bigint | Total size of data saved in the am queue of disk cache, in KB. |
| a1in_fill_rate | numeric(5,2) | Fill rate of the a1in queue in disk cache. |
| a1out_fill_rate | numeric(5,2) | Fill rate of the a1out queue in disk cache. |
| am_fill_rate | numeric(5,2) | Fill rate of the am queue in disk cache. |
| fd | Integer | Number of file descriptors currently in use by disk cache. |

| Column | Type | Description |
|-----------------|--------|--|
| pin_block_count | Bigint | Number of pinned blocks in disk cache. This field is supported only by 9.1.0.100 and later cluster versions. |

Example

Query the number of file descriptors used by disk cache on each node.

```
SELECT fd FROM pgxc_disk_cache_all_stats;  
fd  
-----  
1000  
1000  
0  
0  
0  
0  
(6 rows)
```

18.3.192 PGXC_DISK_CACHE_PATH_INFO

PGXC_DISK_CACHE_PATH_INFO records information about the hard disk where the file cache is stored. This system view is supported only by clusters of version 9.1.0 or later.

Table 18-266 PGXC_DISK_CACHE_PATH_INFO columns

| Column | Type | Description |
|----------------|------------------|---|
| path_name | Text | Path name. |
| node_name | Text | Name of the node the hard disk belongs to. |
| cache_size | Bigint | Total size of cache files in the hard disk, in bytes. |
| disk_available | Bigint | Available space in the hard disk, in bytes. |
| disk_size | Bigint | Total capacity of the hard drive, in bytes. |
| disk_use_ratio | Double precision | Disk space usage. |

Example

Query information about the hard disk used by the file cache.

```
SELECT * FROM pgxc_disk_cache_path_info order by 1;  
path_name | node_name | cache_size | disk_available | disk_size | disk_use_ratio  
-----+-----+-----+-----+-----+-----  
dn_6001_6002_0 | dn_6001_6002 | 19619 | 137401716736 | 160982630400 | .146481105479564
```

| | | | | | |
|----------------|--------------|-------|--------------|--------------|------------------|
| dn_6001_6002_1 | dn_6001_6002 | 35968 | 137401716736 | 160982630400 | .146481105479564 |
| dn_6003_6004_0 | dn_6003_6004 | 27794 | 121600655360 | 160982630400 | .244634933235629 |
| dn_6003_6004_1 | dn_6003_6004 | 26158 | 121600655360 | 160982630400 | .244634933235629 |
| dn_6005_6006_0 | dn_6005_6006 | 24533 | 134394839040 | 160982630400 | .165159379579873 |
| dn_6005_6006_1 | dn_6005_6006 | 31065 | 134394839040 | 160982630400 | .165159379579873 |

18.3.193 PGXC_GET_STAT_ALL_TABLES

PGXC_GET_STAT_ALL_TABLES displays information about insertion, update, and deletion operations on tables and the dirty page rate of tables.

Before running **VACUUM FULL** on a system catalog with a high dirty page rate, ensure that no user is performing operations on it.

You are advised to run **VACUUM FULL** to tables (excluding system catalogs) whose dirty page rate exceeds 80% or run it based on service scenarios.

NOTE

For clusters of 8.2.0.100 or later, **PGXC_STAT_TABLE_DIRTY** is recommended for querying the dirty page rate.

Table 18-267 PGXC_GET_STAT_ALL_TABLES columns

| Column | Type | Description |
|-----------------|-------------------|--------------------------------|
| relid | OID | Table OID |
| relname | Name | Table name |
| schemaname | Name | Schema name of the table |
| n_tup_ins | Numeric | Number of inserted tuples |
| n_tup_upd | Numeric | Number of updated tuples |
| n_tup_del | Numeric | Number of deleted tuples |
| n_live_tup | Numeric | Number of live tuples |
| n_dead_tup | Numeric | Number of dead tuples |
| dirty_page_rate | numeric(5,2)
) | Dirty page rate (%) of a table |

For details, see "Functions and Operators" > "System Administration Functions" > "Other Functions" in the *Data Warehouse Service (DWS) SQL Syntax*.

Examples

Use the view **PGXC_GET_STAT_ALL_TABLES** to query the tables whose dirty page rate is greater than 30%.

```
SELECT * FROM PGXC_GET_STAT_ALL_TABLES WHERE dirty_page_rate>30;
relid |      relname      | schemaname | n_tup_ins | n_tup_upd | n_tup_del | n_live_tup | n_dead_tup |
dirty_page_rate
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+
```

```

2840 | pg_toast_2619 | pg_toast | 7415 | 0 | 7415 | 0 | 291 | 88.00
9001 | pgxc_class | pg_catalog | 56331 | 3 | 56285 | 54 | 143 | 72.59

(7 rows)

```

18.3.194 PGXC_GET_STAT_ALL_PARTITIONS

PGXC_GET_STAT_ALL_PARTITIONS displays information about insertion, update, and deletion operations on partitions of partitioned tables and the dirty page rate of tables.

The statistics of this view depend on the **ANALYZE** operation. To obtain the most accurate information, perform the **ANALYZE** operation on the partitioned table first.

NOTE

For clusters of 8.2.0.100 or later, **PGXC_STAT_TABLE_DIRTY** is recommended for querying the dirty page rate.

Table 18-268 PGXC_GET_STAT_ALL_PARTITIONS columns

| Column | Type | Description |
|-----------------|--------------|--------------------------------|
| relid | OID | Table OID |
| partid | OID | Partition OID |
| schemaname | Name | Schema name of the table |
| relname | Name | Table name |
| partname | Name | Partition name |
| n_tup_ins | Numeric | Number of inserted tuples |
| n_tup_upd | Numeric | Number of updated tuples |
| n_tup_del | Numeric | Number of deleted tuples |
| n_live_tup | Numeric | Number of live tuples |
| n_dead_tup | Numeric | Number of dead tuples |
| page_dirty_rate | numeric(5,2) | Dirty page rate (%) of a table |

Example

Query partition tables whose dirty page rate is greater than 30%.

```

SELECT * FROM PGXC_GET_STAT_ALL_PARTITIONS WHERE dirty_page_rate>30;
relid | partid | schemaname | relname | partname | n_tup_ins | n_tup_upd | n_tup_del | n_live_tup |
n_dead_tup | dirty_page_rate

```

| | | | | | | | | | |
|--------|-----------|-----------------|-----------------|--------------------|----------------|----|---|---|---|
| 58320 | 58626 | schema_subquery | store_hash_par | p1 | 2 | 0 | 2 | 0 | 2 |

| 100.00 | 58320 | 58657 | schema_subquery | store_hash_par | p1 | 3 | 0 | 3 | 0 |
| 100.00 | (10 rows) | | | | | | | | |

18.3.195 PGXC_GET_TABLE_SKEWNESS

PGXC_GET_TABLE_SKEWNESS displays the data skew on tables in the current database. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

You are advised to use **PGXC_GET_TABLE_SKEWNESS** to query data skew when there are less than 10,000 tables in a database.

Table 18-269 PGXC_GET_TABLE_SKEWNESS columns

| Column | Type | Description |
|------------|------------------|--|
| schemaname | Name | Schema name of a table |
| tablename | Name | Name of a table |
| totalsize | Numeric | Total size of a table, in bytes |
| avgsz | numeric(1000, 0) | Average table size (total table size divided by the number of DNs), which is the ideal size of tables distributed on each DN |
| maxratio | numeric(10,3) | Ratio of the maximum table size on a single DN to the value of avgsz . |
| minratio | numeric(10,3) | Ratio of the minimum table size on a single DN to avgsz |
| skewsize | Bigint | Table skew rate (the maximum table size on a single DN minus the minimum table size on a single DN) |
| skewratio | numeric(10,3) | Table skew rate (skewsize/avgsz) |

| Column | Type | Description |
|------------|------------------|--|
| skewstddev | numeric(1000, 0) | Standard deviation of table distribution (For two tables of the same size, a larger deviation indicates a more severe skew.) |

18.3.196 PGXC_GLOBAL_TEMP_ATTACHED_PIDS

This view displays information about sessions of resources occupied by global temporary tables on CNs. This view is supported only by clusters of 8.2.1.220 and later versions.

Table 18-270 PG_GLOBAL_TEMP_ATTACHED_PIDS columns

| Column | Type | Description |
|------------|--------|------------------|
| nodename | Name | Node name |
| schemaname | Name | Schema name |
| tablename | Name | Table name |
| pid | Bigint | PID of a session |

18.3.197 PGXC_GTM_SNAPSHOT_STATUS

PGXC_GTM_SNAPSHOT_STATUS displays transaction information on the current GTM.

Table 18-271 PGXC_GTM_SNAPSHOT_STATUS columns

| Column | Type | Description |
|--------------|---------|--|
| xmin | Xid | Minimum ID of the running transactions |
| xmax | Xid | ID of the transaction next to the executed transaction with the maximum ID |
| csn | Integer | Sequence number of the transaction to be committed |
| oldestxmin | Xid | Minimum ID of the executed transactions |
| xcnt | Integer | Number of the running transactions |
| running_xids | Text | IDs of the running transactions |

18.3.198 PGXC_INSTANCE_TIME

PGXC_INSTANCE_TIME displays the running time of processes on each node in the cluster and the time consumed in each execution phase. Except the **node_name** column, the other columns are the same as those in the [PV_INSTANCE_TIME](#) view. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-272 PGXC_INSTANCE_TIME columns

| Column | Type | Description |
|-----------|---------|--------------------------|
| node_name | Text | Node name |
| stat_id | Integer | Type ID |
| stat_name | Text | Name of the runtime type |
| value | Bigint | Runtime value |

18.3.199 PGXC_LOCKWAIT_DETAIL

PGXC_LOCKWAIT_DETAIL displays detailed information about the lock wait hierarchy on each node in a cluster. If a node has multiple lock wait levels, the entire lock waiting hierarchy is displayed in sequence.

This view is supported only by clusters of version 8.1.3.200 or later.

Table 18-273 PGXC_LOCKWAIT_DETAIL columns

| Column | Type | Description |
|---------------------|----------|---|
| level | Integer | Level in the lock wait hierarchy. The value starts with 1 and increases by 1 when there is a wait relationship. |
| node_name | Name | Node name, corresponding to the node_name column in the pgxc_node table. |
| lock_wait_hierarchy | Text | Lock wait hierarchy, in the format of <i>node-name.process-ID->waiting-process-ID->waiting-process-ID->...</i> |
| lock_type | Text | Type of the locked object |
| database | OID | OID of the database where the locked object is. |
| relation | OID | OID of the relationship of the locked object. |
| page | Integer | Page index in a relationship |
| tuple | Smallint | Row number of a page. |
| virtual_xid | Text | Virtual ID of a transaction. |

| Column | Type | Description |
|---------------------|--------------------------|--|
| transaction_id | Xid | Transaction ID. |
| class_id | OID | OID of the system catalog that contains the object. |
| obj_id | OID | OID of the object within its system catalog. |
| obj_subid | Smallint | Column number of a table |
| virtual_transaction | Text | Virtual ID of the transaction holding or waiting for the lock. |
| pid | Bigint | ID of the thread holding or awaiting this lock |
| mode | Text | Lock level |
| granted | Boolean | Indicates whether a lock is held. |
| fastpath | Boolean | Indicates whether to obtain a lock using FASTPATH. |
| wait_for_pid | Bigint | ID of the thread where a lock conflict occurs. |
| conflict_mode | Text | Level of the conflicted lock held by the thread where it is |
| query_id | Bigint | ID of a query statement. |
| query | Text | Query statement |
| application_name | Text | Name of the application connected to the backend |
| backend_start | Timestamp with time zone | Startup time of the backend process, that is, the time when the client connects to the server |
| xact_start | Timestamp with time zone | Start time of the current transaction |
| query_start | Timestamp with time zone | Start time of the active query |
| state | Text | Overall state of the backend |
| waittime | Timestamp with time zone | Timestamp when the lock wait starts.
This column is available only in clusters of version 9.1.0.200 or later. |
| holdtime | Timestamp with time zone | Timestamp when the lock starts to be obtained.
This column is available only in clusters of version 9.1.0.200 or later. |

Example

Step 1 Connect to the DN, start a transaction, and run the following command:

```
begin;select * from t1;
```

Step 2 Connect to the CN in another window and truncate table **t1**.

```
truncate t1;
```

In this case, truncation is blocked.

Step 3 Open another window to connect to the CN and run the **select * from pgxc_lockwait_detail;** command.

```
SELECT * FROM PGXC_LOCKWAIT_DETAIL;
level | node_name | lock_wait_hierarchy | lock_type | database | relation | page | tuple |
virtual_xid | transaction_id | class_id | obj_id | obj_subid | virtual_transaction | p
id | mode | granted | fastpath | wait_for_pid | conflict_mode | query_id
| query | application_name | backend_start |
xact_start | query_start | state
-----+-----+-----+-----+-----+-----+-----+-----+

----End

18.3.200 PGXC_INSTR_UNIQUE_SQL

PGXC_INSTR_UNIQUE_SQL displays the complete Unique SQL statistics of all CN nodes in the cluster.

Only the system administrator can access this view. The columns in this view are the same as those in the **GS_INSTR_UNIQUE_SQL** view. For details about columns in the view, see [Table 18-274](#).

Table 18-274 GS_INSTR_UNIQUE_SQL columns

| Column | Type | Description |
|-----------|---------|---|
| node_name | Name | Name of the CN that receives SQL statements |
| node_id | Integer | Node ID, which is the same as the value of node_id in the pgxc_node table |

| Column | Type | Description |
|-------------------|--------|---|
| user_name | Name | Username |
| user_id | OID | User ID |
| unique_sql_id | Bigint | Normalized Unique SQL ID |
| query | Text | Normalized SQL text |
| n_calls | Bigint | Number of successful execution times |
| min_elapse_time | Bigint | Minimum running time of the SQL statement in the database (unit: μ s) |
| max_elapse_time | Bigint | Maximum running time of SQL statements in the database (unit: μ s) |
| total_elapse_time | Bigint | Total running time of SQL statements in the database (unit: μ s) |
| n_returned_rows | Bigint | Row activity - Number of rows in the result set returned by the SELECT statement |
| n_tuples_fetched | Bigint | Row activity - Randomly scan rows (column-store tables/foreign tables are not counted.) |
| n_tuples_returned | Bigint | Row activity - Sequential scan rows (Column-store tables/foreign tables are not counted.) |
| n_tuples_inserted | Bigint | Row activity - Inserted rows |
| n_tuples_updated | Bigint | Row activity - Updated rows |
| n_tuples_deleted | Bigint | Row activity - Deleted rows |
| n_blocks_fetched | Bigint | Block access times of the buffer, that is, physical read/I/O |
| n_blocks_hit | Bigint | Block hits of the buffer, that is, logical read/cache |

| Column | Type | Description |
|---------------------|--------|--|
| n_soft_parse | Bigint | Number of soft parsing times (cache plan) |
| n_hard_parse | Bigint | Number of hard parsing times (generation plan) |
| db_time | Bigint | Valid DB execution time, including the waiting time and network sending time. If multiple threads are involved in query execution, the value of DB_TIME is the sum of DB_TIME of multiple threads (unit: μ s). |
| cpu_time | Bigint | CPU execution time, excluding the sleep time (unit: μ s) |
| execution_time | Bigint | SQL execution time in the query executor, DDL statements, and statements (such as Copy statements) that are not executed by the executor are not counted (unit: μ s). |
| parse_time | Bigint | SQL parsing time (unit: μ s) |
| plan_time | Bigint | SQL generation plan time (unit: μ s) |
| rewrite_time | Bigint | SQL rewriting time (unit: μ s) |
| pl_execution_time | Bigint | Execution time of the plpgsql procedural language function (unit: μ s) |
| pl_compilation_time | Bigint | Compilation time of the plpgsql procedural language function (unit: μ s) |

| Column | Type | Description |
|---------------|--------------------------|---|
| net_send_time | Bigint | Network time, including the time spent by the CN in sending data to the client and the time spent by the DN in sending data to the CN (unit: μ s) |
| data_io_time | Bigint | File I/O time (unit: μ s) |
| first_time | Timestamp with time zone | Time of the first SQL statement execution |
| last_time | Timestamp with time zone | Time of the last SQL statement execution |

18.3.201 PGXC_LOCK_CONFLICTS

PGXC_LOCK_CONFLICTS displays information about conflicting locks in the cluster.

When a lock is waiting for another lock or another lock is waiting for this one, a lock conflict occurs.

Currently, **PGXC_LOCK_CONFLICTS** collects only information about locks whose **locktype** is **relation**, **partition**, **page**, **tuple**, or **transactionid**.

Table 18-275 PGXC_LOCK_CONFLICTS columns

| Column | Type | Description |
|----------|------|--|
| locktype | Text | Type of the locked object |
| nodename | Name | Name of the node where the locked object resides |
| dbname | Name | Name of the database where the locked object resides. The value is NULL if the locked object is a transaction. |
| nspname | Name | Name of the namespace of the locked object |
| relname | Name | Name of the relation targeted by the lock. The value is NULL if the object is not a relation or part of a relation. |
| partname | Name | Name of the partition targeted by the lock. The value is NULL if the locked object is not a partition. |

| Column | Type | Description |
|---------------|--------------------------|--|
| page | Integer | Number of the page targeted by the lock.
The value is NULL if the locked object is neither a page nor a tuple. |
| tuple | Smallint | Number of the tuple targeted by the lock.
The value is NULL if the locked object is not a tuple. |
| transactionid | Xid | ID of the transaction targeted by the lock.
The value is NULL if the locked object is not a transaction. |
| username | Name | Name of the user who applies for the lock |
| gxid | Xid | ID of the transaction that applies for the lock |
| xactstart | Timestamp with time zone | Start time of the transaction that applies for the lock |
| queryid | Bigint | Latest query ID of the thread that applies for the lock |
| query | Text | Latest query statement of the thread that applies for the lock |
| pid | Bigint | ID of the thread that applies for the lock |
| mode | Text | Lock mode |
| granted | Boolean | <ul style="list-style-type: none">• TRUE if the lock has been held• FALSE if the lock is still waiting for another lock |

18.3.202 PGXC_LWLOCKS

PGXC_LWLOCK offers details on lightweight locks that are currently held or being waited for by all instances in the cluster. This view is supported only by 9.1.0.200 and later cluster versions.

Table 18-276 PGXC_LWLOCKS columns

| Column | Type | Description |
|----------|---------|--|
| nodename | Name | Name of the node where the locked object resides |
| pid | Bigint | ID of the backend thread |
| query_id | Bigint | ID of a query |
| lwtid | Integer | Lightweight thread ID of the backend thread |

| Column | Type | Description |
|--------------|---------|--|
| reqlockid | Integer | ID of the lightweight lock that is being requested by the current thread |
| reqlock | Text | Name of the lightweight lock corresponding to reqlockid |
| heldlocknums | Integer | Number of lightweight locks obtained by the current thread |
| heldlockid | Integer | Lightweight lock ID obtained by the current thread |
| heldlock | Text | Name of the lightweight lock corresponding to heldlockid |
| heldlockmode | Text | Lightweight lock mode corresponding to heldlockid |

Example

Use the **PGXC_LWLOCKS** view to get details on lightweight locks that are currently held or being waited for by all instances in the cluster.

```
SELECT * FROM pgxc_lwlocks;
nodename | pid | query_id | lwtid | reqlockid | reqlock | heldlocknums | heldlockid |
heldlock | heldlockmode
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
datanode1 | 139810224193360 | 78250043525924188 | 54844 | | | 1 | 76390 |
BUFFER_POOL_LWLOCK | Shared
datanode1 | 139810224198200 | 78250043525924886 | 54922 | | | 1 | 957438 |

datanode2 | 140262654050288 | 0 | 54832 | | | 1 | 7 |
WALWriteLock | Exclusive
datanode2 | 140262654052488 | 78250043525923195 | 54847 | | | 1 | 15862 |
BUFFER_POOL_LWLOCK | Shared
(4 rows)
```

18.3.203 PGXC_MEMORY_DEBUG_INFO

PGXC_MEMORY_DEBUG_INFO displays memory error information for each node in the current cluster when executing jobs, making it easy to locate memory error issues. When an error message "memory is temporarily unavailable" is prompted during statement execution, this view can be used to query memory error information for all nodes, which is the same as the memory error information displayed in the log. This view is supported only by clusters of version 8.3.0 or later.

NOTICE

This view only displays the most recent cluster information for errors, and repeated error information will be overwritten. If the same query requests memory multiple times and errors occur, the information will not be updated.

Table 18-277 PGXC_MEMORY_DEBUG_INFO columns

| Column | Type | Description |
|-------------|--------|--|
| node_name | Text | Instance name, including CNs and DN. |
| query_id | Bigint | ID of the query that is currently requesting memory. |
| memory_info | Text | Current instance's memory usage, including: <ul style="list-style-type: none">• process_used_memory: memory size used by the DWS process.• max_dynamic_memory: maximum dynamic memory.• dynamic_used_memory: used dynamic memory.• dynamic_peak_memory: dynamic peak value of memory.• dynamic_used_shrctx: maximum dynamic shared memory context.• dynamic_peak_shrctx: dynamic peak value of shared memory context.• shared_used_memory: used shared memory.• cstore_used_memory: memory size used for column store.• comm_used_memory: memory size used by the communication library.• comm_peak_memory: peak value of memory used by the communication library.• other_used_memory: memory size used by other components.• topsql_used_memory: memory size used by topsql.• large_storage_memory: memory size used for column-store compression and decompression.• os_totalmem: total memory size of the operating system.• os_freemem: remaining memory size of the operating system. |
| summary | Text | The total estimated memory consumption and actual memory consumption of jobs on the instance. |

| Column | Type | Description |
|-----------------|--------------------------|--|
| abnormal_query | Text | Thread ID and query ID with abnormal memory usage, including two cases:
1. Session with the maximum current memory usage.
2. Session with the largest difference between estimated memory and actual memory usage. |
| abnormal_memory | Text | Memory block with the highest usage, including the maximum shared memory context usage and the maximum common memory context usage. |
| top_thread | Text | Information on the top three threads with the highest memory usage:
context name : memory block currently in use.
contextlevel : context level.
sessType : type of the top-level context node.
totalsize[274,13,260]MB : total memory, released memory, and used memory size of the current memory context, in MB. |
| create_time | Timestamp with time zone | Time when the memory shortage error occurred. |

18.3.204 PGXC_NODE_ENV

PGXC_NODE_ENV displays the environmental variables information about all nodes in a cluster.

Table 18-278 PGXC_NODE_ENV columns

| Column | Type | Description |
|---------------|---------|---|
| node_name | Text | Names of all nodes in the cluster. |
| host | Text | Host names of all nodes in the cluster. |
| process | Integer | Process IDs of all nodes in the cluster. |
| port | Integer | Port numbers of all nodes in the cluster. |
| installpath | Text | Installation directory of all nodes in the cluster. |
| datapath | Text | Data directories of all nodes in the cluster. |
| log_directory | Text | Log directories of all nodes in the cluster. |

18.3.205 PGXC_NODE_STAT_RESET_TIME

PGXC_NODE_STAT_RESET_TIME displays the time when statistics of each node in the cluster are reset. All columns except **node_name** are the same as those in the [GS_NODE_STAT_RESET_TIME](#) view. This view is accessible only to users with system administrators rights.

Table 18-279 PGXC_NODE_STAT_RESET_TIME columns

| Column | Type | Description |
|------------|-----------|---|
| node_name | Text | Node name |
| reset_time | Timestamp | Time when statistics on each node are reset |

18.3.206 PGXC_OBS_IO_SCHEDULER_STATS

PGXC_OBS_IO_SCHEDULER_STATS displays the latest real-time statistics about read/write requests of the OBS I/O Scheduler. This system view is supported only by clusters of version 9.1.0 or later.

Table 18-280 PGXC_OBS_IO_SCHEDULER_STATS columns

| Column | Type | Description |
|---------------------|------|--|
| node_name | Text | Node name. |
| io_type | Char | Type of I/O operation, including: <ul style="list-style-type: none">• r: read.• w: write.• s: file operation. |
| current_bps | INT8 | Current bandwidth rate, in KB/s. |
| best_bps | INT8 | Best bandwidth rate achieved recently, in KB/s. |
| waiting_request_num | Int | Number of queued requests currently waiting. |
| mean_request_size | INT8 | Average length of requests processed recently, in KB. |
| total_token_num | Int | Total number of I/O tokens. |
| available_token_num | Int | Number of available I/O tokens. |
| total_worker_num | Int | Total number of working threads. |
| idle_worker_num | Int | Number of idle working threads. |

Example

Step 1 Query statistics about read requests of OBS I/O Scheduler on each node:

```
SELECT * FROM pgxc_obs_io_scheduler_stats WHERE io_type = 'r' ORDER BY node_name;
```

| node_name | io_type | current_bps | best_bps | waiting_request_num | mean_request_size | total_token_num | available_token_num | total_worker_num | idle_worker_num |
|--------------|---------|-------------|----------|---------------------|-------------------|-----------------|---------------------|------------------|-----------------|
| dn_6001_6002 | r | 26990 | 26990 | 0 | 215 | 18 | 16 | | |
| dn_6003_6004 | r | 21475 | 21475 | 10 | 190 | 30 | 30 | | |
| dn_6005_6006 | r | 12384 | 12384 | 36 | 133 | 30 | 27 | | |

According to the result, this is a snapshot of the statistics at a certain time point when the current I/O scheduler reads I/Os. At this time, the bandwidth is increasing, and **current_bps** is equal to **best_bps**. Take **dn_6003_6004** as an example. You can see that there are queuing requests on the current DN. The value of **total_token_num** is the same as that of **available_token_num**, indicating that the I/O scheduler has not started to process these requests when the view is queried.

Step 2 Wait for a while and initiate the query again.

```
SELECT * FROM pgxc_obs_io_scheduler_stats WHERE io_type = 'r' ORDER BY node_name;
```

| node_name | io_type | current_bps | best_bps | waiting_request_num | mean_request_size | total_token_num | available_token_num | total_worker_num | idle_worker_num |
|--------------|---------|-------------|----------|---------------------|-------------------|-----------------|---------------------|------------------|-----------------|
| dn_6001_6002 | r | 13228 | 26990 | 0 | 609 | 18 | 18 | | |
| dn_6003_6004 | r | 15717 | 21475 | 0 | 622 | 30 | 30 | | |
| dn_6005_6006 | r | 18041 | 21767 | 0 | 609 | 30 | 30 | | |

When the queue is empty and the value of **available_token_num** is equal to that of **total_token_num**, it indicates that the I/O scheduler has finished processing all requests and there are no new requests in line. The **current_bps** value is not 0 because it represents the average bandwidth (in bit/s) over a three-second period. Therefore, the displayed value reflects the data from three seconds ago.

Step 3 After a short period of time, the query result is as follows. The value of **current_bps** changes to 0.

```
SELECT * FROM pgxc_obs_io_scheduler_stats WHERE io_type = 'r' ORDER BY node_name;
```

| node_name | io_type | current_bps | best_bps | waiting_request_num | mean_request_size | total_token_num | available_token_num | total_worker_num | idle_worker_num |
|--------------|---------|-------------|----------|---------------------|-------------------|-----------------|---------------------|------------------|-----------------|
| dn_6001_6002 | r | 0 | 26990 | 0 | 609 | 18 | 18 | | |
| dn_6003_6004 | r | 0 | 21475 | 0 | 622 | 30 | 30 | | |
| dn_6005_6006 | r | 0 | 21767 | 0 | 609 | 30 | 30 | | |

----End

18.3.207 PGXC_OBS_IO_SCHEDULER_PERIODIC_STATS

PGXC_OBS_IO_SCHEDULER_PERIODIC_STATS provides statistics on the number of requests and flow control information for different types of OBS I/O Scheduler requests, including read, write, and file operations. This system view is supported only by clusters of version 9.1.0 or later.

The first query result shows the statistics from the cluster startup to the query time, with detailed columns listed in the table below.

Table 18-281 PGXC_OBS_IO_SCHEDULER_PERIODIC_STATS columns

| Column | Type | Description |
|--------------------------|--------------|---|
| node_name | Name | Name of a CN or DN, for example, dn_6001_6002 . |
| io_type | Char | Type of I/O operation, including: <ul style="list-style-type: none">• R: read• W: write• S: file operation |
| recent_throttled_req_num | Int | Number of times flow control was applied between two query views. |
| total_throttled_req_num | Int | Total number of times flow control was applied. |
| last_throttled_dur(s) | INT8 | Time interval since the last occurrence of flow control. |
| waiting_req_num | Int | Number of queued requests currently waiting. |
| mean_tps | numeric(7,2) | Average TPS (transactions per second) between two query views. |
| mean_req_size(KB) | INT8 | Average length of requests between two query views, in KB. |
| mean_req_latency(ms) | INT8 | Average latency of requests between two query views, in ms. |
| max_req_latency(ms) | INT8 | Maximum latency of requests before two query views, in ms. |

| Column | Type | Description |
|----------------|------|---|
| mean_bps(KB/s) | INT8 | Average read or write speed between two query views, in KB/s. |
| duration(s) | Int | Time interval between two query views, in seconds. |

Example

Run the **SELECT * FROM pgxc_obs_io_scheduler_periodic_stats** statement to query the view content. The following is an example of the query result:

```
SELECT * FROM pgxc_obs_io_scheduler_periodic_stats;
```

| node_name | io_type | recent_throttled_req_num | total_throttled_req_num | last_throttled_dur(s) | waiting_req_num | mean_tps | mean_req_size(KB) | mean_req_latency(ms) | max_req_latency(ms) | mean_bps(KB/s) | duration(s) |
|-----------|---------|--------------------------|-------------------------|-----------------------|-----------------|----------|-------------------|----------------------|---------------------|----------------|-------------|
|-----------|---------|--------------------------|-------------------------|-----------------------|-----------------|----------|-------------------|----------------------|---------------------|----------------|-------------|

| dn_6001_6002 S | | dn_6001_6002 R | | dn_6001_6002 W | | cn_5001 S | | cn_5001 R | | cn_5001 W | |
|------------------|------|------------------|------|------------------|------|-------------|-----|-------------|------|-------------|------|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 207 | 0 | 0 | 0 | 288 |
| 155 | 155 | 155 | 155 | 155 | 155 | 155 | 519 | 155 | 155 | 155 | 288 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0.00 | 0.00 | 0.00 | 0.00 | 0.00 | 0.00 | 0.00 | .03 | 0.00 | 0.00 | .01 | 0.00 |

To display **0** before the decimal point in the value of **mean_tps**, set the **display_leading_zero** option in the **behavior_compat_options** parameter.

Run the **select * from pgxc_obs_io_scheduler_periodic_stats** statement. The following information is displayed:

```
SELECT * FROM pgxc_obs_io_scheduler_periodic_stats;
```

| node_name | io_type | recent_throttled_req_num | total_throttled_req_num | last_throttled_dur(s) | waiting_req_num | mean_tps | mean_req_size(KB) | mean_req_latency(ms) | max_req_latency(ms) | mean_bps(KB/s) | duration(s) |
|-----------|---------|--------------------------|-------------------------|-----------------------|-----------------|----------|-------------------|----------------------|---------------------|----------------|-------------|
| node1 | read | 100 | 100 | 0.001 | 0 | 1000 | 1024 | 100 | 1000 | 1000 | 1000 |
| node2 | write | 50 | 50 | 0.001 | 0 | 500 | 512 | 50 | 500 | 500 | 500 |
| node3 | read | 200 | 200 | 0.001 | 0 | 2000 | 2048 | 200 | 2000 | 2000 | 2000 |
| node4 | write | 75 | 75 | 0.001 | 0 | 750 | 768 | 75 | 750 | 750 | 750 |
| node5 | read | 150 | 150 | 0.001 | 0 | 1500 | 1536 | 150 | 1500 | 1500 | 1500 |
| node6 | write | 60 | 60 | 0.001 | 0 | 600 | 614 | 60 | 600 | 600 | 600 |
| node7 | read | 180 | 180 | 0.001 | 0 | 1800 | 1856 | 180 | 1800 | 1800 | 1800 |
| node8 | write | 40 | 40 | 0.001 | 0 | 400 | 409 | 40 | 400 | 400 | 400 |
| node9 | read | 120 | 120 | 0.001 | 0 | 1200 | 1228 | 120 | 1200 | 1200 | 1200 |
| node10 | write | 90 | 90 | 0.001 | 0 | 900 | 921 | 90 | 900 | 900 | 900 |

| dn_6001_6002 | | S | | R | | W | | 0 | | 0.36 | |
|--------------|---|-----|---|-----|---|-----|---|---|---|------|--|
| dn_6001_6002 | S | 132 | 0 | 326 | 0 | 177 | 0 | 0 | 0 | 0.36 | |
| dn_6001_6002 | R | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0.00 | |
| dn_6001_6002 | W | 0 | 0 | 0 | 0 | 177 | 0 | 0 | 0 | 0.00 | |
| cn_5001 | S | 0 | 0 | 0 | 0 | 177 | 0 | 0 | 0 | 0.00 | |
| cn_5001 | R | 0 | 0 | 0 | 0 | 177 | 0 | 0 | 0 | 0.00 | |
| cn_5001 | W | 0 | 0 | 0 | 0 | 177 | 0 | 0 | 0 | 0.00 | |

18.3.208 PGXC_OS_RUN_INFO

PGXC_OS_RUN_INFO displays the OS running status of each node in the cluster. All columns except **node_name** are the same as those in the [PV_OS_RUN_INFO](#) view. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-282 PGXC_OS_RUN_INFO field columns

| Column | Type | Description |
|------------|---------|--|
| node_name | Text | Node name |
| id | Integer | ID |
| Name | Text | Name of the OS running status |
| value | Numeric | Value of the OS status |
| comments | Text | Remarks of the OS status |
| cumulative | boolean | Whether the value of the OS status is cumulative |

18.3.209 PGXC_OS_THREADS

PGXC_OS_THREADS displays thread status information under all normal nodes in the current cluster.

Table 18-283 PGXC_OS_THREADS columns

| Column | Type | Description |
|---------------|--------------------------|---|
| node_name | Text | Names of all normal nodes currently in the cluster. |
| pid | Bigint | Thread IDs currently running in the processes of all normal nodes in the cluster. |
| lwpid | Integer | Lightweight thread IDs corresponding to the PIDs. |
| thread_name | Text | Thread names corresponding to the PIDs. |
| creation_time | Timestamp with time zone | Creation time of the threads corresponding to the PIDs. |

18.3.210 PGXC_POOLER_STATUS

PGXC_POOLER_STATUS displays the pooler cache connection status of each CN in the current cluster. This view can be queried only on CNs to display the connection

cache information of the pooler module on all CNs. The **PGXC_POOLER_STATUS** view is supported only by clusters of version 8.3.0 or later.

Table 18-284 PGXC_POOLER_STATUS columns

| Column | Type | Description |
|----------------|---------|---|
| coorname | Text | Name of the CN node. |
| database | Text | Database name. |
| user_name | Text | Username. |
| tid | Bigint | ID of the thread used for the connection to the CN. |
| node_oid | Bigint | OID of the node connected to. |
| node_name | Name | Name of the node connected to. |
| in_use | boolean | Whether the connection is currently in use. The options are: <ul style="list-style-type: none">• t (true): The connection is in use.• f (false): The connection is not in use. |
| fdsock | Bigint | Peer socket. |
| remote_pid | Bigint | Peer thread ID. |
| session_params | Text | GUC session parameters issued by this connection. |

18.3.211 PGXC_PREPARED_XACTS

PGXC_PREPARED_XACTS displays the two-phase transactions in the **prepared** phase.

Table 18-285 PGXC_PREPARED_XACTS columns

| Column | Type | Description |
|--------------------|------|--|
| pgxc_prepared_xact | Text | Two-phase transactions in the prepared phase. |

18.3.212 PGXC_REDO_STAT

PGXC_REDO_STAT displays statistics on redoing Xlogs of each node in the cluster. All columns except **node_name** are the same as those in the [PV_REDO_STAT](#) view. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-286 PGXC_REDO_STAT columns

| Column | Type | Description |
|-----------|--------|-----------------------------------|
| node_name | Text | Node name |
| phywrts | Bigint | Number of physical writes |
| phyblkwrt | Bigint | Number of physical blocks written |
| writetim | Bigint | Time taken for physical writes |
| avgiotim | Bigint | Average time taken per write |
| lstiotim | Bigint | Time taken for the last write |
| miniotim | Bigint | Minimum time taken for a write |
| maxiowtm | Bigint | Maximum time taken for a write |

18.3.213 PGXC_REL_IOSTAT

PGXC_REL_IOSTAT displays disk read/write statistics on each node in the cluster. This view is accessible only to users with system administrators rights.

Table 18-287 PGXC_REL_IOSTAT columns

| Column | Type | Description |
|-----------|--------|-------------------------|
| node_name | Text | Node name |
| phyrds | Bigint | Number of disk reads |
| phywrts | Bigint | Number of disk writes |
| phyblkrd | Bigint | Number of read pages |
| phyblkwrt | Bigint | Number of written pages |

18.3.214 PGXC_REPLICATION_SLOTS

PGXC_REPLICATION_SLOTS displays the replication information of DNs in the cluster. All columns except **node_name** are the same as those in the [PG_REPLICATION_SLOTS](#) view. This view is accessible only to users with system administrators rights.

Table 18-288 PGXC_REPLICATION_SLOTS columns

| Column | Type | Description |
|-----------|------|----------------------------|
| node_name | Text | Node name |
| slot_name | Text | Name of a replication node |

| Column | Type | Description |
|---------------|---------|--|
| plugin | Name | Name of the output plug-in of the logical replication slot |
| slot_type | Text | Type of a replication node |
| datoid | OID | OID of the database on the replication node |
| database | Name | Name of the database on the replication node |
| active | boolean | Whether the replication node is active |
| xmin | Xid | Transaction ID of the replication node |
| catalog_xmin | Text | ID of the earliest-decoded transaction corresponding to the logical replication slot |
| restart_lsn | Text | Xlog file information on the replication node |
| dummy_standby | boolean | Whether the replication node is the dummy standby node |

18.3.215 PGXC_RESPOOL_RUNTIME_INFO

PGXC_RESPOOL_RUNTIME_INFO displays the running information about all resource pool jobs on all CNs.

Table 18-289 PGXC_RESPOOL_RUNTIME_INFO columns

| Column | Type | Description |
|-----------|------|---|
| nodename | Name | CN name. |
| nodegroup | Name | Name of the logical cluster the resource pool belongs to. The default cluster is installation . |
| rpname | Name | Resource pool name. |
| ref_count | Int | Number of jobs that reference the resource pool. This count includes both controlled and uncontrolled jobs. |
| fast_run | Int | Number of jobs currently running in the resource pool's fast lane. |
| fast_wait | Int | Number of jobs currently queued in the resource pool's fast lane. |
| slow_run | Int | Number of jobs currently running in the resource pool's slow lane. |
| slow_wait | Int | Number of jobs currently queued in the resource pool's slow lane. |

18.3.216 PGXC_RESPOOL_RESOURCE_INFO

PGXC_RESPOOL_RESOURCE_INFO displays the real-time monitoring information about the resource pools on all instances.

NOTE

- On a DN, it only displays the monitoring information of the logical cluster that the DN belongs to.
- Cluster 8.2.0 and later versions provide the negative memory feedback mechanism. The CCN can decrease the estimated memory usage of statements based on their actual memory usage on DNs, improving resource utilization by reducing overestimation. However, the estimated memory usage on CNs remains unchanged. If the CCN allows more jobs to run, the total estimated memory usage in the resource pool monitoring view may exceed the memory upper limit of the resource pool.
- Only the operators occupying large memory are under statement memory control. The memory, thread initialization costs, and expression costs of the operators with small memory usage are not controlled. So the value of **used_mem** of the resource pool may exceed the value of **mem_limit** to a limited extent.

Table 18-290 PGXC_RESPOOL_RESOURCE_INFO columns

| Column | Type | Description |
|------------|------|--|
| nodename | Name | Instance name, including CNs and DNs. |
| nodegroup | Name | Name of the logical cluster of the resource pool. The default value is installation . |
| rpname | Name | Resource pool name. |
| cgroup | Name | Name of the Cgroup associated with the resource pool. |
| ref_count | Int | Number of jobs referenced by the resource pool. The number is counted regardless of whether the jobs are controlled by the resource pool. This parameter is valid only on CNs. |
| fast_run | Int | Number of running jobs in the fast lane of the resource pool. This parameter is valid only on CNs. |
| fast_wait | Int | Number of jobs queued in the fast lane of the resource pool. This parameter is valid only on CNs. |
| fast_limit | Int | Limit on the number of concurrent jobs in the fast lane in a resource pool. This parameter is valid only on CNs. |
| slow_run | Int | Number of running jobs in the slow lane of the resource pool. This parameter is valid only on CNs. |

| Column | Type | Description |
|-----------------|--------|---|
| slow_wait | Int | Number of jobs queued in the slow lane of the resource pool. This parameter is valid only on CNs. |
| slow_limit | Int | Limit on the number of concurrent jobs in the slow lane in a resource pool. This parameter is valid only on CNs. |
| used_cpu | Double | Average number of CPUs used by the resource pool in a 5s monitoring period. The value is accurate to two decimal places. <ul style="list-style-type: none">On a DN, it indicates the number of CPUs used by the resource pool on the current DN.On a CN, it indicates the total CPU usage of resource pools on all DNs. |
| cpu_limit | Int | It indicates the upper limit of available CPUs for resource pools. If the CPU share is limited, this parameter indicates the available CPUs for DWS. If the CPU limit is specified, this parameter indicates the available CPUs for associated Cgroups. <ul style="list-style-type: none">On a DN, it indicates the upper limit of available CPUs for the resource pool on the current DN.On a CN, it indicates the total upper limit of available CPUs for resource pools on all DNs. |
| used_mem | Int | Memory size used by the resource pool (unit: MB) <ul style="list-style-type: none">On a DN, it indicates the memory usage of the resource pool on the current DN.On a CN, it indicates the total memory usage of resource pools on all DNs. |
| estimate_memory | Int | Estimated memory used by the jobs running in the resource pools on the current CN. This parameter is valid only on CNs. |
| mem_limit | Int | Upper limit of available memory for the resource pool (unit: MB). <ul style="list-style-type: none">On a DN, it indicates the upper limit of available memory for the resource pool on the current DN.On a CN, it indicates the total upper limit of available memory for resource pools on all DNs. |

| Column | Type | Description |
|--------------|--------|--|
| read_kbytes | Bigint | Number of logical read bytes in the resource pool within a 5s monitoring period (unit: KB). <ul style="list-style-type: none">On a DN, it indicates the number of logical read bytes in the resource pool on the current DN.On a CN, it indicates the total logical read bytes of resource pools on all DNs. |
| write_kbytes | Bigint | Number of logical write bytes in the resource pool within a 5s monitoring period (unit: KB). <ul style="list-style-type: none">On a DN, it indicates the number of logical write bytes in the resource pool on the current DN.On a CN, it indicates the total logical write bytes of resource pools on all DNs. |
| read_counts | Bigint | Number of logical reads in the resource pool within a 5s monitoring period. <ul style="list-style-type: none">On a DN, it indicates the number of logical reads in the resource pool on the current DN.On a CN, it indicates the total number of logical reads in resource pools on all DNs. |
| write_counts | Bigint | Number of logical writes in the resource pool within a 5s monitoring period. <ul style="list-style-type: none">On a DN, it indicates the number of logical writes in the resource pool on the current DN.On a CN, it indicates the total number of logical writes in resource pools on all DNs. |
| read_speed | Double | Average logical read rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the logical read rate of the resource pool on the current DN.On a CN, it indicates the overall logical read rate of resource pools on all DNs. |
| write_speed | Double | Average logical write rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the logical write rate of the resource pool on the current DN.On a CN, it indicates the overall logical write rate of resource pools on all DNs. |

| Column | Type | Description |
|------------|--------|---|
| send_speed | Double | Average network sending rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the network sending rate of the resource pool on the current DN.On a CN, it indicates the sum of the network sending rates of the resource pool on all DNs. |
| recv_speed | Double | Average network sending rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the network sending rate of the resource pool on the current DN.On a CN, it indicates the sum of the network sending rates of the resource pool on all DNs. |

18.3.217 PGXC_RESPOOL_RESOURCE_HISTORY

PGXC_RESPOOL_RESOURCE_HISTORY is used to query historical monitoring information about resource pools on all instances.

Table 18-291 PGXC_RESPOOL_RESOURCE_HISTORY columns

| Column | Type | Description |
|-----------|-----------|--|
| nodename | Name | Instance name, including CNs and DNs |
| Timestamp | Timestamp | Time when resource pool monitoring information is persistently stored |
| nodegroup | Name | Name of the logical cluster the resource pool belongs to. The default cluster is installation . |
| rpname | Name | Resource pool name |
| cgroup | Name | Name of the Cgroup associated with the resource pool |
| ref_count | Int | Number of jobs referenced by the resource pool. The number is counted regardless of whether the jobs are controlled by the resource pool. This parameter is valid only on CNs. |
| fast_run | Int | Number of running jobs in the fast lane of the resource pool. This parameter is valid only on CNs. |
| fast_wait | Int | Number of jobs queued in the fast lane of the resource pool. This parameter is valid only on CNs. |

| Column | Type | Description |
|-----------------|--------|--|
| fast_limit | Int | Limit on the number of concurrent jobs in the fast lane in a resource pool. This parameter is valid only on CNs. |
| slow_run | Int | Number of running jobs in the slow lane of the resource pool. This parameter is valid only on CNs. |
| slow_wait | Int | Number of jobs queued in the slow lane of the resource pool. This parameter is valid only on CNs. |
| slow_limit | Int | Limit on the number of concurrent jobs in the slow lane in a resource pool. This parameter is valid only on CNs. |
| used_cpu | Double | <p>Average number of CPUs used by the resource pool in a 5s monitoring period. The value is accurate to two decimal places.</p> <ul style="list-style-type: none">On a DN, it indicates the number of CPUs used by the resource pool on the current DN.On a CN, it indicates the total CPU usage of resource pools on all DNs. |
| cpu_limit | Int | <p>It indicates the upper limit of available CPUs for resource pools. If the CPU share is limited, this parameter indicates the available CPUs for DWS. | used_mem | Int | <p>Memory used by the resource pool, in MB</p> <ul style="list-style-type: none">On a DN, it indicates the memory usage of the resource pool on the current DN.On a CN, it indicates the total memory usage of resource pools on all DNs. |
| estimate_memory | Int | Estimated memory used by the jobs running in the resource pools on the current CN. This parameter is valid only on CNs. |

| Column | Type | Description |
|--------------|--------|---|
| mem_limit | Int | Upper limit of available memory for the resource pool, in MB <ul style="list-style-type: none">On a DN, it indicates the upper limit of available memory for the resource pool on the current DN.On a CN, it indicates the total upper limit of available memory for resource pools on all DNs. |
| read_kbytes | Bigint | Number of logical read bytes in the resource pool within a 5s monitoring period, in KB <ul style="list-style-type: none">On a DN, it indicates the number of logical read bytes in the resource pool on the current DN.On a CN, it indicates the total logical read bytes of resource pools on all DNs. |
| write_kbytes | Bigint | Number of logical write bytes in the resource pool within a 5s monitoring period, in KB <ul style="list-style-type: none">On a DN, it indicates the number of logical write bytes in the resource pool on the current DN.On a CN, it indicates the total logical write bytes of resource pools on all DNs. |
| read_counts | Bigint | Number of logical reads in the resource pool within a 5s monitoring period <ul style="list-style-type: none">On a DN, it indicates the number of logical reads in the resource pool on the current DN.On a CN, it indicates the total number of logical reads in resource pools on all DNs. |
| write_counts | Bigint | Number of logical writes in the resource pool within a 5s monitoring period. <ul style="list-style-type: none">On a DN, it indicates the number of logical writes in the resource pool on the current DN.On a CN, it indicates the total number of logical writes in resource pools on all DNs. |
| read_speed | Double | Average logical read rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the logical read rate of the resource pool on the current DN.On a CN, it indicates the overall logical read rate of resource pools on all DNs. |

| Column | Type | Description |
|-------------|--------|---|
| write_speed | Double | Average logical write rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the logical write rate of the resource pool on the current DN.On a CN, it indicates the overall logical write rate of resource pools on all DNs. |
| send_speed | Double | Average network sending rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the network sending rate of the resource pool on the current DN.On a CN, it indicates the sum of the network sending rates of the resource pool on all DNs. |
| recv_speed | Double | Average network receiving rate of a resource pool in a 5-second monitoring period, in KB/s <ul style="list-style-type: none">On a DN, it indicates the network receiving rate of the resource pool on the current DN.On a CN, it indicates the sum of the network receiving rates of the resource pool on all DNs. |

18.3.218 PGXC_ROW_TABLE_IO_STAT

PGXC_ROW_TABLE_IO_STAT provides I/O statistics of all row-store tables of the database on all CNs and DNs in the cluster. Except the **nodename** column of the name type added in front of each row, the names, types, and sequences of other columns are the same as those in the **GS_ROW_TABLE_IO_STAT** view. For details about the columns, see [Table 18-292](#).

Table 18-292 GS_ROW_TABLE_IO_STAT columns

| Column | Type | Description |
|------------|--------|---|
| schemaname | Name | Namespace of a table |
| relname | Name | Name of a table |
| heap_read | Bigint | Number of blocks logically read in the heap |
| heap_hit | Bigint | Number of block hits in the heap |
| idx_read | Bigint | Number of blocks logically read in the index |
| idx_hit | Bigint | Number of block hits in the index |
| toast_read | Bigint | Number of blocks logically read in the TOAST table |

| Column | Type | Description |
|-----------|--------|--|
| toast_hit | Bigint | Number of block hits in the TOAST table |
| tidx_read | Bigint | Number of indexes logically read in the TOAST table |
| tidx_hit | Bigint | Number of index hits in the TOAST table |

18.3.219 PGXC_RUNNING_XACTS

PGXC_RUNNING_XACTS displays information about running transactions on each node in the cluster. The content is the same as that displayed in [PG_RUNNING_XACTS](#).

Table 18-293 PGXC_RUNNING_XACTS columns

| Column | Type | Description |
|-------------|---------|---|
| handle | Integer | Handle corresponding to the transaction in GTM |
| gxid | Xid | Transaction ID |
| state | tinyint | Transaction status (3 : prepared or 0 : starting) |
| node | Text | Node name |
| xmin | Xid | Minimum transaction ID xmin on the node |
| vacuum | boolean | Whether the current transaction is lazy vacuum |
| timeline | Bigint | Number of database restarts |
| prepare_xid | Xid | Transaction ID in prepared state. If the status is not prepared , the value is 0 . |
| pid | Bigint | Thread ID corresponding to the transaction |
| next_xid | Xid | Transaction ID sent from a CN to a DN |

18.3.220 PGXC_SETTINGS

PGXC_SETTINGS displays the database running status of each node in the cluster. All columns except **node_name** are the same as those in the [PG_SETTINGS](#) view. This view is accessible only to users with system administrators rights.

Table 18-294 PGXC_SETTINGS columns

| Column | Type | Description |
|------------|---------|---|
| node_name | Text | Node name |
| Name | Text | Parameter name |
| setting | Text | Current value of the parameter |
| unit | Text | Implicit unit of the parameter |
| category | Text | Logical group of the parameter |
| short_desc | Text | Brief description of the parameter |
| extra_desc | Text | Detailed description of the parameter |
| context | Text | Context of parameter values including internal , postmaster , sighup , backend , superuser , and user . |
| vartype | Text | Parameter type. It can be bool , enum , integer , real , or string . |
| source | Text | Method of assigning the parameter value |
| min_val | Text | Minimum value of the parameter. If the parameter type is not numeric data, the value of this column is null. |
| max_val | Text | Maximum value of the parameter. If the parameter type is not numeric data, the value of this column is null. |
| enumvals | Text[] | Valid values of an enum-typed parameter. If the parameter type is not enum, the value of this column is null. |
| boot_val | Text | Default parameter value used upon the database startup |
| reset_val | Text | Default parameter value used upon the database reset |
| sourcefile | Text | Configuration file used to set parameter values. If parameter values are not configured using the configuration file, the value of this column is null. |
| sourceline | Integer | Row number of the configuration file for setting parameter values. If parameter values are not configured using the configuration file, the value of this column is null. |

18.3.221 PGXC_SESSION_WLMSTAT

PGXC_SESSION_WLMSTAT displays load management information about ongoing jobs executed on each CN in the current cluster.

Table 18-295 PGXC_SESSION_WLMSTAT columns

| Column | Type | Description |
|------------------|---------|--|
| nodename | Name | Node name. |
| datid | OID | OID of the database the backend is connected to. |
| datname | Name | Name of the database the backend is connected to. |
| threadid | Bigint | ID of the backend thread. |
| processid | Integer | PID of a backend thread |
| usesysid | OID | OID of the user who logged in to the backend |
| appname | Text | Name of the application that is connected to the backend |
| username | Name | Name of the user logged in to the backend |
| priority | Bigint | Priority of Cgroup where the statement is located |
| attribute | Text | Statement attributes <ul style="list-style-type: none">• Ordinary: default attribute of a statement before it is parsed by the database• Simple: simple statements• Complicated: complicated statements• Internal: internal statement of the database |
| block_time | Bigint | Pending duration of the statements by now (unit: s) |
| elapsed_time | Bigint | Actual execution duration of the statements by now (unit: s) |
| total_cpu_time | Bigint | Total CPU usage duration of the statement on the DN in the last period (unit: s) |
| cpu_skew_percent | Integer | CPU usage inclination ratio of the statement on the DN in the last period |
| statement_mem | Integer | Estimated memory required for statement execution. This column is reserved. |
| active_points | Integer | Number of concurrently active points occupied by the statement in the resource pool |
| dop_value | Integer | DOP value obtained by the statement from the resource pool |

| Column | Type | Description |
|---------------|------|--|
| control_group | Text | Cgroup currently used by the statement |
| status | Text | Status of a statement, including: <ul style="list-style-type: none">• pending• running: The statement is being executed.• finished: The execution is finished normally. (If enqueue is set to StoredProc or Transaction, this state indicates that only some of the jobs in the statement have been executed. This state persists until the finish of this statement.)• aborted: terminated unexpectedly• active: normal status except for those above• unknown: unknown status |
| enqueue | Text | Current queuing status of the statements, including: <ul style="list-style-type: none">• Global: global queuing.• Respool: resource pool queuing.• CentralQueue: queuing on the CCN• Transaction: The statements are in the same transaction block.• StoredProc: The statement is in a stored procedure.• None: not in a queue• Forced None: The transaction block statement or stored procedure statement is being forcibly executed because the statement waiting time exceeds the specified value. |
| resource_pool | Name | Current resource pool where the statements are located. |
| query | Text | Text of this backend's most recent query. If state is active , this column shows the executing query. In all other states, it shows the last query that was executed. |
| isplana | Bool | In logical cluster mode, indicates whether a statement occupies the resources of other logical clusters. The default value is f , indicating that resources of other logical clusters are not occupied. |
| node_group | Text | Logical cluster of the user running the statement |

| Column | Type | Description |
|--------|------|--|
| lane | Text | Fast or slow lane for statement queries. <ul style="list-style-type: none">• fast: fast lane• slow: slow lane• none: not controlled |

18.3.222 PGXC_STAT_ACTIVITY

PGXC_STAT_ACTIVITY displays information about the query performed by the current user on all the CNs in the current cluster.

Table 18-296 PGXC_STAT_ACTIVITY columns

| Column | Type | Description |
|------------------|---------|---|
| coorname | Text | Name of the CN in the current cluster |
| datid | OID | OID of the database that the user session connects to in the backend |
| datname | Name | Name of the database that the user session connects to in the backend |
| pid | Bigint | ID of the backend thread |
| lwtid | Integer | Lightweight thread ID of the backend thread |
| usesysid | OID | OID of the user logging in to the backend |
| username | Name | Name of the user logging in to the backend |
| application_name | Text | Name of the application connected to the backend |
| client_addr | inet | IP address of the client connected to the backend. If this column is null , it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| client_hostname | Text | Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will only be non-null for IP connections, and only when log_hostname is enabled. |

| Column | Type | Description |
|---------------|--------------------------|---|
| client_port | Integer | TCP port number that the client uses for communication with this backend, or -1 if a Unix socket is used |
| backend_start | Timestamp with time zone | Startup time of the backend process, that is, the time when the client connects to the server |
| xact_start | Timestamp with time zone | Time when the current transaction was started, or NULL if no transaction is active. If the current query is the first of its transaction, this column is equal to the query_start column. |
| query_start | Timestamp with time zone | Time when the currently active query was started, or time when the last query was started if state is not active |
| state_change | Timestamp with time zone | Time for the last status change |
| waiting | boolean | The value is t if the backend is waiting for a lock or node. Otherwise, the value is f . |

| Column | Type | Description |
|---------|------|--|
| enqueue | Text | <p>Queuing status of a statement. Its value can be:</p> <ul style="list-style-type: none">• waiting in global queue: The statement is in the global concurrent queues.• waiting in respool queue: The statement is queuing in the resource pool. The scenarios are as follows:<ol style="list-style-type: none">1. When dynamic load balancing is enabled, the number of simple jobs exceeds the upper limit (max_dop) of concurrent jobs on the fast lane.2. When dynamic load balancing is disabled, the number of simple jobs exceeds the upper limit (max_dop) of concurrent jobs on the fast lane or the number of complex jobs exceeds the upper limit of concurrent jobs on the slow lane.• waiting in ccn queue: The job is in the CCN queue, which may be global memory queuing, slow lane memory queuing, or concurrent queuing.• Empty or no waiting queue: The statement is running. |

| Column | Type | Description |
|-----------------|--------|--|
| state | Text | <p>Overall state of the backend. Its value can be:</p> <ul style="list-style-type: none">• active: The backend is executing a query.• idle: The backend is waiting for a new client command.• idle in transaction: The backend is in a transaction, but there is no statement being executed in the transaction.• idle in transaction (aborted): The backend is in a transaction, but there are statements failed in the transaction.• fastpath function call: The backend is executing a fast-path function.• disabled: This state is reported if track_activities is disabled in this backend. <p>NOTE
Only system administrators can view the session status of their accounts. The state information of other accounts is empty.</p> |
| resource_pool | Name | Resource pool used by the user |
| stmt_type | Text | Type of a user statement |
| query_id | Bigint | ID of a query |
| query | Text | Text of this backend's most recent query
If the state is active , this column shows the executing query. In all other states, it shows the last query that was executed. |
| connection_info | Text | A string in JSON format recording the driver type, driver version, driver deployment path, and process owner of the connected database (for details, see connection_info). |

Example

Run the following command to view blocked query statements.

```
SELECT datname,username,state,query FROM PGXC_STAT_ACTIVITY WHERE waiting = true;
```

Check the working status of the snapshot thread.

```
SELECT application_name,backend_start,state_change,state,query FROM PGXC_STAT_ACTIVITY WHERE  
application_name='WDRSnapshot';
```

View the running query statements.

```
SELECT datname,username,state,pid FROM PGXC_STAT_ACTIVITY;  
datname | username | state | pid  
-----+-----+-----+-----  
gaussdb | Ruby    | active | 140298793514752  
gaussdb | Ruby    | active | 140298718004992  
gaussdb | Ruby    | idle   | 140298650908416  
gaussdb | Ruby    | idle   | 140298625742592  
gaussdb | dbadmin | active | 140298575406848  
(5 rows)
```

View the number of session connections that have been used by postgres. **1** indicates the number of session connections that have been used by **postgres**.

```
SELECT COUNT(*) FROM PGXC_STAT_ACTIVITY WHERE DATNAME='postgres';  
count  
-----  
1  
(1 row)
```

18.3.223 PGXC_STAT_BAD_BLOCK

PGXC_STAT_BAD_BLOCK displays statistics about page or CU verification failures after all nodes in a cluster are started.

Table 18-297 PGXC_STAT_BAD_BLOCK columns

| Column | Type | Description |
|--------------|--------------------------|----------------------------------|
| nodename | Text | Node name. |
| databaseid | Integer | Database OID. |
| tablespaceid | Integer | Tablespace OID. |
| relfilenode | Integer | File object ID. |
| forknum | Integer | File type. |
| error_count | Integer | Number of verification failures. |
| first_time | Timestamp with time zone | Time of the first occurrence. |
| last_time | Timestamp with time zone | Time of the latest occurrence. |

18.3.224 PGXC_STAT_BGWRITER

PGXC_STAT_BGWRITER displays statistics on the background writer of each node in the cluster. All columns except **node_name** are the same as those in the [PG_STAT_BGWRITER](#) view. This view is accessible only to users with system administrators rights.

Table 18-298 PGXC_STAT_BGWRITER columns

| Column | Type | Description |
|-----------------------|--------------------------|---|
| node_name | Text | Node name |
| checkpoints_timed | Bigint | Number of scheduled checkpoints that have been performed |
| checkpoints_req | Bigint | Number of requested checkpoints that have been performed |
| checkpoint_write_time | Double precision | Time spent on writing files to the disk during checkpoints, in milliseconds |
| checkpoint_sync_time | Double precision | Time spent on synchronizing data to the disk during checkpoints, in milliseconds |
| buffers_checkpoint | Bigint | Number of buffers written during checkpoints |
| buffers_clean | Bigint | Number of buffers written by the background writer |
| maxwritten_clean | Bigint | Number of times the background writer stopped a cleaning scan because it had written too many buffers |
| buffers_backend | Bigint | Number of buffers written directly by a backend |
| buffers_backend_fsync | Bigint | Number of times that a backend has to execute fsync |
| buffers_alloc | Bigint | Number of buffers allocated |
| stats_reset | Timestamp with time zone | Time at which these statistics were reset |

18.3.225 PGXC_STAT_DATABASE

PGXC_STAT_DATABASE displays the database status and statistics of each node in the cluster. All columns except **node_name** are the same as those in the **PG_STAT_DATABASE** view. This view is accessible only to users with system administrators rights.

Table 18-299 PGXC_STAT_DATABASE columns

| Column | Type | Description |
|-----------|------|--------------|
| node_name | Text | Node name |
| datid | OID | Database OID |

| Column | Type | Description |
|---------------|---------|---|
| datname | Name | Database name |
| numbackends | Integer | Number of backends currently connected to this database on the current node. This is the only column in this view that reflects the current state value. All columns return the accumulated value since the last reset. |
| xact_commit | Bigint | Number of transactions in this database that have been committed on the current node |
| xact_rollback | Bigint | Number of transactions in this database that have been rolled back on the current node |
| blks_read | Bigint | Number of disk blocks read in this database on the current node |
| blks_hit | Bigint | Number of disk blocks found in the buffer cache on the current node, that is, the number of blocks hit in the cache. (This only includes hits in the DWS buffer cache, not in the file system cache.) |
| tup_returned | Bigint | Number of rows returned by queries in this database on the current node |
| tup_fetched | Bigint | Number of rows fetched by queries in this database on the current node |
| tup_inserted | Bigint | Number of rows inserted in this database on the current node |
| tup_updated | Bigint | Number of rows updated in this database on the current node |
| tup_deleted | Bigint | Number of rows deleted from this database on the current node |
| conflicts | Bigint | Number of queries canceled due to database recovery conflicts on the current node (conflicts occurring only on the standby server). For details, see PG_STAT_DATABASE_CONFLICTS . |
| temp_files | Bigint | Number of temporary files created by this database on the current node. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the log_temp_files setting. |

| Column | Type | Description |
|----------------|--------------------------|---|
| temp_bytes | Bigint | Size of temporary files written to this database on the current node. All temporary files are counted, regardless of why the temporary file was created, and regardless of the log_temp_files setting. |
| deadlocks | Bigint | Number of deadlocks in this database on the current node |
| blk_read_time | Double precision | Time spent reading data file blocks by backends in this database on the current node, in milliseconds |
| blk_write_time | Double precision | Time spent writing into data file blocks by backends in this database on the current node, in milliseconds |
| stats_reset | Timestamp with time zone | Time when the database statistics are reset on the current node |

18.3.226 PGXC_STAT_OBJECT

PGXC_STAT_OBJECT displays statistics and autovacuum efficiency information about tables of all instances in a cluster. This system view is supported only by clusters of version 8.2.1 or later.

Table 18-300 PGXC_STAT_OBJECT columns

| Column | Type | Reference | Description |
|--------------|------|--------------------------------------|--|
| nodename | Name | - | Node name |
| datname | Name | - | Name of the database where the table is located. |
| relnamespace | Name | - | Name of the schema where the table is located. |
| relname | Name | - | Table name. |
| partname | Name | - | Partition name of the partitioned table |
| databaseid | OID | PG_DATA
BASE.oid | Database OID. |
| relid | OID | PG_CLAS
S.oid | Table OID. It is the OID of the primary table for a partitioned table. |

| Column | Type | Reference | Description |
|------------------------------------|--------------------------|----------------------------------|---|
| partid | OID | PG_PARTITION.oid | Partition OID. If the table is not partitioned, the value is 0 . |
| numscans | Bigint | - | Number of times that sequential scans are started. |
| tuples_returned | Bigint | - | Number of visible tuples fetched by sequential scans. |
| tuples_fetched | Bigint | - | Number of visible tuples fetched. |
| tuples_inserted | Bigint | - | Number of inserted records. |
| tuples_updated | Bigint | - | Number of updated records. |
| tuples_deleted | Bigint | - | Number of deleted records. |
| tuples_hot_updated | Bigint | - | Number of HOT updates. |
| n_live_tuples | Bigint | - | Number of visible tuples. |
| last_autovacuum_begin_n_dead_tuple | Bigint | - | Number of tuples deleted before Autovacuum is executed. |
| n_dead_tuples | Bigint | - | Number of tuples deleted after Autovacuum is successful. |
| changes_since_analyze | Bigint | - | Last data modification time after Analyze. |
| blocks_fetched | Bigint | - | Number of selected pages. |
| blocks_hit | Bigint | - | Number of scanned pages. |
| cu_mem_hit | Bigint | - | Number of CU memory hits. |
| cu_hdd_sync | Bigint | - | Times that CUs are synchronously read from disks. |
| cu_hdd_async | Bigint | - | Times that CUs are asynchronously read from disks. |
| data_changed_timestamp | Timestamp with time zone | - | Last data modification time. |

| Column | Type | Reference | Description |
|------------------------------|--------------------------|-----------|--|
| data_access_timestamp | Timestamp with time zone | - | Last access time of a table. |
| analyze_timestamp | Timestamp with time zone | - | Last Analyze time. |
| analyze_count | Bigint | - | Total number of Analyze times. |
| autovac_analyze_timestamp | Timestamp with time zone | - | Last Autoanalyze time. |
| autovac_analyze_count | Bigint | - | Total number of Autoanalyze times. |
| vacuum_timestamp | Timestamp with time zone | - | Time of the latest Vacuum. |
| vacuum_count | Bigint | - | Total number of Vacuum times. |
| autovac_vacuum_timestamp | Timestamp with time zone | - | Last Autovacuum time. |
| autovac_vacuum_count | Bigint | - | Total number of Autovacuum times. |
| autovacuum_success_count | Bigint | - | Total number of successful Autovacuum operations. |
| last_autovacuum_time_cost | Bigint | - | Time spent on the latest successful Autovacuum, in microseconds. |
| avg_autovacuum_time_cost | Bigint | - | Average execution time of successful Autovacuum operations. Unit: μ s. |
| last_autovacuum_failed_count | Bigint | - | Total number of autovacuum failures since the last successful Autovacuum. |
| last_autovacuum_trigger | Smallint | - | Triggering mode of the latest autovacuum, which helps maintenance personnel determine the Vacuum status. |

| Column | Type | Reference | Description |
|----------------------------------|--------|-----------|---|
| last_autovacuum_oldestxmin | Bigint | - | oldestxmin after the latest successful Autovacuum execution. If the table-level oldestxmin feature is enabled, this field records the value of oldestxmin used by the latest (AUTO)VACUUM of the table. |
| last_autovacuum_scan_pages | Bigint | - | Number of pages last scanned by autovacuum (only for row-store tables). |
| last_autovacuum_dirty_pages | Bigint | - | Number of pages last modified by Autovacuum (only for row-store tables). |
| last_autovacuum_clear_deadtuples | Bigint | - | Number of dead tuples last cleared by Autovacuum (only for row-store tables) |
| sum_autovacuum_scan_pages | Bigint | - | Total number of pages scanned by Autovacuum since database initialization (only for row-store tables). |
| sum_autovacuum_dirty_pages | Bigint | - | Number of pages modified by Autovacuum since database initialization (only for row-store tables). |
| sum_autovacuum_clear_deadtuples | Bigint | - | Total number of dead tuples cleared by Autovacuum since database initialization (only for row-store tables). |
| last_autovacuum_begin_cu_size | Bigint | - | Size of the CU file before the latest Autovacuum operation (only for column-store tables). |
| last_autovacuum_cu_size | Bigint | - | Size of the CU file after the latest Autovacuum (only for column-store tables). |
| last_autovacuum_rewrite_size | Bigint | - | Size of the column-store file last rewritten by autovacuum (only for column-store tables). |
| last_autovacuum_clear_size | Bigint | - | Size of the column-store file last cleared by Autovacuum (only for column-store tables). |

| Column | Type | Reference | Description |
|-------------------------------------|--------------------------|-----------|---|
| last_autovacuum_clear_cbtree_tuples | Bigint | - | Number of cbtree tuples last cleared by Autovacuum (only for column-store tables). |
| sum_autovacuum_rewrite_size | Bigint | - | Total size of column-store files rewritten by Autovacuum since database initialization (only for column-store tables). |
| sum_autovacuum_clear_size | Bigint | - | Total size of column-store files cleared by Autovacuum since database initialization (only for column-store tables). |
| sum_autovacuum_clear_cbtree_tuples | Bigint | - | Total number of cbtree tuples cleared by Autovacuum since database initialization (only for column-store tables). |
| last_autovacuum_csn | Bigint | - | If the table-level oldestxmin feature is enabled, this field records the CSN value corresponding to the latest oldestxmin value used by the table (AUTO)VACUUM . |
| last_reference_timestamp | Timestamp with time zone | - | Last access time of a table. (This field is supported only by cluster versions 8.3.0 and later.)

This parameter corresponds to the latest time between data_changed_time_stamp (last modification time) and data_access_timestamp (last access time) in PG_STAT_OBJECT . |
| extra1 | Bigint | - | Reserved field 1. |
| extra2 | Bigint | - | Reserved field 2. |
| extra3 | Bigint | - | Reserved field 3. |
| extra4 | Bigint | - | Reserved field 4. |

18.3.227 PGXC_STAT_REPLICATION

PGXC_STAT_REPLICATION displays the log synchronization status of each node in the cluster. All columns except **node_name** are the same as those in the [PG_STAT_REPLICATION](#) view. This view is accessible only to users with system administrators rights.

Table 18-301 PGXC_STAT_REPLICATION columns

| Column | Type | Description |
|--------------------------|--------------------------|---|
| node_name | Text | Node name |
| pid | Bigint | PID of the thread |
| usesysid | OID | User system ID |
| username | Name | Username |
| application_name | Text | Program name |
| client_addr | inet | Client address |
| client_hostname | Text | Client name |
| client_port | Integer | Client port number |
| backend_start | Timestamp with time zone | Program start time |
| state | Text | Log replication state (catch-up or consistent streaming) |
| sender_sent_location | Text | Location where the sender sends logs |
| receiver_write_location | Text | Location where the receiver writes logs |
| receiver_flush_location | Text | Location where the receiver flushes logs |
| receiver_replay_location | Text | Location where the receiver replays logs |
| sync_priority | Integer | Priority of synchronous duplication (0 indicates asynchronization) |
| sync_state | Text | Synchronization state (asynchronous duplication, synchronous duplication, or potential synchronization) |

18.3.228 PGXC_STAT_TABLE_DIRTY

PGXC_STAT_TABLE_DIRTY displays statistics about all the tables on all the CNs and DN in the current cluster, and the dirty page rate of tables on a single CN or DN. This view is supported only by clusters of version 8.1.3 or later.

 NOTE

The statistics of this view depend on the **ANALYZE** operation. To obtain the most accurate information, perform the **ANALYZE** operation on the table first.

Table 18-302 PGXC_STAT_TABLE_DIRTY columns

| Column | Type | Description |
|-------------------|-------------------------|--|
| nodename | Text | Node name |
| schema | Name | Schema name of the table |
| tablename | Name | Table name |
| partname | Name | Partition name of the partitioned table |
| last_vacuum | timestampwith time zone | Time of the last manual VACUUM |
| last_autovacuum | timestampwith time zone | Time of the last AUTOVACUUM |
| last_analyze | timestampwith time zone | Time when the last non-automatic rolling analysis is performed. |
| last_autoanalyze | timestampwith time zone | Time when the last automatic rolling analysis is performed. |
| vacuum_count | Bigint | Number of times VACUUM operations |
| autovacuum_count | Bigint | Number of AUTOVACUUM operations |
| analyze_count | Bigint | Number of ANALYZE operations |
| autoanalyze_count | Bigint | Number of times of automatically performing the ANALYZE operation |
| n_tup_ins | Bigint | Number of rows inserted |
| n_tup_upd | Bigint | Number of rows updated |
| n_tup_del | Bigint | Number of rows deleted |
| n_tup_hot_upd | Bigint | Number of rows with HOT updates |
| n_tup_change | Bigint | Number of changed rows after ANALYZE |
| n_live_tup | Bigint | Estimated number of live rows |
| n_dead_tup | Bigint | Estimated number of dead rows |

| Column | Type | Description |
|-------------------|-------------------------|---|
| dirty_rate | Bigint | Dirty page rate of a single CN or DN |
| last_data_changed | timestampwith time zone | Time when a table was last modified

This column is left empty in cluster 8.2.0 and later versions. For details, see PG_STAT_ALL_TABLES . |

Suggestion

- Before running **VACUUM FULL** on a system catalog with a high dirty page rate, ensure that no user is performing operations on it.
- You are advised to run **VACUUM FULL** to tables (excluding system catalogs) whose dirty page rate exceeds 80% or run it based on service scenarios.

Scenarios

1. Query the overall dirty page rate of all the user tables in a database.

```
select
  t1.schema,
  t1.tablename,
  t1.total_ins,
  t1.total_upd,
  t1.total_del,
  t1.total_tup_hot_upd,
  t1.total_change,
  t1.total_live,
  t1.total_dead,
  t1.total_dirty_rate,
  t1.max_dirty,
  t2.max_node,
  t1.min_dirty,
  t2.min_node
from
  (select
    a.schema,
    a.tablename,
    sum(a.n_tup_ins) as total_ins,
    sum(a.n_tup_upd) as total_upd,
    sum(a.n_tup_del) as total_del,
    sum(a.n_tup_hot_upd) as total_tup_hot_upd,
    sum(a.n_tup_change) as total_change,
    sum(a.n_live_tup) as total_live,
    sum(a.n_dead_tup) as total_dead,
    Round((total_dead / (total_dead + total_live + 0.0001) * 100),2) AS total_dirty_rate,
    max(a.dirty_rate) as max_dirty,
    min(a.dirty_rate) as min_dirty
    from pg_catalog.pgxc_stat_table_dirty a where a.partname is null and a.schema not in
    ('pg_toast','cstore','gs_logical_cluster','sys','dbms_om','information_schema','pg_catalog','dbms_output',
    'dbms_random','utl_raw','utl_raw dbms_sql','dbms_lob') group by a.tablename, a.schema
  ) t1,
  (select distinct
    tablename, schema,
    first_value(nodename) over(partition by tablename, schema order by dirty_rate) as min_node,
    first_value(nodename) over(partition by tablename, schema order by dirty_rate desc) as max_node
    from (select * from pg_catalog.pgxc_stat_table_dirty)) t2
where t1.tablename = t2.tablename and t1.schema = t2.schema;
```

2. Query the overall dirty page rate of all the tables (user tables and system catalogs) in a database.

```
select
  t1.schema,
  t1.tablename,
  t1.total_ins,
  t1.total_upd,
  t1.total_del,
  t1.total_tup_hot_upd,
  t1.total_change,
  t1.total_live,
  t1.total_dead,
  t1.total_dirty_rate,
  t1.max_dirty,
  t2.max_node,
  t1.min_dirty,
  t2.min_node
from
  (select
    a.schema,
    a.tablename,
    sum(a.n_tup_ins) as total_ins,
    sum(a.n_tup_upd) as total_upd,
    sum(a.n_tup_del) as total_del,
    sum(a.n_tup_hot_upd) as total_tup_hot_upd,
    sum(a.n_tup_change) as total_change,
    sum(a.n_live_tup) as total_live,
    sum(a.n_dead_tup) as total_dead,
    Round((total_dead / (total_dead + total_live + 0.0001) * 100),2) AS total_dirty_rate,
    max(a.dirty_rate) as max_dirty,
    min(a.dirty_rate) as min_dirty
  from pg_catalog.pgxc_stat_table_dirty a where a.partname is null group by a.tablename, a.schema
  ) t1,
  (select distinct
    tablename, schema,
    first_value(nodename) over(partition by tablename, schema order by dirty_rate) as min_node,
    first_value(nodename) over(partition by tablename, schema order by dirty_rate desc) as max_node
  from (select * from pg_catalog.pgxc_stat_table_dirty)) t2
where t1.tablename = t2.tablename and t1.schema = t2.schema;
```

3. Query all system catalogs in a database.

```
select * from pgxc_stat_table_dirty where schema in
('pg_toast','cstore','gs_logical_cluster','sys','dbms_om','information_schema','pg_catalog','dbms_output',
dbms_random','utl_raw','utl_raw dbms_sql','dbms_lob');
```

18.3.229 PGXC_STAT_WAL

PGXC_STAT_WAL displays the WAL logs and data page traffic information of the current query. This view is supported only by clusters 8.2.0 and later versions.

Table 18-303 PGXC_STAT_WAL columns

| Column | Type | Description |
|----------------------|-----------|--|
| query_id | Bigint | ID of the current query |
| query_start | Timestamp | Start time of the query |
| global_wal | Bigint | Total number of WAL logs generated by the current query in the cluster, in bytes |
| global_avg_wal_speed | Bigint | Average rate of WAL log generation for the current query in the cluster, in byte/s |

| Column | Type | Description |
|----------------------------|--------|--|
| global_datapage | Bigint | Total size of data pages generated by the current query in the cluster, in bytes |
| global_avg_data_page_speed | Bigint | Average rate of data page generation for the current query in the cluster, in byte/s |
| min_wal_node | Text | Name of the instance group that generates the smallest volume of WAL logs in the current query |
| min_wal | Bigint | Minimum WAL logs generated by a node, in bytes |
| max_wal_node | Text | Name of the instance group that generates the largest volume of WAL logs in the current query |
| max_wal | Bigint | Maximum WAL logs generated by a node, in bytes |
| min_datapage_node | Text | Name of the instance group that generates the smallest volume of data pages in the current query |
| min_data_page | Bigint | Minimum data pages generated by a node, in bytes |
| max_datapage_node | Text | Name of the instance group that generates the largest volume of data pages in the current query |
| max_data_page | Bigint | Maximum data pages generated by a node, in bytes |
| avg_wal_per_node | Bigint | Average WAL logs generated by each node, in bytes |
| avg_datapage_per_node | Bigint | Average data pages generated by each node, in bytes |
| query | Text | Statement that is being executed |

 NOTE

When row-store data is imported in batches without indexes, the Xlogs related to logical new pages are generated during data page copy. If the volume of Xlogs is greater than the default value, flow control will be triggered.

Examples

Query the statements that are being executed in the cluster, the total volumes of WAL logs and data pages generated by these statements, their average generation rates, and their distribution on DN.

```
SELECT * FROM PGXC_STAT_WAL;  
query_id | query_start | global_wal | global_avg_wal_speed | global_datapage |  
global_avg_datapage_speed | min_wal_node | min_wal | max_wal_node | max_wal | min_datapage_node |
```

```

min_data_page | max_datapage_node | max_data_page | avg_wal_per_node |
avg_datapage_per_node | query

(2 rows)

```

18.3.230 PGXC_SQL_COUNT

PGXC_SQL_COUNT displays the node-level and user-level statistics for the SQL statements of **SELECT**, **INSERT**, **UPDATE**, **DELETE**, and **MERGE INTO** and DDL, DML, and DCL statements of each CN in a cluster in real time, identifies query types with heavy load, and measures the capability of a cluster or a node to perform a specific type of query. You can calculate QPS based on the quantities and response time of the preceding types of SQL statements at certain time points. For example, **USER1 SELECT** is counted as **X1** at T1 and as **X2** at T2. The **SELECT** QPS of the user can be calculated as follows: $(X2 - X1)/(T2 - T1)$. In this way, the system can draw cluster-user-level QPS curve graphs and determine cluster throughput, monitoring changes in the service load of each user. If there are drastic changes, the system can locate the specific statement type (such as **SELECT**, **INSERT**, **UPDATE**, **DELETE**, and **MERGE INTO**). You can also observe QPS curves to determine the time points when problems occur and then locate the problems using other tools. The curves provide a basis for optimizing cluster performance and locating problems.

Columns in the **PGXC_SQL_COUNT** view are the same as those in the **GS_SQL_COUNT** view. For details, see [Table 18-146](#).

NOTE

If a **MERGE INTO** statement can be pushed down and a DN receives it, the statement will be counted on the DN and the value of the **mergeinto_count** column will increment by 1. If the pushdown is not allowed, the DN will receive an **UPDATE** or **INSERT** statement. In this case, the **update_count** or **insert_count** column will increment by 1.

18.3.231 PGXC_TABLE_CHANGE_STAT

PGXC_TABLE_CHANGE_STAT displays the changes of all tables of the database on all CNs in the cluster. Except the **nodename** column of the name type added in front of each row, the names, types, and sequences of other columns are the same as those in the [GS_TABLE_CHANGE_STAT](#) view.

Table 18-304 PGXC_TABLE_CHANGE_STAT columns

| Column | Type | Description |
|------------|------|-----------------|
| nodename | Name | Node name |
| schemaname | Name | Table namespace |

| Column | Type | Description |
|-------------------|--------------------------|---|
| relname | Name | Table name |
| last_vacuum | Timestamp with time zone | Time when the last VACUUM operation is performed manually |
| vacuum_count | Bigint | Number of times of manually performing the VACUUM operation |
| last_autovacuum | Timestamp with time zone | Time when the last VACUUM operation is performed automatically |
| autovacuum_count | Bigint | Number of times of automatically performing the VACUUM operation |
| last_analyze | Timestamp with time zone | Time when the last non-automatic rolling analysis is performed. |
| analyze_count | Bigint | Number of times of performing the ANALYZE operation (both manually and automatically) |
| last_autoanalyze | Timestamp with time zone | Time when the last automatic rolling analysis is performed. |
| autoanalyze_count | Bigint | Number of times of automatically performing the ANALYZE operation |
| last_change | Bigint | Time when the last modification (INSERT , UPDATE , or DELETE) is performed |

18.3.232 PGXC_TABLE_STAT

PGXC_TABLE_STAT provides statistics of all tables of the database on all CNs and DN in the cluster. Except the **nodename** column of the name type added in front of each row, the names, types, and sequences of other columns are the same as those in the **GS_TABLE_STAT** view.

Table 18-305 PGXC_TABLE_STAT columns

| Column | Type | Description |
|------------|------|-----------------|
| nodename | Name | Node name |
| schemaname | Name | Table namespace |
| relname | Name | Table name |

| Column | Type | Description |
|-------------------|--------|---|
| seq_scan | Bigint | Number of sequential scans. Only row-store tables are counted. For a partitioned table, the sum of the number of scans of each partition is displayed. |
| seq_tuple_read | Bigint | Number of rows scanned in sequence. Only row-store tables are counted. |
| index_scan | Bigint | Number of index scans. Only row-store tables are counted. |
| index_tuple_read | Bigint | Number of rows scanned by the index. Only row-store tables are counted. |
| tuple_inserted | Bigint | Number of rows inserted |
| tuple_updated | Bigint | Number of rows updated |
| tuple_deleted | Bigint | Number of rows deleted |
| tuple_hot_updated | Bigint | Number of rows with HOT updates. |
| live_tuples | Bigint | Number of live tuples. Query the view on the CN. If ANALYZE is executed, the total number of live tuples in the table is displayed. Otherwise, 0 is displayed. This indicator applies only to row-store tables. |
| dead_tuples | Bigint | Number of dead tuples. Query the view on the CN. If ANALYZE is executed, the total number of dead tuples in the table is displayed. Otherwise, 0 is displayed. This indicator applies only to row-store tables. |

18.3.233 PGXC_THREAD_WAIT_STATUS

PGXC_THREAD_WAIT_STATUS displays all the call layer hierarchy relationship between threads of the SQL statements on all the nodes in a cluster, and the waiting status of the block for each thread, so that you can easily locate the causes of process response failures and similar phenomena.

The definitions of **PGXC_THREAD_WAIT_STATUS** view and **PG_THREAD_WAIT_STATUS** view are the same, because the essence of the **PGXC_THREAD_WAIT_STATUS** view is the query summary result of the **PG_THREAD_WAIT_STATUS** view on each node in the cluster.

Table 18-306 PGXC_THREAD_WAIT_STATUS columns

| Column | Type | Description |
|-----------|------|-------------------|
| node_name | Text | Current node name |

| Column | Type | Description |
|-------------|---------|---|
| db_name | Text | Database name |
| thread_name | Text | Thread name |
| query_id | Bigint | Query ID. It is equivalent to debug_query_id . |
| tid | Bigint | Thread ID of the current thread |
| lwtid | Integer | Lightweight thread ID of the current thread |
| ptid | Integer | Parent thread of the streaming thread |
| tlevel | Integer | Level of the streaming thread |
| smpid | Integer | Concurrent thread ID |
| wait_status | Text | Waiting status of the current thread. For details about the waiting status, see Table 18-239 . |
| wait_event | Text | If wait_status is acquire lock , acquire lwlock , or wait io , this column describes the lock, lightweight lock, and I/O information, respectively. If wait_status is not any of the three values, this column is empty. |

Example:

Assume you run a statement on coordinator1, and no response is returned after a long period of time. In this case, establish another connection to coordinator1 to check the thread status on it.

```
select * from pg_thread_wait_status where query_id > 0;
 node_name | db_name | thread_name | query_id |   tid   |   lwtid | ptid | tlevel | smpid |
 wait_status | wait_event
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 coordinator1 | gaussdb | gsql       | 20971544 | 140274089064208 | 22579 |    |    0 |    0 | wait node:
 datanode4 |
(1 rows)
```

Furthermore, you can view the statement working status on each node in the entire cluster. In the following example, no DNs have threads blocked, and there is a huge amount of data to be read, causing slow execution.

```
select * from pgxc_thread_wait_status where query_id=20971544;
 node_name | db_name | thread_name | query_id |   tid   |   lwtid | ptid | tlevel | smpid |
 wait_status | wait_event
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 datanode1 | gaussdb | coordinator1 | 20971544 | 139902867994384 | 22735 |    |    0 |    0 | wait
 node: datanode3 |
 datanode1 | gaussdb | coordinator1 | 20971544 | 139902838634256 | 22970 | 22735 |    5 |    0 |

(13 rows)
```

18.3.234 PGXC_TOTAL_MEMORY_DETAIL

PGXC_TOTAL_MEMORY_DETAIL displays the memory usage in the cluster. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-307 PGXC_TOTAL_MEMORY_DETAIL columns

| Column | Type | Description |
|----------|------|-------------|
| nodename | Text | Node name |

| Column | Type | Description |
|------------|------|---|
| memorytype | Text | <p>Memory name, which can be set to any of the following values:</p> <ul style="list-style-type: none">• max_process_memory: memory used by a DWS cluster instance• process_used_memory: memory used by a DWS process• max_dynamic_memory: maximum dynamic memory• dynamic_used_memory: used dynamic memory• dynamic_peak_memory: dynamic peak value of the memory• dynamic_used_shrctx: maximum dynamic shared memory context• dynamic_peak_shrctx: dynamic peak value of the shared memory context• max_shared_memory: maximum shared memory• shared_used_memory: used shared memory• max_cstore_memory: maximum memory allowed for column store• cstore_used_memory: memory used for column store• max_sctpcomm_memory: maximum memory allowed for the communication library• sctpcomm_used_memory: memory used for the communication library• sctpcomm_peak_memory: memory peak of the communication library• other_used_memory: other used memory• gpu_max_dynamic_memory: maximum GPU memory• gpu_dynamic_used_memory: sum of the available GPU memory and temporary GPU memory• gpu_dynamic_peak_memory: maximum memory used for GPU• pooler_conn_memory: memory used for pooler connections• pooler_freeconn_memory: memory used for idle pooler connections |

| Column | Type | Description |
|-------------|---------|---|
| | | <ul style="list-style-type: none">• storage_compress_memory: memory used for column-store compression and decompression• udf_reserved_memory: memory reserved for the UDF Worker process• mmap_used_memory: memory used for mmap |
| memorybytes | Integer | Size of the used memory (MB) |

18.3.235 PGXC_TOTAL_SCHEMA_INFO

PGXC_TOTAL_SCHEMA_INFO displays the schema space information of all instances in the cluster, providing visibility into the schema space usage of each instance. This view can be queried only on CNs.

Table 18-308 PGXC_TOTAL_SCHEMA_INFO columns

| Column | Type | Description |
|--------------|--------|--------------------|
| schemaname | Text | Schema name. |
| schemaid | OID | Schema OID. |
| databasename | Text | Database name. |
| databaseid | OID | Database OID. |
| nodename | Text | Instance name. |
| nodegroup | Text | Node group name. |
| usedspace | Bigint | Used space size. |
| permspace | Bigint | Space upper limit. |

18.3.236 PGXC_TOTAL_SCHEMA_INFO_ANALYZE

PGXC_TOTAL_SCHEMA_INFO_ANALYZE displays the overall schema space information of the cluster, including the total cluster space, average space of instances, skew ratio, maximum space of a single instance, minimum space of a single instance, and names of the instances with the maximum space and minimum space. It provides visibility into the schema space usage of the entire cluster. This view can be queried only on CNs.

Table 18-309 PGXC_TOTAL_SCHEMA_INFO_ANALYZE columns

| Column | Type | Description |
|--------------|---------|--|
| schemaname | Text | Schema name. |
| databasename | Text | Database name. |
| nodegroup | Text | Node group name. |
| total_value | Bigint | Total cluster space in this schema. |
| avg_value | Bigint | Average space per instance in this schema. |
| skew_percent | Integer | Skew ratio. |
| extend_info | Text | The extended information includes the maximum and minimum space values for a single instance, as well as the names of the instances with the maximum and minimum space values. |

18.3.237 PGXC_TOTAL_USER_RESOURCE_INFO

The **PGXC_TOTAL_USER_RESOURCE_INFO** view displays real-time resource consumption information of users on all instances. This view is supported only by clusters of version 8.2.0 or later.

Table 18-310 PGXC_TOTAL_USER_RESOURCE_INFO columns

| Column | Type | Description |
|-------------|---------|---|
| nodename | Name | Instance name, including CNs and DN. |
| username | Name | Username |
| used_memory | Integer | Used memory (unit: MB)
On a DN, it indicates a user's memory usage on the current DN.
On a CN, it indicates a user's total memory usage on all DNs. |

| Column | Type | Description |
|--------------|------------------|--|
| total_memory | Integer | <p>Available memory (unit: MB). 0 indicates that the available memory is not limited and depends on the maximum memory available in the database.</p> <p>On a DN, it indicates the memory available to a user on the current DN.</p> <p>On a CN, it indicates the total memory available to a user on all DNs.</p> |
| used_cpu | Double precision | <p>Number of CPU cores in use. Only the CPU usage of complex jobs in the non-default resource pool is collected, and the value is the CPU usage of the related cgroup.</p> <p>On a DN, it indicates a user's CPU core usage on the current DN.</p> <p>On a CN, it indicates a user's total CPU core usage on all DNs.</p> |
| total_cpu | Integer | <p>Total number of CPU cores of the Cgroups associated with a user.</p> <p>On a DN, it indicates the CPU cores available to a user on the current DN.</p> <p>On a CN, it indicates the total CPU cores available to a user on all DNs.</p> |
| used_space | Bigint | <p>Used permanent table storage space (unit: KB)</p> <p>On a DN, it indicates the size of the permanent table storage space used by a user on the current DN.</p> <p>On a CN, it indicates the total size of the permanent table storage space used by a user on all DNs.</p> |
| total_space | Bigint | <p>Available storage space (unit: KB). -1 indicates that the storage space is not limited.</p> <p>On a DN, it indicates the size of the permanent table storage space available to a user on the current DN.</p> <p>On a CN, it indicates the total size of the permanent table storage space available to a user on all DNs.</p> |

| Column | Type | Description |
|-------------------|--------|--|
| used_temp_space | Bigint | Used temporary table storage space (unit: KB)
On a DN, it indicates the size of the temporary table storage space used by a user on the current DN.
On a CN, it indicates the total size of the temporary table storage space used by a user on all DNs. |
| total_temp_space | Bigint | Available temporary table storage space (unit: KB). -1 indicates that the storage space is not limited.
On a DN, it indicates the size of the temporary table storage space available to a user on the current DN.
On a CN, it indicates the total size of the temporary table storage space available to a user on all DNs. |
| used_spill_space | Bigint | Size of space used for operator spill to disk, in KB.
On a DN, it indicates the space used by a user to spill operators to disk on the current DN.
On a CN, it indicates the total space used by a user's operators spilled to disk on all DNs. |
| total_spill_space | Bigint | Size of space available for operator spill to disk, in KB. The value -1 indicates that the space is not limited.
On a DN, it indicates the space available for a user to spill operators to disk on the current DN.
On a CN, it indicates the total space available for a user to spill operators to disk on all DNs. |
| read_kbytes | Bigint | On a CN, it indicates the total number of bytes logically read by a user on all DNs in the last 5 seconds, in KB.
On a DN, it indicates the total number of bytes logically read by a user from the instance startup time to the current time, in KB. |
| write_kbytes | Bigint | On a CN, it indicates the total number of bytes logically written by a user on all DNs in the last 5 seconds, in KB.
On a DN, it indicates the total number of bytes logically written by a user from the instance startup time to the current time, in KB. |

| Column | Type | Description |
|--------------|------------------|--|
| read_counts | Bigint | On a CN, it indicates the total number of logical reads performed by a user on all DNs in the last 5 seconds.
On a DN, it indicates the total number of logical reads performed by a user from the instance startup time to the current time. |
| write_counts | Bigint | On a CN, it indicates the total number of logical writes performed by a user on all DNs in the last 5 seconds.
On a DN, it indicates the total number of logical writes performed by a user from the instance startup time to the current time. |
| read_speed | Double precision | On a CN, it indicates the average logical read rate of a user on a single DN in the last 5 seconds, in KB/s.
On a DN, it indicates the average logical read rate of a user on the DN in the last 5 seconds, in KB/s. |
| write_speed | Double precision | On a CN, it indicates the average logical write rate of a user on a single DN in the last 5 seconds, in KB/s.
On a DN, it indicates the average logical write rate of a user on the DN in the last 5 seconds, in KB/s. |
| send_speed | Double precision | On a CN, it indicates the sum of the average network sending rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average network sending rate of a user on the DN in the last 5 seconds, in KB/s. |
| recv_speed | Double precision | On a CN, it indicates the sum of the average network receiving rates of a user on all DNs in the last 5 seconds, in KB/s.
On a DN, it indicates the average network receiving rate of a user on the DN in the last 5 seconds, in KB/s. |

18.3.238 PGXC_USER_TRANSACTION

PGXC_USER_TRANSACTION provides transaction information about users on all CNs. It is accessible only to users with system administrator rights. This view is valid only if the real-time resource monitoring function is enabled, that is, if [enable_resource_track](#) is **on**.

Table 18-311 PGXC_USER_TRANSACTION columns

| Column | Type | Description |
|------------------|--------|------------------------|
| node_name | Name | Node name. |
| username | Name | Username. |
| commit_counter | Bigint | Number of commits. |
| rollback_counter | Bigint | Number of rollbacks. |
| resp_min | Bigint | Minimum response time. |
| resp_max | Bigint | Maximum response time. |
| resp_avg | Bigint | Average response time. |
| resp_total | Bigint | Total response time. |

18.3.239 PGXC_VARIABLE_INFO

PGXC_VARIABLE_INFO displays information about XIDs and OIDs of all nodes in a cluster.

Table 18-312 PGXC_VARIABLE_INFO columns

| Column | Type | Description |
|---------------------------|---------|---|
| node_name | Text | Node name. |
| nextOid | OID | Next OID to be generated under this node. |
| nextXid | Xid | Next transaction OID to be generated under this node. |
| oldestXid | Xid | Oldest transaction ID for a node |
| xidVacLimit | Xid | Critical point for forcing autovacuum. |
| oldestXidDB | OID | Database OID with the minimum datafrozenxid under this node. |
| lastExtendCSNL
ogpage | Integer | Page number of the last extension of csnlog. |
| startExtendCSN
Logpage | Integer | Starting page number of the csnlog extension. |
| nextCommitSeq
No | Integer | Next CSN to be generated under this node. |
| latestCompleted
Xid | Xid | Latest transaction ID on the node after commit or rollback. |

| Column | Type | Description |
|---------------|------|---|
| startupMaxXid | Xid | Last transaction ID before the node shutdown. |

18.3.240 PGXC_WAIT_DETAIL

PGXC_WAIT_DETAIL displays detailed information about the SQL waiting hierarchy of all nodes in a cluster. This view is supported only by clusters of version 8.1.3.200 or later.

Table 18-313 PGXC_WAIT_DETAIL columns

| Column | Type | Description |
|---------------------|---------|---|
| level | Integer | Level in the wait hierarchy. The value starts with 1 and increases by 1 when there is a wait relationship. |
| lock_wait_hierarchy | Text | Wait hierarchy, in the format of <i>Node name: Process ID->Node name:Waiting process ID->Node name:Waiting process ID->...</i> |
| node_name | Text | Node name |
| db_name | Text | Database name |
| thread_name | Text | Thread name |
| query_id | Bigint | ID of a query statement |
| tid | Bigint | Thread ID of the current thread |
| lwtid | Integer | Lightweight thread ID of the current thread |
| ptid | Integer | Parent thread of the streaming thread |
| tlevel | Integer | Level of the streaming thread |
| smpid | Integer | Concurrent thread ID |
| wait_status | Text | Waiting status of the current thread |
| wait_event | Text | Virtual ID of the transaction holding or awaiting this lock |
| exec_cn | Boolean | SQL execution CN |
| wait_node | Text | Lock level |
| query | Text | Query statement |
| application_name | Text | Name of the application connected to the backend |

| Column | Type | Description |
|---------------|--------------------------|--|
| backend_start | Timestamp with time zone | Startup time of the backend process, that is, the time when the client connects to the server |
| xact_start | Timestamp with time zone | Start time of the current transaction |
| query_start | Timestamp with time zone | Start time of the active query |
| waiting | Boolean | Waiting status |
| state | Text | Overall state of the backend |
| waittime | Timestamp with time zone | Timestamp when the lock wait starts.
This column is available only in clusters of version 9.1.0.200 or later. |
| holdtime | Timestamp with time zone | Timestamp when the lock starts to be obtained.
This column is available only in clusters of version 9.1.0.200 or later. |

Example

Step 1 Connect to the CN, start a transaction, and perform the update operation.

```
begin;update td set c2=6 where c1=1;
```

Step 2 Open another window to connect to the CN, start another transaction, and perform the update operation. (Do not update the same record concurrently.)

```
begin;update td set c2=6 where c1=7;
```

In this case, the update operation is blocked.

Step 3 Open another window to connect to the CN node and create an index.

```
create index c2_key on td(c2);
```

Step 4 Run the `select * from pgxc_wait_detail;` command.

```
SELECT * FROM PGXC_WAIT_DETAIL;
level | lock_wait_hierarchy          | node_name | db_name | thread_name | query_id
| tid    | lwtid | ptid | tlevel | sm
pid | wait_status | wait_event | exec_cn | wait_node | query            | application_name |
backend_start      | xact_st
art               | query_start   | waiting | state
-----+-----+-----+-----+-----+-----+-----
+-+---+----+---+--+
+-+---+----+---+--+

18.3.241 PGXC_WAIT_EVENTS

PGXC_WAIT_EVENTS displays statistics on the waiting status and events of each node in the cluster. The content is the same as that displayed in [GS_WAIT_EVENTS](#). This view is accessible only to users with system administrators rights.

Table 18-314 PGXC_WAIT_EVENTS columns

| Column | Type | Description |
|-----------------|--------|--|
| nodename | Name | Node name. |
| type | Text | Event type, which can be STATUS , LOCK_EVENT , LWLOCK_EVENT , or IO_EVENT |
| event | Text | Event name. For details, see PG_THREAD_WAIT_STATUS . |
| wait | Bigint | Number of times an event occurs. This column and all the columns below are values accumulated during process running. |
| failed_wait | Bigint | Number of waiting failures. In the current version, this column is used only for counting timeout errors and waiting failures of locks such as LOCK and LWLOCK . |
| total_wait_time | Bigint | Total duration of the event |
| avg_wait_time | Bigint | Average duration of the event |
| max_wait_time | Bigint | Maximum wait time of the event |

| Column | Type | Description |
|---------------|--------|--------------------------------|
| min_wait_time | Bigint | Minimum wait time of the event |

18.3.242 PGXC_WLM_OPERATOR_HISTORY

PGXC_WLM_OPERATOR_HISTORY displays operator information when a job is finished on all CNs. This view is used to query data from DWS, and the data in the database is cleared periodically every 3 minutes.

Only the system administrator or the preset role **gs_role_read_all_stats** can access this view. For details about columns in the view, see [Table 18-315](#).

Table 18-315 GS_WLM_OPERATOR_INFO columns

| Column | Type | Description |
|---------------------|--------------------------|---|
| nodename | Text | Name of the CN where the statement is executed |
| queryid | Bigint | Internal query_id used for statement execution |
| pid | Bigint | Backend thread ID |
| plan_node_id | Integer | plan_node_id of the execution plan of a query |
| plan_node_name | Text | Name of the operator corresponding to plan_node_id |
| start_time | Timestamp with time zone | Time when an operator starts to process the first data record |
| duration | Bigint | Total execution time of an operator. The unit is ms. |
| query_dop | Integer | Degree of parallelism (DOP) of the current operator |
| estimated_rows | Bigint | Number of rows estimated by the optimizer |
| tuple_processed | Bigint | Number of elements returned by the current operator |
| min_peak_memory | Integer | Minimum peak memory used by the current operator on all DN. The unit is MB. |
| max_peak_memory | Integer | Maximum peak memory used by the current operator on all DN. The unit is MB. |
| average_peak_memory | Integer | Average peak memory used by the current operator on all DN. The unit is MB. |

| Column | Type | Description |
|---------------------|---------|--|
| memory_skew_percent | Integer | Memory usage skew of the current operator among DNs |
| min_spill_size | Integer | Minimum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| max_spill_size | Integer | Maximum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| average_spill_size | Integer | Average spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_cpu_time | Bigint | Minimum execution time of the operator on all DNs. The unit is ms. |
| max_cpu_time | Bigint | Maximum execution time of the operator on all DNs. The unit is ms. |
| total_cpu_time | Bigint | Total execution time of the operator on all DNs. The unit is ms. |
| cpu_skew_percent | Integer | Skew of the execution time among DNs. |
| warning | Text | Warning. The following warnings are displayed:
1. Sort/SetOp/HashAgg/HashJoin spill
2. The max spill size exceeds the alarm size 256MB
3. The max broadcast size exceeds the alarm size 100MB
4. Early spill
5. Spill times is greater than 3
6. Spill on memory adaptive
7. Hash table conflict
8. NestLoop in hashjoin |

18.3.243 PGXC_WLM_OPERATOR_INFO

PGXC_WLM_OPERATOR_INFO displays the operator information of completed jobs executed on CNs. The data in this view is obtained from [GS_WLM_OPERATOR_INFO](#).

Only the system administrator or the **gs_role_read_all_stats** role can access this view.

NOTICE

The **PGXC_WLM_OPERATOR_INFO** view can be queried only in the **postgres** database. If the view is queried in other databases, an error is reported.

GS_WLM_OPERATOR_INFO lists the columns in the **PGXC_WLM_OPERATOR_INFO** view.

Table 18-316 GS_WLM_OPERATOR_INFO columns

| Column | Type | Description |
|---------------------|--------------------------|--|
| nodename | Text | Name of the CN where the statement is executed |
| queryid | Bigint | Internal query_id used for statement execution |
| pid | Bigint | Backend thread ID |
| plan_node_id | Integer | plan_node_id of the execution plan of a query |
| plan_node_name | Text | Name of the operator corresponding to plan_node_id |
| start_time | Timestamp with time zone | Time when an operator starts to process the first data record |
| duration | Bigint | Total execution time of an operator. The unit is ms. |
| query_dop | Integer | Degree of parallelism (DOP) of the current operator |
| estimated_rows | Bigint | Number of rows estimated by the optimizer |
| tuple_processed | Bigint | Number of elements returned by the current operator |
| min_peak_memory | Integer | Minimum peak memory used by the current operator on all DNs. The unit is MB. |
| max_peak_memory | Integer | Maximum peak memory used by the current operator on all DNs. The unit is MB. |
| average_peak_memory | Integer | Average peak memory used by the current operator on all DNs. The unit is MB. |
| memory_skew_percent | Integer | Memory usage skew of the current operator among DNs |

| Column | Type | Description |
|--------------------|---------|--|
| min_spill_size | Integer | Minimum spilled data among all DN's when a spill occurs. The unit is MB. The default value is 0. |
| max_spill_size | Integer | Maximum spilled data among all DN's when a spill occurs. The unit is MB. The default value is 0. |
| average_spill_size | Integer | Average spilled data among all DN's when a spill occurs. The unit is MB. The default value is 0. |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_cpu_time | Bigint | Minimum execution time of the operator on all DN's. The unit is ms. |
| max_cpu_time | Bigint | Maximum execution time of the operator on all DN's. The unit is ms. |
| total_cpu_time | Bigint | Total execution time of the operator on all DN's. The unit is ms. |
| cpu_skew_percent | Integer | Skew of the execution time among DN's. |
| warning | Text | Warning. The following warnings are displayed:
1. Sort/SetOp/HashAgg/HashJoin spill
2. The max spill size exceeds the alarm size 256MB
3. The max broadcast size exceeds the alarm size 100MB
4. Early spill
5. Spill times is greater than 3
6. Spill on memory adaptive
7. Hash table conflict
8. NestLoop in hashjoin |

18.3.244 PGXC_WLM_OPERATOR_STATISTICS

PGXC_WLM_OPERATOR_STATISTICS displays the operator information of jobs being executed on CN's. The system administrator can query job operator information of all users in the cluster, while common users can query only their own job operator information.

[Table 18-160](#) lists the columns in the **PGXC_WLM_OPERATOR_STATISTICS** view.

Table 18-317 GS_WLM_OPERATOR_STATISTICS columns

| Column | Type | Description |
|---------------------|--------------------------|---|
| queryid | Bigint | Internal query_id used for statement execution |
| pid | Bigint | ID of the backend thread |
| plan_node_id | Integer | plan_node_id of the execution plan of a query |
| plan_node_name | Text | Name of the operator corresponding to plan_node_id . The maximum length of the operator name is 127 characters (excluding format characters such as spaces). |
| start_time | Timestamp with time zone | Time when the operator starts to be executed for the first time. |
| duration | Bigint | Total execution time of the operator from the start to the end, in milliseconds. |
| status | Text | Execution status of the current operator. The value can be waiting , running , or finished . |
| query_dop | Integer | DOP of the current operator |
| estimated_rows | Bigint | Number of rows estimated by the optimizer. If the number of returned estimated rows exceeds int64_max, int64_max is displayed. |
| tuple_processed | Bigint | Total number of elements returned by the current operator on all DN. If the estimated number of returned rows exceeds int64_max, int64_max is displayed. |
| min_peak_memory | Integer | Minimum peak memory used by the current operator on all DN. The unit is MB. |
| max_peak_memory | Integer | Maximum peak memory used by the current operator on all DN. The unit is MB. |
| average_peak_memory | Integer | Average peak memory used by the current operator on all DN. The unit is MB. |
| memory_skew_percent | Integer | Memory usage skew of the current operator among DN |
| min_spill_size | Integer | Minimum logical spilled data among all DN when a spill occurs, in MB. The default value is 0. |
| max_spill_size | Integer | Maximum logical spilled data among all DN when a spill occurs, in MB. The default value is 0. |

| Column | Type | Description |
|--------------------|---------|--|
| average_spill_size | Integer | Average logical spilled data among all DNs when a spill occurs, in MB. The default value is 0. |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_cpu_time | Bigint | Minimum execution time of the operator on all DNs. The unit is ms. |
| max_cpu_time | Bigint | Maximum execution time of the operator on all DNs. The unit is ms. |
| total_cpu_time | Bigint | Total execution time of the operator on all DNs. The unit is ms. |
| cpu_skew_percent | Integer | Skew of the execution time among DNs. |
| warning | Text | Warning. The following warnings are displayed:
1. Sort/SetOp/HashAgg/HashJoin spill
2. The max spill size exceeds the alarm size 256MB
3. The max broadcast size exceeds the alarm size 100MB
4. Early spill
5. Spill times is greater than 3
6. Spill on memory adaptive
7. Hash table conflict
8. NestLoop in hashjoin |
| parent_id | Integer | Parent node ID of the operator node. |
| exec_count | Integer | Maximum number of times that the operator node can be executed on all DNs. |
| progress | Text | Progress information of the operator. For the first operator, it is the overall progress of the job. For other operators, it is the progress of the current operator. |
| min_net_size | Bigint | Minimum network communication data volume (KB) of the operator on all DNs. It mainly applies to network operators. |
| max_net_size | Bigint | Maximum network communication data volume (KB) of the operator on all DNs. It mainly applies to network operators. |

| Column | Type | Description |
|-------------------|--------|--|
| total_net_size | Bigint | Total network communication data volume (KB) of the operator on all DNs. It mainly applies to network operators. |
| min_read_bytes | Bigint | Minimum amount of data read by the operator from disks on all DNs. The unit is KB. |
| max_read_bytes | Bigint | Maximum amount of data read by the operator from disks on all DNs. The unit is KB. |
| total_read_bytes | Bigint | Total amount of data read by the operator from disks on all DNs, in KB. |
| min_write_bytes | Bigint | Minimum amount of data written by the operator to disks on all DNs. The unit is KB. |
| max_write_bytes | Bigint | Maximum amount of data written by the operator to disks on all DNs. The unit is KB. |
| total_write_bytes | Bigint | Total amount of data written by the operator to disks on all DNs, in KB. |

18.3.245 PGXC_WLM_SESSION_INFO

PGXC_WLM_SESSION_INFO displays load management information for completed jobs executed on all CNs. The view information comes from the [GS_WLM_SESSION_INFO](#) system catalog.

NOTICE

The **PGXC_WLM_SESSION_INFO** view can be queried only in the **postgres** database. If the view is queried in other databases, an error is reported.

Table 18-318 PGXC_WLM_SESSION_INFO columns

| Column | Type | Description |
|------------|------|--|
| datid | OID | OID of the database the backend is connected to |
| dbname | Text | Name of the database the backend is connected to |
| schemaname | Text | Schema name |
| nodename | Text | Name of the CN where the statement is run |
| username | Text | User name used for connecting to the backend |

| Column | Type | Description |
|---------------------|--------------------------|--|
| application_name | Text | Name of the application that is connected to the backend |
| client_addr | inet | IP address of the client connected to this backend. If this column is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| client_hostname | Text | Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will only be non-null for IP connections, and only when log_hostname is enabled. |
| client_port | Integer | TCP port number used by the client to communicate with the backend. If a Unix socket is used, it is -1 . |
| query_band | Text | Job type, which can be set using the GUC parameter query_band and is a null string by default. |
| block_time | Bigint | Duration that a statement is blocked before being executed, including the statement parsing and optimization duration. The unit is ms. |
| start_time | Timestamp with time zone | Time when the statement starts to be executed |
| finish_time | Timestamp with time zone | Time when the statement execution ends |
| duration | Bigint | Execution time of a statement. The unit is ms. |
| estimate_total_time | Bigint | Estimated execution time of a statement. The unit is ms. |
| status | Text | Final statement execution status. Its value can be finished (normal) or aborted (abnormal). The statement status here is the execution status of the database server. If the statement is successfully executed on the database server but an error is reported in the result set, the statement status is finished . |
| abort_info | Text | Exception information displayed if the final statement execution status is aborted . |
| resource_pool | Text | Resource pool used by the user |

| Column | Type | Description |
|----------------------|---------|--|
| control_group | Text | Cgroup used by the statement |
| estimate_memory | Integer | Estimated memory used by a statement on a single instance. The unit is MB. |
| min_peak_memory | Integer | Minimum memory peak of a statement across all DNs. The unit is MB. |
| max_peak_memory | Integer | Maximum memory peak of a statement across all DNs. The unit is MB. |
| average_peak_memory | Integer | Average memory usage during statement execution. The unit is MB. |
| memory_skew_percent | Integer | Memory usage skew of a statement among DNs |
| spill_info | Text | Spill information for the statement on all DNs. The options are:
None : The statement has not been spilled to disks on any DNs.
All : The statement has been spilled to disks on all DNs.
[<i>a</i>:<i>b</i>] : The statement has been spilled to disks on <i>a</i> of <i>b</i> DNs. |
| min_spill_size | Integer | Minimum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0 . |
| max_spill_size | Integer | Maximum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0 . |
| average_spill_size | Integer | Average spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0 . |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_dn_time | Bigint | Minimum execution time of a statement across all DNs. The unit is ms. |
| max_dn_time | Bigint | Maximum execution time of a statement across all DNs. The unit is ms. |
| average_dn_time | Bigint | Average execution time of a statement across all DNs. The unit is ms. |
| dn_time_skew_percent | Integer | Execution time skew of a statement among DNs. |

| Column | Type | Description |
|-------------------|---------|--|
| min_cpu_time | Bigint | Minimum CPU time of a statement across all DNs. The unit is ms. |
| max_cpu_time | Bigint | Maximum CPU time of a statement across all DNs. The unit is ms. |
| total_cpu_time | Bigint | Total CPU time of a statement across all DNs. The unit is ms. |
| cpu_skew_percent | Integer | CPU time skew of a statement among DNs. |
| min_peak_iops | Integer | Minimum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| max_peak_iops | Integer | Maximum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| average_peak_iops | Integer | Average IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| iops_skew_percent | Integer | I/O skew across DNs |
| warning | Text | Warning. The following warnings and warnings related to SQL self-diagnosis tuning are displayed:
<ol style="list-style-type: none">1. The max spill size exceeds the alarm size 256MB2. The max broadcast size exceeds the alarm size 100MB3. Early spill4. Spill times is greater than 35. Spill on memory adaptive6. Hash table conflict7. NestLoop in hashjoin |
| queryid | Bigint | Internal query ID used for statement execution |
| query | Text | Statement to be executed. A maximum of 64 KB of strings can be retained. |

| Column | Type | Description |
|---------------------|--------|--|
| query_plan | Text | Execution plan of a statement
Specification restrictions:
1. Execution plans are displayed only for DML statements.
2. In 8.2.1.100 and later versions, the number of data binding times is added to the execution plans of Parse Bind Execute (PBE) statements to facilitate statement analysis. The number of data binding times is displayed in the format of PBE bind times: Times . |
| node_group | Text | Logical cluster of the user running the statement |
| pid | Bigint | PID of the backend thread for the statement. |
| lane | Text | Fast/Slow lane where the statement is executed |
| unique_sql_id | Bigint | ID of the normalized unique SQL |
| session_id | Text | Unique identifier of a session in the database system. Its format is session_start_time.tid.node_name . |
| min_read_bytes | Bigint | Minimum I/O read bytes of a statement across all DN. The unit is byte. |
| max_read_bytes | Bigint | Maximum I/O read bytes of a statement across all DN. The unit is byte. |
| average_read_bytes | Bigint | Average I/O read bytes of a statement across all DN. |
| min_write_bytes | Bigint | Minimum I/O write bytes of a statement across all DN. |
| max_write_bytes | Bigint | Maximum I/O write bytes of a statement across all DN. |
| average_write_bytes | Bigint | Average I/O write bytes of a statement across all DN. |
| recv_pkg | Bigint | Total number of communication packages received by a statement across all DN. |
| send_pkg | Bigint | Total number of communication packages sent by a statement across all DN. |
| recv_bytes | Bigint | Total received data of the statement stream, in byte. |

| Column | Type | Description |
|-----------------------------|--------------|---|
| send_bytes | Bigint | Total sent data of the statement stream, in byte. |
| stmt_type | Text | Query type corresponding to the statement. |
| except_info | Text | Information about the exception rule triggered by the statement. |
| parse_time | Bigint | Total parsing time before the statement is queued (including lexical and syntax parsing, optimization rewriting, and plan generation time), in milliseconds. This column is only supported in version 8.3.0.100 or later. |
| unique_plan_id | Bigint | ID of the normalized unique plan. |
| sql_hash | Text | Normalized SQL hash. |
| plan_hash | Text | Normalized plan hash. |
| disk_cache_hit_ratio | numeric(5,2) | Disk cache hit rate. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_disk_read_size | Bigint | Total size of data read from disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_disk_write_size | Bigint | Total size of data written to disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_remote_read_size | Bigint | Total size of data read remotely from OBS due to disk cache read failure, in MB. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_remote_read_time | Bigint | Total number of times data is read remotely from OBS due to disk cache read failure. This column only applies to OBS 3.0 tables and foreign tables. |
| vfs_scan_bytes | Bigint | Total number of bytes scanned by the OBS virtual file system in response to upper-layer requests, in bytes. This column only applies to OBS 3.0 tables and foreign tables. |
| vfs_remote_read_bytes | Bigint | Total number of bytes actually read from OBS by the OBS virtual file system, in bytes. This column only applies to OBS 3.0 tables and foreign tables. |
| preload_submit_time | Bigint | Total time for submitting I/O requests in the prefetching process, in microseconds. This column only applies to OBS 3.0 tables. |

| Column | Type | Description |
|-----------------------------|--------|---|
| preload_wait_time | Bigint | Total time for waiting for I/O requests in the prefetching process, in microseconds. This column only applies to OBS 3.0 tables. |
| preload_wait_count | Bigint | Total number of times that the prefetching process waits for I/O requests. This column only applies to OBS 3.0 tables. |
| disk_cache_load_time | Bigint | Total time for reading from disk cache, in microseconds. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_conflict_count | Bigint | Number of times a block in the disk cache produces a hash conflict. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_error_count | Bigint | Number of disk cache read failures. This column only applies to OBS 3.0 tables and foreign tables. |
| disk_cache_error_code | Bigint | Error code for disk cache read failures. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_avg_rtt | Bigint | Average Round Trip Time (RTT) for OBS I/O requests, in microseconds. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_avg_latency | Bigint | Average delay for OBS I/O requests, in microseconds. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_latency_gt_1s | Bigint | Number of OBS I/O requests with a latency exceeding 1 second. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_latency_gt_10s | Bigint | Number of OBS I/O requests with a latency exceeding 10 seconds. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_count | Bigint | Total number of OBS I/O requests. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_retry_count | Bigint | Total number of retries for OBS I/O requests. This column only applies to OBS 3.0 tables and foreign tables. |
| obs_io_req_rate_limit_count | Bigint | Total number of times OBS I/O requests are flow-controlled. This column only applies to OBS 3.0 tables and foreign tables. |

18.3.246 PGXC_WLM_SESSION_HISTORY

PGXC_WLM_SESSION_HISTORY displays load management records after job execution on all CNs. This view is used to query data from DWS, and the data in the database is cleared periodically every 3 minutes.

NOTICE

The **PGXC_WLM_SESSION_HISTORY** view can be queried only in the **postgres** database. If the view is queried in other databases, an error is reported.

GS_WLM_SESSION_HISTORY lists the columns in the **PGXC_WLM_SESSION_HISTORY** view.

Table 18-319 GS_WLM_SESSION_HISTORY columns

| Column | Type | Description |
|------------------|---------|--|
| datid | OID | OID of the database this backend is connected to |
| dbname | Text | Name of the database the backend is connected to |
| schemaname | Text | Schema name |
| nodename | Text | Name of the CN where the statement is run |
| username | Text | User name used for connecting to the backend |
| application_name | Text | Name of the application that is connected to the backend |
| client_addr | inet | IP address of the client connected to this backend. If this column is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| client_hostname | Text | Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will only be non-null for IP connections, and only when log_hostname is enabled. |
| client_port | Integer | TCP port number that the client uses for communication with this backend, or -1 if a Unix socket is used |
| query_band | Text | Job type, which can be set using the GUC parameter query_band and is a null string by default. |

| Column | Type | Description |
|---------------------|--------------------------|--|
| block_time | Bigint | Duration that a statement is blocked before being executed, including the statement parsing and optimization duration. The unit is ms. |
| start_time | Timestamp with time zone | Time when the statement starts to be run |
| finish_time | Timestamp with time zone | Time when the statement execution ends |
| duration | Bigint | Execution time of a statement. The unit is ms. |
| estimate_total_time | Bigint | Estimated execution time of a statement. The unit is ms. |
| status | Text | Final statement execution status. Its value can be finished (normal) or aborted (abnormal). The statement status here is the execution status of the database server. If the statement is successfully executed on the database server but an error is reported in the result set, the statement status is finished . |
| abort_info | Text | Exception information displayed if the final statement execution status is aborted . |
| resource_pool | Text | Resource pool used by the user |
| control_group | Text | Cgroup used by the statement |
| estimate_memory | Integer | Estimated memory used by a statement on a single instance. The unit is MB. |
| min_peak_memory | Integer | Minimum memory peak of a statement across all DN. The unit is MB. |
| max_peak_memory | Integer | Maximum memory peak of a statement across all DN. The unit is MB. |
| average_peak_memory | Integer | Average memory usage during statement execution. The unit is MB. |
| memory_skew_percent | Integer | Memory usage skew of a statement among DN. |

| Column | Type | Description |
|----------------------|---------|--|
| spill_info | Text | Statement spill information on all DNs.
None indicates that the statement has not been spilled to disks on any DNs.
All : The statement has been spilled to disks on all DNs.
[<i>a</i>:<i>b</i>] : The statement has been spilled to disks on <i>a</i> of <i>b</i> DNs. |
| min_spill_size | Integer | Minimum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| max_spill_size | Integer | Maximum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| average_spill_size | Integer | Average spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_dn_time | Bigint | Minimum execution time of a statement across all DNs. The unit is ms. |
| max_dn_time | Bigint | Maximum execution time of a statement across all DNs. The unit is ms. |
| average_dn_time | Bigint | Average execution time of a statement across all DNs. The unit is ms. |
| dn_time_skew_percent | Integer | Execution time skew of a statement among DNs. |
| min_cpu_time | Bigint | Minimum CPU time of a statement across all DNs. The unit is ms. |
| max_cpu_time | Bigint | Maximum CPU time of a statement across all DNs. The unit is ms. |
| total_cpu_time | Bigint | Total CPU time of a statement across all DNs. The unit is ms. |
| cpu_skew_percent | Integer | CPU time skew of a statement among DNs. |
| min_peak_iops | Integer | Minimum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |

| Column | Type | Description |
|-------------------|---------|---|
| max_peak_iops | Integer | Maximum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| average_peak_iops | Integer | Average IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| iops_skew_percent | Integer | I/O skew across DNs. |
| warning | Text | Warning. The following warnings and warnings related to SQL self-diagnosis tuning are displayed:
<ol style="list-style-type: none">1. The max spill size exceeds the alarm size 256MB2. The max broadcast size exceeds the alarm size 100MB3. Early spill4. Spill times is greater than 35. Spill on memory adaptive6. Hash table conflict7. NestLoop in hashjoin |
| queryid | Bigint | Internal query ID used for statement execution |
| query | Text | Statement to be executed. A maximum of 64 KB of strings can be retained. |
| query_plan | Text | Execution plan of a statement.
Specification restrictions:
<ol style="list-style-type: none">1. Execution plans are displayed only for DML statements.2. In 8.2.1.100 and later versions, the number of data binding times is added to the execution plans of Parse Bind Execute (PBE) statements to facilitate statement analysis. The number of data binding times is displayed in the format of PBE bind times: Times. |
| node_group | Text | Logical cluster of the user running the statement |
| pid | Bigint | PID of the backend thread of the statement |
| lane | Text | Fast/Slow lane where the statement is executed |

| Column | Type | Description |
|---------------------|--------|---|
| unique_sql_id | Bigint | ID of the normalized unique SQL. |
| session_id | Text | Unique identifier of a session in the database system. Its format is session_start_time.tid.node_name . |
| min_read_bytes | Bigint | Minimum I/O read bytes of a statement across all DN. The unit is byte. |
| max_read_bytes | Bigint | Maximum I/O read bytes of a statement across all DN. The unit is byte. |
| average_read_bytes | Bigint | Average I/O read bytes of a statement across all DN. |
| min_write_bytes | Bigint | Minimum I/O write bytes of a statement across all DN. |
| max_write_bytes | Bigint | Maximum I/O write bytes of a statement across all DN. |
| average_write_bytes | Bigint | Average I/O write bytes of a statement across all DN. |
| recv_pkg | Bigint | Total number of communication packages received by a statement across all DN. |
| send_pkg | Bigint | Total number of communication packages sent by a statement across all DN. |
| recv_bytes | Bigint | Total received data of the statement stream, in byte. |
| send_bytes | Bigint | Total sent data of the statement stream, in byte. |
| stmt_type | Text | Query type corresponding to the statement. |
| except_info | Text | Information about the exception rule triggered by the statement. |
| unique_plan_id | Bigint | ID of the normalized unique plan. |
| sql_hash | Text | Normalized SQL hash. |
| plan_hash | Text | Normalized plan hash. |
| use_plan_baseline | Text | Indicates whether the bound plan is used for executing the current statement. If it is used, the name of the plan_baseline column in pg_plan_baseline is displayed. |
| outline_name | Text | Name of the outline used for the statement plan. |

| Column | Type | Description |
|-----------------------------|--------------|---|
| loader_status | Text | The JSON string for storing import and export service information is as follows.
<ol style="list-style-type: none">1. address: indicates the IP address of the peer cluster. The port number is displayed for the source cluster.2. direction: indicates the import and export service type. The value can be gds to file, gds from file, gds to pipe, gds from pipe, copy from or copy to.3. min/max/total_lines/bytes: indicates the minimum value, maximum value, total lines, and bytes of the import and export statements on all DNs. |
| parse_time | Bigint | Total parsing time before the statement is queued (including lexical and syntax parsing, optimization rewriting, and plan generation time), in milliseconds. This column is available only in clusters of version 8.3.0.100 or later. |
| disk_cache_hit_ratio | numeric(5,2) | Disk cache hit rate. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_disk_read_size | Bigint | Total size of data read from disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_disk_write_size | Bigint | Total size of data written to disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_remote_read_size | Bigint | Total size of data read remotely from OBS due to disk cache read failure, in MB. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_remote_read_time | Bigint | Total number of times data is read remotely from OBS due to disk cache read failure. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| vfs_scan_bytes | Bigint | Total number of bytes scanned by the OBS virtual file system in response to upper-layer requests, in bytes. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |

| Column | Type | Description |
|---------------------------|--------|--|
| vfs_remote_read_bytes | Bigint | Total number of bytes actually read from OBS by the OBS virtual file system, in bytes. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| preload_submit_time | Bigint | Total time for submitting I/O requests in the prefetching process, in microseconds. This column only applies to OBS 3.0 tables with storage and compute decoupled. |
| preload_wait_time | Bigint | Total time for waiting for I/O requests in the prefetching process, in microseconds. This column only applies to OBS 3.0 tables with storage and compute decoupled. |
| preload_wait_count | Bigint | Total number of times that the prefetching process waits for I/O requests. This column only applies to OBS 3.0 tables with storage and compute decoupled. |
| disk_cache_loaded_time | Bigint | Total time for reading from disk cache, in microseconds. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_conflict_count | Bigint | Number of times a block in the disk cache produces a hash conflict. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| disk_cache_error_count | Bigint | Number of disk cache read failures. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |

| Column | Type | Description |
|---------------------------|--------|---|
| disk_cache_error_code | Bigint | <p>Error code for disk cache read failures. Multiple error codes may be generated. If the disk cache fails to be read, OBS remote read is initiated and cache blocks are rewritten. The error code types are as follows: This column only applies to OBS 3.0 tables and foreign tables.</p> <ul style="list-style-type: none">• 1: A hash conflict occurs in the disk cache block.• 2: The generation time of the disk cache block is later than that of the OldestXmin transaction.• 4: Invoking the pread system when reading cache files from the disk cache failed.• 8: The data version of the disk cache block does not match.• 16: The version of the data written to the write cache does not match the latest version.• 32: Opening the cache file corresponding to the cache block failed.• 64: The size of the data read from the disk cache does not match.• 128: The CSN recorded in the disk cache block does not match. |
| obs_io_req_avg_rtt | Bigint | Average Round Trip Time (RTT) for OBS I/O requests, in microseconds. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| obs_io_req_avg_latency | Bigint | Average delay for OBS I/O requests, in microseconds. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| obs_io_req_latency_gt_1s | Bigint | Number of OBS I/O requests with a latency exceeding 1 second. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| obs_io_req_latency_gt_10s | Bigint | Number of OBS I/O requests with a latency exceeding 10 seconds. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| obs_io_req_count | Bigint | Total number of OBS I/O requests. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |

| Column | Type | Description |
|-----------------------------|--------|---|
| obs_io_req_retry_count | Bigint | Total number of retries for OBS I/O requests. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |
| obs_io_req_rate_limit_count | Bigint | Total number of times OBS I/O requests are flow-controlled. This column only applies to OBS 3.0 tables and foreign tables with storage and compute decoupled. |

18.3.247 PGXC_WLM_SESSION_STATISTICS

PGXC_WLM_SESSION_STATISTICS displays load management information about jobs that are being executed on CNs.

Table 18-320 PGXC_WLM_SESSION_STATISTICS columns

| Column | Type | Description |
|------------------|---------|--|
| datid | OID | OID of the database this backend is connected to |
| dbname | Name | Name of the database the backend is connected to |
| schemaname | Text | Schema name |
| nodename | Text | Name of the CN where the statement is executed |
| username | Name | User name used for connecting to the backend |
| application_name | Text | Name of the application that is connected to the backend |
| client_addr | inet | IP address of the client connected to this backend. If this column is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| client_hostname | Text | Host name of the connected client, as reported by a reverse DNS lookup of client_addr . This column will only be non-null for IP connections, and only when log_hostname is enabled. |
| client_port | Integer | TCP port number used by the client to communicate with the backend. If a Unix socket is used, it is -1 . |

| Column | Type | Description |
|---------------------|--------------------------|--|
| query_band | Text | Job type, which can be set using the GUC parameter query_band and is a null string by default. |
| pid | Bigint | ID of the backend thread |
| block_time | Bigint | Block time before the statement is executed. The unit is ms. |
| start_time | Timestamp with time zone | Time when the statement starts to be executed |
| duration | Bigint | For how long a statement has been executing. The unit is ms. |
| estimate_total_time | Bigint | Estimated execution time of a statement. The unit is ms. |
| estimate_left_time | Bigint | Estimated remaining time of statement execution. The unit is ms. |
| enqueue | Text | Workload management resource status |
| resource_pool | Name | Resource pool used by the user |
| control_group | Text | Cgroup used by the statement |
| estimate_memory | Integer | Estimated memory used by a statement on a single instance. The unit is MB. |
| min_peak_memory | Integer | Minimum memory peak of a statement across all DN. The unit is MB. |
| max_peak_memory | Integer | Maximum memory peak of a statement across all DN. The unit is MB. |
| average_peak_memory | Integer | Average memory usage during statement execution. The unit is MB. |
| memory_skew_percent | Integer | Memory usage skew of a statement among DN. |
| spill_info | Text | Spill information for the statement on all DN. The options are:
None : The statement has not been spilled to disks on any DN.
All : The statement has been spilled to disks on all DN.
[a:b] : The statement has been spilled to disks on <i>a</i> of <i>b</i> DN. |

| Column | Type | Description |
|----------------------|---------|---|
| min_spill_size | Integer | Minimum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| max_spill_size | Integer | Maximum spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| average_spill_size | Integer | Average spilled data among all DNs when a spill occurs. The unit is MB. The default value is 0. |
| spill_skew_percent | Integer | DN spill skew when a spill occurs |
| min_dn_time | Bigint | Minimum execution time of a statement across all DNs. The unit is ms. |
| max_dn_time | Bigint | Maximum execution time of a statement across all DNs. The unit is ms. |
| average_dn_time | Bigint | Average execution time of a statement across all DNs. The unit is ms. |
| dn_time_skew_percent | Integer | Execution time skew of a statement among DNs. |
| min_cpu_time | Bigint | Minimum CPU time of a statement across all DNs. The unit is ms. |
| max_cpu_time | Bigint | Maximum CPU time of a statement across all DNs. The unit is ms. |
| total_cpu_time | Bigint | Total CPU time of a statement across all DNs. The unit is ms. |
| cpu_skew_percent | Integer | CPU time skew of a statement among DNs. |
| min_peak_iops | Integer | Minimum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| max_peak_iops | Integer | Maximum IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |
| average_peak_iops | Integer | Average IOPS peak of a statement across all DNs. It is counted by ones in a column-store table and by ten thousands in a row-store table. |

| Column | Type | Description |
|---------------------|---------|--|
| iops_skew_percent | Integer | I/O skew across DNs. |
| min_read_speed | Integer | Minimum I/O read rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| max_read_speed | Integer | Maximum I/O read rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| average_read_speed | Integer | Average I/O read rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| min_write_speed | Integer | Minimum I/O write rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| max_write_speed | Integer | Maximum I/O write rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| average_write_speed | Integer | Average I/O write rate of a statement across all DNs within a monitoring period (5s). The unit is KB/s. |
| recv_pkg | Bigint | Total number of communication packages received by a statement across all DNs. |
| send_pkg | Bigint | Total number of communication packages sent by a statement across all DNs. |
| recv_bytes | Bigint | Total received data of the statement stream, in byte. |
| send_bytes | Bigint | Total sent data of the statement stream, in byte. |
| warning | Text | Warning. The following warnings and warnings related to SQL self-diagnosis tuning are displayed:
<ol style="list-style-type: none">1. The max spill size exceeds the alarm size 256MB2. The max broadcast size exceeds the alarm size 100MB3. Early spill4. Spill times is greater than 35. Spill on memory adaptive6. Hash table conflict7. NestLoop in hashjoin |

| Column | Type | Description |
|----------------------------|---------------|--|
| unique_sql_id | Bigint | ID of the normalized unique SQL. |
| queryid | Bigint | Internal query ID used for statement execution |
| query | Text | Statement that is being executed |
| query_plan | Text | Execution plan of a statement
Specification restrictions:
1. Execution plans are displayed only for DML statements.
2. In 8.2.1.100 and later versions, the number of data binding times is added to the execution plans of Parse Bind Execute (PBE) statements to facilitate statement analysis. The number of data binding times is displayed in the format of PBE bind times: Times . |
| node_group | Text | Logical cluster of the user running the statement |
| stmt_type | Text | Query type corresponding to the statement. |
| except_info | Text | Information about the exception rule triggered by the statement. |
| parse_time | Bigint | Total parsing time before the statement is queued (including lexical and syntax parsing, optimization rewriting, and plan generation time), in milliseconds. This column is only supported in version 8.3.0.100 or later. |
| unique_plan_id | Bigint | ID of the normalized unique plan. |
| sql_hash | Text | Normalized SQL hash. |
| plan_hash | Text | Normalized plan hash. |
| disk_cache_hit_ratio | numeric(5, 2) | Disk cache hit rate. This column only applies to OBS 3.0 tables and foreign tables in decoupled storage and compute scenarios. |
| disk_cache_disk_read_size | Bigint | Total size of data read from disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables in decoupled storage and compute scenarios. |
| disk_cache_disk_write_size | Bigint | Total size of data written to disk cache, in MB. This column only applies to OBS 3.0 tables and foreign tables in decoupled storage and compute scenarios. |

| Column | Type | Description |
|-----------------------------|--------|--|
| disk_cache_remote_read_size | Bigint | Total size of data read remotely from OBS due to disk cache read failure, in MB. This column only applies to OBS 3.0 tables and foreign tables in decoupled storage and compute scenarios. |
| disk_cache_remote_read_time | Bigint | Total number of times data is read remotely from OBS due to disk cache read failure. This column only applies to OBS 3.0 tables and foreign tables in decoupled storage and compute scenarios. |
| block_name | Text | Name of the interception rule that matches the statement. |

18.3.248 PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS

PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS displays data skews of tables in the current database. You can quickly query the storage space skew of all tables in the current database on each node. This view is supported only by clusters of version 8.2.1 or later.

Suggestions:

- When you analyze the disk space skew of each table in a database in a large cluster with a large amount of data, the **PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS** view delivers better query performance than the **gs_table_distribution()** function and the **PGXC_GET_TABLE_SKEWNESS** view. You are advised to use the **PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS** view to query the table skew status overview, and then use the **gs_table_distribution(schemaname text, tablename text)** function to obtain the disk space distribution of a specified table on each node.
- To use this view to query the storage distribution information of a specified table, you must have the **SELECT** permission on the table.
- This function is based on the physical file storage space recorded in the **PG_RELFILENODE_SIZE** system catalog. Ensure that the GUC parameters **use_workload_manager** and **enable_perm_space** are enabled.

Table 18-321 PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS columns

| Column | Type | Description |
|-------------|---------|---|
| schema_name | Name | Name of the schema where a table is |
| table_name | Name | Table name |
| total_size | Numeric | Total storage space of a table on all nodes, in bytes |

| Column | Type | Description |
|--------------|-----------------|---|
| avg_size | numeric(1000,0) | Average storage space of a table on each node, in bytes |
| max_percent | Numeric | Percentage (%) of the maximum storage space of a table on each node to the total storage space |
| min_percent | Numeric | Percentage (%) of the minimum storage space of a table on each node to the total storage space |
| skew_percent | Numeric | Skew rate (%) of a table
The formula for calculating the skew rate as follows: Skew rate (skew_percent) = (Maximum value of dnsize - Average value of dnsize) x 100/Maximum value of dnsize . |

Example

You can use the **PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS** view to query the table skew status overview, and then use the **gs_table_distribution(schemaname text, tablename text)** function to obtain the disk space distribution of a specified table on each node.

Step 1 Use the **PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS** view to query the table skew status overview.

```
tpcds_col=# select * from pgxc_wlm_table_distribution_skewness;
```

The query result is as follows:

| tpcds_col=# select * from pgxc_wlm_table_distribution_skewness; | schema_name | table_name | total_size | avg_size | max_percent | min_percent | skew_percent |
|---|-------------|-----------------------------------|------------|----------|-------------|-------------|--------------|
| | pg_catalog | pg_namespace_oid_index | 98304 | 16384 | 16.67 | 16.67 | 0.00 |

| | pg_catalog | pg_namespace_nspname_index | 98304 | 16384 | 16.67 | 16.67 | 0.00 |
| | pg_catalog | pg_synonym_name_nsp_index | 49152 | 8192 | 16.67 | 16.67 | 0.00 |
| | pg_catalog | pg_proc_proname_args_nsp_index | 2015232 | 335872 | 16.67 | 16.67 | 0.00 |
| | public | dbgen_version | 32768 | 10923 | 100.00 | 0.00 | 66.67 |
| | pg_catalog | pg_amop_opr_fam_index | 294912 | 49152 | 16.67 | 16.67 | 0.00 |
| | pg_catalog | pg_global_temp | 0 | 0 | 0.00 | 0.00 | 0.00 |
| | pg_catalog | pg_workload_group_name_index | 0 | 0 | 0.00 | 0.00 | 0.00 |
| | public | date_dim | 7159808 | 2386603 | 34.10 | 32.95 | 2.24 |
| | pg_catalog | pg_operator_oid_index | 245760 | 40960 | 16.67 | 16.67 | 0.00 |

The data skew of the **dbgen_version** table is severe.

Step 2 Use the **gs_table_distribution(schemaname text, tablename text)** function to query the disk space distribution of the **dbgen_version** table on each node.

```
tpcds_col=# select * from gs_table_distribution('public','dbgen_version');
```

The query result is as follows:

| tpcds_col=# select * from gs_table_distribution('public','dbgen_version'); | schemaname | tablename | relkind | relpersistence | nodename | dnsize | sessionid |
|--|------------|---------------|---------|----------------|--------------|--------|-----------|
| | public | dbgen_version | r | p | dn_6001_6002 | 0 | |
| | public | dbgen_version | r | p | dn_6005_6006 | 32768 | |
| | public | dbgen_version | r | p | dn_6003_6004 | 0 | |
| (3 rows) | | | | | | | |

According to the preceding information, data skew occurs in the disk space occupied by the table on DNs. Most data is stored on **dn_6005_6006**.

----End

18.3.249 PGXC_WLM_USER_RESOURCE_HISTORY

The **PGXC_WLM_USER_RESOURCE_HISTORY** view displays historical information about resource consumption of all users on the corresponding instances. This view is supported only by clusters of version 8.2.0 or later.

Table 18-322 PGXC_WLM_USER_RESOURCE_HISTORY columns

| Column | Type | Description |
|--------------|--------------------------|--|
| nodename | Name | Instance name, including CNs and DNs. |
| username | Text | Username |
| Timestamp | Timestamp with time zone | Timestamp |
| used_memory | Integer | Used memory (unit: MB).
On a DN, it indicates a user's memory usage on the current DN.
On a CN, it indicates a user's total memory usage on all DNs. |
| total_memory | Integer | Available memory (unit: MB). 0 indicates that the available memory is not limited and depends on the maximum memory available in the database.
On a DN, it indicates the memory available to a user on the current DN.
On a CN, it indicates the total memory available to a user on all DNs. |
| used_cpu | Double precision | Number of CPU cores in use. Only the CPU usage of complex jobs in the non-default resource pool is collected, and the value is the CPU usage of the related cgroup.
On a DN, it indicates a user's CPU core usage on the current DN.
On a CN, it indicates a user's total CPU core usage on all DNs. |

| Column | Type | Description |
|------------------|---------|--|
| total_cpu | Integer | Total number of CPU cores of the Cgroups associated with a user.
On a DN, it indicates the CPU cores available to a user on the current DN.
On a CN, it indicates the total CPU cores available to a user on all DNs. |
| used_space | Bigint | Used permanent table storage space (unit: KB)
On a DN, it indicates the size of the permanent table storage space used by a user on the current DN.
On a CN, it indicates the total size of the permanent table storage space used by a user on all DNs. |
| total_space | Bigint | Available storage space, in KB. -1 indicates that the storage space is not limited.
On a DN, it indicates the size of the permanent table storage space available to a user on the current DN.
On a CN, it indicates the total size of the permanent table storage space available to a user on all DNs. |
| used_temp_space | Bigint | Used temporary table storage space (unit: KB)
On a DN, it indicates the size of the temporary table storage space used by a user on the current DN.
On a CN, it indicates the total size of the temporary table storage space used by a user on all DNs. |
| total_temp_space | Bigint | Available temporary table storage space, in KB. -1 indicates that the storage space is not limited.
On a DN, it indicates the size of the temporary table storage space available to a user on the current DN.
On a CN, it indicates the total size of the temporary table storage space available to a user on all DNs. |

| Column | Type | Description |
|-------------------|--------|---|
| used_spill_space | Bigint | <p>Size of space used for operator spill to disk, in KB.</p> <p>On a DN, it indicates displays the size of the operator flushing space used by the user on the current DN.</p> <p>On a CN, it indicates the total space used by a user's operators spilled to disk on all DNs.</p> |
| total_spill_space | Bigint | <p>Size of space available for operator spill to disk, in KB. The value -1 indicates that the space is not limited.</p> <p>On a DN, it indicates displays the size of the operator flushing space that can be used by the user on the current DN.</p> <p>On a CN, it indicates the total space available for a user to spill operators to disk on all DNs.</p> |
| read_kbytes | Bigint | <p>On a CN, it indicates total number of bytes read by a user's complex jobs on all DNs in the last 5 seconds. The unit is KB.</p> <p>On a DN, it indicates the total number of bytes read by a user's complex jobs from the instance startup time to the current time. The unit is KB.</p> |
| write_kbytes | Bigint | <p>On a CN, it indicates total number of bytes written by a user's complex jobs on all DNs in the last 5 seconds.</p> <p>On a DN, it indicates the total number of bytes written by a user's complex jobs from the instance startup time to the current time. The unit is KB.</p> |
| read_counts | Bigint | <p>On a CN, it indicates total number of read times of a user's complex jobs on all DNs in the last 5 seconds.</p> <p>On a DN, it indicates total number of read times of a user's complex jobs from the instance startup time to the current time.</p> |
| write_counts | Bigint | <p>On a CN, it indicates total number of write times of a user's complex jobs on all DNs in the last 5 seconds.</p> <p>On a DN, it indicates total number of write times of a user's complex jobs from the instance startup time to the current time.</p> |

| Column | Type | Description |
|-------------|------------------|---|
| read_speed | Double precision | On a CN, it indicates the average read rate of a user's complex jobs on a single DN in the last 5 seconds, in KB/s.

On a DN, it indicates the average read rate of a user's complex jobs on the DN in the last 5 seconds, in KB/s. |
| write_speed | Double precision | On a CN, it indicates the average write rate of a user's complex jobs on a single DN in the last 5 seconds, in KB/s.

On a DN, it indicates the average write rate of a user's complex jobs on the DN in the last 5 seconds, in KB/s. |
| send_speed | Double precision | On a CN, it indicates the sum of the average network sending rates of a user on all DNs in a 5s monitoring period, in KB/s.

On a DN, it indicates the average network sending rate of a user on the DN in a 5s monitoring period, in KB/s. |
| recv_speed | Double precision | On a CN, it indicates the sum of the average network receiving rates of a user on all DNs in a 5s monitoring period, in KB/s.

On a DN, it indicates the average network receiving rate of a user on the DN in a 5s monitoring period, in KB/s. |

18.3.250 PGXC_WLM_WORKLOAD_RECORDS

PGXC_WLM_WORKLOAD_RECORDS displays the status of job executed by the current user on CNs. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view. This view is available only when **enable_dynamic_workload** is set to **on**.

Table 18-323 PGXC_WLM_WORKLOAD_RECORDS columns

| Column | Type | Description |
|-----------|---------|---|
| node_name | Text | Name of the CN where the job is executed. |
| thread_id | Bigint | ID of the backend thread. |
| processid | Integer | lwpid of the thread. |
| Timestamp | Bigint | Start time of statement execution. |
| username | Name | Username logged in to the backend. |
| memory | Integer | Memory required for the statement. |

| Column | Type | Description |
|---------------|---------|--|
| active_points | Integer | Number of resources consumed by the statement on the resource pool. |
| max_points | Integer | Maximum number of resources in the resource pool. |
| priority | Integer | Priority of a job. |
| resource_pool | Text | Resource pool where a job is. |
| status | Text | Job execution status. The options are:
pending
running
finished
aborted
unknown |
| control_group | Text | Cgroups used by a job. |
| enqueue | Text | Queue for the job, including:
GLOBAL : global queue.
RESPOOL : resource pool queue.
ACTIVE : not queued. |
| query | Text | Statement currently being executed. |

18.3.251 PGXC_WORKLOAD_SQL_COUNT

PGXC_WORKLOAD_SQL_COUNT displays statistics on the number of SQL statements executed in workload Cgroups on all CNs in a cluster, including the number of **SELECT**, **UPDATE**, **INSERT**, and **DELETE** statements and the number of DDL, DML, and DCL statements. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-324 PGXC_WORKLOAD_SQL_COUNT columns

| Column | Type | Description |
|--------------|--------|-------------------------------------|
| node_name | Name | Node name. |
| workload | Name | Workload Cgroup name. |
| select_count | Bigint | Number of SELECT statements. |
| update_count | Bigint | Number of UPDATE statements. |

| Column | Type | Description |
|--------------|--------|-------------------------------------|
| insert_count | Bigint | Number of INSERT statements. |
| delete_count | Bigint | Number of DELETE statements. |
| ddl_count | Bigint | Number of DDL statements. |
| dml_count | Bigint | Number of DML statements. |
| dcl_count | Bigint | Number of DCL statements. |

18.3.252 PGXC_WORKLOAD_SQL_ELAPSE_TIME

PGXC_WORKLOAD_SQL_ELAPSE_TIME displays statistics on the response time of SQL statements in workload Cgroups on all CNs in a cluster, including the maximum, minimum, average, and total response time of **SELECT**, **UPDATE**, **INSERT**, and **DELETE** statements. The unit is microsecond. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view.

Table 18-325 PGXC_WORKLOAD_SQL_ELAPSE_TIME columns

| Column | Type | Description |
|---------------------|--------|--|
| node_name | Name | Node name. |
| workload | Name | Workload Cgroup name. |
| total_select_elapse | Bigint | Total response time of SELECT statements. |
| max_select_elapse | Bigint | Maximum response time of SELECT statements. |
| min_select_elapse | Bigint | Minimum response time of SELECT statements. |
| avg_select_elapse | Bigint | Average response time of SELECT statements. |
| total_update_elapse | Bigint | Total response time of UPDATE statements. |
| max_update_elapse | Bigint | Maximum response time of UPDATE statements. |
| min_update_elapse | Bigint | Minimum response time of UPDATE statements. |

| Column | Type | Description |
|---------------------|--------|--|
| avg_update_elapse | Bigint | Average response time of UPDATE statements. |
| total_insert_elapse | Bigint | Total response time of INSERT statements. |
| max_insert_elapse | Bigint | Maximum response time of INSERT statements. |
| min_insert_elapse | Bigint | Minimum response time of INSERT statements. |
| avg_insert_elapse | Bigint | Average response time of INSERT statements. |
| total_delete_elapse | Bigint | Total response time of DELETE statements. |
| max_delete_elapse | Bigint | Maximum response time of DELETE statements. |
| min_delete_elapse | Bigint | Minimum response time of DELETE statements. |
| avg_delete_elapse | Bigint | Average response time of DELETE statements. |

18.3.253 PGXC_WORKLOAD_TRANSACTION

PGXC_WORKLOAD_TRANSACTION provides transaction information about workload cgroups on all CNs. Only the system administrator or the preset role **gs_role_read_all_stats** can access this view. This view is valid only when the real-time resource monitoring function is enabled, that is, when [enable_resource_track](#) is **on**.

Table 18-326 PGXC_WORKLOAD_TRANSACTION columns

| Column | Type | Description |
|------------------|--------|---|
| node_name | Name | Node name. |
| workload | Name | Workload Cgroup name. |
| commit_counter | Bigint | Number of the commits. |
| rollback_counter | Bigint | Number of rollbacks. |
| resp_min | Bigint | Minimum response time, in microseconds. |
| resp_max | Bigint | Maximum response time, in microseconds. |

| Column | Type | Description |
|------------|--------|---|
| resp_avg | Bigint | Average response time, in microseconds. |
| resp_total | Bigint | Total response time, in microseconds. |

18.3.254 PLAN_TABLE

PLAN_TABLE displays the plan information collected by **EXPLAIN PLAN**. Plan information is in a session-level life cycle. After the session exits, the data will be deleted. Data is isolated between sessions and between users.

Table 18-327 PLAN_TABLE columns

| Column | Type | Description |
|--------------|----------------|---|
| statement_id | varchar2(30) | Query tag specified by a user |
| plan_id | Bigint | ID of a plan to be queried |
| id | Int | ID of each operator in a generated plan |
| operation | varchar2(30) | Operation description of an operator in a plan |
| options | varchar2(255) | Operation parameters |
| object_name | Name | Name of an operated object. It is defined by users, not the object alias used in the query. |
| object_type | varchar2(30) | Object type |
| object_owner | Name | User-defined schema to which an object belongs |
| projection | varchar2(4000) | Returned column information |

NOTE

- A valid **object_type** value consists of a relkind type defined in **PG_CLASS** (**TABLE** ordinary table, **INDEX**, **SEQUENCE**, **VIEW**, **FOREIGN TABLE**, **COMPOSITE TYPE**, or **TOASTVALUE TOAST** table) and the rtekind type used in the plan (**SUBQUERY**, **JOIN**, **FUNCTION**, **VALUES**, **CTE**, or **REMOTE_QUERY**).
- For RangeTableEntry (RTE), **object_owner** is the object description used in the plan. Non-user-defined objects do not have **object_owner**.
- Information in the **statement_id**, **object_name**, **object_owner**, and **projection** columns is stored in letter cases specified by users and information in other columns is stored in uppercase.
- **PLAN_TABLE** supports only **SELECT** and **DELETE** and does not support other DML operations.

18.3.255 PV_FILE_STAT

By collecting statistics about the data file I/Os, **PV_FILE_STAT** displays the I/O performance of the data to detect the performance problems, such as abnormal I/O operations.

Table 18-328 PV_FILE_STAT columns

| Column | Type | Description |
|-----------|--------|---|
| filenum | OID | File ID. |
| dbid | OID | Database ID. |
| spcid | OID | Tablespace ID. |
| phyrds | Bigint | Number of physical files read. |
| phywrts | Bigint | Number of physical files written. |
| phyblkrd | Bigint | Number of physical file blocks read. |
| phyblkwrt | Bigint | Number of physical file blocks written. |
| readtim | Bigint | Total duration of file reads, in microseconds. |
| writetim | Bigint | Total duration of file writes, in microseconds. |
| avgiotim | Bigint | Average duration of file reads and writes, in microseconds. |
| lstiotim | Bigint | Duration of the last file read, in microseconds. |
| miniotim | Bigint | Minimum duration of file reads and writes, in microseconds. |
| maxiowtm | Bigint | Maximum duration of file reads and writes, in microseconds. |

18.3.256 PV_INSTANCE_TIME

PV_INSTANCE_TIME collects statistics on the running time of processes and the time consumed in each execution phase, in microseconds.

PV_INSTANCE_TIME records time consumption information of the current node. The time consumption information is classified into the following types:

- **DB_TIME**: time spent by a process on multi-core parallel computing
- **CPU_TIME**: time spent by a process on the CPU core
- **EXECUTION_TIME**: time spent on the executor
- **PARSE_TIME**: time spent on parsing SQL statements
- **PLAN_TIME**: time spent on generating plans
- **REWRITE_TIME**: time spent on rewriting SQL statements

- **PL_EXECUTION_TIME**: execution time of the PL/pgSQL stored procedure
- **PL_COMPILATION_TIME**: compilation time of the PL/pgSQL stored procedure
- **NET_SEND_TIME**: time spent on the network
- **DATA_IO_TIME**: time spent on I/O

Table 18-329 PV_INSTANCE_TIME columns

| Column | Type | Description |
|-----------|---------|---------------------------|
| stat_id | Integer | Type ID. |
| stat_name | Text | Name of the runtime type. |
| value | Bigint | Runtime value. |

18.3.257 PV_MATVIEW_DETAIL

PV_MATVIEW_DETAIL displays detailed information about a materialized view. This view is supported only by clusters of version 9.1.0 200 or later.

Table 18-330 PV_MATVIEW_DETAIL columns

| Column | Type | Description |
|--------------------|-----------|---|
| matview | Text | Materialized view name |
| baserel | Text | Base table name |
| partids | oidvector | OID of a specified partition. |
| contain_entire_rel | Boolean | Whether to create a materialized view based on the entire base table |
| build_mode | Text | Build mode of the materialized view. <ul style="list-style-type: none">• 'd': indicates "deferred", which means that data is contained in the materialized view only when the view is refreshed for the first time.• 'i': indicates "immediate", which means that the latest data is included when the materialized view is created. |
| refresh_mode | Text | Refresh mode of the materialized view.
'd': stands for demand, indicating on-demand update. |
| refresh_method | Text | Refresh method of the materialized view.
'c' indicates a full refresh. |
| mapping | Text | Mapping between base table partitions and materialized view partitions |

| Column | Type | Description |
|---------------------|--------------------------|---|
| active | Boolean | Whether the materialized view needs to be refreshed |
| refresh_start_time | Timestamp with time zone | Start time of the last refresh |
| refresh_finish_time | Timestamp with time zone | End time of the last refresh |

18.3.258 PV_OS_RUN_INFO

PV_OS_RUN_INFO displays the running status of the current operating system.

Table 18-331 PV_OS_RUN_INFO columns

| Column | Type | Description |
|------------|---------|---|
| id | Integer | ID. |
| Name | Text | Name of the operating system status. |
| value | Numeric | Value of the operating system status. |
| comments | Text | Comments on the operating system status. |
| cumulative | boolean | Whether the value of the operating system status is cumulative. |

18.3.259 PV_REDO_STAT

PV_REDO_STAT displays statistics on redoing Xlogs on the current node.

Table 18-332 PV_REDO_STAT columns

| Name | Type | Description |
|-----------|--------|------------------------------------|
| phywrts | Bigint | Number of physical writes. |
| phyblkwrt | Bigint | Number of physical blocks written. |
| writetim | Bigint | Time taken for physical writes. |
| avgiotim | Bigint | Average time taken per write. |
| lstiotim | Bigint | Time taken for the last write. |
| miniotim | Bigint | Minimum time taken for a write. |

| Name | Type | Description |
|----------|--------|---------------------------------|
| maxiowtm | Bigint | Maximum time taken for a write. |

18.3.260 PV_RUNTIME_ATTSTATS

PV_RUNTIME_ATTSTATS displays table-level statistics in the memory generated by autoanalyze. The descriptions of the columns in **PV_RUNTIME_RELSTATS** are the same as those in **PG_STATS**. This view is used only by clusters of version 8.2.0 or later.

Table 18-333 PV_RUNTIME_ATTSTATS columns

| Column | Type | Reference | Description |
|------------|---------|--|---|
| schemaname | Name | PG_NAMESP
ACE .nspname | Name of the schema that contains the table |
| tablename | Name | PG_CLASS .rel
name | Table name |
| attname | Name | PG_ATTRIBU
TE .attname | Column name |
| inherited | boolean | - | If the value is true , the inherited subcolumns are included. If the value is false , only the columns in a specified table are included. |
| null_frac | Real | - | Percentage of column entries that are null |
| avg_width | Integer | - | Average width in bytes of column's entries |

| Column | Type | Reference | Description |
|-----------------------|----------|-----------|---|
| n_distinct | Real | - | <ul style="list-style-type: none">• If the value is greater than 0, it indicates the estimated number of distinct values in the column.• Negative of the number of distinct values divided by the number of rows if the value is less than 0 <p>The negated form is used when ANALYZE believes that the number of distinct values is likely to increase as the table grows.</p> <p>The positive form is used when the column seems to have a fixed number of possible values. For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</p> |
| n_dndistinct | Real | - | <p>Number of unique non-null data values in the dn1 column</p> <ul style="list-style-type: none">• Exact number of distinct values if the value is greater than 0• Negative of the number of distinct values divided by the number of rows if the value is less than 0 (For example, if the value of a column appears twice in average, set n_dndistinct=-0.5.)• The number of distinct values is unknown if the value is 0. |
| most_commo
n_vals | anyarray | - | List of the most common values in a column. If this combination does not have the most common values, it will be NULL . |
| most_commo
n_freqs | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals is NULL) |

| Column | Type | Reference | Description |
|------------------------|----------|-----------|---|
| histogram_bounds | anyarray | - | List of values that divide the column's values into groups of equal proportion. The values in most_common_vals , if present, are omitted from this histogram calculation. This field is null if the field data type does not have a < operator or if the most_common_vals list accounts for the entire population. |
| correlation | Real | - | Statistical correlation between physical row ordering and logical ordering of the column values. It ranges from -1 to +1. When the value is near to -1 or +1, an index scan on the column is estimated to be cheaper than when it is near to zero, due to reduction of random access to the disk. This column is null if the column data type does not have a < operator. |
| most_common_elems | anyarray | - | A list of the most commonly used non-null element values |
| most_common_elem_freqs | real[] | - | A list of the frequencies of the most commonly used element values |
| elem_count_histogram | real[] | - | A histogram of the counts of distinct non-null element values |
| partname | Name | - | Partition name This column is available only in clusters of version 8.2.1.200 or later. |

18.3.261 PV_RUNTIME_EXPRSTATS

PV_RUNTIME_EXPRSTATS displays expression statistics generated by **autoanalyze** in the memory. This view is supported only by clusters of version 8.2.1.200 or later.

Table 18-334 PV_RUNTIME_EXPRSTATS columns

| Column | Type | Reference | Description |
|------------|------|---|--|
| schemaname | Name | PG_NAMESP
ACE.nspname | Name of the schema that contains the table |

| Column | Type | Reference | Description |
|---------------------------|---------|---------------------------------------|---|
| tablename | Name | PG_CLASS .rel
name | Table name |
| statistics_sche
maname | Name | - | Name of the schema where
expression objects whose statistics
are collected is located |
| statistics_nam
e | Name | - | Name of the expression object
whose statistics are collected |
| statistics_own
er | Name | - | Owner of the expression object
whose statistics are collected |
| expr | Text | - | Expression |
| inherited | boolean | - | If the value is true , the inherited
subcolumns are included. If the
value is false , only the columns in
a specified table are included. |
| null_frac | Real | - | Percentage of column entries that
are null |
| avg_width | Integer | - | Average width in bytes of column's
entries |
| n_distinct | Real | - | <ul style="list-style-type: none">• If the value is greater than 0, it
indicates the estimated number
of distinct values in the column.• Negative of the number of
distinct values divided by the
number of rows if the value is
less than 0 <p>The negated form is used when
ANALYZE believes that the number
of distinct values is likely to
increase as the table grows.</p> <p>The positive form is used when the
column seems to have a fixed
number of possible values. For
example, -1 indicates a unique
column in which the number of
distinct values is the same as the
number of rows.</p> |

| Column | Type | Reference | Description |
|-------------------|----------|-----------|--|
| n_dndistinct | Real | - | Number of unique non-null data values in the dn1 column <ul style="list-style-type: none">Exact number of distinct values if the value is greater than 0Negative of the number of distinct values divided by the number of rows if the value is less than 0 (For example, if the value of a column appears twice in average, set n_dndistinct=-0.5.)The number of distinct values is unknown if the value is 0. |
| most_common_vals | anyarray | - | List of the most common values in a column. If this combination does not have the most common values, it will be NULL . |
| most_common_freqs | real[] | - | List of the frequencies of the most common values, that is, the number of occurrences of each value divided by the total number of rows. (NULL if most_common_vals is NULL) |
| histogram_bounds | anyarray | - | List of values that divide the column's values into groups of equal proportion. The values in most_common_vals , if present, are omitted from this histogram calculation. This field is null if the field data type does not have a < operator or if the most_common_vals list accounts for the entire population. |
| correlation | Real | - | Statistical correlation between physical row ordering and logical ordering of the column values. It ranges from -1 to +1. When the value is near to -1 or +1, an index scan on the column is estimated to be cheaper than when it is near to zero, due to reduction of random access to the disk. This column is null if the column data type does not have a < operator. |
| most_common_elems | anyarray | - | A list of the most commonly used non-null element values |

| Column | Type | Reference | Description |
|------------------------|--------|-----------|--|
| most_common_elem_freqs | real[] | - | A list of the frequencies of the most commonly used element values |
| elem_count_histogram | real[] | - | A histogram of the counts of distinct non-null element values |
| level | Text | - | Current phase of the memory statistics generated by the lightweight autoanalyze. It can be local , sendlist , or global . |

18.3.262 PV_RUNTIME_RELSTATS

PV_RUNTIME_RELSTATS displays table-level statistics in the memory generated by autoanalyze. The descriptions of the columns in **PV_RUNTIME_RELSTATS** are the same as those in **PG_CLASS**. This view is used only by clusters of version 8.2.0 or later.

Table 18-335 PV_RUNTIME_RELSTATS columns

| Name | Type | Description |
|---------------|------------------|--|
| nspname | Name | Schema name. |
| relname | Name | Name of an object, such as a table or index. |
| relpages | Double precision | Size of the on-disk representation of this table in pages (of size BLCKSZ). This is only an estimate used by the optimizer. |
| reltuples | Double precision | Number of rows in the table. This is only an estimate used by the optimizer. |
| relallvisible | Integer | Number of pages marked as all visible in the table. This column is used by the optimizer for optimizing SQL execution. |
| relhasindex | Boolean | Its value is true if this column is a table and has (or recently had) at least one index. It is set by CREATE INDEX but is not immediately cleared by DROP INDEX . If the VACUUM process detects that a table has no index, it clears the relhasindex column and sets the value to false . |
| changes | Bigint | Total historical modifications in the table by the time the lightweight autoanalyze is triggered. |

| Name | Type | Description |
|----------|------|--|
| level | Text | Current phase of the memory statistics generated by the lightweight autoanalyze. It can be local , sendlist , or global . |
| partname | Name | Partition name This column is available only in clusters of version 8.2.1.200 or later. |

18.3.263 PV_SESSION_MEMORY

PV_SESSION_MEMORY displays statistics about memory usage at the session level in the unit of MB, including all the memory allocated to Postgres and Stream threads on DNs for jobs currently executed by users.

Table 18-336 PV_SESSION_MEMORY columns

| Column | Type | Description |
|----------|---------|---|
| sessid | Text | Thread start time + Thread ID + Node name (string format: <i>timestamp.threadid.nodename</i>)
NOTE
In cluster versions earlier than 8.2.1, sessid contains only the thread start time and thread ID. In cluster versions 8.2.1 and later, the node name is added to sessid , which is in the following format: <i>timestamp.threadid.nodename</i> . |
| init_mem | Integer | Memory allocated to the currently executed task before the task enters the executor, in MB. |
| used_mem | Integer | Memory allocated to the currently executed task, in MB. |
| peak_mem | Integer | Peak memory allocated to the currently executed task, in MB. |

18.3.264 PV_SESSION_MEMORY_DETAIL

PV_SESSION_MEMORY_DETAIL displays statistics about thread memory usage by memory context.

The memory context TempSmallContextGroup collects information about all memory contexts whose value in the **totalsize** column is less than 8192 bytes in the current thread, and the number of the collected memory contexts is recorded in the **usedsize** column. Therefore, the **totalsize** and **freesize** columns for TempSmallContextGroup in the view display the corresponding information about all the memory contexts whose value in the **totalsize** column is less than 8192 bytes in the current thread, and the **usedsize** column displays the number of these memory contexts.

You can run the **SELECT * FROM pv_session_memctx_detail (threadid, '');** statement to record information about all memory contexts of a thread into the

threadid_timestamp.log file in the */tmp/dumpmem* directory. *threadid* can be obtained from the following table.

Table 18-337 PV_SESSION_MEMORY_DETAIL columns

| Column | Type | Description |
|-------------|----------|---|
| sessid | Text | Thread start time + Thread ID + Node name (string format: <i>timestamp.threadid.nodename</i>) |
| sesstype | Text | Thread name |
| contextname | Text | Name of the memory context |
| level | Smallint | Hierarchy of the memory context |
| parent | Text | Name of the parent memory context |
| totalsize | Bigint | Total size of the memory context, in bytes |
| freesize | Bigint | Total size of released memory in the memory context, in bytes |
| usedsize | Bigint | Size of used memory in the memory context, in bytes. For TempSmallContextGroup, this parameter specifies the number of collected memory contexts. |

Example

Query the usage of all MemoryContexts on the current node.

Locate the thread in which the MemoryContext is created and used based on **sessid**. Check whether the memory usage meets the expectation based on **totalsize**, **freesize**, and **usedsize** to see whether memory leakage may occur.

```
SELECT * FROM pv_session_memory_detail;
      sessid      |      sesstype      |      contextname      | level |
parent      | totalsize | freesize | usedsize

18.3.265 PV_SESSION_STAT

PV_SESSION_STAT displays session state statistics based on session threads or the **AutoVacuum** thread.

Table 18-338 PV_SESSION_STAT columns

| Column | Type | Description |
|----------|---------|--|
| sessid | Text | Thread start time + Thread ID + Node name (string format: <i>timestamp.threadid.nodename</i>) |
| statid | Integer | Statistics ID. |
| statname | Text | Name of the statistics session. |
| statunit | Text | Unit of the statistics session. |
| value | Bigint | Value of the statistics session. |

18.3.266 PV_SESSION_TIME

PV_SESSION_TIME displays statistics about the running time of session threads and time consumed in each execution phase, in microseconds.

Table 18-339 PV_SESSION_TIME columns

| Column | Type | Description |
|--------|------|--|
| sessid | Text | Thread start time + Thread ID + Node name (string format: <i>timestamp.threadid.nodename</i>) |

| Column | Type | Description |
|-----------|---------|---------------------------|
| stat_id | Integer | Statistics ID. |
| stat_name | Text | Name of the runtime type. |
| value | Bigint | Runtime value. |

18.3.267 PV_TOTAL_MEMORY_DETAIL

PV_TOTAL_MEMORY_DETAIL displays statistics about memory usage of the current database node in the unit of MB.

Table 18-340 PV_TOTAL_MEMORY_DETAIL columns

| Name | Type | Description |
|----------|------|-------------|
| nodename | Text | Node name |

| Name | Type | Description |
|------------|------|---|
| memorytype | Text | <p>Memory type. Its value can be:</p> <ul style="list-style-type: none">• max_process_memory: memory used by a DWS cluster instance• process_used_memory: memory used by a DWS process• max_dynamic_memory: maximum dynamic memory• dynamic_used_memory: used dynamic memory• dynamic_peak_memory: dynamic peak value of the memory• dynamic_used_shrctx: maximum dynamic shared memory context• dynamic_peak_shrctx: dynamic peak value of the shared memory context• max_shared_memory: maximum shared memory• shared_used_memory: used shared memory• max_cstore_memory: maximum memory allowed for column store• cstore_used_memory: memory used for column store• max_sctpcomm_memory: maximum memory allowed for the communication library• sctpcomm_used_memory: memory used for the communication library• sctpcomm_peak_memory: memory peak of the communication library• other_used_memory: other used memory• gpu_max_dynamic_memory: maximum GPU memory• gpu_dynamic_used_memory: sum of the available GPU memory and temporary GPU memory• gpu_dynamic_peak_memory: maximum memory used for GPU• pooler_conn_memory: memory used for pooler connections• pooler_freeconn_memory: memory used for idle pooler connections• storage_compress_memory: memory used for column-store compression and decompression• udf_reserved_memory: memory reserved for the UDF Worker process |

| Name | Type | Description |
|-------------|---------|--|
| | | <ul style="list-style-type: none">• mmap_used_memory: memory used for mmap |
| memorybytes | Integer | Size of allocated memory-typed memory |

18.3.268 REDACTION_COLUMNS

REDACTION_COLUMNS displays information about all redaction columns in the current database.

Table 18-341 REDACTION_COLUMNS columns

| Name | Type | Description |
|------------------------|---------|--|
| object_schema | name | Redacted object schema. |
| object_owner | Name | Redacted object owner. |
| object_name | Name | Redacted object name. |
| column_name | Name | Redacted column name. |
| function_type | Integer | Redaction type. |
| function_parameters | Text | Parameter used when the redaction type is partial (reserved). |
| regexp_pattern | Text | Pattern string when the redaction type is regexp (reserved). |
| regexp_replace_string | Text | Replacement string when the redaction type is regexp (reserved). |
| regexp_position | Integer | Start and end replacement positions when the redaction type is regexp (reserved). |
| regexp_occurrence | Integer | Replacement times when the redaction type is regexp (reserved). |
| regexp_match_parameter | Text | Regular control parameter used when the redaction type is regexp (reserved). |
| function_info | Text | Redaction function information. |

| Name | Type | Description |
|--------------------|------|--|
| column_description | Text | Description of the redacted column. |
| inherited | Bool | Whether a redacted column is inherited from another redacted column. |
| policy_name | Name | Name of the data masking policy. This parameter is supported only by clusters of version 8.2.1.100 or later. |

18.3.269 REDACTION_POLICIES

REDACTION_POLICIES displays information about all redaction objects in the current database.

Table 18-342 REDACTION_POLICIES columns

| Name | Type | Description |
|--------------------|---------|--|
| object_schema | name | Redacted object schema. |
| object_owner | Name | Redacted object owner. |
| object_name | Name | Redacted object name. |
| policy_name | Name | Name of the redaction policy. |
| expression | Text | Policy effective expression (for users). |
| enable | Boolean | Policy status (enabled or disabled). |
| policy_description | Text | Policy description. |
| inherited | Bool | Whether a redacted column is inherited from another redacted column. |

18.3.270 REMOTE_TABLE_STAT

REMOTE_TABLE_STAT provides statistics of all tables of the database on all DNs in the cluster. Except the **nodename** column of the name type added in front of

each row, the names, types, and sequences of other columns are the same as those in the [GS_TABLE_STAT](#) view.

Table 18-343 REMOTE_TABLE_STAT columns

| Name | Type | Description |
|-------------------|--------|---|
| nodename | Name | Node name |
| schemaname | Name | Table namespace |
| relname | Name | Table name |
| seq_scan | Bigint | Number of sequential scans. Only row-store tables are counted. For a partitioned table, the sum of the number of scans of each partition is displayed. |
| seq_tuple_read | Bigint | Number of rows scanned in sequence. Only row-store tables are counted. |
| index_scan | Bigint | Number of index scans. Only row-store tables are counted. |
| index_tuple_read | Bigint | Number of rows scanned by the index. Only row-store tables are counted. |
| tuple_inserted | Bigint | Number of rows inserted |
| tuple_updated | Bigint | Number of rows updated |
| tuple_deleted | Bigint | Number of rows deleted |
| tuple_hot_updated | Bigint | Number of rows with HOT updates. |
| live_tuples | Bigint | Number of live tuples. Query the view on the CN. If ANALYZE is executed, the total number of live tuples in the table is displayed. Otherwise, 0 is displayed. This indicator applies only to row-store tables. |
| dead_tuples | Bigint | Number of dead tuples. Query the view on the CN. If ANALYZE is executed, the total number of dead tuples in the table is displayed. Otherwise, 0 is displayed. This indicator applies only to row-store tables. |

18.3.271 SHOW_TSC_INFO

Queries TSC information about the current node. This view is supported only by clusters of version 8.2.1 or later.

Table 18-344 Parameter

| Name | Type | Description |
|-----------------------|---------|---|
| node_name | text | Node name |
| tsc_mult | bigint | TSC conversion multiplier |
| tsc_shift | bigint | TSC conversion shifts |
| tsc_frequency | float8 | TSC frequency. |
| tsc_use_frequency | boolean | Indicates whether to use the TSC frequency for time conversion. |
| tsc_ready | boolean | Indicates whether the TSC frequency can be used for time conversion |
| tsc_scalar_error_info | text | Error information about obtaining TSC conversion information |
| tsc_freq_error_info | text | Error information about obtaining TSC frequency information |

18.3.272 SHOW_ALL_TSC_INFO

Queries TSC information about all nodes. This view is supported only by clusters of version 8.2.1 or later.

Table 18-345 Parameter

| Name | Type | Description |
|-----------------------|---------|---|
| node_name | text | Node name |
| tsc_mult | bigint | TSC conversion multiplier |
| tsc_shift | bigint | TSC conversion shifts |
| tsc_frequency | float8 | TSC frequency. |
| tsc_use_frequency | boolean | Indicates whether to use the TSC frequency for time conversion. |
| tsc_ready | boolean | Indicates whether the TSC frequency can be used for time conversion |
| tsc_scalar_error_info | text | Error information about obtaining TSC conversion information |
| tsc_freq_error_info | text | Error information about obtaining TSC frequency information |

18.3.273 USER_COL_COMMENTS

USER_COL_COMMENTS stores the column comments of the tables and views that the current user can access.

| Column | Type | Description |
|-------------|-----------------------|----------------------------|
| column_name | character varying(64) | Column name |
| table_name | character varying(64) | Table or view name |
| owner | character varying(64) | Owner of the table or view |
| comments | Text | Comments |

18.3.274 USER_CONSTRAINTS

USER_CONSTRAINTS displays the table constraint information accessible to the current user.

| Column | Type | Description |
|-----------------|------------------------|---|
| constraint_name | vcharacter varying(64) | Constraint name |
| constraint_type | Text | Constraint type <ul style="list-style-type: none">• C: Check constraint• F: Foreign key constraint• P: Primary key constraint• U: Unique constraint. |
| table_name | character varying(64) | Name of constraint-related table |
| index_owner | character varying(64) | Owner of constraint-related index (only for the unique constraint and primary key constraint) |
| index_name | character varying(64) | Name of constraint-related index (only for the unique constraint and primary key constraint) |

Example

Query constraints on a specified table of the current user. Replace **t1** with the actual table name.

```
SELECT * FROM USER_CONSTRAINTS WHERE table_name='t1';
constraint_name | constraint_type | table_name | index_owner | index_name
-----+-----+-----+-----+-----
c_custkey_key   | p               | t1         | u1          | c_custkey_key
(1 row)
```

18.3.275 USER_CONS_COLUMNS

USER_CONS_COLUMNS displays the information about constraint columns in the tables accessible to the current user.

| Column | Type | Description |
|-----------------|-----------------------|-------------------------------------|
| table_name | character varying(64) | Name of constraint-related table |
| column_name | character varying(64) | Name of constraint-related column |
| constraint_name | character varying(64) | Constraint name |
| position | Smallint | Position of the column in the table |

18.3.276 USER_INDEXES

USER_INDEXES displays index information in the current schema.

| Column | Type | Description |
|-------------|-----------------------|---|
| owner | character varying(64) | Index owner |
| index_name | character varying(64) | Index name |
| table_name | character varying(64) | Name of the table corresponding to the index |
| uniqueness | Text | Whether the index is unique |
| generated | character varying(1) | Whether the index name is generated by the system |
| partitioned | character(3) | Whether the index has the property of the partition table |

18.3.277 USER_IND_COLUMNS

USER_IND_COLUMNS displays column information about all indexes accessible to the current user.

| Column | Type | Description |
|-------------|-----------------------|-------------|
| index_owner | character varying(64) | Index owner |

| Column | Type | Description |
|-----------------|-----------------------|-----------------------------------|
| index_name | character varying(64) | Index name |
| table_owner | character varying(64) | Table owner |
| table_name | character varying(64) | Table name |
| column_name | Name | Column name |
| column_position | Smallint | Position of a column in the index |

18.3.278 USER_IND_EXPRESSIONS

USER_IND_EXPRESSIONS displays information about the function-based expression index accessible to the current user.

| Column | Type | Description |
|-------------------|-----------------------|---|
| index_owner | character varying(64) | Index owner |
| index_name | character varying(64) | Index name |
| table_owner | character varying(64) | Table owner |
| table_name | character varying(64) | Table name |
| column_expression | Text | Function-based index expression of a specified column |
| column_position | Smallint | Position of a column in the index |

18.3.279 USER_IND_PARTITIONS

USER_IND_PARTITIONS displays information about index partitions accessible to the current user.

| Column | Type | Description |
|-------------|-----------------------|---|
| index_owner | character varying(64) | Name of the owner of the partitioned table index to which the index partition belongs |
| schema | character varying(64) | Schema of the partitioned index to which the index partition belongs |
| index_name | character varying(64) | Index name of the partitioned table to which the index partition belongs |

| Column | Type | Description |
|------------------------|-----------------------|--|
| partition_name | character varying(64) | Name of the index partition |
| index_partition_usable | boolean | Whether the index partition is available |
| high_value | Text | Boundary of the table partition corresponding to the index partition. For a range partition, the boundary is the upper boundary. For a list partition, the boundary is the boundary value set.

Reserved field for forward compatibility. The parameter pretty_high_value is added in version 8.1.3 to record the information. |
| pretty_high_value | Text | Boundary of the table partition corresponding to the index partition. For a range partition, the boundary is the upper boundary. For a list partition, the boundary is the boundary value set.

The query result is the instant decompilation output of the partition boundary expression. The output of this column is more detailed than that of high_value . The output information can be collation and column data type. |
| def_tablespace_name | Name | Tablespace name of the index partition |

18.3.280 USER_JOBS

USER_JOBS displays all scheduled jobs owned by the current user. This view is accessible only to users with system administrator rights.

Table 18-346 USER_JOBS columns

| Column | Type | Description |
|-----------|---------------|--------------------------------------|
| job | INT4 | Job ID |
| log_user | name not null | User name of the job creator |
| priv_user | name not null | User name of the job executor |
| dbname | name not null | Database in which the job is created |

| Column | Type | Description |
|------------|-----------------------------|---|
| start_date | Timestamp without time zone | Job start time |
| start_suc | Text | Start time of the successful job execution |
| last_date | Timestamp without time zone | Start time of the last job execution |
| last_suc | Text | Start time of the last successful job execution |
| this_date | Timestamp without time zone | Start time of the ongoing job execution |
| this suc | Text | Same as THIS_DATE |
| next_date | Timestamp without time zone | Schedule time of the next job execution |
| next suc | Text | Same as next_date |
| broken | Text | Task status
Y : the system does not try to execute the task.
N : the system attempts to execute the task. |
| status | Char | Status of the current job. The value range is 'r', 's', 'f', 'd'. The default value is 's'. The indications are as follows: <ul style="list-style-type: none">• r: running• s: finished• f: failed• d: aborted |
| interval | Text | Time expression used to calculate the next execution time. If this parameter is set to null , the job will be executed once only. |
| failures | Smallint | Number of consecutive failures. |
| what | Text | Body of the PL/SQL blocks or anonymous block that the job executes |

18.3.281 USER_OBJECTS

USER_OBJECTS displays all database objects accessible to the current user.

| Column | Type | Description |
|---------------|--------------------------|--|
| owner | Name | Owner of the object |
| object_name | Name | Object name |
| object_id | OID | OID of the object |
| object_type | Name | Type of the object |
| namespace | OID | Namespace containing the object |
| created | Timestamp with time zone | Object creation time |
| last_ddl_time | Timestamp with time zone | Last time when the object was modified |

NOTICE

For details about the value ranges of **last_ddl_time** and **last_ddl_time**, see [PG_OBJECT](#).

18.3.282 USER_PART_INDEXES

USER_PART_INDEXES displays information about partitioned table indexes accessible to the current user.

| Column | Type | Description |
|-------------------|-----------------------|---|
| index_owner | character varying(64) | Name of the owner of the partitioned table index |
| schema | character varying(64) | Schema of the partitioned table index |
| index_name | character varying(64) | Name of the partitioned table index |
| table_name | character varying(64) | Name of the partitioned table to which the partitioned table index belongs |
| partitioning_type | Text | Partition policy of the partitioned table
NOTE
Currently, only range partitioning and list partitioning are supported. |
| partition_count | Bigint | Number of index partitions of the partitioned table index |

| Column | Type | Description |
|------------------------|---------|---|
| def_tablespace_name | Name | Tablespace name of the partitioned table index |
| partitioning_key_count | Integer | Number of partition keys of the partitioned table |

18.3.283 USER_PART_TABLES

USER_PART_TABLES displays information about partitioned tables accessible to the current user.

| Column | Type | Description |
|------------------------|-----------------------|---|
| table_owner | character varying(64) | Name of the owner of the partitioned table |
| schema | character varying(64) | Schema of the partitioned table |
| table_name | character varying(64) | Name of the partitioned table |
| partitioning_type | Text | Partition policy of the partitioned table
NOTE
Currently, only range partitioning and list partitioning are supported. |
| partition_count | Bigint | Number of partitions of the partitioned table |
| def_tablespace_name | Name | Tablespace name of the partitioned table |
| partitioning_key_count | Integer | Number of partition keys of the partitioned table |

18.3.284 USER_PROCEDURES

USER_PROCEDURES displays information about all stored procedures and functions in the current schema.

| Column | Type | Description |
|--------|-----------------------|---|
| owner | character varying(64) | Owner of the stored procedure or the function |

| Column | Type | Description |
|-----------------|-----------------------|--|
| object_name | character varying(64) | Name of the stored procedure or the function |
| argument_number | Smallint | Number of the input parameters in the stored procedure |

18.3.285 USER_SEQUENCES

USER_SEQUENCES displays sequence information in the current schema.

| Column | Type | Description |
|----------------|-----------------------|-----------------------|
| sequence_owner | character varying(64) | Owner of the sequence |
| sequence_name | character varying(64) | Name of the sequence |

18.3.286 USER_SOURCE

USER_SOURCE displays information about stored procedures or functions in this mode, and provides the columns defined by the stored procedures or the functions.

| Column | Type | Description |
|--------|-----------------------|--|
| owner | character varying(64) | Owner of the stored procedure or the function |
| Name | character varying(64) | Name of the stored procedure or the function |
| Text | Text | Definition of the stored procedure or the function |

18.3.287 USER_SYNONYMS

USER_SYNONYMS displays synonyms accessible to the current user.

Table 18-347 USER_SYNONYMS columns

| Name | Type | Description |
|--------------|------|--|
| schema_name | Text | Name of the schema the synonym belongs to. |
| synonym_name | Text | Synonym name. |

| Name | Type | Description |
|-------------------|------|--|
| table_owner | Text | Owner of the associated object. |
| table_schema_name | Text | Name of the schema the associated object belongs to. |
| table_name | Text | Name of the associated object. |

18.3.288 USER_TAB_COLUMNS

USER_TAB_COLUMNS stores information about columns of the tables and views that the current user can access.

| Column | Type | Description |
|----------------|------------------------|---|
| owner | character varying(64) | Owner of a table/view |
| table_name | character varying(64) | Table/View name |
| column_name | character varying(64) | Column name |
| data_type | character varying(128) | Data type of the column |
| column_id | Integer | Sequence number of the column when a table/view is created |
| data_length | Integer | Length of the column, in bytes |
| comments | Text | Comments |
| avg_col_len | Numeric | Average length of a column, in bytes |
| nullable | bpchar | Whether the column can be empty. For the primary key constraint and non-null constraint, the value is n. |
| data_precision | Integer | Precision of the data type. This parameter is valid for the numeric data type and NULL for other data types. |
| data_scale | Integer | Number of decimal places. This parameter is valid for the numeric data type and 0 for other data types. |

| Column | Type | Description |
|-------------|-----------------------|---|
| char_length | Numeric | Length of a column, in characters. This parameter is valid only for the varchar, nvarchar2, bpchar, and char types. |
| schema | character varying(64) | Namespace that contains the table or view. |
| kind | Text | Type of the current record. If the column belongs to a table, the value of this column is table . If the column belongs to a view, the value of this column is view . |

18.3.289 USER_TAB_COMMENTS

USER_TAB_COMMENTS displays comments about all tables and views accessible to the current user.

| Column | Type | Description |
|------------|-----------------------|----------------------------|
| owner | character varying(64) | Owner of the table or view |
| table_name | character varying(64) | Name of the table or view |
| comments | Text | Comments |

18.3.290 USER_TAB_PARTITIONS

USER_TAB_PARTITIONS displays all table partitions accessible to the current user. Each partition of a partitioned table accessible to the current user has a piece of record in **USER_TAB_PARTITIONS**.

| Column | Type | Description |
|----------------|-----------------------|--|
| table_owner | character varying(64) | Owner of the table that contains the partition |
| schema | character varying(64) | Schema of the partitioned table |
| table_name | character varying(64) | Table name |
| partition_name | character varying(64) | Name of the partition |

| Column | Type | Description |
|-------------------|------|---|
| high_value | Text | Upper boundary of a range partition or boundary value set of a list partition

Reserved field for forward compatibility. The parameter pretty_high_value is added in version 8.1.3 to record the information. |
| pretty_high_value | Text | Upper boundary of a range partition or boundary value set of a list partition

The query result is the instant decompilation output of the partition boundary expression. The output of this column is more detailed than that of high_value . The output information can be collation and column data type. |
| tablespace_name | Name | Name of the tablespace that contains the partition |

18.3.291 USER_TABLES

USER_TABLES displays table information in the current schema.

| Column | Type | Description |
|-----------------|-----------------------|--|
| owner | character varying(64) | Table owner |
| table_name | character varying(64) | Table name |
| tablespace_name | character varying(64) | Name of the tablespace that contains the table |
| status | character varying(8) | Whether the current record is valid |
| temporary | character(1) | Whether the table is a temporary table <ul style="list-style-type: none">• Y indicates that it is a temporary table.• N indicates that it is not a temporary table. |

| Column | Type | Description |
|----------|-------------------|--|
| dropped | character varying | Whether the current record is deleted <ul style="list-style-type: none">• YES indicates that it is deleted.• NO indicates that it is not deleted. |
| num_rows | Numeric | Estimated number of rows in the table |

18.3.292 USER_TRIGGERS

USER_TRIGGERS displays the information about triggers accessible to the current user.

| Column | Type | Description |
|--------------|-----------------------|---|
| trigger_name | character varying(64) | Trigger name |
| table_name | character varying(64) | Name of the table that defines the trigger |
| table_owner | character varying(64) | Owner of the table that defines the trigger |

18.3.293 USER_VIEWS

USER_VIEWS displays information about all views in the current schema.

| Column | Type | Description |
|-----------|-----------------------|-------------------|
| owner | character varying(64) | Owner of the view |
| view_name | character varying(64) | View name |

18.3.294 V\$SESSION

V\$SESSION displays all session information about the current session.

Table 18-348 V\$SESSION columns

| Name | Type | Description |
|------|--------|---|
| sid | Bigint | OID of the background process of the current activity |

| Name | Type | Description |
|----------|---------|---|
| serial# | Integer | Sequence number of the active background process, which is 0 in DWS. |
| user# | OID | OID of the user that has logged in to the background process |
| username | Name | Name of the user that has logged in to the background process |

18.3.295 V\$SESSION_LONGOPS

V\$SESSION_LONGOPS displays the progress of ongoing operations.

Table 18-349 V\$SESSION_LONGOPS columns

| Name | Type | Description |
|-----------|---------|--|
| sid | Bigint | OID of the running background process |
| serial# | Integer | Sequence number of the running background process, which is 0 in DWS. |
| sofar | Integer | Completed workload, which is empty in DWS. |
| totalwork | Integer | Total workload, which is empty in DWS. |

19 GUC Parameters of the DWS Database

19.1 Viewing GUC Parameters

DWS GUC parameters can control database system behaviors. You can check and adjust the GUC parameters based on your business scenario and data volume.

- Method 1: After a cluster is installed, you can check database parameters on the DWS management console.
- Method 2: You can also connect to a cluster and run SQL commands to check the GUC parameters.
 - Run the **SHOW** command.

NOTE

Method 2 can only be used to check the GUC parameter values of CNs, while the GUC parameter values of DN can be viewed through Method 1: by using the management console.

To view a certain parameter, run the following command:

```
SHOW server_version;
```

server_version indicates the database version.

Run the following command to view values of all parameters:

```
SHOW ALL;
```

- Use the **pg_settings** view.

To view a certain parameter, run the following command:

```
SELECT * FROM pg_settings WHERE NAME='server_version';
```

Run the following command to view values of all parameters:

```
SELECT * FROM pg_settings;
```

19.2 Configuring GUC Parameters

To ensure the optimal performance of DWS, you can adjust the GUC parameters in the database.

Parameter Types and Values

- The GUC parameters of DWS are classified into the following types:
 - **SUSET**: database administrator parameters. This type of parameters takes effect immediately after they are set. You do not need to restart the cluster. If a parameter of this type is set in the current session, the parameter takes effect only in the current session.
 - **USERSET**: common user parameters. This type of parameters takes effect immediately after they are set. You do not need to restart the cluster. If a parameter of this type is set in the current session, the parameter takes effect only in the current session.
 - **POSTMASTER**: database server parameters. This type of parameters takes effect only after the cluster is restarted. After you modify a parameter of this type, the system displays a message indicating that the cluster is to be restarted. You are advised to manually restart the cluster during off-peak hours for the setting to take effect.
 - **SIGHUP**: global database parameters. This type of parameters takes effect globally and cannot take effect for single sessions.
 - **BACKEND**: global database parameters. This type of parameters takes effect globally and cannot take effect for single sessions.
- All parameter names are case insensitive. A parameter value can be an integer, floating point number, string, Boolean value, or enumerated value.
 - The Boolean values can be **on/off**, **true/false**, **yes/no**, or **1/0**, and are case-insensitive.
 - The enumerated value range is specified in the **enumvals** column of the system catalog **pg_settings**.
- For parameters using units, specify their units during the setting, or default units are used.
 - The default units are specified in the **unit** column of **pg_settings**.
 - The unit of memory can be KB, MB, or GB.
 - The unit of time can be ms, s, min, h, or d.

Setting GUC Parameters

You can configure GUC parameters in the following ways:

- Method 1: After a cluster is created, log in to the DWS console and modify the database parameters of the cluster. For details, see "Modifying GUC Parameters of the DWS Cluster" in the *Data Warehouse Service (DWS) User Guide*.
- Method 2: Connect to a cluster and run SQL commands to configure the parameters of the SUSET or USERSET type.

Set parameters at database, user, or session levels.

- Set a database-level parameter.

```
ALTER DATABASE dbname SET paraname TO value;
```

The setting takes effect in the next session.
- Set a user-level parameter.

```
ALTER USER username SET paraname TO value;
```

The setting takes effect in the next session.

- Set a session-level parameter.

```
SET paraname TO value;
```

Parameter value in the current session is changed. After you exit the session, the setting becomes invalid.

Procedure

The following example shows how to set **explain_perf_mode**.

Step 1 View the value of **explain_perf_mode**.

```
SHOW explain_perf_mode;  
explain_perf_mode  
-----  
normal  
(1 row)
```

Step 2 Set **explain_perf_mode**.

Perform one of the following operations:

- Set a database-level parameter.

```
ALTER DATABASE gaussdb SET explain_perf_mode TO pretty;
```

If the following information is displayed, the setting has been modified.

```
ALTER DATABASE
```

The setting takes effect in the next session.

- Set a user-level parameter.

```
ALTER USER dbadmin SET explain_perf_mode TO pretty;
```

If the following information is displayed, the setting has been modified.

```
ALTER USER
```

The setting takes effect in the next session.

- Set a session-level parameter.

```
SET explain_perf_mode TO pretty;
```

If the following information is displayed, the setting has been modified.

```
SET
```

Step 3 Check whether the parameter is correctly set.

```
SHOW explain_perf_mode;  
explain_perf_mode  
-----  
pretty  
(1 row)
```

----End

19.3 GUC Parameter Usage

The database provides many operation parameters. Configuration of these parameters affects the behavior of the database system. Before modifying these parameters, learn the impact of these parameters on the database. Otherwise, unexpected results may occur.

Precautions

- If the value range of a parameter is a string, the string should comply with the naming conventions of the path and file name in the OS running the database.
- If the allowed maximum value of a parameter is **INT_MAX**, it indicates the maximum parameter value varies by OS.
- If the allowed maximum value of a parameter is **DBL_MAX**, it indicates the maximum parameter value varies by OS.

19.4 Connection and Authentication

19.4.1 Connection Settings

This section describes parameters related to the connection mode between the client and server.

max_connections

Parameter description: Specifies the maximum number of allowed parallel connections to the database. This parameter influences the concurrent processing capability of the cluster.

Type: POSTMASTER

Value range: an integer. For CNs, the value ranges from 100 to 16384. For DNs, the value ranges from 100 to 262143. Because there are internal connections in the cluster, the maximum value is rarely reached. If **invalid value for parameter "max_connections"** is displayed in the log, you need to decrease the **max_connections** value for DNs.

Default value: **800** for CNs and **5000** for DNs. If the default value is greater than the maximum value supported by kernel (determined when the **gs_initdb** command is executed), an error message will be displayed.

Setting suggestions:

Retain the default value of this parameter on CNs. On a DN, the value of this parameter is calculated as follows:

$\text{dop_limit} \times 20 \times 6 + 24$: **dop_limit** indicates the number of CPUs of each DN in the cluster. It is calculated as follows: **dop_limit** = Number of logical CPU cores of a single server/Number of DNs of a single server.

The minimum value is 5000.

If the parameter is set to a large value, DWS requires more SystemV shared memories or semaphores, which may exceed the maximum default configuration of the OS. In this case, modify the value as needed.

NOTICE

The value of **max_connections** is related to **max_prepared_transactions**. Before setting **max_connections**, ensure that the value of **max_prepared_transactions** is greater than or equal to that of **max_connections**. In this way, each session has a prepared transaction in the waiting state.

application_name

Parameter description: Specifies the name of the client program connecting to the database.

Type: USERSET

Value range: a string

Default value: `gsq`

connection_info

Parameter description: Specifies the database connection information, including the driver type, driver version, driver deployment path, and process owner. (This is an O&M parameter. Do not configure it by yourself.)

Type: USERSET

Value range: a string

Default value: an empty string

 NOTE

- An empty string indicates that the driver connected to the database does not support automatic setting of the **connection_info** parameter or the parameter is not set by users in applications.
- The following is an example of the concatenated value of **connection_info**:

```
{"driver_name":"ODBC","driver_version": "(GaussDB x.x.x build 39137c2d) compiled at 2022-09-23 15:43:11 commit 3629 last mr 5138 debug","driver_path":"/usr/local/lib/psqlodbcw.so","os_user":"omm"}
```

By default, **driver_name**, **driver_version**, **driver_path**, and **os_user** are displayed for ODBC, JDBC, and `gsq` connections. For other connections, **driver_name** and **driver_version** are displayed by default. The display of **driver_path** and **os_user** is controlled by users (see [Connecting to a Database](#) and [Configuring a Data Source in the Linux OS](#)).

19.4.2 Security and Authentication (postgresql.conf)

This section describes parameters about how to securely authenticate the client and server.

session_timeout

Parameter description: Specifies the maximum idle time without any operations after a connection to the server is established.

Type: USERSET

Value range: an integer ranging from 0 to 86400. The minimum unit is second (s). 0 means to disable the timeout.

Default value: 10 min

NOTICE

- The gsql client of DWS has an automatic reconnection mechanism. If the initialized local connection of a user to the server times out, gsql disconnects from and reconnects to the server.
 - Connections from the pooler connection pool to other CNs and DNPs are not controlled by the **session_timeout** parameter.
-

ssl_renegotiation_limit

Parameter description: Specifies the traffic volume over the SSL-encrypted channel before the session key is renegotiated. The renegotiation traffic limitation mechanism reduces the probability that attackers use the password analysis method to crack the key based on a huge amount of data but causes big performance losses. The traffic indicates the sum of sent and received traffic.

Type: USERSET

NOTE

You are advised to retain the default value, that is, disable the renegotiation mechanism. You are not advised to use the **gs_guc** tool or other methods to set the **ssl_renegotiation_limit** parameter in the **postgresql.conf** file. The setting does not take effect.

Value range: an integer ranging from 0 to **INT_MAX**. The unit is KB. 0 indicates that the renegotiation mechanism is disabled.

Default value: 0

failed_login_attempts

Parameter description: Specifies the maximum number of incorrect password attempts before an account is locked. The account will be automatically unlocked after the time specified in **password_lock_time**. For example, incorrect password attempts during login and password input failures when using the **ALTER USER** command

Type: SIGHUP

Value range: an integer ranging from 0 to 1000

- 0 indicates that the automatic locking function does not take effect.
- A positive number indicates that an account is locked when the number of incorrect password attempts reaches the value of **failed_login_attempts**.

Default value: 10

NOTICE

- The locking and unlocking functions take effect only when the values of **failed_login_attempts** and **password_lock_time** are positive numbers.
 - **failed_login_attempts** works with the SSL connection mode of the client to identify the number of incorrect password attempts. If PGSSLMODE is set to **allow** or **prefer**, two connection requests are generated for a password connection request. One request attempts an SSL connection, and the other request attempts a non-SSL connection. In this case, the number of incorrect password attempts perceived by the user is the value of **failed_login_attempts** divided by 2.
-

19.4.3 Communication Library Parameters

This section describes parameter settings and value ranges for communication libraries.

tcp_keepalives_idle

Parameter description: Specifies the interval between keepalive signal sending in an OS that supports the **TCP_KEEPIDLE** socket parameter. If no keepalive signal is transmitted, the connection is in idle state.

Type: USERSET

NOTICE

- If the OS does not support the **TCP_KEEPIDLE** parameter, set this parameter to 0.
 - The parameter is ignored on the OS where connections are established using the Unix domain socket.
-

Value range: an integer ranging from 0 to 3600. The unit is second (s).

Default value: 0

tcp_keepalives_interval

Parameter description: Specifies the response time before retransmission when the OS supports the **TCP_KEEPINTVL** socket parameter.

Type: USERSET

Value range: an integer ranging from 0 to 180. The unit is second (s).

Default value: 0

NOTICE

- If the OS does not support the **TCP_KEEPINTVL** parameter, set this parameter to **0**.
 - The parameter is ignored on the OS where connections are established using the Unix domain socket.
-

tcp_keepalives_count

Parameter description: Specifies the number of keepalived signals that can be waited before the DWS server is disconnected from the client if the OS supports the **TCP_KEEPCNT** socket parameter.

Type: USERSET

NOTICE

- If the OS does not support the **TCP_KEEPCNT** parameter, set this parameter to **0**.
 - The parameter is ignored on the OS where connections are established using the Unix domain socket.
-

Value range: an integer ranging from 0 to 100. **0** indicates that the connection is immediately broken if DWS does not receive a keepalived signal from the client.

Default value: 0

comm_max_datanode

Parameter description: Specifies the maximum number of DN's supported by the communication library.

Type: USERSET

Value range: an integer ranging from 1 to 8192

Default value: actual number of DN's

NOTICE

Increasing this parameter value takes effect immediately, while decreasing the value takes effect after the cluster is restarted.

comm_max_stream

Parameter description: maximum number of logical connection data structures cached in the communication library.

Type: SIGHUP

Value range: an integer ranging from 1 to 65535

Default value: 1024

 NOTE

If the value of `comm_max_datanode` is small, the process memory is sufficient. In this case, you can increase the value of `comm_max_stream`.

`max_stream_pool`

Parameter description: Specifies the maximum number of stream threads that can be contained in a stream thread pool. This feature is supported in 8.1.2 or later.

Type: SUSET

Value range: an integer ranging from -1 to INT_MAX. The values -1 and 0 indicate that the stream thread pool is disabled.

Default value:

- The formula for a new cluster is `max_stream_pool=MIN(max_connections, max_process_memory/16/5MB, 1024)`.
- The formula for a cluster upgraded from versions earlier than 8.3.0.100 is `max_stream_pool = MIN(max_connections, max_process_memory/16/5MB, 1024, value-of-the-old-cluster)`. During the upgrade, the settings for the new cluster are forcibly used. The old value is used if it is smaller.

 NOTE

- The number of stream threads in a thread pool can be reduced in real time. If the value of this parameter is increased, the number of stream threads is increased to meet the service requirements.
- Generally, you are advised not to change the value of this parameter because the stream thread pool supports the automatic cleanup function.
- If too many idle stream threads occupy the memory, you can decrease the value of this parameter to save the memory.

`enable_stream_sync_quit`

Parameter description: whether the stream threads exit synchronously when the stream plan ends. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that threads in the stream thread group exit after the stream plan ends.
- **off** indicates that stream threads exit directly after the stream plan ends without waiting for the threads in the stream thread group to exit.

Default value: off

enable_connect_standby

Parameter description: Sets the connection between a CN and a standby DN. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the CN connects to the standby server.
- **off** indicates that the CN connects to the primary DN.

Default value: off

CAUTION

- You are not advised to use this parameter in routine services. This parameter applies only to O&M operations. You are not advised to use the **gs_guc tool** for global settings. Otherwise, problems such as data inconsistency and result set errors may occur.
 - Enabling this parameter for a session with temporary tables will delete the temporary table data on DNs and prevent further actions on those tables.
-

comm_quota_size

Parameter description: Specifies the maximum size of packets that can be continuously sent by the communication library. When you use a 1GE NIC, a small value ranging from 20 KB to 40 KB is recommended.

Type: USERSET

Value range: an integer ranging from 0 to 102400. The default unit is KB. The value **0** indicates that the quota mechanism is not used.

Default value: 1 MB

comm_usable_memory

Parameter description: Specifies the maximum memory that can be used by the communication library cache on a single DN.

Type: SIGHUP

Value range: an integer ranging from 1 to 256. The default unit is KB. The minimum size cannot be less than 1 GB for installation.

Default value: max_process_memory/8

NOTICE

This parameter must be specifically set based on environment memory and the deployment method. If it is too large, out-of-memory (OOM) may occur. If it is too small, the performance of the communication library may deteriorate.

comm_client_bind

Parameter description: Specifies whether to bind the client of the communication library to a specified IP address when the client initiates a connection.

Type: USERSET

Value range: Boolean

- **on** indicates that the client is bound to a specified IP address.
- **off** indicates that the client is not bound to any IP addresses.

NOTICE

If multiple IP addresses of a node in a cluster are on the same communication network segment, set this parameter to **on**. In this case, the client is bound to the IP address specified by **listen_addresses**. The concurrency performance of a cluster depends on the number of random ports because a port can be used only by one client at a time.

Default value: off

comm_no_delay

Parameter description: Specifies whether to use the **NO_DELAY** attribute of the communication library connection. Restart the cluster for the setting to take effect.

Type: USERSET

Value range: Boolean

Default value: off

NOTICE

If packet loss occurs because a large number of packets are received per second, set this parameter to **off** to reduce the total number of packets.

comm_debug_mode

Parameter description: Specifies the debug mode of the communication library, that is, whether to print logs about the communication layer. The setting is effective at the session layer.

NOTICE

When the switch is set to **on**, the number of printed logs is huge, adding extra overhead and reducing database performance. Therefore, set the switch to **on** only in the debug mode.

Type: USERSET

Value range: Boolean

- **on** indicates the detailed debug log of the communication library is printed.
- **off** indicates the detailed debug log of the communication library is not printed.

Default value: off

comm_ackchk_time

Parameter description: Specifies the duration after which the communication library server automatically triggers ACK when no data package is received.

Type: USERSET

Value range: an integer ranging from 0 to 20000. The unit is millisecond (ms). 0 indicates that automatic ACK triggering is disabled.

Default value: 2000

comm_timer_mode

Parameter description: Specifies the timer mode of the communication library, that is, whether to print timer logs in each phase of the communication layer. The setting is effective at the session layer.

NOTICE

When the switch is set to **on**, the number of printed logs is huge, adding extra overhead and reducing database performance. Therefore, set the switch to **on** only in the debug mode.

Type: USERSET

Value range: Boolean

- **on** indicates the detailed timer log of the communication library is printed.
- **off** indicates the detailed timer log of the communication library is not printed.

Default value: off

comm_stat_mode

Parameter description: Specifies the stat mode of the communication library, that is, whether to print statistics about the communication layer. The setting is effective at the session layer.

NOTICE

When the switch is set to **on**, the number of printed logs is huge, adding extra overhead and reducing database performance. Therefore, set the switch to **on** only in the debug mode.

Type: USERSET

Value range: Boolean

- **on** indicates the statistics log of the communication library is printed.
- **off** indicates the statistics log of the communication library is not printed.

Default value: off

client_connection_check_interval

Parameter description: Specifies the interval for checking the client connection status. This parameter is supported by clusters of version 8.2.0 or later.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX. The unit is ms. The value 0 indicates that the client connection status is not checked.

Default value: 10000

NOTICE

During a long query executed in a session where a client (such as gsql, JDBC, or ODBC) directly connects to the CN,

- The CN checks the client connection status at the interval specified by **client_connection_check_interval**. If it detects that the client has been disconnected from the CN, the server terminates the long query and releases related resources to avoid waste of cluster resources.
- The DN checks its connection to the CN at the interval specified by **client_connection_check_interval**. If the DN detects that it has been disconnected from the CN, it terminates the long query and releases related resources to avoid waste of cluster resources.

conn_recycle_timeout

Parameter description: the interval for reclaiming idle connections between a CN and other nodes to the connection pool. This parameter is supported only by clusters of version 8.2.1 or later.

Type: USERSET

Value range: an integer ranging from 0 to 3600, in second (s). 0 indicates that the function of reclaiming idle connections is disabled.

Default value: 30

19.5 Resource Consumption

19.5.1 Memory

This section describes memory parameters.

NOTICE

Parameters described in this section take effect only after the database service restarts.

max_process_memory

Parameter description: Specifies the maximum physical memory of a database node.

Type: SIGHUP

Value range: an integer ranging from $2 \times 1024 \times 1024$ to $\text{INT_MAX}/2$. The unit is KB.

Default value: Determined based on non-secondary DNs. If multiple DNs are deployed on a server, the value is $(\text{Physical memory size}) \times 0.8 / (1 + \text{Number of primary DNs})$. If a single DN is deployed on a server, the value is $(\text{Physical memory size}) \times 0.6$. If the calculation result is less than 2 GB, the value is 2 GB by default. The default size of the secondary DN is 12 GB.

Setting suggestions:

 CAUTION

Single-node deployment applies only to existing users.

- On DNs, the value of this parameter is determined based on the server's physical memory and the number of DNs deployed on a single node.

If multiple DNs are deployed on a server, the calculation formula for the **max_process_memory** value is as follows: $(\text{Physical memory size} - \text{vm.min_free_kbytes}) \times 0.8 / (n + \text{Number of primary DNs})$. If only one DN is deployed on a server, the calculation formula for the **max_process_memory** value is $(\text{Physical memory size} - \text{vm.min_free_kbytes}) \times 0.6$.

This parameter aims to ensure system reliability, preventing node OOM caused by increasing memory usage. **vm.min_free_kbytes** indicates OS memory reserved for kernels to receive and send data. Its value is at least 5% of the total memory. That is, **max_process_memory** = $\text{Physical memory} \times 0.8 / (n + \text{Number of primary DNs})$. If the cluster scale (number of nodes in the cluster) is smaller than 256, $n=1$; if the cluster scale is larger than 256 and smaller than 512, $n=2$; if the cluster scale is larger than 512, $n=3$.

- You are not advised to set this parameter to the minimum threshold.
- Set this parameter on CNs to the same value as that on DN.
- RAM is the maximum memory allocated to the cluster.
- In DWS 8.2.0 and later versions, the initial value of **max_process_memory** is increased to improve memory resource utilization. However, in an unbalanced cluster where a server has two primary DNs running, using the initial value of **max_process_memory** may cause OOM. In DWS 8.2.0 and later versions, the **max_process_memory** parameter is changed to the SIGHUP type and can be manually adjusted. The **max_process_memory_auto_adjust** parameter is added. If a cluster is unbalanced, its CM will dynamically adjust **max_process_memory** based on the cluster status. The value of **max_process_memory** is $(\text{Physical memory} - \text{vm.min_free_kbytes}) \times 0.8 / \text{Number of primary DNs}$.
- In DWS 8.2.1 or later, the application scope of dynamically adjusting the value of **max_process_memory** is expanded from clusters where each server has only one DN to all cluster deployment modes.
 - If **max_process_memory_auto_adjust** is set to **on**, the value of **max_process_memory** is dynamically adjusted between the upper limit and the lower limit. The lower limit is calculated as follows: $(\text{Physical memory size}) \times 0.8 / (1 + \text{Number of primary DNs})$. The upper limit is specified by the GUC parameter **max_process_memory_balanced**. (For details about how to set **max_process_memory_balanced**, contact technical support.)
 - When the cluster works in load balancing mode, the upper limit of **max_process_memory** is used to improve the overall memory usage of the node. Compared with earlier versions, the memory usage is improved.
 - When the cluster is not in load balancing mode, the lower limit of **max_process_memory** is used. The overall memory usage of the node is the same as that in versions earlier than 8.2.1.
 - In upgrade scenarios, to ensure forward compatibility, the system does not set **max_process_memory_balanced**, and **max_process_memory** uses the value set before the upgrade by default.

max_process_memory_auto_adjust

Parameter description: Specifies whether to enable automatic adjustment for **max_process_memory** parameter. (This parameter is supported only by cluster versions 8.2.0 and later.)

Type: SIGHUP

Value range: Boolean

Default value: on

shared_buffers

Parameter description: Specifies the size of shared memory used by DWS. If this parameter is set to a large value, DWS may require more System V shared memory than the default setting.

Type: POSTMASTER

Value range: an integer ranging from 128 to INT_MAX. The unit is 8 KB.

Changing the value of **BLCKSZ** will result in a change in the minimum value of the **shared_buffers**.

Default value: The value of this parameter for CNs is half of that for DN, which is calculated using the formula **POWER(2,ROUND(LOG(2,max_process_memory/18),0))**. If the maximum value allowed by the OS is smaller than 32 MB, this parameter will be automatically changed to the maximum value allowed by the OS during database initialization.

Setting suggestions:

You are advised to set this parameter for DN to a value greater than that for CN, because DWS pushes its most queries down to DN.

It is recommended that **shared_buffers** be set to a value less than 40% of the memory. Set it to a large value for row-store tables and a small value for column-store tables. For column-store tables: **shared_buffers** = (Memory of a single server / Number of DN on the single server) x 0.4 x 0.25

If you want to increase the value of **shared_buffers**, you also need to increase the value of **checkpoint_segments**, because a longer period of time is required to write a large amount of new or changed data.

bulk_write_ring_size

Parameter description: Specifies the size of the ring buffer used for data parallel import.

Type: USERSET

Value range: an integer ranging from 16384 to INT_MAX. The unit is KB.

Default value: 2 GB

Setting suggestions: Increase the value of this parameter on DN if a huge amount of data is to be imported.

buffer_ring_ratio

Parameter description: ring buffer threshold for parallel data export

Type: USERSET

Value range: integer in the range 1–1000

Default value: 250

 NOTE

- The default value indicates that the threshold is 250/1000 (a quarter) of **shared_buffers**.
- The minimum value is 1/1000 of the value of **shared_buffers**.
- The maximum value is the value of **shared_buffers**.

Setting suggestions: If the cache hit ratio is not as expected during export, you are advised to configure this parameter on DN.

enable_cstore_ring_buffer

Parameter description: Specifies whether to enable column-store RingBuffer. This parameter is supported only by cluster versions 8.2.0 and later.

Type: USERSET

Value range: Boolean

Default value: off

Suggestion: If workloads have been running for a period of time, a large amount of frequently queried data has been stored in the CStoreBuffer, and you want to query large tables that are rarely accessed, you are advised to enable this function before the query and disable it after the query.

temp_buffers

Parameter description: Specifies the maximum size of local temporary buffers used by each database session.

Type: USERSET

Value range: an integer ranging from 800 to INT_MAX/2. The unit is 8 KB.

Default value: 8 MB

NOTE

- This parameter can be modified only before the first use of temporary tables within each session. Subsequent attempts to change the value of this parameter will not take effect on that session.
- Based on the value of **temp_buffers**, a session allocates temporary buffers as required. The cost of setting a large value in sessions that do not require many temporary buffers is only a buffer descriptor. If a buffer is used, 8192 bytes will be consumed for it.

max_prepared_transactions

Parameter description: Specifies the maximum number of transactions that can stay in the **prepared** state simultaneously. If this parameter is set to a large value, DWS may require more System V shared memory than the default setting.

When DWS is deployed as an HA system, set this parameter on the standby server to the same value or a value greater than that on the primary server. Otherwise, queries will fail on the standby server.

Type: POSTMASTER

Value range: an integer ranging from 0 to 536870911. The value of CN set to 0 indicates that the prepared transaction feature is disabled.

Default value: 800 for CNs and 5000 for DN

NOTE

Set this parameter to a value greater than or equal to that of **max_connections** to avoid failures in preparation.

work_mem

Parameter description: Specifies the memory capacity to be used by internal sort operations and Hash tables before writing to temporary disk files. Sort operations are used for **ORDER BY**, **DISTINCT**, and merge joins. Hash tables are required for Hash joins as well as Hash-based aggregations and **IN** subqueries.

For a complex query, several sort or Hash operations may be running in parallel; each operation will be allowed to use as much memory as this value specifies. If the memory is insufficient, data is written into temporary files. In addition, several running sessions could be performing such operations concurrently. Therefore, the total memory used may be many times the value of **work_mem**.

Type: USERSET

Value range: an integer ranging from 64 to INT_MAX. The unit is KB.

Default value: 512 MB for small-scale memory and 2 GB for large-scale memory (If **max_process_memory** is greater than or equal to 30 GB, it is large-scale memory. Otherwise, it is small-scale memory.)

Setting suggestions:

If the physical memory specified by **work_mem** is insufficient, additional operator calculation data will be written into temporary tables based on query characteristics and the degree of parallelism. This reduces performance by five to ten times, and prolongs the query response time from seconds to minutes.

- In complex serial query scenarios, each query requires five to ten associated operations. Set **work_mem** using the following formula: **work_mem** = 50% of the memory/10.
- In simple serial query scenarios, each query requires two to five associated operations. Set **work_mem** using the following formula: **work_mem** = 50% of the memory/5.
- For concurrent queries, use the formula: **work_mem** = **work_mem** in serialized scenario/Number of concurrent SQL statements.

NOTICE

Once memory adaptation is enabled, there is no need to use **work_mem** to optimize operator memory usage after collecting statistics. The system generates a plan for each statement and estimates the memory usage of each operator and the entire statement based on the current workload. The system then schedules the queue based on the workload and the overall memory usage of the statement, which can result in statement queuing in high-concurrency scenarios.

query_mem

Parameter description: Specifies the memory used by query. If the value of **query_mem** is greater than 0, the optimizer adjusts the estimated query memory to this value when generating an execution plan.

Type: USERSET

Value range: 0 or an integer greater than 32 MB. The default unit is KB. If the value is set to a negative value or less than 32 MB, the default value 0 is used. In this case, the optimizer does not adjust the estimated query memory.

Default value: 0

query_max_mem

Parameter description: Specifies the maximum memory that can be used by query. If the value of **query_max_mem** is greater than 0, when generating an execution plan, the optimizer uses this value to set the available memory for operators. If job memory usage exceeds the value of this parameter, an error is reported and the job exits.

Type: USERSET

Value range: 0 or an integer greater than 32 MB. The default unit is KB. If the value is less than 32 MB, the system automatically sets this parameter to the default value 0. In this case, the optimizer does not limit the memory usage of jobs.

Default value: 0

agg_max_mem

Parameter description: Specifies the maximum memory that can be used by the Agg operator when the number of aggregation columns exceeds 5. This parameter takes effect only if the value of **agg_max_mem** is greater than 0. (This parameter is supported only in 8.1.3.200 and later cluster versions.)

Type: USERSET

Value range: 0 or an integer greater than 32 MB. The default unit is KB. If the value is less than 32 MB, the system automatically sets this parameter to the default value 0. In this case, the memory usage of the Agg operator is not limited based on the value.

Default value:

- If the current cluster is upgraded from an earlier version to 8.1.3 or later, the value in the earlier version is inherited. The default value is **INT_MAX**.
- If the current cluster version is 8.1.3 or later, the default value is **2GB**.

enable_rowagg_memory_control

Parameter description: Specifies the upper limit of the memory used by the row-store agg operator.

Type: USERSET

Value range: Boolean

- **on** indicates that the memory usage limit of the row-store agg operator is enabled. Setting this parameter to **on** can avoid OOM caused by the row-store agg operator, but may affect the agg performance.

- **off** indicates that the memory usage limit of the row-store agg operator is disabled. If this parameter is set to **off**, the system memory may be unavailable.

Default value: on

maintenance_work_mem

Parameter description: Specifies the maximum size of memory to be used for maintenance operations, such as **VACUUM**, **CREATE INDEX**, and **ALTER TABLE ADD FOREIGN KEY**. This parameter may affect the execution efficiency of VACUUM, VACUUM FULL, CLUSTER, and CREATE INDEX.

Type: USERSET

Value range: an integer ranging from 1024 to INT_MAX. The unit is KB.

Default value: 512 MB for small-scale memory and 2 GB for large-scale memory (If **max_process_memory** is greater than or equal to 30 GB, it is large-scale memory. Otherwise, it is small-scale memory.)

Setting suggestions:

- You are advised to set this parameter to the same value of **work_mem** so that database dump can be cleared or restored more quickly. In a database session, only one maintenance operation can be performed at a time. Maintenance is usually performed when there are not much sessions.
- When the **Automatic Cleanup** process is running, up to **autovacuum_max_workers** times of this memory may be allocated. Set **maintenance_work_mem** to a value equal to or larger than the value of **work_mem**.
- If a large amount of data needs to be processed in the cluster, increase the value of this parameter in sessions.

psort_work_mem

Parameter description: Specifies the memory used for internal sort operations on column-store tables before they are written into temporary disk files. This parameter can be used for inserting tables having a partial cluster key or index, creating a table index, and deleting or updating a table.

Type: USERSET

NOTICE

Multiple running sessions may perform partial sorting on a table at the same time. Therefore, the total memory usage may be several times of the **psort_work_mem** value.

Value range: an integer ranging from 64 to INT_MAX. The unit is KB.

Default value: 512 MB

max_loaded_cudesc

Parameter description: Specifies the number of loaded CuDescs per column when a column-store table is scanned. Increasing the value will improve the query performance and increase the memory usage, particularly when there are many columns in the column tables.

Type: USERSET

Value range: an integer ranging from 100 to INT_MAX/2

Default value: 1024

NOTICE

When the value of **max_loaded_cudesc** is set to a large value, the memory may be insufficient.

max_stack_depth

Parameter description: Specifies the maximum safe depth of DWS execution stack. The safety margin is required because the stack depth is not checked in every routine in the server, but only in key potentially-recursive routines, such as expression evaluation.

Type: SUSERSET

Take the following into consideration when setting this parameter:

- The ideal value of this parameter is the maximum stack size enforced by the kernel (value of **ulimit -s**).
- Setting this parameter to a value larger than the actual kernel limit means that a running recursive function may crash an individual backend process. In an OS where DWS can check the kernel limit, such as the SLES, DWS will prevent this parameter from being set to a value greater than the kernel limit.
- Since not all the OSs provide this function, you are advised to set a specific value for this parameter.

Value range: an integer ranging from 100 to INT_MAX. The unit is KB.

Default value: 2 MB

NOTE

2 MB is a small value and will not incur system breakdown in general, but may lead to execution failures of complex functions.

cstore_buffers

Parameter description: Specifies the size of the shared buffer used by ORC, Parquet, or CarbonData data of column-store tables and OBS or HDFS column-store foreign tables.

Type: POSTMASTER

Value range: an integer ranging from 16384 to INT_MAX. The unit is KB.

Default value: The value of this parameter for CNs is 32 MB, while that for DN is calculated using the formula **POWER(2,ROUND(LOG(2,max_process_memory/18),0))**.

Setting suggestions:

Column-store tables use the shared buffer specified by **cstore_buffers** instead of that specified by **shared_buffers**. When column-store tables are mainly used, reduce the value of **shared_buffers** and increase that of **cstore_buffers**.

Use **cstore_buffers** to specify the cache of ORC, Parquet, or CarbonData metadata and data for OBS or HDFS foreign tables. The metadata cache size should be 1/4 of **cstore_buffers** and not exceed 2 GB. The remaining cache is shared by column-store data and foreign table column-store data.

dfs_max_memory

Parameter description: Specifies the maximum memory that can be occupied during ORC export. If the memory is insufficient when a wide table is exported, increase the value of this parameter and try again. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: an integer ranging from 131072 to 10485760. The unit is KB.

Default value: 262144 KB (256 MB)

schedule_splits_threshold

Parameter description: Specifies the maximum number of files that can be stored in memory when you schedule an HDFS foreign table. If the number is exceeded, all files in the list will be spilled to disk for scheduling.

Type: USERSET

Value range: an integer ranging from 1 to INT_MAX

Default value: 60000

bulk_read_ring_size

Parameter description: Specifies the ring buffer size used for data parallel export.

Type: USERSET

Value range: an integer ranging from 256 to INT_MAX. The unit is KB.

Default value: 16 MB

check_cu_size_threshold

Parameter description: When inserting data into a column-store table, if the amount of data already inserted in a CU exceeds the value of this parameter, row-level size verification will be performed to prevent the creation of uncompressed CUs larger than 1 GB.

Type: USERSET

Value range: an integer ranging from 0 to 1048576. The unit is KB.

Default value: 1 GB

NOTICE

If row-level size verification fails multiple times, you are advised to temporarily set the parameter to **0** at the session level.

memory_spread_strategy

Parameter description: Specifies the DN memory expansion policy of a customized resource pool. You are advised to set this parameter for services with sufficient memory. After this parameter is set, the query performance is improved. The maximum memory can be the same as that of the default resource pool. However, there may be errors caused by insufficient memory in some service scenarios if the memory is small. This parameter is supported only by clusters of version 8.1.3 or later.

Type: USERSET

Value range: enumerated values

- **none:** indicates that the memory is not expanded.
- **negative:** indicates that the memory and operators are expanded based on the estimated usage.
- **crazy:** indicates that the memory is directly expanded, which is equivalent to the memory expansion policy of the default resource pool. However, there may be errors caused by insufficient memory in some service scenarios if the memory is small.

Default value: none

19.5.2 Statement Disk Space Control

This section describes parameters related to statement disk space control, which are used to limit the disk space usage of statements.

sql_use_spacelimit

Parameter description: Specifies the allowed maximum space for files to be spilled to disks in a single SQL statement on a single DN. This parameter limits the space occupied by ordinary tables, temporary tables, and intermediate result sets spilled to disks. System administrators are also restricted by this parameter.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX. The unit is KB. **-1** indicates no limit.

Default value: Set **sql_use_spacelimit** to 10% of the total disk space of the instance.

 NOTE

For example, if **sql_use_spacelimit** is set to **100** in the statement, and the data spilled to disks on a single DN exceeds 100 KB, DWS will stop the query and display a message indicating threshold exceeded.

```
insert into user1.t1 select * from user2.t1;  
ERROR: The space used on DN (104 kB) has exceeded the sql use space limit (100 kB).
```

Handling suggestion:

- Optimize the statement to reduce the data spilled to disks.
- If the disk space is sufficient, increase the value of this parameter.

temp_file_limit

Parameter description: Specifies the total space for files spilled to disks in a single thread. The temporary file can be the one used by sorting or hash tables, or cursors in a session.

This is a session-level setting.

Type: SUSET

Value range: an integer ranging from -1 to INT_MAX. The unit is KB. **-1** indicates no limit.

Default value: Set **temp_file_limit** to 10% of the total disk space of the instance.

NOTICE

This parameter does not apply to disk space occupied by temporary tablespaces used for executing SQL queries.

bi_page_reuse_factor

Parameter description: Specifies the percentage of idle space of old pages that can be reused when page replication is used for data synchronization between primary and standby DNs in the scenario where data is inserted into row-store tables in batches.

Type: USERSET

Value range: an integer ranging from 0 to 100. The value is a percentage. Value **0** indicates that the old pages are not reused and new pages are requested.

Default value: 70

NOTICE

- You are not advised to set this parameter to a value less than **50** (except **0**). If the idle space of the reused page is small, too much old page data will be transmitted between the primary and standby DNs. As a result, the batch insertion performance deteriorates.
- You are not advised to set this parameter to a value greater than **90**. If this parameter is set to a value greater than **90**, idle pages will be frequently queried, but old pages cannot be reused.

19.5.3 Kernel Resources

This section describes kernel resource parameters. Whether these parameters take effect depends on OS settings.

max_files_per_node

Parameter description: Specifies the maximum number of files that can be opened by a single SQL statement on a single node. Generally, you do not need to set this parameter.

Type: SUSET

Value range: an integer ranging from **-1** to **INT_MAX**. The value **-1** indicates that the maximum number is limited.

Default value: 50000

 NOTE

- For a newly installed cluster of 9.1.0 or later, the default value of this parameter is **50000**.
- In an upgrade scenario, if the original cluster supports the **max_files_per_node** parameter, the default value of this parameter remains the same for forward compatibility.
- In the upgrade scenario, if the original cluster does not support the **max_files_per_node** parameter, the default value of this parameter is **-1** after the upgrade.
- If error message "The last file name is [%s] and %d files have already been opened on data node [%s] with a maximum of %d files." is displayed during statement execution, increase the value of **max_files_per_node**.

19.5.4 Cost-based Vacuum Delay

The purpose of cost-based vacuum delay is to allow administrators to reduce the I/O impact of **VACUUM** and **ANALYZE** statements on concurrently active databases. For example, when maintenance statements such as **VACUUM** and **ANALYZE** do not need to be executed quickly and do not interfere with other database operations, administrators can use this function to achieve this purpose.

NOTICE

Certain operations hold critical locks and should be complete as quickly as possible. In DWS, cost-based vacuum delays do not take effect during such operations. To avoid uselessly long delays in such cases, the actual delay is calculated as follows and is the maximum value of the following calculation results:

- $\text{vacuum_cost_delay} * \text{accumulated_balance} / \text{vacuum_cost_limit}$
- $\text{vacuum_cost_delay} * 4$

During the execution of the ANALYZE | ANALYSE and VACUUM statements, the system maintains an internal counter that keeps track of the estimated cost of the various I/O operations that are performed. When the accumulated cost reaches a limit (specified by **vacuum_cost_limit**), the process performing the operation will sleep for a short period of time (specified by **vacuum_cost_delay**). Then, the counter resets and the operation continues.

By default, this feature is disabled. To enable this feature, set **vacuum_cost_delay** to a value other than 0.

vacuum_cost_delay

Parameter description: Specifies the length of time that the process will sleep when **vacuum_cost_limit** has been exceeded.

Type: USERSET

Value range: an integer ranging from 0 to 100. The unit is millisecond (ms). A positive number enables cost-based vacuum delay and **0** disables cost-based vacuum delay.

Default value: 0

NOTICE

- On many systems, the effective resolution of sleep length is 10 ms. Therefore, setting this parameter to a value that is not a multiple of 10 has the same effect as setting it to the next higher multiple of 10.
- This parameter is set to a small value, such as 10 or 20 milliseconds. Adjusting vacuum's resource consumption is best done by changing other parameters.

vacuum_cost_page_hit

Parameter description: Specifies the estimated cost for vacuuming a buffer found in the shared buffer. It represents the cost to lock the buffer pool, look up the shared Hash table, and scan the page.

Type: USERSET

Value range: an integer ranging from 0 to 10000. The unit is millisecond (ms).

Default value: 1

vacuum_cost_page_miss

Parameter description: Specifies the estimated cost for vacuuming a buffer read from the disk. It represents the cost to lock the buffer pool, look up the shared Hash table, read the desired block from the disk, and scan the block.

Type: USERSET

Value range: an integer ranging from 0 to 10000. The unit is millisecond (ms).

Default value: 2

vacuum_cost_page_dirty

Parameter description: Specifies the estimated cost charged when vacuum modifies a block that was previously clean. It represents the I/Os required to flush the dirty block out to disk again.

Type: USERSET

Value range: an integer ranging from 0 to 10000. The unit is millisecond (ms).

Default value: 20

vacuum_cost_limit

Parameter description: Specifies the cost limit. The cleanup process will sleep if this limit is exceeded.

Type: USERSET

Value range: an integer ranging from 1 to 10000. The unit is ms.

Default value: 200

19.5.5 Asynchronous I/O Operations

enable_adio_debug

Parameter description: Specifies whether to enable logging related to ADIO, which helps to locate ADIO-related issues. General users are not advised to set this O&M parameter.

Type: SUSET

Value range: Boolean

- **on** or **true** indicates the log switch is enabled.
- **off** or **false** indicates the log switch is disabled.

Default value: off

enable_fast_allocate

Parameter description: Specifies whether the quick allocation switch of the disk space is enabled. This switch can be enabled only in the XFS file system.

Type: SUSET

Value range: Boolean

- **on** or **true** indicates that this function is enabled.
- **off** or **false** indicates that the function is disabled.

Default value: off

prefetch_quantity

Parameter description: Specifies the number of row-store prefetches using the ADIO.

Type: USERSET

Value range: an integer ranging from 1024 to 1048576. The unit is 8 KB.

Default value: 32 MB

backwrite_quantity

Parameter description: Specifies the number of row-store writes using the ADIO.

Type: USERSET

Value range: an integer ranging from 1024 to 1048576. The unit is 8 KB.

Default value: 8MB

cstore_prefetch_quantity

Parameter description: Specifies the number of column-store prefetches using the ADIO.

Type: USERSET

Value range: an integer. The value range is from 1024 to 1048576 and the unit is KB.

Default value: 32 MB

cstore_backwrite_quantity

Parameter description: Specifies the number of column-store writes using the ADIO.

Type: USERSET

Value range: an integer. The value range is from 1024 to 1048576 and the unit is KB.

Default value: 8MB

cstore_backwrite_max_threshold

Parameter description: Specifies the maximum number of column-store writes buffered in the database using the ADIO.

Type: USERSET

Value range: an integer ranging from 4096 to INT_MAX/2, in KB

Default value: 2 GB

fast_extend_file_size

Parameter description: Specifies the disk size that the row-store pre-scales using the ADIO.

Type: SUSET

Value range: an integer. The value range is from 1024 to 1048576 and the unit is KB.

Default value: 8MB

effective_io_concurrency

Parameter description: Specifies the number of requests that can be simultaneously processed by the disk subsystem. For the RAID array, the parameter value must be the number of disk drive spindles in the array.

Type: USERSET

Value range: an integer ranging from 0 to 1000

Default value: 1

cu_preload_max_distance

Parameter description: Specifies the maximum number of CU groups that can be prefetched. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: an integer ranging from 0 to 1024. The value 0 indicates that prefetching is disabled.

Default value: 20

cu_preload_count

Parameter description: Specifies the maximum number of CUs to be prefetched. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: an integer. The value ranges from 0 to 10000. The value 0 indicates that prefetching is disabled.

Default value: 600

19.5.6 Disk Caching

The following parameters are supported only by clusters of version 9.1.0 or later.

enable_disk_cache

Parameter description: Specifies whether to enable file caching. Setting this parameter to **on** only takes effect when **enable_aio_scheduler** is set to **on** and **obs_worker_pool_size** is greater than or equal to 4.

Type: USERSET

Value range: Boolean

Default value: off

enable_disk_cache_recovery

Parameter description: Specifies whether file caching can be restored when the cluster is restarted.

Type: USERSET

Value range: Boolean

Default value: off

19.6 Parallel Data Import

DWS provides a parallel data import function that enables a large amount of data to be imported in a fast and efficient manner. This section describes parameters for importing data in parallel in DWS.

raise_errors_if_no_files

Parameter description: Specifies whether distinguish between the problems "the number of imported file records is empty" and "the imported file does not exist". If set to **TRUE**, DWS reports the error "file does not exist" when the issue "the imported file does not exist" occurs.

Type: SUSET

Value range: Boolean

- **on** indicates the messages of "the number of imported file records is empty" and "the imported file does not exist" are distinguished when files are imported.
- **off** indicates the messages of "the number of imported file records is empty" and "the imported file does not exist" are not distinguished when files are imported.

Default value: off

partition_max_cache_size

Parameter description: To optimize the inserting of column-store partitioned tables in batches, data is cached during the inserting process and then written to the disk in batches. You can use **partition_max_cache_size** to specify the size of the data buffer. If the value is too large, much memory will be consumed. If it is

too small, the performance of inserting column-store partitioned tables in batches will deteriorate.

Type: USERSET

Value range: 4096 to INT_MAX/2. The minimum unit is KB.

Default value: 2 GB

partition_mem_batch

Parameter description: To optimize the performance of batch insert into column-store partitioned tables, data is cached during the inserting process and then written to the disk in batches. If **partition_max_cache_size** is configured, **partition_mem_batch** can be used to specify the number of caches. If this parameter is set to a large value, the available cache of each partition will be small, and the performance of batch insert into column-store partitioned tables will deteriorate. If this parameter is set to a small value, the available cache of each partition will be large, consuming much system memory.

Type: USERSET

Value range: 1 to 65535

Default value: 256

gds_debug_mod

Parameter description: Specifies whether to enable the debug function of General Data Service (GDS), which is a parallel data loading tool. This parameter is used to better locate and analyze GDS faults. After the debug function is enabled, types of packets received or sent by GDS, peer end of GDS during command interaction, and other interaction information about GDS are written into the logs of corresponding nodes. In this way, state switching on the GaussDB state machine and the current state are recorded. If this function is enabled, additional log I/O resources will be consumed, affecting log performance and validity. You are advised to enable this function only when locating GDS faults.

Type: USERSET

Value range: Boolean

- **on** indicates that the GDS debug function is enabled.
- **off** indicates that the GDS debug function is disabled.

Default value: off

max_copy_data_display

Parameter description: GUC control added for the length of the **rawrecord** field in the copy error table, in the text type. The maximum value is 1 GB minus 8203 bytes (that is, 1073733621 bytes). This parameter is supported only by clusters of version 8.2.1.100 or later.

When this parameter is set, it indicates the maximum number of characters that can be displayed. If the number of characters exceeds the maximum, an ellipsis (...) is displayed at the end.

Type: USERSET

Value range: 0 to 1073733616

Default value: 1024

enable_parallel_batch_insert

Parameter description: Specifies whether to enable the concurrent import function for row-store and column-store tables. This parameter is available only for clusters of version 8.2.0.102 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that concurrent import is enabled. Enabling the concurrent import function can effectively improve the execution speed of the INSERT, UPSERT, UPDATE, and DELETE statements for row-store and column-store tables.
- **off** indicates that concurrent import is **disabled**.

Default value: off

19.7 Write Ahead Logs

19.7.1 Settings

synchronous_commit

Parameter description: Specifies the synchronization mode of the current transaction.

Type: USERSET

Value range: enumerated values

- **on** indicates synchronization logs of a standby server are updated to disks.
- **off** indicates asynchronous commit.
- **local** indicates local commit.
- **remote_write** indicates synchronization logs of a standby server are written to disks.
- **remote_receive** indicates synchronization logs of a standby server are required to receive data.

Default value: on

wal_skip_fpw_level

Parameter description: Specifies whether to write the whole page to WALs when a page is modified for the first time after a checkpoint on a DN. This parameter controls if FPWs of different kinds are logged in WAL to avoid space shortage or slow synchronization between primary and standby nodes due to too many WAL

logs. This parameter is supported by cluster versions 8.3.0 and later. For versions earlier than 8.3.0, see **write_fpi_hint**.

Type: USERSET

Value range: an integer

- **0:** enables All FPWs.
- **1:** specifies that when setting hintbits for the heap tuples is the first change since checkpoint, FPW logs are not written. Whether this function takes effect is not affected by the **enable_crc_check** and **wal_log_hints** parameters. If this parameter is set to **1**, it is equivalent to **write_fpi_hint=off** in an earlier version. For details, see **write_fpi_hint**.
- **2:** FPW logs of indexes and FPW logs after the hintbits on the heap page is modified are not recorded.

Default value: 1

wal_decelerate_policy

Parameter description: Specifies the behavior policy after rate limiting is triggered. This parameter is supported only by clusters of 8.2.0 and later versions.

Type: USERSET

Value range: enumerated values

- **warning** indicates that an alarm is generated but the rate is not limited.
- **decelerate** indicates that the rate will be limited based on policy settings.

Default value: warning

NOTE

Setting the parameter to **warning** does not affect performance. Setting it to **decelerate** will limit the rate based on policy settings if the rate exceeds the threshold.

wal_write_speed

Parameter description: Specifies the maximum WAL write speed (byte/s) allowed by each query on a single DN. This parameter is supported only by clusters of 8.2.0 or later.

Type: USERSET

Value range: an integer ranging from 1024 to 10240000, in KB.

Default value: 30MB

NOTE

The rate of a large number of jobs with index copy and deletion operations will be limited.

wal_decelerate_trigger_threshold

Parameter description: Specifies the threshold of WAL write rate limiting for each query on a single DN. This parameter is supported only by cluster versions 8.2.0 and later.

Type: USERSET

Value range: an integer ranging from 1024 to 100000000000, in KB.

Default value: 128MB

 NOTE

This function is triggered only if the number of Xlogs generated by a single query is greater than the value of this parameter. DDL operations or a small number of DML operations are not affected.

commit_delay

Parameter description: Specifies the duration of committed data be stored in the WAL buffer.

Type: USERSET

Value range: an integer, ranging from 0 to 100000 (unit: μ s). **0** indicates no delay.

Default value: 0

NOTICE

- When this parameter is set to a value other than 0, the committed transaction is stored in the WAL buffer instead of being written to the WAL immediately. Then, the WalWriter process flushes the buffer out to disks periodically.
 - If system load is high, other transactions are probably ready to be committed within the delay. If no transactions are waiting to be submitted, the delay is a waste of time.
-

commit_siblings

Parameter description: Specifies a limit on the number of ongoing transactions. If the number of ongoing transactions is greater than the limit, a new transaction will wait for the period of time specified by [commit_delay](#) before it is submitted. If the number of ongoing transactions is less than the limit, the new transaction is immediately written into a WAL.

Type: USERSET

Value range: an integer ranging from 0 to 1000

Default value: 5

wal_compression

Parameter description: Specifies whether to compress FPI pages.

Type: USERSET

Value range: Boolean

- **on:** enable the compression

- **off**: disable the compression

Default value: on

NOTICE

- Only zlib compression algorithm is supported.
 - For clusters that are upgraded to the current version from an earlier version, this parameter is set to **off** by default. You can run the **gs_guc** command to enable the FPI compression function if needed.
 - If the current version is a newly installed version, this parameter is set to **on** by default.
 - If this parameter is manually enabled for a cluster upgraded from an earlier version, the cluster cannot be rolled back.
-

wal_compression_level

Parameter description: Specifies the compression level of zlib compression algorithm when the **wal_compression** parameter is enabled.

Type: USERSET

Value range: an integer ranging from 0 to 9.

- **0** indicates no compression.
- **1** indicates the lowest compression ratio.
- **9** indicates the highest compression ratio.

Default value: 9

19.7.2 Checkpoints

checkpoint_segments

Parameter description: minimum number of WAL segment files in the period specified by **checkpoint_timeout**. The size of each log file is 16 MB.

Type: SIGHUP

Value range: an integer. The minimum value is 1.

Default value: 64

NOTICE

Increasing the value of this parameter speeds up the import of big data. Set this parameter based on **checkpoint_timeout** and **shared_buffers**. This parameter affects the number of WAL log segment files that can be reused. Generally, the maximum number of reused files in the **pg_xlog** folder is twice the number of checkpoint segments. The reused files are not deleted and are renamed to the WAL log segment files which will be later used.

19.8 HA Replication

19.8.1 Primary Server

`enable_data_replicate`

Parameter description: Specifies the data synchronization mode between the primary and standby servers when data is imported to row-store tables in a database.

Type: USERSET

Value range: Boolean

- **on** indicates that data pages are used for the data synchronization between the primary and standby servers when data is imported to row-store tables in a database. This parameter cannot be set to **on** if **replication_type** is set to **1**.
- **off** indicates that the primary and standby servers synchronize data using Xlogs while the data is imported to a row-store table.

Default value: on

`ha_module_debug`

Parameter description: This command is used to view the replication status log of a specific data block during data replication.

Type: USERSET

Value range: Boolean

- **on** indicates that the log records the status of each data block during data replication.
- **off** indicates that the status of each data block is not recorded in logs during data replication.

Default value: off

19.9 Query Planning

19.9.1 Optimizer Method Configuration

These configuration parameters provide a crude method of influencing the query plans chosen by the query optimizer. If the default plan chosen by the optimizer for a particular query is not optimal, a temporary solution is to use one of these configuration parameters to force the optimizer to choose a different plan. Better ways include adjusting the optimizer cost constants, manually running **ANALYZE**, increasing the value of the [default_statistics_target](#) configuration parameter, and adding the statistics collected in a specific column using **ALTER TABLE SET STATISTICS**.

enable_bitmapscan

Parameter description: Controls whether the query optimizer uses the bitmap-scan plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_hashagg

Parameter description: Controls whether the query optimizer uses the Hash aggregation plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_mixedagg

Parameter description: Controls whether the query optimizer uses the Mixed Agg plan type.

Type: USERSET

Value range: Boolean

- **on** indicates that a Mixed Agg query plan is generated for the Grouping Sets statement (including Rollup or Cube) that meets certain conditions.
- **off** indicates it is disabled.

Default value: on

NOTICE

- The default value of this parameter is **on** in a newly installed cluster of 9.1.0.200 or later. In an upgrade scenario, the default value of this parameter is retained for forward compatibility.
- The Mixed Agg query plan can be used to improve the performance of statements dealing with a large amount of data (the data volume of a single DN table is greater than 100 GB).

Mixed Agg is not supported in the following scenarios:

- The data type of the columns in the **GROUP BY** clause do not support hashing.
- The aggregate function uses **DISTINCT** for deduplication or **ORDER BY** for sorting.
- The **GROUPING SETS** clause does not contain empty groups.

enable_hashjoin

Parameter description: Controls whether the query optimizer uses the Hash-join plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_indexscan

Parameter description: Controls whether the query optimizer uses the index-scan plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_indexonlyscan

Parameter description: Controls whether the query optimizer uses the index-only-scan plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.

- **off** indicates it is disabled.

Default value: on

enable_material

Parameter description: Controls whether the query optimizer uses materialization. It is impossible to suppress materialization entirely, but setting this parameter to **off** prevents the optimizer from inserting materialized nodes.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_mergejoin

Parameter description: Controls whether the query optimizer uses the merge-join plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: off

enable_nestloop

Parameter description: Controls whether the query optimizer uses the nested-loop join plan type to fully scan internal tables. It is impossible to suppress nested-loop joins entirely, but setting this parameter to **off** allows the optimizer to choose other methods if available.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: off

enable_index_nestloop

Parameter description: Controls whether the query optimizer uses the nested-loop join plan type to scan the parameterized indexes of internal tables.

Type: USERSET

Value range: Boolean

- **on** indicates the query optimizer uses the nested-loop join plan type.
- **off** indicates the query optimizer does not use the nested-loop join plan type.

Default value: The default value for a newly installed cluster is **on**. If the cluster is upgraded from R8C10, the forward compatibility is retained. If the version is upgraded from R7C10 or an earlier version, the default value is **off**.

left_join_estimation_enhancement

Parameter description: Specifies whether to use the optimized estimated number of rows for left join. This parameter is supported only by clusters of version 8.3.0.100 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimized value is used.
- **off** indicates it is disabled.

Default value: off

enable_seqscan

Parameter description: Controls whether the query optimizer uses the sequential scan plan type. It is impossible to suppress sequential scans entirely, but setting this variable to **off** allows the optimizer to preferentially choose other methods if available.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_sort

Parameter description: Controls whether the query optimizer uses the sort method. It is impossible to suppress explicit sorts entirely, but setting this variable to **off** allows the optimizer to preferentially choose other methods if available.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

max_opt_sort_rows

Parameter description: Specifies the maximum number of optimized limit+offset rows in an ORDER BY clause. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

- If the value is 0, the parameter does not take effect.
- If this parameter is set to any other value, the optimization takes effect when the number of limit+offset rows in the ORDER BY clause is less than the value of this parameter. If the number of limit+offset rows in the order by clause is greater than the value of this parameter, the optimization does not take effect. After the optimization, the time required is reduced, but the memory usage may increase.

Default value: 0

enable_tidscan

Parameter description: Controls whether the query optimizer uses the Tuple ID (TID) scan plan type.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_kill_query

Parameter description: In CASCADE mode, when a user is deleted, all the objects belonging to the user are deleted. This parameter specifies whether the queries of the objects belonging to the user can be unlocked when the user is deleted.

Type: SUSERSET

Value range: Boolean

- **on** indicates the unlocking is allowed.
- **off** indicates the unlocking is not allowed.

Default value: off

enforce_oracle_behavior

Parameter description: Controls the rule matching modes of regular expressions.

Type: USERSET

Value range: Boolean

- **on** indicates that the ORACLE matching rule is used.
- **off** indicates that the POSIX matching rule is used.

Default value: on

enable_stream_concurrent_update

Parameter description: Controls the use of **stream** in concurrent updates. This parameter is restricted by the [enable_stream_operator](#) parameter.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimizer can generate stream plans for the **UPDATE** statement.
- **off** indicates that the optimizer can generate only non-stream plans for the **UPDATE** statement.

Default value: on

enable_stream_ctescan

Parameter description: Specifies whether a stream plan supports **ctescan**.

Type: USERSET

Value range: Boolean

- **on** indicates that **ctescan** is supported for the stream plan.
- **off** indicates that **ctescan** is not supported for the stream plan.

Default value: on

NOTE

In upgrade scenarios, the default value of this parameter is forward compatible, and the original value is retained.

enable_stream_operator

Parameter description: Controls whether the query optimizer uses streams.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_stream_recursive

Parameter description: Specifies whether to push **WITH RECURSIVE** join queries to DNs for processing.

This parameter is discarded in 8.2.1.210 and later cluster versions. To ensure forward compatibility, the setting can be successful but does not take effect. You are advised to use the [stream_recursive_option](#) parameter.

Type: USERSET

Value range: Boolean

- **on:** **WITH RECURSIVE** join queries will be pushed down to DNs.
- **off:** **WITH RECURSIVE** join queries will not be pushed down to DNs.

Default value: on

stream_recursive_option

Parameter description: Specifies whether to push **WITH RECURSIVE** join queries to DNs for processing. This parameter is supported only by 8.2.1.210 and later cluster versions.

Type: USERSET

Value range: enumerated values

- **none:** **WITH RECURSIVE** queries will not be pushed down to DNs.
- **normal:** **WITH RECURSIVE** join queries can be pushed down to DNs for distributed execution in single-logical cluster scenarios.
- **nodegroup:** **WITH RECURSIVE** join queries can be pushed down to DNs for distributed execution in multi-logical cluster scenarios.

Default value: normal

enable_value_redistribute

Parameter description: Specifies whether to generate value redistribute plans. In 8.2.0 and later cluster versions, this parameter takes effect for **rank**, **dense_rank**, and **row_number** without the **PARTITION BY** clause.

Type: USERSET

Value range: Boolean

- **on** indicates that value redistribute plans are generated.
- **off** indicates that no value redistribute plans are generated.

Default value: on

max_recursive_times

Parameter description: Specifies the maximum number of **WITH RECURSIVE** iterations.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 200

enable_vector_engine

Parameter description: Controls whether the query optimizer uses the vectorized executor.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_broadcast

Parameter description: Controls whether the query optimizer uses the broadcast distribution method when it evaluates the cost of stream.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

enable_redistribute

Parameter description: Controls whether the query optimizer uses the local redistribute or split redistribute distribution method when estimating the cost of streams. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that either of the distribution methods is used.
- **off** indicates that none of the distribution methods is used.

Default value: on

enable_change_hjcost

Parameter description: Specifies whether the optimizer excludes internal table running costs when selecting the Hash Join cost path. If it is set to **on**, tables with a few records and high running costs are more possible to be selected.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: off

enable_fstream

Parameter description: Controls whether the query optimizer uses streams when it delivers statements. This parameter is only used for external HDFS tables.

This parameter has been discarded. To reserve forward compatibility, set this parameter to **on**, but the setting does not make a difference.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: off

enable_hashfilter

Parameter description: Controls whether hashfilters can be generated for plans that contain replication tables (including dual and constant tables). This parameter is supported by clusters of version 8.2.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that hashfilters can be generated.
- **off** indicates that no hashfilters can be generated.

Default value: on

best_agg_plan

Parameter description: The query optimizer generates three plans for the aggregate operation under the stream:

1. hashagg+gather(redistribute)+hashagg
2. redistribute+hashagg(+gather)
3. hashagg+redistribute+hashagg(+gather).

This parameter is used to control the query optimizer to generate which type of hashagg plans.

Type: USERSET

Value range: an integer ranging from 0 to 3.

- When the value is set to **1**, the first plan is forcibly generated.
- When the value is set to **2** and if the **group by** column can be redistributed, the second plan is forcibly generated. Otherwise, the first plan is generated.
- When the value is set to **3** and if the **group by** column can be redistributed, the third plan is generated. Otherwise, the first plan is generated.
- When the value is set to **0**, the query optimizer chooses the most optimal plan based on the estimated costs of the three plans above.

Default value: 0

turbo_engine_version

Parameter description: For tables with the turbo storage format specified during table creation (by setting the **enable_turbo_store** parameter to **on** in the table properties), and when the query does not involve merge join or sort agg operators, the executor can use the turbo execution engine, which can significantly improve performance.

Type: USERSET

Value range: an integer ranging from 0 to 3.

- The value **0** indicates that the turbo execution engine is disabled.
- The value **1** indicates that the turbo execution engine is only used for single-table aggregate queries.
- The value **2** indicates that the turbo execution engine is only used for single-table aggregate or multi-table join queries.
- The value **3** indicates that the turbo execution engine can be used to accelerate most commonly used operators, except for operators such as merge join and sort agg. When the data volume is large and **turbo_engine_version** is set to **3**, the occurrence of merge join and sort agg operators is relatively rare, so turbo execution engine acceleration can be achieved for almost SQL statements.

Default value: 3

enable_bucket_stream_opt

Parameter description: Specifies whether to use the **bucket agg** and **bucket join** policies for level-2 partitioned tables or 3.0 hash distributed tables. It speeds up SQL statement execution by avoiding local data redistribution or broadcast. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: Boolean

- **true:** The optimizer uses the **bucket agg** and **bucket join** execution policies to generate plans when the conditions for the policy to be applied are met. If this optimization policy is used, "Bucket Stream: true" is displayed at the end of the **EXPLAIN** statement.
- **false:** The optimizer does not use the **bucket agg** and **bucket join** execution policies to generate plans.

Default value: true

NOTICE

- The default value of this parameter is **true** in a newly installed cluster of 9.1.0.200 or later. In an upgrade scenario, the default value of this parameter is retained for forward compatibility.
- The **bucket agg** and **bucket join** execution policies take effect only when the current query has 16 or fewer available CPUs and meets one of the following conditions:
 1. The distribution column for level-2 partitions must match the **secondary_part_column** of these partitions. It is recommended that the number of level-2 partitions be the number of DN's multiplied by 12. Supported multiples include 4, 6, 8, 12, and 16.
 2. Tables in version 3.0 must use hash distribution, with the number of buckets or DN's exceeding 10.
- If the local stream cost in the plan is low, the query may not select the **bucket agg** and **bucket join** policies.

spill_compression

Parameter description: Specifies the compression algorithm used when the executor operator runs out of memory and needs to spill data to disk. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: enumerated values

- 'lz4' indicates that the lz4 compression algorithm is used, which provides better performance for scenarios with smaller spill volumes, but requires more storage space.
- 'zstd' indicates that the zstd compression algorithm is used, which provides better performance for scenarios with larger spill volumes where I/O is the main bottleneck, and requires approximately 2/3 of the storage space used by lz4.

Default value: 'lz4'

index_selectivity_cost

Parameter description: Controls the cost calculation of cbtree when scanning column-store table indexes (for selectivity > 0.001). This parameter is only supported by clusters of version 8.2.1.100 or later.

Type: USERSET

Value range: a floating point number, which can be -1 or ranges from 0 to 1000.

- If this parameter is set to **0**, the index selection rate is not affected by the threshold 0.001.
- If the value is **-1**, the value is impacted by **disable_cost**.
- When it is set to other values, the value is the coefficient for cbtree cost calculation.

Default value: -1

index_cost_limit

Parameter description: threshold for disabling the cost calculation of cbtree during column-store table index scanning. This parameter is supported only by clusters of version 8.2.1.100 or later.

Type: USERSET

Value range: an integer ranging from 0 to 2147483647

- If the value is **0**, the parameter does not take effect.
- If this parameter is set to other values and the number of rows in a table is less than the value of this parameter, the table is not affected by the index selection rate threshold 0.001.

Default value: 0

volatile_shipping_version

Parameter description: Controls the execution scope of volatile functions to be pushed down.

Type: USERSET

Value range: 0, 1, 2, 3

- When set to **3**, it extends the support for pushing down InlineCTE when it is only referenced once, on top of the support provided by a value **2**. It also extends the support for pushing down the use of volatile functions in UPSERT operations involving replicated tables.
- When the value is **2**, pushdown can be performed when VOLATILE functions are contained in the target column of the copied CTE result.
- If this parameter is set to **1**, the **nextval**, **uuid_generate_v1**, **sys_guid**, and **uuid** functions can be completely pushed down if they are in the target column of a statement.
- If this parameter is set to **0**, random functions can be completely pushed down. The **nextval** and **uuid_generate_v1** functions can be pushed down only if **INSERT** contains simple query statements.

Default value: 3

agg_redistribute_enhancement

Parameter description: When the aggregate operation is performed, which contains multiple **group by** columns and all of the columns are not in the distribution column, you need to select one **group by** column for redistribution. This parameter controls the policy of selecting a redistribution column.

Type: USERSET

Value range: Boolean

- **on** indicates the column that can be redistributed and evaluates the most distinct value for redistribution.

- **off** indicates the first column that can be redistributed for redistribution.

Default value: off

enable_valuepartition_pruning

Parameter description: Specifies whether to perform static or dynamic optimization on the partitioned tables in a distributed file system (DFS).

Type: USERSET

Value range: Boolean

- **on** indicates that the DFS partitioned table is dynamically or statically optimized.
- **off** indicates that the DFS partitioned table is not dynamically or statically optimized.

Default value: on

expected_computing_nodegroup

Parameter description: Specifies a computing Node Group or the way to choose such a group. The Node Group mechanism is now for internal use only. You do not need to set it.

During join or aggregation operations, a Node Group can be selected in four modes. In each mode, the specified candidate computing Node Groups are listed for the optimizer to select an appropriate one for the current operator.

Type: USERSET

Value range: a string

- **optimal:** The list of candidate computing Node Groups consists of the Node Group where the operator's operation objects are located and the DNs in the Node Groups on which the current user has the COMPUTE permission.
- **query:** The list of candidate computing Node Groups consists of the Node Group where the operator's operation objects are located and the DNs in the Node Groups where base tables involved in the query are located.
- **bind:** If the current session user is a logical cluster user, the candidate computing Node Group is the Node Group of the logical cluster associated with the current user. If the session user is not a logical cluster user, the candidate computing Node Group selection rule is the same as that when this parameter is set to **query**.
- Node Group name:
 - If [enable_nodegroup_debug](#) is set to **off**, the list of candidate computing Node Groups consists of the Node Group where the operator's operation objects are located and the specified Node Group.
 - If [enable_nodegroup_debug](#) is set to **on**, the specified Node Group is used as the candidate Node Group.

Default value: bind

enable_nodegroup_debug

Parameter description: Specifies whether the optimizer assigns computing workloads to a specific Node Group when multiple Node Groups exist in an environment. The Node Group mechanism is now for internal use only. You do not need to set it.

This parameter takes effect only when **expected_computing_nodegroup** is set to a specific Node Group.

Type: USERSET

Value range: Boolean

- **on** indicates that computing workloads are assigned to the Node Group specified by **expected_computing_nodegroup**.
- **off** indicates no Node Group is specified to compute.

Default value: off

stream_multiple

Parameter description: Specifies the weight used for optimizer to calculate the final cost of stream operators.

The base stream cost is multiplied by this weight to make the final cost.

Type: USERSET

Value range: a floating point number ranging from 0 to 10000

Default value: 1

NOTICE

This parameter is applicable only to Redistribute and Broadcast streams.

qrw_inlist2join_optmode

Parameter description: Specifies whether enable inlist-to-join (inlist2join) query rewriting.

Type: USERSET

Value range: a string

- **disable:** inlist2join disabled
- **cost_base:** cost-based inlist2join query rewriting
- **rule_base:** forcible rule-based inlist2join query rewriting
- A positive integer: threshold of Inlist2join query rewriting. If the number of elements in the list is greater than the threshold, the rewriting is performed.

Default value: disable

enable_inlist_hashing

Parameter description: Specifies whether to use inlist hash optimization. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that inlist hash optimization is enabled.
- **off** indicates that inlist hash optimization is disabled.

Default value: on

setop_optmode

Parameter description: Specifies whether to perform deduplication on the query branch statements of a set operation (**UNION/EXCEPT/INTERSECT**) without the **ALL** option.

Type: USERSET

Value range: enumerated values

- **disable:** The query branch does not perform deduplication.
- **force:** The query branch forcibly performs deduplication.
- **cost:** The optimizer evaluates the costs of query branches with and without deduplication and selects the execution mode with the lower cost.

Default value: cost

NOTICE

- The default value of this parameter is **cost** in a newly installed cluster of 9.1.0.200 or later. In an upgrade scenario, the default value of this parameter is retained for forward compatibility.
 - This parameter takes effect only if the execution plan of a SQL statement meets the following conditions:
 - The **UNION**, **EXCEPT**, and **INTERSECT** operations in the SQL statement do not contain the **ALL** option.
 - Data redistribution has been performed on the query branches where the set operation is to be performed.
-

skew_option

Parameter description: Specifies whether an optimization policy is used

Type: USERSET

Value range: a string

- **off:** policy disabled
- **normal:** radical policy. All possible skews are optimized.

- **lazy**: conservative policy. Uncertain skews are ignored.

Default value: normal

enable_expr_skew_optimization

Parameter description: Specifies whether to use expression statistics in the skew optimization policy. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that expression statistics are used to determine whether data skew occurs in the skew optimization policy.
- **off** indicates that expression statistics are not used to determine whether data skew occurs in the skew optimization policy.

Default value: on

prefer_hashjoin_path

Parameter description: whether to preferentially generate hashjoin paths so that other paths with high costs can be pre-pruned to shorten the overall plan generation time. This parameter is supported only by clusters of version 8.2.1 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimization of generating hash join paths in advance is enabled.
- **off** indicates that the optimization of generating hash join paths in advance is disabled.

Default value: on

enable_hashfilter_test

Parameter description: whether to add hash filters to columns for base table scan to check whether the results meet expectations. In addition, this parameter determines whether to check the DN accuracy when data is inserted (that is, whether the current data should be inserted into the current DN).

Type: USERSET

Value range: Boolean

- **on** adds a hash filter for the distribution column to the base table scan and performs accurate DN verification during data insertion.
- **off** does not add a hash filter for the distribution column to the base table scan and does not perform DN verification during data insertion.

Default value: on

NOTICE

- This parameter is valid only for tables distributed in hash mode.
- If this parameter is set to **on**, DN accuracy is verified during data insertion, affecting data insertion performance.

enable_cu_align_8k

Parameter description: Specifies whether to set the CUs in V3 tables to 8 KB. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the CUs in V3 tables are set to 8,192 bytes.
- **off** indicates that the CUs in V3 tables are set to 512 bytes.

Default value: off

enable_cu_batch_insert

Parameter description: Specifies whether to enable the multi-column CU batch write feature for V2 tables. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the multi-column CU batch write feature is enabled for V2 tables.
- **off** indicates that the multi-column CU batch write feature is disabled for V2 tables.

Default value: off

enable_topk_optimization

Parameter description: Specifies whether to enable Top K sorting optimization. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that Top K sorting optimization is enabled.
- **off** indicates that Top K sorting optimization is disabled.

Default value: on

19.9.2 Optimizer Cost Constants

This section describes the optimizer cost constants. The cost variables described in this section are measured on an arbitrary scale. Only their relative values matter,

therefore scaling them all in or out by the same factor will result in no differences in the optimizer's choices. By default, these cost variables are based on the cost of sequential page fetches, that is, **seq_page_cost** is conventionally set to **1.0** and the other cost variables are set with reference to the parameter. However, you can use a different scale, such as actual execution time in milliseconds.

seq_page_cost

Parameter description: Specifies the optimizer's estimated cost of a disk page fetch that is part of a series of sequential fetches.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 1

random_page_cost

Parameter description: Specifies the optimizer's estimated cost of an out-of-sequence disk page fetch.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 4

NOTE

- Although the server allows you to set the value of **random_page_cost** to less than that of **seq_page_cost**, it is not physically sensitive to do so. However, setting them equal makes sense if the database is entirely cached in RAM, because in that case there is no penalty for fetching pages out of sequence. Also, in a heavily-cached database you should lower both values relative to the CPU parameters, since the cost of fetching a page already in RAM is much smaller than it would normally be.
- This value can be overwritten for tables and indexes in a particular tablespace by setting the tablespace parameter of the same name.
- Comparing to **seq_page_cost**, reducing this value will cause the system to prefer index scans and raising it makes index scans relatively more expensive. You can increase or decrease both values at the same time to change the disk I/O cost relative to CPU cost.

cpu_tuple_cost

Parameter description: Specifies the optimizer's estimated cost of processing each row during a query.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 0.01

cpu_index_tuple_cost

Parameter description: Specifies the optimizer's estimated cost of processing each index entry during an index scan.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 0.005

cpu_operator_cost

Parameter description: Specifies the optimizer's estimated cost of processing each operator or function during a query.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 0.0025

effective_cache_size

Parameter description: Specifies the optimizer's assumption about the effective size of the disk cache that is available to a single query.

When setting this parameter you should consider both DWS's shared buffer and the kernel's disk cache. Also, take into account the expected number of concurrent queries on different tables, since they will have to share the available space.

This parameter has no effect on the size of shared memory allocated by DWS. It is used only for estimation purposes and does not reserve kernel disk cache. The value is in the unit of disk page. Usually the size of each page is 8192 bytes.

Type: USERSET

Value range: an integer ranging is from 1 to INT_MAX. The unit is 8 KB.

A value greater than the default one may enable index scanning, and a value less than the default one may enable sequence scanning.

Default value: 128MB

allocate_mem_cost

Parameter description: Specifies the query optimizer's estimated cost of creating a Hash table for memory space using Hash join. This parameter is used for optimization when the Hash join estimation is inaccurate.

Type: USERSET

Value range: a floating point number ranging from 0 to DBL_MAX

Default value: 0

smp_thread_cost

Parameter description: Specifies the optimizer's cost for calculating parallel threads of an operator. This parameter is used for tuning if **query_dop** is not suitable for system load management. (This parameter is supported only by clusters of version 8.2.0 or later.)

Type: USERSET

Value range: a floating point number ranging from 1 to 10000

Default value: 1000

19.9.3 Genetic Query Optimizer

This section describes parameters related to genetic query optimizer. The genetic query optimizer (GEQO) is an algorithm that plans queries by using heuristic searching. This algorithm reduces planning time for complex queries and the cost of producing plans are sometimes inferior to those found by the normal exhaustive-search algorithm.

geqo

Parameter description: Controls the use of genetic query optimization.

Type: USERSET

Value range: Boolean

- **on** indicates GEQO is enabled.
- **off** indicates GEQO is disabled.

Default value: on

NOTICE

Generally, do not set this parameter to **off**. **geqo_threshold** provides more subtle control of GEQO.

geqo_threshold

Parameter description: Specifies the number of **FROM** items. Genetic query optimization is used to plan queries when the number of statements executed is greater than this value.

Type: USERSET

Value range: an integer ranging from 2 to INT_MAX

Default value: 12

NOTICE

- For simpler queries it is best to use the regular, exhaustive-search planner, but for queries with many tables it is better to use GEQO to manage the queries.
 - A **FULL OUTER JOIN** construct counts as only one **FROM** item.
-

geqo_effort

Parameter description: Controls the trade-off between planning time and query plan quality in GEQO.

Type: USERSET

Value range: an integer ranging from 1 to 10

Default value: 5

NOTICE

- Larger values increase the time spent in query planning, but also increase the probability that an efficient query plan is chosen.
 - **geqo_effort** does not have direct effect. This parameter is only used to compute the default values for the other variables that influence GEQO behavior. You can manually set other parameters as required.
-

geqo_pool_size

Parameter description: Specifies the pool size used by GEQO, that is, the number of individuals in the genetic population.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

NOTICE

The value of this parameter must be at least **2**, and useful values are typically from **100** to **1000**. If this parameter is set to **0**, DWS selects a proper value based on **geqo_effort** and the number of tables.

Default value: 0

geqo_generations

Parameter description: Specifies the number parameter iterations of the algorithm used by GEQO.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

NOTICE

The value of this parameter must be at least **1**, and useful values are typically from **100** to **1000**. If it is set to **0**, a suitable value is chosen based on **geqo_pool_size**.

Default value: 0

geqo_selection_bias

Parameter description: Specifies the selection bias used by GEQO. The selection bias is the selective pressure within the population.

Type: USERSET

Value range: a floating point number ranging from 1.5 to 2.0

Default value: 2

NOTE

A larger value indicates higher selective pressure, and the probability of selecting better individuals is higher. A smaller value indicates lower selection pressure and more diversity.

geqo_seed

Parameter description: Specifies the initial value of the random number generator used by GEQO to select random paths through the join order search space.

Type: USERSET

Value range: a floating point number ranging from 0.0 to 1.0

NOTICE

Varying the value changes the setting of join paths explored, and may result in a better or worse path being found.

Default value: 0

19.9.4 Other Optimizer Options

default_statistics_target

Parameter description: Specifies the default statistics target for table columns without a column-specific target set via **ALTER TABLE SET STATISTICS**. If this parameter is set to a positive number, it indicates the number of samples of statistics information. If this parameter is set to a negative number, percentage is used to set the statistic target. The negative number converts to its corresponding percentage, for example, -5 means 5%. During sampling, a random sample size is determined by multiplying the **default_statistics_target** by 300. For example, if the default value is **100**, then 30,000 pages will be randomly read and 30,000 data records will be randomly selected from them to complete the random sampling.

Type: USERSET

Value range: an integer ranging from -100 to 10000

NOTICE

- A larger positive number than the parameter value increases the time required to do **ANALYZE**, but might improve the quality of the optimizer's estimates.
- Changing settings of this parameter may result in performance deterioration. If query performance deteriorates, you can:
 1. Restore to the default statistics.
 2. Use hints to optimize the query plan. For details, see [Hint-based Tuning](#).
- If this parameter is set to a negative value, the number of samples is greater than or equal to 2% of the total data volume, and the number of records in user tables is less than 1.6 million, the time taken by running **ANALYZE** will be longer than when this parameter uses its default value.
- **AUTOANALYZE** does not allow you to set a sampling size for temporary table sampling. Its default value will be used for sampling.
- If statistics are forcibly calculated based on memory, the sampling size is limited by the **maintenance_work_mem** parameter.

Default value: 100

random_function_version

Parameter description: Specifies the random function version selected by ANALYZE during data sampling. This feature is supported only in 8.1.2 or later.

Type: USERSET

Value range: enumerated values

- The value **0** indicates that the random function provided by the C standard library is used.
- The value **1** indicates that the optimized and enhanced random function is used.

Default value:

- If the current cluster is upgraded from an earlier version to 8.2.0.100, the default value is **0** to ensure forward compatibility.
- If the cluster version 8.2.0.100 is newly installed, the default value is **1**.

constraint_exclusion

Parameter description: Controls the query optimizer's use of table constraints to optimize queries.

Type: USERSET

Value range: enumerated values

- **on** indicates the constraints for all tables are examined.
- **off**: No constraints are examined.
- **partition** indicates that only constraints for inherited child tables and **UNION ALL** subqueries are examined.

NOTICE

When **constraint_exclusion** is set to **on**, the optimizer compares query conditions with the table's **CHECK** constraints, and omits scanning tables for which the conditions contradict the constraints.

Default value: partition

 NOTE

Currently, this parameter is set to **on** by default to partition tables. If this parameter is set to **on**, extra planning is imposed on simple queries, which has no benefits. If you have no partitioned tables, set it to **off**.

cursor_tuple_fraction

Parameter description: Specifies the optimizer's estimated fraction of a cursor's rows that are retrieved.

Type: USERSET

Value range: a floating point number ranging from 0.0 to 1.0

NOTICE

Smaller values than the default value bias the optimizer towards using **fast start** plans for cursors, which will retrieve the first few rows quickly while perhaps taking a long time to fetch all rows. Larger values put more emphasis on the total estimated time. At the maximum setting of **1.0**, cursors are planned exactly like regular queries, considering only the total estimated time and how soon the first rows might be delivered.

Default value: 0.1

from_collapse_limit

Parameter description: Specifies whether the optimizer merges sub-queries into upper queries based on the resulting FROM list. The optimizer merges sub-queries into upper queries if the resulting FROM list would have no more than this many items.

Type: USERSET

Value range: an integer ranging from 1 to INT_MAX

Default value: 8

 CAUTION

Smaller values reduce planning time but may lead to inferior execution plans.

join_collapse_limit

Parameter description: Specifies whether the optimizer rewrites **JOIN** constructs (except **FULL JOIN**) into lists of **FROM** items based on the number of the items in the result list.

Type: USERSET

Value range: an integer ranging from 1 to INT_MAX

Default value: 8

NOTICE

- Setting this parameter to **1** prevents join reordering. As a result, the join order specified in the query will be the actual order in which the relations are joined. The query optimizer does not always choose the optimal join order. Therefore, advanced users can temporarily set this variable to **1**, and then specify the join order they desire explicitly.
 - Smaller values reduce planning time but lead to inferior execution plans.
-

join_search_mode

Parameter description: plan path search mode.

Type: USERSET

Value range: enumerated values

- **exhaustive:** Traditional dynamic planning and genetic methods are used to search for planned paths.
- **heuristic:** The heuristic method is used to search for planned paths. This method improves the plan generation performance, but there is a possibility that the optimal plan is ignored. This setting only takes effect for scenarios where a Drive Hint is specified or the number of joined tables exceeds **from_collapse_limit**.

Default value: **heuristic**

enable_from_collapse_hint

Parameter description: Specifies whether to rewrite the **FROM** list to make the hint take effect, and then rewrite it again based on the **from_collapse_limit** and **join_collapse_limit** parameters. This parameter is supported by clusters of version 8.2.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the **FROM** list is first rewritten in hint mode.
- **off** indicates that the **FROM** list is rewritten without difference.

NOTICE

- If this parameter is enabled, the optimizer preferentially rewrites the **FROM** list in hint mode. However, you can learn whether a hint takes effect only after the plan is generated.
- If this parameter is disabled, the plan is generated in the same way as that in versions earlier than 8.2.0. That is, the plan is generated regardless of whether the table has hints.

Default value: on

plan_mode_seed

Parameter description: This is a commissioning parameter. Currently, it supports only OPTIMIZE_PLAN and RANDOM_PLAN. **OPTIMIZE_PLAN** indicates the optimal plan, the cost of which is estimated using the dynamic planning algorithm, and its value is 0. **RANDOM_PLAN** indicates the plan that is randomly generated. If **plan_mode_seed** is set to -1, you do not need to specify the value of the seed identifier. Instead, the optimizer generates a random integer ranging from 1 to 2147483647, and then generates a random execution plan based on this random number. If **plan_mode_seed** is set to an integer ranging from 1 to 2147483647, you need to specify the value of the seed identifier, and the optimizer generates a random execution plan based on the seed value.

Type: USERSET

Value range: an integer ranging from -1 to 2147483647

Default value: 0

NOTICE

- If **plan_mode_seed** is set to **RANDOM_PLAN**, the optimizer generates different random execution plans, which may not be the optimal. Therefore, to guarantee the query performance, the default value 0 is recommended during upgrade, scale-out, scale-in, and O&M.
- If this parameter is not set to 0, the specified hint will not be used.

enable_hdfs_predicate_pushdown

Parameter description: Specifies whether the function of pushing down predicates the native data layer is enabled.

Type: SUSET

Value range: Boolean

- **on** indicates this function is enabled.
- **off** indicates this function is disabled.

Default value: on

windowagg_pushdown_enhancement

Parameter description: Specifies whether to enable enhanced predicate pushdown for window functions in aggregation scenarios. (This parameter is supported only by clusters of version 8.2.0 or later.)

Type: SUSET

Value range: Boolean

- **on** indicates that the predicate pushdown enhancement for window functions is enabled in aggregation scenarios.
- **off** indicates that the predicate pushdown enhancement for window functions is disabled in aggregation scenarios.

Default value: on

implied_quality_optmode

Parameter description: Specifies how to pass conditions for the equivalent columns in a statement. (This parameter is supported only by clusters of version 8.2.0 or later.)

Type: SUSET

Value range: enumerated values

- **normal** indicates forward compatibility with 8.1.3 and earlier versions, that is, the implied expression behavior is optimized.
- **negative** indicates that the implied expression behavior is not optimized.
- **positive** indicates that type conversion expressions are optimized in addition to the operations specified by **normal**.

Default value: normal

enable_random_datanode

Parameter description: Specifies whether the function that random query about DN in the replication table is enabled. A complete data table is stored on each DN for random retrieval to release the pressure on nodes.

Type: USERSET

Value range: Boolean

- **on:** This function is enabled.
- **off:** This function is disabled.

Default value: on

hashagg_table_size

Parameter description: Specifies the hash table size during **HASH AGG** execution.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX/2

Default value: 0

enable_codegen

Parameter description: Specifies whether code optimization can be enabled. Currently, the code optimization uses the LLVM optimization.

Type: USERSET

Value range: Boolean

- **on** indicates code optimization can be enabled.
- **off** indicates code optimization cannot be enabled.

Default value: off

CAUTION

- In clusters of version 9.1.0.218 or later (new installation and upgrade scenarios), the default value of this parameter is **off**. In clusters of version earlier than 9.1.0.218, the default value of this parameter is **on**.
 - Currently, the LLVM optimization only supports the vectorized executor and SQL on Hadoop features. You are advised to set this parameter to **off** in other cases.
-

codegen_strategy

Parameter description: Specifies the codegen optimization strategy that is used when an expression is converted to codegen-based.

Type: USERSET

Value range: enumerated values

- **partial** indicates that you can still call the LLVM dynamic optimization strategy using the codegen framework of an expression even if functions that are not codegen-based exist in the expression.
- **pure** indicates that the LLVM dynamic optimization strategy can be called only when all functions in an expression can be codegen-based.

NOTICE

In the scenario where query performance reduces after the codegen function is enabled, you can set this parameter to **pure**. In other scenarios, do not change the default value **partial** of this parameter.

Default value: partial

enable_codegen_print

Parameter description: Specifies whether the LLVM IR function can be printed in logs.

Type: USERSET

Value range: Boolean

- **on** indicates that the LLVM IR function can be printed in logs.
- **off** indicates that the LLVM IR function cannot be printed in logs.

Default value: off

codegen_cost_threshold

Parameter description: The LLVM compilation takes some time to generate executable machine code. Therefore, LLVM compilation is beneficial only when the actual execution cost is more than the sum of the code required for generating machine code and the optimized execution cost. This parameter specifies a threshold. If the estimated execution cost exceeds the threshold, LLVM optimization is performed.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 10000

llvm_compile_expr_limit

Parameter description: Specifies the limit for compiling expressions with LLVM. If there are more expressions than the limit, only the first ones are compiled and an alarm is generated. (To allow the alarm to be generated, execute **SET analysis_options="on(LLVM_COMPILE)"** before **explain performance** is executed.)

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX

Default value: 500

llvm_compile_time_limit

Parameter description: If the percentage of the LLVM compilation time to the executor running time exceeds the threshold specified by **llvm_compile_time_limit**, an alarm is generated. (To allow the alarm to be generated, execute **SET analysis_options="on(LLVM_COMPILE)"** before **explain performance** is executed.) This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: a floating point number ranging from 0.0 to 1.0

Default value: 0.2

enable_constraint_optimization

Parameter description: Specifies whether the informational constraint optimization execution plan can be used for an HDFS foreign table.

Type: SUSET

Value range: Boolean

- **on** indicates the plan can be used.
- **off** indicates the plan cannot be used.

Default value: on

enable_bloom_filter

Parameter description: Specifies whether the BloomFilter optimization is used.

Type: USERSET

Value range: Boolean

- **on** indicates the BloomFilter optimization can be used.
- **off** indicates the BloomFilter optimization cannot be used.

Default value: on

NOTICE

Scenario: If in a HASH JOIN, the thread of the foreign table contains HDFS tables or column-store tables, the Bloom filter is triggered.

Constraints:

1. Only **INNER JOIN**, **SEMI JOIN**, **RIGHT JOIN**, **RIGHT SEMI JOIN**, **RIGHT ANTI JOIN** and **RIGHT ANTI FULL JOIN** are supported.
 2. JOIN condition of the internal table: It cannot be an expression for HDFS internal or foreign tables. It can be an expression for column-store tables, but only at the non-join layer.
 3. The join condition of the foreign table must be simple column join.
 4. When the join conditions of the internal and foreign tables (HDFS) are both simple column joins, the estimated data that can be removed at the plan layer must be over 1/3.
 5. Joined columns cannot contain NULL values.
 6. Data type:
 - HDFS internal and foreign tables support SMALLINT, INTEGER, BIGINT, REAL/FLOAT4, DOUBLE PRECISION/FLOAT8, CHAR(n)/CHARACTER(n)/NCHAR(n), VARCHAR(n)/CHARACTER VARYING(n), CLOB and TEXT.
 - Column-store tables support SMALLINT, INTEGER, BIGINT, OID, "char", CHAR(n)/CHARACTER(n)/NCHAR(n), VARCHAR(n)/CHARACTER VARYING(n), NVARCHAR2(n), CLOB, TEXT, DATE, TIME, TIMESTAMP and TIMESTAMPTZ. The collation of the character type must be C.
-

runtime_filter_type

Parameter description : Specifies the type of runtime filter used, and only takes effect when [enable_bloom_filter](#) is enabled. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: enumerated values

- **All** indicates that the runtime filters in all scenarios are used.
- **Topn_filter** indicates the runtime filters in the **ORDER BY** scenario with **LIMIT** are used.
- **Bloom_filter** indicates that only runtime filters in join scenarios are used, and a bloom filter is generated for filtering after meeting certain conditions.
- **Min_max** indicates that only the runtime filters in join scenarios are used and only a **min_max** filter is generated for filtering.
- **None** indicates that no runtime filters are used, and only the original bloom filter has filtering effect.

Default value: All

NOTICE

- Application scenario: Plan type of the **HASH JOIN** foreign table in a column-store table and the **ORDER BY** plan type with **LIMIT** in a column-store table.
 - Constraints:
 - The usage restrictions for JOIN scenarios are the same as those for the [enable_bloom_filter](#) parameter.
 - In the order by scenario with limit, the order by field types only support **SMALLINT**, **INTEGER**, **BIGINT**, **"char"**, **CHAR(n)/CHARACTER(n)/NCHAR(n)**, **VARCHAR(n)/CHARACTER VARYING(n)**, **NVARCHAR2(n)**, **TEXT**, **DATE**, **TIME**, **TIMESTAMP**, and **TIMESTAMPZ**, and the sorting rules for character types must be specified as **C**.
-

runtime_filter_ratio

Parameter description: Specifies the threshold for using bloom filter for fine-grained row-level filtering in join scenarios in runtime filter, and only takes effect when [runtime_filter_type](#) is set to a value greater than or equal to **Bloom_filter**. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: a floating point number ranging from 0.0 to 1.0

Default value: 0.01

NOTICE

- Application scenario: HASH JOIN of column-store tables, where the internal table **estimate_join_rows**/foreign table **estimate_join_rows** ≤ **runtime_filter_ratio**. Fine-grained row-level filtering is only recommended for join scenarios where there is a significant difference in data volume between the internal and foreign tables. Improper **runtime_filter_ratio** settings may lead to degraded performance in join scenarios.
- Usage restrictions: Fine-grained row-level filtering is only supported for join field types of **SMALLINT**, **INTEGER**, **BIGINT**, and **FLOAT**.

runtime_filter_cost_options

Parameter description : Specifies whether to generate a runtime filter plan based on the cost. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: a string

- **apply_partial**: The runtime filter path can be generated as long as the **build** end contains a table required by a runtime filter on the **probe** end.
- **apply_all**: The runtime filter path can be generated only when the **build** end contains all tables required by the runtime filter that can be applied to the **probe** end.

Default value: "", indicating that runtime filters are not used during plan generation, regardless of the cost.

NOTICE

If both **apply_partial** and **apply_all** are set, the setting of **apply_all** takes effect.

enable_extrapolation_stats

Parameter description: Specifies whether to use the extrapolation logic based on historical statistics. Using this logic may increase the accuracy of estimation for tables whose statistics have not been collected. However, there is also a possibility that the estimation is too large due to incorrect inference.

Type: USERSET

Value range: Boolean

- **on** indicates that the extrapolation logic is used for data of DATE type based on historical statistics.
- **off** indicates that the extrapolation logic is not used for data of DATE type based on historical statistics.

Default value:

- If the current cluster is upgraded from an earlier version to 8.2.0.100, the default value is **off** to ensure forward compatibility.

- If the cluster version 8.2.0.100 is newly installed, the default value is **on**.

autoanalyze

Parameter description: Specifies whether to allow automatic statistics collection for a table that has no statistics or a table whose amount of data modification reaches the threshold for triggering **ANALYZE** when a plan is generated. In this case, **AUTOANALYZE** cannot be triggered for foreign tables or temporary tables with the **ON COMMIT [DELETE ROWS|DROP]** option. To collect statistics, you need to manually perform the **ANALYZE** operation. If an exception occurs in the database during the execution of autoanalyze on a table, after the database is recovered, the system may still prompt you to collect the statistics of the table when you run the statement again. In this case, manually perform the **ANALYZE** operation on the table to synchronize statistics.

NOTICE

If the amount of data modification reaches the threshold for triggering **ANALYZE**, the amount of data modification exceeds **autovacuum_analyze_threshold + autovacuum_analyze_scale_factor * reltuples**. *reltuples* indicates the estimated number of rows in the table recorded in **pg_class**.

Type: SUSET

Value range: Boolean

- **on** indicates that the table statistics are automatically collected.
- **off** indicates that the table statistics are not automatically collected.

Default value: on

enable_analyze_partition

Parameter description: Specifies whether to support collecting statistics for a specific partition of a table. After enabling this parameter, you can collect statistics for a specific partition using **ANALYZE table_name PARTITION (partition_name)**, and when querying data on this partition of the table, the optimizer will choose to use partition statistics.

Type: USERSET

Value range: Boolean

- **on** indicates supporting collecting statistics for a specific partition of a table.
- **off** indicates that collecting statistics for a specific partition of a table is not supported.

Default value: off

analyze_use_dn_correlation

Parameter description: Specifies whether CNs use correlation statistics of DN's when executing **ANALYZE**. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that CNs use correlation statistics of DNs.
- **off** indicates that CNs do not use correlation statistics of DNs.

Default value: on

analyze_predicate_column_threshold

Parameter description: Specifies whether to enable ANALYZE operations for predicate columns and the minimum number of columns supported. This is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: an integer ranging from 0 to 10000

- The value **0** indicates that ANALYZE operations are disabled for predicate columns and predicate columns are not collected or analyzed.
- A value greater than 0 indicates that predicate column collection is enabled and predicate column analysis is performed only on tables whose number of columns is greater than or equal to the value of this parameter.

Default value: 10

enable_runtime_analyze_concurrent

Parameter description: Specifies whether to support concurrent RUNTIME ANALYZE operations on a table. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that concurrent operations are supported.
- **off** indicates that concurrent operations are not supported.

Default value: on

analyze_max_columns_count

Parameter description: Specifies the maximum number of columns supported by ANALYZE. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: an integer ranging from -1 to 10000

- **-1** indicates that the number of columns supported by ANALYZE is not limited.
- A value greater than **-1** indicates that only columns up to this value will be collected, and any columns beyond this value will not be collected.

Default value: -1

query_dop

Parameter description: Specifies the user-defined degree of parallelism.

Type: USERSET

Value range: an integer ranging from -64 to 64.

[1, 64]: Fixed SMP is enabled, and the system will use the specified degree.

0: SMP adaptation function is enabled. The system dynamically selects the optimal parallelism degree [1,8] (x86 platforms) or [1,64] (Kunpeng platforms) for each query based on the resource usage and query plans.

[-64, -1]: SMP adaptation is enabled, and the system will dynamically select a degree from the limited range.

NOTE

- For TP services that mainly involve short queries, if services cannot be optimized through lightweight CNs or statement delivery, it will take a long time to generate an SMP plan. You are advised to set **query_dop** to **1**. For AP services with complex statements, you are advised to set **query_dop** to **0**.
- After enabling concurrent queries, ensure you have sufficient CPU, memory, network, and I/O resources to achieve the optimal performance.
- To prevent performance deterioration caused by an overly large value of **query_dop**, the system calculates the maximum number of available CPU cores for a DN and uses the number as the upper limit for this parameter. If the value of **query_dop** is greater than 4 and also the upper limit, the system resets **query_dop** to the upper limit.

Default value: 1 (0 for cloud flavors with 64 GB or larger memory)

query_dop_ratio

Parameter description: Specifies the DOP multiple used to adjust the optimal DOP preset in the system when **query_dop** is set to **0**. That is, $DOP = \text{Preset DOP} \times \text{query_dop_ratio}$ (ranging from 1 to 64). If this parameter is set to **1**, the DOP cannot be adjusted.

Type: USERSET

Value range: a floating point number ranging from 0 to 64

Default value: 1

debug_group_dop

Parameter description: Specifies the unified DOP parallelism degree allocated to the groups that use the Stream operator as the vertex in the generated execution plan when the value of **query_dop** is **0**. This parameter is used to manually specify the DOP for specific groups for performance optimization. Its format is **G1,D1,G2,D2,...**, where **G1** and **G2** indicate the group IDs that can be obtained from logs and **D1** and **D2** indicate the specified DOP values and can be any positive integers.

Type: USERSET

Value range: a string

Default value: empty

NOTICE

This parameter is used only for internal optimization and cannot be set. You are advised to use the default value.

enable_analyze_check

Parameter description: Checks whether statistics were collected about tables whose **reltuples** and **relpages** are shown as **0** in **pg_class** during plan generation. **This parameter has been discarded in clusters of version 8.1.3 or later, but is reserved for compatibility with earlier versions. The setting of this parameter does not take effect.**

Type: SUSET

Value range: Boolean

- **on** enables the check.
- **off** disables the check.

Default value: on

enable_sonic_hashagg

Parameter description: Specifies whether to use the Hash Agg operator for column-oriented hash table design when certain constraints are met.

Type: USERSET

Value range: Boolean

- **on** indicates that the Hash Agg operator is used for column-oriented hash table design when certain constraints are met.
- **off** indicates that the Hash Agg operator is not used for column-oriented hash table design.

 NOTE

- If **enable_sonic_hashagg** is enabled and certain constraints are met, the Hash Agg operator will be used for column-oriented hash table design, and the memory usage of the operator can be reduced. However, in scenarios where the code generation technology (enabled by [enable_codegen](#)) can significantly improve performance, the performance of the operator may deteriorate.
- If **enable_sonic_hashagg** is set to **on**, when certain constraints are met, the hash aggregation operator designed for column-oriented hash tables is used and its name is displayed as **Sonic Hash Aggregation** in the output of the Explain Analyze/Performance operation. When the constraints are not met, the operator name is displayed as **Hash Aggregation**.

Default value: on

enable_sonic_hashjoin

Parameter description: Specifies whether to use the Hash Join operator for column-oriented hash table design when certain constraints are met.

Type: USERSET

Value range: Boolean

- **on** indicates that the Hash Join operator is used for column-oriented hash table design when certain constraints are met.
- **off** indicates that the Hash Join operator is not used for column-oriented hash table design.

NOTE

- Currently, the parameter can be used only for Inner Join.
- If **enable_sonic_hashjoin** is enabled, the memory usage of the Hash Inner operator can be reduced. However, in scenarios where the code generation technology can significantly improve performance, the performance of the operator may deteriorate.
- If **enable_sonic_hashjoin** is set to **on**, when certain constraints are met, the hash join operator designed for column-oriented hash tables is used and its name is displayed as **Sonic Hash Join** in the output of the Explain Analyze/Performance operation. When the constraints are not met, the operator name is displayed as **Hash Join**.

Default value: on

enable_sonic_optspill

Parameter description: Specifies whether to optimize the number of hash join or hash agg files spilled to disks in the sonic scenario. This parameter takes effect only when **enable_sonic_hashjoin** or **enable_sonic_hashagg** is enabled.

Type: USERSET

Value range: Boolean

- **on** indicates that the number of files spilled to disks is optimized.
- **off** indicates that the number of files spilled to disks is not optimized.

NOTE

For the hash join or hash agg operator that meets the sonic criteria, if this parameter is set to **off**, one file is spilled to disks for each column. If this parameter is set to **on** and the data types of different columns are similar, only one file (a maximum of five files) will be spilled to disks.

Default value: on

expand_hashtable_ratio

Parameter description: Specifies the expansion ratio used to resize the hash table during the execution of the Hash Agg and Hash Join operators.

Type: USERSET

Value range: a floating point number of 0 or ranging from 0.5 to 10

 NOTE

- Value **0** indicates that the hash table is adaptively expanded based on the current memory size.
- The value ranging from 0.5 to 10 indicates the multiple used to expand the hash table. Generally, a larger hash table delivers better performance but occupies more memory space. If the memory space is insufficient, data may be spilled to disks in advance, causing performance deterioration.

Default value: 0

plan_cache_mode

Parameter description: Specifies the policy for generating an execution plan in the **prepare** statement.

Type: USERSET

Value range: enumerated values

- **auto** indicates that the **custom plan** or **generic plan** is selected by default.
- **force_generic_plan** indicates that the **generic plan** is forcibly used.
- **force_custom_plan** indicates that the **custom plan** is forcibly used.

 NOTE

- This parameter is valid only for the **prepare** statement. It is used when the parameterized field in the **prepare** statement has severe data skew.
- The **custom plan** is a plan generated after you run a prepared statement where parameters in the EXECUTE statement are embedded. The **custom plan** generates a plan based on specific parameters in the execute statement. This scheme generates a preferred plan based on specific parameters each time and has good execution performance. The disadvantage is that the plan needs to be regenerated before each execution, resulting in a large amount of repeated optimizer overhead.
- The **generic plan** is a plan generated after you run a prepared statement. The plan policy binds parameters to the plan when you run the EXECUTE statement and execute the plan. The advantage of this solution is that repeated optimizer overheads can be avoided in each execution. The disadvantage is that the plan may not be optimal when data skew occurs for the bound parameter field. When some bound parameters are used, the plan execution performance is poor.

Default value: auto

wlm_query_accelerate

Parameter description: Specifies whether the query needs to be accelerated when short query acceleration is enabled.

Type: USERSET

Value range: an integer ranging from -1 to 1

- **-1:** indicates that short queries are controlled by the fast lane, and the long queries are controlled by the slow lane.
- **0:** indicates that queries are not accelerated. Both short and long queries are controlled by the slow lane.
- **1:** indicates that queries are accelerated. Both short queries and long queries are controlled by the fast lane.

Default value: -1

show_unshippable_warning

Parameter description: Specifies whether to print the alarm for the statement pushdown failure to the client.

Type: USERSET

Value range: Boolean

- **on:** Records the reason why the statement cannot be pushed down in a WARNING log and prints the log to the client.
- **off:** Logs the reason why the statement cannot be pushed down only.

Default value: off

hashjoin_spill_strategy

Parameter description: specifies the hash join policy for spilling data to disks. This feature is supported in 8.1.2 or later.

Type: USERSET

Value range: The value is an integer ranging from 0 to 6.

- **0:** If an inner table is too large to be fully stored in database memory, the table will be partitioned. If the table cannot be further partitioned and there is not enough memory for storing it, the system will check whether the foreign table can be stored in memory and be used to create a hash table. If the foreign table can be stored in the memory and used to create a hash table, HashJoin will be performed. Otherwise, NestLoop will be performed.
- **1:** If an inner table is too large to be fully stored in database memory, the table will be partitioned. If the table cannot be further partitioned and there is still not enough memory for storing it, the system will check whether the foreign table can be stored in memory and be used to create a hash table. If both the inner and outer tables are large, a hash join is forcibly performed.
- **2:** If the size of the inner table is large and cannot be partitioned after data is spilled to disks for multiple times, HashJoin will be forcibly performed.
- **3:** If the size of the inner table is large and cannot be partitioned after data is spilled to disks for multiple times, the system attempts to place the outer table in the available memory of the database to create a hash table. If both the inner and outer tables are large, an error is reported.
- **4:** If the size of the inner table is large and cannot be partitioned after data is spilled to disks for multiple times, an error is reported.
- **5:** If the inner table is large and cannot be fully stored in database memory, and the foreign table can be fully stored in memory, the foreign table will be used to create a hash table and perform HashJoin. If the foreign table cannot be fully stored in memory, it will be partitioned until the inner and foreign tables cannot be further partitioned. Then, NestLoop will be performed.
- **6:** If the inner table is large and cannot be fully stored in database memory, and the foreign table can be fully stored in memory, the foreign table will be used to create a hash table and perform HashJoin. If the foreign table cannot be fully stored in memory, it will be partitioned until the inner and foreign

tables cannot be further partitioned. Then, HashJoin will be forcibly performed.

 NOTE

- This parameter is valid only for a vectorized hash join operator.
- If the number of distinct values is small and the data volume is large, data may fail to be flushed to disks. As a result, the memory usage is too high and the memory is out of control. If this parameter is set to **0**, the system attempts to swap the inner and outer tables or perform a nested loop join to prevent this problem. However, a nested loop join may deteriorate performance in some scenarios. In this case, this parameter can be set to **1**, **2**, or **6** to forcibly perform HashJoin.
- The value **0** does not take effect for a vectorized full join, and the behavior is the same as that of the value **1**. The system attempts to create a hash table only for the outer table and does not perform a nested loop join.
- If the inner table is too large to be fully stored in memory, but the foreign table can be stored in memory, you are advised to set this parameter to **5** or **6** rather than **0** or **1**, directly performing Hashjoin on the foreign table without multiple rounds of partitioning and spill to disk. If a foreign table contains only a small amount of distinct data, creating a hash table using the foreign table may cause performance deterioration. In this case, you can change the value of this parameter to **0** or **1**.

Default value: 0

max_streams_per_query

Parameter description: Controls the number of Stream nodes in a query plan. (This parameter is supported only in 8.1.1 and later cluster versions.)

Type: SUSET

Value range: an integer ranging from -1 to 10000.

- **-1** indicates that the number of Stream nodes in the query plan is not limited.
- A value within the range **0** to **10000** indicates that when the number of Stream nodes in the query plan exceeds the specified value, an error is reported and the query plan will not be executed.

 NOTE

- This parameter controls only the Stream nodes on DN and does not control the Gather nodes on the CN.
- This parameter does not affect the EXPLAIN query plan, but affects EXPLAIN ANALYZE and EXPLAIN PERFORMANCE.

Default value: -1

enable_agg_limit_opt

Parameter description: Specifies whether to optimize **select distinct col from table limit N**. This parameter is valid only if N is less than 16,384. The parameter **table** indicates a column-store table. This parameter is supported only by clusters of version 8.2.0.101 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimization is enabled. After this function is enabled, query results are from different DN, and you do not need to create a full hash table on each DN, significantly improving query performance.
- **off** indicates that the optimization is disabled.

Default value: on

stream_ctescan_pred_threshold

Parameter description: minimum number of filter criteria contained in a CTE when **enable_stream_ctescan** is set to **on** and the CTE contains only a single table filtering condition. If the value is greater than or equal to the value of this parameter, the share scan mode is used. If the value is less than the value of this parameter, the inline mode is used. This parameter is supported only by clusters of version 8.2.1 or later.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 2

stream_ctescan_max_estimate_mem

Parameter description: maximum estimated memory value of the CTE when **enable_stream_ctescan** is set to **on**. This parameter must be used together with **stream_ctescan_refcount_threshold**. If the estimated memory is greater than the value of **stream_ctescan_max_estimate_mem** and the number of references is less than the value of **stream_ctescan_refcount_threshold**, the inline mode is used. Otherwise, the sharescan mode is used. This parameter is supported only by clusters of version 8.2.1 or later.

Type: SUSET

Value range: an integer ranging from 32 x 1024 (32 MB) to INT_MAX, in KB.

Default value: 256 MB

stream_ctescan_refcount_threshold

Parameter description: maximum number of times that the CTE can be referenced when **enable_stream_ctescan** is set to **on**. This parameter must be used together with **stream_ctescan_max_estimate_mem**. If the estimated memory is greater than the value of **stream_ctescan_max_estimate_mem** and the number of references is less than the value of **stream_ctescan_refcount_threshold**, the inline mode is used. Otherwise, the sharescan mode is used. This parameter is supported only by clusters of version 8.2.1 or later.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 4

 NOTE

This parameter takes effect only when the value is greater than 0. When the value is 0, only **stream_ctescan_max_estimate_mem** is used to control the inline behavior.

inlist_rough_check_threshold

Parameter description: Specifies the maximum number of values in the **IN** condition when **enable_csqual_pushdown** is enabled and the filter criterion is **IN** for rough check pushdown. If the number of values in the **IN** filter condition exceeds the value of this parameter, the maximum and minimum values in the **IN** filter condition are used for pushdown. This parameter is supported only by clusters of version 8.2.0.101 or later.

Type: SUSET

Value range: an integer ranging from 0 to 10000

Default value: 100

 NOTE

If the **IN** condition is executed on the only distribution column of a table, values can be filtered on DN. In this case, the maximum number of values in the **IN** condition is **inlist_rough_check_threshold** multiplied by the number of DN.

enable_array_optimization

Parameter description: whether to split the Array type generated by the **IN**, **ANY**, or **ALL** condition into common expressions for execution. This parameter will support multiple optimizations such as vectorized execution, rough check pruning, and partition pruning. This parameter is supported only by clusters of version 8.2.1 or later.

Type: SUSET

Value range: Boolean

- **on** indicates that expressions of the Array type are split for optimization.
- **off** indicates that expressions of the Array type are not split for optimization.

Default value: on

max_skew_num

Parameter description: controls the number of skew values allowed by the optimizer for redistribution optimization. This parameter is supported only by clusters of version 8.2.1 or later.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 10

enable_dict_plan

Parameter description: Specifies whether the optimizer uses dictionary encoding to speed up queries that use operators such as **Group By** and **Filter**. This parameter is supported only by clusters of 8.3.0 or later.

Type: USERSET

Value range: Boolean

- **on:** enables the optimizer dictionary encoding.
- **off:** disables the optimizer dictionary encoding.

Default value: **off**

dict_plan_distinct_limit

Parameter description: Specifies the distinct value of a column in a table. Dictionary encoding is enabled only when the value is less than or equal to the threshold. This parameter is supported only by clusters of 8.3.0 or later.

Type: USERSET

Value range: 0 to INT_MAX

Default value: 10000

NOTE

The two parameters **dict_plan_distinct_limit** and **dict_plan_duplicate_ratio** determine if dictionary encoding is applied.

dict_plan_duplicate_ratio

Parameter description: Specifies the repetition rate threshold of a column. Dictionary encoding is enabled only when the repetition rate of the column is greater than or equal to the threshold. Dictionary encoding is suitable for columns with a small number of distinct values and a high repetition rate. This parameter is supported only by clusters of 8.3.0 or later.

Type: USERSET

Value range: 0.0 to 100, in percentage

Default value: 90

NOTE

The two parameters **dict_plan_distinct_limit** and **dict_plan_duplicate_ratio** determine if dictionary encoding is applied.

enable_cu_predicate_pushdown

Parameter description:

1. Function overview: Specifies whether simple filter criteria are pushed down to the CU for filtering. Enabling this will enhance query performance, particularly when working with the **bitmap_columns** column and PCK sorting column. It

applies to specific **WHERE**, **IS NULL**, and **IN** conditions. This parameter is supported only by clusters of 8.3.0 or later.

2. Supported column types:

- Integer type: INT2, INT4, and INT8
- Date and time type: DATE, TIMESTAMP, and TIMESTAMPTZ
- String types: VARCHAR and TEXT
- Numeral type: NUMERIC (a maximum of 19 characters)

3. Query conditions: This function supports multiple **WHERE** expressions, including:

- **IN** expression: matches multiple values.
- **IS NULL** / **IS NOT NULL** condition: checks whether the column value is null.
- Comparison expressions: greater than (>), less than (<), equal to (=), and not equal to (<>), which is used for range query and exact match.

Type: USERSET

Value range: Boolean

- **on:** Simple filter criteria are pushed down to the CU for filtering.
- **off:** Simple filter criteria are not pushed down to the CU for filtering.

Default value: on

 NOTE

The basic filter conditions for the dictionary column include the equality operator (=), the **IN** expression, and the **IS (NOT) NULL** condition. This filter is known as the CU Predicate Filter, as it is pushed down to the storage layer and applied during the VectorBatch filling process.

info_constraint_options

Parameter description: Specifies whether or which kind of informational constraints can be created. This is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: enumerated values

- **none:** indicates that no informational constraint can be created.
- **foreign_key:** indicates that foreign key constraints can be created.

Default value: none

19.10 Error Reporting and Logging

19.10.1 Logging Destination

log_statement_length_limit

Parameter description: Specifies the length of SQL statements to be printed. If the length of an SQL statement exceeds the specified value, the SQL statement is recorded in the **statement-*Timestamp*.log** file. This parameter is supported only by 9.1.0.200 and later versions.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX.

Default value: 1024

19.10.2 Logging Time

client_min_messages

Parameter description: Specifies which level of messages are sent to the client. Each level covers all the levels following it. The lower the level is, the fewer messages are sent.

Type: USERSET

NOTICE

When the values of **client_min_messages** and **log_min_messages** are the same, the levels are different.

Valid values: Enumerated values. Valid values: **debug5, debug4, debug3, debug2, debug1, info, log, notice, warning, error** For details about the parameters, see [Table 19-1](#).

Default value: notice

log_min_messages

Parameter description: Specifies which level of messages will be written into server logs. Each level covers all the levels following it. The lower the level is, the fewer messages will be written into the log.

Type: SUSET

NOTICE

When the values of **client_min_messages** and **log_min_messages** are the same, the levels are different.

Value range: enumerated type. Valid values: **debug5, debug4, debug3, debug2, debug1, info, log, notice, warning, error, fatal, panic** For details about the parameters, see [Table 19-1](#).

Default value: warning

log_min_error_statement

Parameter description: Specifies which SQL statements that cause errors condition will be recorded in the server log.

Type: SUSET

Value range: enumerated type. Valid values: **debug5, debug4, debug3, debug2, debug1, info, log, notice, warning, error, fatal, panic** For details about the parameters, see [Table 19-1](#).

NOTE

- The default is **error**, indicating that statements causing errors, log messages, fatal errors, or panics will be logged.
- **panic**: This feature is disabled.

Default value: error

log_min_duration_statement

Parameter description: Specifies the threshold for logging statement execution durations. The execution duration that is greater than the specified value will be logged.

This parameter helps track query statements that need to be optimized. For clients using extended query protocol, durations of the Parse, Bind, and Execute are logged independently.

Type: SUSET

NOTICE

If this parameter and [log_statement](#) are used at the same time, statements recorded based on the value of **log_statement** will not be logged again after their execution duration exceeds the value of this parameter. If you are not using **syslog**, it is recommended that you log the process ID (PID) or session ID using **log_line_prefix** so that you can link the current statement message to the last logged duration.

Value range: an integer ranging from -1 to INT_MAX. The unit is millisecond.

- If this parameter is set to **250**, execution durations of SQL statements that run 250 ms or longer will be logged.
- **0**: Execution durations of all the statements are logged.
- **-1**: This feature is disabled.

Default value: 30min

backtrace_min_messages

Parameter description: Prints the function's stack information to the server's log file if the level of information generated is greater than or equal to this parameter level.

Type: SUSET

NOTICE

This parameter is used for locating customer on-site problems. Because frequent stack printing will affect the system's overhead and stability, therefore, when you locate the onsite problems, set the value of this parameter to ranks other than **fatal** and **panic**.

Value range: enumerated values

Valid values: **debug5, debug4, debug3, debug2, debug1, info, log, notice, warning, error, fatal, panic** For details about the parameters, see [Table 19-1](#).

Default value: panic

[Table 19-1](#) explains the message security levels used in DWS. If logging output is sent to **syslog** or **eventlog**, severity is translated in DWS as shown in the table.

Table 19-1 Message Severity Levels

| Severity | Description | syslog | eventlog |
|------------|--|---------|-------------|
| debug[1-5] | Provides detailed debug information. | DEBUG | INFORMATION |
| log | Reports information of interest to administrators, for example, checkpoint activity. | INFO | INFORMATION |
| info | Provides information implicitly requested by the user, for example, output from VACUUM VERBOSE . | INFO | INFORMATION |
| notice | Provides information that might be helpful to users, for example, notice of truncation of long identifiers and index created as part of the primary key. | NOTICE | INFORMATION |
| warning | Provides warnings of likely problems, for example, COMMIT outside a transaction block. | NOTICE | WARNING |
| error | Reports an error that causes a command to terminate. | WARNING | ERROR |

| Severity | Description | syslog | eventlog |
|----------|--|--------|----------|
| fatal | Reports the reason that causes a session to terminate. | ERR | ERROR |
| panic | Reports an error that caused all database sessions to terminate. | CRIT | ERROR |

plog_merge_age

Parameter description: Specifies the output interval of performance log data.

Type: SUSET

NOTICE

This parameter value is in milliseconds. You are advised to set this parameter to a value that is a multiple of 1000. That is, the value is in seconds. Name extension of the performance log files controlled by this parameter is .prf. These log files are stored in the **\$GAUSSLOG/gs_profile/<node_name>** directory. *node_name* is the value of **pgxc_node_name** in the **postgres.conf** file. You are advised not to use this parameter externally.

Value range: an integer ranging from 0 to INT_MAX. The unit is millisecond (ms).

- **0** indicates that the current session will not output performance log data.
- A value other than 0 indicates the output interval of performance log data. As the value decreases, more log data is generated, which negatively impacts performance.

Default value: 3s

profile_logging_module

Parameter description: Specifies the type of performance logs. When using this parameter, ensure that the value of **plog_merge_age** is not 0. This parameter is a session-level parameter, and you are not advised to use the **gs_guc** tool to set it. Only clusters of 8.1.3 and later versions support this function.

Type: USERSET

Value range: a string

Default value: OBS, HADOOP and REMOTE_DATANODE are enabled. MD is disabled. You can run the **SHOW profile_logging_module** command to view the value.

Setting method: First, you can run **SHOW profile_logging_module** to view which module is controllable. For example, the query output result is as follows:

```
show profile_logging_module;  
profile_logging_module
```

```
-----  
ALL,on(OBS,HADOOP,REMOTE_DATANODE),off(MD)(1 row)
```

Open the MD performance log and view the setting. The ALL identifier is equivalent to a shortcut operation. That is, logs of all modules can be enabled or disabled.

```
set profile_logging_module='on(md)';  
SET  
  
show profile_logging_module;  
profile_logging_module  
-----  
ALL,on(MD,OBS,HADOOP,REMOTE_DATANODE),off()(1 row)
```

19.10.3 Logging Content

debug_pretty_print

Parameter description: Specifies the logs produced by **debug_print_parse**, **debug_print_rewritten**, and **debug_print_plan**. The output format is more readable but much longer than the output generated when this parameter is set to **off**.

Type: USERSET

Value range: Boolean

- **on** indicates the indentation is enabled.
- **off** indicates the indentation is disabled.

Default value: on

log_duration

Parameter description: Specifies whether to record the duration of every completed SQL statement. For clients using extended query protocols, the time required for parsing, binding, and executing steps are logged independently.

Type: SUSET

Value range: Boolean

- If this parameter is set to **off**, the difference between setting this parameter and setting **log_min_duration_statement** is that when **log_min_duration_statement** is exceeded, the query text is logged, but this parameter does not log it.
- If this parameter is set to **on** and **log_min_duration_statement** has a positive value, all durations are logged but the query text is included only for statements exceeding the threshold. This behavior can be used for gathering statistics in high-load situation.

Default value: on

log_error_verbosity

Parameter description: Specifies the amount of detail written in the server log for each message that is logged.

Type: SUSET

Value range: enumerated values

- **terse** indicates that the output excludes the logging of DETAIL, HINT, QUERY, and CONTEXT error information.
- **verbose** indicates that the output includes the SQLSTATE error code, the source code file name, function name, and number of the line in which the error occurs.
- **default** indicates that the output includes the logging of DETAIL, HINT, QUERY, and CONTEXT error information, and excludes the SQLSTATE error code, the source code file name, function name, and number of the line in which the error occurs.

Default value: default

log_lock_waits

Parameter description: If the time that a session used to wait a lock is longer than the value of [deadlock_timeout](#), this parameter specifies whether to record this message in the database. This is useful in determining if lock waits are causing poor performance.

Type: SUSET

Value range: Boolean

- **on** indicates the information is recorded.
- **off** indicates the information is not recorded.

Default value: off

log_statement

Parameter description: Specifies whether to record SQL statements. For clients using extended query protocols, logging occurs when an execute message is received, and values of the Bind parameters are included (with any embedded single quotation marks doubled).

Type: SUSET

NOTICE

Statements that contain simple syntax errors are not logged even if **log_statement** is set to **all**, because the log message is emitted only after basic parsing has been completed to determine the statement type. If the extended query protocol is used, this setting also does not log statements before the execution phase (during parse analysis or planning). Set **log_min_error_statement** to ERROR or lower to log such statements.

Value range: enumerated values

- **none** indicates that no statement is recorded.

- **ddl** indicates that all data definition statements, such as CREATE, ALTER, and DROP, are recorded.
- **mod** indicates that all DDL statements and data modification statements, such as INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM, are recorded.
- **all** indicates that all statements are recorded. The PREPARE, EXECUTE, and EXPLAIN ANALYZE statements are also recorded.

Default value: none

log_temp_files

Parameter description: Specifies whether to record the delete information of temporary files. Temporary files can be created for sorting, hashing, and temporary querying results. A log entry is generated for each temporary file when it is deleted.

Type: SUSET

Value range: an integer ranging from -1 to INT_MAX. The unit is KB.

- A positive value indicates that the delete information of temporary files whose values are larger than that of **log_temp_files** is recorded.
- If the parameter is set to **0**, all the delete information of temporary files is recorded.
- If the parameter is set to **-1**, the delete information of no temporary files is recorded.

Default value: -1

logging_module

Parameter description: Specifies whether module logs can be output on the server. This parameter is a session-level parameter, and you are not advised to use the **gs_guc** tool to set it.

Type: USERSET

Value range: a string

Default value: off. All the module logs on the server can be viewed by running **show logging_module**.

Setting method: First, you can run **show logging_module** to view which module is controllable. For example, the query output result is as follows:

```
show logging_module;
logging_module
-----
ALL,on(),off(DFS,GUC,HDFS,ORC,SLRU,MEM_CTL,AUTOVAC,ANALYZE,CACHE,ADIO,SSL,GDS,TBLSPC,WLM,SP
ACE,OBS,EXECUTOR,VEC_EXECUTOR,STREAM,LLVM,OPT,OPT_REWRITE,OPT_JOIN,OPT_AGG,OPT_SUBPLAN,
OPT_SETOP,OPT_CARD,OPT_SKEW,SMP,UDF,COOP_ANALYZE,WLMCPACCELERATE,PLANHINT,PARQUET,CARB
ONDATA,SNAPSHOT,XACT,HANDLE,CLOG,TQUAL,EC,REMOTE,CN_RETRY,PLSQL,TEXTSEARCH,SEQ,INSTR,CO
MM_IPC,COMM_PARAM,CSTORE,JOB,STREAMPOOL,STREAM_CTSCAN)
(1 row)
```

Controllable modules are identified by uppercase letters, and the special ID ALL is used for setting all module logs. You can control module logs to be exported by setting the log modules to **on** or **off**. Enable log output for SSL:

```
set logging_module='on(SSL)';
SET
show
logging_module;
```

| logging_module |
|--|
| ALL,on(SSL),off(DFS,GUC,HDFS,ORC,SLRU,MEM_CTL,AUTOVAC,ANALYZE,CACHE,ADIO,GDS,TBLSPC,WLM,SPACE,OBS,EXECUTOR,VEC_EXECUTOR,STREAM,LLVM,OPT,OPT_REWRITE,OPT_JOIN,OPT_AGG,OPT_SUBPLAN,OPT_SETOP,OPT_CARD,OPT_SKEW,SMP,UDF,COOP_ANALYZE,WLMCP,ACCELERATE,PLANHINT,PARQUET,CARBONDATA,SNAPSHOT,XACT,HANDLE,CLOG,TQUAL,EC,REMOTE,CN_RETRY,PLSQL,TEXTSEARCH,SEQ,INSTR,COMM_IPC,COMM_PARAM,CSTORE,JOB,STREAMPOOL,STREAM_CTESCAN) |

(1 row)

SSL log output is enabled.

The ALL identifier is equivalent to a shortcut operation. That is, logs of all modules can be enabled or disabled.

```
set logging_module='off(ALL)';
SET
show
logging_module;
```

| logging_module |
|---|
| ALL,on(),off(DFS,GUC,HDFS,ORC,SLRU,MEM_CTL,AUTOVAC,ANALYZE,CACHE,ADIO,SSL,GDS,TBLSPC,WLM,SPACE,OBS,EXECUTOR,VEC_EXECUTOR,STREAM,LLVM,OPT,OPT_REWRITE,OPT_JOIN,OPT_AGG,OPT_SUBPLAN,OPT_SETOP,OPT_CARD,OPT_SKEW,SMP,UDF,COOP_ANALYZE,WLMCP,ACCELERATE,PLANHINT,PARQUET,CARBONDATA,SNAPSHOT,XACT,HANDLE,CLOG,TQUAL,EC,REMOTE,CN_RETRY,PLSQL,TEXTSEARCH,SEQ,INSTR,COMM_IPC,COMM_PARAM,CSTORE,JOB,STREAMPOOL,STREAM_CTESCAN) |

(1 row)

```
set logging_module='on(ALL)';
SET
show
logging_module;
```

| logging_module |
|---|
| ALL,on(DFS,GUC,HDFS,ORC,SLRU,MEM_CTL,AUTOVAC,ANALYZE,CACHE,ADIO,SSL,GDS,TBLSPC,WLM,SPACE,OBS,EXECUTOR,VEC_EXECUTOR,STREAM,LLVM,OPT,OPT_REWRITE,OPT_JOIN,OPT_AGG,OPT_SUBPLAN,OPT_SETOP,OPT_CARD,OPT_SKEW,SMP,UDF,COOP_ANALYZE,WLMCP,ACCELERATE,PLANHINT,PARQUET,CARBONDATA,SNAPSHOT,XACT,HANDLE,CLOG,TQUAL,EC,REMOTE,CN_RETRY,PLSQL,TEXTSEARCH,SEQ,INSTR,COMM_IPC,COMM_PARAM,CSTORE,JOB,STREAMPOOL,STREAM_CTESCAN),off() |

(1 row)

COMM_IPC logs must be enabled or disabled explicitly. You can run either of the following command to enable the log function of COMM_IPC:

```
set logging_module='on(ALL)';  
SET  
set logging_module='on(COMM_IPC)';  
SET
```

After the setting is performed, the log function of the COMM_IPC module will not be automatically disabled. To disable the log function of the COMM_IPC module, you must run the following commands:

```
set logging_module='off(ALL)';  
SET  
set logging_module='off(COMM_IPC)';  
SET
```

Dependency relationship: The value of this parameter depends on the settings of [log_min_messages](#).

enable_unshipping_log

Parameter description: Specifies whether to log statements that are not pushed down. The logs help locate performance issues that may be caused by statements not pushed down.

Type: SUSET

Value range: Boolean

- **on:** Statements not pushed down will be logged.
- **off:** Statements not pushed down will not be logged.

Default value: on

log_statement_filter_list

Parameter description: Specifies whether to record SQL statements. It sets a collection of error codes, with multiple error codes separated by commas, for example: **GS_001, GS_002**. No SQL statement is recorded in the error code log. This parameter is supported only by 9.1.0.200 and later versions.

Type: SUSET

Value range: a string

Default value: an empty string

19.11 Runtime Statistics

19.11.1 Query and Index Statistics Collector

The query and index statistics collector is used to collect statistics during database running. The statistics include the times of inserting and updating a table and an index, the number of disk blocks and tuples, and the time required for the last cleanup and analysis on each table. The statistics can be viewed by querying system view families `pg_stats` and `pg_statistic`. The following parameters are used to set the statistics collection feature in the server scope.

track_activities

Parameter description: Collects statistics about the commands that are being executed in session.

Type: SUSET

Value range: Boolean

- **on** indicates that the statistics collection function is enabled.
- **off** indicates that the statistics collection function is disabled.

Default value: on

track_counts

Parameter description: Collects statistics about data activities.

Type: SUSET

Value range: Boolean

- **on** indicates that the statistics collection function is enabled.
- **off** indicates that the statistics collection function is disabled.

NOTE

When the database to be cleaned up is selected from the AutoVacuum automatic cleanup process, the database statistics are required. In this case, the default value is set to **on**.

Default value: on

track_io_timing

Parameter description: Collects statistics about I/O invoking timing in the database. The I/O timing statistics can be queried by using the **pg_stat_database** parameter.

Type: SUSET

Value range: Boolean

- If this parameter is set to **on**, the collection function is enabled. In this case, the collector repeatedly queries the OS at the current time. As a result, large numbers of costs may occur on some platforms. Therefore, the default value is set to **off**.
- **off** indicates that the statistics collection function is disabled.

Default value: off

track_functions

Parameter description: Collects statistics about invoking times and duration in a function.

Type: SUSET

NOTICE

When the SQL functions are set to inline functions queried by the invoking, these SQL functions cannot be traced no matter these functions are set or not.

Value range: enumerated values

- **pl** indicates that only procedural language functions are traced.
- **all** indicates that SQL and C language functions are traced.
- **none** indicates that the function tracing function is disabled.

Default value: none

update_process_title

Parameter description: Collects statistics updated with a process name each time the server receives a new SQL statement.

The process name can be viewed on Windows task manager by running the **ps** command.

Type: SUSET

Value range: Boolean

- **on** indicates that the statistics collection function is enabled.
- **off** indicates that the statistics collection function is disabled.

Default value: off

track_thread_wait_status_interval

Parameter description: Specifies the interval of collecting the thread status information periodically.

Type: SUSET

Value range: an integer ranging from 0 to 1440, in minutes.

Default value: 30min

enable_save_datachanged_timestamp

Parameter description: Specifies whether to record the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** is performed on table data.

Type: USERSET

Value range: Boolean

- **on** indicates that the time when an operation is performed on table data will be recorded.
- **off** indicates that the time when an operation is performed on table data will not be recorded.

Default value: on

enable_save_dataaccess_timestamp

Parameter description: Specifies whether to record the last access time of a table. This parameter is supported only by 8.2.1.210 and later cluster versions.

Type: USERSET

Value range: Boolean

- **on** indicates that the last access time of the table is recorded.
- **off** indicates that the last access time of the table is not recorded.

Default value: off

instr_unique_sql_count

Parameter description: Specifies whether to collect Unique SQL statements and the maximum number allowed.

Type: SIGHUP

Value range: an integer ranging from 0 to INT_MAX

- If it is set to **0**, Unique SQL statistics are not collected.
- If the value is greater than **0**, the number of Unique SQL statements collected on the CN cannot exceed the value of this parameter. When the number of collected Unique SQL statements reaches the upper limit, the collection is stopped. In this case, you can increase the value of **reload** to continue the collection.

Default value: 0

CAUTION

If a new value is smaller than the original value, the Unique SQL statistics collected on the CN will be cleared.

track_sql_count

Parameter description: Specifies whether to collect statistics on the number of the **SELECT**, **INSERT**, **UPDATE**, **DELETE**, and **MERGE INTO** statements that are being executed in each session, the response time of the **SELECT**, **INSERT**, **UPDATE**, and **DELETE** statements, and the number of DDL, DML, and DCL statements.

Type: SUSET

Value range: Boolean

- **on** indicates that the statistics collection function is enabled.
- **off** indicates that the statistics collection function is disabled.

Default value: on

 NOTE

- The **track_sql_count** parameter is restricted by the **track_activities** parameter.
 - If **track_activities** is set to **on** and **track_sql_count** is set to **off**, a warning message indicating that **track_sql_count** is disabled will be displayed when the view **gs_sql_count**, **pgxc_sql_count**, **gs_workload_sql_count**, **pgxc_workload_sql_count**, **global_workload_sql_count**, **gs_workload_sql_elapse_time**, **pgxc_workload_sql_elapse_time**, or **global_workload_sql_elapse_time** are queried.
 - If both **track_activities** and **track_sql_count** are set to **off**, two logs indicating that **track_activities** is disabled and **track_sql_count** is disabled will be displayed when the views are queried.
 - If **track_activities** is set to **off** and **track_sql_count** is set to **on**, a log indicating that **track_activities** is disabled will be displayed when the views are queried.
- If this parameter is disabled, querying the view returns **0**.

enable_parallel_analyze

Parameter description: Specifies whether to use parallel sampling for internal and foreign table analysis. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: Boolean

- **true** indicates that parallel sampling is used for internal and foreign table analysis.
- **false** indicates that parallel sampling is not used for internal and foreign table analysis.

Default value: true

 CAUTION

- When **enable_parallel_analyze** is set to **true** and analyzing foreign tables, try to avoid adding NOT NULL constraints to the target foreign table columns to prevent constraint failure due to data source changes. Currently, parallel sampling does not support materialized views. If analyze fails due to such reasons, set this parameter to **false**.
 - Currently, parallel sampling only supports analyzing ordinary column-store internal tables. This optimization does not take effect when the internal table uses hstore/hstore_opt or is declared as a replicated table.
 - Currently, parallel sampling only supports analyzing foreign tables stored in parquet/orc format. This optimization does not take effect when the foreign table is in another format.
-

parallel_analyze_workers

Parameter description: Specifies the number of concurrent threads for parallel analyze sampling. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: an integer ranging from 0 to 64

Default value: 10

 NOTE

The value of this parameter should correspond to the cluster load. When the cluster load is low, you can increase the parameter value appropriately based on the cluster configuration to further improve the efficiency of analyze execution.

analyze_sample_multiplier

Parameter description: Specifies the multiplier for the stripe sampling rate used in analyzing foreign tables. This parameter is supported only by clusters of version 9.1.0 or later.

Type: SUSERSET

Value range: an integer ranging from 0 to 100. 0 indicates that the stripe sampling rate is 100%.

Default value: 3

19.11.2 Performance Statistics

During database operation, accessing locks, disk I/O operations, and handling invalid messages can all be performance bottlenecks for the database. DWS provides performance statistics methods that can help easily locate performance issues.

Generating Performance Statistics Logs

Parameter description: For each query, the following four parameters control the performance statistics of corresponding modules recorded in the server log:

- The **og_parser_stats** parameter controls the performance statistics of a parser recorded in the server log.
- The **log_planner_stats** parameter controls the performance statistics of a query optimizer recorded in the server log.
- The **log_executor_stats** parameter controls the performance statistics of an executor recorded in the server log.
- The **log_statement_stats** parameter controls the performance statistics of the whole statement recorded in the server log.

All these parameters can only provide assistant analysis for administrators, which are similar to the `getrusage()` of the Linux OS.

Type: SUSERSET

NOTICE

- **log_statement_stats** records the total statement statistics while other parameters only record statistics about each statement.
- The **log_statement_stats** parameter cannot be enabled together with other parameters recording statistics about each statement.

Value range: Boolean

- **on** indicates the function of recording performance statistics is enabled.
- **off** indicates the function of recording performance statistics is disabled.

Default value: off

19.12 Resource Management

If database resource usage is not controlled, concurrent tasks easily preempt resources. As a result, the OS will be overloaded and cannot respond to user tasks; or even crash and cannot provide any services to users. The DWS workload management function balances the database workload based on available resources to avoid database overloading.

space_once_adjust_num

Parameter description: In the space control and space statistics functions, specifies the threshold of the number of files processed each time during slow building and fine-grained calibration. This parameter is supported only by clusters of version 8.1.3 or later.

Type: SIGHUP

Value range: an integer ranging from 0 to INT_MAX

- The value **0** indicates that the slow build and fine-grained calibration functions are disabled.

Default value: 300

 NOTE

The file quantity threshold affects database resources. You are advised to set the threshold to a proper value.

default_partition_cache_strategy

Parameter description: Specifies the default policy for controlling partition caching. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: enumerated values

- **cache_each_partition_as_possible** enables maximum data caching. Data may not be written to CUs when being inserted into different partitions.

- **flush_when_switch_partition** indicates that data is written to CUs if the data belongs to different partitions during insertion.

Default value: `cache_each_partition_as_possible`

max_active_statements

Parameter description: Specifies the maximum global concurrency. This parameter applies to a job on a CN.

The database administrator changes the value of this parameter based on system resources (for example, CPU, I/O, and memory resources) so that the system fully supports the concurrency tasks and avoids too many concurrency tasks resulting in system crash.

Type: SIGHUP

Value range: an integer ranging from -1 to INT_MAX. The values -1 and 0 indicate that the number of concurrent requests is not limited.

Default value: 60

cgroup_name

Parameter description: Specifies the name of the Cgroup in use. It can be used to change the priorities of jobs in the queue of a Cgroup.

If you set **cgroup_name** and then **session_respool**, the Cgroups associated with **session_respool** take effect. If you reverse the order, Cgroups associated with **cgroup_name** take effect.

If the Workload Cgroup level is specified during the **cgroup_name** change, the database does not check the Cgroup level. The level ranges from 1 to 10.

Type: USERSET

You are not advised to set **cgroup_name** and **session_respool** at the same time.

Value range: a string

Default value: `DefaultClass:Medium`

NOTE

DefaultClass:Medium indicates the **Medium** Cgroup belonging to the **Timeshare** Cgroup under the **DefaultClass** Cgroup.

enable_cgroup_switch

Parameter description: Specifies whether the database automatically switches to the **TopWD** group when executing statements by group type.

Type: USERSET

Value range: Boolean

- **on:** The database automatically switches to the **TopWD** group when executing statements by group type.

- **off**: The database does not automatically switch to the **TopWD** group when executing statements by group type.

Default value: off

memory_tracking_mode

Parameter description: Specifies the memory information recording mode.

Type: USERSET

Value range:

- **none**: Memory statistics is not collected.
- **normal**: Only memory statistics is collected in real time and no file is generated.
- **executor**: The statistics file is generated, containing the context information about all allocated memory used by the execution layer.
- **fullexec**: The generated file includes the information about all memory contexts requested by the execution layer.

Default value: none

memory_detail_tracking

Parameter description: Specifies the sequence number of the memory background information distributed in the needed thread and **plannodeid** of the query where the current thread is located.

Type: USERSET

Value range: a string

Default value: empty

NOTICE

It is recommended that you retain the default value for this parameter.

enable_resource_track

Parameter description: Specifies whether the real-time resource monitoring function is enabled. This parameter must be applied on both CNs and DN.

Type: SIGHUP

Value range: Boolean

- **on** indicates the resource monitoring function is enabled.
- **off** indicates the resource monitoring function is disabled.

Default value: on

enable_resource_record

Parameter description: Specifies whether resource monitoring records are archived. When this parameter is enabled, records that have been executed are archived to the corresponding **INFO** views (**GS_WLM_SESSION_INFO** and **GS_WLM_OPERATOR_INFO**). This parameter must be applied on both CNs and DNs.

Type: SIGHUP

Value range: Boolean

- **on** indicates that the resource monitoring records are archived.
- **off** indicates that the resource monitoring records are not archived.

Default value: on

NOTE

The default value of this parameter is **on** for a new cluster. In upgrade scenarios, the default value of this parameter is the same as that of the source version.

enable_track_record_subsql

Parameter description: Specifies whether to enable the function of recording and archiving sub-statements. When this function is enabled, sub-statements in stored procedures and anonymous blocks are recorded and archived to the corresponding **INFO** table (**GS_WLM_SESSION_INFO**). This parameter is a session-level parameter. It can be configured and take effect in the session connected to the CN and affects only the statements in the session. It can also be configured on both the CN and DN and take effect globally.

Type: USERSET

Value range: Boolean

- **on** indicates that the sub-statement resource monitoring records are archived.
- **off** indicates that the sub-statement resource monitoring records are not archived.

Default value: on

block_rule_cost

Parameter description: Specifies the minimum cost to trigger a query filter. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX

- Value **-1** indicates that the system filters all statements without considering the cost.
- Value **0** indicates that all statements whose cost is greater than 0 are intercepted, but special statements (whose cost is 0) are not intercepted.
- If the value is greater than **0** and the statement cost is less than the value of **block_rule_cost**, the statement is not intercepted; otherwise, it is intercepted.

Default value: -1

enable_user_metric_persistent

Parameter description: Specifies whether the user historical resource monitoring dumping function is enabled. When this function is enabled, data in the [PG_TOTAL_USER_RESOURCE_INFO](#) view is periodically sampled and saved to the [GS_WLM_USER_RESOURCE_HISTORY](#) system catalog, and data in the [GS_RESPOOL_RESOURCE_INFO](#) view is periodically sampled and saved to the [GS_RESPOOL_RESOURCE_HISTORY](#) system catalog.

Type: SIGHUP

Value range: Boolean

- **on** indicates that the user historical resource monitoring dumping function is enabled.
- **off** indicates that the user historical resource monitoring dumping function is disabled.

Default value: on

user_metric_retention_time

Parameter description: Specifies the retention time of the user historical resource monitoring data.

Type: SIGHUP

Value range: an integer ranging from 0 to 3650. The unit is day.

- If this parameter is set to **0**, user historical resource monitoring data is permanently stored.
- If the value is greater than **0**, user historical resource monitoring data is stored for the specified number of days.

Default value: 7

resource_track_level

Parameter description: Specifies the resource monitoring level of the current session. This parameter is valid only when **enable_resource_track** is set to **on**.

Type: USERSET

Value range: enumerated values

- **none:** Resources are not monitored.
- **query:** enables query-level resource monitoring. If this function is enabled, the plan information (similar to the output information of EXPLAIN) of SQL statements will be recorded in top SQL statements.
- **perf:** enables the perf-level resource monitoring. If this function is enabled, the plan information (similar to the output information of EXPLAIN ANALYZE) that contains the actual execution time and the number of execution rows will be recorded in the top SQL.

- **operator_realtime:** enables the operator-level resource monitoring. If this function is enabled, the operator information of jobs running in real time is recorded in the top SQL statements, but is not persisted to the historical top SQL statements.
- **operator:** enables the operator-level resource monitoring. If this function is enabled, not only the information including the actual execution time and number of execution rows is recorded in the top SQL statement, but also the operator-level execution information is updated to the top SQL statement.

Default value: query

fast_obs_tablesize_method

Parameter description: Specifies the method for quickly calculating the size of column-store V3 and V3 HStore Opt tables. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: enumerated values

- **0:** The table size is calculated by listing OBS files.
- **1:** The table size is calculated through WLM background statistics using **pg_relfilenode_size**.
- **2:** The table size is estimated by calculating the maximum offset of each file in cudesc.

Default value: 2

fast_obs_dbsize_method

Parameter description: Specifies the method for quickly calculating the size of database data on OBS. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: enumerated values

- **0:** The size of the database is directly estimated based on the OBS bucket.
- **1:** The size of the entire database is normally calculated in regular mode.

Default value: 0

resource_track_cost

Parameter description: Specifies the minimum execution cost for resource monitoring on statements in the current session. This parameter is valid only when **enable_resource_track** is set to **on**.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX

- **-1** indicates that resource monitoring is disabled.

- A value greater than or equal to **0** indicates that statements whose execution cost exceeds this value will be monitored.

Default value: 0

 NOTE

The default value of this parameter is **0** for a new cluster. In upgrade scenarios, the default value of this parameter is the same as that of the source version.

resource_track_duration

Parameter description: Specifies the minimum statement execution time that determines whether information about jobs of a statement recorded in the real-time view (see [Table 15-1](#)) will be dumped to a historical view after the statement is executed. Job information will be dumped from the real-time view (with the suffix **statistics**) to a historical view (with the suffix **history**) if the statement execution time is no less than this value. This parameter is valid only when **enable_resource_track** is set to **on**.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX. The unit is second (s).

- **0** indicates that information about all statements recorded in the real-time resource monitoring view (see [Table 15-1](#)) will be archived into historical views.
- If the value is greater than **0**, the system archives historical information if the total execution and queuing time of statements in the real-time resource monitoring view ([Table 15-1](#)) goes over the parameter value.

Default value: 60s

resource_track_subsql_duration

Parameter description: Filters the minimum execution time of substatements in a stored procedure. This parameter is supported only by clusters of version 8.2.1 or later.

If the execution time of a sub-statement in a stored procedure is greater than the value of this parameter, the job information is dumped to the top SQL archive table. This parameter takes effect only when **enable_track_record_subsql** is set to **on**.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX. The unit is second (s).

- If the value is **0**, historical information about all substatements in the stored procedure is archived.
- If the value is greater than **0**, historical information is archived when the execution time of a substatement in a stored procedure exceeds the value of this parameter.

Default value: 180s

query_exception_count_limit

Parameter description: Specifies the maximum number of times that a job triggers an exception rule. If the number of times that a job triggers an exception rule reaches the upper limit, the job will be automatically added to the blocklist and cannot be executed anymore. The job can be resumed only after it is removed from the blocklist.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX

- If the value is **-1**, the number of times that a job triggers an exception rule is not limited. That is, the job will not be automatically added to blocklist even if it triggers an exception rule for many times.
- If the value is greater than or equal to **0**, the job will be added to the blocklist immediately when the number of times it triggers an exception rule reaches the threshold. The values **0** and **1** both indicate that a job is added to blocklist once the job triggers an exception rule.

Default value: -1

disable_memory_protect

Parameter description: Stops memory protection. To query system views when system memory is insufficient, set this parameter to **on** to stop memory protection. This parameter is used only to diagnose and debug the system when system memory is insufficient. Set it to **off** in other scenarios.

Type: USERSET

Value range: Boolean

- **on** indicates that memory protection stops.
- **off** indicates that memory is protected.

Default value: off

query_band

Parameter description: Specifies the job type of the current session.

Type: USERSET

Value range: a string

Default value: empty

 CAUTION

Pay attention to the following when modifying this parameter:

1. When this parameter is disabled, it means that the user does not need CCN control function, and the CCN memory negative feedback mechanism will be invalid.
2. When a job is running, if the value of GUC is changed from **OFF** to **ON**, the CCN memory negative feedback mechanism takes effect. If the concurrency is high, the memory may be temporarily unavailable. After the running job is done, the dynamic load function recovers.
3. When a job is running and most jobs are delivered by users from the default resource pool, you are not advised to change the GUC parameter from **enabled** to **disabled**. It may cause a memory error. When there is no job delivered by users from the default resource pool, then you can change the parameter. You are advised to bind a user resource pool before delivering jobs.

wlm_memory_feedback_adjust

Parameter description: Specifies whether to enable memory negative feedback in dynamic load management. (This parameter is supported only by clusters of version 8.2.0 or later.)

Memory is preempted based on the estimated statement memory usage calculated on the CN. If the estimated memory usage of a statement is too high, it will preempt too much memory, causing subsequent jobs to be queued. With the negative memory feedback mechanism, if the cluster memory usage has been overestimated for a period of time, the CCN node will dynamically release some memory for subsequent jobs, improving resource utilization.

Type: SIGHUP

Value range: a string

- **on** indicates that memory negative feedback is enabled.
- **off** indicates that memory negative feedback is disabled.
- **on()** enables the memory negative feedback function and specifies the time and estimated memory percentage parameter required to trigger the negative feedback. For example, **on(60,50)** indicates that to trigger the negative feedback mechanism, the memory must be overestimated for 60 consecutive seconds, and the preempted memory needs must exceed 50% of the available memory. By default, the wait time before the negative feedback mechanism takes effect is 50 seconds. The minimum estimated total memory usage for triggering the mechanism is over 40% of the available system memory.

Default value: on

bbox_dump_count

Parameter description: Specifies the maximum number of core files that are generated by DWS and can be stored in the path specified by **bbox_dump_path**. If the number of core files exceeds this value, old core files will be deleted. This parameter is valid only if **enable_bbox_dump** is set to **on**.

Type: USERSET

Value range: an integer ranging from 1 to 20

Default value: 8

 NOTE

When core files are generated during concurrent SQL statement execution, the number of files may be larger than the value of **bbox_dump_count**.

io_limits

Parameter description: This parameter has been discarded in version 8.1.2 and is reserved for compatibility with earlier versions. This parameter is invalid in the current version.

Type: USERSET

Value range: an integer ranging from 0 to 1073741823

Default value: 0

io_priority

Parameter description: This parameter has been discarded in version 8.1.2 and is reserved for compatibility with earlier versions. This parameter is invalid in the current version.

Type: USERSET

Value range: enumerated values

- None
- Low
- Medium
- High

Default value: None

session_respool

Parameter description: Specifies the resource pool associated with the current session.

Type: USERSET

If you set **cgroup_name** and then **session_respool**, the Cgroups associated with **session_respool** take effect. If you reverse the order, Cgroups associated with **cgroup_name** take effect.

If the Workload Cgroup level is specified during the **cgroup_name** change, the database does not check the Cgroup level. The level ranges from 1 to 10.

You are not advised to set **cgroup_name** and **session_respool** at the same time.

Value range: a string. This parameter can be set to the resource pool configured through **create resource pool**.

Default value: `invalid_pool`

enable_transaction_parctl

Parameter description: whether to control transaction block statements and stored procedure statements.

Type: USERSET

Value range: Boolean

- **on:** Transaction block statements and stored procedure statements are controlled.
- **off:** Transaction block statements and stored procedure statements are not controlled.

Default value: `on`

session_history_memory

Parameter description: Specifies the memory size of a historical query view.

Type: SIGHUP

Value range: an integer ranging from 10 MB to 50% of `max_process_memory`

Default value: `100MB`

topsql_retention_time

Parameter description: Specifies the retention period of historical Top SQL data in the `gs_wlm_session_info` and `gs_wlm_operator_info` tables.

Type: SIGHUP

Value range: an integer ranging from 0 to 3650. The unit is day.

- If it is set to `0`, the data is stored permanently.
- If the value is greater than `0`, the data is stored for the specified number of days.

Default value: `30`

CAUTION

- Before setting this GUC parameter to enable the data retention function, delete data from the `gs_wlm_session_info` and `gs_wlm_operator_info` tables.
 - The default value of this parameter is `30` for a new cluster. In upgrade scenarios, the default value of this parameter is the same as that of the source version.
-

transaction_pending_time

Parameter description: maximum queuing time of transaction block statements and stored procedure statements if `enable_transaction_parctl` is set to `on`.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX. The unit is second (s).

- **-1 or 0:** No queuing timeout is specified for transaction block statements and stored procedure statements. The statements can be executed when resources are available.
- **Value greater than 0:** If transaction block statements and stored procedure statements have been queued for a time longer than the specified value, they are forcibly executed regardless of the current resource situation.

Default value: 0

NOTICE

This parameter is valid only for internal statements of stored procedures and transaction blocks. That is, this parameter takes effect only for the statements whose **enqueue** value (for details, see [PG_SESSION_WLMSTAT](#)) is **Transaction** or **StoredProc**.

enable_concurrency_scaling

Parameter description: Specifies whether to enable the elastic concurrent expansion function. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: Boolean

- **on** indicates that the elastic concurrent expansion function is enabled.
- **off** indicates that the elastic concurrent expansion function is disabled.

Default value: off

concurrency_scaling_max_idle_time

Parameter description: Specifies the maximum idle time of the elastic logical cluster created for concurrent expansion. If it exceeds the set value of this parameter, it will enter the process of destroying the elastic logical cluster. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: an integer ranging from 0 to 60, in minutes. The value **0** indicates that the elastic logical cluster created during concurrent expansion will not be destroyed. Exercise caution when setting this value.

Default value: 5

concurrency_scaling_limit_per_main_vw

Parameter description: Specifies the maximum number of concurrent elastic logical clusters that can be created for each classic logical cluster. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: an integer ranging from 0 to 32

Default value: 5

concurrency_scaling_max_vw_active_statements

Parameter description: Specifies the maximum number of concurrent tasks that can be executed in an elastic logical cluster. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: an integer ranging from -1 to INT_MAX

- Value **0** indicates that the elastic logical cluster does not execute any jobs. Exercise caution when setting this value.
- **-1** indicates that the elastic logical cluster is not under concurrency control. Exercise caution when setting this value. This value is supported only by clusters of version 9.1.0.200 or later.

Default value: 60

concurrency_scaling_max_waiting_statements

Parameter description: Specifies the number of queued elastic jobs in the global queue that trigger the creation process of the elastic logical cluster for concurrent expansion. This parameter is supported only by clusters of version 9.1.0.100 or later.

If the number of queued elastic jobs is greater than or equal to the value set for this parameter, and the number of concurrently created elastic logical clusters does not exceed the value set for **concurrency_scaling_limit_per_main_vw**, the process of creating a concurrent expansion elastic logical cluster will be triggered automatically.

Type: SIGHUP

Value range: an integer ranging from 0 to INT_MAX. The value **0** indicates that an elastic logical cluster is created even if there are no queued jobs. If set to **0**, a large number of resources are consumed. Exercise caution when setting this value.

Default value: 10

19.13 Automatic Cleanup

The automatic cleanup process in the system automatically runs the **VACUUM** and **ANALYZE** statements to reclaim the record space marked as deleted and update statistics in the table.

autovacuum_compaction_rows_limit

Parameter description: Specifies the small CU threshold. A CU whose number of live tuples is less than the value of this parameter is considered as a small CU.

Type: USERSET

Value range: an integer ranging from -1 to 5000

Default value: 2500

CAUTION

- **You are advised not to modify this parameter. If you need to modify this parameter, contact technical support.**
 - If the version is earlier than 9.1.0.100, do not set this parameter, or there may be duplicate data in primary keys.
 - If the version is earlier than 9.1.0.100, value **-1** indicates that the 0 CU switch is disabled.
 - In version 9.1.0.100, the default value of this parameter is **0**.
 - In 9.1.0.200 and later versions, the default value of this parameter is **2500**.
-

autoanalyze_mode

Parameter description: Specifies the autoanalyze mode. This parameter is supported by clusters of version 8.2.0 or later.

Type: USERSET

Value range: enumerated values

- **normal** indicates common autoanalyze.
- **light** indicates lightweight autoanalyze.

Default value:

- If the current cluster is upgraded from an earlier version to 8.2.0, the default value is **normal** to ensure forward compatibility.
- If the cluster version 8.2.0 is newly installed, the default value is **light**.

analyze_stats_mode

Parameter description: Specifies the mode for **ANALYZE** to calculate statistics.

Type: USERSET

Value range: enumerated values

- **memory** indicates that the memory is forcibly used to calculate statistics. Multi-column statistics are not calculated.
- **sample_table** indicates that temporary sampling tables are forcibly used to calculate statistics. Temporary tables do not support this mode.
- **dynamic** indicates that the statistics calculation mode is determined based on the size of **maintenance_work_mem**. If **maintenance_work_mem** can store samples, the memory mode is used. Otherwise, the temporary sampling table mode is used.

Default value:

- If the current cluster is upgraded from an earlier version to 8.2.0.100, the default value is **memory** to ensure forward compatibility.
- If the cluster version 8.2.0.100 is newly installed, the default value is **dynamic**.

analyze_sample_mode

Parameter description: Specifies the sampling model used by **ANALYZE**.

Type: USERSET

Value range: an integer ranging from **0** to **2**

- **0** indicates the default reservoir sampling.
- **1** indicates the optimized reservoir sampling.
- **2** indicates range sampling.

Default value: 0

autovacuum_max_workers

Parameter description: Specifies the maximum number of automatic cleanup threads running at the same time.

Type: SIGHUP

Value range: an integer ranging from 0 to 128. **0** indicates that **autovacuum** is disabled.

Default value: 6

NOTE

This parameter works with autovacuum. The rules for clearing system catalogs and user tables are as follows:

- When **autovacuum_max_workers** is set to **0**, **autovacuum** is disabled and no tables are cleared.
- When **autovacuum_max_workers** is set to a value greater than 0 and **autovacuum** is set to **off**, the system only clears the system catalogs and column-store tables with delta tables enabled (such as vacuum delta tables, vacuum cudesc tables, and delta merge).
- When **autovacuum_max_workers** is set to a value greater than 0 and **autovacuum** is set to **on**, all tables will be cleared.

autovacuum_max_workers_hstore

Parameter description: Specifies the maximum number of concurrent automatic cleanup threads used for hstore tables in **autovacuum_max_workers**.

Type: SIGHUP

Value range: an integer ranging from 0 to 128. **0** indicates that the automatic cleanup function of HStore tables is disabled.

Default value: 3

 NOTE

To use HStore tables, set the following parameters, or the HStore performance will deteriorate severely. The recommended settings are as follows:

autovacuum_max_workers_hstore=3, autovacuum_max_workers=6, autovacuum=true

autovacuum_naptime

Parameter description: Specifies the interval between two automatic cleanup operations.

Type: SIGHUP

Value range: an integer ranging from 1 to 2147483. The unit is second.

Default value: 60s

autovacuum_vacuum_cost_delay

Parameter description: Specifies the value of the cost delay used in the **autovacuum** operation.

Type: SIGHUP

Value range: an integer ranging from -1 to 100. The unit is ms. -1 indicates that the normal vacuum cost delay is used.

Default value: 2ms

check_crossvw_write

Parameter description: Specifies whether to enable cross-VW write detection. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: USERSET

Value range: an integer, -1 or 1.

- The value -1 indicates that it is compatible with the capabilities of version 9.0.3. For the v3 table vacuum, it only clears non-last files for all epochs.
- The value 1 indicates checking whether it is a cross-VW write scenario. For the v3 table vacuum, if it is determined to be a non-cross-VW write scenario, it clears non-last files for all epochs, clears the last file for the current epoch, and clears the last file for epochs that are less than the current epoch. If it is determined to be a cross-VW write scenario, CNs will obtain epoch information from all DN and package it into an epochList to be sent to the metadata VW. The v3 table vacuum will clear non-last files for all epochs and clear the last file for epochs that are less than max{epochList} and not in epochList.

Default value: 1

enable_pg_stat_object

Parameter description: Specifies whether **AUTO VACUUM** updates the **PG_STAT_OBJECT** system catalog. This parameter is supported only by clusters of version 8.2.1 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the **PG_STAT_OBJECT** system catalog is updated during **AUTO VACUUM**.
- **off** indicates that the **PG_STAT_OBJECT** system catalog is not updated during **AUTO VACUUM**.

Default value: on

19.14 Default Settings of Client Connection

19.14.1 Statement Behavior

This section describes related default parameters involved in the execution of SQL statements.

search_path

Parameter description: Specifies the order in which schemas are searched when an object is referenced with no schema specified. The value of this parameter consists of one or more schema names. Different schema names are separated by commas (,).

Type: USERSET

- If the schema of a temporary table exists in the current session, the scheme can be listed in **search_path** by using the alias **pg_temp**, for example, '**pg_temp,public**'. The schema of a temporary table has the highest search priority and is always searched before all the schemas specified in **pg_catalog** and **search_path**. Therefore, do not explicitly specify **pg_temp** to be searched after other schemas in **search_path**. This setting will not take effect and an error message will be displayed. If the alias **pg_temp** is used, the temporary schema will be only searched for database objects, including tables, views, and data types. Functions or operator names will not be searched for.
- The schema of a system catalog, **pg_catalog**, has the second highest search priority and is the first to be searched among all the schemas, excluding **pg_temp**, specified in **search_path**. Therefore, do not explicitly specify **pg_catalog** to be searched after other schemas in **search_path**. This setting will not take effect and an error message will be displayed.
- When an object is created without specifying a particular schema, the object will be placed in the first valid schema listed in **search_path**. An error will be reported if the search path is empty.
- The current effective value of the search path can be examined through the SQL function **current_schema**. This is different from examining the value of **search_path**, because the **current_schema** function displays the first valid schema name in **search_path**.

Value range: a string

 NOTE

- When this parameter is set to "**\$user**", **public**, a database can be shared (where no users have private schemas, and all share use of public), and private per-user schemas and combinations of them are supported. Other effects can be obtained by modifying the default search path setting, either globally or per-user.
- When this parameter is set to a null string (""), the system automatically converts it into a pair of double quotation marks ("").
- If the content contains double quotation marks, the system considers them as insecure characters and converts each double quotation mark into a pair of double quotation marks.

Default value: "**\$user**",**public**

 NOTE

\$user indicates the name of the schema with the same name as the current session user. If the schema does not exist, **\$user** will be ignored.

current_schema

Parameter description: Specifies the current schema.

Type: USERSET

Value range: a string

Default value: "**\$user**",**public**

 NOTE

\$user indicates the name of the schema with the same name as the current session user. If the schema does not exist, **\$user** will be ignored.

default_tablespace

Parameter description: Specifies the default tablespace of the created objects (tables and indexes) when a **CREATE** command does not explicitly specify a tablespace.

- The value of this parameter is either the name of a tablespace, or an empty string that specifies the use of the default tablespace of the current database. If a non-default tablespace is specified, users must have CREATE privilege for it. Otherwise, creation attempts will fail.
- This parameter is not used for temporary tables. For them, the [temp_tablespaces](#) is consulted instead.
- This parameter is not used when users create databases. By default, a new database inherits its tablespace setting from the template database.

Type: USERSET

Value range: a string. An empty string indicates that the default tablespace is used.

Default value: empty

default_storage_nodegroup

Parameter description: Specifies the Node Group where a table is created by default. This parameter takes effect only for ordinary tables.

Type: USERSET

Value range: a string

- **installation:** indicates that the table is created in the installed Node Group by default.
- **random_node_group:** indicates that the table is created in a randomly selected Node Group by default. This feature is supported in 8.1.2 or later and is used only in the test environment.
- **roach_group:** indicates that the table is created in all nodes by default. This value is reserved for the Roach tool and cannot be used in other scenarios.
- A value other than the preceding three options indicates that the table is created in a specified Node Group.

Default value: installation

temp_tablespaces

Parameter description: Specifies tablespaces to which temporary objects will be created (temporary tables and their indexes) when a **CREATE** command does not explicitly specify a tablespace. Temporary files for sorting large data are created in these tablespaces.

The value of this parameter is a list of names of tablespaces. When there is more than one name in the list, DWS chooses a random tablespace from the list upon the creation of a temporary object each time. Except that within a transaction, successively created temporary objects are placed in successive tablespaces in the list. If the element selected from the list is an empty string, DWS will automatically use the default tablespace of the current database instead.

Type: USERSET

Value range: a string An empty string indicates that all temporary objects are created only in the default tablespace of the current database. For details, see [default_tablespace](#).

Default value: empty

check_function_bodies

Parameter description: Specifies whether to enable validation of the function body string during the execution of **CREATE FUNCTION**. Verification is occasionally disabled to avoid problems, such as forward references when you restore function definitions from a dump.

Type: USERSET

Value range: Boolean

- **on** indicates that validation of the function body string is enabled during the execution of **CREATE FUNCTION**.

- **off** indicates that validation of the function body string is disabled during the execution of **CREATE FUNCTION**.

Default value: on

default_transaction_isolation

Parameter description: Specifies the default isolation level of each transaction.

Type: USERSET

Value range: enumerated values

- **READ COMMITTED:** Only committed data is read. This is the default.
- **READ UNCOMMITTED:** DWS does not support **READ UNCOMMITTED**. If **READ UNCOMMITTED** is set, **READ COMMITTED** is executed instead.
- **REPEATABLE READ:** Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.
- **SERIALIZABLE:** DWS does not support **SERIALIZABLE**. If **SERIALIZABLE** is set, **REPEATABLE READ** is executed instead.

Default value: READ COMMITTED

default_transaction_read_only_probe

Parameter description: Specifies whether to terminate the execution of special statements (e.g., statements for flushing data to disks and generating new tables or physical files) when the database is about to become read-only (disk usage reaches 90%). The CM module checks and sets the disk usage threshold. It is not advised to set this parameter. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the execution of the special statement is terminated.
- **off** indicates that the execution of the special statement is not terminated.

Default value: off

default_transaction_deferrable

Parameter description: Specifies the default delaying state of each new transaction. It currently has no effect on read-only transactions or those running at isolation levels lower than serializable.

DWS does not support the serializable isolation level of each transaction. The parameter is insignificant.

Type: USERSET

Value range: Boolean

- **on** indicates a transaction is delayed by default.

- **off** indicates a transaction is not delayed by default.

Default value: off

session_replication_role

Parameter description: Specifies the behavior of replication-related triggers and rules for the current session.

Type: USERSET

NOTICE

Setting this parameter will discard all the cached execution plans.

Value range: enumerated values

- **origin** indicates that the system copies operations such as insert, delete, and update from the current session.
- **replica** indicates that the system copies operations such as insert, delete, and update from other places to the current session.
- **local** indicates that the system will detect the role that has logged in to the database when using the function to copy operations and will perform related operations.

Default value: origin

statement_timeout

Parameter description: If the statement execution time (starting when the server receives the command) is longer than the duration specified by the parameter, error information is displayed when you attempt to execute the statement and the statement then exits.

Type: USERSET

Value range: an integer ranging from 0 to 2147483647. The unit is ms.

Default value:

- If the current cluster is upgraded from an earlier version to 8.2.0, the value in the earlier version is inherited. The default value is **0**.
- If the cluster version 8.2.0 is newly installed, the default value is **24h**.

vacuum_freeze_min_age

Parameter description: Specifies the minimum cutoff age (in the same transaction), based on which **VACUUM** decides whether to replace transaction IDs with FrozenXID while scanning a table.

Type: USERSET

Value range: an integer from 0 to 576460752303423487.

 NOTE

Although you can set this parameter to a value ranging from **0** to **1000000000** anytime, **VACUUM** will limit the effective value to half the value of **autovacuum_freeze_max_age** by default.

Default value: 5000000000

vacuum_freeze_table_age

Parameter description: Specifies the time that VACUUM freezes tuples while scanning the whole table. **VACUUM** performs a whole-table scan if the value of the [pg_class.relfrozexid](#) column of the table has reached the specified time.

Type: USERSET

Value range: an integer from 0 to 576460752303423487.

 NOTE

Although users can set this parameter to a value ranging from **0** to **2000000000** anytime, **VACUUM** will limit the effective value to 95% of **autovacuum_freeze_max_age** by default. Therefore, a periodic manual VACUUM has a chance to run before an anti-wraparound autovacuum is launched for the table.

Default value: 15000000000

bytea_output

Parameter description: Specifies the output format for values of the bytea type.

Type: USERSET

Value range: enumerated values

- **hex** indicates the binary data is converted to the two-byte hexadecimal digit.
- **escape** indicates the traditional PostgreSQL format is used. It takes the approach of representing a binary string as a sequence of ASCII characters, while converting those bytes that cannot be represented as an ASCII character into special escape sequences.

Default value: hex

xmlbinary

Parameter description: Specifies how binary values are to be encoded in XML.

Type: USERSET

Value range: enumerated values

- base64
- hex

Default value: base64

xmloption

Parameter description: Specifies whether DOCUMENT or CONTENT is implicit when converting between XML and string values.

Type: USERSET

Value range: enumerated values

- **document** indicates an HTML document.
- **content** indicates a common string.

Default value: content

gin_pending_list_limit

Parameter description: Specifies the maximum capacity of the pending list when FASTUPDATE is enabled for GIN indexes.

Pending List is a data structure specific to GIN indexes and is used to temporarily store index update operations. When the **FASTUPDATE** parameter is enabled for a GIN index, new index items are not directly written to the main index structure, but are stored in the pending list. When conditions are met, the index items are merged into the main index in batches.

If the pending list grows larger than this maximum size, data in the list will be moved to the GIN index data structure in batches. This setting can be overridden for individual GIN indexes by modifying index storage parameters.

Type: USERSET

Value range: an integer ranging from 64 to INT_MAX. The unit is KB.

Default value: 4 MB

19.14.2 Zone and Formatting

This section describes parameters related to the time format setting.

DateStyle

Parameter description: Specifies the display format for date and time values, as well as the rules for interpreting ambiguous date input values.

This variable contains two independent components: the output format specifications (ISO, Postgres, SQL, or German) and the input/output order of year/month/day (DMY, MDY, or YMD). The two components can be set separately or together. The keywords Euro and European are synonyms for DMY; the keywords US, NonEuro, and NonEuropean are synonyms for MDY.

Type: USERSET

Value range: a string

Default value: ISO, MDY

NOTE

gs_initdb will initialize this parameter so that its value is the same as that of **lc_time**.

Suggestion: The ISO format is recommended. Postgres, SQL, and German use abbreviations for time zones, such as **EST**, **WST**, and **CST**.

IntervalStyle

Parameter description: Specifies the display format for interval values.

Type: USERSET

Value range: enumerated values

- **sql_standard** indicates that output matching SQL standards will be generated.
- **postgres** indicates that output matching PostgreSQL 8.4 will be generated when the **DateStyle** parameter is set to **ISO**.
- **postgres_verbose** indicates that output matching PostgreSQL 8.4 will be generated when the **DateStyle** parameter is set to **non_ISO**.
- **iso_8601** indicates that output matching the time interval "format with designators" defined in ISO 8601 will be generated.
- **oracle** indicates the output result that matches the numtodsinterval function in the Oracle database. For details, see numtodsinterval.

NOTICE

The **IntervalStyle** parameter also affects the interpretation of ambiguous interval input.

Default value: postgres

TimeZone

Parameter description: Specifies the time zone for displaying and interpreting time stamps.

Type: USERSET

Value range: a string. You can obtain it by querying the **pg_timezone_names** view.

Default value: UTC

NOTE

gs_initdb will set a time zone value that is consistent with the system environment.

timezone_abbreviations

Parameter description: Specifies the time zone abbreviations that will be accepted by the server.

Type: USERSET

Value range: a string. You can obtain it by querying the **pg_timezone_names** view.

Default value: Default

 NOTE

Default indicates an abbreviation that works in most of the world. There are also other abbreviations, such as **Australia** and **India** that can be defined for a particular installation.

extra_float_digits

Parameter description: Specifies the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits (FLT_DIG or DBL_DIG as appropriate).

Type: USERSET

Value range: an integer ranging from -15 to 3

 NOTE

- This parameter can be set to **3** to include partially-significant digits. It is especially useful for dumping float data that needs to be restored exactly.
- This parameter can also be set to a negative value to suppress unwanted digits.

Default value: 0

client_encoding

Parameter description: Specifies the client-side encoding type (character set).

Set this parameter as needed. Try to keep the client code and server code consistent to improve efficiency.

Type: USERSET

Value range: encoding compatible with PostgreSQL. **UTF8** indicates that the database encoding is used.

 NOTE

- You can run the **locale -a** command to check and set the system-supported zone and the corresponding encoding format.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.
- To use consistent encoding for communication within a cluster, you are advised to retain the default value of **client_encoding**. Modification to this parameter in the **postgresql.conf** file (by using the **gs_guc** tool, for example) does not take effect.

Default value: UTF8

Recommended value: SQL_ASCII or UTF8

lc_messages

Parameter description: Specifies the language in which messages are displayed.

Valid values depend on the current system. On some systems, this zone category does not exist. Setting this variable will still work, but there will be no effect. In addition, translated messages for the desired language may not exist. In this case, you can still see the English messages.

Type: SUSET

Value range: a string

 NOTE

- You can run the **locale -a** command to check and set the system-supported zone and the corresponding encoding format.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.

Default value: C

lc_monetary

Parameter description: Specifies the display format of monetary values. It affects the output of functions such as `to_char`. Valid values depend on the current system.

Type: USERSET

Value range: a string

 NOTE

- You can run the **locale -a** command to check and set the system-supported zone and the corresponding encoding format.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.

Default value: C

lc_numeric

Parameter description: Specifies the display format of numbers. It affects the output of functions such as `to_char`. Valid values depend on the current system.

Type: USERSET

Value range: a string

 NOTE

- You can run the **locale -a** command to check and set the system-supported zone and the corresponding encoding format.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.

Default value: C

lc_time

Parameter description: Specifies the display format of time and zones. It affects the output of functions such as `to_char`. Valid values depend on the current system.

Type: USERSET

Value range: a string

 NOTE

- You can run the **locale -a** command to check and set the system-supported zone and the corresponding encoding format.
- By default, **gs_initdb** will initialize the setting of this parameter based on the current system environment. You can also run the **locale** command to check the current configuration environment.

Default value: C

default_text_search_config

Parameter description: Specifies the text search configuration.

If the specified text search configuration does not exist, an error will be reported. If the specified text search configuration is deleted, set **default_text_search_config** again. Otherwise, an error will be reported, indicating incorrect configuration.

- The text search configuration is used by text search functions that do not have an explicit argument specifying the configuration.
- When a configuration file matching the environment is determined, **gs_initdb** will initialize the configuration file with a setting that corresponds to the environment.

Type: USERSET

Value range: a string

 NOTE

DWS supports the following two configurations: **pg_catalog.english** and **pg_catalog.simple**.

Default value: **pg_catalog.english**

19.14.3 Other Default Parameters

This section describes the default database loading parameters of the database system.

dynamic_library_path

Parameter description: Specifies the path for saving the shared database files that are dynamically loaded for data searching. When a dynamically loaded module needs to be opened and the file name specified in the **CREATE FUNCTION** or **LOAD** command does not have a directory component, the system will search this path for the required file.

The value of **dynamic_library_path** must be a list of absolute paths separated by colons (:) or by semi-colons (;) on the Windows OS. The special variable **\$libdir** in the beginning of a path will be replaced with the module installation directory provided by DWS. Example:

```
dynamic_library_path = '/usr/local/lib/postgresql:/opt/testgs/lib:$libdir'
```

Type: SUSET

Value range: a string

 NOTE

If the value of this parameter is set to an empty character string, the automatic path search is turned off.

Default value: \$libdir

gin_fuzzy_search_limit

Parameter description: Specifies the upper limit of the size of the set returned by GIN indexes.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX. The value **0** indicates no limit.

Default value: 0

19.15 Lock Management

In DWS, concurrent transactions may cause single-node deadlocks or distributed deadlocks due to resource competition. This section describes parameters used for managing transaction lock mechanisms.

deadlock_timeout

Parameter description: Specifies the time, in milliseconds, to wait on a lock before checking whether there is a deadlock condition. When the applied lock exceeds the preset value, the system will check whether a deadlock occurs.

- The check for deadlock is relatively expensive. Therefore, the server does not check it when waiting for a lock every time. Deadlocks do not frequently occur when the system is running. Therefore, the system just needs to wait on the lock for a while before checking for a deadlock. Increasing this value reduces the time wasted in needless deadlock checks, but slows down reporting of real deadlock errors. On a heavily loaded server, you may need to raise it. The value you have set needs to exceed the transaction time. By doing this, the possibility that a lock will be released before the waiter decides to check for deadlocks will be reduced.
- When [log_lock_waits](#) is set, this parameter also determines the duration you need to wait before a log message about the lock wait is issued. If you are trying to investigate locking delays, you need to set this parameter to a value smaller than normal **deadlock_timeout**.

Type: SUSET

Value range: an integer ranging from 1 to 2147483647. The unit is millisecond (ms).

Default value: 1s

ddl_lock_timeout

Parameter description: Indicates the number of seconds a DDL command should wait for the locks to become available. If the time spent in waiting for a lock exceeds the specified time, an error is reported. This parameter is supported only by clusters of version 8.1.3.200 or later.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX. The unit is millisecond (ms).

- If the value of this parameter is 0, this parameter does not take effect.
- If the value of this parameter is greater than 0, the lock wait time of DDL statements is the value of this parameter, and the lock wait time of other locks is the value of **lockwait_timeout**.

Default value: 0

NOTE

This parameter has a higher priority than **lockwait_timeout** and takes effect only for **AccessExclusiveLock**.

ddl_select_concurrent_mode

Parameter description: Specifies the concurrency mode of DDL and **SELECT** statements. This parameter is supported only by clusters of version 8.1.3.320, 8.2.1, or later.

Type: SUSET

Value range: a string

- **none:** DDL and select statements cannot be executed concurrently. Waiting statements are in the lock wait state.
- **truncate:** When the **TRUNCATE** statement is blocked by the **SELECT** statement, the **SELECT** statement is interrupted and the **TRUNCATE** statement is executed first.
- **exchange:** When the **EXCHANGE** statement is blocked by the **SELECT** statement, the **SELECT** statement is interrupted and the **EXCHANGE** statement is executed first.
- **vacuum_full:** When the **vacuum_full** statement is blocked by the **SELECT** statement, the **SELECT** statement is interrupted and the **vacuum_full** statement is executed first. This is supported only by clusters of version 9.1.0.200 or later.
- **insert_overwrite:** When the **insert_overwrite** statement is blocked by the **SELECT** statement, the **SELECT** statement is interrupted and the **insert_overwrite** statement is executed first. This is supported only by clusters of version 9.1.0.200 or later.

Default value: none

 NOTE

- To reserve time for the **SELECT** statement to respond to signals, if the value of **ddl_lock_timeout** is less than 1 second in the current version, 1 second is used.
- Concurrency is not supported when there are conflicts with locks of higher levels (more than one level). For example, **autoanalyze** is triggered by **SELECT** when **autoanalyze_mode** is set to **normal**.
- This parameter allows for **SELECT** statements in either a single statement or a transaction block. However, in other versions, it only supports **SELECT** statements in a single statement. For concurrent **SELECT** operations in a single statement or transaction block, learn more information in the description of parameter [enable_cancel_select_in_txnblock](#).
- Values other than **none** can be used together. For example, if this parameter is set to **truncate**, **exchange**, the **TRUNCATE** and **EXCHANGE** statements are blocked by the **SELECT** statement. The **SELECT** statement is interrupted and executed first.

enable_cancel_select_in_txnblock

Parameter description: Specifies whether the **SELECT** statement in a transaction block can be interrupted.

Type: USERSET

Value range: Boolean

- **on** indicates that the select operation in the transaction block can be interrupted.
- **off** indicates that the select operation in the transaction block cannot be interrupted.

Default value: on

 NOTE

- This parameter is supported by 8.2.1.236 and later versions in 8.2.1.2 xx clusters. This parameter is supported by clusters of version 9.1.0.200 or later.
- This parameter controls whether the **SELECT** statement in a transaction block can be interrupted by the DDL operation specified in **ddl_select_concurrent_mode**.
- The **ddl_select_concurrent_mode** parameter controls DDL statements such as **TRUNCATE** and **EXCHANGE**, and the **enable_cancel_select_in_txnblock** parameter controls **SELECT** statements.

lockwait_timeout

Parameter description: Specifies the longest time to wait before a single lock times out. If the time you wait before acquiring a lock exceeds the specified time, an error is reported.

Type: SUSERSET

Value range: an integer ranging from 0 to INT_MAX. The unit is millisecond (ms).

Default value: 20 min

update_lockwait_timeout

Parameter description: sets the maximum duration that a lock waits for concurrent updates on a row to complete when the concurrent update feature is

enabled. If the time you wait before acquiring a lock exceeds the specified time, an error is reported.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX. The unit is millisecond (ms).

Default value: 2min

partition_lock_upgrade_timeout

Parameter description: Specifies the time to wait before the attempt of a lock upgrade from ExclusiveLock to AccessExclusiveLock times out on partitions.

- When you do MERGE PARTITION and CLUSTER PARTITION on a partitioned table, temporary tables are used for data rearrangement and file exchange. To concurrently perform as many operations as possible on the partitions, ExclusiveLock is acquired for the partitions during data rearrangement and AccessExclusiveLock is acquired during file exchange.
- Generally, a partition waits until it acquires a lock, or a timeout occurs if the partition waits for a period of time longer than specified by the [lockwait_timeout](#) parameter.
- When doing MERGE PARTITION or CLUSTER PARTITION on a partitioned table, you need to acquire AccessExclusiveLock during file exchange. If the lock fails to be acquired, the acquisition is retried in 50 ms. This parameter specifies the time to wait before the lock acquisition attempt times out.
- If this parameter is set to -1, the lock upgrade never times out. The lock upgrade is continuously retried until it succeeds.

Type: USERSET

Value range: an integer ranging from -1 to 3000, in seconds

Default value: 1800

enable_release_scan_lock

Parameter description: Specifies whether a SELECT statement releases a level-1 lock after the statement execution is complete. This parameter reduces DDL conflicts with SELECT locks within transaction blocks. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that DDL operations will be blocked to wait for the release of cluster locks. The SELECT statement releases the level-1 lock after it finishes, not when the transaction commits.
- **off** indicates that DDL operations will not be blocked.

Default value: off

vacuum_full_interruptible

Parameter description: Controls the behavior that the **VACUUM FULL** statement gives a lock to other statements. This is supported only by clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that DDL operations will be blocked to wait for the release of cluster locks. When **VACUUM FULL** blocks other statements, it interrupts the execution and gives the lock to other statements.
- **off** indicates that DDL operations will not be blocked. When **VACUUM FULL** blocks other statements, it does not interrupt the execution. Other statements can be executed only after **VACUUM FULL** has completed and released the lock.

Default value: off

19.16 Version and Platform Compatibility

19.16.1 Compatibility with Earlier Versions

DWS provides parameter controls for the downward compatibility and external compatibility features of the database. The backward compatibility of the database system can provide support for old versions of database applications. The parameters introduced in this section mainly control the backward compatibility of the database.

array_nulls

Parameter description: Determines whether the array input parser recognizes unquoted NULL as a null array element.

Type: USERSET

Value range: Boolean

- **on** indicates that null values can be entered in arrays.
- **off** indicates backward compatibility with the old behavior. Arrays containing **NULL** values can still be created when this parameter is set to **off**.

Default value: on

backslash_quote

Parameter description: Determines whether a single quotation mark can be represented by \' in a string text.

Type: USERSET

NOTICE

When the string text meets the SQL standards, \ has no other meanings. This parameter only affects the handling of non-standard-conforming string texts, including escape string syntax (E'...').

Value range: enumerated values

- **on** indicates that the use of \ is always allowed.
- **off** indicates that the use of \ is rejected.
- **safe_encoding** indicates that the use of \ is allowed only when client encoding does not allow ASCII \ within a multibyte character.

Default value: **safe_encoding**

default_with_oids

Parameter description: Determines whether **CREATE TABLE** and **CREATE TABLE AS** include an **OID** field in newly-created tables if neither **WITH OIDS** nor **WITHOUT OIDS** is specified. It also determines whether OIDs will be included in tables created by **SELECT INTO**.

It is not recommended that OIDs be used in user tables. Therefore, this parameter is set to **off** by default. When OIDs are required for a particular table, **WITH OIDS** needs to be specified during the table creation.

Type: USERSET

Value range: Boolean

- **on** indicates **CREATE TABLE** and **CREATE TABLE AS** can include an **OID** field in newly-created tables.
- **off** indicates **CREATE TABLE** and **CREATE TABLE AS** cannot include any **OID** field in newly-created tables.

Default value: **off**

enable_parquet_integer_decimal

Parameter description: Specifies whether to use the **INT64** or **FIXED_LEN_BYTE_ARRAY** type for storage when the **decimal** (p,s) type is written in the Parquet foreign tables and p is less than or equal to 18.

Type: USERSET

Value range: Boolean

- **on:** The **INT64** type is used for storage.
- **off:** The **FIXED_LEN_BYTE_ARRAY** is used for storage.

Default value: **off**

 NOTE

- In cluster version 9.1.0, only 9.1.0.222 and later versions support this parameter. To be compatible with the Hive behavior (Hive uses **FIXED_LEN_BYTE_ARRAY**), the default value of this parameter is **FIXED_LEN_BYTE_ARRAY** and historical behavior compatibility is retained.
- In cluster versions that do not support this parameter, the Parquet foreign tables in DWS store the $p \leq 18$ decimal as the **INT64** type by default.
- **INT64** or **FIXED_LEN_BYTE_ARRAY** indicates the type defined in Parquet. Different external engines may select different types.

escape_string_warning

Parameter description: Specifies a warning on directly using a backslash (\) as an escape in an ordinary character string.

- Applications that wish to use a backslash (\) as an escape need to be modified to use escape string syntax (E'...'). This is because the default behavior of ordinary character strings is now to treat the backslash as an ordinary character in each SQL standard.
- This variable can be enabled to help locate codes that need to be changed.

Type: USERSET

Value range: Boolean

Default value: on

lo_compat_privileges

Parameter description: Determines whether to enable backward compatibility for the privilege check of large objects.

Type: SUSET

Value range: Boolean

on indicates that the privilege check is disabled when users read or modify large objects. This setting is compatible with versions earlier than PostgreSQL 9.0.

Default value: off

quote_all_identifiers

Parameter description: When the database generates SQL, this parameter forcibly quotes all identifiers even if they are not keywords. This will affect the output of EXPLAIN as well as the results of functions, such as pg_get_viewdef. For details, see the **--quote-all-identifiers** option in section "gs_dump" in the *Data Warehouse Service (DWS) Tool Guide*.

Type: USERSET

Value range: Boolean

- **on** indicates the forcible quotation function is enabled.
- **off** indicates the forcible quotation function is disabled.

Default value: off

sql_inheritance

Parameter description: Determines whether to inherit semantics.

Type: USERSET

Value range: Boolean

off indicates that child tables cannot be accessed by various commands. That is, an **ONLY** keyword is used by default. This setting is compatible with versions earlier than PostgreSQL 7.1.

Default value: on

standard_conforming_strings

Parameter description: Determines whether ordinary string texts ('...') treat backslashes as ordinary texts as specified in the SQL standard.

- Applications can check this parameter to determine how string texts will be processed.
- It is recommended that characters be escaped by using the escape string syntax (E'...').

Type: USERSET

Value range: Boolean

- **on** indicates that the function is enabled.
- **off** indicates that the function is disabled.

Default value: on

synchronize_seqscans

Parameter description: Controls sequential scans of tables to synchronize with each other. Concurrent scans read the same data block about at the same time and share the I/O workload.

Type: USERSET

Value range: Boolean

- **on** indicates that a scan may start in the middle of the table and then "wrap around" the end to cover all rows to synchronize with the activity of scans already in progress. This may result in unpredictable changes in the row ordering returned by queries that have no **ORDER BY** clause.
- **off** indicates that the scan always starts from the table heading.

Default value: on

enable_beta_features

Parameter description: Controls whether certain limited features, such as GDS table join, are available. These features are not explicitly prohibited in earlier versions, but are not recommended due to their limitations in certain scenarios.

Type: USERSET

Value range: Boolean

- **on** indicates that the features are enabled and forward compatible, but may incur errors in certain scenarios.
- **off** indicates that the features are disabled.

Default value: off

19.16.2 Platform and Client Compatibility

Database systems are widely used across many platforms, and their external compatibility offers a great deal of convenience.

transform_null_equals

Parameter description: Determines whether expressions of the form `expr = NULL` (or `NULL = expr`) are treated as `expr IS NULL`. They return true if `expr` evaluates to **NULL**, and false otherwise.

- The correct SQL-standard-compliant behavior of `expr = NULL` is to always return null (unknown).
- Filtered forms in Microsoft Access generate queries that appear to use `expr = NULL` to test for null values. If you turn this option on, you can use this interface to access the database.

Type: USERSET

Value range: Boolean

- **on** indicates expressions of the form `expr = NULL` (or `NULL = expr`) are treated as `expr IS NULL`.
- **off** indicates `expr = NULL` always returns **NULL**.

Default value: off

NOTE

New users are always confused about the semantics of expressions involving **NULL** values. Therefore, **off** is used as the default value.

td_compatible_truncation

Parameter description: Determines whether to enable features compatible with a Teradata database. You can set this parameter to **on** when connecting to a database compatible with the Teradata database, so that when you perform the INSERT operation, overlong strings are truncated based on the allowed maximum length before being inserted into char- and varchar-type columns in the target table. This ensures all data is inserted into the target table without errors reported.

 NOTE

- The string truncation function cannot be used if the **INSERT** statement includes a foreign table.
- If inserting multi-byte character data (such as Chinese characters) to database with the character set byte encoding (SQL_ASCII, LATIN1), and the character data crosses the truncation position, the string is truncated based on its bytes instead of characters. Unexpected result will occur in tail after the truncation. If you want correct truncation result, you are advised to adopt encoding set such as UTF8, which has no character data crossing the truncation position.

Type: USERSET

Value range: Boolean

- **on** indicates overlong strings are truncated.
- **off** indicates overlong strings are not truncated.

Default value: off

behavior_compat_options

Parameter description: Specifies the database compatibility behavior, which consists of multiple items separated by commas (,). Compatibility configurations are applied according to the database type (such as Oracle/Teradata/MySQL). For details, see [Table 19-2](#).

Type: USERSET

Value range: a string

Default value: In upgrade scenarios, the default value of this parameter is the same as that in the cluster before the upgrade. When a new cluster is installed, the default value of this parameter is

check_function_conflicts,check_function_shippable,unsupported_set_function_case to prevent serious issues caused by incorrect function attributes that users define.

 NOTE

- Currently, only items in [Table 19-2](#) are supported.
- Multiple items are separated by commas (,), for example, **set behavior_compat_options='end_month_calculate,display_leading_zero';**
- **strict_concat_functions** and **strict_text_concat_td** are mutually exclusive.
- You are not advised to set **behavior_compat_options** to **'return_null_string'** in Oracle compatibility mode. If this option is set, do not insert query results into tables.

Table 19-2 Compatibility configuration items

| Configuratio
n Item | Behavior | Appl
icabl
e Com
pati
bilit
y Mod
e |
|---------------------------|---|---|
| display_leadi
ng_zero | <p>Specifies how floating point numbers are displayed.</p> <ul style="list-style-type: none">• If this item is not specified, decimal numbers between -1 and 0, and between 0 and 1, do not display the leading zero before the decimal point. For example, 0.25 is displayed as .25.• If this item is specified, decimal numbers between -1 and 0, and between 0 and 1, display the leading zero before the decimal point. For example, 0.25 is displayed as 0.25. | ORA
TD |
| end_month_c
alculate | <p>Specifies the calculation logic of the add_months function.</p> <p>Assuming that the two parameters of the add_months function are param1 and param2, and the sum of the months of param1 and param2 is result:</p> <ul style="list-style-type: none">• If this item is not specified, and the Day of param1 indicates the last day of a month shorter than result, the Day in the calculation result will equal that in param1. For example: <pre>select add_months('2018-02-28',3) from dual;
add_months

2018-05-28 00:00:00
(1 row)</pre> <ul style="list-style-type: none">• If this item is specified, and the Day of param1 indicates the last day of a month shorter than result, the Day in the calculation result will equal that in result. For example: <pre>select add_months('2018-02-28',3) from dual;
add_months

2018-05-31 00:00:00
(1 row)</pre> | ORA
TD |
| compat_anal
yze_sample | <p>Specifies the sampling behavior of the ANALYZE operation.</p> <p>If this item is specified, the sample collected by the ANALYZE operation will be limited to around 30,000 records, controlling CN memory consumption and maintaining the stability of ANALYZE.</p> | ORA
TD

QL |

| Configuration Item | Behavior | Applicable Compatibility Mode |
|---------------------------|---|-------------------------------|
| bind_schema_tablespace | Binds a schema with the tablespace with the same name.

If a tablespace name is the same as <i>schema_name</i> , default_tablespace will also be set to <i>schema_name</i> if search_path is set to <i>schema_name</i> . | ORA
TD
MySQL |
| bind_procedure_searchpath | Specifies the search path of the database object for which no schema name is specified.

If no schema name is specified for a stored procedure, the search is performed in the schema the stored procedure belongs to.

If the stored procedure is not found, the following operations are performed: <ul style="list-style-type: none"> • If this item is not specified, the system reports an error and exits. • If this item is specified, the search continues based on the settings of search_path. If the issue persists, the system reports an error and exits. | ORA
TD
MySQL |
| correct_to_number | Controls the compatibility of the to_number() result.

If this item is specified, the result of the to_number() function is the same as that of PG11. Otherwise, the result is the same as that of Oracle. | ORA |
| unbind_divide_bound | Controls the range check on the result of integer division. <ul style="list-style-type: none"> • If this item is not specified, the division result is checked. If the result is out of the range, an error is reported. In the following example, an out-of-range error is reported because the value of INT_MIN/(-1) is greater than the value of INT_MAX.

 <pre>SELECT (-2147483648)::int / (-1)::int; ERROR: integer out of range</pre> • If this item is specified, the range of the division result does not need to be checked. In the following example, INT_MIN/(-1) can be used to obtain the output result INT_MAX+1.

 <pre>SELECT (-2147483648)::int / (-1)::int; ?column? ----- 2147483648 (1 row)</pre> | ORA
TD |

| Configuration Item | Behavior | Applicable Compatibility Mode |
|--------------------------|---|-------------------------------|
| merge_update_multi | Specifies whether to perform an update when MERGE INTO is executed to match multiple rows.

If this item is specified, no error is reported when multiple rows are matched. Otherwise, an error is reported (same as Oracle). | ORATD |
| disable_row_update_multi | Specifies whether to perform an update when multiple rows of a row-store table are matched.

If this item is specified, an error is reported when multiple rows are matched. Otherwise, multiple rows can be matched and updated by default. | ORATD |
| return_null_string | Specifies how to display the empty result (empty string ") of the lpad() , rpadd() , repeat() , regexp_split_to_table() , and split_part() functions. <ul style="list-style-type: none">If this item is not specified, the empty string is displayed as NULL.
<pre>select length(lpad('123',0,'*')) from dual;
length

(1 row)</pre>If this item is specified, the empty string is displayed as single quotation marks (").
<pre>select length(lpad('123',0,'*')) from dual;
length

0
(1 row)</pre> | ORA |
| compat_concat_variadic | Specifies the compatibility of variadic results of the concat() and concat_ws() functions.

If this item is specified and a concat function has a parameter of the variadic type, different result formats in Oracle and Teradata are retained. If this item is not specified and a concat function has a parameter of the variadic type, the result format of Oracle is retained for both Oracle and Teradata. | ORATD |

| Configuration Item | Behavior | Applicable Compatibility Mode |
|---------------------------------|---|-------------------------------|
| convert_string_digit_to_numeric | <p>Specifies the type casting priority for binary BOOL operations on the CHAR type and INT type.</p> <ul style="list-style-type: none">• If this item is not specified, the type casting priority is the same as that of PG9.6.• After this item is configured, all binary BOOL operations of the CHAR type and INT type are forcibly converted to the NUMERIC type for computation. After this configuration item is set, the CHAR types that are affected include BPCHAR, VARCHAR, NVARCHAR2, and TEXT, and the INT types that are affected include INT1, INT2, INT4, and INT8. <p>CAUTION
This configuration item is valid only for binary BOOL operation, for example, INT2>TEXT and INT4=BPCHAR. Non-BOOL operation is not affected. This configuration item does not support conversion of UNKNOWN operations such as INT>'1.1'. After this configuration item is enabled, all BOOL operations of the CHAR and INT types are preferentially converted to the NUMERIC type for computation, which affects the computation performance of the database. When the JOIN column is a combination of affected types, the execution plan is affected.</p> | ORAD
MySQL |

| Configuration Item | Behavior | Applicable Compatibility Mode |
|--------------------------|--|-------------------------------|
| check_function_conflicts | <p>Controls the check of the custom plpgsql/SQL function attributes.</p> <ul style="list-style-type: none">• If this parameter is not specified, the IMMUTABLE/STABLE/VOLATILE attributes of a custom function are not checked.• If this parameter is specified, the IMMUTABLE attribute of a custom function is checked. If the function contains a table or the STABLE/VOLATILE function, an error is reported during the function execution. In a custom function, a table or the STABLE/VOLATILE function conflicts with the IMMUTABLE attribute, thus function behaviors are not IMMUTABLE in this case. <p>For example, when this parameter is specified, an error is reported in the following scenarios:</p> <pre>CREATE OR replace FUNCTION sql_immutable (INTEGER) RETURNS INTEGER AS 'SELECT a+\$1 from shipping_schema.t4 where a=1;' LANGUAGE SQL IMMUTABLE RETURNS NULL ON NULL INPUT; select sql_immutable(1); ERROR: IMMUTABLE function cannot contain SQL statements with relation or Non-IMMUTABLE function. CONTEXT: SQL function "sql_immutable" during startup referenced column: sql_immutable</pre> | ORA
TD
MySQL |

| Configuration Item | Behavior | Applicable Compatibility Mode |
|---------------------|--|-------------------------------|
| varray_verification | <p>Indicates whether to verify the array length and array type length. This parameter is compatible with DWS of versions earlier than 8.1.0.</p> <p>If this parameter is specified, the array length and array type length are not verified.</p> <p>Scenario 1</p> <pre>CREATE OR REPLACE PROCEDURE varray_verification AS TYPE org_varray_type IS varray(5) OF VARCHAR2(2); v_org_varray org_varray_type; BEGIN v_org_varray(1) := '111'; --If the value exceeds the limit of VARCHAR2(2), the setting will be consistent with that in the historical version and no verification is performed after configuring this option. END; /</pre> <p>Scenario 2</p> <pre>CREATE OR REPLACE PROCEDURE varray_verification_i3_1 AS TYPE org_varray_type IS varray(2) OF NUMBER(2); v_org_varray org_varray_type; BEGIN v_org_varray(3) := 1; --If the value exceeds the limit of varray(2) specified for array length, the setting will be consistent with that in the historical version and no verification is performed after configuring this option. MySQL |

enable_matview

Parameter description: Specifies whether to enable the materialized view function.

Type: USERSET

Value range: Boolean

- **on:** The materialized view function is enabled.
- **off:** The materialized view function is disabled.

Default value: off

mv_max_cascade_depth

Parameter description: Specifies the maximum depth of nested materialized views. This parameter is available only for clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: an integer ranging from 1 to 10

Default value: 3

hive_compat_options

Parameter description: Specifies whether to convert an empty string to **NULL** when data is inserted into a numeric field using **INSERT INTO VALUES** or into a

character field using **INSERT INTO SELECT** in MySQL mode of DWS. This parameter is available only for clusters of version 9.1.0.210 or later.

For the examples of setting this parameter, see "INSERT" in *SQL Syntax Reference*.

Type: USERSET

Value range: enumerated values

- **empty_str_to_null:** An empty string will be converted to **NULL** when data is inserted into a numeric field or a character field.
- **empty:** When data is inserted into a numeric field using **INSERT INTO VALUES** or into a character field using **INSERT INTO SELECT**, empty strings are not processed.

Default value: empty

19.17 Fault Tolerance

This section describes parameters used for controlling the methods that the server processes an error occurring in the database system.

exit_on_error

Parameter description: Specifies whether to terminate the current session.

Type: SUSET

Value range: Boolean

- **on** indicates that any error will terminate the current session.
- **off** indicates that only a FATAL error will terminate the current session.

Default value: off

omit_encoding_error

Parameter description: When performing character encoding conversion in the database, if a character encoding error occurs and the target character set encoding is UTF-8, the converted character with the error can be ignored and replaced with "?".

Type: USERSET

Value range: Boolean

- **on** indicates that characters that have conversion errors will be ignored and replaced with question marks (?), and error information will be recorded in logs.
- **off** indicates that characters that have conversion errors cannot be converted and error information will be directly displayed.

Default value: off

max_query_retry_times

Parameter description: Specifies the maximum number of retries for the automatic retry feature when a SQL statement encounters an error. Currently, the supported error types for retry include **Connection reset by peer**, **Lock wait timeout**, and **Connection timed out**. Setting this parameter to **0** will disable the retry feature.

Type: USERSET

Value range: an integer ranging from 0 to 20

Default value: 6

retry_ecode_list

Parameter description: Specifies the list of SQL error types that support automatic retry.

Type: USERSET

Value range: a string

Default value: YY001 YY002 YY003 YY004 YY005 YY006 YY007 YY008 YY009
YY010 YY011 YY012 YY013 YY014 YY015 53200 08006 08000 57P01 XX003 XX009
YY016 CG003 CG004 F0011 F0012 45003 42P30

19.18 Connection Pool Parameters

When a connection pool is used to access the database, database connections are established and then stored in the memory as objects during system running. When you need to access the database, no new connection is established. Instead, an existing idle connection is selected from the connection pool. After you finish accessing the database, the database does not disable the connection but puts it back into the connection pool. The connection can be used for the next access request.

max_pool_size

Parameter description: Specifies the maximum number of connections between a CN's connection pool and another CN/DN.

Type: POSTMASTER

Value range: an integer ranging from 1 to 65535

Default value: **800** for CNs and **5000** for DN

persistent_datanode_connections

Parameter description: Specifies whether to release the connection for the current session.

Type: USERSET

Value range: Boolean

- **off** indicates that the connection for the current session will be released.
- **on** indicates that the connection for the current session will not be released.

NOTICE

After this function is enabled, a session may hold a connection but does not run a query. As a result, other query requests fail to be connected. To fix this problem, the number of sessions must be less than or equal to **max_active_statements**.

Default value: off

cache_connection

Parameter description: Specifies whether to reclaim the connections of a connection pool.

Type: USERSET

Value range: Boolean

- **on** indicates that the connections of a connection pool will be reclaimed.
- **off** indicates that the connections of a connection pool will not be reclaimed.

Default value: on

enable_force_reuse_connections

Parameter description: Specifies whether a session forcibly reuses a new connection.

Type: USERSET

Value range: Boolean

- **on** indicates that the new connection is forcibly used.
- **off** indicates that the current connection is used.

Default value: off

syscache_clean_policy

Parameter description: Specifies the policy for clearing the memory and number of idle DN connections. This is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: a string

This parameter policy consists of three values:

1. The first value ranges from 0 to 1 and represents the percentage of total available memory used by DNs. When the percentage of used memory reaches this value, 1/4 of the stream threads will be cleared, and the second value will be evaluated.

2. The second value ranges from 0 to 1 and represents the percentage of total available memory used by syscache on DNs. When the percentage of syscache memory usage reaches this value, the third value will be evaluated.
3. The third value ranges from 0 to INT_MAX and is measured in MB. It represents the size of syscache memory used by idle threads. When the syscache memory usage of an idle thread reaches this value, the syscache used by that thread will be cleared.

Default value: 0.8,0.3,64

NOTICE

- Before setting this parameter, evaluate the memory usage using views [PV_SESSION_MEMORY_DETAIL](#) and [PV_TOTAL_MEMORY_DETAIL](#).
 - When setting this parameter, follow the specified format, ensuring that the three values are separated by commas without spaces.
 - If the parameter is not set according to the specified format and the setting fails, a WARNING log will be generated in the log, and the parameter value displayed when using the SHOW command to query the parameter will be the last successfully set value. If the setting fails and the system is restarted, the parameter will be set to the default value.
 - During the Readcommand phase, if a thread on CN times out after 30 seconds, it will clear DNs if syscache is greater than 256 MB. There are two operations:
 1. If the overall memory usage reaches 80%, an auxiliary thread will monitor the memory usage and clear 1/4 of the stream threads. It will also check if syscache usage exceeds 30% of the total memory usage. If it does, it will clear the syscache of Readcommand phase pg threads greater than 64 MB.
 2. If a stream thread is idle for more than 30 seconds and syscache usage is greater than 64 MB, it will clear the syscache.
-

19.19 Cluster Transaction Parameters

This section describes the settings and value ranges of cluster transaction parameters.

transaction_isolation

Parameter description: Specifies the isolation level of the current transaction.

Type: USERSET

Value range:

- **READ COMMITTED:** Only committed data is read. This is the default.
- **READ UNCOMMITTED:** DWS does not support **READ UNCOMMITTED**. If **READ UNCOMMITTED** is set, **READ COMMITTED** is executed instead.
- **REPEATABLE READ:** Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.

- **SERIALIZABLE**: DWS does not support **SERIALIZABLE**. If **SERIALIZABLE** is set, **REPEATABLE READ** is executed instead.

Default value: READ COMMITTED

transaction_read_only

Parameter description: Specifies that the current transaction is a read-only transaction.

Type: USERSET

Value range: Boolean

- **on** indicates that the current transaction is a read-only transaction.
- **off** indicates that the current transaction can be a read/write transaction.

Default value: off for CNs and on for DN

xc_maintenance_mode

Parameter description: Specifies whether the system is in maintenance mode.

Type: SUSERSET

Value range: Boolean

- **on** indicates that maintenance mode is enabled.
- **off** indicates that the maintenance mode is disabled.

Default value: off

NOTICE

Enable the maintenance mode with caution to avoid cluster data inconsistencies.

allow_concurrent_tuple_update

Parameter description: Specifies whether to allow concurrent update.

Type: USERSET

Value range: Boolean

- **on** indicates it is enabled.
- **off** indicates it is disabled.

Default value: on

gtm_backup_barrier

Parameter description: Specifies whether to create a restoration point for the GTM starting point.

Type: SUSERSET

Value range: Boolean

- **on** indicates that a restoration point will be created for the GTM starting point.
- **off** indicates that a restoration point will not be created for the GTM starting point.

Default value: off

transaction_deferrable

Parameter description: Specifies whether to delay the execution of a read-only serial transaction without incurring an execution failure. Assume this parameter is set to **on**. When the server detects that the tuples read by a read-only transaction are being modified by other transactions, it delays the execution of the read-only transaction until the other transactions finish modifying the tuples. Currently, this parameter is not used in DWS. Similar to this parameter, the [default_transaction_deferrable](#) parameter is used to specify whether to allow delayed execution of a transaction.

Type: USERSET

Value range: Boolean

- **on** indicates that the execution of a read-only serial transaction can be delayed.
- **off** indicates that the execution of a read-only serial transaction cannot be delayed.

Default value: off

enforce_two_phase_commit

Parameter description: This parameter is reserved for compatibility with earlier versions. This parameter is invalid in the current version.

enable_show_any_tuples

Parameter description: This parameter is available only in a read-only transaction and is used for analysis. When this parameter is set to **on/true**, all versions of tuples in the table are displayed.

Type: USERSET

Value range: Boolean

- **on/true** indicates that all versions of tuples in the table are displayed.
- **off/false** indicates that no versions of tuples in the table are displayed.

Default value: off

idle_in_transaction_timeout

Parameter description: duration during which a transaction is allowed to be in the idle state. When a transaction is in the idle state for a period specified by this parameter, the transaction is terminated. This function takes effect only for client

connections that are directly connected to CNs and does not take effect for direct DN connections or internal connections. This parameter is supported only by clusters of version 8.2.1.100 or later.

Type: USERSET

Value range: 0 to 86400, in second.

Default value: 3600

19.20 Developer Operations

enable_light_colupdate

Parameter description: Specifies whether to enable the lightweight column-store update.

Type: USERSET

Value range: Boolean

- **on** indicates that the lightweight column-store update is enabled.
- **off** indicates that the lightweight column-store update is disabled.

Default value: off

NOTE

There is a low probability that an error is reported when lightweight **UPDATE** and backend column-store **AUTOVACUUM** coexist. You can run **ALTER TABLE** to set the table-level parameter **enable_column_autovacuum_garbage** to **off** to avoid this issue. If the table-level parameter **enable_column_autovacuum_garbage** is set to **off**, the backend column-store **AUTOVACUUM** of the table is disabled.

enable_fast_query_shipping

Parameter description: Specifies whether to use the distributed framework for a query planner.

Type: USERSET

Value range: Boolean

- **on** indicates that execution plans are generated on CNs and DN connections separately.
- **off** indicates that the distributed framework is used. Execution plans are generated on CNs and then sent to DN connections for execution.

Default value: on

enable_trigger_shipping

Parameter description: Specifies whether the trigger can be pushed to DN connections for execution.

Type: USERSET

Value range: Boolean

- **on** indicates that the trigger can be pushed to DN for execution.
- **off** indicates that the trigger cannot be pushed to DN. It must be executed on the CN.

Default value: on

enable_remotejoin

Parameter description: Specifies whether JOIN operation plans can be delivered to DN for execution.

Type: USERSET

Value range: Boolean

- **on** indicates that JOIN operation plans can be delivered to DN for execution.
- **off** indicates that JOIN operation plans cannot be delivered to DN for execution.

Default value: on

enable_remotegroup

Parameter description: Specifies whether the execution plans of **GROUP BY** and **AGGREGATE** can be delivered to DN for execution.

Type: USERSET

Value range: Boolean

- **on** indicates that the execution plans of **GROUP BY** and **AGGREGATE** can be delivered to DN for execution.
- **off** indicates that the execution plans of **GROUP BY** and **AGGREGATE** cannot be delivered to DN for execution.

Default value: on

enable_remotelimit

Parameter description: Specifies whether the execution plan specified in the LIMIT clause can be pushed down to DN for execution.

Type: USERSET

Value range: Boolean

- **on** indicates that the execution plan specified in the LIMIT clause can be pushed down to DN for execution.
- **off** indicates that the execution plan specified in the LIMIT clause cannot be delivered to DN for execution.

Default value: on

enable_limit_stop

Parameter description: whether to enable the **early stop** optimization for **LIMIT** statements. For a **LIMIT n** statement, if **early stop** is enabled, the CN requests the

DN to end the execution after receiving *n* pieces of data. This method is applicable to complex queries with **LIMIT**. This parameter is supported only by clusters of version 8.1.3.320 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that **early stop** is enabled for LIMIT statements.
- **off** indicates that **early stop** is disabled for LIMIT statements.

Default value: on

enable_remotesort

Parameter description: Specifies whether the execution plan of the ORDER BY clause can be delivered to DNs for execution.

Type: USERSET

Value range: Boolean

- **on** indicates that the execution plan of the ORDER BY clause can be delivered to DNs for execution.
- **off** indicates that the execution plan of the ORDER BY clause cannot be delivered to DNs for execution.

Default value: on

enable_join_pseudoconst

Parameter description: Specifies whether joining with the pseudo constant is allowed. A pseudo constant indicates that the variables on both sides of a join are identical to the same constant.

Type: USERSET

Value range: Boolean

- **on** indicates that joining with the pseudo constant is allowed.
- **off** indicates that joining with the pseudo constant is not allowed.

Default value: off

cost_model_version

Parameter description: Specifies the model used for cost estimation in the application scenario. This parameter affects the distinct estimation of the expression, HashJoin cost model, estimation of the number of rows, distribution key selection during redistribution, and estimation of the number of aggregate rows.

Type: USERSET

Value range: 0, 1, 2, 3, or 4

- **0** indicates that the original cost estimation model is used.

- **1** indicates that the enhanced distinct estimation of the expression, HashJoin cost estimation model, estimation of the number of rows, distribution key selection during redistribution, and estimation of the number of aggregate rows are used on the basis of **0**.
- **2** indicates that the ANALYZE sampling algorithm with better randomness is used on the basis of **1** to improve the accuracy of statistics collection.
- **3** indicates that the broadcast cost estimation in large cluster scenarios is optimized based on **2** so that the optimizer can select a better plan. This option is supported only by clusters of version 8.3.0 or later.
- **4** indicates that in addition to the optimizations made to the cost estimation of hashjoin parallelization, skew, and column-store index ordering in **3**, there are also optimized row estimations for coalesce expressions and improved recognition of skew optimization for subquery constant output columns during joins.

Default value: 4

debug_assertions

Parameter description: Specifies whether to enable various assertion checks. This parameter assists in debugging. If you are experiencing strange problems or crashes, set this parameter to **on** to identify programming defects. To use this parameter, the macro USE_ASSERT_CHECKING must be defined (through the configure option **--enable-cassert**) during the DWS compilation.

Type: USERSET

Value range: Boolean

- **on** indicates that various assertion checks are enabled.
- **off** indicates that various assertion checks are disabled.

NOTE

This parameter is set to **on** by default if DWS is compiled with various assertion checks enabled.

Default value: off

distribute_test_param

Parameter description: Specifies whether the embedded test stubs for testing the distribution framework take effect. In most cases, developers embed some test stubs in the code during fault injection tests. Each test stub is identified by a unique name. The value of this parameter is a triplet that includes three values: thread level, test stub name, and error level of the injected fault. The three values are separated by commas (,).

Type: USERSET

Value range: a string indicating the name of any embedded test stub.

Default value: -1, default, default

ignore_checksum_failure

Parameter description: Sets whether to ignore check failures (but still generates an alarm) and continues reading data. This parameter is valid only if **enable_crc_check** is set to **on**. Continuing reading data may result in breakdown, damaged data being transferred or hidden, failure of data recovery from remote nodes, or other serious problems. You are not advised to modify the settings.

Type: SUSET

Value range: Boolean

- **on** indicates that data check errors are ignored.
- **off** indicates that data check errors are reported.

Default value: off

default_table_behavior

Parameter description: behavior type of the default table. This parameter is supported only by clusters of version 8.2.1 or later.

Type: USERSET

Value range: **column_btree_index**, **column_high_compress**, **column_middle_compress**, or **column_low_compress**

- **column_btree_index** indicates that the default index for creating a column-store table is **B-Tree**.
- **column_high_compress** indicates that the default compression level of column-store tables is **high**.
- **column_middle_compress** indicates that the default compression level of column-store tables is **middle**.
- **column_low_compress** indicates that the default compression level of column-store tables is **low**.

Default value: an empty string

enable_colstore

Parameter description: Specifies whether to create a table as a column-store table by default when no storage method is specified. The value for each node must be the same. This parameter is used for tests. Users are not allowed to enable it.

Type: SUSET

Value range: Boolean

Default value: off

enable_force_vector_engine

Parameter description: Specifies whether to forcibly generate vectorized execution plans for a vectorized execution operator if the operator's child node is a non-vectorized operator. When this parameter is set to **on**, vectorized execution

plans are forcibly generated. When **enable_force_vector_engine** is enabled, no matter it is a row-store table, column-store table, or hybrid row-column store table, if the plantree does not contain scenarios that do not support vectorization, the vectorized executor is forcibly used.

Type: USERSET

Value range: Boolean

Default value: off

enable_csqual_pushdown

Parameter description: Specifies whether to deliver filter criteria for a rough check during query.

Type: USERSET

Value range: Boolean

- **on** indicates that a rough check is performed with filter criteria delivered during query.
- **off** indicates that a rough check is performed without filter criteria delivered during query.

Default value: on

explain_dna_file

Parameter description: Specifies the name of a CSV file exported when **explain_perf_mode** is set to **run**.

Type: USERSET

NOTICE

The value of this parameter must be an absolute path plus a file name with the extension **.csv**.

Value range: a string

Default value: NULL

explain_perf_mode

Parameter description: Specifies the display format of the **explain** command.

Type: USERSET

Value range: **normal**, **pretty**, **summary**, and **run**

- **normal** indicates that the default printing format is used.
- **pretty** indicates that the optimized display mode of DWS is used. A new format contains a plan node ID, directly and effectively analyzing performance.

- **summary** indicates that the analysis result based on such information is printed in addition to the printed information in the format specified by **pretty**.
- **run** indicates that in addition to the printed information specified by **summary**, the database exports the information as a CSV file.

Default value: pretty

join_num_distinct

Parameter description: Controls the default distinct value of the join column or expression in application scenarios.

Type: USERSET

Value range: a double-precision floating point number greater than or equal to -100. Decimals may be truncated when displayed on clients.

- If the value is greater than 0, the value is used as the default distinct value.
- If the value is greater than or equal to -100 and less than 0, it means the percentage used to estimate the default distinct value.
- If the value is 0, the default distinct value is 200.

Default value: -20

outer_join_max_rows_multipler

Parameter description: Specifies the maximum number of estimated rows for outer joins.

Type: USERSET

Value range: 0 or a double-precision floating point number greater than or equal to 1. Decimals may be truncated when displayed on clients.

- If the value is 0, the estimated number of rows for outer joins is not limited.
- If the value is greater than or equal to 1, the estimated number of rows cannot exceed a multiple of the number of rows in the foreign table in the outer join.

Default value: 1.1

qual_num_distinct

Parameter description: Controls the default distinct value of the filter column or expression in application scenarios.

Type: USERSET

Value range: a double-precision floating point number greater than or equal to -100. Decimals may be truncated when displayed on clients.

- If the value is greater than 0, the value is used as the default distinct value.
- If the value is greater than or equal to -100 and less than 0, it means the percentage used to estimate the default distinct value.

- If the value is **0**, the default distinct value is **200**.

Default value: 200

trace_notify

Parameter description: Specifies whether to generate a large amount of debugging output for the **LISTEN** and **NOTIFY** commands. [client_min_messages](#) or [log_min_messages](#) must be **DEBUG1** or lower so that such output can be recorded in the logs on the client or server separately.

Type: USERSET

Value range: Boolean

- **on** indicates that the function is enabled.
- **off** indicates that the function is disabled.

Default value: off

trace_sort

Parameter description: Specifies whether to display information about resource usage during sorting operations in logs. This parameter is available only when the macro **TRACE_SORT** is defined during the DWS compilation. However, **TRACE_SORT** is currently defined by default.

Type: USERSET

Value range: Boolean

- **on** indicates that the function is enabled.
- **off** indicates that the function is disabled.

Default value: off

zero_damaged_pages

Parameter description: Specifies whether to detect a damaged page header that causes DWS to report an error, aborting the current transaction.

Type: SUSET

Value range: Boolean

- **on** indicates that the function is enabled.
- **off** indicates that the function is disabled.

 NOTE

- Setting this parameter to **on** causes the system to report a warning, pad the damaged page with zeros, and then continue with subsequent processing. This behavior will damage data, that is, all rows on the damaged page. However, it allows you to bypass the error and retrieve rows from any undamaged pages that are present in the table. Therefore, it is useful for restoring data that is damaged due to a hardware or software error. In most cases, you are not advised to set this parameter to **on** unless you do not want to restore data from the damaged pages of a table.
- For a column-store table, the system will skip the entire CU and then continue processing. The supported scenarios include the CRC check failure, magic check failure, and incorrect CU length.

Default value: off

replication_test

Parameter description: Specifies whether to enable internal testing on the data replication function.

Type: USERSET

Value range: Boolean

- **on** indicates that internal testing on the data replication function is enabled.
- **off** indicates that internal testing on the data replication function is disabled.

Default value: off

cost_param

Parameter description: Controls use of different estimation methods in specific customer scenarios, allowing estimated values approximating to onsite values. This parameter can control various methods simultaneously by performing AND (&) operations on the bit for each method. A method is selected if its value is not 0.

If **cost_param & 1** is not set to 0, an improvement mechanism is selected for calculating a non-equi join selection rate, which is more accurate in estimation of self-join (join between two same tables). In V300R002C00 and later, **cost_param & 1=0** is not used. That is, an optimized formula is selected for calculation.

When **cost_param & 2** is set to a value other than 0, the selection rate is estimated based on multiple filter criteria. The lowest selection rate among all filter criteria, but not the product of the selection rates for two tables under a specific filter criterion, is used as the total selection rate. This method is more accurate when a close correlation exists between the columns to be filtered.

When **cost_param & 4** is not 0, the selected debugging model is not recommended when the stream node is evaluated.

When **cost_param & 16** is not 0, the model between fully correlated and fully uncorrelated models is used to calculate the comprehensive selection rate of two or more filtering conditions or join conditions. If there are many filtering conditions, the strongly-correlated model is preferred.

Type: USERSET

Value range: an integer ranging from 1 to INT_MAX

Default value: 16

convert_string_to_digit

Parameter description: Specifies the implicit conversion priority, which determines whether to preferentially convert strings into numbers.

Type: USERSET

Value range: Boolean

- **on** indicates that strings are preferentially converted into numbers.
- **off** indicates that strings are not preferentially converted into numbers.

Default value: on

NOTICE

Modify this parameter only when absolutely necessary because the modification will change the rule for converting internal data types and may cause unexpected results.

nls_timestamp_format

Parameter description: Specifies the default timestamp format.

Type: USERSET

Value range: a string

Default value: DD-Mon-YYYY HH:MI:SS.FF AM

enable_partitionwise

Parameter description: Specifies whether to select an intelligent algorithm for joining partitioned tables.

Type: USERSET

Value range: Boolean

- **on** indicates that an intelligent algorithm is selected.
- **off** indicates that an intelligent algorithm is not selected.

Default value: off

enable_partition_dynamic_pruning

Parameter description: Specifies whether dynamic pruning is enabled during partition table scanning.

Type: USERSET

Value range: Boolean

- **on**: enable
- **off**: disable

Default value: on

max_user_defined_exception

Parameter description: Specifies the maximum number of exceptions. The default value cannot be changed.

Type: USERSET

Value range: an integer

Default value: 1000

datanode_strong_sync

Parameter description: This parameter no longer takes effect.

Type: USERSET

Value range: Boolean

- **on** indicates that forcible synchronization between stream nodes is enabled.
- **off** indicates that forcible synchronization between stream nodes is disabled.

Default value: off

enable_global_stats

Parameter description: Specifies the current statistics mode. This parameter is used to compare global statistics generation plans and the statistics generation plans for a single DN. This parameter is used for tests. Users are not allowed to enable it.

Type: SUSET

Value range: Boolean

- **on** or **true** indicates the global statistics mode.
- **off** or **false** indicates the single-DN statistics mode.

Default value: on

enable_fast_numeric

Parameter description: Specifies whether to enable optimization for numeric data calculation. Calculation of numeric data is time-consuming. Numeric data is converted into int64- or int128-type data to improve numeric data calculation performance.

Type: USERSET

Value range: Boolean

- **on/true** indicates that optimization for numeric data calculation is enabled.

- **off/false** indicates that optimization for numeric data calculation is disabled.

Default value: on

enable_row_fast_numeric

Parameter description: Specifies the format in which numeric data in a row-store table is spilled to disks.

Type: USERSET

Value range: Boolean

- **on/true** indicates that numeric data in a row-store table is spilled to disks in bigint format.
- **off/false** indicates that numeric data in a row-store table is spilled to disks in the original format.

NOTICE

If this parameter is set to **on**, you are advised to enable **enable_force_vector_engine** to improve the query performance of large data sets. However, compared with the original format, there is a high probability that the bigint format occupies more disk space. For example, the TPC-H test set occupies about 7% more space (reference value, may vary depending on the environment).

Default value: off

rewrite_rule

Parameter description: Specifies the rewriting rule for enabled optional queries. Some query rewriting rules are optional. Enabling them cannot always improve query efficiency. In a specific customer scenario, you can set the query rewriting rules through the GUC parameter to achieve optimal query efficiency.

This parameter can control the combination of query rewriting rules, for example, there are multiple rewriting rules: rule1, rule2, rule3, and rule4. To set the parameters, you can perform the following operations:

```
set rewrite_rule=rule1;      --Enable query rewriting rule rule1.
set rewrite_rule=rule2,rule3; --Enable query rewriting rules rule2 and rule3.
set rewrite_rule=none;       --Disable all optional query rewriting rules.
```

Type: USERSET

Value range: a string

- **none:** No optional query rewrite rules are used.
- **Lazyagg:** The Lazy Agg query rewrite rule is used to eliminate aggregate operations in subqueries.
- **magicset:** The Magic Set query rewrite rule is used to push conditions from the main query down to promoted sublinks.
- **uniquecheck:** Uses the Unique Check rewriting rule. (The scenario where the target column does not contain the expression sublink of the aggregate

function can be improved. The function can be enabled only when the value of the target column is unique after the sublink is aggregated based on the associated column. This function is recommended to be used by optimization engineers.)

- **disablerep**: Uses the function that prohibits pulling up sublinks of the replication table. (Disables sublink pull-up for the replication table.)
- **projection_pushdown**: the Projection Pushdown rewriting rule (Removes columns that are not used by the parent query from the subquery).
- **or_conversion**: the OR conversion rewriting rule (eliminates the association OR conditions that are inefficient to execute).
- **plain_lazyagg**: the **Plain Lazy Agg** query rewriting rule (eliminates aggregation operations in a single subquery). This option is supported only by clusters of version 8.1.3.100 or later.
- **eager_magicset**: Uses the **eager_magicset** query rewriting rule (to push down conditions from the main query to subqueries). This option is supported only by clusters of version 8.2.0 or later.
- **casewhen_simplification**: This rewrite rule uses the CASE WHEN statement to simplify queries. When enabled, it rewrites **(case when xxx then const1 else const2)=const1**. It simplifies the CASE WHEN statement and reduces redundant calculation to improve query performance. This option is supported only by clusters of version 8.3.0 or later.
- **outer_join_quality_imply**: When there is an equi-join condition between a left outer join and a right outer join, this rule pushes the expression condition on the outer table's join column down to the inner table's join column. This option is supported only by clusters of version 8.3.0 or later.
- **inlist_merge**: This query rewrite rule uses the **inlist_or_inlist** method to merge **OR** statements with the same base table column. When enabled, it merges and rewrites **(where a in (list1) or a in (list2))** to support **inlist2join**. This option is supported only by clusters of version 8.3.0 or later.
- **subquery_qual_pull_up**: For subqueries that cannot be promoted, if the subquery has filtering conditions on columns that are also used for joining with other tables, this rule extracts the filtering conditions from the subquery and passes them to the other side of the join condition. Currently, only **var op const** forms without type conversion, such as **a > 2**, are supported. When enabled, it is assumed that **outer_join_quality_imply** is also enabled. This is supported only by clusters of version 9.1.0 or later.
- **not_distinct_from_opt**: When this function is enabled, the **is not distinct from** expression is temporarily rewritten to an equal sign expression so that statements containing this syntax can generate HASH JOIN or MERGE JOIN plans, improving execution performance. This is supported only by clusters of version 9.1.0.218 or later.

Default value: **magicset**, **or_conversion**, **projection_pushdown**, **plain_lazyagg**, or **subquery_qual_pull_up**

mv_rewrite_rule

Parameter description: whether to enable the rewriting rule for the materialized view.

Type: USERSET

Value range: a string

- **none:** No materialized view rewriting rule is used. This value is available only in clusters of version 8.2.1.100 or later.
- **text:** materialized view rewriting rule that uses text matching. This value is available only in clusters of version 8.2.1.100 or later.
- **general:** structure matching. This value is supported only by 9.1.0.200 and later cluster versions.
- **predicate:** expression framework for structure matching rewriting. This parameter is used for preprocessing and regularization of filter and association conditions. It takes effect only when **general** is enabled. This value is supported only by 9.1.0.210 and later cluster versions.
- **view_delta:** used to use primary and foreign key relationships to eliminate redundant joins in materialized views and then match the materialized views with queries. This value is supported only by 9.1.0.210 and later cluster versions.
- **single:** The single-table materialized view uses the materialized view rewriting rule. This value is supported only by clusters of version 9.1.0.222 or later.

Default value: **text**, **general**, **predicate**, and **single**.

NOTICE

general, **predicate**, and **view_delta** are restricted for commercial use. To use them, contact technical support.

enable_compress_spill

Parameter description: Specifies whether to enable the compression function of writing data to a disk.

Type: USERSET

Value range: Boolean

- **on/true** indicates that optimization for writing data to a disk is enabled.
- **off/false** indicates that optimization for writing data to a disk is disabled.

Default value: **on**

analysis_options

Parameter description: Specifies whether to enable corresponding features, such as data validation and performance statistics.

Type: USERSET

Value range: a string

- **LLVM_COMPILE** indicates that the codegen compilation time of each thread is displayed on the explain performance page.

- **HASH_CONFLICT** indicates that the log file in the **pg_log** directory of the DN process displays the hash table statistics, including the hash table size, hash chain length, and hash conflict information.
- **STREAM_DATA_CHECK** indicates that a CRC check is performed on data before and after network data transmission.
- **TURBO_DATA_CHECK** indicates that the data context of the **ScalarVector** and **VectorBatch** operators of Turbo is verified. This parameter is supported only by clusters of version 8.3.0.100 or later.
- **KEEP_SAMPLE_DATA**: This parameter retains the sampling data used in each analyze operation in the form of temporary tables. This parameter is supported only by clusters of version 9.1.0 or later.
- **BLOCK_RULE**: indicates that the time required for checking the query filter is displayed on the explain performance page. This is supported only by 9.1.0.100 and later cluster versions.

Default value: **off(ALL)**, which indicates that no location function is enabled.

resource_track_log

Parameter description: Specifies the log level of self-diagnosis. Currently, this parameter takes effect only in multi-column statistics.

Type: USERSET

Value range: a string

- **summary**: Brief diagnosis information is displayed.
- **detail**: Detailed diagnosis information is displayed.

Currently, the two parameter values differ only when there is an alarm about multi-column statistics not collected. If the parameter is set to **summary**, such an alarm will not be displayed. If it is set to **detail**, such an alarm will be displayed.

Default value: **summary**

hll_default_log2m

Parameter description: Specifies the number of buckets for HLL data. The number of buckets affects the precision of distinct values calculated by HLL. As the number of buckets increases, the deviation becomes smaller. The deviation range is as follows: $[-1.04/2^{\log 2m^{1/2}}, +1.04/2^{\log 2m^{1/2}}]$

Type: USERSET

Value range: an integer ranging from 10 to 16

Default value: 11

hll_default_regwidth

Parameter description: Specifies the number of bits in each bucket for HLL data. A larger value indicates more memory occupied by HLL. **hll_default_regwidth** and **hll_default_log2m** determine the maximum number of distinct values that can be calculated by HLL. For details, see [Table 19-3](#).

Type: USERSET

Value range: an integer ranging from 1 to 5

Default value: 5

Table 19-3 Maximum number of calculated distinct values determined by hll_default_log2m and hll_default_regwidth

| log2m | regwidth = 1 | regwidth = 2 | regwidth = 3 | regwidth = 4 | regwidth = 5 |
|-------|--------------|--------------|--------------|--------------|--------------|
| 10 | 7.4e+02 | 3.0e+03 | 4.7e+04 | 1.2e+07 | 7.9e+11 |
| 11 | 1.5e+03 | 5.9e+03 | 9.5e+04 | 2.4e+07 | 1.6e+12 |
| 12 | 3.0e+03 | 1.2e+04 | 1.9e+05 | 4.8e+07 | 3.2e+12 |
| 13 | 5.9e+03 | 2.4e+04 | 3.8e+05 | 9.7e+07 | 6.3e+12 |
| 14 | 1.2e+04 | 4.7e+04 | 7.6e+05 | 1.9e+08 | 1.3e+13 |
| 15 | 2.4e+04 | 9.5e+04 | 1.5e+06 | 3.9e+08 | 2.5e+13 |

hll_default_expthresh

Parameter description: Specifies the default threshold for switching from the **explicit** mode to the **sparse** mode.

Type: USERSET

Value range: an integer ranging from -1 to 7 -1 indicates the auto mode; 0 indicates that the **explicit** mode is skipped; a value from 1 to 7 indicates that the mode is switched when the number of distinct values reaches $2^{\text{hll_default_expthresh}}$.

Default value: -1

hll_default_sparseon

Parameter description: Specifies whether to enable the **sparse** mode by default.

Type: USERSET

Valid value: 0 and 1 0 indicates that the **sparse** mode is disabled by default. 1 indicates that the **sparse** mode is enabled by default.

Default value: 1

hll_max_sparse

Parameter description: Specifies the size of **max_sparse**.

Type: USERSET

Value range: an integer ranging from -1 to INT_MAX

Default value: -1

enable_compress_hll

Parameter description: Specifies whether to enable memory optimization for HLL.

Type: USERSET

Value range: Boolean

- **on** or **true** indicates that memory optimization is enabled.
- **off** or **false** indicates that memory optimization is disabled.

Default value: off

approx_count_distinct_precision

Parameter description: Specifies the number of buckets in the HyperLogLog++ (HLL++) algorithm. This parameter can be used to adjust the error rate of the **approx_count_distinct** aggregate function. The number of buckets affects the precision of estimating the distinct value. Having more buckets increases the accuracy of the estimation. The deviation range is as follows: $[-1.04/2^{\log_2 m^{1/2}}, +1.04/2^{\log_2 m^{1/2}}]$

Type: USERSET

Value range: an integer ranging from 10 to 20.

Default value: 17

udf_memory_limit

Parameter description: Controls the maximum physical memory that can be used when each CN or DN executes UDFs.

Type: POSTMASTER

Value range: an integer ranging from 200 x 1024 to the value of [max_process_memory](#) and the unit is KB.

Default value: 0.05 * max_process_memory

FencedUDFMemoryLimit

Parameter description: Controls the virtual memory used by each fenced udf worker process.

Type: USERSET

Suggestion: You are not advised to set this parameter. You can set [udf_memory_limit](#) instead.

Value range: an integer. The unit can be KB, MB, or GB. 0 indicates that the memory is not limited.

Default value: 0

enable_pbe_optimization

Parameter description: Specifies whether the optimizer optimizes the query plan for statements executed in Parse Bind Execute (PBE) mode.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimizer optimizes the query plan.
- **off** indicates that the optimization does not optimize the query plan.

Default value: on

enable_light_proxy

Parameter description: Specifies whether the optimizer optimizes the execution of simple queries on CNs.

Type: USERSET

Value range: Boolean

- **on** indicates that the optimizer optimizes the execution.
- **off** indicates that the optimization does not optimize the execution.

Default value: on

enable_parallel_ddl

Parameter description: Controls whether multiple CNs can concurrently perform DDL operations on the same database object.

Type: USERSET

Value range: Boolean

- **on** indicates that DDL operations can be performed safely and that no distributed deadlock occurs.
- **off** indicates that DDL operations cannot be performed safely and that distributed deadlocks may occur.

Default value: on

gc_fdw_verify_option

Parameter description: Specifies whether to enable the logic for verifying the number of rows in a result set in the collaborative analysis. This parameter is supported only by clusters of version 8.1.3.310 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the logic for verifying the number of rows in the result set is enabled. The **SELECT COUNT** statement is used to obtain the expected number of rows and compare it with the actual number of rows.

- **off** indicates that the logic for verifying the number of rows in the result set is disabled and only the required result set is obtained.

Default value: on

 NOTE

- If this parameter is enabled, the performance deteriorates slightly. In performance-sensitive scenarios, you can disable this parameter to improve the performance.
- If the result set row count check fails, an exception will be reported. To enable cooperative analysis logs, set **log_min_messages** to **debug1** and **logging_module** to **'on(COOP_ANALYZE)'**.

show_acce_estimate_detail

Parameter description: When the DWS cluster is accelerated ([acceleration_with_compute_pool](#) is set to **on**), specifies whether the **EXPLAIN** statement displays the evaluation information about execution plan pushdown to computing Node Groups. The evaluation information is generally used by O&M personnel during maintenance, and it may affect the output display of the **EXPLAIN** statement. Therefore, this parameter is disabled by default. The evaluation information is displayed only if the **verbose** option of the **EXPLAIN** statement is enabled.

Type: USERSET

Value range: Boolean

- **on** indicates that the evaluation information is displayed in the output of the **EXPLAIN** statement.
- **off** indicates that the evaluation information is not displayed in the output of the **EXPLAIN** statement.

Default value: off

full_group_by_mode

Parameter description: Used in conjunction with **disable_full_group_by_mysql** in [behavior_compat_options](#) to control two different behaviors when **disable_full_group_by_mysql syntax** is enabled.

Type: USERSET

Value range: a string

- **nullpadding** indicates that NULL values in non-aggregate columns are filled with the non-NULL values in that column, potentially resulting in different rows in the result set.
- **notpadding** indicates that NULL values in non-aggregate columns are not processed, and the entire row data is used, resulting in a random row for non-aggregate columns in the result set.

Default value: notpadding

NOTICE

This parameter only takes effect when **disable_full_group_by_mysql** is enabled in the MySQL-compatible library and non-aggregate columns are present in the query. The two behaviors of this parameter only apply to non-aggregate columns in the query.

enable_cudesc_streaming

Parameter description: Specifies whether to use the cudesc streaming path for accessing data across logical clusters in the decoupled storage and compute architecture. This parameter is supported only by clusters of version 9.1.0 or later.

Type: SUSET

Value range: enumerated values

- **off** indicates that cudesc streaming is disabled.
- **on** indicates that cudesc streaming is enabled.
- **only_read_on** indicates that cudesc streaming is supported only during data reading.

Default value: on

force_read_from_rw

Parameter description: Forces data to be read from other logical clusters in the decoupled storage and compute architecture (i.e., read data from the logical cluster where the table resides). This parameter is supported only by clusters of version 9.0.0 or later.

Type: USERSET

Value range: Boolean

Default value: off

kv_sync_up_timeout

Parameter description: Specifies the timeout interval for KV synchronization in the decoupled storage and compute architecture. This parameter is supported only by clusters of version 9.0.0 or later.

Type: USERSET

Value range: an integer ranging from 0 to 2147483647

Default value: 10min

enable_insert_foreign_table_dop

Parameter description: Specifies whether to enable DOP acceleration when data is written into an OBS foreign table. The number of DOP threads on each DN is determined by **query_dop**. By adjusting its value, you can control the level of parallelism for your queries. This parameter is supported only in 9.1.0.200 and later versions.

Type: USERSET

Value range: Boolean

- **on** indicates that foreign table DOP acceleration is enabled.
- **off** indicates that foreign table DOP acceleration is disabled.

Default value: off

enable_insert_foreign_table_dop_opt

Parameter description: Specifies whether to enable partition redistribution optimization after **insert dop** is enabled for a foreign table. If the number of partitions to be exported is greater than 10 times the number of partitions, you are advised to enable this function to reduce small files in a single partition and improve export performance. This parameter is supported only by 9.1.0.200 and later versions.

Type: USERSET

Value range: Boolean

- **on** indicates that the **insert dop** redistribution optimization of the partitioned foreign table is enabled.
- **off** indicates that the insert dop redistribution optimization of the partitioned foreign table is disabled.

Default value: off

enable_hstore_binlog_table

Parameter description: Specifies whether binlog tables can be created.

Type: SIGHUP

Value range: Boolean

- **on** indicates that binlog tables can be created.
- **off** indicates that binlog tables cannot be created.

Default value: off

enable_generate_binlog

Parameter description: Specifies whether binlogs are generated for DML operations on binlog tables in the current session. This parameter is available only for clusters of version 9.1.0.200 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that binlogs are generated.
- **off** indicates that binlogs are not generated.

Default value: on

binlog_consume_timeout

Parameter description: Specifies the duration for cyclically determining whether all binlog records are consumed during binlog table scaling or **VACUUM FULL** operations. This parameter is available only for clusters of version 8.3.0.100 or later. The unit is second.

Type: SIGHUP

Value range: an integer ranging from 0 to 86400

Default value: 3600

19.21 Auditing

19.21.1 Audit Switch

audit_enabled

Parameter description: Specifies whether to enable or disable the audit process. After the audit process is enabled, the auditing information written by the background process can be read from the pipe and written into audit files.

Type: SIGHUP

Value range: Boolean

- **on** indicates that the auditing function is enabled.
- **off** indicates that the auditing function is disabled.

Default value: on

audit_space_limit

Parameter description: Specifies the total disk space occupied by audit files.

Type: SIGHUP

Value range: an integer ranging from **1024** to **1073741824**. The unit is KB.

Default value: 1GB

audit_object_name_format

Parameter description: Specifies the format of the object name displayed in the **object_name** field of audit logs.

Type: USERSET

Value range: enumerated values

- **single** indicates that the **object_name** field displays a single object name, which is the name of the target object.
- **all** indicates that the **object_name** field displays multiple object names.

Default value: single

 NOTE

If the default value is set to **all**, multiple object names are displayed for SELECT, DELETE, UPDATE, INSERT, MERGE, CREATE TABLE AS, CREATE VIEW AS, DROP USER... CASCADE, DROP OWNED BY... CASCADE, DROP SCHEMA... CASCADE, DROP TABLE... CASCADE, DROP FOREIGN TABLE... CASCADE, and DROP VIEW... CASCADE.

audit_object_details

Parameter description: whether to record the **object_details** field in audit logs. This field indicates the table name, column name, and column type in the audit statement. This parameter is supported only by clusters of version 8.2.1.100 or later.

Type: USERSET

Value range: Boolean

- **on** indicates that the **object_details** field is recorded during the audit.
- **off** indicates that the **object_details** field is not recorded during the audit.

Default value: off

 NOTE

- If this parameter is set to **on**, the table name, column name, and column type in the statement will be audited, which may affect the performance. So, exercise caution when setting this parameter to **on**.
- If this parameter is set to **on**, the **object_details** field records the following statements: **SELECT**, **DELETE**, **UPDATE**, **INSERT**, **MERGE**, **CREATE TABLE AS SELECT**, **GRANT**, and **DECLARE CURSOR**. **GRANT** statements that fail to be executed are not recorded.

19.21.2 Operation Audit

security_enable_options

Parameter description: This parameter lets you use the **grant_to_public**, **grant_with_grant_option**, and **foreign_table_options** functions. These functions are off by default for security. Set this parameter as needed. It works with clusters version 8.2.0 and later.

Type: SIGHUP

Value range: a string

- **grant_to_public** indicates that **grant to public** can be used.
- **grant_with_grant_option** indicates that **with grant option** can be used.
- **foreign_table_options** allows users to perform operations on foreign tables without explicitly granting the **useft** permission to users.

Default value: empty

 NOTE

- In a newly installed cluster, this parameter is left blank by default, indicating that none of **grant_to_public**, **grant_with_grant_option**, and **foreign_table_options** can be used.
- In upgrade scenarios, the default value of this parameter is forward compatible. If the default values of **enable_grant_public** and **enable_grant_option** are **ON** before the upgrade, the default value of **security_enable_options** is **grant_to_public**, **grant_with_grant_option** after the upgrade.

19.22 Transaction Monitoring

By setting transaction timeout alerts, you can monitor transactions that are automatically rolled back and identify statement issues, as well as monitor statements that take too long to execute.

transaction_sync_naptime

Parameter description: For data consistency, when the local transaction's status differs from that in the snapshot of the GTM, other transactions will be blocked. You need to wait for a few minutes until the transaction status of the local host is consistent with that of the GTM. The **gs_clean** tool is automatically triggered for cleansing when the waiting period on the CN exceeds that of **transaction_sync_naptime**. The tool will shorten the blocking time after it completes the cleansing.

Type: USERSET

Value range: an integer. The minimum value is **0**. The unit is second.

Default value: 5s

 NOTE

If the value of this parameter is set to **0**, **gs_clean** will not be automatically invoked for the cleansing before the blocking arrives the duration. Instead, the **gs_clean** tool is invoked by **gs_clean_timeout**. The default value is 5 minutes.

transaction_sync_timeout

Parameter description: For data consistency, when the local transaction's status differs from that in the snapshot of the GTM, other transactions will be blocked. You need to wait for a few minutes until the transaction status of the local host is consistent with that of the GTM. An exception is reported when the waiting duration on the CN exceeds the value of **transaction_sync_timeout**. Roll back the transaction to avoid system blocking due to long time of process response failures (for example, sync lock).

Type: USERSET

Value range: an integer. The minimum value is **0**. The unit is second.

Default value: 10min

 NOTE

- If the value is **0**, no error is reported when the blocking times out or the transaction is rolled back.
- The value of this parameter must be greater than **gs_clean_timeout**. Otherwise, unnecessary transaction rollback will probably occur due to a block timeout caused by residual transactions that have not been deleted by **gs_clean** on a DN.

19.23 GTM Parameters

log_min_messages

Parameter description: Specifies which level of messages will be written into server logs. Each level covers all the levels following it. The lower the level is, the fewer messages will be written into the log.

NOTICE

If the values of **client_min_messages** and **log_min_messages** are the same, they indicate different levels.

Type: SUSET

Valid values: enumerated values. Valid values are **debug**, **debug5**, **debug4**, **debug3**, **debug2**, **debug1**, **info**, **log**, **notice**, **warning**, **error**, **fatal**, and **panic**. For details about the parameters, see [Table 19-1](#).

Default value: warning

19.24 Miscellaneous Parameters

server_version

Parameter description: Specifies the server version number in the string format.

Type: INTERNAL ((Fixed parameter. You are not advised to configure this parameter because incorrect values may cause compatibility issues.)

Value range: a string

Default value: 9.2.4

server_version_num

Parameter description: Specifies the server version number in the integer format.

Type: INTERNAL ((Fixed parameter. You are not advised to configure this parameter because incorrect values may cause compatibility issues.)

Value range: an integer

Default value: 90204

enable_cluster_resize

Parameter description: Indicates whether the current session is for scaling or redistributing data. It should only be used for these specific sessions and not set for other service sessions.

Type: SUSET

Value range: Boolean

- **on** indicates that the current session is for scaling or redistributing data, and allows the execution of specific SQL statements for redistribution.
- **off** indicates that the current session is not for scaling or redistributing data, and does not allow the execution of specific SQL statements for redistribution.

Default value: off

NOTE

This parameter is used for internal O&M. Do not set it to **on** unless absolutely necessary.

dfs_partition_directory_length

Parameter description: Specifies the largest directory name length for the partition directory of a table partitioned by VALUE in the HDFS.

Type: USERSET

Value range: 92 to 7999

Default value: 512

enable_hadoop_env

Parameter description: Sets whether local row- and column-store tables can be created in a database while the Hadoop feature is used. In the DWS cluster, it is set to **off** by default to support local row- and column- based storage and cross-cluster access to Hadoop. You are not advised to change the value of this parameter.

Type: USERSET

Value range: Boolean

- **on** or **true**, indicating that local row- and column-store tables cannot be created in a database while the Hadoop feature is used.
- **off** or **false**, indicating that local row- and column-based tables can be created in a database while the Hadoop feature is used.

Default value: off

enable_upgrade_merge_lock_mode

Parameter description: If this parameter is set to **on**, the delta merge operation internally increases the lock level, and errors can be avoided when update and delete operations are performed at the same time.

Type: USERSET

Value range: Boolean

- If this parameter is set to **on**, the delta merge operation internally increases the lock level. In this way, when any two of the **DELTAMERGE**, **UPDATE**, and **DELETE** operations are concurrently performed, an operation can be performed only after the previous one is complete.
- If this parameter is set to **off**, and any two of the **DELTAMERGE**, **UPDATE**, and **DELETE** operations are concurrently performed to data in a row in the delta table of the HDFS table, errors will be reported during the later operation, and the operation will stop.

Default value: off

job_queue_processes

Parameter description: Specifies the number of jobs that can be concurrently executed.

Type: POSTMASTER

Value range: 0 to 1000

Functions:

- Setting **job_queue_processes** to **0** indicates that the scheduled task function is disabled and that no job will be executed. (Enabling scheduled tasks may affect the system performance. At sites where this function is not required, you are advised to disable it.)
- Setting **job_queue_processes** to a value that is greater than **0** indicates that the scheduled task function is enabled and this value is the maximum number of tasks that can be concurrently processed.

After the scheduled task function is enabled, the **job_scheduler** thread at a scheduled interval polls the **pg_jobs** system catalog. The scheduled task check is performed every second by default.

Too many concurrent tasks consume many system resources, so you need to set the number of concurrent tasks to be processed. If the current number of concurrent tasks reaches **job_queue_processes** and some of them expire, these tasks will be postponed to the next polling period. Therefore, you are advised to set the polling interval (the **interval** parameter of the **submit** API) based on the execution duration of each task to avoid the problem that tasks in the next polling period cannot be properly processed because overlong task execution time.

Note: If the number of parallel jobs is large and the value is too small, these jobs will wait in queues. However, a large parameter value leads to large resource consumption. You are advised to set this parameter to **100** and change it based on the system resource condition.

Default value: 10

ngram_gram_size

Parameter description: Specifies the length of the ngram parser segmentation.

Type: USERSET

Value range: an integer ranging from 1 to 4

Default value: 2

nggram_grapsymbol_ignore

Parameter description: Specifies whether the ngram parser ignores graphical characters.

Type: USERSET

Value range: Boolean

- **on:** Ignores graphical characters.
- **off:** Does not ignore graphical characters.

Default value: off

nggram_punctuation_ignore

Parameter description: Specifies whether the ngram parser ignores punctuations.

Type: USERSET

Value range: Boolean

- **on:** Ignores punctuations.
- **off:** Does not ignore punctuations.

Default value: on

zhparser_multi_duality

Parameter description: Specifies whether Zhparser aggregates segments in long words with duality.

Type: USERSET

Value range: Boolean

- **on:** Aggregates segments in long words with duality.
- **off:** Does not aggregate segments in long words with duality.

Default value: off

zhparser_multi_short

Parameter description: Specifies whether Zhparser executes long words composite divide.

Type: USERSET

Value range: Boolean

- **on:** Performs compound segmentation for long words.
- **off:** Does not perform compound segmentation for long words.

Default value: on

zhparser_multi_zall

Parameter description: Specifies whether Zhparser displays all single words individually.

Type: USERSET

Value range: Boolean

- **on:** Displays all single words separately.
- **off:** Does not display all single words separately.

Default value: off

zhparser_multi_zmain

Parameter description: Specifies whether Zhparser displays important single words separately.

Type: USERSET

Value range: Boolean

- **on:** Displays important single words separately.
- **off:** Does not display important single words separately.

Default value: off

zhparser_punctuation_ignore

Parameter description: Specifies whether the Zhparser segmentation result ignores special characters including punctuations (\r and \n will not be ignored).

Type: USERSET

Value range: Boolean

- **on:** Ignores all the special characters including punctuations.
- **off:** Does not ignore all the special characters including punctuations.

Default value: on

zhparser_seg_with_duality

Parameter description: Specifies whether Zhparser aggregates segments in long words with duality.

Type: USERSET

Value range: Boolean

- **on:** Aggregates segments in long words with duality.
- **off:** Does not aggregate segments in long words with duality.

Default value: off

acceleration_with_compute_pool

Parameter description: Specifies whether to use the computing resource pool for acceleration when OBS is queried.

Type: USERSET

Value range: Boolean

- **on** indicates that the query covering OBS is accelerated based on the cost when the computing resource pool is available.
- **off** indicates that no query is accelerated using the computing resource pool.

Default value: off

redact_compat_options

Parameter description: Specifies the compatibility option for calculation using masked data. This parameter is supported only by clusters of version 8.1.3.310 or later.

Type: USERSET

Value range: enumerated values

- **none** indicates that compatibility options are specified.
- **disable_comparison_operator_mask** indicates that comparison operators that do not expose raw data can bypass the data masking check and generate the actual calculation result.
- **relaxed_redact_check** indicates that the data masking column type verification is weakly controlled, and the table field column type that depends on data masking can be modified. This option is supported only by clusters of version 9.1.0.223 or later.

Default value: none

table_skewness_warning_threshold

Parameter description: Specifies the threshold for triggering a table skew alarm.

Type: SUSET

Value range: a floating point number ranging from 0 to 1

Default value: 1

table_skewness_warning_rows

Parameter description: Specifies the minimum number of rows for triggering a table skew alarm.

Type: SUSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 100000

enable_view_update

Parameter description: Enables the view update function or not.

Type: POSTMASTER

Value range: Boolean

- **on** indicates that the view update function is enabled.
- **off** indicates that the view update function is disabled.

Default value: off

view_independent

Parameter description: Decouples views from tables, functions, and synonyms or not. After the base table is restored, automatic association and re-creation are supported.

Type: SIGHUP

Value range: Boolean

- **on** indicates that the view decoupling function is enabled. Tables, functions, synonyms, and other views on which views depend can be deleted separately (except temporary tables and temporary views). Associated views are reserved but unavailable.
- **off** indicates that the view decoupling function is disabled. Tables, functions, synonyms, and other views on which views depend cannot be deleted separately. You can only delete them in the cascade mode.

Default value: off

assign_abort_xid

Parameter description: Determines the transaction to be aborted based on the specified XID in a query.

Type: USERSET

Value range: a character string with the specified XID

CAUTION

This parameter is used only for quick restoration if a user deletes data by mistake (DELETE operation). Do not use this parameter in other scenarios. Otherwise, visible transaction errors may occur.

default_distribution_mode

Parameter description: Specifies the default distribution mode of a table. This feature is supported only in 8.1.2 or later.

Type: USERSET

Value range: enumerated values

- **roundrobin**: If the distribution mode is not specified during table creation, the default distribution mode is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation, round-robin distribution is selected.
- **hash**: If the distribution mode is not specified during table creation, the default distribution mode is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation but there are columns whose data types can be used as distribution columns, hash distribution is selected. The distribution column is the first column whose data type can be used as a distribution column.
 - c. If the primary key or unique constraint is not included during table creation and no column whose data type can be used as a distribution column exists, round-robin distribution is selected.

Default value: roundrobin

 NOTE

The default value of this parameter is **roundrobin** for a new DWS 8.1.2 cluster and is **hash** for an upgrade to DWS 8.1.2.

object_mtime_record_mode

Parameter description: Sets the update action of the **mtime** column in the **PG_OBJECT** system catalog.

Type: SIGHUP

Value range: a string

- **default**: **ALTER**, **COMMENT**, **GRANT/REVOKE**, and **TRUNCATE** operations update the **mtime** column by default.
- **disable**: The **mtime** column is not updated.
- **disable_acl**: **GRANT** or **REVOKE** operation does not update the **mtime** column.
- **disable_truncate**: **TRUNCATE** operations do not update the **mtime** column.
- **disable_partition**: Partition **ALTER** operations do not update the **mtime** column.

Default value: default

max_volatile_tables

Parameter description: Specifies the maximum number of volatile tables created for each session, including volatile tables and their auxiliary tables. This parameter is supported by clusters of version 8.2.0 or later.

Type: USERSET

Value range: an integer ranging from 0 to INT_MAX

Default value: 300

query_cache_refresh_time

Parameter description: Specifies the cache refresh interval for queries for which the **enable_accelerate_select** parameter takes effect. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: a floating point number ranging from 0 to 10000.0, in seconds

Default value: 60.0

vector_engine_strategy

Parameter description: Specifies the vectorization enhancement policy. This parameter is supported only by clusters of version 8.3.0 or later.

Type: USERSET

Value range: enumerated values

- **force** specifies that the vectorization-enhanced plan is forcibly rolled back to the row storage plan when there are scenarios that do not support vectorization.
- **improve** specifies that vectorization enhancement is enabled even when there are scenarios that do not support vectorization.

Default value: improve

default temptable_type

Parameter description: Specifies the type of temporary table created when **CREATE TABLE** is used to create a temporary table without specifying the table type before **TEMP** or **TEMPORARY**. This parameter is supported only by clusters of version 9.1.0 or later.

Type: USERSET

Value range: enumerated values

- **local**: creates a local temporary table when the type is not specified.
- **volatile**: creates a volatile temporary table when the type is not specified.

Default value: local

pgxc_node_readonly

Parameter description: Specifies whether a CN or DN is an elastic or classic DN. This parameter is supported only by clusters of version 9.1.0 or later.

Type: SUSET

Value range: Boolean

- **on** indicates that the CN or DN is an elastic node.
- **off** indicates that the CN or DN is a classic node.

Default value: off

hudi_sync_max_commits

Parameter description: Specifies the maximum number of commits for a single synchronization task in Hudi. This parameter is supported only by clusters of version 9.1.0.100 or later.

Type: SIGHUP

Value range: an integer ranging from -1 to INT_MAX

- **-1** indicates no limit.
- **0** indicates no limit.
- Any other value indicates the maximum number of commits.

Default value: -1

foreign_table_default_rw_options

Parameter description: Specifies the default permissions when creating a foreign table without specifying them. This parameter is supported only by clusters of version 9.0.3 or later.

Type: USERSET

Value range: a string

- **READ_ONLY** indicates the read-only permission.
- **WRITE_ONLY** indicates the write-only permission.
- **READ_WRITE** indicates the read-write permission.

Default value: READ_ONLY

20 DWS Developer Terms

A~E

Table 20-1 Terms A to E

| Term | Description |
|--------------|--|
| ACID | Four essential properties that a transaction should have in a DBMS: Atomicity, Consistency, Isolation, and Durability. |
| cluster ring | A cluster ring consists of several physical servers. The primary-standby-secondary relationships among its DNs do not involve external DNs. That is, none of the primary, standby, or secondary counterparts of DNs belonging to the ring are deployed in other rings. A ring is the smallest unit used for scaling. |
| Bgwriter | A background write thread created when the database starts. The thread pushes dirty pages in the database to a permanent device (such as a disk). |
| bit | The smallest unit of information handled by a computer. One bit is expressed as a 1 or a 0 in a binary numeral, or as a true or a false logical condition. A bit is physically represented by an element such as high or low voltage at one point in a circuit, or a small spot on a disk that is magnetized in one way or the other. A single bit conveys little information a human would consider meaningful. A group of eight bits, however, makes up a byte, which can be used to represent many types of information, such as a letter of the alphabet, a decimal digit, or other character. |
| Bloom filter | Bloom filter is a space-efficient binary vectorized data structure, conceived by Burton Howard Bloom in 1970, that is used to test whether an element is a member of a set. False positive matches are possible, but false negatives are not, in other words, a query returns either "possibly in set (possible error)" or "definitely not in set". In the cases, Bloom filter sacrificed the accuracy for time and space. |

| Term | Description |
|---------|---|
| CCN | The Central Coordinator (CCN) is a node responsible for determining, queuing, and scheduling complex operations in each CN to enable the dynamic load management of DWS. |
| CIDR | Classless Inter-Domain Routing (CIDR). CIDR abandons the traditional class-based (class A: 8; class B: 16; and class C: 24) address allocation mode and allows the use of address prefixes of any length, effectively improving the utilization of address space. A CIDR address is in the format of <i>IP address/Number of bits in a network ID</i> . For example, in 192.168.23.35/21, 21 indicates that the first 21 bits are the network prefix and others are the host ID. |
| Cgroups | A control group (Cgroup), also called a priority group (PG) in DWS. The Cgroup is a kernel feature of SUSE Linux and Red Hat that can limit, account for, and isolate the resource usage of a collection of processes. |
| CLI | Command-line interface (CLI). Users use the CLI to interact with applications. Its input and output are based on texts. Commands are entered through keyboards or similar devices and are compiled and executed by applications. The results are displayed in text or graphic forms on the terminal interface. |
| CM | Cluster Manager (CM) manages and monitors the running status of functional units and physical resources in the distributed system, ensuring stable running of the entire system. |
| CMS | The Cluster Management Service (CMS) component manages the cluster status. |
| CN | The Coordinator (CN) stores database metadata, splits query tasks and supports their execution, and aggregates the query results returned from DNs. |
| CTE | A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later in SELECT, INSERT, UPDATE, or DELETE statements multiple times. It simplifies complex queries, and enhances code readability and maintainability. CTEs can significantly improve the maintainability of complex SQL statements, and have obvious advantages in recursive or step-by-step data processing. |
| CU | A compression unit is the smallest storage unit of a column-store table. |

| Term | Description |
|-----------|---|
| core file | <p>A file that is created when memory overwriting, assertion failures, or access to invalid memory occurs in a process, causing it to fail. This file is then used for further analysis.</p> <p>A core file contains a memory dump, in an all-binary and port-specific format. The name of a core file consists of the word "core" and the OS process ID.</p> <p>The core file is available regardless of the type of platform.</p> |
| core dump | <p>When a program stops abnormally, the core dump, memory dump, or system dump records the state of the working memory of the program at that point in time. In practice, other key pieces of program state are usually dumped at the same time, including the processor registers, which may include the program counter and stack pointer, memory management information, and other processor and OS flags and information. A core dump is often used to assist diagnosis and computer program debugging.</p> |
| DBA | <p>A database administrator (DBA) instructs or executes database maintenance operations.</p> |
| DBLINK | <p>An object defining the path from one database to another. A remote database object can be queried with DBLINK.</p> |
| DBMS | <p>Database Management System (DBMS) is a piece of system management software that allows users to access information in a database. This is a collection of programs that allows you to access, manage, and query data in a database. A DBMS can be classified as memory DBMS or disk DBMS based on the location of the data.</p> |
| DCL | <p>Data control language (DCL)</p> |
| DDL | <p>Data definition language (DDL)</p> |
| DFS | <p>A Distributed File System (DFS) stores files on multiple physical nodes and allows access to the files via unified access interfaces. It is not a specific technique, but a system type.</p> <p>For example, Hadoop Distributed File System (HDFS) is a type of DFS and is designed for big data scenarios. It is suitable for high-throughput and batch processing tasks.</p> |
| DML | <p>Data manipulation language (DML)</p> |
| DN | <p>Datanode performs table data storage and query operations.</p> |
| ETCD | <p>The Editable Text Configuration Daemon (ETCD) is a distributed key-value storage system used for configuration sharing and service discovery (registration and search).</p> |
| ETL | <p>Extract-Transform-Load (ETL) refers to the process of data transmission from the source to the target database.</p> |

| Term | Description |
|------------------------|---|
| Extension Connector | Extension Connector is provided by DWS to process data across clusters. It can send SQL statements to Spark, and can return execution results to your database. |
| Backup | A backup, or the process of backing up, refers to the copying and archiving of computer data in case of data loss. |
| backup and restoration | A collection of concepts, procedures, and strategies to protect data loss caused by invalid media or misoperations. |
| standby server | A node in the DWS HA solution. It functions as a backup of the primary server. If the primary server is behaving abnormally, the standby server is promoted to primary, ensuring data service continuity. |
| crash | A crash (or system crash) is an event in which a computer or a program (such as a software application or an OS) ceases to function properly. Often the program will exit after encountering this type of error. Sometimes the offending program may appear to freeze or hang until a crash reporting service documents details of the crash. If the program is a critical part of the OS kernel, the entire computer may crash (possibly resulting in a fatal system error). |
| encoding | Encoding is representing data and information using code so that it can be processed and analyzed by a computer. Characters, digits, and other objects can be converted into digital code, or information and data can be converted into the required electrical pulse signals based on predefined rules. |
| encoding technology | A technology that presents data using a specific set of characters, which can be identified by computer hardware and software. |
| table | A set of columns and rows. Each column is referred to as a field. The value in each field represents a data type. For example, if a table contains people's names, cities, and states, it has three columns: Name , City , and State . In every row in the table, the Name column contains a name, the City column contains a city, and the State column contains a state. |
| tablespace | A tablespace is a logical storage structure that contains tables, indexes, large objects, and long data. A tablespace provides an abstract layer between physical data and logical data, and provides storage space for all database objects. When you create a table, you can specify which tablespace it belongs to. |
| concurrency control | A DBMS service that ensures data integrity when multiple transactions are concurrently executed in a multi-user environment. In a multi-threaded environment, DWS concurrency control ensures that database operations are safe and all database transactions remain consistent at any given time. |

| Term | Description |
|------------------------|---|
| query | A request sent to a database, which may include updates, modifications, retrieval, or deletions of information. |
| query operator | An iterator or a query tree node, which is a basic unit for the execution of a query. Execution of a query can be split into one or more query operators. Common query operators include scan, join, and aggregation. |
| query fragment | Each query task can be split into one or more query fragments. Each query fragment consists of one or more query operators and can independently run on a node. Query fragments exchange data through data flow operators. |
| durability | One of the ACID features of database transactions. Durability indicates that transactions that have been committed will permanently survive and not be rolled back. |
| stored procedure | A group of SQL statements compiled into a single execution plan and stored in a large database system. Users can specify a name and parameters (if any) for a stored procedure to execute the procedure. |
| OS | An operating system (OS) is loaded by a bootstrap program to a computer to manage other programs in the computer. Other programs are applications or application programs. |
| secondary server | To ensure high cluster availability, the primary server synchronizes logs to the secondary server if data synchronization between the primary and standby servers fails. If the primary server suddenly breaks down, the standby server is promoted to primary and synchronizes logs from the secondary server for the duration of the breakdown. |
| BLOB | Binary large object (BLOB) is a collection of binary data stored in a database, such as videos, audio, and images. |
| recursive query | Recursive query is an advanced technology in database query. It is mainly used to process hierarchical data or used in scenarios where layer-by-layer iterative calculation is required. It traverses and analyzes tree structures, graph structures, and chain relationships through recursive invocation. In the SELECT syntax, WITH RECURSIVE is often used to declare recursive queries. For the examples of using recursive queries, see "SELECT" in SQL Syntax. |
| dynamic load balancing | In DWS, dynamic load balancing automatically adjusts the number of concurrent jobs based on the usage of CPU, I/O, and memory to avoid service errors and to prevent the system from stop responding due to system overload. |

| Term | Description |
|---------|--|
| segment | A segment in the database indicates a part containing one or more regions. Region is the smallest range of a database and consists of data blocks. One or more segments comprise a tablespace. |

F~J**Table 20-2** Terms F to J

| Term | Description |
|----------|---|
| Failover | Automatic switchover from a faulty node to its standby node. Reversely, automatic switchback from the standby node to the primary node is called failback. |
| FDW | A foreign data wrapper (FDW) is a SQL interface provided by Postgres. It is used to access big data objects stored in remote data so that DBAs can integrate data from unrelated data sources and store them in public schema in the database. |
| freeze | An operation automatically performed by the AutoVacuum Worker process when transaction IDs are exhausted. DWS records transaction IDs in row headings. When a transaction reads a row, the transaction ID in the row heading and the actual transaction ID are compared to determine whether this row is explicit. Transaction IDs are integers containing no symbols. If exhausted, transaction IDs are re-calculated outside of the integer range, causing the explicit rows to become implicit. To prevent such a problem, the freeze operation marks a transaction ID as a special ID. Rows marked with these special transaction IDs are explicit to all transactions. |
| GDB | As a GNU debugger, GDB allows you to see what is going on 'inside' another program while it executes or what another program was doing the moment that it crashed. GDB can perform four main kinds of things (make PDK functions stronger) to help you catch bugs in the act: <ul style="list-style-type: none">• Starts your program, specifying anything that might affect its behavior.• Stops a program in a specific condition.• Checks what happens when a program stops.• Modifies the program content to rectify the fault and proceeds with the next one. |
| GDS | General Data Service (GDS). To import data to DWS, you need to deploy the tool on the server where the source data is stored so that DNs can use this tool to obtain data. |

| Term | Description |
|-----------|--|
| GIN index | Generalized inverted index (GIN) is used for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. |
| GNU | The GNU Project was publicly announced on September 27, 1983 by Richard Stallman, aiming at building an OS composed wholly of free software. GNU is a recursive acronym for "GNU's Not Unix!". Stallman announced that GNU should be pronounced as Guh-NOO. Technically, GNU is similar to Unix in design, a widely used commercial OS. However, GNU is free software and contains no Unix code. |
| gsql | DWS interaction terminal. It enables you to interactively type in queries, issue them to DWS, and view the query results. Queries can also be entered from files. gsql supports many meta commands and shell-like commands, allowing you to conveniently compile scripts and automate tasks. |
| GTM | Global Transaction Manager (GTM) manages the status of transactions. |
| GUC | Grand unified configuration (GUC) includes parameters for running databases, the values of which determine database system behavior. |
| HA | High availability (HA) is a solution in which two modules operate in primary/standby mode to achieve high availability. This solution helps to minimize the duration of service interruptions caused by routine maintenance (planned) or sudden system breakdowns (unplanned), improving the system and application usability. |
| HBA | Host-based authentication (HBA) allows hosts to authenticate on behalf of all or some of the system users. It can apply to all users on a system or a subset using the Match directive. This type of authentication can be useful for managing computing clusters and other fairly homogenous pools of machines. In all, three files on the server and one on the client must be modified to prepare for host-based authentication. |
| HDFS | Hadoop Distributed File System (HDFS) is a subproject of Apache Hadoop. HDFS is highly fault tolerant and is designed to run on low-end hardware. The HDFS provides high-throughput access to large data sets and is ideal for applications having large data sets. |
| server | A combination of hardware and software designed for providing clients with services. This word alone refers to the computer running the server OS, or the software or dedicated hardware providing services. |

| Term | Description |
|----------------------|---|
| advanced package | Logical and functional stored procedures and functions provided by DWS. |
| isolation | One of the ACID features of database transactions. Isolation means that the operations inside a transaction and data used are isolated from other concurrent transactions. The concurrent transactions do not affect each other. |
| relational database | A database created using a relational model. It processes data using methods of set algebra. |
| archive thread | A thread started when the archive function is enabled on a database. The thread archives database logs to a specified path. |
| failover | The automatic substitution of a functionally equivalent system component for a failed one. The system component can be a processor, server, network, or database. |
| environment variable | An environment variable defines the part of the environment in which a process runs. For example, it can define the part of the environment as the main directory, command search path, terminal that is in use, or the current time zone. |
| checkpoint | A mechanism that stores data in the database memory to disks at a certain time. DWS periodically stores the data of committed and uncommitted transactions to disks. The data and redo logs can be used for database restoration if a database restarts or breaks down. |
| encryption | A function hiding information content during data transmission to prevent the unauthorized use of the information. |
| node | Cluster nodes (or nodes) are physical and virtual servers that make up the DWS cluster environment. |
| error correction | A technique that automatically detects and corrects errors in software and data streams to improve system stability and reliability |
| process | An instance of a computer program that is being executed. A process may be made up of multiple threads of execution. Other processes cannot use a thread occupied by the process. |
| PITR | Point-In-Time Recovery (PITR) is a backup and restoration feature of DWS. Data can be restored to a specified point in time if backup data and WALs are normal. |
| record | In a relational database, a record corresponds to data in each row of a table. |
| cluster | A cluster is an independent system consisting of servers and other resources, ensuring high availability. In certain conditions, clusters can implement load balancing and concurrent processing of transactions. |

K~O

Table 20-3 Terms K to O

| Term | Description |
|--------------------------|--|
| LLVM | <p>LLVM is short for Low Level Virtual Machine. Low Level Virtual Machine (LLVM) is a compiler framework written in C++ and is designed to optimize the compile-time, link-time, run-time, and idle-time of programs that are written in arbitrary programming languages. It is open to developers and compatible with existing scripts.</p> <p>DWS LLVM dynamic compilation can be used to generate customized machine code for each query to replace original common functions. Query performance is improved by reducing redundant judgment conditions and virtual function invocation, and by making local data more accurate during actual queries.</p> |
| LVS | Linux Virtual Server (LVS), a virtual server cluster system, is used for balancing the load of a cluster. |
| logical replication | Data synchronization mode between primary and standby databases or between two clusters. Different from physical replication which replays physical logs, logical replication transfers logical logs between two clusters or synchronizes data through SQL statements in logical logs. |
| logical log | Logs recording database changes made through SQL statements. Generally, the changes are logged at the row level. Logical logs are different from physical logs that record changes of physical pages. |
| logical decoding | Logic decoding is a process of extracting all permanent changes in database tables into a clear and easy-to-understand format by decoding Xlogs. |
| logical replication slot | In a logical replication process, logic replication slots are used to prevent Xlogs from being reclaimed by the system or VACUUM . In DWS, a logical replication slot is an object that records logical decoding positions. It can be created, deleted, read, and pushed by invoking SQL functions. |
| MPP | Massive Parallel Processing (MPP) refers to cluster architecture that consists of multiple machines. The architecture is also called a cluster system. |
| MVCC | Multi-Version Concurrency Control (MVCC) is a protocol that allows a tuple to have multiple versions, on which different query operations can be performed. A basic advantage is that read and write operations do not conflict. |

| Term | Description |
|-----------------------|---|
| NameNode | The NameNode is the centerpiece of a Hadoop file system, managing the namespace of the file system and client access to files. |
| mmap | Memory map, that is, memory mapping. mmap maps files or other objects into the address space of a process. The files or devices can be accessed as if they were in the memory, without being read or written. mmap enables efficient file reading and writing and inter-process communications. |
| Node Group | In DWS, a Node Group refers to a DN set, which is a sub-cluster. Node Groups can be classified into Storage Node Groups, which store local table data; and Computing Node Groups, which perform aggregation and join for queries. |
| NULL FIRST | <p>In SQL, NULL FIRST is a clause used to explicitly control the positions of NULL values during sorting. It is usually used in the ORDER BY statement. It puts NULL values before non-NULL values.</p> <p>When NULL FIRST is used in ORDER BY, all rows with NULL values are displayed first in the result set, followed by the rows with non-null values, regardless of whether the sorting order is ASC or DESC.</p> |
| OLAP | Online analytical processing (OLAP) is the most important application in the database warehouse system. It is dedicated to complex analytical operations, helps decision makers and executives to make decisions, and rapidly and flexibly processes complex queries involving a great amount of data based on analysts' requirements. In addition, the OLAP provides decision makers with query results that are easy to understand, allowing them to learn the operating status of the enterprise. These decision makers can then produce informed and accurate solutions based on the query results. |
| OM | Operations Management (OM) provides management interfaces and tools for routine maintenance and configuration management of the cluster. |
| ORC | Optimized Row Columnar (ORC) is a widely used file format for structured data in a Hadoop system. It was introduced from the Hadoop HIVE project. |
| client | A computer or program that accesses or requests services from another computer or program. |
| free space management | A mechanism for managing free space in a table. This mechanism enables the database system to record free space in each table and establish an easy-to-search data structure, accelerating operations (such as INSERT) performed on the free space. |

| Term | Description |
|---------------|--|
| cross-cluster | In DWS, users can access data in other DBMS through foreign tables or using an Extension Connector. Such access is cross-cluster. |
| junk tuple | A tuple that is deleted using the DELETE and UPDATE statements. When deleting a tuple, DWS only marks the tuples that are to be cleared. The Vacuum thread will then periodically clear these junk tuples. |
| column | An equivalent concept of "field". A database table consists of one or more columns. Together they describe all attributes of a record in the table. |
| logical node | Multiple logical nodes can be installed on the same node. A logical node is a database instance. |
| schema | A collection of database objects that define the logical structure, such as tables, views, sequences, stored procedures, synonyms, indexes, clusters, and database links. |
| schema file | A SQL file that determines the database structure. |

P~T**Table 20-4** Terms P to T

| Term | Description |
|-------------|--|
| Page | Minimum memory unit for row storage in the DWS relational object structure. The default size of a page is 8 KB. By default, the page size is determined during database initialization and cannot be dynamically changed. |
| PostgreSQL | An open-source DBMS developed by volunteers all over the world. PostgreSQL is not controlled by any companies or individuals. Its source code can be used for free. |
| Postgres-XC | Postgres-XC is an open source PostgreSQL cluster to provide write-scalable, synchronous, multi-master PostgreSQL cluster solution. |
| Postmaster | A thread started when the database service is started. It listens to connection requests from other nodes in the cluster or from clients.

After receiving and accepting a connection request from the standby server, the primary server creates a WAL Sender thread to interact with the standby server. |
| RHEL | Red Hat Enterprise Linux (RHEL) |

| Term | Description |
|-----------------------------|--|
| redo log | A log that contains information required for performing an operation again in a database. If a database is faulty, redo logs can be used to restore the database to its original state. |
| SCTP | The Stream Control Transmission Protocol (SCTP) is a transport-layer protocol defined by Internet Engineering Task Force (IETF) in 2000. The protocol ensures the reliability of datagram transport based on unreliable service transmission protocols by transferring SCN narrowband signaling over IP network. |
| savepoint | A savepoint marks the end of a sub-transaction (also known as a nested transaction) in a relational DBMS. The process of a long transaction can be divided into several parts. After a part is successfully executed, a savepoint will be created. If later execution fails, the transaction will be rolled back to the savepoint instead of being totally rolled back. This is helpful for recovering database applications from complex errors. If an error occurs in a multi-statement transaction, the application can recover by rolling back to the save point without terminating the entire transaction. |
| session | A task created by a database for a connection when an application attempts to connect to the database. Sessions are managed by the session manager. They execute initial tasks to perform all user operations. |
| shared-nothing architecture | A distributed computing architecture, in which none of the nodes share CPUs or storage resources. This architecture has good scalability. |
| SIMD | Single Instruction, Multiple Data (SIMD) is a parallel computing technique where a single instruction operates on multiple data elements simultaneously. It significantly improves the performance of compute-intensive tasks. |
| SLES | SUSE Linux Enterprise Server (SLES) is an enterprise Linux OS provided by SUSE. |
| SMP | Symmetric multiprocessing (SMP) lets multiple CPUs run on a computer and share the same memory and bus. To ensure an SMP system achieves high performance, an OS must support multi-tasking and multi-thread processing. In databases, SMP means to concurrently execute queries using the multi-thread technology, efficiently using all CPU resources and improving query performance. |
| SQL | Structure Query Language (SQL) is a standard database query language. It consists of DDL, DML, and DCL. |

| Term | Description |
|----------------------|--|
| SSL | Secure Socket Layer (SSL) is a network security protocol introduced by Netscape. It is a security protocol based on the TCP and IP communications protocols and uses the public key technology. SSL supports a wide range of networks and provides three basic security services, all of which use the public key technology. SSL ensures the security of service communication through the network by establishing a secure connection between the client and server and then sending data through this connection. |
| convergence ratio | Downlink to uplink bandwidth ratio of a switch. A high convergence ratio indicates a highly converged traffic environment and severe packet loss. |
| TCP | Transmission Control Protocol (TCP) sends and receives data through the IP protocol. It splits data into packets for sending, and checks and reassembles received package to obtain original information. TCP is a connection-oriented, reliable protocol that ensures information correctness in transmission. |
| trace | A way of logging to record information about the way a program is executed. This information is typically used by programmers for debugging purposes. System administrators and technical support can diagnose common problems by using software monitoring tools and based on this information. |
| escape character | In a database, an escape character is a special character used to escape other characters. It enables the database system to identify and correctly process characters that have special meanings and may conflict with SQL syntax (such as quotation marks and special characters) as common characters. Common escape characters include backslashes (\) and double quotation marks ("). |
| full backup | Backup of the entire database cluster. |
| full synchronization | A data synchronization mechanism specified in the DWS HA solution. Used to synchronize all data from the primary server to a standby server. |
| log file | A file to which a computer system writes a record of its activities. |
| transaction | A logical unit of work performed within a DBMS against a database. A transaction consists of a limited database operation sequence, and must have ACID features. |
| data | A representation of facts or directives for manual or automatic communication, explanation, or processing. Data includes constants, variables, arrays, and strings. |
| data redistribution | A process whereby a data table is redistributed among nodes after users change the data distribution mode. |

| Term | Description |
|--------------------|---|
| data distribution | A mode in which table data is split and stored on each database instance in a distributed system. Table data can be distributed in hash, replication, or random mode. In hash mode, a hash value is calculated based on the value of a specified column in a tuple, and then the target storage location of the tuple is determined based on the mapping between nodes and hash values. In replication mode, tuples are replicated to all nodes. In random mode, data is randomly distributed to the nodes. |
| data partitioning | A division of a logical database or its constituent elements into multiple parts (partitions) whose data does not overlap based on specified ranges. Data is mapped to storage locations based on the value ranges of specific columns in a tuple. |
| database | A collection of data that is stored together and can be accessed, managed, and updated. Data in a view in the database can be classified into the following types: numerals, full text, digits, and images. |
| DB instance | A database instance consists of a process in DWS and files controlled by the process. DWS installs multiple database instances on one physical node. GTM, CM, CN, and DN installed on cluster nodes are all database instances. A database instance is also called a logical node. |
| database HA | DWS provides a highly reliable HA solution. Every logical node in DWS is identified as a primary or standby node. Only one DWS node is identified as primary at a time. When the HA system is deployed for the first time, the primary server synchronizes all data from each standby server (full synchronization). The HA system then synchronizes only data that is new or has been modified from each standby server (incremental synchronization). When the HA system is running, the primary server can receive data read and write operation requests and the standby servers only synchronize logs. |
| database file | A binary file that stores user data and the data inside the database system. |
| data flow operator | An operator that exchanges data among query fragments. By their input/output relationships, data flows can be categorized into Gather flows, Broadcast flows, and Redistribution flows. Gather combines multiple query fragments of data into one. Broadcast forwards the data of one query fragment to multiple query fragments. Redistribution reorganizes the data of multiple query fragments and then redistributes the reorganized data to multiple query fragments. |
| data dictionary | A reserved table within a database which is used to store information about the database itself. The information includes database design information, stored procedure information, user rights, user statistics, database process information, database increase statistics, and database performance statistics. |

| Term | Description |
|------------|--|
| deadlock | Unresolved contention for the use of resources. |
| index | An ordered data structure in the database management system. An index accelerates querying and the updating of data in database tables. |
| statistics | Information that is automatically collected by databases, including table-level information (number of tuples and number of pages) and column-level information (column value range distribution histogram). Statistics in databases are used to estimate the cost of execution plans to find the plan with the lowest cost. |
| stop word | In computing, stop words are words which are filtered out before or after processing of natural language data (text), saving storage space and improving search efficiency. |

U~Z

Table 20-5 Terms U to Z

| Term | Description |
|----------------|---|
| unlogged table | Unlogged tables are a special type of tables that do not record write-ahead logs (WALs) for data operations. These table can significantly improve write performance in some scenarios. However, they are automatically truncated upon conflicts, OS restart, forcible restart, power-off, or unexpected shutdown, which may cause data loss. The content of an unlogged table is not replicated to standby servers. Any indexes created on an unlogged table are not automatically logged as well.
The CREATE TABLE syntax creates unlogged tables if UNLOGGED is specified. |
| Vacuum | A thread that is periodically started up by a database to clear junk tuples. Multiple Vacuum threads can be started concurrently by setting a parameter. |
| V2 table | A V2 table refers to a table whose colversion defined in the CREATE TABLE syntax is 2.0 during table creation, indicating that each column of the column-store table is combined and stored in a file named relfilenode.C1.0 , and data is stored on the local disk. For storage-compute coupled clusters, if colversion is not specified, the created column-store table is a V2 table by default. |

| Term | Description |
|----------------|---|
| V3 table | A V3 table refers to a table whose colversion defined in the CREATE TABLE syntax is 3.0 during table creation, indicating that each column of the column-store table is stored in a file named C1_field.0 , and data is stored in the OBS file system. For storage-compute coupled clusters, if colversion is not specified, the created column-store table is a V3 table by default. |
| verbose | The VERBOSE option specifies the information to be displayed. |
| WAL | Write-ahead logging (WAL) is a standard method for logging a transaction. Corresponding logs must be written into a permanent device before a data file (carrier for a table and index) is modified. |
| WAL Receiver | A thread created by the standby server during database duplication. The thread is used to receive data and commands from the primary server and to tell the primary server that the data and commands have been acknowledged. Only one WAL receiver thread can run on one standby server. |
| WAL Sender | Name of a thread created by the primary node after the primary node receives a connection request from the standby node during database replication. This thread is used to send data and commands to standby servers and to receive responses from the standby servers. Multiple WAL Sender threads may run on one primary server. Each WAL Sender thread corresponds to a connection request initiated by a standby server. |
| WAL Writer | A thread for writing redo logs that are created when a database is started. This thread is used to write logs in the memory to a permanent device, such as a disk. |
| WLM | The WorkLoad Manager (WLM) is a module for controlling and allocating system resources in DWS. |
| Xlog | A transaction log. A logical node can have only one Xlog file. |
| xDR | X detailed record. It refers to detailed records on the user and signaling plans and can be categorized into charging data records (CDRs), user flow data records (UFDRs), transaction detail records (TDRs), and data records (SDRs). |
| network backup | Network backup provides a comprehensive and flexible data protection solution to Windows, UNIX, and Linux platforms. Network backup can back up, archive, and restore files, folders, directories, volumes, and partitions on a computer. |
| Predicate | A predicate is a logical expression used to filter or limit data. It is essentially a conditional expression that returns a Boolean value (TRUE , FALSE , or NULL). Predicates are used in WHERE, CHECK, and JOIN clauses. For example, salary > 5000 in WHERE salary > 5000 , is a predicate. |

| Term | Description |
|-------------------|---|
| predicate column | A predicate column is a column referenced in a predicate expression. For example, salary in salary > 5000 is the predicate column. If the predicate column in a query contains an index, the query optimizer may use the index to accelerate data filtering. This is called "index scan". DWS collects statistics on predicate columns (supported by clusters of version 9.1.0.100 and later) to help generate better query plans. |
| physical node | A physical machine or device. |
| materialized view | A materialized view is a special database object. It pre-computes complex query results and stores them in the database to accelerate queries. |
| system catalog | A table storing meta information about the database. The meta information includes user tables, indexes, columns, functions, and the data types in a database. |
| pushdown | DWS is a distributed database, where CN can send a query plan to multiple DNs for parallel execution. This CN behavior is called pushdown. It achieves better query performance than extracting data to CN for query. |
| compression | Data compression, source coding, or bit-rate reduction involves encoding information that uses fewer bits than the original representation. Compression can be either lossy or lossless. Lossless compression reduces bits by identifying and eliminating statistical redundancy. No information is lost in lossless compression. Lossy compression reduces bits by identifying and removing unnecessary or unimportant information. The process of reducing the size of a data file is commonly referred as data compression, although its formal name is source coding (coding done at the source of the data, before it is stored or transmitted). |
| consistency | One of the ACID features of database transactions. Consistency is a database status. In such a status, data in the database must comply with integrity constraints. |
| metadata | Data that provides information about other data. Metadata describes the source, size, format, or other characteristics of data. In database columns, metadata explains the content of a data warehouse. |
| atomicity | One of the ACID features of database transactions. Atomicity means that a transaction is composed of an indivisible unit of work. All operations performed in a transaction must either be committed or uncommitted. If an error occurs during transaction execution, the transaction is rolled back to the state when it was not committed. |

| Term | Description |
|-----------------------------|--|
| Zhparser | Zhparser is an extension for full-text search of Chinese. It provides Chinese word segmentation, enabling DWS to process Chinese text search and analysis requests more efficiently. |
| online scale-out | Online scale-out means that data can be saved to the database and query services are not interrupted during redistribution in DWS. |
| dirty page | A page that has been modified and is not written to a permanent device. |
| incremental backup | Incremental backup stores all files changed since the last valid backup. |
| incremental synchronization | A data synchronization mechanism in the DWS HA solution. Only data modified since the last synchronization is synchronized to the standby server. |
| Host | A node that receives data read and write operations in the DWS HA system and works with all standby servers. At any time, only one node in the HA system is identified as the primary server. |
| thesaurus | Standardized words or phrases that express document themes and are used for indexing and retrieval. |
| dump file | A specific type of the trace file. A dump is typically a one-time output of diagnostic data in response to an event, whereas a trace tends to be continuous output of diagnostic data. |
| resource pool | Resource pools used for allocating resources in DWS. By binding a user to a resource pool, you can limit the priority of the jobs executed by the user and resources available to the jobs. |
| tenant | A database service user who runs services using allocated computing (CPU, memory, and I/O) and storage resources. Service level agreements (SLAs) are met through resource management and isolation. |
| minimum restoration point | A method used by DWS to ensure data consistency. During startup, DWS checks consistency between the latest WAL logs and the minimum restoration point. If the record location of the minimum restoration point is greater than that of the latest WAL logs, the database fails to start. |

21 SQL Syntax Reference

21.1 DWS SQL Overview

What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, section "SQL Reference" describes data types, expressions, functions, and operators in addition to SQL syntax.

Development of SQL Standards

Released SQL standards are as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999: ISO/IEC 9075:1999, SQL:1999 (SQL3)
- 2003: ISO/IEC 9075:2003, SQL:2003 (SQL4)
- 2011: ISO/IEC 9075:200N, SQL:2011 (SQL5)

Supported SQL Standards

DWS is compatible with Postgres-XC features and supports the major features of SQL2, SQL3, and SQL4 by default, and some features of SQL5.

Languages Supported by DWS

DWS supports PL/pgSQL and PL/Java.

SQL Example Description

SQL examples in this manual are developed based on the TPC-DS model. Before you execute the examples, install the TPC-DS benchmark by following the instructions on the official website <https://www.tpc.org/tpcds/>.

21.2 DWS SQL Syntax

To better understand how to use the syntax, you can refer to the following description of SQL syntax text conventions.

Table 21-1 SQL Syntax Description

| Format | Description |
|--------------------------|--|
| Uppercase characters | Keywords must be in uppercase. |
| Lowercase characters | Parameters must be in lowercase. |
| [] | Optional syntax item. Items in brackets [] are optional. |
| { } | Mandatory syntax item. |
| ... | Preceding elements can appear repeatedly. |
| [x y ...] | One item is selected from two or more options or no item is selected. |
| { x y ... } | One item is selected from two or more options. |
| [x y ...] [...] | You can choose either multiple parameters or no parameters. If you choose multiple parameters, simply separate them with spaces. |
| [x y ...] [,...] | You can choose either multiple parameters or no parameters. If you choose multiple parameters, simply separate them with commas (,). |
| { x y ... } [...] | You must select at least one parameter. If you select multiple parameters, separate them with spaces. |
| { x y ... } [,...] | You must select at least one parameter. If you select multiple parameters, separate them with commas (,). |

21.3 Differences Between DWS and PostgreSQL

The differences between DWS and PostgreSQL are sorted based on PostgreSQL 9.X. The differences are as follows:

Client Differences

DWS **gsql** differs from PostgreSQL **psql** in that the former has made the following changes to enhance security:

- User passwords cannot be set by running the **\password** meta-command.
- The **\i+**, **\ir+**, and **\include_relative+** meta-commands and the input and output parameter **-k** are added to encrypt imported and exported files.
- Historical command lines cannot be printed to files using the **\s** meta-command.
- SQL statements related to sensitive operations, such as those containing passwords, are not recorded. Users cannot see such records when they turn pages or press up or down arrow keys to view the SQL history.
- After a connection is set up, a message is displayed to inform users of password expiration and to show version information.

gsql provides the following additional functions based on **psql**:

- The output format parameter **-r** is added to allow you to adjust the focus by pressing the **Tab** key or arrow keys when entering commands.
- The **\parallel** meta-command is added to improve execution performance.
- The **\set RETRY** meta-command is added to support retry upon statement errors.
- Slashes (/) are used as the default terminator at the end of PL/SQL statements **CREATE OR REPLACE FUNCTION/PROCEDURE**.

libpq:

During the development of certain DWS functions such as the gsql client connection tool, PostgreSQL libpq is greatly modified. However, the libpq interface is not verified in application development. Therefore, underlying risks probably exist. You can use the ODBC or JDBC APIs instead.

SQL Statement Differences

Table 21-2 PostgreSQL syntaxes not supported by DWS

| Type | Syntaxes Not Supported by DWS | Description |
|------|-------------------------------|---|
| Data | Geometric lines | For details about the data types supported by DWS, see Data Types . |
| | pg_node_tree | |

| Type | Syntaxes Not Supported by DWS | Description |
|------------|--|--|
| Functions | Enumeration functions: <ul style="list-style-type: none">enum_first(anyenum)enum_last(anyenum)enum_range(anyenum)enum_range(anyenum, anyenum) | For details about the functions supported by DWS, see Functions and Operators . |
| | Access permission query functions: <ul style="list-style-type: none">has_sequence_privilege(user, sequence, privilege)has_sequence_privilege(sequence, privilege) | |
| | System directory information functions: <ul style="list-style-type: none">pg_get_triggerdef(trigger_oid)pg_get_triggerdef(trigger_oid, pretty_bool) | |
| | Geometric type conversion function:
line(point, point) | |
| | pg_node_tree | |
| SQL syntax | CREATE TABLE clause:
INHERITS (parent_table [, ...]) | Inherits tables. |
| | CREATE TABLE column constraints:
REFERENCES reftable [(refcolumn)]
[MATCH FULL MATCH PARTIAL MATCH SIMPLE] [ON DELETE action] [ON UPDATE action] | Use REFERENCES reftable [(refcolumn)] [MATCH FULL MATCH PARTIAL MATCH SIMPLE] [ON DELETE action] [ON UPDATE action] to create a foreign key constraint for a table. |
| | CREATE TABLE table constraints:
EXCLUDE [USING index_method]
(exclude_element WITH operator [, ...]) | Use EXCLUDE [USING index_method] (exclude_element WITH operator [, ...]) to create exclusion constraints for a table. |
| | CREATE/ALTER/DROP EXTENSION | Loads, modifies, and deletes extensions. |
| | CREATE/ALTER/DROP AGGREGATE | Defines, modifies, and deletes aggregate functions. |

| Type | Syntaxes Not Supported by DWS | Description |
|------|--|---|
| | CREATE/ALTER/DROP OPERATOR | Creates, modifies, and deletes operators. |
| | CREATE/ALTER/DROP OPERATOR CLASS | Creates, modifies, and deletes operator classes. |
| | CREATE/ALTER/DROP OPERATOR FAMILY | Creates, modifies, and deletes operator families. |
| | CREATE/ALTER/DROP TEXT SEARCH PARSER | Creates, modifies, and deletes text search parsers. |
| | CREATE/ALTER/DROP TEXT SEARCH TEMPLATE | Create, modify, and delete text search templates. |
| | CREATE/ALTER/DROP COLLATION | Creates, modifies, and deletes collation rules. |
| | CREATE/ALTER/DROP CONVERSION | Defines, modifies, and deletes the conversion of character set encoding. |
| | CREATE/ALTER/DROP RULE | Creates, modifies, and deletes rules. |
| | CREATE/ALTER/DROP LANGUAGE | Registers, modifies, and deletes procedural languages (LANGUAGE). |
| | CREATE/ALTER/DROP DOMAIN | Creates, modifies, and deletes domains. |
| | CREATE/DROP CAST | Defines and deletes casts. |
| | CREATE/ALTER/DROP USER MAPPING | Defines, modifies, and deletes user mapping. |
| | SECURITY LABEL | Defines or changes the security tag of an object. |
| | NOTIFY | Generates a notification. |
| | LISTEN | Listens to a notification. |
| | UNLISTEN | Stops listening to a notification. |
| | LOAD | Loads or reloads a shared library file. |
| | DISCARD | Releases session resources of a database. (Clusters of 8.2.0 and later versions support DISCARD .) |

| Type | Syntaxes Not Supported by DWS | Description |
|-------|---------------------------------|---|
| | MOVE BACKWARD | Moves a cursor backward. |
| | COPY FROM FILE and COPY TO FILE | To isolate permissions, COPY FROM FILE and COPY TO FILE are disabled in DWS. |
| Other | User-defined C functions | For details about user-defined functions supported by DWS, see "Data Warehouse Service (DWS) Developer Guide" > "DWS User-Defined Functions". |

21.4 Keyword

The SQL contains reserved and non-reserved words. Reserved keywords must not be used as other identifiers in accordance with standards. Non-reserved keywords have special meanings only in specific environments and can be used as identifiers in other environments. Even so, do not use non-reserved keywords.

You can use **SELECT * FROM pg_get_keywords();** to query the keyword of DWS.

Example: **AUTHORIZATION** is a reserved keyword. Using it as a table name causes an error and prevents the table from being created.

However, you can use **AUTHORIZATION** as a function or type name under certain conditions (see the table below).

Figure 21-1 Using a keyword as a table name

Figure 21-2 Using a keyword as a function name

Identifier Naming Conventions

A database identifier is a name that uniquely identifies an object (such as a table, column, or index) in a database. In a database, identifiers are often used to reference database objects in SQL query statements to ensure the accuracy and consistency of database operations. It is important to name and use identifiers properly. The naming of DWS identifiers must comply with the following rules:

- The identifier must consist of letters (a-z), underscores (_), digits (0-9), and dollar signs (\$).
- An identifier name should start with a letter (a-z) or an underscore (_).
- The identifier can contain a maximum of 63 characters.
- Avoid using SQL reserved words as identifiers. Be careful with non-reserved keywords too.
- If the database uses GBK, UTF8, or SQL_ASCII, identifiers can include Chinese characters. In UTF8 or SQL_ASCII, each Chinese character takes up three bytes, with a maximum of 21 characters. In GBK, each Chinese character takes up two bytes, with a maximum of 31 characters. The **Latin1** character set does not support Chinese characters. The character set is set when creating the database. For details, see [CREATE DATABASE](#).

Table 21-3 SQL keyword list

| Keyword | DWS | SQL:1999 | SQL:1992 |
|----------|--------------|--------------|----------|
| ABORT | Non-reserved | - | - |

21.5 Data Types

21.5.1 Numeric Types

Numeric types consist of two-, four-, and eight-byte integers, four- and eight-byte floating-point numbers, and selectable-precision decimals.

For details about numeric operators and functions, see [Numeric Functions and Operators](#).

DWS supports integers, arbitrary precision numbers, floating point types, and serial integers.

Integer Types

The types TINYINT, SMALLINT, INTEGER, BINARY_INTEGER, and BIGINT store whole numbers, that is, numbers without fractional components, of various ranges. Saving a number with a decimal in any of the data types will result in errors.

The type INTEGER is the common choice. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.

Table 21-4 Integer types

| Column | Description | Storage Space | Range |
|---------|--------------------------------|---------------|---------|
| TINYINT | Tiny integer, also called INT1 | 1 byte | 0 ~ 255 |

| Column | Description | Storage Space | Range |
|----------------|--|---------------|--|
| SMALLINT | Small integer, also called INT2 | 2 bytes | -32,768 ~ +32,767 |
| INTEGER | Typical choice for integer, also called INT4 | 4 bytes | -2,147,483,648 ~ +2,147,483,647 |
| BINARY_INTEGER | INTEGER alias, compatible with Oracle | 4 bytes | -2,147,483,648 ~ +2,147,483,647 |
| BIGINT | Big integer, also called INT8 | 8 bytes | -9,223,372,036,854,775,808 ~ 9,223,372,036,854,775,807 |

Examples:

Create a table containing TINYINT, INTEGER, and BIGINT data.

```
CREATE TABLE int_type_t1
(
  a TINYINT,
  b TINYINT,
  c INTEGER,
  d BIGINT
);
```

Insert data.

```
INSERT INTO int_type_t1 VALUES(100, 10, 1000, 10000);
```

View data.

```
SELECT * FROM int_type_t1;
 a | b | c | d
---+---+---+---
100 | 10 | 1000 | 10000
(1 row)
```

Arbitrary Precision Types

The type NUMBER can store numbers with a very large number of digits. It is especially recommended for storing monetary amounts and other quantities where exactness is required. The arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results than integer types.

The scale of a NUMBER value is the count of decimal digits in the fractional part, to the right of the decimal point. The precision of a NUMBER value is the total count of significant digits in the whole number, that is, the number of digits to both sides of the decimal point. So the number 23.5141 has a precision of 6 and a scale of 4. Integers can be considered to have a scale of zero.

To configure a numeric or decimal column, you are advised to specify both the maximum precision (p) and the maximum scale (s) of the column.

If the precision or scale of a value is greater than the declared scale of the column, the system will round the value to the specified number of fractional digits. Then, if the number of digits to the left of the decimal point exceeds the declared precision minus the declared scale, an error will be reported.

Table 21-5 Any-precision types

| Column | Description | Storage Space | Range |
|---------------------------------------|---|--|---|
| NUMERIC[(p[,s])],
DECIMAL[(p[,s])] | The value range of p (precision) is [1,1000], and the value range of s (standard) is [0,p]. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified |
| NUMBER[(p[,s])] | Alias for type NUMERIC, compatible with Oracle | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified |

Examples:

Create a table with DECIMAL values.

```
CREATE TABLE decimal_type_t1 (DT_COL1 DECIMAL(10,4));
```

Insert data.

```
INSERT INTO decimal_type_t1 VALUES(123456.122331);
```

View data.

```
SELECT * FROM decimal_type_t1;  
dt_col1  
-----  
123456.1223  
(1 row)
```

Floating-Point Types

The floating-point type is an inexact, variable-precision numeric type. This type is an implementation of IEEE Standard 754 for Binary Floating-Point Arithmetic (single and double precision, respectively), to the extent that the underlying processor, OS, and compiler support it.

Table 21-6 Floating point types

| Column | Description | Storage Space | Range |
|------------------------------------|--|--|---|
| REAL,
FLOAT4 | Single precision floating points, inexact | 4 bytes | Six bytes of decimal digits |
| DOUBLE
PRECISION
,
FLOAT8 | Double precision floating points, inexact | 8 bytes | 1E-307~1E+308,
15 bytes of decimal digits |
| FLOAT[(p)
] | Floating points, inexact. The value range of precision (p) is [1,53].
NOTE
p is the precision, indicating the total decimal digits. | 4 or 8 bytes | REAL or DOUBLE PRECISION is selected as an internal identifier based on different precision (p). If no precision is specified, DOUBLE PRECISION is used as the internal identifier. |
| BINARY_D
OUBLE | DOUBLE PRECISION alias, compatible with Oracle | 8 bytes | 1E-307~1E+308,
15 bytes of decimal digits |
| DEC[(p[,s])
] | The value range of p (precision) is [1,1000], and the value range of s (standard) is [0,p].
NOTE
p indicates the total digits, and s indicates the decimal digit. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified |
| INTEGER[(
p[,s])] | The value range of p (precision) is [1,1000], and the value range of s (standard) is [0,p]. | The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data. | Up to 131,072 digits before the decimal point; and up to 16,383 digits after the decimal point when no precision is specified |

Examples:

Create a table with floating-point values.

```
CREATE TABLE float_type_t2  
(
```

```
FT_COL1 INTEGER,  
FT_COL2 FLOAT4,  
FT_COL3 FLOAT8,  
FT_COL4 FLOAT(3),  
FT_COL5 BINARY_DOUBLE,  
FT_COL6 DECIMAL(10,4),  
FT_COL7 INTEGER(6,3)  
) DISTRIBUTE BY HASH ( ft_col1);
```

Insert data.

```
INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654, 123.123654);
```

View data.

```
SELECT * FROM float_type_t2;  
ft_col1 | ft_col2 | ft_col3 | ft_col4 | ft_col5 | ft_col6 | ft_col7  
-----+-----+-----+-----+-----+-----+-----  
10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124  
(1 row)
```

Serial Integers

SMALLSERIAL, SERIAL, and BIGSERIAL are not true types, but merely a notational convenience for creating unique identifier columns. Therefore, an integer column is created and its default value plans to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases you would also want to attach a UNIQUE or PRIMARY KEY constraint to prevent duplicate values from being inserted unexpectedly. Lastly, the sequence is marked as "owned by" the column, so that it will be dropped if the column or table is dropped. Currently, the SERIAL column can be specified only when you create a table. You cannot add the SERIAL column in an existing table. In addition, SERIAL columns cannot be created in temporary tables. Because SERIAL is not a data type, columns cannot be converted to this type.

Table 21-7 Sequence integer

| Column | Description | Storage Space | Range |
|-------------|--------------------------------------|---------------|-------------------------------|
| SMALLSERIAL | Two-byte auto-incrementing integer | 2 bytes | 1 ~ 32,767 |
| SERIAL | Four-byte auto-incrementing integer | 4 bytes | 1 ~ 2,147,483,647 |
| BIGSERIAL | Eight-byte auto-incrementing integer | 8 bytes | 1 ~ 9,223,372,036,854,775,807 |

Examples:

Create a table with serial values.

```
CREATE TABLE smallserial_type_tab(a SMALLSERIAL);
```

Insert data.

```
INSERT INTO smallserial_type_tab VALUES(default);
```

Insert data again.

```
INSERT INTO smallserial_type_tab VALUES(default);
```

View data.

```
SELECT * FROM smallserial_type_tab;  
a  
---  
1  
2  
(2 rows)
```

21.5.2 Monetary Types

The **money** type stores a currency amount with fixed fractional precision. The range shown in [Table 21-8](#) assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as \$1,000.00. Output is generally in the latter form but depends on the locale.

Table 21-8 Monetary types

| Name | Storage Size | Description | Range |
|-------|--------------|-----------------|--|
| money | 8 bytes | Currency amount | -92233720368547758.08 to +92233720368547758.07 |

Values of the **numeric**, **int**, and **bigint** data types can be cast to **money**. Conversion from the **real** and **double precision** data types can be done by casting to **numeric** first, for example:

```
SELECT '12.34'::float8::numeric::money;
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A **money** value can be cast to **numeric** without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
SELECT '52093.89'::money::numeric::float8;
```

When a **money** value is divided by another **money** value, the result is **double precision** (that is, a pure number, not money); the currency units cancel each other out in the division.

21.5.3 Boolean Type

Table 21-9 Boolean type

| Name | Description | Storage Space | Value |
|---------|--------------|---------------|--|
| BOOLEAN | Boolean type | 1 byte | <ul style="list-style-type: none">• true• false• null (unknown) |

Valid literal values for the "true" state are:

TRUE, 't', 'true', 'y', 'yes', '1'

Valid literal values for the "false" state include:

FALSE, 'f', 'false', 'n', 'no', '0'

TRUE and **FALSE** are standard expressions, compatible with SQL statements.

Examples

Data type **boolean** is displayed with letters **t** and **f**.

```
-- Create a table:
CREATE TABLE bool_type_t1
(
    BT_COL1 BOOLEAN,
    BT_COL2 TEXT
) DISTRIBUTE BY HASH(BT_COL2);

--Insert data:
INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data:
SELECT * FROM bool_type_t1;
bt_col1 | bt_col2
-----+-----
t      | sic est
f      | non est
(2 rows)

SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
bt_col1 | bt_col2
-----+-----
t      | sic est
(1 row)

-- Delete the tables:
DROP TABLE bool_type_t1;
```

21.5.4 Character Types

Table 21-10 lists the character types that can be used in DWS. For string operators and related built-in functions, see [String Processing Functions and Operators](#).

Table 21-10 Character types

| Name | Description | Length | Storage Space |
|---|--|--|---|
| CHAR (n) or
BPCHAR
CHARACTER(n)
NCHAR(n) | Fixed-length string. If the length exceeds the value of n , the excess part is truncated. If the length is less than the value of n , spaces are padded. | n indicates the byte length. If it is not specified, the default precision 1 is used. The value of n is less than 10485761 . | The maximum size is 10 MB. |
| VARCHAR(n)
CHARACTER
VARYING(n) | Variable-length string. | n indicates the byte length. The value of n is less than 10485761 . | The maximum size is 10 MB. |
| VARCHAR2(n) | Variable-length string. It is an alias for VARCHAR(n) type, compatible with Oracle. | n indicates the byte length. The value of n is less than 10485761 . | The maximum size is 10 MB. |
| NVARCHAR2(n) | Variable-length string. | n indicates the string length. The value of n is less than 10485761 . | The maximum size is 10 MB. |
| CLOB | Variable-length string. A big text object. It is an alias for TEXT type, compatible with Oracle. | - | The maximum size is 1,073,733,621 bytes (1 GB – 8,203 bytes). |
| TEXT | Variable-length string. | - | The maximum size is 1,073,733,621 bytes (1 GB – 8,203 bytes). |

 NOTE

- In addition to the size limitation on each column, the total size of each tuple is 1,073,733,621 bytes (1 GB – 8,023 bytes).
- For string data, you are advised to use variable-length strings and specify the maximum length. To avoid truncation, ensure that the specified maximum length is greater than the maximum number of characters to be stored. You are not advised to use fixed-length character types such as CHAR(n), NCHAR(n), and CHARACTER(n) unless you know that the data type is a fixed-length character string. In DWS, operations of the fixed-length character type will use extra storage and memory resources.
- Generally, if the data contains Chinese characters, use NCHAR/NVARCHAR2. If the data contains only English characters and digits, use CHAR/VARCHAR.

DWS has two other fixed-length character types, as listed in [Table 21-11](#).

The name type is used only in the internal system catalog as the storage identifier. The length of this type is 64 bytes (63 characters plus the terminator). This data type is not recommended for common users. When the name type is aligned with other data types (for example, in multiple branches of **case when**, one branch returns the name type and other branches return the text type), the name type may be aligned but characters may be truncated. If you do not want to have 64-bit truncated characters, you need to forcibly convert the name type to the text type.

The type **"char"** only uses one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

Table 21-11 Special character types

| Name | Description | Storage Space |
|--------|--------------------------------|---------------|
| name | Internal type for object names | 64 bytes |
| "char" | Single-byte internal type | 1 byte |

Length

If a field is defined as **char(n)** or **varchar(n)**, **n** indicates the maximum length. No matter which type is used, the maximum length that can be set cannot exceed 10,485,760 bytes (that is, 10 MB).

When the data length exceeds the specified length **n**, the error "value too long" is reported. Of course, you can also specify to automatically truncate the data that exceeds the length.

Example:

1. Create table **t1** and specify the character type of its columns.

```
CREATE TABLE t1 (a char(5),b varchar(5));
```
2. An error is reported when the length of data inserted into the table **t1** exceeds the specified byte length.

```
INSERT INTO t1 VALUES('bookstore','123');  
ERROR: value too long for type character(5)  
CONTEXT: referenced column: a
```
3. Insert data into table **t1** and specify that the data is automatically truncated when the length exceeds the specified bytes.

```
INSERT INTO t1 VALUES('bookstore'::char(5),'12345678'::varchar(5));
INSERT 0 1

SELECT a,b FROM t1;
 a | b
-----+-----
books | 12345
(1 row)
```

Fixed Length and Variable Length

All character types can be classified into fixed-length strings and variable-length strings.

- For a fixed-length string, the length must be specified. If the length is not specified, the default length **1** is used. If the data length does not reach the specified length, spaces are automatically added to the end of the string. However, the added spaces are meaningless and will be ignored in actual operations, such as comparison, sorting, and type conversion.
- For a variable-length string, if the length is specified, the specified length indicates the maximum length of the data that can be stored. If the length is not specified, it means any length is available.

Example:

1. Create table **t2** and specify the character type of its columns.

```
CREATE TABLE t2 (a char(5),b varchar(5));
```

2. Insert data into table **t2** and query the byte length of column **a**. During table creation, the character type of column **a** is specified as **char(5)** and fixed-length. If the data length does not reach 5 bytes, spaces are added. Therefore, the queried byte length is **5**.

```
INSERT INTO t2 VALUES('abc','abc');
INSERT 0 1
```

```
SELECT a,lengthb(a),b FROM t2;
 a | lengthb | b
-----+-----
abc |      5 | abc
(1 row)
```

3. After the conversion by using the function, the actual queried length of the column **a** is **3** bytes.

```
SELECT a = b from t2;
?column?
```

```
-----
t
(1 row)
```

```
SELECT cast(a as text) as val,lengthb(val) FROM t2;
 val | lengthb
-----+-----
abc |      3
(1 row)
```

Bytes and Characters

n means differently in **VARCHAR2(n)** and **NVARCHAR2(n)**.

- In **VARCHAR2(n)** **n** indicates the number of bytes.
- In **NVARCHAR2(n)**, **n** indicates the number of characters.

 NOTE

Take an UTF8-encoded database as an example. A letter occupies one byte, and a Chinese character occupies three bytes. **VARCHAR2(6)** allows for six letters or two Chinese characters, and **NVARCHAR2(6)** allows for six letters or six Chinese characters.

Empty Strings and NULL

In Oracle compatibility mode, empty strings and NULL are not distinguished. When a statement is executed to query or import data, empty strings are processed as NULL.

As such, `= ''` cannot be used as the query condition, and so does `is ''`. Otherwise, no result set is returned. The correct usage is **is null**, or **is not null**.

Example:

1. Create table **t4** and specify the character type of its columns.

```
CREATE TABLE t4 (a text);
```
2. Insert data into table **t4**. The inserted value contains an empty string and NULL.

```
INSERT INTO t4 VALUES('abc',''),(null);
INSERT 0 3
```
3. Check whether **t4** contains null values.

```
SELECT a,a isnull FROM t4;
a | ?column?
-----+-----
| t
| t
abc | f
(3 rows)

SELECT a,a isnull FROM t4 WHERE a is null;
a | ?column?
-----+-----
| t
| t
(2 rows)
```

In Teradata and MySQL compatibility mode, empty strings are distinguished from null.

- Example in Teradata compatibility mode:

```
SELECT '' is null , null is null;
isnull | isnull
-----+-----
f      | t
(1 rows)
```

- Example in MySQL compatibility mode:

```
SELECT '' is null , null is null;
isnull | isnull
-----+-----
f      | t
(1 rows)
```

21.5.5 Binary Data Types

Table 21-12 lists the binary data types that can be used in DWS.

Table 21-12 Binary Data Types

| Name | Description | Storage Space |
|-------|--|---|
| BLOB | <p>Binary large object.</p> <p>Currently, BLOB only supports the following external access interfaces:</p> <ul style="list-style-type: none">• DBMS_LOB.GETLENGTH• DBMS_LOB.READ• DBMS_LOB.WRITE• DBMS_LOB.WRITEAPPEND• DBMS_LOB.COPY• DBMS_LOB.ERASE <p>For details about these interfaces, see section "DBMS_LOB" in the <i>Data Warehouse Service (DWS) Developer Guide</i>.</p> <p>NOTE
Column storage cannot be used for the BLOB type.</p> | The maximum size is 10,7373,3621 bytes (1 GB - 8203 bytes). |
| RAW | <p>Variable-length hexadecimal string</p> <p>NOTE
Column storage cannot be used for the raw type.</p> | 4 bytes plus the actual hexadecimal string. The maximum size is 10,7373,3621 bytes (1 GB - 8203 bytes). |
| BYTEA | Variable-length binary string | 4 bytes plus the actual binary string. The maximum size is 10,7373,3621 bytes (1 GB - 8203 bytes). |

 NOTE

In addition to the size limitation on each column, the total size of each tuple is 8203 bytes less than 1 GB.

Examples

```
-- Create a table:
CREATE TABLE blob_type_t1
(
    BT_COL1 INTEGER,
    BT_COL2 BLOB,
    BT_COL3 RAW,
    BT_COL4 BYTEA
) DISTRIBUTE BY REPLICATION;

--Insert data:
INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\xDEADBEEF');
```

```
-- Query data in the table:
SELECT * FROM blob_type_t1;
bt_col1 | bt_col2 | bt_col3 | bt_col4
-----+-----+-----+-----
      10 |      | DEADBEEF | \xdeadbeef
(1 row)

-- Delete the tables:
DROP TABLE blob_type_t1;
```

21.5.6 Date/Time Types

Table 21-13 lists date and time types supported by DWS. For the operators and built-in functions of the types, see [Date and Time Processing Functions and Operators](#).

NOTE

If the time format of another database is different from that described in DWS, modify the value of the **DateStyle** parameter to keep them consistent.

Table 21-13 Date/Time Types

| Name | Description | Storage Space |
|------------------------------------|--|--|
| DATE | In Oracle compatibility mode, it is equivalent to timestamp(0) and records the date and time.
In other modes, it records the date. | In Oracle compatibility mode, it occupies 8 bytes.
In Oracle compatibility mode, it occupies 4 bytes. |
| TIME [(p)] [WITHOUT TIME ZONE] | Specifies time within one day.
p indicates the precision after the decimal point. The value ranges from 0 to 6. | 8 bytes |
| TIME [(p)] [WITH TIME ZONE] | Specifies time within one day (with time zone).
p indicates the precision after the decimal point. The value ranges from 0 to 6. | 12 bytes |
| TIMESTAMP[(p)] [WITHOUT TIME ZONE] | Specifies the date and time.
p indicates the precision after the decimal point. The value ranges from 0 to 6. | 8 bytes |

| Name | Description | Storage Space |
|------------------------------------|---|---------------|
| TIMESTAMP[(p)]
[WITH TIME ZONE] | Specifies the date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ.

p indicates the precision after the decimal point. The value ranges from 0 to 6. | 8 bytes |
| SMALLDATETIME | Specifies the date and time (without time zone).

The precision level is minute. 31s to 59s are rounded into 1 minute. | 8 bytes |
| INTERVAL DAY (l)
TO SECOND (p) | Specifies the time interval (X days X hours X minutes X seconds). <ul style="list-style-type: none">• l: indicates the precision of days. The value ranges from 0 to 6. To adapt to Oracle syntax, the precision functions are not supported.• p: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed. | 16 bytes |

| Name | Description | Storage Space |
|------------------------------|--|---------------|
| INTERVAL [FIELDS]
[(p)] | <p>Specifies the time interval.</p> <ul style="list-style-type: none">• fields: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, DAY TO HOUR, DAY TO MINUTE, DAY TO SECOND, HOUR TO MINUTE, HOUR TO SECOND, and MINUTE TO SECOND.• p: indicates the precision of seconds. The value ranges from 0 to 6. p takes effect only when fields are SECOND, DAY TO SECOND, HOUR TO SECOND, or MINUTE TO SECOND. The digit 0 at the end of a decimal number is not displayed. <p>NOTE
In MySQL compatibility mode of cluster version 9.1.0.200 and later, when the fields are YEAR, MONTH, DAY, HOUR, MINUTE, or SECOND, you can use an integer or floating point number as the input parameter (the number should not include positive or negative signs). For example, you can use INTERVAL 1 YEAR or INTERVAL 2.5 MONTH.</p> | 12 bytes |
| reltime | <p>Relative time interval. The format is:</p> <p><i>X</i> years <i>X</i> months <i>X</i> days <i>XX:XX:XX</i></p> <ul style="list-style-type: none">• The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value. The output format is POSTGRES. | 4 bytes |

Example:

```
--Create a table:
CREATE TABLE date_type_tab(coll date);

--Insert data:
INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data:
SELECT * FROM date_type_tab;
      coll
-----
2010-12-10 00:00:00
(1 row)
```

```
-- Delete the tables:
DROP TABLE date_type_tab;

--Create a table:
CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh timestamp without
time zone,dfga timestamp with time zone, vbg smalldatetime);

--Insert data:
INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11 pst','2003-04-12
04:05:06');

-- View data:
SELECT * FROM time_type_tab;
   da   |   dai   |   dfgh   |   dfga   |   vbg
-----+-----+-----+-----+-----
21:21:21 | 21:21:21-08 | 2010-12-12 00:00:00 | 2013-12-11 16:00:00+08 | 2003-04-12 04:05:00
(1 row)

-- Delete the tables:
DROP TABLE time_type_tab;

--Create a table:
CREATE TABLE day_type_tab (a int,b INTERVAL DAY(3) TO SECOND (4));

--Insert data:
INSERT INTO day_type_tab VALUES (1, INTERVAL '3' DAY);

-- View data:
SELECT * FROM day_type_tab;
 a | b
---+-----
 1 | 3 days
(1 row)

-- Delete the tables:
DROP TABLE day_type_tab;

--Create a table:
CREATE TABLE year_type_tab(a int, b interval year (6));

--Insert data:
INSERT INTO year_type_tab VALUES(1,interval '2' year);

-- View data:
SELECT * FROM year_type_tab;
 a | b
---+-----
 1 | 2 years
(1 row)

-- Delete the tables:
DROP TABLE year_type_tab;
```

Date Input

Date and time input is accepted in almost any reasonable formats, including ISO 8601, SQL-compatible, and traditional POSTGRES. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotes, and the syntax is as follows:

type [(p)] 'value'

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. [Table 21-14](#) shows some possible inputs for the **date** type.

Table 21-14 Date input

| Example | Description |
|------------------|--|
| 1999-01-08 | ISO 8601 (recommended format). January 8, 1999 in any mode |
| January 8, 1999 | Unambiguous in any date input mode |
| 1/8/1999 | January 8 in MDY mode. August 1 in DMY mode |
| 1/18/1999 | January 18 in MDY mode, rejected in other modes |
| 01/02/03 | <ul style="list-style-type: none">January 2, 2003 in MDY modeFebruary 1, 2003 in DMY modeFebruary 3, 2001 in YMD mode |
| 1999-Jan-08 | January 8 in any mode |
| Jan-08-1999 | January 8 in any mode |
| 08-Jan-1999 | January 8 in any mode |
| 99-Jan-08 | January 8 in YMD mode, else error |
| 08-Jan-99 | January 8, except error in YMD mode |
| Jan-08-99 | January 8, except error in YMD mode |
| 19990108 | ISO 8601. January 8, 1999 in any mode |
| 990108 | ISO 8601. January 8, 1999 in any mode |
| 1999.008 | Year and day of year |
| J2451187 | Julian date |
| January 8, 99 BC | Year 99 BC |

Example:

```
--Create a table:
CREATE TABLE date_type_tab(coll date);

--Insert data:
INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data:
SELECT * FROM date_type_tab;

DROP TABLE date_type_tab;
```

Times

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see [Table 21-15](#). For details about time zone input types, see [Table 21-16](#).

Table 21-15 Time input

| Example | Description |
|----------------|---|
| 05:06.8 | ISO 8601 |
| 4:05:06 | ISO 8601 |
| 4:05 | ISO 8601 |
| 40506 | ISO 8601 |
| 4:05 AM | Same as 04:05. AM does not affect value |
| 4:05 PM | Same as 16:05. Input hour must be <= 12 |
| 04:05:06.789-8 | ISO 8601 |
| 04:05:06-08:00 | ISO 8601 |
| 04:05-08:00 | ISO 8601 |
| 040506-08 | ISO 8601 |
| 04:05:06 PST | Time zone specified by abbreviation |

Table 21-16 Time zone input

| Example | Description |
|---------|--|
| PST | Abbreviation (for Pacific Standard Time) |
| -8:00 | ISO-8601 offset for PST |
| -800 | ISO-8601 offset for PST |
| -8 | ISO-8601 offset for PST |

Example:

```
SELECT time '04:05:06';
time
-----
04:05:06
(1 row)

SELECT time '04:05:06 PST';
time
-----
04:05:06
(1 row)

SELECT time with time zone '04:05:06 PST';
timetz
-----
04:05:06-08
(1 row)
```

Special Values

The special values supported by DWS are converted to common date/time values when being read. For details, see [Table 21-17](#).

Table 21-17 Special Values

| Input String | Applicable Type | Description |
|--------------|-----------------------|--|
| epoch | date, timestamp | 1970-01-01 00:00:00+00 (Unix system time zero) |
| infinity | timestamp | Later than any other timestamps |
| -infinity | timestamp | Earlier than any other timestamps |
| now | date, time, timestamp | Start time of the current transaction |
| today | date, timestamp | Today midnight |
| tomorrow | date, timestamp | Tomorrow midnight |
| yesterday | date, timestamp | Yesterday midnight |

| Input String | Applicable Type | Description |
|--------------|-----------------|-----------------|
| allballs | time | 00:00:00.00 UTC |

Interval Input

The input of **reltime** can be any valid interval in TEXT format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format, ISO-8601 format, or POSTGRES format. In addition, the text input needs to be enclosed with single quotation marks (').

For details, see [Table 21-18](#).

Table 21-18 Interval input

| Input | Output | Description |
|--------------------------------|-------------------------------------|---|
| 60 | 2 mons | Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are also allowed. Particularly, a negative interval syntactically means how long before. |
| 31.25 | 1 mons 1 days 06:00:00 | |
| -365 | -12 mons -5 days | |
| 1 years 1 mons 8 days 12:00:00 | 1 years 1 mons 8 days 12:00:00 | Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input. |
| -13 months -10 hours | -1 years -25 days -04:00:00 | |
| -2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00 | |
| P-1.1Y10M | -3 mons -5 days -06:00:00 | Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input. |
| -12H | -12:00:00 | |

Example:

```
-- Create a table.
CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
INSERT INTO reltime_type_tab VALUES ('90', '90');
INSERT INTO reltime_type_tab VALUES ('-366', '-366');
INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5 MONTHS 10 DAYS');
```

```
INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
SELECT * FROM reltime_type_tab;
      col1          |          col2
-----+-----
1975.25             | 5 years 4 mons 29 days
-2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00
P-1.1Y10M           | -3 mons -5 days -06:00:00
-366                | -1 years -18:00:00
90                  | 3 mons
30 DAYS 12:00:00    | 1 mon 12:00:00
(6 rows)

-- Delete tables.
DROP TABLE reltime_type_tab;
```

21.5.7 Geometric Types

Table 21-19 lists the geometric types that can be used in DWS. The most fundamental type, the point, forms the basis for all of the other types.

Table 21-19 Geometric Type

| Name | Storage Space | Description | Representation |
|---------|---------------|----------------------------------|-------------------------------------|
| point | 16 bytes | Point on a plane | (x,y) |
| lseg | 32 bytes | Finite line segment | ((x1,y1),(x2,y2)) |
| box | 32 bytes | Rectangular Box | ((x1,y1),(x2,y2)) |
| path | 16+16n bytes | Closed path (similar to polygon) | ((x1,y1),...) |
| path | 16+16n bytes | Open path | [(x1,y1),...] |
| polygon | 40+16n bytes | Polygon (similar to closed path) | ((x1,y1),...) |
| circle | 24 bytes | Circle | <(x,y),r> (center point and radius) |

A rich set of functions and operators is available in DWS to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see [Geometric Functions and Operators](#).

Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntaxes:

```
( x , y )
x , y
```

where x and y are the respective coordinates, as floating-point numbers.

Points are output using the first syntax.

Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]  
( ( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

where (x1,y1) and (x2,y2) are the end points of the line segment.

Line segments are output using the first syntax.

Rectangular Box

Boxes are represented by pairs of points that are opposite corners of the box. Values of the **box** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ( x2 , y2 ) )  
( x1 , y1 ) , ( x2 , y2 )  
x1 , y1 , x2 , y2
```

where (x1,y1) and (x2,y2) are any two opposite corners of the box.

Boxes are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Path

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of the **path** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]  
( ( x1 , y1 ) , ... , ( xn , yn ) )  
( x1 , y1 ) , ... , ( xn , yn )  
( x1 , y1 , ... , xn , yn )  
x1 , y1 , ... , xn , yn
```

where the points are the end points of the line segments comprising the path. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntaxes, a closed path is assumed.

Paths are output using the first or second syntax.

Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ... , ( xn , yn ) )  
( x1 , y1 ) , ... , ( xn , yn )  
( x1 , y1 , ... , xn , yn )  
x1 , y1 , ... , xn , yn
```

where the points are the end points of the line segments comprising the boundary of the polygon.

Polygons are output using the first syntax.

Circle

Circles are represented by a center point and radius. Values of the **circle** type are specified using any of the following syntaxes:

```
< ( x , y ) , r >  
(( x , y ) , r )  
( x , y ) , r  
x , y , r
```

where **(x,y)** is the center point and **r** is the radius of the circle.

Circles are output using the first syntax.

21.5.8 Array

An array is a set of data. The array type allows a single database field to have multiple values. It is usually used to store and process data with similar attributes.

Syntax

```
ARRAY [ param ]
```

or

```
'{ param }'
```

The **param** parameter is described as follows:

- **param**: value contained in the array. It can be zero or many. Multiple values are separated by commas (.). If there is no value, set this parameter to NULL.
- When you specify an array constant in '{ *param* }' format, the elements of the string type cannot start or end with a single quotation mark. Instead, a double quotation mark is needed. Two consecutive single quotation marks will be converted to one single quotation mark.
- The data type of the first element is used as the data type of the array. All elements in an array must be of the same type, or their types can be converted to each other.

Definition of the Array Type

An array type is defined by adding values in the square brackets ([]) at the end of a data type.

Create the **books** table. The type of the **price** column (book prices) is a one-dimensional integer array, and the type of the **tags** column (book tags) is a two-dimensional text array.

```
CREATE TABLE books (id SERIAL PRIMARY KEY, title VARCHAR(100), price_by_quarter int[], tags TEXT[][]);
```

The **CREATE TABLE** syntax can specify the array size. For example:

```
CREATE TABLE test ( a int[3]);
```

In current database implementation, the array size limits of statements are ignored. Statements with array size limits behave the same as those without. At the same time, the number of declared dimensions is not required. Arrays of a particular element type are all treated as the same type. Their size or number of dimensions are ignored.

You can also use the keyword **ARRAY** to define a one-dimensional array. The **price** column in the **books** table is defined using **ARRAY** and the array size is specified as follows:

```
price_by_quarter int ARRAY[4]
```

Use **ARRAY** without specifying the array size:

```
price_by_quarter int ARRAY
```

Array Value Input

When entering an array value, write each array value as a literal constant, surround element values with braces, and separate them with commas. The general format of an array constant is as follows:

```
'{ val1 delim val2 delim ... }'
```

delim indicates a delimiter, and each **val** may be a constant or a subarray of an array element type.

An example of an array constant is as follows:

```
'{{1,2,3},{4,5,6},{7,8,9}}'
```

The constant is a two-dimensional, 3-by-3 array consisting of three integer subarrays.

Insert data into the **books** table and query the **books** table.

```
INSERT INTO books
VALUES (1, 'One Hundred years of Solitude', {25,25,25,25}, {'fiction'}, {adventure}),
      (2, 'Robinson Crusoe', {30,32,32,32}, {'adventure'}, {fiction}),
      (3, 'Gone with the Wind', {27,27,29,28}, {'romance'}, {fantasy});
```

```
SELECT * FROM books;
id | title | price_by_quarter | tags
---+-----+-----+-----
1 | One Hundred years of Solitude | {25,25,25,25} | {{fiction},{adventure}}
2 | Robinson Crusoe | {30,32,32,32} | {{adventure},{fiction}}
3 | Gone with the Wind | {27,27,29,28} | {{romance},{fantasy}}
(3 rows)
```

CAUTION

When multi-dimensional array data is inserted, each dimension of the array must have a matching length.

Use the **ARRAY** keyword to insert data.

```
INSERT INTO books
VALUES (1, 'One Hundred years of Solitude', ARRAY[25,25,25,25], ARRAY['fiction', 'adventure']),
```

```
(2, 'Robinson Crusoe', ARRAY[30,32,32,32], ARRAY['adventure', 'fiction']),  
(3, 'Gone with the Wind', ARRAY[27,27,29,28], ARRAY['romance', 'fantasy']);
```

Accessing Arrays

Accessing Array Elements

Query the names of the books whose prices change in the second quarter.

```
SELECT title FROM books WHERE price_by_quarter[1] <> price_by_quarter[2];  
title  
-----  
Robinson Crusoe  
(1 row)
```

Search for the prices of all books in the third quarter:

```
SELECT price_by_quarter[3] FROM books;  
price_by_quarter  
-----  
29  
25  
32  
(3 rows)
```

Accessing Array Slices

Any rectangular slice or subarray of an array can be accessed. An array slice can be defined by specifying [lower bound: upper bound] on one or more array dimensions.

Query the second label of **Gone with the Wind**.

```
SELECT tags[2:2] FROM books WHERE title = 'Gone with the Wind';  
tags  
-----  
{fantasy}  
(1 row)
```

Using Functions to Access Arrays

Use the **array_dims** function to obtain the dimension of an array value.

```
SELECT array_dims(tags) FROM books WHERE title = 'Robinson Crusoe';  
array_dims  
-----  
[1:2]  
(1 row)
```

You can also use **array_upper** and **array_lower** to obtain the array dimension. They return the upper and lower bounds of a specified array, respectively.

```
SELECT array_upper(tags, 1) FROM books WHERE title = 'Robinson Crusoe';  
array_upper  
-----  
2  
(1 row)
```

The **array_length** function returns the length of a specified array dimension.

```
SELECT array_length(tags, 1) FROM books WHERE title = 'Robinson Crusoe';  
array_length  
-----  
2  
(1 row)
```

Modifying an Array

Updating an Array

Update the entire array data:

```
UPDATE books SET price_by_quarter = '{30,30,30,30}'  
WHERE title = 'Robinson Crusoe';
```

Use the ARRAY expression to update the entire array data:

```
UPDATE books SET price_by_quarter = ARRAY[30,30,30,30]  
WHERE title = 'Robinson Crusoe';
```

Update an element in the array:

```
UPDATE books SET price_by_quarter[4] = 35  
WHERE title = 'Robinson Crusoe';
```

Update a slice element in the array:

```
UPDATE books SET price_by_quarter[1:2] = '{27,27}'  
WHERE title = 'Robinson Crusoe';
```

A stored array value can be expanded by assigning a value to a new element. The position between an existing element and the new element is filled with null values. For example, if the array **myarray** currently has four elements, it will have six elements after a value is assigned to **myarray[6]** using **UPDATE**. **myarray[5]** is filled with null. Currently, this method can be used only on one-dimensional arrays.

Building a New Array

New arrays can also be constructed using the concatenation operator ||. The concatenation operator allows a single element to be added to the beginning or end of a one-dimensional array. It can also accept two *N* dimensional arrays, or an *N* dimensional array and an *N*+1 dimensional array.

```
SELECT ARRAY[1,2] || ARRAY[3,4];  
?column?  
-----  
{1,2,3,4}  
(1 row)  
  
SELECT ARRAY[5,6] || ARRAY[[1,2],[3,4]];  
?column?  
-----  
{{5,6},{1,2},{3,4}}  
(1 row)
```

Use the **array_prepend**, **array_append**, or **array_cat** function to build an array.

```
SELECT array_prepend(1, ARRAY[2,3]);  
array_prepend  
-----  
{1,2,3}  
(1 row)  
  
SELECT array_append(ARRAY[1,2], 3);  
array_append  
-----  
{1,2,3}  
(1 row)  
  
SELECT array_cat(ARRAY[1,2], ARRAY[3,4]);  
array_cat  
-----
```

```
{1,2,3,4}
(1 row)

SELECT array_cat(ARRAY[[1,2],[3,4]], ARRAY[5,6]);

   array_cat
-----
{{1,2},{3,4},{5,6}}
(1 row)

SELECT array_cat(ARRAY[5,6], ARRAY[[1,2],[3,4]]);

   array_cat
-----
{{5,6},{1,2},{3,4}}
(1 row)
```

21.5.9 Enumeration Type

An enumeration (enum) type is a data type consisting of a static, ordered set of values. They are equivalent to the enum types used in many programming languages. The enumeration type can be a date in a week or a set of status values.

Declaration of Enumeration Types

Enumeration types can be created using the **CREATE TYPE** command. For example:

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
```

After an enumeration type is created, it can be used in table and function definitions.

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (name text, current_mood mood);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
 name | current_mood
-----+-----
 Moe  | happy
(1 row)
```

Sorting

The order of enumeration values is the order of the values listed when the type is created.

```
INSERT INTO person VALUES ('Larry', 'sad');
INSERT INTO person VALUES ('Curly', 'ok');

SELECT * FROM person WHERE current_mood > 'sad';
 name | current_mood
-----+-----
 Moe  | happy
Curly | ok
(2 rows)

SELECT * FROM person WHERE current_mood > 'sad' ORDER BY current_mood;
 name | current_mood
-----+-----
Curly | ok
 Moe  | happy
(2 rows)

SELECT name FROM person WHERE current_mood = (SELECT MIN(current_mood) FROM person);
```

```
name
-----
Larry
(1 row)
```

Security of Enumeration Types

Each enumeration data type is independent and cannot be compared with other enumeration types.

```
CREATE TYPE happiness AS ENUM ('happy', 'very happy', 'ecstatic');
CREATE TABLE holidays (num_weeks integer, happiness happiness);
INSERT INTO holidays(num_weeks,happiness) VALUES (4, 'happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (6, 'very happy');
INSERT INTO holidays(num_weeks,happiness) VALUES (8, 'ecstatic');

INSERT INTO holidays(num_weeks,happiness) VALUES (2, 'sad');
ERROR: invalid input value for enum happiness: "sad"

SELECT person.name, holidays.num_weeks FROM person, holidays
       WHERE person.current_mood = holidays.happiness;
ERROR: operator does not exist: mood = happiness
```

If comparison is required, you can use a customized operator or add an explicit type to the query.

```
SELECT person.name, holidays.num_weeks FROM person, holidays
       WHERE person.current_mood::text = holidays.happiness::text;
name | num_weeks
-----+-----
Moe  |         4
(1 row)
```

Precautions

- Enumeration tags are case sensitive. 'happy' is different from 'HAPPY'. Spaces in tags also have meanings.
- Although enumeration types are primarily intended for static collections of values, there are ways to add new and renamed values to existing enumeration types (see [ALTER TYPE](#)). Existing values cannot be removed from an enumeration type, and the order of these values cannot be changed unless the enumeration type is deleted and recreated.
- The mapping between enumerated values and text tags is stored in the **PG_ENUM** system catalog.

21.5.10 Network Address Types

DWS offers data types to store IPv4, IPv6, and MAC addresses.

It is better to use network address types instead of plaintext types to store IPv4, IPv6, and MAC addresses, because these types offer input error checking and specialized operators and functions. For details, see [Network Address Functions and Operators](#).

Table 21-20 Network Address Types

| Name | Storage Space | Description |
|------|---------------|-----------------------|
| cidr | 7 or 19 bytes | IPv4 or IPv6 networks |

| Name | Storage Space | Description |
|---------|---------------|---------------------------------|
| inet | 7 or 19 bytes | IPv4 or IPv6 hosts and networks |
| macaddr | 6 bytes | MAC addresses |

When sorting **inet** or **cidr** data types, IPv4 addresses will always sort before IPv6 addresses, including IPv4 addresses encapsulated or mapped to IPv6 addresses, such as ::10.2.3.4 or ::ffff:10.4.3.2.

cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 or IPv6 network specification. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 or IPv6 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input.

- Example 1: Convert a value in the CIDR format to an IP address segment.

For example, **10.0.0.0/8** is converted into a 32-bit binary address **00001010.00000000.00000000.00000000**. **/8** indicates an 8-bit network ID. The first eight bits of the 32-bit binary address are fixed. The corresponding network segment is 00001010.00000000.00000000-00001010.11111111.11111111.11111111. **10.0.0.0/8** indicates that the subnet mask is 255.0.0.0 and the corresponding network segment is 10.0.0.0-10.255.255.255.

- Example 2: Convert an IP address segment to the CIDR format.

For the IP address segment **192.168.0.0–192.168.31.255**, the last two segments can be converted into a binary address **00000000.00000000-00011111.11111111**. The first 19 bits ($8 \times 2 + 3$) are fixed. Therefore, the binary address is 192.168.0.0/19.

Table 21-21 cidr type input examples

| cidr Input | cidr Output | abbrev (cidr) |
|--------------------|--------------------|--------------------|
| 192.168.100.128/25 | 192.168.100.128/25 | 192.168.100.128/25 |
| 192.168/24 | 192.168.0.0/24 | 192.168.0/24 |
| 192.168/25 | 192.168.0.0/25 | 192.168.0.0/25 |
| 192.168.1 | 192.168.1.0/24 | 192.168.1/24 |
| 192.168 | 192.168.0.0/24 | 192.168.0/24 |
| 10.1.2 | 10.1.2.0/24 | 10.1.2/24 |
| 10.1 | 10.1.0.0/16 | 10.1/16 |
| 10 | 10.0.0.0/8 | 10/8 |

| cidr Input | cidr Output | abbrev (cidr) |
|--|--|--------------------------------------|
| 10.1.2.3/32 | 10.1.2.3/32 | 10.1.2.3/32 |
| 2001:4f8:3:ba::/64 | 2001:4f8:3:ba::/64 | 2001:4f8:3:ba::/64 |
| 2001:4f8:3:ba:2e0:81ff:fe
22:d1f1/128 | 2001:4f8:3:ba:2e0:81ff:fe
22:d1f1/128 | 2001:4f8:3:ba:2e0:81ff:fe
22:d1f1 |

inet

The **inet** type holds an IPv4 or IPv6 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is IPv4, then the value does not indicate a subnet, only a single host. In IPv6, the address length is 128 bits, so 128 bits specify a unique host address.

The input format for this type is **address/y** where **address** is an IPv4 or IPv6 address and **y** is the number of bits in the netmask. If the **/y** portion is missing, the netmask is 32 for IPv4 and 128 for IPv6, so the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'  
'08-00-2b-01-02-03'  
'08002b:010203'  
'08002b-010203'  
'0800.2b01.0203'  
'08002b010203'
```

These examples would all specify the same address. Upper and lower cases are accepted for the digits a through f. Output is always in the first of the forms shown.

21.5.11 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

DWS supports two SQL bit types: **bit(n)** and **bit varying(n)**, where **n** is a positive integer.

The **bit** type data must match the length **n** exactly. It is an error to attempt to store shorter or longer bit strings. The **bit varying** data is of variable length up to the maximum length **n**; longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while **bit varying** without a length specification means unlimited length.

 NOTE

If one explicitly casts a bit-string value to **bit(n)**, it will be truncated or zero-padded on the right to be exactly **n** bits, without raising an error. Similarly, if one explicitly casts a bit-string value to **bit varying(n)**, the bits after **n** places will be truncated.

The following is an example of using the bit string type:

1. Create a sample table **bit_type_t1**.

```
CREATE TABLE bit_type_t1
(
  BT_COL1 INTEGER,
  BT_COL2 BIT(3),
  BT_COL3 BIT VARYING(5)
) DISTRIBUTE BY REPLICATION;
```

2. Insert data:

```
INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');
```

An error is reported if an inserted string exceeds the length of this data type.

```
INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');
ERROR: bit string length 2 does not match type bit(3)
CONTEXT: referenced column: bt_col2
```

3. Data is converted if it exceeds the length of this data type.

```
INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');
```

4. View data:

```
SELECT * FROM bit_type_t1;
bt_col1 | bt_col2 | bt_col3
-----+-----
1 | 101 | 00
2 | 100 | 101
(2 rows)
```

21.5.12 Text Search Types

DWS offers **tsvector** and **tsquery** data types to support full text search. The **tsvector** type represents a document in a form optimized for text search. The **tsquery** type similarly represents a text query.

tsvector

The **tsvector** type represents a retrieval unit, usually a row of text fields in a database table or a combination of these fields.

A **tsvector** value is a sorted list of distinct lexemes, which are words that have been normalized to merge different variants of the same word. Sorting and duplicate-elimination are done automatically during input.

The **to_tsvector** function is used to parse and normalize a document string.

Use **tsvector** to segment a string into lexemes by space. The lexemes are sorted by letter and length. The following is an example:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
tsvector
-----
'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
(1 row)
```

To represent lexemes containing whitespace or punctuation, surround them with quotes:

```
SELECT '$the lexeme ' ' contains spaces$'::tsvector;
tsvector
```

```
-----  
' ' 'contains' 'lexeme' 'spaces' 'the'  
(1 row)
```

If a string is enclosed in common single quotation marks, the single quotation marks (') and backslashes (\) embedded in the string must be double-written for escape.

```
SELECT $$the lexeme 'Joe's' contains a quote$$::tsvector;  
tsvector  
-----  
'Joe's' 'a' 'contains' 'lexeme' 'quote' 'the'  
(1 row)
```

Optionally, integer positions can be attached to lexemes:

```
SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;  
tsvector  
-----  
'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4  
(1 row)
```

A position normally indicates the source word's location in the document. Positional information can be used for proximity ranking. Position values range from 1 to 16383. The default maximum value is **16383**. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a weight, which can be **A**, **B**, **C**, or **D**. **D** is the default weight. It is not displayed in the output:

```
SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;  
tsvector  
-----  
'a':1A 'cat':5 'fat':2B,4C  
(1 row)
```

Weights usually are used to reflect document structure, for example, by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.

The following is an example of the standard usage of the tsvector type:

```
SELECT 'The Fat Rats'::tsvector;  
tsvector  
-----  
'Fat' 'Rats' 'The'  
(1 row)
```

For most English-text-searching applications the above words would be considered non-normalized, which should usually be passed through **to_tsvector** to normalize the words appropriately for searching:

```
SELECT to_tsvector('english', 'The Fat Rats');  
to_tsvector  
-----  
'fat':2 'rat':3  
(1 row)
```

tsquery

The **tsquery** type represents a retrieval condition. A **tsquery** value stores lexemes that are to be searched for, and combines them honoring the **Boolean** operators **&** (**AND**), **|** (**OR**), and **!** (**NOT**). Parentheses can be used to enforce grouping of the operators. If there is no parenthesis, (**NOT**) has the highest priority, followed by

&(AND), and finally **| (OR)**. The **to_tsquery** and **plainto_tsquery** functions will normalize lexemes before the lexemes are converted to the **tsquery** type.

```
SELECT 'fat & rat'::tsquery;
      tsquery
-----
'fat' & 'rat'
(1 row)

SELECT 'fat & (rat | cat)'::tsquery;
      tsquery
-----
'fat' & ( 'rat' | 'cat' )
(1 row)

SELECT 'fat & rat & ! cat'::tsquery;
      tsquery
-----
'fat' & 'rat' & '!cat'
(1 row)
```

Lexemes in a **tsquery** can be labeled with one or more weight letters, which match only **tsvector** lexemes with matching weights.

```
SELECT 'fat:ab & cat'::tsquery;
      tsquery
-----
'fat':AB & 'cat'
(1 row)
```

Also, lexemes in a **tsquery** can be labeled with ***** to specify prefix matching. The following query will match any word in a **tsvector** that begins with "super".

```
SELECT 'super:*'::tsquery;
      tsquery
-----
'super':*
(1 row)
```

Note that prefix matches are first checked by the text search analyzer. For example, the stem extracted from **postgres** is **postgr**, which matches **postgraduate**. The following result is true:

```
SELECT to_tsvector( 'postgraduate' ) @@ to_tsquery( 'postgres:*' ) AS RESULT;
      result
-----
t
(1 row)

SELECT to_tsquery('postgres:*');
      to_tsquery
-----
'postgr':*
(1 row)
```

The **to_tsquery** function normalizes words before converting them to the **tsquery** type. **'Fat:ab & Cats'** is normalized to the **tsquery** type as follows:

```
SELECT to_tsquery('Fat:ab & Cats');
      to_tsquery
-----
'fat':AB & 'cat'
(1 row)
```

21.5.13 UUID Type

Universally Unique Identifier (UUID) is a 128-bit identifier used in the computer system to identify information.

All elements in a distributed system can be uniquely identified by an UUID, without having to be identified in the central control end. In many application scenarios, an ID is required to identify only one object. A common example is the ID column of a database table. Another example is the front end UI libraries, because they usually need to dynamically create various UI elements that require unique IDs.

For details about UUID functions and UUID application examples supported by DWS, see [UUID Functions](#).

UUID Formats

UUIDs are standardized as part of the Distributed Computing Environment (DCE) in RFC 4122 released by the Internet Engineering Task Force (IETF) of the Open Software Foundation (OSF). A standard UUID consists of 36 characters, including 32 hexadecimal digits and four hyphens (-). The format is 8-4-4-4-12. An example of a standard UUID is as follows:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

DWS also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, and adding a hyphen after any group of four digits. Examples

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11  
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}  
a0eebc99c0b4ef8bb6d6bb9bd380a11  
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

UUID Composition

A UUID uses time and space information to ensure global uniqueness. A UUID consists of a timestamp, a clock sequence, and a node ID (MAC address). However, multiple nodes in a distributed DWS cluster may be deployed on the same machine and have the same MAC address. As a result, UUID conflicts may occur. Therefore, DWS replaces the last 48 bits of the MAC address with the sequence number of the CN or DN that generates the UUID and the current thread ID to ensure that the UUID is globally unique in the distributed cluster.

21.5.14 JSON Types

JavaScript Object Notation (JSON) data types are used for storing JSON data.

It can be an independent scalar, an array, or a key-value object. An array and an object can be called a container.

1. Scalar: a number, Boolean, string, or null
2. Array: defined in a pair of square brackets ([]), in which elements can be of any JSON data type, and are not necessarily of the same type.
3. Object: defined in a pair of braces ({}), in which objects are stored in the format of **key:value**. Each key must be a string enclosed in double quotation marks (""), and its value can be of any JSON data type. In case of duplicate keys, the last key-value pair will be used.

DWS supports the JSON and JSONB data types to store JSON data. Where:

- json copies all entered strings and parses them when they are used. During this process, the entered spaces, duplicate keys, and sequence are retained.
- jsonb parses the binary data of the input. During parsing, jsonb deletes semantic-irrelevant details and duplicate keys, and sorts key values, so that the data does not to be parsed again during use.

Both JSON and JSONB are of JSON data type, and the same strings can be entered as input. The main difference between JSON and JSONB is the efficiency. Because json data is an exact copy of the input text, the data must be parsed on every execution. In contrast, jsonb data is stored in a decomposed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data form is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

Input Format

The input must be a JSON-compliant string, which is enclosed in single quotation marks (').

Null (null-json): Only null is supported, and all letters are in lowercase.

```
SELECT 'null':json; -- suc
SELECT 'NULL':jsonb; -- err
```

Number (num-json): The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
SELECT '1':json;
SELECT '-1.5':json;
SELECT '-1.5e-5':jsonb, '-1.5e+2':jsonb;
SELECT '001':json, '+15':json, 'NaN':json; -- Redundant leading zeros, plus signs (+), NaN, and infinity are not supported.
```

Boolean (bool-json): The value can only be **true** or **false** in lowercase.

```
SELECT 'true':json;
SELECT 'false':jsonb;
```

String (str-json): The value must be a string enclosed in double quotation marks (").

```
SELECT '"a"':json;
SELECT '"abc"':jsonb;
```

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
SELECT '[1, 2, "foo", null]':json;
SELECT '[]':json;
SELECT '[1, 2, "foo", null, [], {}]':jsonb;
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
SELECT '{}':json;
SELECT '{"a": 1, "b": {"a": 2, "b": null}}':json;
SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}':jsonb;
```

 CAUTION

- Note that **'null::jsonb** and **null::jsonb** are different. The difference is similar to that between the strings **str=""** and **str=null**.
- For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.

JSONB Advanced Features

The main difference between JSON and JSONB is the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has more advanced features than JSON.

Normalizes formats

- After the input **object-json** string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:

```
SELECT ' [1, " a ", {"a" :1  }] '::jsonb;
jsonb
-----
[1, " a ", {"a": 1}]
(1 row)
```

- For **object-json**, duplicate key-values are deleted and only the last key-value is retained. An example is as follows:

```
SELECT '{"a" : 1, "a" : 2} '::jsonb;
jsonb
-----
{"a": 2}
(1 row)
```

- For **object-json**, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted last. An example is as follows:

```
SELECT '{"aa" : 1, "b" : 2, "a" : 3} '::jsonb;
jsonb
-----
{"a": 3, "b": 2, "aa": 1}
(1 row)
```

Compares sizes

Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes can be compared according to a specific rule.

1. First, type comparison: **object-jsonb** > **array-jsonb** > **bool-jsonb** > **num-jsonb** > **str-jsonb** > **null-jsonb**
2. Content is compared if the data type is the same:
 - **str-json**: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.
 - **num-json**: numeric comparison
 - **bool-json**: **true** > **false**
 - **array-jsonb**: long elements > short elements. If the lengths are the same, compare each element in sequence.

- **object-jsonb**: long key-value pairs > short key-value pairs. If the lengths are the same, compare each key-value pair in sequence, first the key and then the value.

CAUTION

For comparison within the **object-jsonb** type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be so intuitive as direct input.

Creates an index

The JSONB type in row-store tables supports both B-tree and GIN indexes, while the JSONB type in column-store tables only supports B-tree indexes.

If the entire JSONB column uses a B-tree index, the following operators can be used: =, <, <=, >, and >=.

Example: Create the table **test** and insert data into it.

```
CREATE TABLE test(id bigserial, data JSONB, PRIMARY KEY (id));
INSERT INTO test(data) VALUES('{"name":"Jack", "age":10, "nick_name":["Jacky","baobao"], "phone_list":
["1111","2222"]}::jsonb);
```

- Create a B-tree index.

```
CREATE INDEX idx_test_data_age ON test USING btree(((data->>'age')::int));
```

Use the B-tree index to query data where "age">1".

```
SELECT * FROM test WHERE (data->>'age')::int>1;
```

- Create a GIN index.

```
CREATE INDEX idx_test_data ON test USING gin (data);
```

Use the GIN index to check whether there are top-level keywords.

```
SELECT * FROM test WHERE data ? 'id';
```

```
SELECT * FROM test WHERE data ?| array['id','name'];
```

- Use the GIN index to check whether there are non-top-level keywords.

```
CREATE INDEX idx_test_data_nick_name ON test USING gin((data->'nick_name'));
SELECT * FROM test WHERE data->'nick_name' ? 'Jacky';
```

- Use @> to check whether JSON contains nested JSON objects.

```
SELECT * FROM test WHERE data @> '{"age":10, "nick_name":["Jacky"]}';
```

Includes elements in a JSON

An important capability of JSONB is to query whether a JSON contains some elements or whether some elements exist in a JSON.

- Simple scalar/original values contain only the same value.

```
SELECT '"foo"'::jsonb @> '"foo"'::jsonb;
```

- The array on the left contains the string on the right.

```
SELECT '[1, "aa", 3]'::jsonb ? 'aa';
```

- The array on the left contains all elements of the array on the right. The sequence and repetition are not important.

```
SELECT '[1, 2, 3]'::jsonb @> '[1, 3, 1]'::jsonb;
```

- The **object-json** on the left contains all key-values of the **object-json** on the right.

```
SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @> '{"version":9.4}'::jsonb;
```

- The array on the left does not contain all elements in the array on the right, because the three elements in the array on the left are **1**, **2**, and **[1,3]**, and the elements on the right are **1** and **3**.

```
SELECT '[1, 2, [1, 3]]::jsonb @> '[1, 3]::jsonb; -- false
```
- The array on the right does not contain all elements in the array on the left in the following example:

```
SELECT '{"foo": {"bar": "baz"}}::jsonb @> '{"bar": "baz"}::jsonb; -- false
```

21.5.15 RoaringBitmap

In DWS 8.1.3 and later, you can use the RoaringBitmap data type to store bitmap datasets.

The RoaringBitmap data type supports row-store and column-store tables.

Table 21-22 RoaringBitmap

| Name | Storage Size | Description | Range |
|---------------|--------------|--------------------------|------------------------------|
| RoaringBitmap | 32 bytes | Stores bitmap data sets. | -2,147,483,648~2,147,483,647 |

Example: Create a table with the RoaringBitmap data type.

```
CREATE TABLE r_row (a int ,b text, c roaringbitmap);  
CREATE TABLE r_col (a int ,b text, c roaringbitmap) with (orientation=column);
```

21.5.16 HLL Data Types

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a data set. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a data set, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

Table 21-23 compares HLL with other algorithms.

Table 21-23 Comparison between HLL and other algorithms

| Item | Sorting Algorithm | Hash Algorithm | HLL |
|---------------------------|-------------------|------------------|------------|
| Time complexity | O(nlogn) | O(n) | O(n) |
| Space complexity | O(n) | O(n) | 1280 bytes |
| Error rate | 0 | 0 | ≈2% |
| Storage space requirement | Size of raw data | Size of raw data | 1280 bytes |

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs $O(n \log n)$ time for sorting, and the hash algorithm and HLL need $O(n)$ time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of only 1280 bytes.

NOTICE

- In default specifications, the maximum number of distinct values is 1.6e plus 12, and the maximum error rate is only 2.3%. If a calculation result exceeds the maximum number, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
 - When default parameter configuration is used, the calculated number of distinct values is 1.6e plus 12. If the calculated result is **NaN**, you need to adjust **log2m** and **regwidth** to accommodate more distinct values.
 - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

[Table 21-24](#) describes main HLL data structures.

Table 21-24 Main HLL data structures

| Data Type | Description |
|-----------|---|
| hll | Its size is always 1280 bytes, which can be directly used to calculate the number of distinct values. |

Application Scenarios of HLL

- Using the HLL Data Type
 - a. Create an HLL table and insert an empty HLL into the table.

```
CREATE TABLE helloworld (id integer, set hll);
INSERT INTO helloworld(id, set) VALUES (1, hll_empty());
```
 - b. Add an integer that has gone through hash calculation into to the HLL.

```
UPDATE helloworld SET set = hll_add(set, hll_hash_integer(12345)) WHERE id = 1;
```
 - c. Add a string that has gone through hash calculation into to the HLL.

```
UPDATE helloworld SET set = hll_add(set, hll_hash_text('hello world')) WHERE id = 1;
```
 - d. Obtain the number of distinct values of the HLL.

```
SELECT hll_cardinality(set) FROM helloworld WHERE id = 1;
hll_cardinality
-----
```

```

      2
(1 row)

```

- Using HLL to Collect Website Visitor Statistics

- Create the original data table **facts** to record the time when a user accesses a website.

```

CREATE TABLE facts (
  date      date,
  user_id   integer
);

```

- Insert user visits data.

```

INSERT INTO facts VALUES ('2019-02-20', generate_series(1,100));
INSERT INTO facts VALUES ('2019-02-21', generate_series(1,200));
INSERT INTO facts VALUES ('2019-02-22', generate_series(1,300));
INSERT INTO facts VALUES ('2019-02-23', generate_series(1,400));
INSERT INTO facts VALUES ('2019-02-24', generate_series(1,500));
INSERT INTO facts VALUES ('2019-02-25', generate_series(1,600));
INSERT INTO facts VALUES ('2019-02-26', generate_series(1,700));
INSERT INTO facts VALUES ('2019-02-27', generate_series(1,800));

```

- Create another table and specify an HLL column: Group data by date and insert the data into the HLL:

```

CREATE TABLE daily_uniques (
  date      date UNIQUE,
  users     hll
);

INSERT INTO daily_uniques(date, users)
SELECT date, hll_add_agg(hll_hash_integer(user_id))
FROM facts
GROUP BY 1;

```

- Calculate the numbers of users visiting the website every day:

```

SELECT date, hll_cardinality(users) FROM daily_uniques ORDER BY date;

```

| date | hll_cardinality |
|---------------------|------------------|
| 2019-02-20 00:00:00 | 100 |
| 2019-02-21 00:00:00 | 203.813355588808 |
| 2019-02-22 00:00:00 | 308.048239950384 |
| 2019-02-23 00:00:00 | 410.529188080374 |
| 2019-02-24 00:00:00 | 513.263875705319 |
| 2019-02-25 00:00:00 | 609.271181107416 |
| 2019-02-26 00:00:00 | 702.941844662509 |
| 2019-02-27 00:00:00 | 792.249946595237 |

(8 rows)

- Calculate the number of users who had visited the website in the week from February 20, 2019 to February 26, 2019:

```

SELECT hll_cardinality(hll_union_agg(users)) FROM daily_uniques WHERE date >=
'2019-02-20'::date AND date <= '2019-02-26'::date;

```

| hll_cardinality |
|------------------|
| 702.941844662509 |

(1 row)

- Calculate the number of users who had visited the website yesterday but have not visited the website today:

```

SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1
PRECEDING);

```

| date | lost_uniques |
|---------------------|--------------|
| 2019-02-20 00:00:00 | 0 |
| 2019-02-21 00:00:00 | 0 |
| 2019-02-22 00:00:00 | 0 |
| 2019-02-23 00:00:00 | 0 |
| 2019-02-24 00:00:00 | 0 |
| 2019-02-25 00:00:00 | 0 |

```
2019-02-26 00:00:00 | 0
2019-02-27 00:00:00 | 0
(8 rows)
```

- HLL Format Errors

When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported.

For example, when `E\1234` is inserted, the data does not comply with the HLL data structure and cannot be parsed. As a result, an error is reported.

```
CREATE TABLE test(id integer, set hll);
INSERT INTO test VALUES(1, 'E\1234');
ERROR: invalid input syntax for integer: "E\1234"
```

21.5.17 Object Identifier Types

Object identifiers (OIDs) are used internally by DWS as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The **OID** type represents an object identifier.

The **OID** type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

Table 21-25 Object identifier types

| Name | Reference | Description | Examples |
|-----------|--------------|---|----------|
| OID | - | Numeric object identifier | 564182 |
| CID | - | A command identifier. This is the data type of the system columns cmin and cmax . Command identifiers are 32-bit quantities. | - |
| XID | - | A transaction identifier. This is the data type of the system columns xmin and xmax . Transaction identifiers are also 32-bit quantities. | - |
| TID | - | A row identifier. This is the data type of the system column ctid . A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table. | - |
| REGCONFIG | pg_ts_config | Text search configuration | english |

| Name | Reference | Description | Examples |
|---------------|-------------|-------------------------------------|---------------------------------------|
| REGDICTIONARY | pg_ts_dict | Text search dictionary | simple |
| REGOPER | pg_operator | Operator name | + |
| REGOPERATOR | pg_operator | Operator with argument types | *(integer,integer) or -(NONE,integer) |
| REGPROC | pg_proc | Indicates the name of the function. | sum |
| REGPROCEDURE | pg_proc | Function with argument types | sum(int4) |
| REGCLASS | pg_class | Relation name | pg_type |
| REGTYPE | pg_type | Data type name | integer |

The **OID** type is used for a column in the database system catalog.

Example:

```
SELECT oid FROM pg_class WHERE relname = 'pg_type';
oid
-----
1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
SELECT attrelid,attname,atttypid,attstattarget FROM pg_attribute WHERE attrelid = 'pg_type'::REGCLASS;
attrelid | attname | atttypid | attstattarget
-----+-----+-----+-----
1247 | xc_node_id | 23 | 0
1247 | tableoid | 26 | 0
1247 | cmax | 29 | 0
1247 | xmax | 28 | 0
1247 | cmin | 29 | 0
1247 | xmin | 28 | 0
1247 | oid | 26 | 0
1247 | ctid | 27 | 0
1247 | typname | 19 | -1
1247 | typnamespace | 26 | -1
1247 | typowner | 26 | -1
1247 | typplen | 21 | -1
1247 | typbyval | 16 | -1
1247 | typtype | 18 | -1
1247 | typcategory | 18 | -1
1247 | typispreferred | 16 | -1
1247 | typisdefined | 16 | -1
1247 | typdelim | 18 | -1
1247 | typrelid | 26 | -1
1247 | typelem | 26 | -1
1247 | typarray | 26 | -1
1247 | typinput | 24 | -1
1247 | typoutput | 24 | -1
```

| | | | | | |
|-----------|---------------|--|------|--|----|
| 1247 | typreceive | | 24 | | -1 |
| 1247 | typsend | | 24 | | -1 |
| 1247 | typmodin | | 24 | | -1 |
| 1247 | typmodout | | 24 | | -1 |
| 1247 | typanalyze | | 24 | | -1 |
| 1247 | typalign | | 18 | | -1 |
| 1247 | typstorage | | 18 | | -1 |
| 1247 | typnotnull | | 16 | | -1 |
| 1247 | typbasetype | | 26 | | -1 |

| 1247 | typdefault | | 25 | | -1 |
| 1247 | typacl | | 1034 | | -1 |
| (38 rows) | | | | | |

21.5.18 Pseudo-Types

DWS has a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Pseudotypes are highly beneficial in functions that require more complex input and output than standard SQL data types. [Table 21-26](#) lists all pseudo-types.

Table 21-26 Pseudo-Types

| Name | Description |
|------------------|---|
| any | Indicates that a function accepts any input data type. |
| anyelement | Indicates that a function accepts any data type. |
| anyarray | Indicates that a function accepts any array data type. |
| anynonarray | Indicates that a function accepts any non-array data type. |
| anyenum | Indicates that a function accepts any enum data type. |
| anyrange | Indicates that a function accepts any range data type. |
| cstring | Indicates that a function accepts or returns a null-terminated C string. |
| internal | Indicates that a function accepts or returns a server-internal data type. |
| language_handler | Indicates that a procedural language call handler is declared to return language_handler . |
| fdw_handler | Indicates that a foreign-data wrapper handler is declared to return fdw_handler . |
| record | Identifies a function returning an unspecified row type. |
| trigger | Indicates that a trigger function is declared to return trigger . |
| void | Indicates that a function returns no value. |

| Name | Description |
|--------|--|
| opaque | Indicates an obsolete type name that formerly served all the above purposes. |

Functions coded in C (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the **anyelement**, **anyarray**, **anynonarray**, **anyenum**, and **anyrange** types.

The **internal** pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct call in an SQL query. If a function has at least one **internal**-type argument, it cannot be called from SQL. You are not advised to create any function that is declared to return **internal** unless the function has at least one **internal** argument.

Example:

Create or replace the showall() function:

```
CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from tpeds.store_sales where ss_customer_sk = 9692; $$
LANGUAGE SQL;
```

Invoke the showall() function:

```
SELECT showall();
showall
-----
(35)
(1 row)
```

Delete a function.

```
DROP FUNCTION showall();
```

21.5.19 Range Types

A range type is a data type that represents a range of values for certain element types (subtypes of ranges). For example, the range of a timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is **tsrange** (short for timestamp range), and **timestamp** is the subtype. The subtype must have an overall order so that the element value can be clearly specified as within, before, or after a range.

Range types can express multiple element values in a single range value and can clearly express concepts such as range overlapping. It helps to schedule the timing and duration of an event, and can also be utilized to set price or measurement parameters for equipment.

Built-in Range Types

DWS has the following built-in range types:

- `int4range`: integer range.
- `int8range`: bigint range.
- `numrange`: numeric range.
- `tsrange`: range of timestamp without the time zone.
- `tstzrange`: range of timestamp with the time zone
- `daterange`: date range.

NOTE

DWS does not support user-defined range types.

Create the reservation table and insert data into the table. The **during** column is of the **tsrange** type.

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
```

Query whether the range contains specific values:

```
SELECT int4range(10, 20) @> 3;
?column?
-----
f
(1 row)
```

Query whether the range overlaps with another value:

```
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
?column?
-----
t
(1 row)
```

Obtain the upper bound of the range:

```
SELECT upper(int8range(15, 25));
upper
-----
25
(1 row)
```

Calculate the intersection with another range:

```
SELECT int4range(10, 20) * int4range(15, 25);
?column?
-----
[15,20)
(1 row)
```

Query whether the range is empty:

```
SELECT isempty(numrange(1, 5));
isempty
-----
f
(1 row)
```

Inclusion and Exclusion of Bounds

Each non-empty range has two bounds: a lower bound and an upper bound. All values between the two bounds are included in the range. Inclusion of bounds

means that boundary values are also included in the range, while exclusion of bounds means that boundary values are not included in the range.

Inclusion of lower bound is represented by "[", and exclusion of lower bound is represented by "(". Similarly, inclusion of upper bound is represented by "]", and exclusion of upper bound is represented by ")".

The `lower_inc(anyrange)` and `lower_inc(anyrange)` functions are used to test the upper and lower bounds of a range, respectively.

Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range, for example, `(,3]`. Similarly, when the upper bound of a range is unbounded, all values greater than the upper bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. The missing bounds are automatically converted to exclusions, for example, `[,]` is converted to `(,)`. You can think of these missing values as positive infinity or negative infinity, but they are special range type values and are considered to be positive and negative infinity values that go beyond any range element type.

Element types with the infinity values can be used as explicit bound values. For example, in the timestamp range, `[today, infinity)` does not include a special timestamp value **infinity**.

The functions `lower_inf(anyrange)` and `upper_inf(anyrange)` are used to test whether a range has infinite upper bound or lower bound, respectively.

Input/Output Values of a Range

Range values must follow one of the following patterns:

```
(lower-bound,upper-bound)
(lower-bound,upper-bound]
[lower-bound,upper-bound)
[lower-bound,upper-bound]
empty
```

Parentheses `()` or square brackets `[]` indicate whether the upper and lower bounds are excluded or included. The last format is **empty**, which represents an empty range (a range that does not contain values).

The value of *lower-bound* can be a valid string of the subtype, or left empty, which indicates that there is no lower bound. The value of *upper-bound* can be a valid string of the subtype, or null, which indicates that there is no upper bound.

Each bound value can be referenced using the quotation marks `""`. This is necessary if the bound value contains parentheses `()`, square brackets `[]`, commas `(,)`, quotation marks `""`, or backslashes `\`, because otherwise those characters will be considered part of the range syntax. To put a quotation mark or backslash in a bound value, put a backslash in front of it (and a pair of double quotation marks in a referenced bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL strings). In addition, you can avoid referencing and use backslash escapes to preventing data characters from being used as part of the return syntax. If you want to input a bound value that is an empty string, write `""`, indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses() or square brackets[] is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples

Query all values between 3 and 7, including 3 and excluding 7:

```
SELECT '[3,7)>::int4range;  
int4range  
-----  
[3,7)  
(1 row)
```

Query all values between 3 and 7, excluding 3 and 7:

```
SELECT '(3,7)>::int4range;  
int4range  
-----  
[4,7)  
(1 row)
```

Query the value 4:

```
SELECT '[4,4]>::int4range;  
int4range  
-----  
[4,5)  
(1 row)
```

Query a range containing no values (normalized to **empty**):

```
SELECT '[4,4)>::int4range;  
int4range  
-----  
empty  
(1 row)
```

Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions accept two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded. If a range contains three parameters, the third parameter specifies the range exclusion/inclusion type. The third parameter must be one of the following character strings: (), ([,], or []). The following is an example:

The complete form is: lower bound, upper bound, and textual parameters indicating the inclusion/exclusion of bounds.

```
SELECT numrange(1.0, 14.0, '[');  
numrange  
-----  
(1.0,14.0]  
(1 row)
```

If the third parameter is ignored, the range will be deemed as '[').

```
SELECT numrange(1.0, 14.0);  
numrange  
-----
```

```
[1.0,14.0)
(1 row)
```

Although '[' is specified here, it is converted to the standard form in the return result because `int8range` is a type of **Discrete Ranges**:

```
SELECT int8range(1, 14, '[');
int8range
-----
[2,15)
(1 row)
```

NULL indicates that the range is unbounded.

```
SELECT numrange(NULL, 2.2);
numrange
-----
(,2.2)
(1 row)
```

Discrete Ranges

A discrete range is a range in which its elements have a clearly defined "step", such as integer or date. When there is no valid value between two elements, they are adjacent.

Each element value in a discrete range has a next value and a previous value. You can use the next or previous value to convert between inclusion and exclusion. For example, in an integer range, [4,8] and (3,9) represent the same set of values, but this is not the case for ranges other than numeric ranges.

A discrete range should have a canonical function for identifying the step in the range. The normalization function can convert the equivalents of the range type to expressions of the same meanings, which are consistent with the inclusion or exclusion bounds. If no normalization function is specified, ranges with different formats are always considered unequal, even if they actually express the same set of values.

The built-in range types `int4range`, `int8range`, and `daterange` use the normalized form, which includes the lower bound and excludes the upper bound, that is, [). However, user-defined ranges types can use other conventions.

User-defined Range Types

Users can define range types. To create a range type subtype `float8`, execute the following commands:

```
CREATE TYPE floatrange AS RANGE (
    subtype = float8,
    subtype_diff = float8mi
);

SELECT '[1.234, 5.678]':floatrange;
```

Indexes

You can create GiST indexes for table columns of the range type. Example:

```
CREATE TABLE reservation (room int, during tsrange);
CREATE INDEX reservation_idx ON reservation USING gist (during);
```

GiST indexes can accelerate queries involving the following range operators: =, &&, <@, @>, <>, -|-, &<, and &. >. For details, see [Range Operators](#).

In addition, you can also create B-tree indexes on table columns of the range type. For these index types, basically the only useful range operation is equivalence. B-tree indexes for range types are primarily used to enable sorting within a query. They are not actually created.

21.5.20 Composite Types

A composite type represents the structure of a row or record, which is essentially a list of field names and their data types. DWS allows table columns to be declared as composite types. A composite type is essentially the same as the row type of a table. However, using [CREATE TYPE](#) avoids the need to create an actual table when only a type needs to be defined. A stand-alone composite type is useful as the parameter or return type of a function.

Declaration of Composite Types

DWS allows users to use [CREATE TYPE](#) to define composite types.

```
CREATE TYPE complex AS (  
    r    double precision,  
    i    double precision  
);  
  
CREATE TYPE inventory_item AS (  
    name      text,  
    supplier_id integer,  
    price     numeric  
);
```

After defining a composite type, you can create a table or function.

```
CREATE TABLE on_hand (  
    item    inventory_item,  
    count   integer  
);  
  
INSERT INTO on_hand VALUES (ROW('fuzzy dice', 42, 1.99), 1000);  
CREATE FUNCTION price_extension(inventory_item, integer) RETURNS numeric  
AS 'SELECT $1.price * $2' LANGUAGE SQL;  
  
SELECT price_extension(item, 10) FROM on_hand;
```

Constructing a Compound Value

To write a composite value as a literal constant, enclose the field value in parentheses and separate them with commas. You can add double quotation marks to any field value. This is mandatory if the field value contains commas or parentheses. The general format of a compound constant is as follows:

```
'( val1 , val2 , ... )'
```

'("fuzzy dice",42,1.99)' is a valid value of the **inventory_item** type.

To set a field to NULL, left the position empty. If you want a field to be an empty string, use quotation marks. In the following example, the first column is a non-null empty string, and the third column is NULL.

```
'( "",42, )'
```

ROW expressions can also be used to build composite values. Example:

```
ROW('fuzzy dice', 42, 1.99)
ROW("", 42, NULL)
```

Access Composite Types

To access a field in a composite column, you can write a dot and the name of the field, just like selecting a field from a table. To avoid confusion, you must use parentheses to distinguish it. For example, select some fields from table **on_hand**:

```
SELECT item.name FROM on_hand WHERE item.price > 9.99;
ERROR: missing FROM-clause entry for table "item"
```

This writing is confused with selecting fields from a table because **item** is regarded as a table name instead of a column name of **on_hand**. It must be written as follows:

```
SELECT (item).name FROM on_hand WHERE (item).price > 9.99;
```

If you need to use the table name (for example, in a multi-table query):

```
SELECT (on_hand.item).name FROM on_hand WHERE (on_hand.item).price > 9.99;
```

Objects with parentheses are now correctly interpreted as references to column **item**, from which fields can be selected.

Similar syntax applies when a field is selected from a compound value. For example, to select a field from the result of a function that returns a compound value, write as follows:

```
SELECT (my_func(...)).field FROM ...
```

If there are no additional parentheses, this generates a syntax error.

21.5.21 Data Types Supported by Column-Store Tables

[Table 21-27](#) lists the data types supported by column-store tables. Other data types that are not listed are not supported currently.

Table 21-27 Data Types Supported by Column-Store Tables

| Category | Data Type | Description | Length |
|--------------|-----------|--|-----------------|
| Numeric data | smallint | Small integer, also called INT2 | 2 |
| | integer | Typical choice for integer, also called INT4 | 4 |
| | bigint | Big integer, also called INT8 | 8 |
| | decimal | Arbitrary precision type | Variable length |
| | numeric | Arbitrary precision type | Variable length |

| Category | Data Type | Description | Length |
|----------------|----------------------------------|---|--|
| | real | Single-precision floating point | 4 |
| | double precision | Double-precision floating point | 8 |
| | smallserial | Two-byte auto-incrementing integer | 2 |
| | serial | Four-byte auto-incrementing integer | 4 |
| | bigserial | Eight-byte auto-incrementing integer | 8 |
| Money | money | Currency amount | 8 |
| Character data | character varying(n), varchar(n) | Variable-length string | Variable length |
| | character(n), char(n) | Fixed-length string | n |
| | character, char | Single-byte internal type | 1 |
| | text | Variable-length string | Variable length |
| | nvarchar2 | Variable-length string | Variable length |
| | clob | Big text object | Variable length |
| Date/Time | timestamp with time zone | Date and time (with time zone) | 8 |
| | timestamp without time zone | Date and time | 8 |
| | date | Date and time (Oracle compatibility mode); date (other compatibility modes) | When using Oracle compatibility mode, the storage space is 8 bytes, whereas in other compatibility modes, it is 4 bytes. |
| | time without time zone | Time within one day | 8 |

| Category | Data Type | Description | Length |
|---------------|---------------------|--|-----------------|
| | time with time zone | Time within one day (with time zone) | 12 |
| | interval | Time interval | 16 |
| JSON | json | - | - |
| | jsonb | - | - |
| RoaringBitmap | - | Efficient bitmap, which supports the bitmap calculation of datasets of the int type. | Variable length |

21.5.22 XML

XML data type stores Extensible Markup Language (XML) formatted data. XML data can also be stored as text, but the advantage of the XML data type is that it checks whether each stored value is a well-formed XML value. XML can store well-formed documents and content fragments defined by XML standards. A content fragment can have multiple top-level elements or character nodes.

For functions that support the XML data type, see [XML Functions](#).

Configuring XML Parameters

The syntax is as follows:

```
SET XML OPTION { DOCUMENT | CONTENT };  
SET xmloption TO { DOCUMENT | CONTENT };
```

If a string value is not converted to XML using the **XMLPARSE** or **XMLSERIALIZE** function, the **XML OPTION** session parameter determines it is **DOCUMENT** or **CONTENT**.

The default value is **CONTENT**, indicating that all types of XML data are allowed.

Example:

```
SET XML OPTION DOCUMENT;  
SET  
SET xmloption TO DOCUMENT;  
SET
```

Configuring Binary Data Encoding Format

Syntax:

```
SET xmlbinary TO { base64 | hex};
```

Example:

```
SET xmlbinary TO base64;  
SET
```

```
SELECT xmlelement(name foo, bytea 'bar');
xmlelement
-----
<foo>YmFy</foo>
(1 row)

SET xmlbinary TO hex;
SET

SELECT xmlelement(name foo, bytea 'bar');
xmlelement
-----
<foo>626172</foo>
(1 row)
```

Accessing XML Value

The XML data type is special, and it does not provide any comparison operators, because there is no general comparison algorithm for XML data, so you cannot retrieve data rows by comparing an XML value with a search value. An XML data entry is typically accompanied by an ID for retrieving. Alternatively, you can convert XML values into character strings. However, this is not widely applicable to common scenarios of XML value comparison.

21.6 Constant and Macro

Table 21-28 lists the constants and macros that can be used in DWS.

Table 21-28 Constants and macros

| Parameter | Description | Example SQL Statements |
|-----------------|--|--|
| CURRENT_CATALOG | Specifies the current database. | SELECT CURRENT_CATALOG; |
| CURRENT_ROLE | Current role | SELECT CURRENT_ROLE; |
| CURRENT_SCHEMA | Current database model | SELECT CURRENT_SCHEMA; |
| CURRENT_USER | Current user | SELECT CURRENT_USER; |
| LOCALTIMESTAMP | Current session time (without time zone) | SELECT LOCALTIMESTAMP; |
| NULL | This parameter is left blank. | - |
| SESSION_USER | Current system user | SELECT SESSION_USER; |
| SYSDATE | Current system date | SELECT SYSDATE;
or
SELECT now()::DATE; |

| Parameter | Description | Example SQL Statements |
|-----------|---|------------------------|
| USER | Current user, which is the same as the value of CURRENT_USER . | SELECT USER; |

21.7 Functions and Operators

21.7.1 String Processing Functions and Operators

21.7.1.1 Overview of String Processing Functions and Operators

The string processing functions and operators provided by DWS are used to obtain the string length as well as truncate, concatenate, convert, and compare data.

Before learning about the functions, you can learn about the concepts of bit, byte, and character.

- A bit is the basic unit of data in computers, representing either 0 or 1 in binary. These values correspond to the on/off state of a circuit or the positive/negative polarity of a magnetized surface.
- 1 byte = 8 bits. A byte the basic unit of data storage and transmission in computers.
- A character is a human-readable text symbol, such as a letter, digit, and punctuation. The database character encoding determines how a character is converted into bytes. For details about the database character encoding, see [CREATE DATABASE](#).

For example, in UTF-8 of DWS, an English character takes one byte, and a Chinese character takes three bytes. If a field is defined as VARCHAR(100), the maximum storage would be 100 characters x 3 bytes/character = 300 bytes. In GBK, a single Chinese character can take two bytes.

Application scenarios of string processing functions are as follows:

- **Obtaining the Length of a String**: Query the number of digits and byte length of a string. For example, query the number of digits of the string **World**.
- **Truncating a String**: Extract a substring from a long string. For example, extract **Hello** from **HelloWorld**.
- **Concatenating Strings**: Concatenate two strings, for example, concatenate **DATA** and **BASE** to obtain **DATABASE**.
- **Replacing and Padding Strings**: Replace a character or substring in a string with another character or substring, or delete redundant spaces. For example, delete the space of "**Database**".
- **Deleting a Specified Character**: Delete a specified character from a string, for example, delete **xx** from **DatxBasexx**.
- **Splitting a String**: Split a string into several parts as needed and separate the parts with delimiters. For example, split **hello world** into **hello**, **world**.

- **Converting a String**: Convert a string according to certain rules, for example, convert the case of letters.
- **Comparing Strings**: Compare two strings.
- **Obtaining the Position of a Character or Substring**: For example, obtain the second matching position of the substring **bcd** in the main string **abcdabcdabcd** starting from the second character.
- **Checking If a String Matches a Specific Pattern Using String Matching Functions**: For example, check whether **a** is in the regular expression of **[ac]**.

21.7.1.2 Obtaining the Length of a String

In DWS, you can use the following functions to obtain the length of a string, including the number of bits, bytes, and characters. For details about the differences among bits, bytes, and characters, see [Overview of String Processing Functions and Operators](#).

Table 21-29 Common functions

| Type | Description | Function | Example | Usage Difference |
|------|--|---------------------------|---|------------------|
| Bits | Obtain the number of digits in a string. | bit_length(string) | <pre>SELECT bit_length('world'); bit_length ----- 40 (1 row)</pre> | - |

| Type | Description | Function | Example | Usage Difference |
|------------|--|--|---|---|
| Bytes | Obtain the number of bytes in all string types. | octet_length(string) | <pre>SELECT octet_length('world'); octet_length ----- 5 (1 row)</pre> | <p>The functions of octet_length(string) and lengthb(string) are the same. When developing cross-platform databases such as MySQL and DWS, octet_length(string) is preferred. lengthb(string) is a mapping function for compatibility with Oracle and is used only for Oracle migration.</p> <p>lengthb(text/bpchar) is the same as lengthb(string), but its input parameter is of the text or bpchar type.</p> |
| | Obtain the number of bytes in all string types (only for compatibility with Oracle). | lengthb(string) | <pre>SELECT lengthb('abc'::text); lengthb ----- 3 (1 row)</pre> | |
| | Obtain the number of bytes in text and bpchar (only for compatibility with Oracle). | lengthb(text/bpchar) | <pre>SELECT lengthb('abc'::CHAR(5)); lengthb ----- 5 (1 row)</pre> | |
| Characters | Obtain the number of characters in a string. | char_length(string) or character_length(string)
length(string) | <pre>SELECT length('database'); length ----- 8 (1 row)</pre> | <p>length(string) is equivalent to char_length(string), but its format is simpler.</p> |
| | Obtain the number of characters in a string in the specified encoding format. | length(string bytea, encoding name) | - | - |

bit_length(string)

Description: Obtains the number of bits in a string. That is, the number of bytes multiplied by 8. The number of bits in a string depends on the database encoding

mode. For example, in GBK, a Chinese character is 2 bytes. In UTF-8 and SQL_ASCII, a Chinese character is 3 bytes.

Return type: integer

Example:

```
SELECT bit_length('world');
bit_length
-----
         40
(1 row)
```

octet_length(string)

Description: Obtains the number of bytes in a string. It is important for processing multi-byte characters (such as UTF-8 characters and special symbols) and can accurately obtain the storage size of a string.

Return type: integer

Example:

```
SELECT octet_length('data');
octet_length
-----
          4
(1 row)
```

lengthb(string)

Description: Obtains the length of a string in bytes. It shares the same functions as [octet_length\(string\)](#) and is only used for compatibility with Oracle. If data is migrated from Oracle, use **lengthb(string)**. However, if workloads need to run across databases (for example, DWS and MySQL), use **octet_length(string)** because MySQL does not have the **lengthb** function.

The return result depends on character sets (GBK and UTF-8).

Return type: integer

Example:

```
SELECT lengthb('hello');
lengthb
-----
        5
(1 row)
```

lengthb(text/bpchar)

Description: Obtains the number of bytes of a specified string. The input parameter can be text or bpchar (equivalent to **CHAR(n)**).

- **lengthb(text)** indicates the byte length of actual characters (without padding spaces), which is suitable for most scenarios.
- **lengthb(bpchar)** indicates the byte length of a fixed-length string (including padding spaces), which is suitable for strict fixed-length scenarios (such as

fixed-length codes and certificate numbers). It is not recommended for daily use (implicit problems may be caused by space padding).

Return type: integer

NOTE

- For a string containing newline characters, for example, a string consisting of a newline character and a space, the value of **length** and **lengthb** in DWS is 2.
- This function returns the number of bytes in a specified string. For multi-byte character encoding, such as UTF-8, one character may occupy multiple bytes.

Example:

```
SELECT lengthb('hello');
lengthb
-----
      5
(1 row)
```

Examples of input parameters of the text and bpchar types:

```
-- Case 1: Specify the input parameters as text.
SELECT lengthb('abc'::text); -- 'abc' occupies 3 bytes (UTF-8), and the returned value is 3.
-- Case 2: Specify the input parameters as bpchar or CHAR(5).
SELECT lengthb('abc'::CHAR(5)); -- The value is stored as 'abc..', and the returned value is 5 (each space occupies 1 byte).
```

```
utf8=> SELECT lengthb('abc'::text);
lengthb
-----
      3
(1 row)

utf8=> SELECT lengthb('abc'::CHAR(5));
lengthb
-----
      5
(1 row)
```

char_length(string) or character_length(string)

Description: Obtains the number of characters in a string.

Return type: integer

NOTE

For multi-byte character encoding (such as UTF-8), one character may occupy multiple bytes.

Example:

```
SELECT char_length('hello');
char_length
-----
      5
(1 row)
```

length(string)

Description: Obtains the character length (number of characters) of a string. It is equivalent to `char_length(string)` and is simpler.

Return type: integer

Example:

```
SELECT length('database');
length
-----
      8
(1 row)
```

length(string bytea, encoding name)

Description: Obtains the number of characters in a string in the specified encoding format. In the specified encoding format, **string** must be valid.

Return type: integer

Example:

```
SELECT length('database', 'UTF8');
length
-----
      8
(1 row)
```

21.7.1.3 Truncating a String

Truncation strings is a key technical capability in multidimensional analysis of data warehouses.

Typical applications:

- **Extracting core information:** For example, extract the core serial number **0129A** from **EC2023-BJ-0129A**, and use **substring()** to capture the administrative division code and birth date in a 18-digit ID card code.
- **Masking data for privacy protection:** For example, use **right()** to extract the last four digits of a mobile number for data masking
- **Extracting information accurately:** For example, use **regexp_matches** to match multiple character strings starting with the letter **b**.
- **Clearing redundant data:** For example, clear the redundant spaces or null characters before and after an order No.

DWS provides multiple functions for you to extract strings.

Table 21-30 Common functions

| Type | Description | Function | Example | Usage Difference |
|---------------------------------|---|---|---|---|
| Remove characters at both ends. | Remove the specified characters or spaces at both ends of a string. | btrim(string text [, characters text]) | <pre>SELECT btrim(' string '); btrim ----- string (1 row)</pre> | - |
| Extract a substring, in bytes. | Extract a substring from a given string, where the starting position and length are specified in bytes. | substrb(string,from,count) | <pre>SELECT substrb('ABCDEF',2,2); substrb ----- BC (1 row)</pre> | These four functions work similarly but differ in two ways: what they extract (either the full remaining parts or just specific middle bytes) and their input parameters (whether they accept text-only or all string types). |
| | Extract a substring from a given string, where the starting position and length are specified in bytes. It and the above function work similarly, but the difference is that the input parameter type of the function is text | substrb(text,int,int) | - | |

| Type | Description | Function | Example | Usage Difference |
|------|---|-----------------------------|--|------------------|
| | Extract a substring from a given string, where the starting position is specified in bytes. If from is a negative number, the starting position is counted backward from the end of the string. (It means that the last <i>n</i> bytes are extracted.) | substrb(string,from) | <pre>SELECT substrb('ABCDEF',-2); substrb ----- EF (1 row)</pre> | |
| | Extract a substring from a given string, where the starting position is specified in bytes. They work similarly, but the difference is that the input parameter type of the function is text. | substrb(text,int) | <pre>SELECT substrb('string',2); substrb ----- tring (1 row)</pre> | |

| Type | Description | Function | Example | Usage Difference |
|-------------------------------------|--|---|--|---|
| Extract a substring, in characters. | Extract a substring from a given string, where the starting position and length are specified in characters. | substr(string,from,count) | <pre>SELECT substr('database',0,4) ; substr ----- data (1 row)</pre> | substr(string,from,count) and substring(string [from int] [for int]) work similarly but differ in two ways: what they extract (either the full remaining parts or just specific middle characters) and their SQL syntax (the former is simpler and the latter is standard SQL). |
| | Extract a substring from a given string, where the starting position is specified in characters. | substr(string,from) | <pre>SELECT substr('database',5); substr ----- base (1 row)</pre> | |
| | Extract a substring from a given string, where the starting position and length are specified in characters. It and substr(string,from,count) work similarly. | substring(string [from int] [for int]) | - | |
| | Extract the first several characters. | left(string, n int) | - | - |
| | Extract the last several characters. | right(string, n int) | - | - |

| Type | Description | Function | Example | Usage Difference |
|---|--|--|---|---|
| Extract substrings by regular expression pattern. | Extract a portion of a string that matches a specified regular expression pattern. | substring(string from pattern) | Click the link on the left to view the details. | regexp_substr and substring are similar. substring is a standard SQL function, while regexp_substr is an extended function with stronger regular expression capabilities.
regexp_matches returns text arrays, which is suitable for extracting group information. |
| | Extract a portion of a string that matches a specified regular expression pattern. The escape character can be set. | substring(string from pattern for escape) | | |
| | It is similar to the preceding function, but has a strong regular expression capability. | regexp_substr(text, text) | | |
| | It is similar to the preceding function, but has a strong regular expression capability. | regexp_substr(source_char, pattern) | | |
| | Extract substrings and return text arrays. It works well when you need to match multiple conditions or extract group data. | regexp_matches(string text, pattern text [, flags text]) | | |

btrim(string text [, characters text])

Description: Removes the specified characters from both ends of a string. Only the characters at both ends are processed. The characters in the middle will not be removed even if they match.

Return type: text

Parameters:

- **string**: (mandatory) target string.
- **characters**: (optional) characters to be removed from both ends of the target string. If it is not specified, all whitespace characters are removed by default.

Example:

```
SELECT btrim('sring' , 'ing');
btrim
-----
sr
(1 row)

SELECT btrim(' sting '); -- If characters are not specified, all spaces are deleted by default.
btrim
-----
sting
(1 row)

SELECT btrim('xxdataxxbasex','x'); -- Only the x at both ends is deleted. The x in the middle is not deleted.
btrim
-----
dataxxbase
(1 row)
```

substrb(string,from,count)

Description: Truncates a substring of a specified length from a string. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

It and [substr\(string,from,count\)](#) work similarly, but its calculation unit is byte.

- If **from** starts at 0, it is typically treated as 1.
- If **from** is a positive value, extract **count** bytes starting from **from**.
- If **from** is a negative value, extract the last **n count** bytes in the string, in which **n** indicates the absolute value of **from**.
- When **count** is less than 1, null is returned.

Return type: bytea

Example:

```
SELECT substrb('ABCDEF',2,2);
substrb
-----
BC
(1 row)
```

substrb(text,int,int)

Description: Extracts substrings from a string. The first **int** indicates the start byte position, and the second **int** indicates the number of bytes to be extracted.

Return type: text

Example:

```
SELECT substrb('string',2,3); ---Extracts three bytes starting from the second byte t.
substrb
-----
tri
(1 row)
```

substrb(string,from)

Description: Truncates a specified substring from a string. **from** indicates the starting position. It and **substr(string,from)** work similarly, but its calculation unit is byte.

- If **from** starts at 0, it is typically treated as 1.
- If **from** is a positive value, all bytes from **from** to the end are extracted.
- If **from** is a negative value, the last *n* bytes in the string are extracted, in which *n* indicates the absolute value of **from**.

Return type: bytea

Example:

```
SELECT substrb('ABCDEF',-2);
substrb
-----
EF
(1 row)
```

substrb(text,int)

Description: Extracts a substring from a string. **int** indicates the start byte position of the subtraction.

Return type: text

Example:

```
SELECT substrb('string',2);
substrb
-----
tring
(1 row)
```

substr(string,from,count)

Description: Truncates a substring of a specified length from a string.

from specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

- If **from** starts at 0, it is typically treated as 1.
- If **from** is a positive value, extract **count** characters starting from **from**.
- If **from** is a negative value, extract the last **n count** characters in the string, in which **n** indicates the absolute value of **from**.
- When **count** is less than 1, null is returned.

Return type: varchar

Example:

When **from** is 0, extract the first four characters from the string **database**.

```
SELECT substr('database',0,4);
substr
-----
data
(1 row)
```

When **from** is a positive number, extract the first four characters from the fifth character of the string **database**.

```
SELECT substr('database',5,4);
substr
-----
base
(1 row)
```

If **from** is a negative number, truncate three characters starting from the last fourth character of the string **database**.

```
SELECT substr('database',-4,3);
substr
-----
bas
(1 row)
```

substr(string,from)

Description: Truncates a specified substring from a string.

from indicates the start position of the substring.

- If **from** starts at 0, it is typically treated as 1.
- If **from** is a positive value, all characters from **from** to the end are extracted.
- If **from** is a negative value, the last *n* characters in the string are extracted, in which *n* indicates the absolute value of **from**.

Return type: varchar

Example:

When **from** starts at 0, extract all characters from the first character to the end of the string **database**.

```
SELECT substr('database',0);
substr
-----
database
(1 row)
```

When **from** is a positive value, extract all characters from the fifth character to the end of the string **database**.

```
SELECT substr('database',5);
substr
-----
base
(1 row)
```

When **from** is a negative value, extract all characters from the fourth character from the end to the end of the string **database**.

```
SELECT substr('database',-4);
substr
-----
base
(1 row)
```

substring(string [from int] [for int])

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated. It and [substr\(string,from,count\)](#) work similarly.

Return type: text

Example:

Extract three characters starting from the second character **h** in the string **Thomas**, that is, **hom**.

```
SELECT substring('Thomas' from 2 for 3);
substring
-----
hom
(1 row)
```

left(str text, n int)

Description: Returns first **n** characters in a string.

- In the ORA- or TD-compatible mode, all but the last **|n|** characters are returned if **n** is a negative value.
- In the MySQL-compatible mode, an empty string is returned if **n** is a negative value.

Return type: text

Example:

```
SELECT left('database', 4);
left
-----
data
(1 row)
```

right(str text, n int)

Description: Returns the last **n** characters in a string.

- In the ORA- or TD-compatible mode, all but the first **|n|** characters are returned if **n** is a negative value.
- In the MySQL-compatible mode, an empty string is returned if **n** is a negative value.

Return type: text

Example:

```
SELECT right('abcde', 2);
right
-----
de
(1 row)

SELECT right('abcde', -2);
right
-----
cde
(1 row)
```

substring(string from *pattern*)

Description: Extracts a substring from a string that matches a specified pattern, which is a POSIX regular expression. **string** indicates the original string, and **pattern** indicates the pattern to be matched. If no match is found, NULL is returned. If a match is found, the matched part is returned.

Return type: text

Example:

```
SELECT substring('Thomas' from '...$'); --- Match the last three consecutive characters.
substring
-----
mas
(1 row)

SELECT substring('Thomas' from '^...'); --- Match the first three consecutive characters.
substring
-----
Tho
(1 row)

SELECT substring('Tom' from '....$'); --- Match the last four consecutive characters. Tom has only three
characters and cannot match the condition. Null is returned.
substring
-----
(1 row)

SELECT substring('order_20251120_12345' from '_[0-9]+_'); --- Obtain the order No. between two
underscores (_).
substring
-----
20251120
(1 row)

SELECT substring('tel:13812345678,status:valid' from 'tel:([0-9]{11})'); --- Extract the mobile number
information.
substring
-----
13812345678
(1 row)

SELECT substring('foobar' from 'o(.)b'); -- Match the o(.)b rule. o indicates that the first letter o is matched,
(.) indicates that any character is matched and captured, and b indicates that the letter b is matched. In
foobar, oob is the matched substring. (.) is the middle character (o) of the substring.
substring
-----
```

```
o
(1 row)

SELECT substr('foobar' from '(o(.b))'); -- Use nested capture rules. The outer group captures oob, while
the inner group captures the middle o. The function returns only the first captured group, so the result is
oob.
substr
-----
oob
(1 row)
```

 NOTE

If the POSIX pattern contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. If you want to use parentheses in an expression without causing this exception, you can add a pair of parentheses outside the entire expression.

substring(string from *pattern* for *escape*)

Description: Extracts the substring that matches the SQL regular expression. **string** indicates the original string, **pattern** indicates the pattern that the string must match, and **escape** indicates the escape character, which is specified by **for**. If no pattern is matched, null is returned.

To identify the specific portion of the pattern that should be returned upon a successful match, the pattern must contain two occurrences of the designated escape character, each followed by a double quotation mark ("). The text in the data string that matches the part of the pattern between these two markers is the substring returned by the function.

Return type: text

Example:

```
SELECT substr('Thomas' from '%#"o_a#"_' for '#');
substr
-----
oma
(1 row)
```

Example explanations:

1. **%#"o_a#"_** is the pattern, and **#** is the escape character.
2. **%** indicates the wildcard that matches any number of any prefix. In this example, the prefix **Tho** is matched.
3. **#"** is a marker used to match the text between two **#"**, that is, **o_a**.
4. The last underscore (**_**) indicates that the suffix character **s** is matched.

In conclusion, the pattern body **%#"o_a#"_** is expanded to **% o_a _**, which means that the pattern body matches "any prefix" + o + "single any character" + a + "single any character".

If the string Thomas needs to match this pattern, that is, only the text between the two number signs (**#**) is extracted, that is, **o_a**, where **_** can indicate any character. The result is **oma**.

Example:

Extract the four digits after FX. (The express delivery number is FX**5892**20251124, which is in the format of FX + 4-digit number + 8-digit timestamp.)

```
SELECT substring('FX589220251124' from 'FX#"____#"%' for '#');
substring
-----
5892
(1 row)

SELECT substring('FX564320241024' from 'FX#"____#"%' for '#');
substring
-----
5643
(1 row)
```

regexp_substr(text,text)

Description: Extracts substrings from a regular expression. The first **text** indicates the original string to be processed, and the second **text** indicates the defined regular expression. It is similar to **substr**. When a regular expression contains multiple parallel brackets, all of them are processed.

Return type: text

Example:

```
SELECT regexp_substr('str','[ac]'); --- Match any character in ac from str and return null.
regexp_substr
-----
(1 row)
```

Example: Obtain the first 10 digits from the express number. The other digits after the first 10 digits are timestamps and can be ignored.

```
SELECT regexp_substr('FX58920235822025112404', '\d{10}'); --Search for the first occurrence of 10
consecutive digits in the string by scanning it from left to right.
regexp_substr
-----
5892023582
(1 row)
```

regexp_substr(source_char, pattern)

Description: Extracts substrings from a regular expression. **source_char** indicates the original string, and **pattern** indicates the defined regular expression.

Return type: varchar

Example:

```
-- Find the part of the string that starts with a comma, has at least one non-comma character, and ends
with another comma.
SELECT regexp_substr('500 Hello World, Redwood Shores, CA', '^[^,]+,') "REGEXPR_SUBSTR";
REGEXPR_SUBSTR
-----
, Redwood Shores,
(1 row)
```

regexp_matches(string text, pattern text [, flags text])

Description: Returns all substrings that match the POSIX regular expression. The returned result is a text array. If the pattern does not match, the function returns no rows. This function is flexible in processing complex text parsing, especially when you need to match multiple conditions or extract group data.

- **string** indicates the original string.
- **pattern** indicates the pattern the string must match. The pattern can contain multiple sub-expressions in parentheses, for example, **(bar)(beque)**. If the pattern is matched, a text array with multiple elements is returned, for example, **{bar,beque}**. If the pattern does not contain sub-expressions in parentheses, a text array with a single element is returned, for example, **{barbeque}**.
- **flags** is an optional parameter. If **flags** is set to **i**, the pattern matching is case insensitive. If **flags** is set to **g**, it indicates that the function finds all matches of the pattern within the string, not just the first one.

NOTICE

If the last parameter **flags** is provided but the parameter value is an empty string (") and the SQL compatibility mode of the database is set to ORA, the returned result is null. To resolve this problem, you can:

- Change the database SQL compatibility mode to TD.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: multiple lines of text as an array (setof text[]).

```
-- The rule has two parts: bar and beque. The result is a text array containing two elements.
```

```
SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
regexp_matches
```

```
-----
{bar,beque}
(1 row)
```

```
-- The rule does not contain parentheses. The result is a text array that contains only one element.
```

```
SELECT regexp_matches('foobarbequebaz', 'barbeque');
regexp_matches
```

```
-----
{barbeque}
(1 row)
```

```
-- The rule matches strings starting with 'b' followed by one or more non-'b' characters. It splits the match into two groups: bar and beque. Since g is not included, only the first line matches.
```

```
SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)');
regexp_matches
```

```
-----
{bar,beque}
(1 rows)
```

```
-- Compared with the preceding example, if g is provided, the matching continues and the second line of the text array is displayed.
```

```
SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
regexp_matches
```

```
-----
{bar,beque}
{bazil,barf}
(2 rows)
```

```
-- The rule extracts all 11-digit mobile numbers from the text and causes the function to find all matches of the pattern within the string. All lines are returned.
```

```
SELECT regexp_matches('13812345678,13987654321', '\d{11}', 'g');
regexp_matches
```

```
{13812345678}
{13987654321}
(2 rows)

-- The rule adds i to make the pattern matching case-insensitive.
SELECT regexp_matches('fooBarBeQuebaz', 'barbeque', 'i');
regexp_matches
-----
{BarBeQue}
(1 row)

-- The rule does not contain i, so the pattern matching is case sensitive and null is returned.
SELECT regexp_matches('fooBarBeQuebaz', 'barbeque');
regexp_matches
-----
(0 rows)
```

CAUTION

When a subquery is absent, and the **regexp_matches** function fails to find a match, the table data remains hidden, which is contrary to what is usually intended. To avoid this issue, employ the **regexp_substr(text,text)** function, which can deliver the expected results even without a subquery.

```
SELECT * FROM tab;
c1 | c2
---+---
dws | dws
(1 row)

SELECT c1, regexp_matches(c2, '(bar)(beque)') FROM tab;
c1 | regexp_matches
---+-----
(0 rows)

SELECT c1, c2, (SELECT regexp_matches(c2, '(bar)(beque)')) FROM tab;
c1 | c2 | regexp_matches
---+---+-----
dws | dws |
(1 row)
```

21.7.1.4 Concatenating Strings

rawcat(raw,row)

Description: Concatenates the given strings.

Return type: raw

Example:

```
SELECT rawcat('ab','cd');
rawcat
-----
ABCD
(1 row)
```

repeat(string text, number int)

Description: Outputs a string repeatedly for a specified number of times. If **number int** is set to zero or a negative value, an empty string is returned.

Return type: text

Example:

```
SELECT repeat('abc', 4);
repeat
-----
abcbabcbabcb
(1 row)
```

string || string

Description: Concatenates strings.

Return type: text

Example:

```
SELECT 'DA' || 'TABASE' AS RESULT;
result
-----
DATABASE
(1 row)
```

string || non-string or non-string || string

Description: Concatenates strings and non-strings.

Return type: text

Example:

```
SELECT 'Value: ' || 123 AS RESULT;
result
-----
Value: 123
(1 row)
```

concat(str1,str2)

Description: Connects **str1** and **str2** and returns the string.

- In the ORA- or TD-compatible mode, a combination of all the non-null strings is returned.
- In the MySQL-compatible mode, **NULL** is returned if an input string is **NULL**.

Return type: varchar

Example:

```
SELECT concat('Hello', ' World!');
concat
-----
Hello World!
(1 row)
```

concat_ws(sep text, str"any" [, str"any" [, ...]])

Description: Concatenates all but the first parameter with separators. The first parameter is used as the separator string.

Return type: text

Example:

```
SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
concat_ws
-----
ABCDE,2,22
(1 row)
```

21.7.1.5 Replacing and Padding Strings

lpad(string text, length int [, fill text])

Description: Fills up the string to length by appending the characters fill (a space by default). If the string is already longer than length, it is truncated (on the right).

Return type: text

Example:

```
SELECT lpad('data', 8, 'xy');
lpad
-----
xyxydata
(1 row)
```

overlay(string placing string FROM int [for int])

Description: Replaces the part of a string starting from a specified position with a specified string. It can flexibly replace substring.

Parameters:

FROM int: starts the replacement from the *n*th character of the first string.

for int: (optional) number of characters to be replaced in the first string. If this parameter is not specified, all characters starting from **from** are replaced by default.

Return type: text

Example: Replace part of **abcdef** starting at position 3 with **xyz**. The result is **abxyzf**.

```
SELECT overlay('abcdef' placing 'xyz' FROM 3);
overlay
-----
abxyzf
(1 row)
```

Replace three characters starting at position 2 in **hello** with **world**. The result is **hworldo**.

```
SELECT overlay('hello' placing 'world' from 2 for 3 );
overlay
-----
hworldo
(1 row)
```

replace(string text, from text, to text)

Description: Replace all occurrences in string of substring **from** with substring **to**.

NOTE

The case is sensitive, so you need to ensure that the case of **from text** and **to text** matches that of the original string.

Return type: text

Example:

```
SELECT replace('databasedata', 'data', 'xxx');
replace
-----
xxxbasexxx
(1 row)
```

rpad(string text, length int [, fill text])

Description: Fills up **string** to **length** by appending the characters **fill**. If the string is longer than the specified length, the string is truncated on the right.

Parameters:

- **string**: original string to be processed.
- **length**: length of the target string.
- **fill** (optional): character or string used for filling. The default value is a space.

Return type: text

Example:

Fill the original string (**data**) of length 4 to a target length of 10 using the fill characters **xy**.

```
SELECT rpad('data', 10, 'xy');
rpad
-----
dataxyxyxy
(1 row)
```

Fill the original string **database** using the fill characters **xy**. The string **database** is longer than the target length **4**, and the string is truncated from the end. The returned string is **data**.

```
SELECT rpad('database',4,'xy');
rpad
-----
data
(1 row)
```

rtrim(string text [, characters text])

Description: Removes the specified characters from the right (end) of a string.

Parameters:

- **string**: original string to be processed.
- **characters** (optional): set of characters to be removed from the right of the string. By default, all blank characters (for example, spaces) are removed.

Return type: text

Example:

If the parameter **characters** is not specified, all blank characters on the right of the string **Database** are removed by default.

```
SELECT rtrim('Database ');
rtrim
-----
Database
(1 row)
```

Remove the specified character **x** from the string.

```
SELECT rtrim('trimxxx', 'x');
rtrim
-----
trim
(1 row)
```

rpad(string varchar, length int [, fill varchar])

Description: Adds specified characters to the right of a string until the string reaches the specified length. If the string is longer than the specified length, the string is truncated on the right.

Parameters:

- **string**: original string to be processed.
- **length**: length of the target string. **length** in DWS indicates the character length. One Chinese character is counted as one character.
- **fill** (optional): character or string used for filling. The default value is a space.

Return type: varchar

Example:

```
SELECT rpad('data',10,'xyz');
rpad
-----
dataxyzxyz
(1 row)
SELECT rpad('hi',5,'abcdefg');
rpad
-----
hiabc
(1 row)
```

replace(string varchar, search_string varchar, replacement_string varchar)

Description: Searches for a specific substring (**search_string**) in a string and replaces it with another string (**replacement_string**).

Parameters:

- **string**: original string to be processed.
- **search_string**: substring to be replaced.
- **replacement_string**: new substring used to replace **search_string**.

Return type: varchar

Example:

Replace all substrings **ab** in the string **ababab and mabab** with **cd**.

```
SELECT replace('ababab and mabab','ab','cd');
      replace
-----
cdcdcd and mcdcd
(1 row)
```

lpad(string varchar, length int[, repeat_string varchar])

Description: Adds specified characters to the left of a string until the string reaches the specified length. If the length of the original string is greater than the target length (**length parameter**), the target string is truncated from the right to a string of the **length**.

Parameters:

- **string**: original string to be padded.
- **length**: length of the target string.
- **repeat_string**: (optional) characters used for padding. By default, spaces are used for padding.

Return type: varchar

Example:

Set original string length (**base**) to **4** and the target length to **8**, and use asterisks (*) to pad four characters. After the padding, the string becomes ******base**.

```
SELECT lpad('base',8,'*');
      lpad
-----
****base
(1 row)
```

Set original string length (**database**) to **8** and the target length to **6**, and truncate the string **database** from the right to a string of 6 characters. **databa** is returned.

```
SELECT lpad('database',6,'data');
      lpad
-----
databa
(1 row)
```

regexp_replace(string, pattern, replacement [,flags])

Description: Replaces substring matching POSIX regular expression. The source string is returned unchanged if there is no match to the pattern. If a match is found, the matching substring in the returned string is replaced with the **replacement** string.

The **replacement** string can contain **\n**, where **\n** ranges from 1 to 9, indicating that the substring of the *n*th parenthesized subexpression in the matching pattern

within the string should be inserted. Additionally, it can contain `\&`, indicating that the substring matching the entire pattern should be inserted.

flags (optional parameter) contains zero or multiple single-letter flags that change function behavior. The following table lists the options of **flags**.

Table 21-31 Options of the flags parameter

| Option | Description |
|--------|--|
| g | Replaces all the matched substrings. (By default, only the first matched substring is replaced.) |
| B | By default, uses the Henry Spencer regex library and its regex syntax. Specifying the B option prioritizes using the Boost.Regex library and its regex syntax.

In the following cases, the Henry Spencer's regular expression library and its regular expression syntax will be used even if this option is specified: <ul style="list-style-type: none">Any combination of p, q, w, and x characters is included in the flags.The string or pattern parameters contain multibyte characters. |
| b | Indicates POSIX Basic Regular Expressions (BREs) for matching. |
| c | Indicates the case-sensitive matching. |
| e | Indicates POSIX Extended Regular Expressions (EREs) for matching. When neither b nor e is specified, if the Henry Spencer regex library is chosen, it follows the Advanced Regular Expressions (AREs), similar to Perl Compatible Regular Expressions (PCREs). If the Boost.Regex library is chosen, it adheres to PCREs. |
| i | Indicates the case-insensitive matching. |
| m | Indicates the newline-sensitive matching, synonymous with the n option. |
| n | Indicates the newline-sensitive matching. When this option is active, the newline character influences the matching of metacharacters (<code>.</code> , <code>^</code> , <code>\$</code> , and <code>[]</code>). |
| p | Indicates the partially newline-sensitive matching. When this option is active, the newline character influences the matching of metacharacters (<code>.</code> and <code>[]</code>), partially compared to the n option. |
| q | Resets the regular expression to a double-quoted text string, treating all characters as literals. |
| s | Indicates the non-newline-sensitive matching. |
| t | Indicates the tight syntax (default). When this option takes effect, all characters matter. |
| w | Indicates the inverse partially newline-sensitive matching. When this option is active, the newline character influences the matching of metacharacters (<code>^</code> and <code>\$</code>), inversely partially compared to the n option. |

| Option | Description |
|--------|--|
| x | Indicates the expanded syntax. In contrast to the tight syntax, whitespace characters in regular expressions are ignored in the expanded syntax. Whitespace characters include spaces, horizontal tabs, newlines, and any characters belonging to the space character set. |

Return type: varchar

Example:

```
SELECT regexp_replace('Thomas', '[mN]a.', 'M');
regexp_replace
-----
ThM
(1 row)
SELECT regexp_replace('foobarbaz', 'b(..)', E'X\\1Y', 'g') AS RESULT;
result
-----
fooXarYXazY
(1 row)
```

SPACE(n int)

Description: Returns a string consisting of **n** spaces. If the parameter contains NULL, NULL will be returned.

Return type: text

Example:

```
SELECT SPACE(2) as result;
result
-----
(1 row)
```

21.7.1.6 Deleting a Specified Character

trim([leading |trailing |both] [characters] from string)

Description: Deletes specific characters from the beginning, end, or both ends of a string.

Parameters:

- **leading**: deletes spaces or specified characters at the beginning of a string.
- **trailing**: deletes spaces or specified characters at the end of a string.
- **both**: deletes spaces or specified characters at the beginning and end of a string (default behavior).
- **characters**: (optional) specifies specific characters to be deleted. If this parameter is not specified, spaces are deleted by default.
- **string**: original string to be processed.

Return type: varchar

Examples:

Delete the characters **x** at the beginning and end of the string **xTomxx**.

```
SELECT trim(BOTH 'x' FROM 'xTomxx');
      btrim
-----
      Tom
(1 row)

SELECT trim('x' FROM 'xTomxx');
      btrim
-----
      Tom
(1 row)
```

Delete the character **x** at the beginning of the string **xTomxx**.

```
SELECT trim(LEADING 'x' FROM 'xTomxx');
      ltrim
-----
      Tomxx
(1 row)
```

Delete the character **x** at the end of the string **xTomxx**.

```
SELECT trim(TRAILING 'x' FROM 'xTomxx');
      rtrim
-----
      xTom
(1 row)
```

rtrim(string [, characters])

Description: Deletes the specified characters from the end of a string.

Parameters:

- **string**: original string to be processed.
- **characters** (optional): specifies the set of characters to be deleted from the end of a string. By default, all blank characters (for example, spaces) are deleted.

Return type: varchar

Example:

```
SELECT rtrim('DataxBasexx','x');
      rtrim
-----
      DataBase
(1 row)

SELECT rtrim(' Data ');
      rtrim
-----
      Data
(1 row)
```

ltrim(string [, characters])

Description: Deletes the specified strings from the beginning of a string.

Parameters:

- **string**: original string to be processed.
- **characters** (optional): specifies the set of characters to be deleted from the beginning of a string. By default, all blank characters (for example, spaces) are deleted.

Return type: varchar

Example:

```
SELECT ltrim('xxDataxBaSe','x');
ltrim
-----
DataxBaSe
(1 row)

SELECT ltrim('  Data ');
ltrim
-----
Data
(1 row)
```

21.7.1.7 Splitting a String

regexp_split_to_array(string text, pattern text [, flags text])

Description: Splits **string** using a POSIX regular expression as the delimiter. It is similar to **regexp_split_to_table**, but it returns the result as a text array.

Return type: text[]

Example:

```
SELECT regexp_split_to_array('hello world', E'\\s+');
regexp_split_to_array
-----
{hello,world}
(1 row)
```

regexp_split_to_table(string text, pattern text [, flags text])

Description: Splits **string** using a POSIX regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

The **flags** parameter includes zero or more single-character flags that alter the function's behavior. Flag **i** specifies case-insensitive matching, while flag **g** specifies replacement of each matching substring rather than only the first one.

Return type: setof text

Example:

```
SELECT regexp_split_to_table('hello world', E'\\s+');
regexp_split_to_table
-----
hello
world
(2 rows)
```

 CAUTION

If there is no subquery and the **regexp_split_to_table** function does not find a match, the data in the table will not be output. This is generally not the desired result and such usage should be avoided.

```
SELECT * FROM tab;
c1 | c2
-----+-----
dws |
(1 row)

SELECT c1, regexp_split_to_table(c2, E'\\s+') FROM tab;
c1 | regexp_split_to_table
-----+-----
(0 rows)

SELECT c1, (select regexp_split_to_table(c2, E'\\s+')) FROM tab;
c1 | regexp_split_to_table
-----+-----
dws |
(1 row)
```

split_part(string text, delimiter text, field int)

Description: Splits the original string into several parts based on the specified delimiter (**delimiter** parameter) and returns the given field (**field** parameter). This function is used to extract specific fields from composite strings.

Parameters:

- **string**: original string to be split.
- **delimiter**: delimiter used to split strings.
- **field**: given field returned after the split. The value starts from 1.

Return type: text

Example:

Split the string **abc~@~def~@~ghi** by **~@~** to obtain three parts (**abc**, **def**, and **ghi**), and return the second part, that is, **def**.

```
SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
split_part
-----
def
(1 row)
```

21.7.1.8 Converting a String

upper(string)

Description: Converts the string into the uppercase.

Return type: varchar

Example:

```
SELECT upper('database');
upper
```

```
-----  
DATABASE  
(1 row)
```

ucase(string)

Description: Converts the string into the uppercase.

Return type: varchar

Example:

```
SELECT ucase('database');  
ucase  
-----  
DATABASE  
(1 row)
```

lower(string)

Description: Converts the string into the lowercase.

Return type: varchar

Example:

```
SELECT lower('DATABASE');  
lower  
-----  
database  
(1 row)
```

lcase(string)

Description: Converts the string into the lowercase.

Return type: varchar

Example:

```
SELECT lcase('DATABASE');  
lcase  
-----  
database  
(1 row)
```

initcap(string)

Description: Converts the first letter of each word in the string into the uppercase and the other letters into the lowercase.

Return type: text

Example:

```
SELECT initcap('hi THOMAS');  
initcap  
-----  
Hi Thomas  
(1 row)
```

quote_ident(string text)

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only when necessary (the string contains non-identifier characters or characters that can be converted to uppercase or lowercase). Embedded quotation marks are doubled.

Return type: text

Example:

```
SELECT quote_ident('hello world');
quote_ident
-----
"hello world"
(1 row)
```

quote_literal(string text)

Description: Returns the given string suitably quoted to be used as a text in an SQL statement string (quotation marks are used as required).

Return type: text

Example:

```
SELECT quote_literal('hello');
quote_literal
-----
'hello'
(1 row)
```

If command similar to the following exists, text will be escaped.

```
SELECT quote_literal(E'O\hello');
quote_literal
-----
'O"hello'
(1 row)
```

If command similar to the following exists, backslash will be properly doubled.

```
SELECT quote_literal('O\hello');
quote_literal
-----
E'O\\hello'
(1 row)
```

If the parameter is NULL, NULL is returned. If the parameter may be NULL, you are advised to use **quote_nullable**.

```
SELECT quote_literal(NULL);
quote_literal
-----
(1 row)
```

quote_literal(value anyelement)

Description: Coerces the given value to text and then quotes it as a literal.

Return type: text

Example:

```
SELECT quote_literal(42.5);
quote_literal
-----
'42.5'
(1 row)
```

If command similar to the following exists, the given value will be escaped.

```
SELECT quote_literal(E'O\42.5');
quote_literal
-----
'O"42.5'
(1 row)
```

If command similar to the following exists, backslash will be properly doubled.

```
SELECT quote_literal('O\42.5');
quote_literal
-----
E'O\\42.5'
(1 row)
```

quote_nullable(string text)

Description: Returns the given string suitably quoted to be used as a string literal in an SQL statement string (quotation marks are used as required).

Return type: text

Example:

```
SELECT quote_nullable('hello');
quote_nullable
-----
'hello'
(1 row)
```

If command similar to the following exists, text will be escaped.

```
SELECT quote_nullable(E'O\hello');
quote_nullable
-----
'O"hello'
(1 row)
```

If command similar to the following exists, backslash will be properly doubled.

```
SELECT quote_nullable('O\hello');
quote_nullable
-----
E'O\\hello'
(1 row)
```

If the parameter is **NULL**, **NULL** is returned.

```
SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

quote_nullable(value anyelement)

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
SELECT quote_nullable(42.5);
quote_nullable
-----
'42.5'
(1 row)
```

If command similar to the following exists, the given value will be escaped.

```
SELECT quote_nullable(E'O\42.5');
quote_nullable
-----
'O"42.5'
(1 row)
```

If command similar to the following exists, backslash will be properly doubled.

```
SELECT quote_nullable('O\42.5');
quote_nullable
-----
'E'O\\42.5'
(1 row)
```

If the parameter is NULL, NULL is returned.

```
SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

BIN(n bigint)

Description: Converts the bigint type from decimal to binary and returns the result as a string. If the parameter contains NULL, NULL will be returned.

Return type: text

Example:

```
SELECT BIN(16) as result;
result
-----
10000
(1 row)
```

HEX(n)

Description: Returns the hexadecimal string of **n**. **n** can be an integer or string. If the parameter contains NULL, NULL will be returned.

Return type: text

Example:

```
SELECT HEX(255) as result;
result
-----
FF
(1 row)
SELECT HEX('abc') as result;
result
-----
616263
(1 row)
```

UNHEX(n)

Description: Performs the reverse operation of **HEX(n)**. *n* can be of the int type or a string. Each pair of hexadecimal digits in a parameter is considered as a number and converted into the character represented by the number. If the parameter contains NULL, NULL will be returned. This parameter is supported only by clusters of version 8.2.0 or later.

Return type: bytea

Example:

```
SELECT UNHEX('abc') as result;
result
-----
\x0abc
(1 row)
```

reverse(str)

Description: Returns a string in reverse order.

Return type: text

Example:

```
SELECT reverse('abcde');
reverse
-----
edcba
(1 row)
```

to_hex(number int or bigint)

Description: Converts a number to a hexadecimal number.

Return type: text

Example:

```
SELECT to_hex(2147483647);
to_hex
-----
7fffffff
(1 row)
```

translate(string text, from text, to text)

Description: Replaces any character in the original string that matches a character in the **from** set by the corresponding character in the **to** set. If **from** is longer than **to**, extra characters occurred in **from** are removed.

Parameters:

- **string**: original string to be processed.
- **from**: specifies the characters to be replaced.
- **to**: specifies the characters after replacement.

Return type: text

Example:

Set the **from** parameter to **143** and the **to** parameter **ax**. Replace **1** and **4** in the string **12345** with **a** and **x** respectively. Delete **3** because there is no corresponding replacement character. **a2x5** is returned.

```
SELECT translate('12345', '143', 'ax');
translate
-----
a2x5
(1 row)
```

ascii(string)

Description: Returns the ASCII code of the first character in a string.

Return type: integer

Example:

Return the ASCII code of the first character **x** in the string **xyz**.

```
SELECT ascii('xyz');
ascii
-----
120
(1 row)
```

convert(string bytea, src_encoding name, dest_encoding name)

Description: Converts the string **bytea** to **dest_encoding**. **src_encoding** specifies the source code encoding. **string** must be valid in this encoding.

Return type: bytea

Example:

```
SELECT convert('text_in_utf8', 'UTF8', 'GBK');
convert
-----
\x746578745f696e5f75746638
(1 row)
```

 NOTE

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the **pg_conversion** system catalog for details.

Example:

```
show server_encoding;
server_encoding
-----
LATIN1
(1 row)

SELECT convert_from('some text', 'GBK');
convert_from
-----
some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
convert_to
-----
\x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
convert
-----
\x736f6d652074657874
(1 row)
```

convert_from(string bytea, src_encoding name)

Description: Converts the string **bytea** using the coding mode of the database.

src_encoding specifies the source code encoding. **string** must be valid in this encoding.

Return type: text

Example:

```
SELECT convert_from('text_in_utf8', 'UTF8');
convert_from
-----
text_in_utf8
(1 row)
SELECT convert_from('\x6461746162617365','gbk');
convert_from
-----
database
(1 row)
```

convert_to(string text, dest_encoding name)

Description: Converts the given string into one whose encoding format is **dest_encoding**.

Return type: bytea

Example:

```
SELECT convert_to('some text', 'UTF8');
convert_to
-----
```

```
\x736f6d652074657874
(1 row)
SELECT convert_to('database', 'gbk');
       convert_to
-----
\x6461746162617365
(1 row)
```

chr(integer)

Description: Converts an integer to the corresponding ASCII character.

Return type: varchar

Example:

```
SELECT chr(65);
 chr
-----
 A
(1 row)
```

format(formatstr text [, str"any" [, ...]])

Description: Formats a string.

Return type: text

Example:

```
SELECT format('Hello %s, %1$s', 'World');
       format
-----
Hello World, World
(1 row)
```

md5(string)

Description: Encrypts a string using MD5 and returns a hexadecimal number.

NOTE

MD5 is not recommended for security purposes.

Return type: text

Example:

```
SELECT md5('data');
       md5
-----
8d777f385d3dfec8815d20f7496026dc
(1 row)
```

decode(string text, format text)

Description: Decodes binary data from textual representation.

Return type: bytea

Example:

```
SELECT decode('ZGF0YWJhc2U=', 'base64');
       decode
-----
```

```
-----
\x6461746162617365
(1 row)

SELECT convert_from('\x6461746162617365','utf-8');
convert_from
-----
database
(1 row)
```

encode(data bytea, format text)

Description: Encodes binary data into a textual representation.

Return type: text

Example:

```
SELECT encode('database', 'base64');
encode
-----
ZGF0YWJhc2U=
(1 row)
```

CONV(n, fromBase, toBase)

Description: Converts the given value or string into value of a specific number system and outputs the result as a string. If the parameter contains NULL, NULL will be returned. The value range is [-36, -2] and [2, 36].

Return type: text

Example:

```
SELECT CONV(-1, 10, 16) as result;
result
-----
FFFFFFFFFFFFFFFF
(1 row)
```

21.7.1.9 Comparing Strings

STRCMP(text, text)

Description: Compares two strings. If all strings are the same, **0** is returned. If the first string is less than the second string according to the current classification order, **-1** is returned. Otherwise, **1** is returned. If the parameter contains NULL, NULL will be returned.

Return type: text

Example:

```
SELECT STRCMP('AA', 'AA'), STRCMP('AA', 'AB'), STRCMP('AA', 'A');
STRCMP | STRCMP | STRCMP
-----
0 | -1 | 1
(1 row)
```

21.7.1.10 Obtaining the Position of a Character or Substring

instr(text,text,int,int)

Description: Obtains the position of a substring in the string. If no match is found, **0** is returned.

- First **text**: (mandatory) target string.
- Second **text**: (mandatory) substring to be matched.
- First **int**: start position of the matching. If this parameter is not set, the matching starts from the beginning by default.
- Second **int**: which occurrence of the substring the function should return the position for. If this parameter is not set, the first occurrence is used by default.

Return type: integer

Example:

Obtain the position of the 2nd occurrence of **bcd** starting from position 2 in the main string **abcdabcdabcd**.

```
SELECT instr( 'abcdabcdabcd', 'bcd', 2, 2 );
instr
-----
      6
(1 row)

SELECT instr( 'abcdabcdabcd', 'lmk', 2);
instr
-----
      0
(1 row)
```

position(substring in string)

Description: Returns the position of a specified substring in the string. If the string does not contain substrings, **0** is returned.

Return type: integer

Example:

```
SELECT position('ing' in 'string');
position
-----
      4
(1 row)

SELECT position('ing' in 'strin');
position
-----
      0
(1 row)
```

strpos(string, substring)

Description: Obtains the position of the first occurrence of the specified substring in the string. If the substring does not exist in the string, **0** is returned.

Return type: integer

Example:

```
SELECT strpos('source', 'rc');
-----
      4
(1 row)

SELECT strpos('source', 'data');
-----
      0
(1 row)
```

instr(string,substring[,position,occurrence])

Description: Queries and returns the value of the substring **position** that occurs the **occurrence** (first by default) times from the **position** (1 by default) of the **string**.

- If the value of **position** is **0**, **0** is returned.
- If the value of **position** is negative, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of **position**.

The unit is character. One Chinese character is one character.

Return type: integer

Example:

```
SELECT instr('corporate floor','or', 3);
-----
      5
(1 row)
SELECT instr('corporate floor','or',-3,2);
-----
      2
(1 row)
```

locate(substring,string[,position])

Description: Queries and returns the value of the substring **position** that appears for the first time from the position specified by **position** (1 by default) of **string**. The unit is character. If no substring exists in the **string**, **0** is returned.

Return type: integer

Example:

```
SELECT locate('ball','football');
-----
      5
(1 row)
SELECT locate('er','soccerplayer','6');
-----
     11
(1 row)
```

21.7.1.11 Checking If a String Matches a Specific Pattern Using String Matching Functions

What Are Pattern Matching Functions?

LIKE is a string comparison function used to check whether a string matches a specified pattern rule. It returns a Boolean value (**true/false**, represented by **t/f** in the example).

The differences between **LIKE** and equality (=) operators are as follows:

- = matches the complete string exactly, including its length and content.
- **LIKE** performs a fuzzy match using wildcards to overlook minor character variations while focusing on the main pattern

Scenarios: These functions are mainly used for fuzzy query. For example:

- To find users whose names contain **Zhang**, use **name LIKE '%Zhang%'**;
- To find users whose mobile numbers start with **138**, use **phone LIKE '138%'**;
- To find users whose email addresses end with **@abc.com** and the user name length is **5**, use **email LIKE '____@abc.com'** (**five underscores**).

regexp_like(text,text,text)

Description: Performs a regular expression matching.

Return type: Boolean

Example:

```
SELECT regexp_like('str','[ac]');
regexp_like
-----
f
(1 row)
```

string [NOT] LIKE pattern [ESCAPE escape-character]

Description: Specifies the pattern matching function.

If the pattern contains neither percent signs nor underscores, it stands solely for itself, making **LIKE** behave like the equality operator. An underscore (_) in the pattern matches any single character, while a percent sign (%) matches zero or more characters.

To match an underscore or percent sign literally, the respective character in the pattern must be preceded by an escape character. The default escape character is a backward slash (\) and can be specified using the **ESCAPE** clause. To match with escape characters, enter two escape characters.

Return type: boolean

Example:

```
SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
result
-----
```

```
t
(1 row)
SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
f
(1 row)
SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
t
(1 row)
```

REGEXP_LIKE(source_string, pattern [, match_parameter])

Description: Performs a regular expression matching.

source_string indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match_parameter** indicates the matching items and the values are as follows:

- **i**: case-insensitive.
- **c**: case-sensitive
- **n**: allows the metacharacter "." in a regular expression to be matched with a newline chara
- **m**: allows **source_string** to be regarded as multiple rows.

If **match_parameter** is ignored, case-sensitive will be used by default, meaning that "." will not be matched with a newline character and **source_string** will be regarded as a single row.

Return type: boolean

Example:

```
SELECT regexp_like('ABC', '[A-Z]');
regexp_like
-----
t
(1 row)
SELECT regexp_like('ABC', '[D-Z]');
regexp_like
-----
f
(1 row)
SELECT regexp_like('abc', '[A-Z]', 'i');
regexp_like
-----
t
(1 row)
SELECT regexp_like('abc', '[A-Z]');
regexp_like
-----
f
(1 row)
```

21.7.2 Binary String Functions and Operators

SQL defines some binary string functions that use keywords, rather than commas, to separate arguments. DWS also provides the common syntax used for invoking functions.

octet_length(string)

Description: Returns the number of bytes in the given binary string.

Return type: integer

Example:

```
SELECT octet_length(E'jo\000se'::bytea) AS RESULT;  
result  
-----  
5  
(1 row)
```

overlay(string placing string from int [for int])

Description: Replaces the given substring.

Return type: bytea

Example:

```
SELECT overlay(E'Th\000omas'::bytea placing E'\002\003'::bytea from 2 for 3) AS RESULT;  
result  
-----  
\x5402036d6173  
(1 row)
```

position(substring in string)

Description: Returns the location of the given substring.

Return type: integer

Example:

```
SELECT position(E'\000om'::bytea in E'Th\000omas'::bytea) AS RESULT;  
result  
-----  
3  
(1 row)
```

substring(string [from int] [for int])

Description: Truncates the given substring.

Return type: bytea

Example:

```
SELECT substring(E'Th\000omas'::bytea from 2 for 3) AS RESULT;  
result  
-----  
\x68006f  
(1 row)
```

Truncate the time and obtain the number of hours.

```
SELECT substring('2022-07-18 24:38:15',12,2)AS RESULT;  
result  
-----  
24  
(1 row)
```

trim([both] bytes from string)

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
SELECT trim(E'\000':bytea from E'\000Tom\000':bytea) AS RESULT;  
result  
-----  
\x546f6d  
(1 row)
```

substring_index(string, delim, count)

Description: Searches for delimiters in a case-sensitive manner and returns the substring before the delimiter that appears for the **count** time. If **count** is a negative number, count for the delimiter reversely from the end. If the parameter contains NULL, NULL will be returned. This function is supported by version 8.2.0 or later clusters.

Return type: text

Example: In the string **www.wWw.cloud.wWw.com**, find the delimiter **.wWw.** that appears the second time in a case-sensitive manner. Return the substring before it: **www.wWw.cloud**.

```
SELECT SUBSTRING_INDEX('www.wWw.cloud.wWw.com', '.wWw.', 2) AS RESULT;  
result  
-----  
www.wWw.cloud  
(1 row)
```

btrim(string bytea, bytes bytea)

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```
SELECT btrim(E'\000trim\000':bytea, E'\000':bytea) AS RESULT;  
result  
-----  
\x7472696d  
(1 row)
```

get_bit(string, offset)

Description: Returns the number of bits in the given string.

Return type: integer

Example:

```
SELECT get_bit(E'Th\000omas':bytea, 45) AS RESULT;  
result  
-----  
1  
(1 row)
```

get_byte(string, offset)

Description: Returns the number of bytes in the given string.

Return type: integer

Example:

```
SELECT get_byte(E'Th\\000omas':bytea, 4) AS RESULT;  
result  
-----  
109  
(1 row)
```

set_bit(string,offset, newvalue)

Description: Sets bits in the given string.

Return type: bytea

Example:

```
SELECT set_bit(E'Th\\000omas':bytea, 45, 0) AS RESULT;  
result  
-----  
\x5468006f6d4173  
(1 row)
```

set_byte(string,offset, newvalue)

Description: Sets bytes in the given string.

Return type: bytea

Example:

```
SELECT set_byte(E'Th\\000omas':bytea, 4, 64) AS RESULT;  
result  
-----  
\x5468006f406173  
(1 row)
```

21.7.3 Bit String Functions and Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. When bit shifting, the original length of the string is preserved by zero padding (if necessary).

||

Description: Connects bit strings.

For example:

```
SELECT B'10001' || B'011' AS RESULT;  
result  
-----  
10001011  
(1 row)
```

&

Description: AND operation between bit strings

For example:

```
SELECT B'10001' & B'01101' AS RESULT;  
result  
-----  
00001  
(1 row)
```

|

Description: OR operation between bit strings

For example:

```
SELECT B'10001' | B'01101' AS RESULT;  
result  
-----  
11101  
(1 row)
```

#

Description: OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

For example:

```
SELECT B'10001' # B'01101' AS RESULT;  
result  
-----  
11100  
(1 row)
```

~

Description: NOT operation between bit strings

For example:

```
SELECT ~B'10001' AS RESULT;  
result  
-----  
01110  
(1 row)
```

<<

Description: binary left shift

For example:

```
SELECT B'10001' << 3 AS RESULT;  
result  
-----  
01000  
(1 row)
```

>>

Description: binary right shift

For example:

```
SELECT B'10001' >> 2 AS RESULT;  
result
```

```
-----  
00100  
(1 row)
```

The following SQL-standard functions work on bit strings as well as character strings: **length**, **bit_length**, **octet_length**, **position**, **substring**, and **overlay**.

The following functions work on bit strings as well as binary strings: **get_bit** and **set_bit**. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

Integers and bits can be mutually converted. For example:

```
SELECT 44::bit(10) AS RESULT;  
result  
-----  
0000101100  
(1 row)  
  
SELECT 44::bit(3) AS RESULT;  
result  
-----  
100  
(1 row)  
  
SELECT cast(-44 as bit(12)) AS RESULT;  
result  
-----  
11111010100  
(1 row)  
  
SELECT '1110'::bit(4)::integer AS RESULT;  
result  
-----  
14  
(1 row)
```

NOTE

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

21.7.4 Numeric Functions and Operators

21.7.4.1 Numeric Operators

+

Description: addition

Example:

```
SELECT 2+3 AS RESULT;  
result  
-----  
5  
(1 row)
```

-

Description: subtraction

Example:

```
SELECT 2-3 AS RESULT;  
result  
-----  
    -1  
(1 row)
```

*

Description: multiplication

Example:

```
SELECT 2*3 AS RESULT;  
result  
-----  
     6  
(1 row)
```

/

Description: division (The result is not rounded.)

Example:

```
SELECT 4/2 AS RESULT;  
result  
-----  
     2  
(1 row)  
SELECT 4/3 AS RESULT;  
result  
-----  
1.3333333333333333  
(1 row)
```

+/-

Description: positive/negative

Example:

```
SELECT -2 AS RESULT;  
result  
-----  
    -2  
(1 row)
```

%

Description: modulo (to obtain the remainder)

Example:

```
SELECT 5%4 AS RESULT;  
result  
-----  
     1  
(1 row)
```

@

Description: absolute value

Example:

```
SELECT @ -5.0 AS RESULT;  
result  
-----  
5.0  
(1 row)
```

^

Description: power (exponent calculation)

In MySQL-compatible mode, this operator means exclusive OR. For details, see operator **#** in [Bit String Functions and Operators](#).

Example:

```
SELECT 2.0^3.0 AS RESULT;  
result  
-----  
8.000000000000000  
(1 row)
```

||

Description: square root

Example:

```
SELECT || 25.0 AS RESULT;  
result  
-----  
5  
(1 row)
```

|||

Description: cubic root

Example:

```
SELECT ||| 27.0 AS RESULT;  
result  
-----  
3  
(1 row)
```

!

Description: factorial

Example:

```
SELECT 5! AS RESULT;  
result  
-----  
120  
(1 row)
```

!!

Description: factorial (prefix operator)

Example:

```
SELECT !!5 AS RESULT;  
result  
-----  
120  
(1 row)
```

&

Description: binary AND

Example:

```
SELECT 91&15 AS RESULT;  
result  
-----  
11  
(1 row)
```

|

Description: binary OR

Example:

```
SELECT 32|3 AS RESULT;  
result  
-----  
35  
(1 row)
```

#

Description: binary XOR

Example:

```
SELECT 17#5 AS RESULT;  
result  
-----  
20  
(1 row)
```

~

Description: binary NOT

Example:

```
SELECT ~1 AS RESULT;  
result  
-----  
-2  
(1 row)
```

<<

Description: binary shift left

Example:

```
SELECT 1<<4 AS RESULT;  
result  
-----
```

```
16  
(1 row)
```

>>

Description: binary shift right

Example:

```
SELECT 8>>2 AS RESULT;  
result  
-----  
2  
(1 row)
```

21.7.4.2 Numeric Functions

abs(x)

Description: Returns the absolute value.

Return type: same as the input

Example:

```
SELECT abs(-17.4);  
abs  
-----  
17.4  
(1 row)
```

acos(x)

Description: Returns the arccosine.

Return type: double precision

Example:

```
SELECT acos(-1);  
acos  
-----  
3.14159265358979  
(1 row)
```

asin(x)

Description: Returns the arcsine.

Return type: double precision

Example:

```
SELECT asin(0.5);  
asin  
-----  
0.523598775598299  
(1 row)
```

atan(x)

Description: Returns the arctangent.

Return type: double precision

Example:

```
SELECT atan(1);
      atan
-----
0.785398163397448
(1 row)
```

atan2(y, x)

Description: Returns the arctangent of y/x.

Return type: double precision

Example:

```
SELECT atan2(2, 1);
      atan2
-----
1.10714871779409
(1 row)
```

bitand(integer, integer)

Description: Performs AND (&) operation on two integers.

Return type: bigint

Example:

```
SELECT bitand(127, 63);
      bitand
-----
63
(1 row)
```

cbrt(double precision)

Description: Returns the cubic root.

Return type: double precision

Example:

```
SELECT cbrt(27.0);
      cbrt
-----
3
(1 row)
```

ceil(double precision or numeric)

Description: Returns the minimum integer greater than or equal to a specified number.

Return type: same as the input

Example:

```
SELECT ceil(-42.8);
      ceil
-----
```

```
-42  
(1 row)
```

ceiling(double precision or numeric)

Description: Returns the minimum integer greater than or equal to a specified number. This function is the alias of the ceil(x) function.

Return type: same as the input

Example:

```
SELECT ceiling(-95.3);  
ceiling  
-----  
-95  
(1 row)
```

cos(x)

Description: Returns the cosine.

Return type: double precision

Example:

```
SELECT cos(-3.1415927);  
cos  
-----  
-0.9999999999999999  
(1 row)
```

cot(x)

Description: Returns the cotangent.

Return type: double precision

Example:

```
SELECT cot(1);  
cot  
-----  
0.642092615934331  
(1 row)
```

degrees(double precision)

Description: Converts radians to angles.

Return type: double precision

Example:

```
SELECT degrees(0.5);  
degrees  
-----  
28.6478897565412  
(1 row)
```

div(y numeric, x numeric)

Description: Returns the integer part of y divided by x.

Return type: numeric

Example:

```
SELECT div(9,4);
div
-----
2
(1 row)
```

exp(double precision or numeric)

Description: Returns the natural exponent.

Return type: same as the input

Example:

```
SELECT exp(1.0);
exp
-----
2.7182818284590452
(1 row)
```

floor(double precision or numeric)

Description: Returns the maximum integer less than or equal to a specified number.

Return type: same as the input

Example:

```
SELECT floor(-42.8);
floor
-----
-43
(1 row)
```

radians(double precision)

Description: Converts angles to radians.

Return type: double precision

Example:

```
SELECT radians(45.0);
radians
-----
0.785398163397448
(1 row)
```

random()

Description: Returns a random number between 0.0 and 1.0.

Return type: double precision

Example:

```
SELECT random();
random
-----
```

```
0.824823560658842  
(1 row)
```

rand()

Description: Returns a random number between 0.0 and 1.0. This function is compatible with MySQL. This function is supported by version 8.2.0 or later clusters.

Return type: double precision

Example:

```
SELECT rand();  
      rand  
-----  
0.824823560658842  
(1 row)
```

ln(double precision or numeric)

Description: Returns the natural logarithm.

Return type: same as the input

Example:

```
SELECT ln(2.0);  
      ln  
-----  
0.6931471805599453  
(1 row)
```

log(double precision or numeric)

Description: Returns the logarithm with base 10.

- In the ORA- or TD-compatible mode, this function returns the logarithm with base 10.
- In the MySQL-compatible mode, this function returns the natural logarithm.

Return type: same as the input

Example:

```
-- ORA-compatible mode  
SELECT log(100.0);  
      log  
-----  
2.0000000000000000  
(1 row)  
-- TD-compatible mode  
SELECT log(100.0);  
      log  
-----  
2.0000000000000000  
(1 row)  
-- MySQL-compatible mode  
SELECT log(100.0);  
      log  
-----  
4.6051701859880914  
(1 row)
```

log(b numeric, x numeric)

Description: Returns the logarithm with base b.

Return type: numeric

Example:

```
SELECT log(2.0, 64.0);
      log
-----
6.0000000000000000
(1 row)
```

mod(x,y)

Description: Specifies the remainder of x/y (modulus). If x is 0, 0 is returned. If y is 0, x is returned.

Return type: same as the parameter type

Example:

```
SELECT mod(9,4);
      mod
-----
1
(1 row)
SELECT mod(9,0);
      mod
-----
9
(1 row)
```

pi()

Description: Returns constant π .

Return type: double precision

Example:

```
SELECT pi();
      pi
-----
3.14159265358979
(1 row)
```

power(a double precision, b double precision)

Description: Returns a raised to the power of b.

Return type: double precision

Example:

```
SELECT power(9.0, 3.0);
      power
-----
729.0000000000000000
(1 row)
```

round(double precision or numeric)

Description: Returns the integer closest to the input parameter.

Return type: same as the input

Example:

```
SELECT round(42.4);
round
-----
    42
(1 row)

SELECT round(42.6);
round
-----
    43
(1 row)
```

NOTE

When the **round** function is invoked, the numeric type is rounded to zero. While on most computers, the real number and the double-precision number are rounded to the nearest even number.

round(v numeric, s int)

Description: Rounds to **s** decimal places.

Return type: numeric

Example:

```
SELECT round(42.4382, 2);
round
-----
 42.44
(1 row)
```

setseed(double precision)

Description: Sets seed for the following random() invoking (between -1.0 and 1.0, inclusive).

Return type: void

Example:

```
SELECT setseed(0.54823);
setseed
-----
(1 row)
```

sign(double precision or numeric)

Description: Returns symbols of this parameter.

Return type: **-1** indicates a negative number, **0** indicates 0, and **1** indicates a positive number.

Example:

```
SELECT sign(-8.4);
sign
-----
-1
(1 row)
```

sin(x)

Description: Returns the sine.

Return type: double precision

Example:

```
SELECT sin(1.57079);
sin
-----
0.999999999979986
(1 row)
```

sqrt(double precision or numeric)

Description: Returns the square root.

Return type: same as the input

Example:

```
SELECT sqrt(2.0);
sqrt
-----
1.414213562373095
(1 row)
```

tan(x)

Description: Returns the tangent.

Return type: double precision

Example:

```
SELECT tan(20);
tan
-----
2.23716094422474
(1 row)
```

trunc(double precision or numeric)

Description: Returns the integer part of a number.

Return type: same as the input

Example:

```
SELECT trunc(42.8);
trunc
-----
42
(1 row)
```

trunc(v numeric, s int)

Description: Truncates a number to **s** decimal places.

Return type: numeric

Example:

```
SELECT trunc(42.4382, 2);
trunc
-----
42.43
(1 row)
```

truncate(v numeric, s int)

Description: Truncates **v** to **s** decimal places. In addition to any precision, **v** can also be an integer or float number. The return value type is the same as that of the input parameter **v**. If **s** is a negative number, the integer part is truncated. This function is supported by version 8.2.0 or later clusters.

Return type: numeric

Example:

```
SELECT truncate(42.4382, 2);
truncate
-----
42.4300
(1 row)
```

width_bucket(operand numeric, b1 numeric, b2 numeric, count int)

Description: Sets the minimum value, maximum value, and number of groups in a group range, constructs a specified number of groups with the same size, and returns the ID of the group to which a specified field value belongs. **b1** is the minimum value of the group range, **b2** is the maximum value of the group range, and **count** is the number of groups.

Return type: integer

Example:

```
SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
3
(1 row)
```

width_bucket(operand double precision, b1 double precision, b2 double precision, count int)

Description: Sets the minimum value, maximum value, and number of groups in a group range, constructs a specified number of groups with the same size, and returns the ID of the group to which a specified field value belongs. **b1** is the minimum value of the group range, **b2** is the maximum value of the group range, and **count** is the number of groups.

Return type: integer

Example:

```
SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
3
(1 row)
```

21.7.5 Date and Time Processing Functions and Operators

21.7.5.1 Date and Time Operators

NOTICE

When you use date and time operators, add prefixes of explicit types to the operands to ensure that the operands can be properly parsed by the database.

For example, the operand in the following example does not have an explicit data type, and an error will occur.

```
SELECT date '2001-10-01' - '7' AS RESULT;
```

Table 21-32 Date and time operators

| Operator | Example | Result: |
|----------|--|---|
| + | date + integer → timestamp
Add days to a date.
SELECT date '2001-09-28' + integer '7' AS RESULT; | Add a date with an integer to obtain the time after 7 days.
2001-10-05 00:00:00 |
| + | date + interval → timestamp
Add an interval to a date.
SELECT date '2001-09-28' + interval '1 hour' AS RESULT;
SELECT date '2021-02-28' + interval '1 month' AS RESULT;
SELECT date '2021-01-31' + interval '1 month' AS RESULT; | Sum of the date parameter and the interval parameter
Obtain the time after one hour.
2001-09-28 01:00:00
Obtain the time after one month.
2021-02-28 00:00:00
If the sum or subtraction results fall beyond the date range of a month, the result will be rounded to the last day of the month.
2021-03-28 00:00:00 |
| + | date + time → timestamp
Add the time of a day to a date.
SELECT date '2001-09-28' + time '03:00' AS RESULT; | Add a date and a time to obtain a specific time.
2001-09-28 03:00:00 |
| + | interval + interval → interval
Add an interval.
SELECT interval '1 day' + interval '1 hour' AS RESULT; | Add two intervals to obtain the sum.
1 day 01:00:00 |

| Operator | Example | Result: |
|----------|--|--|
| + | timestamp + interval → timestamp
Add an interval to a timestamp.
SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; | Add a timestamp and an interval to obtain the time after 23 hours.
2001-09-29 00:00:00 |
| + | time + interval → time
Add an interval to a time.
SELECT time '01:00' + interval '3 hours' AS RESULT; | Add a time and an interval to obtain the time after three hours.
04:00:00 |
| - | date - date → integer
Subtract a date from another to obtain the time difference.
SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; | Subtract a date from another to obtain the time difference.
3 days |
| - | date - integer → timestamp
Subtract days from a date.
SELECT date '2001-10-01' - integer '7' AS RESULT; | Subtract an integer from a date to obtain the time difference between them.
2001-09-24 00:00:00 |
| - | date - interval → timestamp
Subtract an interval from a date.
SELECT date '2001-09-28' - interval '1 hour' AS RESULT; | Subtract an interval from a date to obtain the date and time difference.
2001-09-27 23:00:00 |
| - | time - time → interval
Subtract a time.
SELECT time '05:00' - time '03:00' AS RESULT; | Subtract a time from another time to obtain the time difference.
02:00:00 |
| - | time - interval → time
Subtract an interval from a time.
SELECT time '05:00' - interval '2 hours' AS RESULT; | Subtract an interval from a time to obtain the time difference.
03:00:00 |
| - | timestamp - interval → timestamp
Subtract an interval from a timestamp.
SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; | Subtract an interval from a timestamp to obtain the date and time difference.
2001-09-28 00:00:00 |
| - | interval - interval → interval
Subtract an interval.
SELECT interval '1 day' - interval '1 hour' AS RESULT; | Subtract an interval from another interval to obtain the time difference.
23:00:00 |
| - | timestamp - timestamp → interval
Subtract a timestamp.
SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; | Subtract a timestamp from another timestamp to obtain the time difference.
1 day 15:00:00 |

| Operator | Example | Result: |
|----------|--|---|
| - | <p>select now() - interval → timestamp with time zone</p> <p>Obtain the time on the previous day.</p> <pre>select now() - interval '1 day' AS RESULT;</pre> | <p>Obtain the time on the previous day.</p> <pre>2025-07-29 10:54:29.116501+08</pre> |
| * | <p>interval * double precision → interval</p> <p>Multiply an interval by a quantity.</p> <pre>SELECT 900 * interval '1 second' AS RESULT;
SELECT 21 * interval '1 day' AS RESULT;
SELECT double precision '3.5' * interval '1 hour' AS RESULT;</pre> | <p>Multiply the interval of 1 second by 900.</p> <pre>00:15:00</pre> <p>Multiply the interval of one day by 21.</p> <pre>21 days</pre> <p>Multiply the interval of one hour by 3.5.</p> <pre>03:30:00</pre> |
| / | <p>interval / double precision → interval</p> <pre>SELECT interval '1 hour' / double precision '1.5' AS RESULT;</pre> | <p>Divide an interval by a quantity to obtain a time segment.</p> <pre>00:40:00</pre> |

21.7.5.2 Date and Time Functions

age(timestamp, timestamp)

Description: Subtracts arguments and returns the difference. If the result is negative, the returned result is also negative.

Return type: interval

Example:

```
SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');  
age  
-----  
43 years 9 mons 27 days  
(1 row)
```

age(timestamp)

Description: Subtracts the argument from the current date.

Return type: interval

Example:

```
SELECT age(timestamp '1957-06-13');  
age  
-----  
60 years 2 mons 18 days  
(1 row)
```

adddate(date, interval | int)

Description: Returns the result of a given datetime plus the time interval of a specified unit. The default unit is day (when the second parameter is an integer).

Return type: timestamp

Example:

When the input parameter is of the text type:

```
select adddate('2020-11-13', 10);
      adddate
-----
2020-11-23
(1 row)

select adddate('2020-11-13', interval '1' month);
      adddate
-----
2020-12-13
(1 row)

select adddate('2020-11-13 12:15:16', interval '1' month);
      adddate
-----
2020-12-13 12:15:16
(1 row)

select adddate('2020-11-13', interval '1' minute);
      adddate
-----
2020-11-13 00:01:00
(1 row)
```

When the input parameter is of the date type:

```
select adddate(current_date, 10);
      adddate
-----
2021-09-24
(1 row)

select adddate(date '2020-11-13', interval '1' month);
      adddate
-----
2020-12-13 00:00:00
(1 row)
```

addtime(timestamp | time | text, interval | text)

Description: Returns the result of a given datetime plus the time interval of a specified unit. This function is supported by version 8.2.0 or later clusters.

Return type: same as the type of the first input parameter.

Example:

```
SELECT ADDTIME('2020-11-13 01:01:01', '23:59:59');
      addtime
-----
2020-11-14 01:01:00
(1 row)
```

addtime(time, interval)

```
SELECT ADDTIME('20:1:1'::TIME, '20:59:59+8');
      addtime
-----
233:01:00
(1 row)
```

```
SELECT ADDTIME('20:1:1'::TIME, '8 20:59:59');
      addtime
-----
233:01:00
(1 row)
```

addtime(text, interval)

```
SELECT ADDTIME('20:1:1', '20:59:59+8');
      addtime
-----
233:01:00
(1 row)
SELECT ADDTIME('20:1:1', '8 20:59:59');
      addtime
-----
233:01:00
(1 row)
```

subdate(date, interval | int)

Description: Returns the result of a given datetime minus the time interval of a specified unit. The default unit is day (when the second parameter is an integer).

Return type: timestamp

Example:

When the input parameter is of the text type:

```
select subdate('2020-11-13', 10);
      subdate
-----
2020-11-03
(1 row)

select subdate('2020-11-13', interval '2' month);
      subdate
-----
2020-09-13
(1 row)

select subdate('2020-11-13 12:15:16', interval '1' month);
      subdate
-----
2020-10-13 12:15:16
(1 row)

select subdate('2020-11-13', interval '2' minute);
      subdate
-----
2020-11-12 23:58:00
(1 row)
```

When the input parameter is of the date type:

```
select subdate(current_date, 10);
      subdate
-----
2021-09-05
(1 row)
```

```
select subdate(current_date, interval '1' month);
      subdate
-----
2021-08-15 00:00:00
(1 row)
```

subtime(timestamp | time | text, interval | text)

Description: Returns the result of a given datetime minus the time interval of a specified unit. This function is supported by version 8.2.0 or later clusters.

Return type: same as the type of the first input parameter.

Example:

```
select subtime('2020-11-13 01:01:01', '23:59:59');
      addtime
-----
2020-11-12 01:01:02
(1 row)
```

date_add(date, interval)

Description: Returns the result of a given datetime plus the time interval of a specified unit. It is equivalent to [adddate\(date, interval | int\)](#).

Return type: timestamp

date_sub(date, interval)

Description: Returns the result of a given datetime minus the time interval of a specified unit. It is equivalent to [subdate\(date, interval | int\)](#).

Return type: timestamp

timestampadd(field, numeric, timestamp)

Description: Adds an integer interval in the unit of **field** (the number of seconds can be a decimal) to a datetime expression. If the value is negative, the corresponding time interval is subtracted from the given datetime expression. The **field** can be **year**, **month**, **quarter**, **day**, **week**, **hour**, **minute**, **second**, or **microsecond**.

NOTE

When you pass a time expression in the **yyyy-mon-day+{value}** format to the function, the **{value}** part represents the time zone for the given date. For example, **2023-01-31+1** means January 31, 2023, in the UTC+1 time zone. In DWS, this format is handled differently in MySQL. MySQL processes this format only if the loose parsing rule is enabled, interpreting it as 01:00 on January 31, 2023, in the system's default time zone.

Return type: timestamp

Example:

```
select timestampadd(year, 1, timestamp '2020-2-29');
      timestampadd
-----
2021-02-28 00:00:00
(1 row)
```

```
select timestampadd(second, 2.354156, timestamp '2020-11-13');
timestampadd
-----
2020-11-13 00:00:02.354156
(1 row)
```

timestampdiff(field, timestamp1, timestamp2)

Description: Subtracts **timestamp1** from **timestamp2** and returns the difference in the unit of **field**. If the difference is negative, this function returns it normally. The **field** can be **year**, **month**, **quarter**, **day**, **week**, **hour**, **minute**, **second**, or **microsecond**.

Return type: bigint

Example:

```
SELECT timestampdiff(day, timestamp '2001-02-01', timestamp '2003-05-01 12:05:55');
timestampdiff
-----
819
(1 row)
```

timediff(timestamp | time | text, timestamp | time | text)

Description: Subtracts a date from another date. If the difference is negative, this function returns it normally. The types of the two input parameters must be the same. This function is supported by version 8.2.0 or later clusters.

Return type: time

Example:

```
SELECT timediff('2022-7-5 1:1:1', '2021-7-5 1:1:1');
timediff
-----
8760:00:00
(1 row)
```

clock_timestamp()

Description: Returns the current timestamp of the real-time clock.

Return type: timestamp with time zone

Example:

```
SELECT clock_timestamp();
clock_timestamp
-----
2017-09-01 16:57:36.636205+08
(1 row)
```

current_date

Description: Returns the current date.

Return type: date

Example:

```
SELECT current_date;
date
-----
```

```
-----  
2017-09-01  
(1 row)
```

curdate()

Description: Returns the current date. This function is compatible with MySQL. This function is supported by version 8.2.0 or later clusters.

Return type: date

Example:

```
SELECT curdate();  
curdate  
-----  
2022-09-19  
(1 row)
```

current_time

Description: Returns the current time.

Return type: time with time zone

Example:

```
SELECT current_time;  
timetz  
-----  
16:58:07.086215+08  
(1 row)
```

curtime([fsp])

Description: Returns the current time. **fsp** is an optional parameter. Its value is an integer, which indicates the precision of the returned result. This function is supported by version 8.2.0 or later clusters.

Return type: time with time zone

Example:

```
SELECT curtime();  
timetz  
-----  
16:58:07.086215+08  
(1 row)  
SELECT curtime(2);  
timetz  
-----  
16:58:07.08+08  
(1 row)
```

current_timestamp

Description: Returns the current date and time.

Return type: timestamp with time zone

Example:

```
SELECT current_timestamp;  
pg_systimestamp
```

```
-----  
2017-09-01 16:58:19.22173+08  
(1 row)
```

convert_tz(timestamp, from_tz, to_tz)

Description: Converts the datetime value from the time zone provided by **from_tz** (text) to the time zone provided by **to_tz** (text), and returns the converted datetime. This function is supported by version 8.2.0 or later clusters.

Return type: timestamp without time zone

Example:

```
SELECT convert_tz('2018-12-25 13:25:00', '+02:00', '+08:00');  
convert_tz  
-----  
2018-12-25 19:25:00  
(1 row)  
SELECT convert_tz('2000-02-28 23:00:00', 'GMT', 'MET');  
convert_tz  
-----  
2000-02-29 00:00:00  
(1 row)
```

datediff(date1, date2)

Description: Returns the number of days between two given dates.

Return type: bigint

Example:

```
select datediff(date '2020-11-13', date '2012-10-16');  
datediff  
-----  
2950  
(1 row)
```

date_part(text, timestamp)

Description: Obtains the precision specified by **text**.

This function is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
SELECT date_part('hour', timestamp '2001-02-16 20:38:40');  
date_part  
-----  
20  
(1 row)
```

date_part(text, interval)

Description: Obtains the precision specified by **text**. If the value is greater than 12, the remainder of the value divided by 12 is returned.

This function is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
SELECT date_part('month', interval '2 years 3 months');
date_part
-----
      3
(1 row)
```

date_trunc(text, timestamp with time zone | timestamp without time zone | interval)

Description: Truncates the time and date data to the specified precision (**text**). **text** supports microseconds, milliseconds, second, minute, hour, day, week, month, quarter, year, decade, century and millennium.

Return type: timestamp with time zone, timestamp without time zone, and interval

Example:

Truncate the input time to the hour.

```
SELECT date_trunc('hour', timestamp '2025-02-16 20:38:40');
date_trunc
-----
2025-02-16 20:00:00
(1 row)
```

Truncate the input time to the day.

```
SELECT date_trunc('day', timestamptz '2025-02-16 20:38:40+08');
date_trunc
-----
2025-02-16 00:00:00-05
(1 row)
```

Truncate the input time to the month.

```
SELECT date_trunc('month', timestamp '2025-02-16 20:38:40');
date_trunc
-----
2025-02-01 00:00:00
(1 row)
```

Truncate the input timestamp to the first day of a quarter.

```
SELECT DATE_TRUNC('quarter', TIMESTAMP '20250430 04:05:06.789');
date_trunc
-----
2025-04-01 00:00:00
(1 row)
```

Truncate the first day of the current month at 12:00.

```
SELECT date_trunc('month', now()) + interval '12h';
?column?
-----
2025-09-01 12:00:00-04
(1 row)
```

Truncate 09:00 of the current day.

```
SELECT date_trunc('day', now()) + interval '9h';
?column?
-----
2025-09-22 09:00:00-04
(1 row)
```

Truncate the first day of the current year.

```
SELECT date_trunc('year',CURRENT_DATE);
       date_trunc
-----
2025-01-01 00:00:00-05
(1 row)
```

trunc(timestamp)

Description: Truncates a timestamp to day.

Return type: timestamp

Example:

```
SELECT trunc(timestamp '2001-02-16
20:38:40');
       trunc
-----
2001-02-16 00:00:00
(1 row)
```

extract(field from timestamp)

Description: Obtains the value of **field** with the specified precision. For details about the valid values of **field**, see [EXTRACT](#).

Return type: double precision

Example:

```
SELECT extract(hour from timestamp '2001-02-16 20:38:40');
       date_part
-----
20
(1 row)
```

extract(field from interval)

Description: Obtains the value of **field** with the specified precision. If the value is greater than 12, the remainder of the value divided by 12 is returned. For details about the valid values of **field**, see [EXTRACT](#).

Return type: double precision

Example:

```
SELECT extract(month from interval '2 years 3 months');
       date_part
-----
3
(1 row)
```

day(date)

Description: Returns the number of days in the month in which **date** is located. This function is the same as the **dayofmonth** function.

Value range: 1 to 31

Return type: integer

Example:

```
select day('2020-06-28');
day
-----
28
(1 row)
```

dayofmonth(date)

Description: Returns the number of days in the month in which **date** is located.

Value range: 1 to 31

Return type: integer

Example:

```
select dayofmonth('2020-06-28');
dayofmonth
-----
28
(1 row)
```

dayofweek(date)

Description: Returns the week index corresponding to the given date, with Sunday as the start day of the week.

Value range: 1 to 7

Return type: integer

Example:

```
select dayofweek('2020-11-22');
dayofweek
-----
1
(1 row)
```

dayofyear(date)

Description: Returns the number of days of a given date in the current year.

Value range: 1 to 366

Return type: integer

Example:

```
select dayofyear('2020-02-29');
dayofyear
-----
60
(1 row)
```

hour(timestamp with time zone)

Description: Returns the hour value in a timestamp.

Return type: integer

Example:

```
SELECT hour(timestampz '2018-12-13 12:11:15+06');
hour
-----
14
(1 row)
```

isfinite(date)

Description: Checks whether a date is valid.

Return type: boolean

Example:

```
SELECT isfinite(date '2001-02-16');
isfinite
-----
t
(1 row)
SELECT isfinite(date 'infinity');
isfinite
-----
f
(1 row)
```

isfinite(timestamp)

Description: Checks whether a timestamp is valid.

Return type: boolean

Example:

```
SELECT isfinite(timestamp '2001-02-16 21:28:30');
isfinite
-----
t
(1 row)
SELECT isfinite(timestamp 'infinity');
isfinite
-----
f
(1 row)
```

isfinite(interval)

Description: Checks whether an interval is valid.

Return type: boolean

Example:

```
SELECT isfinite(interval '4 hours');
isfinite
-----
t
(1 row)
```

justify_days(interval)

Description: Adjusts an interval so that 30-day time periods are represented as months.

Return type: interval

Example:

```
SELECT justify_days(interval '35 days');
justify_days
-----
1 mon 5 days
(1 row)
```

justify_hours(interval)

Description: Adjusts an interval so that 24-hour time periods are represented as days.

Return type: interval

Example:

```
SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
justify_hours
-----
1 day 03:00:00
(1 row)
```

justify_interval(interval)

Description: Adjusts an interval using **justify_days** and **justify_hours**.

Return type: interval

Example:

```
SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
justify_interval
-----
29 days 23:00:00
(1 row)
```

localtime

Description: Returns the current time.

Return type: time

Example:

```
SELECT localtime AS RESULT;
result
-----
16:05:55.664681
(1 row)
```

localtimestamp

Description: Returns the current date and time.

Return type: timestamp

Example:

```
SELECT localtimestamp;
timestamp
-----
2017-09-01 17:03:30.781902
(1 row)
```

makedate(year, dayofyear)

Description: Returns a date value based on the given year and the number of days in a year.

Return type: date

Example:

```
select makedate(2020, 60);
makedate
-----
2020-02-29
(1 row)
```

maketime(hour, minute, second)

Description: Returns a value of the time type based on the given hour, minute, and second. The value of the time type in DWS ranges from 00:00:00 to 24:00:00. Therefore, this function is not available when the value of hour is greater than 24 or less than 0.

Return type: time

Example:

```
select maketime(12, 15, 30.12);
maketime
-----
12:15:30.12
(1 row)
```

microsecond(timestamp with time zone)

Description: Returns the microsecond value in the time.

Return type: integer

Example:

```
SELECT microsecond(timestampz '2018-12-13 12:11:15.123634+06');
microsecond
-----
123634
(1 row)
```

minute(timestamp with time zone)

Description: Returns the minute value in the time.

Return type: integer

Example:

```
SELECT minute(timestampz '2018-12-13 12:11:15+06');
minute
-----
11
(1 row)
```

month(date)

Description: Returns the month of a given datetime.

Return type: integer

Example:

```
select month('2020-11-30');
month
-----
11
(1 row)
```

now([fsp])

Description: Returns the start time of the transaction. The parameter determines the microsecond output precision. The default value is 6.

Return type: timestamp with time zone

Example:

```
SELECT now();
now
-----
2017-09-01 17:03:42.549426+08
(1 row)
SELECT now(3);
now
-----
2021-09-08 10:59:00.427+08
(1 row)
```

numtodsinterval(num, interval_unit)

Description: Converts a number to an interval. **num** is a numeric-typed number. **interval_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

You can set the **IntervalStyle** parameter to **oracle** to be compatible with the interval output format of the function in the Oracle database.

Example:

```
SELECT numtodsinterval(100, 'HOUR');
numtodsinterval
-----
100:00:00
(1 row)

SET intervalstyle = oracle;
SET
SELECT numtodsinterval(100, 'HOUR');
numtodsinterval
-----
+0000000004 04:00:00.000000000
(1 row)
```

pg_sleep(seconds)

Description: Returns the delay of the server thread in seconds.

Return type: void

Example:

```
SELECT pg_sleep(10);
pg_sleep
```

```
-----  
(1 row)
```

period_add(P, N)

Description: Returns the date of a given period plus *N* months.

Return type: integer

Example:

```
select period_add(200801, 2);  
period_add  
-----  
200803  
(1 row)
```

period_diff(P1, P2)

Description: Returns the number of months between two given dates.

Return type: integer

```
select period_diff(200802, 200703);  
period_diff  
-----  
11  
(1 row)
```

quarter(date)

Description: Returns the quarter to which the date belongs.

Return type: integer

Example:

```
SELECT quarter(date '2018-12-13');  
quarter  
-----  
4  
(1 row)
```

second(timestamp with time zone)

Description: Returns the second in a timestamp.

Return type: integer

Example:

```
SELECT second(timestampz '2018-12-13 12:11:15+06');  
second  
-----  
15  
(1 row)
```

statement_timestamp()

Description: Returns the current date and time.

Return type: timestamp with time zone

Example:

```
SELECT statement_timestamp();
       statement_timestamp
-----
2017-09-01 17:04:39.119267+08
(1 row)
```

sysdate

Description: Returns the current date and time.

Return type: timestamp

Example:

```
SELECT sysdate;
       sysdate
-----
2017-09-01 17:04:49
(1 row)
```

timeofday()

Description: Current date and time (like **clock_timestamp**, but returned as a **text** string)

Return type: text

Example:

```
SELECT timeofday();
       timeofday
-----
Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

transaction_timestamp()

Description: Returns the current date and time. This function is equivalent to **current_timestamp**.

Return type: timestamp with time zone

Example:

```
SELECT transaction_timestamp();
       transaction_timestamp
-----
2017-09-01 17:05:13.534454+08
(1 row)
```

from_unixtime(unix_timestamp[,format])

Description: Converts a Unix timestamp to the datetime type when the format string is set to the default value. If the format string is specified, this function converts the Unix timestamp to a string of a specified format.

Return type: timestamp (default format string) or text (specified format string)

Example:

```
SELECT from_unixtime(875996580);
       from_unixtime
-----
```

```
-----  
1997-10-04 20:23:00  
(1 row)  
SELECT from_unixtime(875996580, '%Y %D %M %h:%i:%s');  
       from_unixtime  
-----  
1997 5th October 04:23:00  
(1 row)
```

unix_timestamp([timestamp with time zone])

Description: Returns the number of seconds from '1970-01-01 00:00:00'UTC to the timestamp specified by the input parameter. If no parameter is input, this function obtains the number of seconds from '1970-01-01 00:00:00'UTC to the current time.

Return type: bigint (no parameter is input) or numeric (parameter is input)

Example:

```
SELECT unix_timestamp();  
unix_timestamp  
-----  
1693906219  
(1 row)  
SELECT unix_timestamp('2018-09-08 12:11:13+06');  
unix_timestamp  
-----  
1536387073.000000  
(1 row)
```

add_months(d,n)

Description: Adds a specified number of months to a date.

Return type: timestamp

Example:

```
SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM dual;  
add_months  
-----  
2018-04-29 00:00:00  
(1 row)
```

last_day(d)

Description: Returns the last day of the month of a specified date.

- In the ORA- or TD-compatible mode, a timestamp is returned.
- In the MySQL-compatible mode, a date is returned.

Example:

```
select last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;  
cal_result  
-----  
2017-01-31 00:00:00  
(1 row)
```

next_day(x,y)

Description: Returns a specified day of the next week of a given date.

- In the ORA- or TD-compatible mode, a timestamp is returned.
- In the MySQL-compatible mode, a date is returned.

Example:

```
select next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
       cal_result
-----
2017-05-28 00:00:00
(1 row)
```

from_days(days)

Description: Returns the corresponding date value based on the given number of days.

Return type: date

Example:

```
select from_days(730669);
       from_days
-----
2000-07-03
(1 row)
```

to_days(timestamp)

Description: Returns the number of days from the first day of year 0 to a specified date.

Return type: integer

Example:

```
SELECT to_days(timestamp '2008-10-07');
       to_days
-----
       733687
(1 row)
```

21.7.5.3 EXTRACT

EXTRACT(*field* FROM *source*)

The **extract** function retrieves subcolumns such as year or hour from date/time values. **source** must be a value expression of type **timestamp**, **time**, or **interval**. (Expressions of type **date** are cast to **timestamp** and can therefore be used as well.) **field** is an identifier or string that selects what column to extract from the source value. The **extract** function returns values of type **double precision**. The following are valid field names:

century

Century

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from **-1** century to **1** century.

Example:

```
SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');
date_part
-----
      20
(1 row)
```

day

- For **timestamp** values, the day (of the month) column (1–31)

```
SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      16
(1 row)
```

- For **interval** values, the number of days

```
SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
date_part
-----
      40
(1 row)
```

decade

Year column divided by 10

```
SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
     200
(1 row)
```

dow

Day of the week as Sunday(0) to Saturday (6)

```
SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
       5
(1 row)
```

doy

Day of the year (1–365 or 366)

```
SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      47
(1 row)
```

epoch

- For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00 UTC (can be negative);
for **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00 local time;
for **interval** values, the total number of seconds in the interval.

```
SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40.12-08');
date_part
-----
```

```
982384720.12
(1 row)
SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
date_part
-----
442800
(1 row)
```

- Way to convert an epoch value back to a timestamp

```
SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1 second' AS RESULT;
result
-----
2001-02-17 12:38:40.12+08
(1 row)
```

hour

Hour column (0–23)

```
SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
20
(1 row)
```

isodow

Day of the week (1–7)

Monday is 1 and Sunday is 7.

NOTE

This is identical to **dow** except for Sunday.

```
SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
date_part
-----
7
(1 row)
```

isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

Each ISO year begins with the Monday of the week containing the 4th of January, so in early January or late December the ISO year may be different from the Gregorian year. For details, see [week](#).

```
SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part
-----
2005
(1 row)
SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part
-----
2006
(1 row)
```

microseconds

The seconds column, including fractional parts, multiplied by 1,000,000

```
SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
date_part
-----
28500000
(1 row)
```

millennium

Millennium

Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

```
SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
3
(1 row)
```

milliseconds

The seconds column, including fractional parts, multiplied by 1000. Note that this includes full seconds.

```
SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
date_part
-----
28500
(1 row)
```

minute

Minutes column (0–59)

```
SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
38
(1 row)
```

month

For **timestamp** values, the number of the month within the year (1–12);

```
SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
2
(1 row)
```

For **interval** values, the number of months, modulo 12 (0–11)

```
SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
date_part
-----
1
(1 row)
```

quarter

Quarter of the year (1–4) that the date is in

```
SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
1
(1 row)
```

```
-----  
      1  
(1 row)
```

second

Seconds column, including fractional parts (0–59)

```
SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');  
date_part  
-----  
      28.5  
(1 row)
```

timezone

The time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

```
SELECT EXTRACT(timezone FROM TIMETZ '17:12:28');  
date_part  
-----  
     28800  
(1 row)
```

timezone_hour

The hour component of the time zone offset

```
SELECT EXTRACT(timezone_hour FROM TIMETZ '17:12:28');  
date_part  
-----  
      8  
(1 row)
```

timezone_minute

The minute component of the time zone offset

```
SELECT EXTRACT(timezone_minute FROM TIMETZ '17:12:28');  
date_part  
-----  
      0  
(1 row)
```

week

The number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. (The ISO-8601 week starts on Monday.) In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st week of the next year. For example, **2005-01-01** is part of the 53rd week of year 2004, **2006-01-01** is part of the 52nd week of year 2005, and **2012-12-31** is part of the 1st week of year 2013. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

```
SELECT EXTRACT(WEEK FROM TIMESTAMP '2001-02-16 20:38:40');  
date_part  
-----
```

```
7
(1 row)
```

year

Year column

```
SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
2001
(1 row)
```

21.7.5.4 date_part

date_part

The **date_part** function is modeled on the traditional Ingres equivalent to the SQL-standard function **extract**:

`date_part('field', source)`

Note that the **field** must be a string, rather than a name. The valid field names are the same as those for **extract**. For details, see [EXTRACT](#).

Example:

```
SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
16
(1 row)
SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
date_part
-----
4
(1 row)
```

21.7.5.5 date_format

date_format(timestamp, fmt)

Converts a date into a string in the format specified by **fmt**.

Example:

```
SELECT date_format('2009-10-04 22:23:00', '%M %D %W');
date_format
-----
October 4th Sunday
(1 row)
SELECT date_format('2021-02-20 08:30:45', '%Y-%m-%d %H:%i:%S');
date_format
-----
2021-02-20 08:30:45
(1 row)
SELECT date_format('2021-02-20 18:10:15', '%r-%T');
date_format
-----
06:10:15 PM-18:10:15
(1 row)
```

Table 21-33 describes the patterns of date parameter values. They can be used for the **date_format**, **time_format**, **str_to_date**, **str_to_time**, and **from_unixtime** functions.

Table 21-33 Formats for the output string

| Format | Description | Value |
|--------|---|-------------------------|
| %a | Abbreviated week name | Sun...Sat |
| %b | Abbreviated month name | Jan...Dec |
| %c | Month | 0...12 |
| %D | Date with a suffix | 0th, 1st, 2nd, 3rd, ... |
| %d | Day in a month (two digits) | 00...31 |
| %e | Day in a month | 0...31 |
| %f | Microsecond | 000000...999999 |
| %H | Hour, in 24-hour format | 00...23 |
| %h | Hour, in 12-hour format | 01...12 |
| %l | Hour, in 12-hour format, same as %h | 01...12 |
| %i | Minute | 00...59 |
| %j | Day in a year | 001...366 |
| %k | Hour, in 24-hour format, same as %H | 0...23 |
| %l | Hour, in 12-hour format, same as %h | 1...12 |
| %M | Month name | January...December |
| %m | Month (two digits) | 00...12 |
| %p | Morning and afternoon | AM PM |
| %r | Time, in 12-hour format | hh:mm:ss AM/PM |
| %S | Second | 00...59 |
| %s | Second, same as %S | 00...59 |
| %T | Time, in 24-hour format | hh:mm:ss |
| %U | Week (Sunday is the first day of a week.) | 00...53 |
| %u | Week (Monday is the first day of a week.) | 00...53 |

| Format | Description | Value |
|--------|---|-------------------|
| %V | Week (Sunday is the first day of a week). It is used together with %X. | 01...53 |
| %v | Week (Monday is the first day of a week). It is used together with %x. | 01...53 |
| %W | Week name | Sunday...Saturday |
| %w | Day of a week. The value is 0 for Sunday. | 0...6 |
| %X | Year (four digits). It is used together with %V. Sunday is the first day of a week. | - |
| %x | Year (four digits). It is used together with %v. Monday is the first day of a week. | - |
| %Y | Year (four digits) | - |
| %y | Year (two digits) | - |
| %% | Character '%' | Character '%' |
| %x | 'x': any character apart from the preceding ones | Character 'x' |

NOTICE

In the preceding table, %U, %u, %V, %v, %X, and %x are not supported currently.

21.7.5.6 time_format

time_format(time, fmt)

Description: The **time_format** function converts the **date** parameter into a string in the format specified by **fmt**. It is similar to the **date_format** function, but the format string can contain only hour, minute, second, and microsecond format specifiers. If other specifiers are contained, **NULL** or **0** is returned.

Return type: text

Example:

```
SELECT time_format('2009-10-04 22:23:00', '%M %D %W');
time_format
-----
(1 row)
SELECT time_format('2021-02-20 08:30:45', '%Y-%m-%d %H:%i:%S');
```

```
time_format
-----
0000-00-00 08:30:45
(1 row)
SELECT time_format('2021-02-20 18:10:15', '%r-%T');
time_format
-----
06:10:15 PM-18:10:15
(1 row)
```

NOTICE

time_format supports only time-related formats (%f, %H, %h, %l, %i, %k, %l, %p, %r, %S, %s, and %T) and does not support date-related formats. In other cases, **time_format** is output as common characters.

str_to_date(str, format)

Description: Converts a string of the date/time type to a value of the date type according to the provided display format.

Return type: timestamp

Example:

```
SELECT str_to_date('01,5,2021','%d,%m,%Y');
str_to_date
-----
2021-05-01 00:00:00
(1 row)
SELECT str_to_date('01,5,2021,09,30,17','%d,%m,%Y,%h,%i,%s');
str_to_date
-----
2021-05-01 09:30:17
(1 row)
```

For details about the input format types applicable to **str_to_date**, see [Table 21-33](#). Only input values of the date or date/time type can be converted. Use **str_to_time** when only values of the time type are input.

str_to_time(str, format)

Description: Converts a string of the time type to a value of the time type according to the provided display format.

Return type: time

Example:

```
SELECT str_to_time('09:30:17','%h:%i:%s');
str_to_time
-----
09:30:17
(1 row)
```

For details about the input format types applicable to **str_to_time**, see [Table 21-33](#). Only input values of the time type can be converted. Use **str_to_date** when values of the date or date/time type are input.

week(date[, mode])

Description: Returns the number of weeks in the year of the specified datetime.
The default value is **0**.

Return type: integer

Table 21-34 Working principle of the mode in the week function

| Sche
ma | First Day of a
Week | Week Range | Rule for Determining the First Week |
|------------|------------------------|------------|--|
| 0 | Sun | 0-53 | Week of the first Sunday after New Year's Day |
| 1 | Mon | 0-53 | Week with four or more days after New Year's Day |
| 2 | Sun | 1-53 | Week of the first Sunday after New Year's Day |
| 3 | Mon | 1-53 | Week with four or more days after New Year's Day |
| 4 | Sun | 0-53 | Week with four or more days after New Year's Day |
| 5 | Mon | 0-53 | Week of the first Monday after New Year's Day |
| 6 | Sun | 1-53 | Week with four or more days after New Year's Day |
| 7 | Mon | 1-53 | Week of the first Monday after New Year's Day |

Example:

```
select week('2018-01-01');
week
-----
0
(1 row)

select week('2018-01-01', 0);
week
-----
0
(1 row)

select week('2020-12-31', 1);
week
-----
53
(1 row)

select week('2020-12-31', 5);
week
-----
```

```
52
(1 row)
```

weekday(date)

Description: Returns the week index corresponding to the given date, with Monday as the start day of the week.

Value range: 0 to 6

Return type: integer

Example:

```
select weekday('2020-11-06');
weekday
-----
4
(1 row)
```

weekofyear(date)

Description: Returns the number of weeks in the current year for the week of the given date. The value ranges from 1 to 53, which is equivalent to week(date, 3).

Return type: integer

Example:

```
select weekofyear('2020-12-30');
weekofyear
-----
53
(1 row)
```

year(date)

Description: Obtains the year of the **date**.

Return type: integer

Example:

```
select year('2020-11-13');
year
-----
2020
(1 row)
```

yearweek(date[, mode])

Description: Returns the year and the number of weeks in the current year for the given date. The number of weeks ranges from 1 to 53.

Return type: integer

Example:

```
select yearweek('2019-12-31');
yearweek
-----
201952
(1 row)
```

```
select yearweek('2019-1-1');
yearweek
-----
201852
(1 row)
```

21.7.6 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

nextval(regclass)

Specifies an increasing sequence and returns a new value.

NOTE

- In order to avoid blocking concurrent transactions that retrieve values from the same sequence, the **nextval** operation does not undo its action. This means that once a value is obtained, it is considered as used and will not be given again. This applies even if the operation is part of a transaction that gets interrupted or if the calling query does not end up using the value. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, sequences in DWS cannot be used to obtain sequence without gaps.
- If the **nextval** function is pushed to DN, each DN will automatically connect to the GTM and requests the next value. For example, in the **INSERT INTO t1 SELECT xxx** statement, a column in table **t1** needs to invoke the **nextval** function. If maximum number of connections on the GTM is 8,192, this type of pushed statements occupies too many GTM connections. Therefore, the number of concurrent connections for these statements is limited to 7,000 divided by the number of cluster DNs. The other 1,192 connections are reserved for other statements.

Return type: bigint

The **nextval** function can be invoked in either of the following ways: (In example 2, the Oracle syntax is supported. Currently, the sequence name cannot contain a dot.)

Example 1:

```
SELECT nextval('seqDemo');
nextval
-----
2
(1 row)
```

Example 2:

```
SELECT seqDemo.nextval;
nextval
-----
2
(1 row)
```

currval(regclass)

Returns the last value of **nextval** for a specified sequence in the current session. If **nextval** has not been invoked for the specified sequence in the current session, an error is reported when **currval** is invoked. By default, **currval** is disabled. To enable it, set **enable_beta_features** to **true**. After **currval** is enabled, **nextval** will not be pushed down.

Return type: bigint

The **currval** function can be invoked in either of the following ways: (In example 2, the Oracle syntax is supported. Currently, the sequence name cannot contain a dot.)

Example 1:

```
SELECT currval('seq1');
currval
-----
      2
(1 row)
```

Example 2:

```
SELECT seq1.currval seq1;
currval
-----
      2
(1 row)
```

lastval()

Returns the last value of **nextval** in the current session. This function is equivalent to **currval**, but **lastval** does not have a parameter. If **nextval** has not been invoked in the current session, an error is reported when **lastval** is invoked.

By default, **lastval** is disabled. To enable it, set **enable_beta_features** or **lastval_supported** to **true**. After **lastval** is enabled, **nextval** will not be pushed down.

Return type: bigint

For example:

```
SELECT lastval();
lastval
-----
      2
(1 row)
```

setval(regclass, bigint)

Sets the current value of a sequence.

Return type: bigint

For example:

```
SELECT setval('seqDemo',1);
setval
-----
      1
(1 row)
```

setval(regclass, bigint, boolean)

Sets the current value of a sequence and the `is_called` sign.

Return type: bigint

For example:

```
SELECT setval('seqDemo',1,true);
setval
-----
1
(1 row)
```

NOTE

The current session and GTM will take effect immediately after **setval** is performed. If other sessions have buffered sequence values, **setval** will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to use **setval** with caution.

Because the sequence is non-transactional, changes made by **setval** will not be canceled when a transaction rolled back.

21.7.7 Array Functions and Operators

21.7.7.1 Array Operators

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

=

Description: Specifies whether two arrays are equal.

Example:

```
SELECT ARRAY[1,1,2,1,3,1]::int[] = ARRAY[1,2,3] AS RESULT;
result
-----
t
(1 row)
```

<>

Description: Specifies whether two arrays are not equal.

Example:

```
SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

<

Description: Specifies whether an array is less than another.

Example:

```
SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```

>

Description: Specifies whether an array is greater than another.

Example:

```
SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;  
result  
-----  
t  
(1 row)
```

<=

Description: Specifies whether an array is less than another.

Example:

```
SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;  
result  
-----  
t  
(1 row)
```

>=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;  
result  
-----  
t  
(1 row)
```

@>

Description: Specifies whether an array contains another.

Example:

```
SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;  
result  
-----  
t  
(1 row)
```

<@

Description: Specifies whether an array is contained in another.

Example:

```
SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;  
result  
-----  
t  
(1 row)
```

&&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;  
result  
-----  
t  
(1 row)
```

||

Description: Array-to-array concatenation

Example:

```
SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;  
result  
-----  
{1,2,3,4,5,6}  
(1 row)  
SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;  
result  
-----  
{{1,2,3},{4,5,6},{7,8,9}}  
(1 row)
```

||

Description: Element-to-array concatenation

Example:

```
SELECT 3 || ARRAY[4,5,6] AS RESULT;  
result  
-----  
{3,4,5,6}  
(1 row)
```

||

Description: Array-to-element concatenation

Example:

```
SELECT ARRAY[4,5,6] || 7 AS RESULT;  
result  
-----  
{4,5,6,7}  
(1 row)
```

21.7.7.2 Array Functions

array_append(anyarray, anyelement)

Description: Appends an element to the end of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
SELECT array_append(ARRAY[1,2], 3) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

array_prepend(anelement, anyarray)

Description: Appends an element to the beginning of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;  
result  
-----  
{1,2,3}  
(1 row)
```

array_cat(anyarray, anyarray)

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: anyarray

Example:

```
SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;  
result  
-----  
{1,2,3,4,5}  
(1 row)  
  
SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;  
result  
-----  
{{1,2},{4,5},{6,7}}  
(1 row)
```

array_ndims(anyarray)

Description: Returns the number of dimensions of the array.

Return type: int

Example:

```
SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;  
result  
-----  
2  
(1 row)
```

array_dims(anyarray)

Description: Returns a text representation of array's dimensions.

Return type: text

Example:

```
SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;  
result  
-----  
[1:2][1:3]  
(1 row)
```

array_length(anyarray, int)

Description: Returns the length of the requested array dimension.

Return type: int

Example:

```
SELECT array_length(array[1,2,3], 1) AS RESULT;  
result  
-----  
3  
(1 row)
```

array_lower(anyarray, int)

Description: Returns lower bound of the requested array dimension.

Return type: int

Example:

```
SELECT array_lower('[0:2]={1,2,3}'::int[], 1) AS RESULT;  
result  
-----  
0  
(1 row)
```

array_upper(anyarray, int)

Description: Returns upper bound of the requested array dimension.

Return type: int

Example:

```
SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;  
result  
-----  
4  
(1 row)
```

array_to_string(anyarray, text [, text])

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '*') AS RESULT;  
result  
-----  
1,2,3*,5  
(1 row)
```

 NOTE

In **string_to_array**, if the null-string parameter is omitted or NULL, none of the substrings of the input will be replaced by NULL.

In **array_to_string**, if the null-string parameter is omitted or NULL, any null elements in the array are simply skipped and not represented in the output string.

string_to_array(text, text [, text])

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: text[]

Example:

```
SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
result
-----
{xx,NULL,zz}
(1 row)
SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
result
-----
{xx,yy,zz}
(1 row)
```

 NOTE

In **string_to_array**, if the delimiter parameter is NULL, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise the input string is split at each occurrence of the delimiter string.

unnest(anyarray)

Description: Expands an array to a set of rows.

Return type: setof anyelement

Example:

```
SELECT unnest(ARRAY[1,2]) AS RESULT;
result
-----
1
2
(2 rows)
```

The **unnest** function is used together with the **string_to_array** array. To convert an array to columns, the statement first splits a string into arrays by comma, and then converts the arrays into columns.

```
SELECT unnest(string_to_array('a,b,c,d',';')) AS RESULT;
result
-----
a
b
c
d
(4 rows)
```

interval(N, N1, N2, N3 ...)

Description: Searches for the last array index that is less than or equal to the target parameter **n** from the input integer array. If **n** is NULL, -1 is returned. The **interval()** function does not support the interval(N, N1) scenario. This function is supported by version 8.2.0 or later clusters.

Return type: int

Example:

```
SELECT INTERVAL(10, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 10, 11) AS RESULT;  
result  
-----  
11  
(1 row)
```

split(string, delim)

Description: Separates strings by a delimiter and returns an array. This function is supported by version 8.2.0 or later clusters.

Return type: text[]

Example:

```
SELECT SPLIT('a-b-c-d-e', '-') AS RESULT;  
result  
-----  
{a,b,c,d,e}  
(1 row)  
SELECT SPLIT('a-b-c-d-e', '-')[4] AS RESULT;  
result  
-----  
d  
(1 row)
```

21.7.8 Logical Operators

The usual logical operators include AND, OR, and NOT. SQL uses a three-valued logical system with true, false, and null, which represents "unknown". Their priorities are NOT > AND > OR.

Table 21-35 lists operation rules, where **a** and **b** represent logical expressions.

Table 21-35 Operation rules

| a | b | a AND b Result | a OR b Result | NOT a Result |
|-------|-------|----------------|---------------|--------------|
| TRUE | TRUE | TRUE | TRUE | FALSE |
| TRUE | FALSE | FALSE | TRUE | FALSE |
| TRUE | NULL | NULL | TRUE | FALSE |
| FALSE | FALSE | FALSE | FALSE | TRUE |
| FALSE | NULL | FALSE | NULL | TRUE |
| NULL | NULL | NULL | NULL | NULL |

 NOTE

The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.

21.7.9 Comparison Operators

Comparison operators can be used for all data types. The return results are Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators. Expressions such as "1<2<3" are invalid because Boolean values cannot be compared with 3.

Table 21-36 describes comparison operators provided by DWS.

Table 21-36 Comparison operators

| Operators | Description |
|-----------|--------------------------|
| < | Less than |
| > | Greater than |
| <= | Less than or equal to |
| >= | Greater than or equal to |
| = | Equality |
| <> or != | Inequality |

21.7.10 Pattern Matching Operators

There are three separate approaches to pattern matching provided by the database: the traditional SQL LIKE operator, the more recent SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

LIKE

Checks whether the string matches the pattern string following **LIKE**. If the string matches the supplied pattern, the LIKE expression returns true (the NOT LIKE expression returns false). Otherwise, the LIKE expression returns false (the NOT LIKE expression returns true).

- Rule
 - a. This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.

- b. The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- c. To match a literal underscore (_) or percent sign (%) without matching other characters, the respective character in pattern must be preceded by the escape character. The default escape character is the backslash but a different one can be selected by using the ESCAPE clause.
- d. To match the escape character itself, write two escape characters. For example: To write a **pattern** constant containing a backslash (\), you need to enter two backslashes in SQL statements.

NOTE

When **standard_conforming_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern matching a single backslash is actually going to write four backslashes in the statement. You can avoid this by selecting a different escape character by using ESCAPE, so that the backslash is no longer a special character of LIKE. But the backslash is still the special character of the character text analyzer, so you still need two backslashes. You can also select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, which makes it impossible to turn off the special meaning of underscore and percent signs in the pattern.

- e. The keyword ILIKE can be used instead of LIKE to make the match case-insensitive.
- f. Operator ~~ is equivalent to LIKE, and operator ~~* corresponds to ILIKE.

- Examples

```
SELECT 'abc' LIKE 'abc' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' LIKE 'a%' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' LIKE '_b_' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' LIKE 'c' AS RESULT;
result
-----
f
(1 row)
```

SIMILAR TO

The **SIMILAR TO** operator determines whether to match a given string based on its own pattern and returns **true** or **false**. It is similar to LIKE, except that it interprets the pattern using the SQL standard's definition of a regular expression.

- Matching rule
 - a. Like LIKE, the SIMILAR TO operator returns true only if its pattern matches the given string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.

- b. The underscore (_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- c. SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX regular expressions:

Table 21-37 Pattern matching metacharacter

| Metacharacter | Description |
|---------------|---|
| | Specifies alternation (either of two alternatives). |
| * | Specifies repetition of the previous item zero or more times. |
| + | Specifies repetition of the previous item one or more times. |
| ? | Specifies repetition of the previous item zero or one time. |
| {m} | Specifies repetition of the previous item exactly <i>m</i> times. |
| {m,} | Specifies repetition of the previous item <i>m</i> or more times. |
| {m,n} | Specifies repetition of the previous item at least <i>m</i> times and does not exceed <i>n</i> times. |
| () | Specifies that parentheses () can be used to group items into a single logical item. |
| [...] | Specifies a character class, just as in POSIX regular expressions. |

- d. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.
- Precautions

If a large number of characters are repeatedly matched in the SIMILAR TO regular expression, the statement fails to be executed and error "invalid regular expression: regular expression is too complex" is reported due to the recursion size restriction. In this case, increase the value of max_stack_depth.
- Regular expression functions

The **substring(string from pattern for escape)** function can be used to intercept a substring that matches an SQL regular expression.
- Examples

```
SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
result
-----
t
(1 row)
```

```
SELECT 'abc' SIMILAR TO 'a' AS RESULT;
result
-----
f
(1 row)
SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' SIMILAR TO '(b|c)%' AS RESULT;
result
-----
f
(1 row)
```

POSIX regular expressions

A regular expression is a character sequence that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular expression described by a regular expression, the string matches the regular expression. POSIX regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. [Table 21-38](#) lists all available operators for POSIX regular expression pattern matching.

Table 21-38 Regular expression match operators

| Operator | Description | Example |
|----------|---|--------------------------|
| ~ | Matches regular expression, which is case-sensitive. | 'thomas' ~ '.*thomas.*' |
| ~* | Matches regular expression, which is case-insensitive. | 'thomas' ~* '.*Thomas.*' |
| !~ | Does not match regular expression, which is case-sensitive. | 'thomas' !~ '.*Thomas.*' |
| !~* | Does not match regular expression, which is case-insensitive. | 'thomas' !~* '.*vadim.*' |

- Matching rule
 - Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
 - Besides the metacharacters mentioned above, POSIX regular expressions also support the following pattern matching metacharacters:

Table 21-39 Pattern matching metacharacters

| Metacharacter | Description |
|---------------|---|
| ^ | Specifies the match starting with a string. |
| \$ | Specifies the match at the end of a string. |
| . | Matches any single character. |

- Regular expression functions

POSIX regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX regular expression pattern.
- The **regexp_replace(string, pattern, replacement [, flags])** function provides the function of replacing the substring matching the POSIX regular expression pattern with the new text.
- The **regexp_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX regular expression pattern.
- The **regexp_split_to_table(string text, pattern text [, flags text])** function splits a string using a POSIX regular expression pattern as a delimiter.
- The **regexp_split_to_array(string text, pattern text [, flags text])** function behaves the same as **regexp_split_to_table**, except that **regexp_split_to_array** returns its result as an array of text.

 NOTE

The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp_matches**, but the former is usually the most commonly used behavior in practice.

- Examples

```
SELECT 'abc' ~ 'Abc' AS RESULT;
result
-----
f
(1 row)
SELECT 'abc' ~* 'Abc' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' !~ 'Abc' AS RESULT;
result
-----
t
(1 row)
SELECT 'abc' !~* 'Abc' AS RESULT;
result
-----
f
(1 row)
```

```
SELECT 'abc' ~ '^a' AS RESULT;  
result  
-----  
t  
(1 row)  
SELECT 'abc' ~ '(b|d)' AS RESULT;  
result  
-----  
t  
(1 row)  
SELECT 'abc' ~ '^ (b|c)' AS RESULT;  
result  
-----  
f  
(1 row)
```

Although most regular expression searches can be executed quickly, the time and memory for regular expression processing can still be manually controlled. Avoid using regular expression search patterns from untrusted sources. If required, set a statement timeout limit. The search with the SIMILAR TO mode has the same security risks as the SIMILAR TO provides many capabilities that are the same as those of the POSIX- style regular expression. For better security with unreliable inputs, prefer the simpler LIKE search over complex alternatives.

21.7.11 Aggregate Functions

sum(expression)

Description: Sum of expression across all input values

Return type:

Generally, same as the argument data type. In the following cases, type conversion occurs:

- **BIGINT** for **SMALLINT** or **INT** arguments
- **NUMBER** for **BIGINT** arguments
- **DOUBLE PRECISION** for floating-point arguments

Example:

```
postgres=#SELECT SUM(ss_ext_tax) FROM tpeds.STORE_SALES;  
sum  
-----  
213267594.69  
(1 row)
```

max(expression)

Description: Specifies the maximum value of **expression** across all input values.

Argument types: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
postgres=#SELECT MAX(inv_quantity_on_hand) FROM tpeds.inventory;  
max  
-----
```

```
1000000  
(1 row)
```

min(expression)

Description: Specifies the minimum value of **expression** across all input values.

Argument types: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
postgres=#SELECT MIN(inv_quantity_on_hand) FROM tpceds.inventory;  
min  
-----  
0  
(1 row)
```

avg(expression)

Description: Average (arithmetic mean) of all input values

Return type:

- **NUMBER** for any integer-type argument.
- **DOUBLE PRECISION** for floating-point parameters.
- Other values are the same as the input data type.

Example:

```
postgres=#SELECT AVG(inv_quantity_on_hand) FROM tpceds.inventory;  
avg  
-----  
500.0387129084044604  
(1 row)
```

median(expression)

Description: Median of all input values Currently, only the numeric and interval types are supported. Null values are not used for calculation.

Return type:

- If all input values are integers, a median of the **NUMERIC** type is returned; otherwise, a median of the same type as the input values is returned.
- In the Teradata-compatible mode, if the input values are integers, the returned median is rounded to the nearest integer.

Example:

```
postgres=#SELECT MEDIAN(inv_quantity_on_hand) FROM tpceds.inventory;  
median  
-----  
500  
(1 row)
```

percentile_cont(const) within group(order by expression)

Description: returns a value corresponding to the specified percentile in the ordering, interpolating between adjacent input items if needed. Null values are not used for calculation.

Input: *const* indicates a number ranging from 0 to 1. Currently, only numeric and interval expressions are supported.

Return type:

- If all input values are integers, a median of the **NUMERIC** type is returned; otherwise, a median of the same type as the input values is returned.
- In the Teradata-compatible mode, if the input values are integers, the returned median is rounded to the nearest integer.

Example:

```
postgres=#SELECT percentile_cont(0.3) within group(order by x) FROM (SELECT generate_series(1,5) AS x) AS t;
percentile_cont
-----
2.2
(1 row)
postgres=#SELECT percentile_cont(0.3) within group(order by x desc) FROM (SELECT generate_series(1,5) AS x) AS t;
percentile_cont
-----
3.8
(1 row)
```

percentile_disc(const) within group(order by expression)

Description: returns the first input value whose position in the ordering equals or exceeds the specified percentile.

Input: *const* indicates a number ranging from 0 to 1. Currently, only numeric and interval expressions are supported. Null values are not used for calculation.

Return type: If all input values are integers, a median of the **NUMERIC** type is returned; otherwise, a median of the same type as the input values is returned.

Example:

```
postgres=#SELECT percentile_disc(0.3) within group(order by x) FROM (SELECT generate_series(1,5) AS x) AS t;
percentile_disc
-----
2
(1 row)
postgres=#SELECT percentile_disc(0.3) within group(order by x desc) FROM (SELECT generate_series(1,5) AS x) AS t;
percentile_disc
-----
4
(1 row)
```

count(expression)

Description: Number of input rows for which the value of expression is not null

Return type: bigint

Example:

```
postgres=#SELECT COUNT(inv_quantity_on_hand) FROM tpeds.inventory;
count
-----
11158087
(1 row)
```

count(*)

Description: Number of input rows

Return type: bigint

Example:

```
postgres=#SELECT COUNT(*) FROM tpeds.inventory;
count
-----
11745000
(1 row)
```

array_agg(expression)

Description: Input values, including nulls, concatenated into an array The input parameters of the function do not support the array format.

Return type: array of the argument type

Example:

Create the **employeeinfo** table and insert data into the table:

```
CREATE TABLE employeeinfo (empno smallint, ename varchar(20), job varchar(20), hiredate date,deptno smallint);
INSERT INTO employeeinfo VALUES (7155, 'JACK', 'SALESMAN', '2018-12-01', 30);
INSERT INTO employeeinfo VALUES (7003, 'TOM', 'FINANCE', '2016-06-15', 20);
INSERT INTO employeeinfo VALUES (7357, 'MAX', 'SALESMAN', '2020-10-01', 30);

SELECT * FROM employeeinfo;
 empno | ename | job   | hiredate       | deptno
-----+-----+-----+-----+-----
 7155 | JACK | SALESMAN | 2018-12-01 00:00:00 |    30
 7357 | MAX  | SALESMAN | 2020-10-01 00:00:00 |    30
 7003 | TOM  | FINANCE  | 2016-06-15 00:00:00 |    20
(3 rows)
```

Query the names of all employees in the department whose ID is **30**:

```
SELECT array_agg(ename) FROM employeeinfo where deptno = 30;
array_agg
-----
{JACK,MAX}
(1 row)
```

Query all employees in the same department:

```
SELECT deptno, array_agg(ename) FROM employeeinfo group by deptno;
deptno | array_agg
-----+-----
    30 | {JACK,MAX}
    20 | {TOM}
(2 rows)

SELECT distinct array_agg(ename) OVER (PARTITION BY deptno) FROM employeeinfo;
array_agg
-----
```

```
{TOM}  
{JACK,MAX}  
(2 rows)
```

Query all department IDs and deduplicate them:

```
SELECT array_agg(distinct deptno) FROM employeeinfo group by deptno;  
array_agg  
-----  
{20}  
{30}  
(2 rows)
```

Sort the deduplicated department IDs in descending order:

```
SELECT array_agg(distinct deptno order by deptno desc) FROM employeeinfo;  
array_agg  
-----  
{30,20}  
(1 row)
```

string_agg(expression, delimiter)

Description: Input values concatenated into a string, separated by delimiter

Return type: same as the argument type

Example:

Query all employees in the same department based on the created table **employeeinfo**:

```
SELECT deptno, string_agg(ename,')') FROM employeeinfo group by deptno;  
deptno | string_agg  
-----+-----  
30 | JACK,MAX  
20 | TOM  
(2 rows)
```

Query employees whose work IDs are smaller than 7156:

```
SELECT string_agg(ename,')') FROM employeeinfo where empno < 7156;  
string_agg  
-----  
TOM,JACK  
(1 row)
```

listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)

Description: Aggregation column data sorted according to the mode specified by **WITHIN GROUP**, and concatenated to a string using the specified delimiter

- **expression**: Mandatory. It specifies an aggregation column name or a column-based, valid expression. It does not support the **DISTINCT** keyword and the **VARIADIC** parameter.
- **delimiter**: Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list**: Mandatory. It specifies the sorting mode in a group.

Return type: text

 NOTE

listagg is a column-to-row aggregation function, compatible with Oracle Database 11g Release 2. You can specify the **OVER** clause as a window function. When **listagg** is used as a window function, the **OVER** clause does not support the window sorting or framework of **ORDER BY**, so as to avoid ambiguity in **listagg** and **ORDER BY** of the **WITHIN GROUP** clause.

Example:

The aggregation column is of the text character set type:

```
postgres=#SELECT deptno, listagg(ename, ',') WITHIN GROUP(ORDER BY ename) AS employees FROM
emp GROUP BY deptno;
 deptno |          employees
-----+-----
      10 | CLARK,KING,MILLER
      20 | ADAMS,FORD,JONES,SCOTT,SMITH
      30 | ALLEN,BLAKE,JAMES,MARTIN,TURNER,WARD
(3 rows)
```

The aggregation column is of the integer type:

```
postgres=#SELECT deptno, listagg(mgrno, ',') WITHIN GROUP(ORDER BY mgrno NULLS FIRST) AS mgrnos
FROM emp GROUP BY deptno;
 deptno |          mgrnos
-----+-----
      10 | 7782,7839
      20 | 7566,7566,7788,7839,7902
      30 | 7698,7698,7698,7698,7698,7839
(3 rows)
```

The aggregation column is of the floating point type:

```
postgres=#SELECT job, listagg(bonus, '($); ') WITHIN GROUP(ORDER BY bonus DESC) || '($)' AS bonus
FROM emp GROUP BY job;
 job |          bonus
-----+-----
CLERK | 10234.21($); 2000.80($); 1100.00($); 1000.22($)
PRESIDENT | 23011.88($)
ANALYST | 2002.12($); 1001.01($)
MANAGER | 10000.01($); 2399.50($); 999.10($)
SALESMAN | 1000.01($); 899.00($); 99.99($); 9.00($)
(5 rows)
```

The aggregation column is of the time type:

```
postgres=#SELECT deptno, listagg(hiredate, ', ') WITHIN GROUP(ORDER BY hiredate DESC) AS hiredates
FROM emp GROUP BY deptno;
 deptno |          hiredates
-----+-----
      10 | 1982-01-23 00:00:00, 1981-11-17 00:00:00, 1981-06-09 00:00:00
      20 | 2001-04-02 00:00:00, 1999-12-17 00:00:00, 1987-05-23 00:00:00, 1987-04-19 00:00:00, 1981-12-03
00:00:00
      30 | 2015-02-20 00:00:00, 2010-02-22 00:00:00, 1997-09-28 00:00:00, 1981-12-03 00:00:00, 1981-09-08
00:00:00, 1981-05-01 00:00:00
(3 rows)
```

The aggregation column is of the time interval type.

```
postgres=#SELECT deptno, listagg(vacationTime, ', ') WITHIN GROUP(ORDER BY vacationTime DESC) AS
vacationTime FROM emp GROUP BY deptno;
 deptno |          vacationtime
-----+-----
      10 | 1 year 30 days; 40 days; 10 days
      20 | 70 days; 36 days; 9 days; 5 days
```

```
30 | 1 year 1 mon; 2 mons 10 days; 30 days; 12 days 12:00:00; 4 days 06:00:00; 24:00:00
(3 rows)
```

By default, the delimiter is empty:

```
postgres=#SELECT deptno, listagg(job) WITHIN GROUP(ORDER BY job) AS jobs FROM emp GROUP BY
deptno;
deptno | jobs
-----+-----
10 | CLERKMANAGERPRESIDENT
20 | ANALYSTANALYSTCLERKCLERKMANAGER
30 | CLERKMANAGERSALESMANSALESMANSALESMANSALESMAN
(3 rows)
```

When **listagg** is used as a window function, the **OVER** clause does not support the window sorting of **ORDER BY**, and the **listagg** column is an ordered aggregation of the corresponding groups.

```
postgres=#SELECT deptno, mgrno, bonus, listagg(ename, ';' ) WITHIN GROUP(ORDER BY hiredate)
OVER(PARTITION BY deptno) AS employees FROM emp;
deptno | mgrno | bonus | employees
-----+-----+-----+-----
10 | 7839 | 10000.01 | CLARK; KING; MILLER
10 | 23011.88 | CLARK; KING; MILLER
10 | 7782 | 10234.21 | CLARK; KING; MILLER
20 | 7566 | 2002.12 | FORD; SCOTT; ADAMS; SMITH; JONES
20 | 7566 | 1001.01 | FORD; SCOTT; ADAMS; SMITH; JONES
20 | 7788 | 1100.00 | FORD; SCOTT; ADAMS; SMITH; JONES
20 | 7902 | 2000.80 | FORD; SCOTT; ADAMS; SMITH; JONES
20 | 7839 | 999.10 | FORD; SCOTT; ADAMS; SMITH; JONES
30 | 7839 | 2399.50 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
30 | 7698 | 9.00 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
30 | 7698 | 1000.22 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
30 | 7698 | 99.99 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
30 | 7698 | 1000.01 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
30 | 7698 | 899.00 | BLAKE; TURNER; JAMES; MARTIN; WARD; ALLEN
(14 rows)
```

group_concat(expression [ORDER BY {col_name | expr} [ASC | DESC]] [SEPARATOR str_val])

Description: concatenates the specified **str_val** delimiters used by column data into a string. The concatenation uses a sorting method that must be specified by the **ORDER BY** clause. **ORDER BY 1** is not allowed.

- **expression**: (mandatory) specifies a column name or a column-based valid expression. It does not support the **DISTINCT** keyword or the **VARIADIC** parameter.
- **str_val**: (optional) specifies a delimiter, which can be a string constant or a deterministic expression based on grouped columns. The default value indicates that commas (,) are used as delimiters.

Return type: text

NOTE

The group_concat function is supported only in 8.1.2 or later.

Example:

The default delimiter is a comma (,).

```
postgres=#SELECT group_concat(sname) FROM group_concat_test;
group_concat
```

```
-----  
ADAMS,FORD,JONES,KING,MILLER,SCOTT,SMITH  
(1 row)
```

Delimiters can be customized for the **group_concat** function.

```
postgres=#SELECT group_concat(sname separator ';') from group_concat_test;  
group_concat  
-----  
ADAMS;FORD;JONES;KING;MILLER;SCOTT;SMITH  
(1 row)
```

The **group_concat** function supports the **ORDER BY** clause, which concatenates column data in sequence.

```
postgres=#SELECT group_concat(sname order by snumber separator ';') FROM group_concat_test;  
group_concat  
-----  
MILLER;FORD;SCOTT;SMITH;KING;JONES;ADAMS  
(1 row)
```

covar_pop(Y, X)

Description: Overall covariance

Return type: double precision

Example:

```
postgres=# SELECT COVAR_POP(sr_fee, sr_net_loss) FROM tpceds.store_returns WHERE sr_customer_sk <  
1000;  
covar_pop  
-----  
829.749627587403  
(1 row)
```

covar_samp(Y, X)

Description: Sample covariance

Return type: double precision

Example:

```
postgres=#SELECT COVAR_SAMP(sr_fee, sr_net_loss) FROM tpceds.store_returns WHERE sr_customer_sk <  
1000;  
covar_samp  
-----  
830.052235037289  
(1 row)
```

stddev_pop(expression)

Description: Overall standard difference

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT STDDEV_POP(inv_quantity_on_hand) FROM tpceds.inventory WHERE inv_warehouse_sk =  
1;  
stddev_pop  
-----  
289.224294957556  
(1 row)
```

stddev_samp(expression)

Description: Sample standard deviation of the input values

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT STDDEV_SAMP(inv_quantity_on_hand) FROM tpcds.inventory WHERE inv_warehouse_sk  
= 1;  
stddev_samp  
-----  
289.224359757315  
(1 row)
```

var_pop(expression)

Description: Population variance of the input values (square of the population standard deviation)

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT VAR_POP(inv_quantity_on_hand) FROM tpcds.inventory WHERE inv_warehouse_sk = 1;  
var_pop  
-----  
83650.692793695475  
(1 row)
```

var_samp(expression)

Description: Sample variance of the input values (square of the sample standard deviation)

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT VAR_SAMP(inv_quantity_on_hand) FROM tpcds.inventory WHERE inv_warehouse_sk = 1;  
var_samp  
-----  
83650.730277028768  
(1 row)
```

bit_and(expression)

Description: The bitwise AND of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
postgres=#SELECT BIT_AND(inv_quantity_on_hand) FROM tpcds.inventory WHERE inv_warehouse_sk = 1;  
bit_and  
-----  
0  
(1 row)
```

bit_or(expression)

Description: The bitwise OR of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
postgres=#SELECT BIT_OR(inv_quantity_on_hand) FROM tpcds.inventory WHERE inv_warehouse_sk = 1;
bit_or
-----
1023
(1 row)
```

bool_and(expression)

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
postgres=#SELECT bool_and(100 <2500);
bool_and
-----
t
(1 row)
```

bool_or(expression)

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
postgres=#SELECT bool_or(100 <2500);
bool_or
-----
t
(1 row)
```

corr(Y, X)

Description: Correlation coefficient

Return type: double precision

Example:

```
postgres=#SELECT CORR(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk < 1000;
corr
-----
0.0381383624904186
(1 row)
```

every(expression)

Description: Equivalent to **bool_and**

Return type: Boolean

Example:

```
postgres=#SELECT every(100 <2500);
every
-----
```

```
t
(1 row)
```

rank(expression)

Description: The tuples in different groups are sorted non-consecutively by **expression**.

Return type: bigint

Example:

```
postgres=#SELECT d_moy, d_fy_week_seq, rank() OVER(PARTITION BY d_moy ORDER BY d_fy_week_seq)
FROM tpceds.date_dim WHERE d_moy < 4 AND d_fy_week_seq < 7 ORDER BY 1,2;
 d_moy | d_fy_week_seq | rank
```

| d_moy | d_fy_week_seq | rank |
|-------|---------------|------|
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 1 | 1 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 2 | 8 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 3 | 15 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 4 | 22 |
| 1 | 5 | 29 |
| 1 | 5 | 29 |
| 2 | 5 | 1 |
| 2 | 5 | 1 |
| 2 | 5 | 1 |
| 2 | 5 | 1 |
| 2 | 5 | 1 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |
| 2 | 6 | 6 |

regr_avgx(Y, X)

Description: Average of the independent variable (**sum(X)/N**)

Return type: double precision

Example:

```
postgres=#SELECT REGR_AVGX(sr_fee, sr_net_loss) FROM tpods.store_returns WHERE sr_customer_sk < 1000;
      regr_avgx
-----
578.606576740795
(1 row)
```

regr_avgy(Y, X)

Description: Average of the dependent variable ($\text{sum}(Y)/N$)

Return type: double precision

Example:

```
postgres=#SELECT REGR_AVGY(sr_fee, sr_net_loss) FROM tpods.store_returns WHERE sr_customer_sk < 1000;
      regr_avgy
-----
50.0136711629602
(1 row)
```

regr_count(Y, X)

Description: Number of input rows in which both expressions are non-null

Return type: bigint

Example:

```
postgres=#SELECT REGR_COUNT(sr_fee, sr_net_loss) FROM tpods.store_returns WHERE sr_customer_sk < 1000;
      regr_count
-----
2743
(1 row)
```

regr_intercept(Y, X)

Description: y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
postgres=#SELECT REGR_INTERCEPT(sr_fee, sr_net_loss) FROM tpods.store_returns WHERE sr_customer_sk < 1000;
      regr_intercept
-----
49.2040847848607
(1 row)
```

regr_r2(Y, X)

Description: Square of the correlation coefficient

Return type: double precision

Example:

```
postgres=#SELECT REGR_R2(sr_fee, sr_net_loss) FROM tpods.store_returns WHERE sr_customer_sk < 1000;
      regr_r2
-----
```

```
0.00145453469345058
(1 row)
```

regr_slope(Y, X)

Description: Slope of the least-squares-fit linear equation determined by the (X, Y) pairs

Return type: double precision

Example:

```
postgres=#SELECT REGR_SLOPE(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk <
1000;
regr_slope
-----
0.00139920009665259
(1 row)
```

regr_sxx(Y, X)

Description: $\text{sum}(X^2) - \text{sum}(X)^2/N$ (sum of squares of the independent variables)

Return type: double precision

Example:

```
postgres=#SELECT REGR_SXX(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk < 1000;
regr_sxx
-----
1626645991.46135
(1 row)
```

regr_sxy(Y, X)

Description: $\text{sum}(X*Y) - \text{sum}(X) * \text{sum}(Y)/N$ ("sum of products" of independent times dependent variable)

Return type: double precision

Example:

```
postgres=#SELECT REGR_SXY(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk < 1000;
regr_sxy
-----
2276003.22847225
(1 row)
```

regr_syy(Y, X)

Description: $\text{sum}(Y^2) - \text{sum}(Y)^2/N$ ("sum of squares" of the dependent variable)

Return type: double precision

Example:

```
postgres=#SELECT REGR_SYY(sr_fee, sr_net_loss) FROM tpcds.store_returns WHERE sr_customer_sk < 1000;
regr_syy
-----
2189417.6547314
(1 row)
```

stddev(expression)

Description: Alias of **stddev_samp**

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT STDDEV(inv_quantity_on_hand) FROM tpods.inventory WHERE inv_warehouse_sk = 1;
stddev
-----
289.224359757315
(1 row)
```

variance(expression)

Description: Alias of **var_samp**

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
postgres=#SELECT VARIANCE(inv_quantity_on_hand) FROM tpods.inventory WHERE inv_warehouse_sk = 1;
variance
-----
83650.730277028768
(1 row)
```

checksum(expression)

Description: Returns the CHECKSUM value of all input values. This function can be used to check whether the data in the tables is the same before and after the backup, restoration, or migration of the DWS database. Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

NOTE

- For large tables, the CHECKSUM function may take a long time.
- If the CHECKSUM values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the CHECKSUM function may incur conflicts. There is low possibility that two tables with different contents may have the same CHECKSUM value. The same problem may occur when CHECKSUM is used for columns.
- If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the CHECKSUM value.
- If the CHECKSUM value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
- If the CHECKSUM value of a column is calculated and the column type cannot be changed to TEXT by default, set *expression* to *Column name::TEXT*.
- If the CHECKSUM value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into TEXT types by default: char, name, int8, int2, int1, int4, raw, pg_node_tree, float4, float8, bpchar, varchar, nvarchar2, date, timestamp, timestamptz, numeric, and smalldatetime. Other types need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
postgres=#SELECT CHECKSUM(inv_quantity_on_hand) FROM tpcds.inventory;
checksum
-----
24417258945265247
(1 row)
```

CHECKSUM value of a column that cannot be converted to the TEXT type by default (Note that the CHECKSUM parameter is *column_name::TEXT*):

```
postgres=#SELECT CHECKSUM(inv_quantity_on_hand::TEXT) FROM tpcds.inventory;
checksum
-----
24417258945265247
(1 row)
```

The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
postgres=#SELECT CHECKSUM(inventory::TEXT) FROM tpcds.inventory;
checksum
-----
25223696246875800
(1 row)
```

approx_count_distinct(col_name)

Description: Uses the HyperLogLog++ (HLL++) algorithm to estimate the cardinality (number of rows in a column after deduplication). This function is supported only by clusters of version 8.3.0 or later.

Input parameter description: **col_name** indicates the column whose cardinality needs to be estimated.

NOTE

You can adjust the error rate by setting the **approx_count_distinct_precision** parameter.

- The value range is [10,20]. The default value is 17. The theoretical error rate is 3%.
- This parameter indicates the number of buckets in the HyperLogLog++ (HLL++) algorithm. A larger value of this parameter indicates a larger number of buckets and a smaller theoretical error rate.
- Increasing this parameter value will increase the computing time and memory usage, but they will still be much lower than the cost of using a **COUNT DISTINCT** query. You are advised to use this function to replace the **COUNT DISTINCT** statement when the estimation cardinality is large.

Example:

```
CREATE TABLE employeeinfo (empno smallint, ename varchar(20), job varchar(20), hiredate date,deptno smallint) WITH (ORIENTATION = COLUMN);
INSERT INTO employeeinfo VALUES (7155, 'JACK', 'SALESMAN', '2018-12-01', 30);
INSERT INTO employeeinfo VALUES (7003, 'TOM', 'FINANCE', '2016-06-15', 20);
INSERT INTO employeeinfo VALUES (7357, 'MAX', 'SALESMAN', '2020-10-01', 30);

SELECT APPROX_COUNT_DISTINCT(empno) from employeeinfo;
approx_count_distinct
```

```
-----
              3
(1 row)

SELECT COUNT(DISTINCT empno) FROM employeeinfo GROUP BY ename;
count
-----
      1
      1
      1
(3 rows)
```

UNIQ(col_name)

Description: Aggregate function for calculating the number of non-duplicated values. Similar to **COUNT DISTINCT**, this function calculates the number of rows in a column after deduplication and returns a value indicating the rows without duplication. This function is supported only by clusters of version 8.3.0 or later.

Input parameter description: **col_name** indicates the column for which the number of rows after deduplication needs to be calculated. The value can be SMALLINT, INTEGER, BIGINT, REAL, DOUBLE PRECISION, TEXT, VARCHAR, TIMESTAMP, TIMESTAMPTZ, DATE, TIMETZ or UUID.

NOTE

- Currently, only DWS column-store tables support the **UNIQ** function.
- When the **UNIQ** function is used, the SQL statement must contain **GROUP BY**. To achieve better performance, the GROUP BY fields must be evenly distributed.
- To deduplicate three or more columns in an SQL statement, you can use the **UNIQ** function, which is more efficient than the **COUNT DISTINCT** function.
- Generally, the memory usage of the **UNIQ** function is lower than that of the **COUNT DISTINCT** function. If the memory usage exceeds the threshold when the **COUNT DISTINCT** function is used, you can use the **UNIQ** function to reduce the memory usage.

Example:

```
CREATE TABLE employeeinfo (empno smallint, ename varchar(20), job varchar(20), hiredate date,deptno
smallint) WITH (ORIENTATION = COLUMN);
INSERT INTO employeeinfo VALUES (7155, 'JACK', 'SALESMAN', '2018-12-01', 30);
INSERT INTO employeeinfo VALUES (7003, 'TOM', 'FINANCE', '2016-06-15', 20);
INSERT INTO employeeinfo VALUES (7357, 'MAX', 'SALESMAN', '2020-10-01', 30);

SELECT UNIQ(deptno) FROM employeeinfo GROUP BY ename;
uniq
-----
      1
      1
      1
(3 rows)
```

21.7.12 Window Functions

Regular aggregate functions return a single value calculated from values in a row, or group all rows into a single output row. Window functions perform a calculation across a set of rows and return a value for each row.

A window function call represents the application of an aggregate-like function over some portion of the rows selected by a query. Therefore, aggregate functions ([Aggregate Functions](#)) can also be used as window functions. A window function

can scan all rows and display the raw data and aggregation analysis results at the same time.

Precautions

- Column-store tables support only the window functions **rank (expression)** and **row_number (expression)** and the aggregate functions **sum**, **count**, **avg**, **min**, and **max**. Row-store tables do not have such restrictions.
- A single query can contain one or more window function expressions.
- Window functions can appear only in output columns. If you want to use the values of a window function for condition filtering, you need to nest the window function in the subquery and use the aliases of the window function expression at the outer layer for condition filtering. Example:

```
SELECT classid, id, score FROM (SELECT *, avg(score) OVER(PARTITION BY classid) as avg_score FROM score) WHERE score >= avg_score;
```
- In the query block where the window function is located, the **GROUP BY** expression can be used for grouping and deduplication. In this case, the **PARTITION BY** clause in the window function must be a subset of the **GROUP BY** expression to ensure that the window function performs calculation on the deduplication result. The expression of the **ORDER BY** clause must be a subset of the **GROUP BY** expression or an aggregate function of an aggregate operation. Example:

```
SELECT classid, rank() OVER(PARTITION BY classid ORDER BY sum(score)) as avg_score FROM score GROUP BY classid, id;
```

Syntax

A window function uses the **OVER** clause to define a window. The **OVER** clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

```
function_name ([expression [, expression ...]]) OVER ( window_definition )  
function_name ([expression [, expression ...]]) OVER window_name  
function_name ( * ) OVER ( window_definition )  
function_name ( * ) OVER window_name
```

window_definition is defined as follows:

```
[ existing_window_name ]  
[ PARTITION BY expression [, ...] ]  
[ ORDER BY expression [ ASC | DESC | USING operator ] [ NULLS { FIRST | LAST } ] [, ...] ]  
[ frame_clause ]
```

The **PARTITION BY** option specifies that rows with the same **PARTITION BY** expression value are grouped.

The **ORDER BY** option is used to control the order in which the window function processes rows. **ORDER BY** must be followed by a column name. If **ORDER BY** is followed by a number, the number is processed as a constant and does not sort the target column.

frame_clause is defined as follows:

```
[ RANGE | ROWS ] frame_start  
[ RANGE | ROWS ] BETWEEN frame_start AND frame_end
```

When you need to specify a window to calculate the results of all rows in a group, you need to specify the start row and end row of the window range. The window range supports the **RANGE** and **ROWS** modes. The **ROWS** mode specifies the

window by the physical unit (row), and the RANGE mode specifies the window as the logical offset.

In **RANGE** and **ROWS**, you can use **BETWEEN** *frame_start* **AND** *frame_end* to specify the window's first and last rows. If only **frame_start** is specified, **frame_end** is **CURRENT ROW** by default.

The values of **frame_start** and **frame_end** are as follows:

- **CURRENT ROW**: The current row is used as the window frame's start or end point.
- **N PRECEDING**: The window frame starts from the *n*th row to the current row.
- **UNBOUNDED PRECEDING**: The window frame starts at the first row of the partition.
- **N FOLLOWING**: The window frame starts from the current row to the *n*th row.
- **UNBOUNDED FOLLOWING**: The window frame ends with the last row of the partition.

frame_start cannot be **UNBOUNDED FOLLOWING**, *frame_end* cannot be **UNBOUNDED PRECEDING**, and *frame_end* cannot be earlier than *frame_start*. For example, **RANGE BETWEEN CURRENT ROW AND N PRECEDING** is not allowed.

RANK()

Description: The **RANK** function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same rank value but with sequence numbers.

Return type: bigint

Example:

In the **score(id, classid, score)** table, the rows are student ID, class ID, and exam score.

Use the **RANK** function to sort student scores.

```
CREATE TABLE score(id int,classid int,score int);
INSERT INTO score VALUES(1,1,95),(2,2,95),(3,2,85),(4,1,70),(5,2,88),(6,1,70);
```

```
SELECT id, classid, score,RANK() OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | rank |
|----|---------|-------|------|
| 1 | 1 | 95 | 1 |
| 2 | 2 | 95 | 1 |
| 6 | 1 | 70 | 5 |
| 4 | 1 | 70 | 5 |
| 5 | 2 | 88 | 3 |
| 3 | 2 | 85 | 4 |

(6 rows)

ROW_NUMBER()

Description: The **ROW_NUMBER** function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```
SELECT id, classid, score, ROW_NUMBER() OVER(ORDER BY score DESC) FROM score ORDER BY score DESC;
```

| id | classid | score | row_number |
|----|---------|-------|------------|
| 1 | 1 | 95 | 1 |
| 2 | 2 | 95 | 2 |
| 5 | 2 | 88 | 3 |
| 3 | 2 | 85 | 4 |
| 6 | 1 | 70 | 5 |
| 4 | 1 | 70 | 6 |

(6 rows)

DENSE_RANK()

Description: The **DENSE_RANK** function is used for generating consecutive sequence numbers for the values in each group. The same values have the same rank value number and the same sequence number.

Return type: bigint

Example:

```
SELECT id, classid, score, DENSE_RANK() OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | dense_rank |
|----|---------|-------|------------|
| 1 | 1 | 95 | 1 |
| 2 | 2 | 95 | 1 |
| 5 | 2 | 88 | 2 |
| 3 | 2 | 85 | 3 |
| 6 | 1 | 70 | 4 |
| 4 | 1 | 70 | 4 |

(6 rows)

PERCENT_RANK()

Description: The **PERCENT_RANK** function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula $\text{Sequence number} = (\text{Rank} - 1) / (\text{Total rows} - 1)$. **Rank** is the corresponding sequence number generated based on the **RANK** function for the value and **Total rows** is the total number of elements in a group.

Return type: double precision

Example:

```
SELECT id, classid, score, PERCENT_RANK() OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | percent_rank |
|----|---------|-------|--------------|
| 1 | 1 | 95 | 0 |
| 2 | 2 | 95 | 0 |
| 3 | 2 | 85 | .6 |
| 4 | 1 | 70 | .8 |
| 5 | 2 | 88 | .4 |
| 6 | 1 | 70 | .8 |

(6 rows)

CUME_DIST()

Description: The **CUME_DIST** function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: $\text{Sequence number} = \text{Number of rows preceding or peer with current row} / \text{Total rows}$.

Return type: double precision

Example:

```
SELECT id,classid,score,CUME_DIST() OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | cume_dist |
|----|---------|-------|-------------------|
| 1 | 1 | 95 | .3333333333333333 |
| 2 | 2 | 95 | .3333333333333333 |
| 5 | 2 | 88 | .5 |
| 3 | 2 | 85 | .6666666666666667 |
| 4 | 1 | 70 | 1 |
| 6 | 1 | 70 | 1 |

(6 rows)

NTILE(num_buckets integer)

Description: The **NTILE** function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num_buckets** according to **num_buckets integer** and allocating the bucket number to each row. Divide the partition as equally as possible.

Return type: integer

Example:

```
SELECT id,classid,score,NTILE(3) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | ntile |
|----|---------|-------|-------|
| 1 | 1 | 95 | 1 |
| 2 | 2 | 95 | 1 |
| 5 | 2 | 88 | 2 |
| 3 | 2 | 85 | 2 |
| 4 | 1 | 70 | 3 |
| 6 | 1 | 70 | 3 |

(6 rows)

LAG(value any [, offset integer [, default any]])

Description: The **LAG** function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **null**.

Return type: same as the parameter type

Example:

```
SELECT id,classid,score,LAG(id,3) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | lag |
|----|---------|-------|-----|
| 1 | 1 | 95 | |
| 2 | 2 | 95 | |
| 5 | 2 | 88 | |
| 3 | 2 | 85 | 1 |
| 4 | 1 | 70 | 2 |
| 6 | 1 | 70 | 5 |

(6 rows)

LEAD(value any [, offset integer [, default any]])

Description: The **LEAD** function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by

moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the number of rows after the moving exceeds the total number for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **null**.

Return type: same as the parameter type

Example:

```
SELECT id,classid,score,LEAD(id,3) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | lead |
|----|---------|-------|------|
| 1 | 1 | 95 | 3 |
| 2 | 2 | 95 | 4 |
| 5 | 2 | 88 | 6 |
| 3 | 2 | 85 | |
| 4 | 1 | 70 | |
| 6 | 1 | 70 | |

(6 rows)

FIRST_VALUE(value any)

Description: The **FIRST_VALUE** function is used for returning the first value of each group.

Return type: same as the parameter type

Example:

```
SELECT id,classid,score,FIRST_VALUE(id) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | first_value |
|----|---------|-------|-------------|
| 1 | 1 | 95 | 1 |
| 2 | 2 | 95 | 1 |
| 5 | 2 | 88 | 1 |
| 3 | 2 | 85 | 1 |
| 4 | 1 | 70 | 1 |
| 6 | 1 | 70 | 1 |

(6 rows)

LAST_VALUE(value any)

Description: Returns the last value of each group.

Return type: same as the parameter type

The **LAST_VALUE** function supports the IGNORE NULLS syntax. This syntax returns the last value in a non-null window. If all values are **NULL**, **NULL** is returned. The format is as follows:

```
LAST_VALUE (expression) [IGNORE NULLS] OVER (window_definition)
```

Currently, only **ROWS between CURRENT ROW and UNBOUNDED FOLLOWING** and **ROWS BETWEEN UNBOUNDED PRECEDING and CURRENT ROW** are supported.

Example:

```
SELECT id,classid,score,LAST_VALUE(id) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | last_value |
|----|---------|-------|------------|
| 1 | 1 | 95 | 2 |
| 2 | 2 | 95 | 2 |
| 5 | 2 | 88 | 5 |

| | | | |
|---|---|----|---|
| 3 | 2 | 85 | 3 |
| 4 | 1 | 70 | 6 |
| 6 | 1 | 70 | 6 |

(6 rows)

NTH_VALUE(value any, nth integer)

Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
SELECT id,classid,score,NTH_VALUE(id,3) OVER(ORDER BY score DESC) FROM score;
```

| id | classid | score | nth_value |
|----|---------|-------|-----------|
| 1 | 1 | 95 | |
| 2 | 2 | 95 | |
| 5 | 2 | 88 | 5 |
| 3 | 2 | 85 | 5 |
| 4 | 1 | 70 | 5 |
| 6 | 1 | 70 | 5 |

(6 rows)

21.7.13 Type Conversion Functions

cast(x as y)

Description: Converts *x* into the type specified by *y*.

Example:

```
SELECT cast('22-oct-1997' as timestamp);
```

| timestamp |
|---------------------|
| 1997-10-22 00:00:00 |

(1 row)

cast(x, y)

Description: Converts *x* into the type specified by *y*. This function is supported by version 8.2.0 or later clusters.

Example:

```
SELECT cast('22-oct-1997', timestamp);
```

| timestamp |
|---------------------|
| 1997-10-22 00:00:00 |

(1 row)

try_cast(x as type)

Description: Converts *x* to a value of the given type. If the conversion fails and the current type is converted to a value allowed by DWS, **NULL** is returned. Otherwise, an error is raised. This function is supported by version 8.2.0 or later clusters.

Example:

```
SELECT try_cast('a' as int4);
```

| int4 |
|------|
| |

```
-----  
(1 row)  
SELECT try_cast('22-oct-1997' as timestamp);  
       timestamp  
-----  
1997-10-22 00:00:00  
(1 row)
```

hextoraw(string)

Description: Converts a string in hexadecimal format into binary format.

Return type: raw

Example:

```
SELECT hextoraw('7D');  
       hextoraw  
-----  
7D  
(1 row)
```

numtoday(numeric)

Description: Converts values of the number type into the timestamp of the specified type.

Return type: timestamp

Example:

```
SELECT numtoday(2);  
       numtoday  
-----  
2 days  
(1 row)
```

pg_systimestamp()

Description: Obtains the system timestamp.

Return type: timestamp with time zone

Example:

```
SELECT pg_systimestamp();  
       pg_systimestamp  
-----  
2015-10-14 11:21:28.317367+08  
(1 row)
```

rawtohex(string)

Description: Converts a string in binary format into hexadecimal format.

The result represents the ASCII codes of the input characters in hexadecimal format.

Return type: varchar

Example:

```
SELECT rawtohex('1234567');
       rawtohex
-----
31323334353637
(1 row)
```

to_char (datetime/interval [, fmt])

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the VARCHAR type according to the format specified by **fmt**.

- The optional parameter **fmt** includes the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include: HH, MI, SS, YYYY, MM, and DD. For details, see [Table 21-41](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: varchar

Example:

```
SELECT to_char(current_timestamp,'HH12:MI:SS');
       to_char
-----
10:19:26
(1 row)
SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
       to_char
-----
10:19:46
(1 row)
```

to_char(double precision, text)

Description: Converts the values of the double-precision type into the strings in the specified format.

Return type: text

Example:

```
SELECT to_char(125.8::real, '999D99');
       to_char
-----
125.80
(1 row)
```

to_char (integer/number[, fmt])

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter **fmt** can be the following types: decimal characters, grouping characters, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (.), and decimal point (.). For details, see [Table 21-40](#).

- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: varchar

Example:

```
SELECT to_char(1485,'9,999');
to_char
-----
1,485
(1 row)
SELECT to_char( 1148.5,'9,999.999');
to_char
-----
1,148.500
(1 row)
SELECT to_char(148.5,'990999.909');
to_char
-----
0148.500
(1 row)
SELECT to_char(123,'XXX');
to_char
-----
7B
(1 row)
```

to_char(interval, text)

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
to_char
-----
15:02:12
(1 row)
```

to_char(int, text)

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
SELECT to_char(125, '999');
to_char
-----
125
(1 row)
```

to_char(numeric, text)

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
SELECT to_char(-125.8, '999D99S');
to_char
-----
125.80-
(1 row)
```

to_char (string)

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the VARCHAR type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: varchar

Example:

```
SELECT to_char('01110');
to_char
-----
01110
(1 row)
```

to_char(timestamp, text)

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
SELECT to_char(current_timestamp, 'HH12:MI:SS');
to_char
-----
10:55:59
(1 row)
```

to_clob(char/nchar/varchar/nvarchar/varchar2/nvarchar2/text/raw)

Description: Convert the RAW type or text character set type CHAR/NCHAR/VARCHAR/VARCHAR2/NVARCHAR2/TEXT into the CLOB type.

Return type: clob

Example:

```
SELECT to_clob('ABCDEF'::RAW(10));
to_clob
-----
ABCDEF
(1 row)
SELECT to_clob('hello111'::CHAR(15));
to_clob
-----
hello111
(1 row)
SELECT to_clob('gauss123'::NCHAR(10));
to_clob
-----
```

```
-----
gauss123
(1 row)
SELECT to_clob('gauss234'::VARCHAR(10));
to_clob
-----
gauss234
(1 row)
SELECT to_clob('gauss345'::VARCHAR2(10));
to_clob
-----
gauss345
(1 row)
SELECT to_clob('gauss456'::NVARCHAR2(10));
to_clob
-----
gauss456
(1 row)
SELECT to_clob('World222!'::TEXT);
to_clob
-----
World222!
(1 row)
```

to_date(text)

Description: Converts values of the text type into the timestamp in the specified format.

Return type: timestamp

Example:

```
SELECT to_date('2015-08-14');
to_date
-----
2015-08-14 00:00:00
(1 row)
```

to_date(text, text)

Description: Converts the values of the string type into the dates in the specified format.

Return type: timestamp

Example:

```
SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date
-----
2000-12-05 00:00:00
(1 row)
```

to_date(string, fmt)

Description: Converts a string into a value of the DATE type according to the format specified by **fmt**. For details about the fmt format, see [Table 21-41](#).

This function cannot support the CLOB type directly. However, a parameter of the CLOB type can be converted using implicit conversion.

Return type: date

Example:

```
SELECT TO_DATE('05 Dec 2010','DD Mon YYYY');
to_date
-----
2010-12-05 00:00:00
(1 row)
```

to_number (expr [, fmt])

Description: Converts **expr** into a value of the NUMBER type according to the specified format.

For details about the type conversion formats, see [Table 21-40](#).

If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

Return type: number

Example:

```
SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

to_number(text, text)

Description: Converts the values of the string type into the numbers in the specified format.

Return type: numeric

Example:

```
SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

to_timestamp(double precision)

Description: Converts a UNIX century into a timestamp.

Return type: timestamp with time zone

Example:

```
SELECT to_timestamp(1284352323);
to_timestamp
-----
2010-09-13 12:32:03+08
(1 row)
```

to_timestamp(string [,fmt])

Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion

according to the format specified by **nls_timestamp_format**. For details about the fmt format, see [Table 21-41](#).

In **to_timestamp** in DWS:

- If the input year *YYYY* is 0, an error will be reported.
- If the input year *YYYY* < 0 to specify *SYYYYY* in *fmt*, the year with the value of *n* (an absolute value) BC is output correctly.

Characters in the *fmt* must match the schema for formatting the data and time. Otherwise, an error is reported.

Return type: timestamp without time zone

Example:

```
SHOW nls_timestamp_format;
      nls_timestamp_format
-----
DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

SELECT to_timestamp('12-sep-2014');
      to_timestamp
-----
2014-09-12 00:00:00
(1 row)
SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
      to_timestamp
-----
2010-09-12 14:10:10.123
(1 row)
SELECT to_timestamp('-1','SYYYYY');
      to_timestamp
-----
0001-01-01 00:00:00 BC
(1 row)
SELECT to_timestamp('98','RR');
      to_timestamp
-----
1998-01-01 00:00:00
(1 row)
SELECT to_timestamp('01','RR');
      to_timestamp
-----
2001-01-01 00:00:00
(1 row)
```

to_timestamp(text, text)

Description: Converts values of the string type into the timestamp of the specified type.

Return type: timestamp

Example:

```
SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
      to_timestamp
-----
2000-12-05 00:00:00
(1 row)
```

The following table describes the value formats of the **to_number** function.

Table 21-40 Template patterns for numeric formatting

| Schema | Description |
|------------|---|
| 9 | Value with specified digits |
| 0 | Values with leading zeros |
| Period (.) | Decimal point |
| Comma (,) | Group (thousand) separator |
| PR | Negative values in angle brackets |
| S | Sign anchored to number (uses locale) |
| L | Currency symbol (uses locale) |
| D | Decimal point (uses locale) |
| G | Group separator (uses locale) |
| MI | Minus sign in the specified position (if the number is less than 0) |
| PL | Plus sign in the specified position (if the number is greater than 0) |
| SG | Plus or minus sign in the specified position |
| RN | Roman numerals (the input values are between 1 and 3999) |
| TH or th | Ordinal number suffix |
| V | Shifts specified number of digits (decimal) |

Table 21-41 describes the patterns of date and time values. They can be used for functions **to_date**, **to_timestamp**, and **to_char**, and the **nls_timestamp_format** parameter.

Table 21-41 Schemas for formatting date and time

| Type | Schema | Description |
|--------|--------|------------------------------------|
| Hour | HH | Number of hours in one day (01-12) |
| | HH12 | Number of hours in one day (01-12) |
| | HH24 | Number of hours in one day (00-23) |
| Minute | MI | Minute (00-59) |
| Second | SS | Second (00-59) |
| | FF | Microsecond (000000-999999) |

| Type | Schema | Description |
|-----------------------|------------|--|
| | SSSSS | Second after midnight (0-86399) |
| Morning and afternoon | AM or A.M. | Morning identifier |
| | PM or P.M. | Afternoon identifier |
| Year | Y,YYY | Year with comma (with four digits or more) |
| | SYYYY | Year with four digits BC |
| | YYYY | Year (with four digits or more) |
| | YYY | Last three digits of a year |
| | YY | Last two digits of a year |
| | Y | Last one digit of a year |
| | IYYY | ISO year (with four digits or more) |
| | IYY | Last three digits of an ISO year |
| | IY | Last two digits of an ISO year |
| | I | Last one digit of an ISO year |
| | RR | <p>Last two digits of a year (A year of the 20th century can be stored in the 21st century.)</p> <p>The password must comply with the following rules:</p> <ul style="list-style-type: none">• If the range of the input two-digit year is between 00 and 49:
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.• If the range of the input two-digit year is between 50 and 99:
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year equal to the first two digits of the current year minus 1. <p>If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.</p> |

| Type | Schema | Description |
|-------------|---|---|
| | RRRR | Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY. |
| | <ul style="list-style-type: none">• BC or B.C.• AD or A.D. | Era indicator Before Christ (BC) and After Christ (AD) |
| Month | MONTH | Full spelling of a month in uppercase (9 characters are filled in if the value is empty.) |
| | MON | Month in abbreviated format in uppercase (with three characters) |
| | MM | Month (01-12) |
| | RM | Month in Roman numerals (I-XII; I=JAN) and uppercase |
| Day | DAY | Full spelling of a date in uppercase (9 characters are filled in if the value is empty.) |
| | DY | Day in abbreviated format in uppercase (with three characters) |
| | DDD | Day in a year (001-366) |
| | DD | Day in a month (01-31) |
| | D | Day in a week (1-7. Sunday is 1.) |
| Week | W | Week in a month (1-5) (The first week starts from the first day of the month.) |
| | WW | Week in a year (1-53) (The first week starts from the first day of the year.) |
| | IW | Week in an ISO year (The first Thursday is in the first week.) |
| Century | CC | Century (with two digits) (The 21st century starts from 2001-01-01.) |
| Julian date | J | Julian date (starting from January 1 of 4712 BC) |
| Quarter | Q | Quarter |

21.7.14 JSON/JSONB Functions and Operators

21.7.14.1 JSON/JSONB Operators

Table 21-42 Common JSON and JSONB Operators

| Operator | Left Operand Type | Right Operand Type | Return Type | Description | Example |
|----------|-------------------|--------------------|-------------|--|--|
| -> | Array-json(b) | int | json(b) | Obtains the array-json element. If the subscript does not exist, NULL is returned. | <pre>SELECT '["a":"foo", {"b":"bar"}, {"c":"baz"}]::json->2; ?column? ----- {"c":"baz"} (1 row)</pre> |
| -> | object-json(b) | text | json(b) | Obtains the value by a key. If no record exists, NULL is returned. | <pre>SELECT '{"a":{"b":"foo"}}::json->'a'; ?column? ----- {"b":"foo"} (1 row)</pre> |
| ->> | Array-json(b) | int | text | Obtains the array-json element. If the subscript does not exist, NULL is returned. | <pre>SELECT '["a":"foo", {"b":"bar"}, {"c":"baz"}]::json->>2; ?column? ----- {"c":"baz"} (1 row)</pre> |
| ->> | object-json(b) | text | text | Obtains the value by a key. If no record exists, NULL is returned. | <pre>SELECT '{"a":{"b":"foo"}}::json->>'a'; ?column? ----- {"b":"foo"} (1 row)</pre> |

| Operator | Left Operand Type | Right Operand Type | Return Type | Description | Example |
|----------|--------------------|--------------------|-------------|---|--|
| #> | container-json (b) | text[] | json | Obtains the JSON object in the specified path. If the path does not exist, NULL is returned.
NOTE
A DWS object identifier can end with a number sign (#). To avoid ambiguity during the parsing of a#>b, you need to add spaces in front of and behind the operator #>. Otherwise, a parsing error is reported. | <pre>SELECT '{"a":{"b":{"c":1}}}'::json #> '{a, b}'; ?column? ----- {"c":1} (1 row)</pre> |
| #>> | container-json (b) | text[] | text | Obtains the JSON object in the specified path. If the path does not exist, NULL is returned. | <pre>SELECT '{"a":{"b":{"c":1}}}'::json #>> '{a, b}'; ?column? ----- {"c":1} (1 row)</pre> |

Table 21-43 Operators supported by jsonb

| Operator | Right Oper and Type | Return Type | Description | Example |
|----------|---------------------|-------------|---|---|
| = | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":1}}}'::jsonb = '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>t</p> <p>(1 row)</p> |
| <> | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":1}}}'::jsonb <> '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>f</p> <p>(1 row)</p> |
| < | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":2}}}'::jsonb < '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>f</p> <p>(1 row)</p> |
| > | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":2}}}'::jsonb > '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>t</p> <p>(1 row)</p> |
| <= | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":2}}}'::jsonb <= '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>f</p> <p>(1 row)</p> |
| >= | jsonb | bool | Same as the jsonb_eq function, which compares the size of two jsonb files. | <pre>SELECT '{"a":{"b":{"c":2}}}'::jsonb >= '{"a":{"b":{"c":1}}}'::jsonb; ?column?</pre> <p>-----</p> <p>t</p> <p>(1 row)</p> |
| ? | text | bool | Whether the string of the key or element exists at the top layer of the JSON value. | <pre>SELECT '{"a":1, "b":2}'::jsonb ? 'b'; ?column?</pre> <p>-----</p> <p>t</p> <p>(1 row)</p> |
| ? | text[] | bool | Whether any of these array strings exists as a top-layer key. | <pre>SELECT '{"a":1, "b":2, "c":3, "d":4}'::jsonb ? {'a, b, e'}::text[]; ?column?</pre> <p>-----</p> <p>t</p> <p>(1 row)</p> |

| Operator | Right Oper and Type | Return Type | Description | Example |
|----------|---------------------|-------------|--|--|
| ?& | text[] | bool | Whether all these array strings exist as top-layer keys. | <pre>SELECT '{"a":1, "b":2, "c":3, "d":4}::jsonb ?& {a, b, c}::text[]; ?column? ----- t (1 row)</pre> |
| <@ | jsonb | bool | Whether all items in the JSON file on the left exist at the top layer of the JSON file on the right. | <pre>SELECT '{"b":3}::jsonb <@ '{"a":{"b":{"c":2}}, "b":3}::jsonb; ?column? ----- t (1 row)</pre> |
| @> | jsonb | bool | Whether all items in the JSON file on the right exist at the top layer of the JSON file on the left. | <pre>SELECT '{"a":{"b":{"c":2}}, "b":3}::jsonb @> {"b":3}::jsonb; ?column? ----- t (1 row)</pre> |
| | jsonb | jsonb | Combines two JSONB objects into one. | <pre>SELECT '{"a":1, "b":2}::jsonb '{"c":3, "d":4}::jsonb; ?column? ----- {"a": 1, "b": 2, "c": 3, "d": 4} (1 row)</pre> |
| - | text | jsonb | Deletes a jsonb object and the specified key-value pair. | <pre>SELECT '{"a":1, "b":2}::jsonb - 'a'; ?column? ----- {"b": 2} (1 row)</pre> |
| - | text | jsonb | Deletes a jsonb object and the specified key-value pair. | <pre>SELECT '{"a":1, "b":2, "c":3, "d":4}::jsonb - '{a, b}::text[]; ?column? ----- {"c": 3, "d": 4} (1 row)</pre> |
| - | int | jsonb | Deletes the element corresponding to the subscript in the JSONB array. | <pre>SELECT '['a', "b", "c"]::jsonb - 2; ?column? ----- ["a", "b"] (1 row)</pre> |
| #- | text[] | jsonb | Deletes the key-value pair corresponding to the path in the JSONB object. | <pre>SELECT '{"a":{"b":{"c":{"d":1}}}, "e":2, "f":3}::jsonb #- '{a, b}::text[]; ?column? ----- {"a": {}, "e": 2, "f": 3} (1 row)</pre> |

21.7.14.2 JSON/JSONB Functions

JSON/JSONB functions are used to generate JSON data (see [JSON Types](#)).

NOTE

- Except the **array_to_json** and **row_to_json** functions, all other JSON/JSONB functions and operators are only supported by clusters of version 8.1.2 or later.
- JSON and JSONB provide only basic functions. If there are other complex or special performance requirements, contact Huawei engineers for evaluation.

array_to_json(anyarray [, pretty_bool])

Description: Returns the array as JSON. A multi-dimensional array becomes a JSON array of arrays. Line feeds will be added between dimension-1 elements if **pretty_bool** is **true**.

Return type: json

Example:

```
postgres=#SELECT array_to_json('{{1,5},{99,100}}':int[]);
array_to_json
-----
[[1,5],[99,100]]
(1 row)
```

row_to_json(record [, pretty_bool])

Description: Returns the row as JSON. Line feeds will be added between level-1 elements if **pretty_bool** is **true**.

Return type: json

Example:

```
postgres=#SELECT row_to_json(row(1,'foo'));
row_to_json
-----
{"f1":1,"f2":"foo"}
(1 row)
```

json_agg(any)

Description: Aggregates values into a JSON array.

Return type: array-json

Example:

```
postgres=#SELECT * FROM classes;
name | score
-----+-----
A    | 2
A    | 3
D    | 5
D    |
(4 rows)
postgres=#SELECT name, json_agg(score) score FROM classes group by name order by name;
name | score
-----+-----
A    | [2, 3]
```

```
D | [5, null]
  | [null]
(3 rows)
```

json_object_agg(any, any)

Description: Aggregates values into a JSON object.

Return type: json

Example:

```
postgres=#SELECT * FROM classes;
name | score
-----+-----
A    |    2
A    |    3
D    |    5
D    |
(4 rows)

postgres=#SELECT json_object_agg(name, score) FROM classes group by name order by name;
 json_object_agg
-----
{ "A" : 2, "A" : 3 }
{ "D" : 5, "D" : null }
(2 rows)
```

json_build_array(VARIADIC "any")

Description: Constructs a JSON array that may be of heterogeneous type from a variable parameter list.

Return type: json

Example:

```
postgres=#SELECT json_build_array(1,2,'3',4,5);
 json_build_array
-----
[1, 2, "3", 4, 5]
(1 row)
```

json_build_object(VARIADIC "any")

Description: Constructs a JSON object from a variable parameter list. The parameter list consists of alternate keys and values. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: json

Example:

```
postgres=#SELECT json_build_object('foo',1,'bar',2);
 json_build_object
-----
{"foo" : 1, "bar" : 2}
(1 row)
```

json_object(text[]), json_object(text[], text[])

Description: Constructs a JSON object from a text array.

This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered alternate key-value pairs. When two text arrays are used, the first array is regarded as a key, and the second array is regarded as a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: json

Example:

```
postgres=#SELECT json_object('{a, 1, b, "def", c, 3.5}');
          json_object
-----
{"a": "1", "b": "def", "c": "3.5"}
(1 row)

postgres=#SELECT json_object('{{a, 1},{b, "def"}',{c, 3.5}}');
          json_object
-----
{"a": "1", "b": "def", "c": "3.5"}
(1 row)

postgres=#SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
          json_object
-----
{"a": "a", "b": "1", "a b c": "1"}
(1 row)
```

to_json(anyelement)

Description: Converts parameters to json.

Return type: json

Example:

```
postgres=#SELECT to_json('Fred said "Hi."::text);
          to_json
-----
"Fred said \"Hi.\""
(1 row)
-- Convert the column-store table json_tbl_2 to JSON:
postgres=# SELECT * FROM json_tbl_2;
 a | b
---+---
 1 | aaa
 1 | bbb
 2 | ccc
 2 | ddd
(4 rows)
postgres=# SELECT to_json(t.*) FROM json_tbl_2 t;
          to_json
-----
{"a":1,"b":"bbb"}
{"a":2,"b":"ddd"}
{"a":1,"b":"aaa"}
{"a":2,"b":"ccc"}
(4 rows)
```

json_strip_nulls(json)

Description: All object fields with null values are ignored, and other values remain unchanged.

Return type: json

Example:

```
postgres=#SELECT json_strip_nulls('{"f1":1,"f2":null},2,null,3');
json_strip_nulls
-----
{"f1":1},2,null,3
(1 row)
```

json_object_field(json, text)

Description: Same as the operator `->`, which returns the value of a specified key in an object.

Return type: json

Example:

```
postgres=#SELECT json_object_field('{"a": {"b":"foo"}}','a');
json_object_field
-----
{"b":"foo"}
(1 row)
```

json_object_field_text(object-json, text)

Description: Same as the operator `->>`, which returns the value of a specified key in an object.

Return type: text

Example:

```
postgres=#SELECT json_object_field_text('{"a": {"b":"foo"}}','a');
json_object_field_text
-----
{"b":"foo"}
(1 row)
```

json_array_element(array-json, integer)

Description: Same as the operator `->`, which returns the element with the specified subscript in the array.

Return type: json

Example:

```
postgres=#SELECT json_array_element('[1,true,[1,[2,3]],null]',2);
json_array_element
-----
[1,[2,3]]
(1 row)
```

json_array_element_text(array-json, integer)

Description: Same as the operator `->>`, which returns the element with the specified subscript in the array.

Return type: text

Example:

```
postgres=#SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);
json_array_element_text
-----
[1,[2,3]]
```

```
-----  
[1,[2,3]]  
(1 row)
```

json_extract_path(json, VARIADIC text[])

Description: Same as the operator `#>`, which returns the JSON value of the path specified by `$2`.

Return type: json

Example:

```
postgres=#SELECT json_extract_path('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');  
json_extract_path  
-----  
\"stringy\"  
(1 row)
```

json_extract_path_text(json, VARIADIC text[])

Description: Same as the operator `#>>`, which returns the text value of the path specified by `$2`.

Return type: text

Example:

```
postgres=#SELECT json_extract_path_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');  
json_extract_path_text  
-----  
stringy  
(1 row)
```

json_array_elements(array-json)

Description: Splits an array. Each element returns a row.

Return type: json

Example:

```
postgres=#SELECT json_array_elements('[1,true,[1,[2,3]],null]');  
json_array_elements  
-----  
1  
true  
[1,[2,3]]  
null  
(4 rows)
```

json_array_elements_text(array-json)

Description: Splits an array. Each element returns a row.

Return type: text

Example:

```
postgres=#SELECT * FROM json_array_elements_text('[1,true,[1,[2,3]],null]');  
value  
-----  
1  
true
```

```
[1,[2,3]]
```

```
(4 rows)
```

json_array_length(array-json)

Description: Returns the array length.

Return type: integer

Example:

```
postgres=#SELECT json_array_length('1,2,3,{"f1":1,"f2":[5,6]},4,null');
json_array_length
```

```
-----
6
```

```
(1 row)
```

json_object_keys(object-json)

Description: Returns all keys at the top layer of the object.

Return type: text

Example:

```
postgres=#SELECT json_object_keys('{"f1":"abc","f2":{"f3":"a","f4":"b"},"f1":"abcd"}');
json_object_keys
```

```
-----
f1
```

```
f2
```

```
f1
```

```
(3 rows)
```

json_each(object-json)

Description: Splits each key-value pair of an object into one row and two columns.

Return type: setof(key text, value json)

Example:

```
postgres=#SELECT * FROM json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
key | value
```

```
-----+-----
f1 | [1,2,3]
```

```
f2 | {"f3":1}
```

```
f4 | null
```

```
(3 rows)
```

json_each_text(object-json)

Description: Splits each key-value pair of an object into one row and two columns.

Return type: setof(key text, value text)

Example:

```
postgres=#SELECT * FROM json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
key | value
```

```
-----+-----
f1 | [1,2,3]
```

```
f2 | {"f3":1}
```

```
f4 |
```

```
(3 rows)
```

json_populate_record(anyelement, object-json [, bool])

Description: *\$1* must be a compound parameter. Each key-value in **object-json** is split. The key is used as the column name to match the column name in *\$1* and fill in the *\$1* format.

NOTE

To define a composite type for the input parameters of a JSON/JSONB function, you can use CREATE TYPE or CREATE TABLE. Here is an example:

```
CREATE TYPE jpop AS (a text, b INT, c timestamp);  
CREATE TABLE jpop2(a text, b INT, c timestamp);
```

Return type: anyelement

Example:

```
postgres=#CREATE TYPE jpop AS (a text, b INT, c timestamp);  
postgres=#SELECT * FROM json_populate_record(null::jpop, '{"a":"blurfl","x":43.2}');  
 a | b | c  
-----+-----+-----  
 blurfl |  |  
(1 row)
```

json_populate_recordset(anyelement, array-json [, bool])

Description: Performs the preceding operations on each element in the *\$2* array by referring to the **json_populate_record** and **jsonb_populate_record** functions. Therefore, each element in the *\$2* array must be of the **object-json** type.

Return type: setof anyelement

Example:

```
postgres=#CREATE TYPE jpop AS (a text, b INT, c timestamp);  
postgres=#SELECT * FROM json_populate_recordset(null::jpop, ' [{"a":1,"b":2}, {"a":3,"b":4}] ');  
 a | b | c  
---+---+---  
 1 | 2 |  
 3 | 4 |  
(2 rows)
```

json_to_record(object-json)

Description: Like all functions that return **record**, the caller must explicitly define the structure of the record using an **AS** clause. The key-value pair of **object-json** is split and reassembled. The key is used as a column name to match and fill in the structure of the record specified by the **AS** clause.

Return type: record

Example:

```
postgres=#SELECT * FROM json_to_record('{"a":1,"b":"foo","c":"bar"}'::json) as x(a int, b text, d text);  
 a | b | d  
---+---+---  
 1 | foo |  
(1 row)
```

json_to_recordset(array-json)

Description: Executes the preceding function on each element in the array by referring to the **json_to_record** function. Therefore, each element in the array must be **object-json**.

Return type: SETOF record

Example:

```
postgres=#SELECT * FROM json_to_recordset('["a":1,"b":{"d":"foo"},"c":true,{"a":2,"c":false,"b":{"d":"bar"}}]') AS x(a INT, b json, c BOOLEAN);
 a |      b      | c
---+-----+---
 1 | {"d":"foo"} | t
 2 | {"d":"bar"} | f
(2 rows)

postgres=#SELECT * FROM json_to_recordset('["a":1,"b":"foo","d":false,{"a":2,"b":"bar","c":true}]') AS x(a INT, b text, c BOOLEAN);
 a | b | c
---+---+---
 1 | foo | 
 2 | bar | t
(2 rows)
```

json_typeof(json)

Description: Checks the JSON type.

Return type: text

Example:

```
postgres=#SELECT value, json_typeof(value) from (values (json '123.4'), (json '"foo"'), (json 'true'), (json 'null'), (json '[1, 2, 3]'), (json '{"x":"foo", "y":123}'), (NULL::json)) as data(value);
 value | json_typeof
-----+-----
 123.4 | number
 "foo" | string
 true  | boolean
 null  | null
 [1, 2, 3] | array
 {"x":"foo", "y":123} | object
(7 rows)
```

jsonb_object(text[])

Description: Constructs an **object-jsonb** from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered alternate key-value pairs.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
 jsonb_object
-----
 {"3": null, "a": "1", "b": "2", "d e f": "a b c"}
(1 row)
```

jsonb_object(text[], text[])

Description: When two text arrays are used, the first array is considered a key and the second array is considered a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_object('{a,b,"a b c"}', '{a,1,1}');
 jsonb_object
-----
{"a": "a", "b": "1", "a b c": "1"}
(1 row)
```

to_jsonb(anyment)

Description: Converts other types to the corresponding jsonb type.

Return type: jsonb

Example:

```
postgres=#SELECT to_jsonb(1.1);
 to_jsonb
-----
1.1
(1 row)
```

jsonb_agg

Description: Aggregates jsonb objects into a jsonb array.

Return type: jsonb

Example:

```
postgres=#SELECT * FROM json_tbl_2;
 a | b
---+---
 1 | aaa
 1 | bbb
 2 | ccc
 2 | ddd
(4 rows)

postgres=#SELECT a, jsonb_agg(b) FROM json_tbl_2 GROUP BY a ORDER BY a;
 a | jsonb_agg
---+-----
 1 | ["aaa", "bbb"]
 2 | ["ccc", "ddd"]
(2 rows)
```

jsonb_object_agg

Description: Aggregates key-value pairs into a JSON object.

Return type: jsonb

Example:

```
postgres=#SELECT * FROM json_tbl_3;
 a | b | c
```

```
-----+-----
1 | aaa | 10
1 | bbb | 20
2 | ccc | 30
2 | ddd | 40
(4 rows)
postgres=#SELECT a, jsonb_object_agg(b, c) FROM json_tbl_3 GROUP BY a ORDER BY a;
a | jsonb_object_agg
-----+-----
1 | {"aaa": 10, "bbb": 20}
2 | {"ccc": 30, "ddd": 40}
(2 rows)
```

jsonb_build_array([VARIADIC "any"])

Description: Constructs a JSON array that may contain heterogeneous types from a variable parameter list.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}',");
jsonb_build_array
-----
["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1, 2, 3]}, null]
(1 row)
```

jsonb_build_object([VARIADIC "any"])

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_build_object(1,2);
jsonb_build_object
-----
{"1": 2}
(1 row)
```

jsonb_strip_nulls(jsonb)

Description: All object fields with null values are omitted. Other null values remain unchanged.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_strip_nulls('["f1":1,"f2":null],2,null,3');
jsonb_strip_nulls
-----
[{"f1": 1}, 2, null, 3]
(1 row)
```

jsonb_object_field(jsonb, text)

Description: Same as the operator ->, which returns the value of a specified key in an object.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_object_field('{"a": {"b":"foo"}}','a');
jsonb_object_field
-----
{"b": "foo"}
(1 row)
```

jsonb_object_field_text(jsonb, text)

Description: Same as the operator ->>, which returns the value of a specified key in an object.

Return type: text

Example:

```
postgres=#SELECT jsonb_object_field_text('{"a": {"b":"foo"}}','a');
jsonb_object_field_text
-----
{"b": "foo"}
(1 row)
```

jsonb_array_element(array-jsonb, integer)

Description: Same as the operator ->, which returns the element with the specified subscript in the array.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_array_element('[1,true,[1,[2,3]],null]',2);
jsonb_array_element
-----
[1, [2, 3]]
(1 row)
```

jsonb_array_element_text(array-jsonb, integer)

Description: Same as the operator ->>, which returns the element with the specified subscript in the array.

Return type: text

Example:

```
postgres=#SELECT jsonb_array_element_text('[1,true,[1,[2,3]],null]',2);
jsonb_array_element_text
-----
[1, [2, 3]]
(1 row)
```

jsonb_extract_path((jsonb, VARIADIC text[]))

Description: Same as the operator #>, which returns the value of the path specified by \$2.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_extract_path('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');
jsonb_extract_path
-----
\"stringy\"
(1 row)
```

jsonb_extract_path_text((jsonb, VARIADIC text[]))

Description: Same as the operator `#>>`, which returns the value of the path specified by `$2`.

Return type: text

Example:

```
postgres=#SELECT jsonb_extract_path_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');
jsonb_extract_path_text
-----
stringy
(1 row)
```

jsonb_extract((jsonb, VARIADIC text[]))

Description: If you enter any object-jsonb or array-jsonb type, the value of the path specified by `$2` is returned. This function is supported only by clusters of version 9.1.0 or later.

Return type: SETOF jsonb

Example:

```
SELECT jsonb_extract('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99},{\"f6\":\"stringy\"}}', 'f2','f3');
jsonb_extract
-----
1
(1 row)

SELECT jsonb_extract('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99},{\"f5\":\"stringy\"}}', 'f4','f5');
jsonb_extract
-----
99
\"stringy\"
(2 rows)
```

jsonb_extract_text((jsonb, VARIADIC text[]))

Description: If you enter any object-jsonb or array-jsonb type, the value of the path specified by `$2` is returned. This function is supported only by clusters of version 9.1.0 or later.

Return type: SETOF text

Example:

```
SELECT jsonb_extract_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99},{\"f6\":\"stringy\"}}', 'f2','f3');
jsonb_extract_text
-----
1
(1 row)

SELECT jsonb_extract_text('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99},{\"f5\":\"stringy\"}}', 'f4','f5');
jsonb_extract_text
-----
99
```

```
stringy  
(2 rows)
```

jsonb_array_elements(array-jsonb)

Description: Splits an array. Each element returns a row.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_array_elements('[1,true,[1,[2,3]],null]');  
jsonb_array_elements  
-----  
1  
true  
[1, [2, 3]]  
null  
(4 rows)
```

jsonb_array_elements_text(array-jsonb)

Description: Splits an array. Each element returns a row.

Return type: text

Example:

```
postgres=#SELECT * FROM jsonb_array_elements_text('[1,true,[1,[2,3]],null]');  
value  
-----  
1  
true  
[1, [2, 3]]  
(4 rows)
```

jsonb_array_length(array-jsonb)

Description: Returns the array length.

Return type: integer

Example:

```
postgres=#SELECT jsonb_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');  
jsonb_array_length  
-----  
6  
(1 row)
```

jsonb_object_keys(object-jsonb)

Description: Returns all keys at the top layer of the object.

Return type: SETOF text

Example:

```
postgres=#SELECT jsonb_object_keys('{ "f1": "abc", "f2": { "f3": "a", "f4": "b" }, "f1": "abcd" }');  
jsonb_object_keys  
-----  
f1  
f2  
(2 rows)
```

jsonb_each(object-jsonb)

Description: Splits each key-value pair of an object into one row and two columns.

Return type: setof(key text, value jsonb)

Example:

```
postgres=#SELECT * FROM jsonb_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
key | value
-----+-----
f1  | [1, 2, 3]
f2  | {"f3": 1}
f4  | null
(3 rows)
```

jsonb_each_text(object-jsonb)

Description: Splits each key-value pair of an object into one row and two columns.

Return type: setof(key text, value text)

Example:

```
postgres=#SELECT * FROM jsonb_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
key | value
-----+-----
f1  | [1, 2, 3]
f2  | {"f3": 1}
f4  | 
(3 rows)
```

jsonb_populate_record(anyelement, object-jsonb [, bool])

Description: *\$1* must be a compound parameter. Each key-value in **object-json** is split. The key is used as the column name to match the column name in *\$1* and fill in the *\$1* format.

Return type: anyelement

Example:

```
postgres=#SELECT * FROM jsonb_populate_record(null::jpop, '{"a":"blurfl","x":43.2}');
a | b | c
-----+-----
blurfl | | 
(1 row)
```

jsonb_populate_recordset(anyelement, array-jsonb [, bool])

Description: Performs the preceding operations on each element in the *\$2* array by referring to the **json_populate_record** and **jsonb_populate_record** functions. Therefore, each element in the *\$2* array must be of the **object-json** type.

Return type: setof anyelement

Example:

```
postgres=#SELECT * FROM jsonb_populate_recordset(null::jpop, '[{"a":1,"b":2},{\"a\":3,\"b\":4}]');
a | b | c
-----+-----
1 | 2 | 
3 | 4 | 
(2 rows)
```

jsonb_to_record(object-json)

Description: Like all functions that return **record**, the caller must explicitly define the structure of the record using an **AS** clause. The key-value pair of **object-json** is split and reassembled. The key is used as a column name to match and fill in the structure of the record specified by the **AS** clause.

Return type: record

Example:

```
postgres=#SELECT * FROM jsonb_to_record('{"a":1,"b":"foo","c":"bar"}'::jsonb) as x(a int, b text, d text);
 a | b | d
---+---+---
 1 | foo | 
(1 row)
```

jsonb_to_recordset(array-json)

Description: Executes the preceding function on each element in the array by referring to the **jsonb_to_record** function. Therefore, each element in the array must be **object-jsonb**.

Return type: SETOF record

Example:

```
postgres=#SELECT * FROM jsonb_to_recordset('["a":1,"b":"foo","d":false,{"a":2,"b":"bar","c":true}]') AS x(a
INT, b text, c boolean);
 a | b | c
---+---+---
 1 | foo | 
 2 | bar | t
(2 rows)
```

jsonb_typeof(jsonb)

Description: Checks the JSONB type.

Return type: text

Example:

```
postgres=#SELECT jsonb_typeof(to_jsonb(1.1));
 jsonb_typeof
-----
 number
(1 row)
```

jsonb_ne(jsonb, jsonb)

Description: Same as the operator <>, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_ne('{"a":1,"b":2}'::jsonb, '{"a":1,"b":3}'::jsonb);
 jsonb_ne
-----
 t
(1 row)
```

jsonb_lt(jsonb, jsonb)

Description: Same as the operator <, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_lt('{"a":1, "b":2}::jsonb, '{"a":1, "b":3}::jsonb);
jsonb_lt
-----
t
(1 row)
```

jsonb_gt(jsonb, jsonb)

Description: Same as the operator >, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_gt('{"a":1, "b":2}::jsonb, '{"a":1, "b":3}::jsonb);
jsonb_gt
-----
f
(1 row)
```

jsonb_le(jsonb, jsonb)

Description: Same as the operator <=, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_le('["a", "b"]', '{"a":1, "b":2}');
jsonb_le
-----
t
(1 row)
```

jsonb_ge(jsonb, jsonb)

Description: Same as the operator >=, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
jsonb_ge
-----
f
(1 row)
```

jsonb_eq(jsonb, jsonb)

Description: Same as the operator =, which compares two values.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
jsonb_eq
-----
f
(1 row)
```

jsonb_cmp(jsonb, jsonb)

Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

Return type: integer

Example:

```
postgres=#SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
jsonb_cmp
-----
-1
(1 row)
```

jsonb_exists(jsonb, text)

Description: Same as the operator **?**, which determines whether all elements in the string array *\$2* exist at the top layer of *\$1* in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_exists('["1",2,3]', '1');
jsonb_exists
-----
t
(1 row)
```

jsonb_exists_any(jsonb, text[])

Description: Same as the operator **?|**, which determines whether all elements in the string array *\$2* exist at the top layer of *\$1* in the form of **key\elem\scalar**.

Return type:

Example:

```
postgres=#SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
jsonb_exists_any
-----
t
(1 row)
```

jsonb_exists_all(jsonb, text[])

Description: Same as the operator **?&**, which determines whether all elements in the string array *\$2* exist at the top layer of *\$1* in the form of **key\elem\scalar**.

Return type:

bool

Example:

```
postgres=#SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
jsonb_exists_all
```

```
-----  
t  
(1 row)
```

jsonb_contained(jsonb, jsonb)

Description: Same as the operator <@, which determines whether all elements in the string array \$1 exist at the top layer of \$2.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');  
jsonb_contained  
-----  
t  
(1 row)
```

jsonb_contains(jsonb, jsonb)

Description: Same as the operator @>, which determines whether all elements in the string array \$2 exist at the top layer of \$1.

Return type: Boolean

Example:

```
postgres=#SELECT jsonb_contains('{"a":1, "b":2, "c":3}::jsonb', '{"a":1}');  
jsonb_contains  
-----  
t  
(1 row)
```

jsonb_concat(jsonb, jsonb)

Description: Combines two JSONB objects into one.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_concat('{"a":1, "b":2}::jsonb', '{"c":3, "d":4}::jsonb');  
jsonb_concat  
-----  
{"a": 1, "b": 2, "c": 3, "d": 4}  
(1 row)
```

jsonb_delete(jsonb, text)

Description: Deletes the key-value pair corresponding to the key value in jsonb.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_delete('{"a":1, "b":2}::jsonb', 'a');  
jsonb_delete  
-----  
{"b": 2}  
(1 row)
```

jsonb_delete_idx(jsonb, text)

Description: Deletes the element corresponding to an array subscript.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_delete_idx('[0,1,2,3,4]::jsonb, 2);
jsonb_delete_idx
-----
[0, 1, 3, 4]
(1 row)
```

jsonb_delete_array(jsonb, VARIADIC text[])

Description: Deletes multiple elements from the jsonb array.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_delete_array('["a", "b", "c"]::jsonb , 'a', 'b');
jsonb_delete_array
-----
["c"]
(1 row)
```

jsonb_delete_path(jsonb, text[])

Description: Deletes elements of a specified path from the jsonb array.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_delete_path('{ "a":{ "b":{ "c":1, "d":2}}, "e":3}::jsonb , array[\'a\', \'b\']);
jsonb_delete_path
-----
{"a": {}, "e": 3}
(1 row)
```

jsonb_set(target jsonb, path text[], new_value jsonb [, create_missing boolean])

Description: Returns *target* with the section designated by *path* replaced by *new_value*, or with *new_value* added if **create_missing** is **true** (**true** by default) and the item designated by *path* does not exist. As with the path-oriented operators, negative integers that appear in *path* count from the end of JSON arrays.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_set('{"f1":1,"f2":null},2,null,3]', '{0,f1}','[2,3,4]', false);
jsonb_set
-----
[{"f1": [2, 3, 4], "f2": null}, 2, null, 3]
(1 row)
```

jsonb_pretty(jsonb)

Description: Returns in indented JSON text.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_pretty('{\"a\":{\"b\":{\"c\":1, \"d\":2}}, \"e\":3}');
jsonb_pretty
-----
{
  \"a\": {
    \"b\": {
      \"c\": 1,
      \"d\": 2
    }
  },
  \"e\": 3
}
(1 row)
```

jsonb_insert(target jsonb, path text[], new_value jsonb [, insert_after boolean])

Description: Returns the target where **new_value** is inserted. When the specified target is located within the **JSONB** array using the path, use the **insert_after** parameter to determine if **new_value** should be inserted after the target. The default value is **false**, meaning that the new value will be inserted after the target. If the target part specified by **path** is in a **JSONB** object, **new_value** is inserted only when the target part does not exist. Like path-oriented operators, a negative integer in **path** indicates that the count starts from the end of the **JSON** array.

Return type: jsonb

Example:

```
postgres=#SELECT jsonb_insert('{\"a\": [0,1,2]}', '{a, 1}', '\"new_value\"');
jsonb_insert
-----
{\"a\": [0, \"new_value\", 1, 2]}
(1 row)
```

ts_headline([config regconfig,] document jsonb, query tsquery [, options text])

Description: Highlights the jsonb search result.

Return type: jsonb

Example:

```
postgres=#SELECT ts_headline('english',
'[{\"id\":\"9928,\"user_id\":\"4562,\"user_name\":\"9LOHR4\",\"create_time\":\"2021-06-22T16:28:16.504518+08:00\"},
{\"id\":\"9959,\"user_id\":\"5524,\"user_name\":\"YID07D\",\"create_time\":\"2021-06-22T16:28:16.557228+08:00\"},
{\"id\":\"9962,\"user_id\":\"7991,\"user_name\":\"7C6QOM\",\"create_time\":\"2021-06-22T16:28:16.56234+08:00\"}]';:jsonb,
to_tsquery('english', '9LOHR4'), 'StartSel = <, StopSel = >');
ts_headline
-----

```

```
[{"id": 9928, "user_id": 4562, "user_name": "<9LOHR4>", "create_time":  
"2021-06-22T16:28:16.504518+08:00"}, {"id": 9959, "user_id": 5524, "user_name": "YID07D", "create_time":  
"2021-06-22T16:28:16.557228+08:00"}, {"id": 9962, "user_id": 7991, "user_name": "7C6QOM",  
"create_time": "2021-06-22T16:28:16.56234+08:00"}]  
(1 row)
```

json_to_tsvector(config regconfig,] json, jsonb)

Description: Converts the json format to the tsvector file format that supports full-text search.

Return type: jsonb

Example:

```
postgres=#SELECT json_to_tsvector('{"a":1, "b":2, "c":3}':json, to_jsonb('key':text));  
json_to_tsvector  
-----  
'b':2 'c':4  
(1 row)
```

21.7.15 Security Functions

gs_password_deadline()

Description: Displays the time before the password of the current account expires. After the password expires, the system prompts the user to change the password. This parameter is related to the GUC parameter **password_effect_time**.

Return type: interval

Example:

```
SELECT gs_password_deadline();  
gs_password_deadline  
-----  
83 days 17:44:32.196094  
(1 row)
```

gs_password_expiration()

Description: Displays the time before the password of the current account expires. After the password expires, the user cannot log in to the database. This parameter is related to the DDL statement **PASSWORD EXPIRATION period** for creating a user. The return value of the function is greater than or equal to -1. If **PASSWORD EXPIRATION period** is not specified during user creation, the default value is -1, indicating that there is no expiration limit.

Return type: interval

Example:

```
SELECT gs_password_expiration();  
gs_password_expiration  
-----  
29 days 23:59:49.731482  
(1 row)
```

login_audit_messages(flag boolean)

Description: Queries login information about a login user.

Return type: tuple

Example:

- Checks the date, time, and IP address successfully authenticated during the last login.

```
SELECT * FROM login_audit_messages(true);
username | database | logintime      | type | result | client_conninfo | session_id
-----+-----+-----+-----+-----+-----+-----
dbadmin  | gaussdb | 2017-06-02 15:28:34+08 | login_success | ok    | gsqr@[local]    | 1663745305.140192538154752.coordinator1
(1 row)
```

- Checks the date, time, and IP address that failed to be authenticated during the last login.

```
SELECT * FROM login_audit_messages(false) ORDER BY logintime desc limit 1;
username | database | logintime      | type | result | client_conninfo | session_id
-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

- Checks the number of failed attempts, date, and time since the previous successful authentication.

```
SELECT * FROM login_audit_messages(false);
username | database | logintime      | type | result | client_conninfo | session_id
-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

login_audit_messages_pid(flag boolean)

Description: Queries login information about a login user. Different from **login_audit_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

Example:

- Checks the date, time, and IP address successfully authenticated during the last login.

```
SELECT * FROM login_audit_messages_pid(true);
username | database | logintime      | type | result | client_conninfo | backendid | session_id
-----+-----+-----+-----+-----+-----+-----+-----
dbadmin  | postgres | 2017-06-02 15:28:34+08 | login_success | ok    | gsqr@[local] | 140311900702464 | 1663745305.140192538154752.coordinator1
(1 row)
```

- Checks the date, time, and IP address that failed to be authenticated during the last login.

```
SELECT * FROM login_audit_messages_pid(false) ORDER BY logintime desc limit 1;
username | database | logintime      | type | result | client_conninfo | backendid | session_id
-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

- Checks the number of failed attempts, date, and time since the previous successful authentication.

```
SELECT * FROM login_audit_messages_pid(false);
username | database | logintime      | type | result | client_conninfo | backendid | session_id
-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

pg_query_audit()

Description: Displays audit logs of the CN.

Return type: record

The following table describes return columns.

Table 21-44 Columns returned by the pg_query_audit() function

| Column | Type | Description |
|-----------------|--------------------------|--|
| begintime | timestamp with time zone | Operation start time |
| endtime | timestamp with time zone | Operation end time |
| operation_type | text | Operation type. For details, see Table 21-45 . |
| audit_type | text | Audit type. For details, see Table 21-46 . |
| result | text | Operation result |
| username | text | Name of the user who performs the operation |
| database | text | Database name |
| client_conninfo | text | Client connection information, that is, gsql, JDBC, or ODBC. |
| object_name | text | Object name |
| object_details | text | Columns involved in the statement and their types. |
| command_text | text | Command used to perform the operation |
| detail_info | text | Operation details |
| transaction_xid | text | Transaction ID |
| query_id | text | Query ID |
| node_name | text | Node name |
| session_id | text | ID of a session. |
| local_port | text | Local port |
| remote_port | text | Remote port |
| result_rows | text | Number of records returned after the statement is executed. |

| Column | Type | Description |
|------------|------|--|
| error_code | text | Error code returned when a statement execution error occurs. |

Table 21-45 Operation types

| Operation type | Description |
|----------------|--|
| audit_switch | Indicates that the operations of enabling and disabling the audit log function are audited. |
| login_logout | Indicates that user login and log-out operations are audited. |
| system | Indicates that the system startup, shutdown, and instance switchover operations are audited. |
| sql_parse | Indicates that SQL statement parsing operations are audited. |
| user_lock | Indicates that user locking and unlocking operations are audited. |
| grant_revoke | Indicates that user permission granting and revoking operations are audited. |
| violation | Indicates that user's access violation operations are audited. |
| ddl | Indicates that DDL operations are audited. DDL operations are controlled at a fine granularity based on operation objects. Therefore, audit_system_object is used to specify which objects' DDL operations should be audited. Note that the audit function is active whenever audit_system_object is configured, regardless of the ddl setting. |
| dml | Indicates that the DML operations are audited. |
| select | Indicates that the SELECT operations are audited. |
| internal_event | Indicates that internal incident operations are audited. |
| user_func | <p>Indicates that operations related to user-defined functions, stored procedures, and anonymous blocks are audited.</p> <p>NOTE</p> <p>If a user-defined function or stored procedure contains a FETCH statement, the common_text field records the corresponding CURSOR content when the fetch statement is audited.</p> |

| Operation type | Description |
|-----------------|---|
| special_func | Indicates that special function invoking operations are audited. Special functions include pg_terminate_backend and pg_cancel_backend . |
| copy | Indicates that the COPY operations are audited. |
| set | Indicates that the SET operations are audited. |
| transaction | Indicates that transaction operations are audited. |
| vacuum | Indicates that the VACUUM operations are audited. |
| analyze | Indicates that the ANALYZE operations are audited. |
| cursor | Indicates that cursor operations are audited. |
| anonymous_block | Indicates that the anonymous block operations are audited. |
| explain | Indicates that the EXPLAIN operations are audited. |
| show | Indicates that the SHOW operations are audited. |
| lock_table | Indicates that table lock operations are audited. |
| comment | Indicates that the COMMENT operations are audited. |
| preparestmt | Indicates that the PREPARE , EXECUTE , and DEALLOCATE operations are audited. |
| cluster | Indicates that the CLUSTER operations are audited. |
| constraints | Indicates that the CONSTRAINTS operations are audited. |
| checkpoint | Indicates that the CHECKPOINT operations are audited. |
| barrier | Indicates that the BARRIER operations are audited. |
| cleanconn | Indicates that the CLEAN CONNECTION operations are audited. |
| seclabel | Indicates that security label operations are audited. |
| notify | Indicates that the notification operations are audited. |
| load | Indicates that the loading operations are audited. |
| discard | Indicates that all global temporary tables of the current session are audited. |

Table 21-46 audit_type parameters

| Parameter | Description |
|--|--|
| audit_open/
audit_close | Indicates that the audit type is operations enabling or disabling audit logs. |
| user_login/
user_logout | Indicates that the audit type is operations and users with successful login/logout. |
| system_start/
system_stop/
system_recover/
system_switch | Indicates that the audit type is system startup, shutdown, and instance switchover. |
| sql_wait/sql_parse | Indicates that the audit type is SQL statement parsing. |
| lock_user/unlock_user | Indicates that the audit type is successful user locking and unlocking. |
| grant_role/
revoke_role | Indicates that the audit type is user permission granting and revoking. |
| user_violation | Indicates that the audit type is unauthorized user access operations. |
| ddl_database_object | <p>Indicates that successful DDL operations are audited. DDL operations are controlled at a fine granularity based on operation objects. So, audit_system_object is used to control the objects whose DDL operations are to be audited. (The audit function takes effect as long as audit_system_object is configured, no matter whether ddl is set.)</p> <p>For example, ddl_sequence indicates that the audit type is sequence-related operations.</p> |
| dml_action_insert/
dml_action_delete/
dml_action_update/
dml_action_merge/
dml_action_select | Indicates that the audit type is DML operations such as INSERT , DELETE , UPDATE , and MERGE . |
| internal_event | Indicates that the audit type is internal events. |
| user_func | <p>Indicates that the audit type is user-defined functions, stored procedures, or anonymous block operations.</p> <p>NOTE</p> <p>If a user-defined function or stored procedure contains a FETCH statement, the common_text field records the corresponding CURSOR content when the fetch statement is audited.</p> |
| special_func | Indicates that the audit type is special function invocation. Special functions include pg_terminate_backend and pg_cancel_backend . |
| copy_to/copy_from | Indicates that the audit type is COPY operations. |

| Parameter | Description |
|---|---|
| set_parameter | Indicates that the audit type is SET operations. |
| trans_begin/
trans_commit/
trans_prepare/
trans_rollback_to/
trans_release/
trans_savepoint/
trans_commit_prepare
/
trans_rollback_prepare
/trans_rollback | Indicates that the audit type is transaction-related operations. |
| vacuum/vacuum_full/
vacuum_merge | Indicates that the audit type is VACUUM operations. |
| analyze/analyze_verify | Indicates that the audit type is ANALYZE operations. |
| cursor_declare/
cursor_move/
cursor_fetch/
cursor_close | Indicates that the audit type is cursor-related operations. |
| codeblock_execute | Indicates that the audit type is anonymous blocks. |
| explain | Indicates that the audit type is EXPLAIN operations. |
| show | Indicates that the audit type is SHOW operations. |
| lock_table | Indicates that the audit type is table locking operations. |
| comment | Indicates that the audit type is COMMENT operations. |
| prepare/execute/
deallocate | Indicates that the audit type is PREPARE , EXECUTE , or DEALLOCATE operations. |
| cluster | Indicates that the audit type is CLUSTER operations. |
| constraints | Indicates that the audit type is CONSTRAINTS operations. |
| checkpoint | Indicates that the audit type is CHECKPOINT operations. |
| barrier | Indicates that the audit type is BARRIER operations. |
| cleanconn | Indicates that the audit type is CLEAN CONNECTION operations. |
| seclabel | Indicates that the audit type is security label operations. |
| notify | Indicates that the audit type is notification operations. |
| load | Indicates that the audit type is loading operations. |

| Parameter | Description |
|-----------|---|
| discard | Indicates that the audit type is DISCARD operations. |

pgxc_query_audit()

Description: Displays audit logs of all CNs.

Return type: record

The return fields of this function are the same as those of the **pg_query_audit** function.

pg_query_audit_details()

Description: Views audit logs and parses the **object_name** and **object_details** columns in audit logs from JSON format. This function is supported only by clusters of version 8.2.1.100 or later.

Return type: record

The following table describes return columns.

Table 21-47 Columns returned by the pg_query_audit() function

| Column | Type | Description |
|-----------------|--------------------------|--|
| begintime | timestamp with time zone | Operation start time |
| endtime | timestamp with time zone | Operation end time |
| operation_type | text | Operation type. For details, see Table 21-45 . |
| audit_type | text | Audit type. For details, see Table 21-46 . |
| result | text | Operation result |
| username | text | Name of the user who performs the operation |
| database | text | Database name |
| client_conninfo | text | Client connection information, that is, gsql, JDBC, or ODBC. |
| transaction_xid | text | Transaction ID |
| query_id | text | Query ID |
| node_name | text | Node name |

| Column | Type | Description |
|--------------|------|---|
| session_id | text | ID of a session. |
| local_port | text | Local port |
| remote_port | text | Remote port |
| object_name | text | Table name, function name, and view name. |
| column_name | text | Column name |
| type_of_use | text | Usage type of an object. The options are as follows:
1: reference only (This flag does not exist in actual use.)
2: accessed during execution (columns in the statement and columns accessed during parsing)
4: found in condition statements (excluding condition expressions and functions)
8: found in inner join
16: found in outer join
32: found in aggregation nodes (including distinct , group by , and aggregate functions)
64: found in full join
The values in this column are displayed in overlay mode. |
| use_type | text | Type parsed by type_of_use :
1: Reference only
2: Access
4: Conditional
8: Inner join
16: Outer join
32: Sum
64: Full join |
| command_text | text | Command used to perform the operation |

Example:

1. Query the column names of all objects and object types used in the statement.

```
SET audit_object_details = on;
SELECT object_name,object_details,result_rows,error_code,command_text FROM
pg_query_audit('2023-05-12-03 8:00:00','2023-05-12 22:55:00') where command_text like '%student%';
```

The query result is as follows:

| object_name | object_details | result_rows | error_code | command_text |
|-----------------------|----------------|-------------|------------|--|
| student | | 0 | | CREATE TABLE student(stuNo int, stuName TEXT); |
| studentscore | | 0 | | CREATE TABLE studentscore(stuNo int, stuscore int); |
| public.student_view01 | | 0 | | REPLACE VIEW student_view01 AS SELECT * FROM student t1 where t1.stuNo in (select stuNo from studentscore t2 where t1.stuNo = t2.stuNo); |
| public.student | | 0 | | SELECT * FROM student_view01 |

- The **object_details** column in the query result displays the columns involved in the execution and their usage types. The columns are recorded in JSON format.

You can use the **pg_query_audit_details** function to parse the **object_name** and **object_details** columns.

```
SELECT database,object_name,column_name,type_of_use,use_type FROM
pg_query_audit_details('2021-02-03 8:00:00','2024-02-03 22:55:00','current') where command_text like '%student%';
```

The query result is as follows:

| database | object_name | column_name | type_of_use | use_type |
|-----------|-----------------------|-------------|-------------|--------------------|
| gaussdb | student | | 2 | Access |
| gaussdb | | | 2 | Access |
| gaussdb | studentscore | | 2 | Access |
| gaussdb | | | 2 | Access |
| gaussdb | public.student_view01 | | 2 | Access |
| gaussdb | public.studentscore | | 2 | Access |
| gaussdb | public.student | | 2 | Access |
| gaussdb | | | 2 | Access |
| gaussdb | public.student | stuno | 6 | Access,Conditional |
| gaussdb | public.student | stuname | 2 | Access |
| gaussdb | public.studentscore | stuno | 6 | Access,Conditional |
| gaussdb | public.student_view01 | | 2 | Access |
| gaussdb | public.student | | 2 | Access |
| gaussdb | public.studentscore | | 2 | Access |
| gaussdb | | | 2 | Access |
| (15 rows) | | | | |

pg_delete_audit()

Description: Deletes audit logs generated in a specified period. This function has been deprecated in 8.1.3 and later cluster versions. Return type: void

NOTE

For database security concerns, this function is unavailable. If you call it, the following message is displayed: "ERROR: For security purposes, it is not allowed to manually delete audit logs."

create_audit_csv_foreign_table()

Description: Creates a partitioned foreign table for reading audit logs. You can invoke this function to generate the audit log foreign table **pgxc_audit_logs**. By reading **pgxc_audit_logs**, you can read audit logs stored on OBS. This function is supported only in clusters of 8.3.0 or later.

Input parameter:

- **obs_server**: OBS server name. The value is of the text type.
- **file_path**: OBS file path. The value is of the text type.

Return type: record

Example:

```
-- Create an OBS server.
CREATE SERVER obs_server FOREIGN DATA WRAPPER DFS_FDW OPTIONS (
  address 'obs.example.xxx:xxx',
  encrypt 'true',
  access_key 'xxxxxxxxx',
  secret_access_key 'xxxxxxxxxxxxxxxxx',
  type 'obs' );
-- Invoke this function to generate a foreign table for audit logs.
SELECT * FROM pg_catalog.create_audit_csv_foreign_table('obs_server','/obs-audit/test/');
create_audit_csv_foreign_table
-----
t
(1 row)
-- Read audit logs stored on OBS.
SELECT * FROM pgxc_audit_logs where year=2023 and month=7 and date=24;
 year | month | date |      begintime      |      endtime      | operation_type | audit_type | result
-----+-----+-----+-----+-----+-----+-----+-----+-----
| username | database | client_conninfo |      object_name      | object_details | command_text |
| detail_info | transaction_xid | query_id | node_name | session_id | local_port |
| remote_port | result_rows | error_code |
-----+-----+-----+-----+-----+-----+-----+-----+-----
|-----+-----+-----+-----+-----+-----+-----+-----+-----
|-----+-----+-----+-----+-----+-----+-----+-----+-----
|-----+-----+-----+-----+-----+-----+-----+-----+-----
|-----+-----+-----+-----+-----+-----+-----+-----+-----
|-----+-----+-----+-----+-----+-----+-----+-----+-----
2023 | 7 | 24 | 2023-07-24 09:56:40.727+08 | 2023-07-24 09:56:42.215+08 | dml | |
dml_action_select | ok | dbadmin | gaussdb | gsqr@[local] | public.pgxc_audit_logs | |
select * f
rom pgxc_audit_logs where year=2023 and date=24 and month=7;
```

21.7.16 Conditional Expression Functions

coalesce(expr1, expr2, ..., exprn)

Description: Returns the first argument that is not **NULL** in the argument list.

COALESCE(expr1, expr2) is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Examples:

```
SELECT coalesce(NULL,'hello');
 coalesce
-----
hello
(1 row)
```

 NOTE

- **NULL** is returned only if all parameters are **NULL**.
- This value is replaced by the default value when data is displayed.
- Like a CASE expression, COALESCE only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-null parameter are not evaluated.

decode(base_expr, compare1, value1, Compare2,value2, ... default)

Description: Compares base_expr with each compare(n) and returns value(n) if they are matched. If base_expr does not match each **compare(n)**, the default value is returned.

Examples:

```
SELECT decode('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

if(bool_expr, expr1, expr2)

Description: Returns **expr1** or **expr2**. If the value of **bool_expr** is **true**, **expr1** is returned. Otherwise, **expr2** is returned.

This function is equivalent to **CASE WHEN bool_expr = true THEN expr1 ELSE expr2 END**.

Examples:

```
SELECT if(1 < 2, 'yes', 'no');
if
----
yes
(1 row)
```

 NOTE

expr1 and **expr2** can be of any type. For details about the available types, see [UNION, CASE, and Related Constructs](#).

ifnull(expr1, expr2)

Description: Returns **expr1** or **expr2**. If **expr1** is not **NULL**, **expr1** is returned. Otherwise, **expr2** is returned.

This function is logically equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.

Examples:

```
SELECT ifnull(NULL,'hello');
ifnull
-----
hello
(1 row)
```

 NOTE

expr1 and **expr2** can be of any type. For details about the available types, see [UNION, CASE, and Related Constructs](#).

isnull(expr)

Description: Checks whether **expr** is **NULL**. If it is **NULL**, **true** is returned. Otherwise, **false** is returned.

This function is logically equivalent to **expr IS NULL**.

Examples:

```
SELECT isnull(NULL), isnull('abc');
isnull | isnull
-----+-----
t      | f
(1 row)
```

nullif(expr1, expr2)

Description: Returns **NULL** or **expr1**. If **expr1** is equal to **expr2**, **NULL** is returned. Otherwise, **expr1** is returned.

nullif(expr1, expr2) is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

Examples:

```
SELECT nullif('hello','world');
nullif
-----
hello
(1 row)
```

Note:

Assume the two parameter data types are different:

- If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed. Otherwise, an error is returned. For example:

```
SELECT nullif('1234'::VARCHAR,123::INT4);
nullif
-----
1234
(1 row)
SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR:  invalid input syntax for type timestamp: "1234"
```

- If implicit conversion is not applied between two data types, an error is displayed. For example:

```
SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE);
ERROR:  operator does not exist: boolean = timestamp without time zone
LINE 1: SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE) FROM DUAL;
      ^
HINT:  No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

nvl(expr1 , expr2)

Description: Returns **expr2** if **expr1** is **NULL**. If **expr1** is not **NULL**, **expr1** is returned.

Examples:

```
SELECT nvl('hello','world');
nvl
-----
hello
(1 row)
```

NOTE

Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the **expr1** data type is returned. If **expr2** cannot be implicitly converted to **expr1** but **expr1** can be implicitly converted to **expr2**, the **expr2** data type is returned. If no implicit type conversion exists between the two parameters and the parameters are different data types, an error is reported.

sys_context('namespace' , 'parameter')

Description: Obtains and returns the parameter values of a specified **namespace**.

Return type: text

Examples:

```
SELECT sys_context('USERENV', 'CURRENT_SCHEMA');
sys_context
-----
public
(1 row)
```

The result varies according to the current actual schema.

NOTE

Currently, only the SYS_CONTEXT('USERENV','CURRENT_SCHEMA') and SYS_CONTEXT('USERENV','CURRENT_USER') formats are supported.

greatest(expr1 [, ...])

Description: Selects the largest value from a list of any number of expressions.

- In Oracle- or Teradata-compatible mode, the returned result is the maximum value of all non-null parameters.
- In MySQL-compatible mode, **null** is returned if an input parameter contains **null**.

Examples:

```
SELECT greatest(1*2,2-3,4-1);
greatest
-----
3
(1 row)
SELECT greatest('ABC', 'BCD', 'CDE');
greatest
-----
```

```
CDE  
(1 row)
```

least(expr1 [, ...])

Description: Selects the smallest value from a list of any number of expressions.

- In Oracle- or Teradata-compatible mode, the returned result is the minimum value of all non-null parameters.
- In MySQL-compatible mode, **null** is returned if an input parameter contains **null**.

Examples:

```
SELECT least(1*2,2-3,4-1);  
least  
-----  
-1  
(1 row)  
SELECT least('ABC','BCD','CDE');  
least  
-----  
ABC  
(1 row)
```

EMPTY_BLOB()

Description: Initiates a BLOB variable in an INSERT or an UPDATE statement to a NULL value.

Return type: BLOB

Examples:

```
-- Create a table:  
CREATE TABLE blob_tb(b blob,id int) DISTRIBUTE BY REPLICATION;  
-- Insert data:  
INSERT INTO blob_tb VALUES (empty_blob(),1);  
--Delete the table.  
DROP TABLE blob_tb;
```

NOTE

The length obtained by using **DBMS.GETLENGTH** is 0.

21.7.17 Range Functions and Operators

21.7.17.1 Range Operators

=

Description: Equals

Example:

```
SELECT int4range(1,5) = '[1,4]::int4range AS RESULT;  
result  
-----  
t  
(1 row)
```

<>

Description: Does not equal to

Example:

```
SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;
result
-----
t
(1 row)
```

<

Description: Is less than

Example:

```
SELECT int4range(1,10) < int4range(2,3) AS RESULT;
result
-----
t
(1 row)
```

>

Description: Is greater than

Example:

```
SELECT int4range(1,10) > int4range(1,5) AS RESULT;
result
-----
t
(1 row)
```

<=

Description: Is less than or equals

Example:

```
SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;
result
-----
t
(1 row)
```

>=

Description: Is greater than or equals

Example:

```
SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;
result
-----
t
(1 row)
```

@>

Description: The object on the left includes the object on the right.

Example:

```
SELECT int4range(2,4) @> int4range(2,3) AS RESULT;
result
-----
t
(1 row)
SELECT '[2011-01-01,2011-03-01)::tsrange @> '2011-01-10)::timestamp AS RESULT;
result
-----
t
(1 row)
```

<@

Description: The object on the right includes the object on the left.

Example:

```
SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;
result
-----
t
(1 row)
SELECT 42 <@ int4range(1,7) AS RESULT;
result
-----
f
(1 row)
```

&&

Description: Overlap (have points in common)

Example:

```
SELECT int8range(3,7) && int8range(4,12) AS RESULT;
result
-----
t
(1 row)
```

<<

Description: Strictly left of

Example:

```
SELECT int8range(1,10) << int8range(100,110) AS RESULT;
result
-----
t
(1 row)
```

>>

Description: Strictly right of

Example:

```
SELECT int8range(50,60) >> int8range(20,30) AS RESULT;
result
-----
t
(1 row)
```

&<

Description: Does not extend to the right of

Example:

```
SELECT int8range(1,20) &< int8range(18,20) AS RESULT;  
result  
-----  
t  
(1 row)
```

&>

Description: Does not extend to the left of

Example:

```
SELECT int8range(7,20) &> int8range(5,10) AS RESULT;  
result  
-----  
t  
(1 row)
```

-|-

Description: Is adjacent to

Example:

```
SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;  
result  
-----  
t  
(1 row)
```

+

Description: Union

Example:

```
SELECT numrange(5,15) + numrange(10,20) AS RESULT;  
result  
-----  
[5,20)  
(1 row)
```

Description: Intersection

Example:

```
SELECT int8range(5,15) * int8range(10,20) AS RESULT;  
result  
-----  
[10,15)  
(1 row)
```

-

Description: Difference

Example:

```
SELECT int8range(5,15) - int8range(10,20) AS RESULT;  
result  
-----  
[5,10)  
(1 row)
```

NOTE

- The simple comparison operators <, >, <=, and >= compare the lower bounds first, and only if those are equal, compare the upper bounds.
- The <<, >>, and -|- operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.
- The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

21.7.17.2 Range Functions

lower(anyrange)

Description: Lower bound of range

Return type: Range's element type

Example:

```
SELECT lower(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
1.1  
(1 row)
```

upper(anyrange)

Description: Upper bound of range

Return type: Range's element type

Example:

```
SELECT upper(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
2.2  
(1 row)
```

isempty(anyrange)

Description: Is the range empty?

Return type: boolean

Example:

```
SELECT isempty(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

lower_inc(anyrange)

Description: Is the lower bound inclusive?

Return type: boolean

Example:

```
SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
t  
(1 row)
```

upper_inc(anyrange)

Description: Is the upper bound inclusive?

Return type: boolean

Example:

```
SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;  
result  
-----  
f  
(1 row)
```

lower_inf(anyrange)

Description: Is the lower bound infinite?

Return type: boolean

Example:

```
SELECT lower_inf('(,)'::daterange) AS RESULT;  
result  
-----  
t  
(1 row)
```

upper_inf(anyrange)

Description: Is the upper bound infinite?

Return type: boolean

Example:

```
SELECT upper_inf('(,)'::daterange) AS RESULT;  
result  
-----  
t  
(1 row)
```

NOTE

The **lower** and **upper** functions return null if the range is empty or the requested bound is infinite. The **lower_inc**, **upper_inc**, **lower_inf**, and **upper_inf** functions all return false for an empty range.

21.7.18 Data Redaction Functions

Data redaction functions are used to mask and protect sensitive data. Generally, you are advised to bind these functions to the columns to be redacted based on the data redaction syntax, rather than use them directly on query statements.

mask_none(column_name)

Description: Masks no data (for internal tests only).

Return type: same as **column_name**

mask_full(column_name)

Description: Replaces all data with a fixed value. The fixed value varies depending on the data type of the redacted column.

Return type: same as **column_name**

mask_partial(column_name, mask_digital, mask_from[, mask_to])

Description: Replaces the digits from the **mask_from** to **mask_to** position in a number with the digit specified by **mask_digital**. The default value of **mask_to** can be used, which indicates that the digits from the **mask_from** position to the end of the number are replaced. **mask_digital** can only be a digit from 0 to 9.

Return type: same as **column_name**

mask_partial(column_name [, input_format, output_format], mask_char, mask_from[, mask_to])

Description: Replaces the digits from the **mask_from** to **mask_to** position in a string with the character specified by **mask_char** based on the given input and output formats.

Parameter description:

- **input_format**
The input format is a character string of V and F, whose length is the same as that of the data in the redacted column. Characters in positions corresponding to V may be masked, and characters in positions corresponding to F are skipped. The V character string specifies which characters are to be masked. The input and output formats apply to data with a fixed length, such as bank card numbers, ID card numbers, and phone numbers.
- **output_format**
The output format is a character string of V and any other character, whose length is the same as that of the data in the redacted column. V characters correspond to those in the **input_format**, and other characters correspond to the F characters in the **input_format**.
For parameters **input_format** and **output_format**, you can use their default values or set them to "". In this case, there is no requirement for the input or output format, and the whole string will be masked.

- **mask_char**
Masking character, which can be any one character, for example, an asterisk (*) or a number sign (#).
- **mask_from**
First character in the string that will be masked. The value must be greater than 0.
- **mask_to**
Last character in the string that will be masked. The default value can be used, which indicates that the character from the **mask_from** position to the last character of the string will be masked.

Return type: same as **column_name**

mask_partial(column_name, mask_field1, mask_value1, mask_field2, mask_value2, mask_field3, mask_value3)

Description: Masks a date or time based on three specified fields. If **mask_value** is -1, the corresponding **mask_field** is not masked. **mask_field** can be **month**, **day**, **year**, **hour**, **minute**, or **second**. The value range of each field must be within that of the actual time unit.

Return type: same as **column_name**

NOTE

Redaction functions are recommended if you want to create redaction policies.

For how to use data masking functions, see the examples in "Database Security Management" > "Sensitive Data Management" > "Data Masking" in the *Data Warehouse Service (DWS) Developer Guide*.

User-Defined Redaction Functions

You can use the PL/pgSQL language to customize redaction functions.

User-defined redaction functions must meet the following requirements:

- The return type must be the same as the data type of the redacted column.
- The functions can be pushed down.
- In addition to the redaction format, only one column can be specified in the argument list for data redaction.
- The functions only implement the formatting for specific data types and do not involve complex association operations with other table objects.

If either of the first two requirements is not met, an error will be reported when you create a redaction policy. If either of the last two requirements is not met, unexpected problems may occur in query execution results.

Deleting the bound user-defined data redaction function will cause an error during query execution due to an invalid redaction policy.

21.7.19 Bitmap Functions and Operators

21.7.19.1 Roaring Bitmap Operators

Starting from DWS 8.1.3, user profiling and precision marketing scenarios benefit from the utilization of efficient bitmap processing operators. This enhancement significantly enhances query performance.

=

Description: Compares two Roaring bitmaps to check whether they are equal.

Return type: bool

Example:

```
SELECT rb_build('{1,2,3}') = rb_build('{1,2,3}');
?column?
-----
t
(1 row)
SELECT rb_build('{2,3}') = rb_build('{1,2,3}');
?column?
-----
f
(1 row)
```

<>

Description: Compares two Roaring bitmaps to check whether they are unequal.

Return type: bool

Example:

```
SELECT rb_build('{1,2,3}') <> rb_build('{1,2,3}');
?column?
-----
f
(1 row)
SELECT rb_build('{2,3}') <> rb_build('{1,2,3}');
?column?
-----
t
(1 row)
```

&

Description: Calculates the intersection of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3}') & rb_build('{1,2,3}'));
rb_to_array
-----
{2,3}
(1 row)
```

|

Description: Calculates the union of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3}') | rb_build('{1,2,3}'));
rb_to_array
-----
{1,2,3}
(1 row)
```

|

Description: Calculates the result of adding an ID to a Roaring bitmap.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3}') | 4);
rb_to_array
-----
{2,3,4}
(1 row)
```

#

Description: XOR result of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3}') # rb_build('{1,2,3}'));
rb_to_array
-----
{1}
(1 row)
```

-

Description: Calculates the result set in the first Roaring bitmap but not in the second Roaring bitmap.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3,4}') - rb_build('{1,2,3}'));
rb_to_array
-----
{4}
(1 row)
```

-

Description: The result set of removing a specified ID from a Roaring bitmap.

Return type: RoaringBitmap

Example:

```
SELECT rb_to_array(rb_build('{2,3,4}') - 3);
rb_to_array
-----
{2,4}
(1 row)
```

@>

Description: Determines whether the Roaring bitmap before an operator contains the Roaring bitmap after the operator.

Return type: bool

Example:

```
SELECT rb_build('{2,3,4}') @> rb_build('{2,3}');
?column?
-----
t
(1 row)
SELECT rb_build('{2,3,4}') @> 4;
?column?
-----
t
(1 row)
```

<@

Description: Determines whether the Roaring bitmap before an operator is contained in the Roaring bitmap after the operator.

Return type: bool

Example:

```
SELECT 4 <@ rb_build('{2,3,4}');
?column?
-----
t
(1 row)
SELECT rb_build('{2,3,4}') <@ rb_build('{2,3}');
?column?
-----
f
(1 row)
```

&&

Description: If two Roaring bitmaps overlap, **true** is returned. Otherwise, **false** is returned.

Return type: bool

Example:

```
SELECT rb_build('{2,3,4}') && rb_build('{2,3}');
?column?
-----
t
(1 row)
SELECT rb_build('{2,3,4}') && rb_build('{7,8,9}');
?column?
-----
f
(1 row)
```

21.7.19.2 Bitmap Functions

Since 8.1.3, DWS supports efficient bitmap processing functions and operators, which can be used in user profiling and precision marketing, greatly improving query performance.

rb_build(array)

Description: Converts an int array to the RoaringBitmap type.

Return type: RoaringBitmap

Example:

```
SELECT rb_build('{1,2,3}');
rb_build
-----
\3a300000010000000000020010000000010002000300
(1 row)
CREATE TABLE r_row (a int, b text, c roaringbitmap);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using round-robin as the distribution mode by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

INSERT INTO r_row values (1, 'a', rb_build('{1,2,3}'));
INSERT 0 1

SELECT * FROM r_row;
 a | b | c
---+---+---
 1 | a | \3a300000010000000000020010000000010002000300
(1 row)

INSERT INTO r_row values (2, 'b', rb_build('{}'));
INSERT 0 1

SELECT * FROM r_row;
 a | b | c
---+---+---
 2 | b | \3a3000000000000000
 1 | a | \3a300000010000000000020010000000010002000300
(2 rows)
```

rb_iterate(roaringbitmap)

Description: Converts roaringbitmap data into int data and outputs the data in multiple lines.

Return type: record (int value in multiple rows)

Example:

```
postgres=#SELECT rb_iterate(c) FROM r_row;
rb_iterate
-----
1
2
3
(3 rows)
```

rb_to_array(roaringbitmap)

Description: Using rb_build reverse operation to convert roaringBitmap into an int array.

Return type: array

Example:

```
postgres=#SELECT rb_to_array(c) FROM r_row;
rb_to_array
-----
{1,2,3}
(1 row)
postgres=#SELECT rb_to_array('\x3a30000001000000000020010000000010002000300');
rb_to_array
-----
{1,2,3}
(1 row)
```

rb_and(roaringbitmap, roaringbitmap)

Description: Calculates the intersection of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_and(rb_build('{1,2,3}'), rb_build('{2,3,4}')));
rb_to_array
-----
{2,3}
(1 row)
```

rb_or(roaringbitmap, roaringbitmap)

Description: Calculates the union of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_or(rb_build('{1,2,3}'), rb_build('{2,3,4}')));
rb_to_array
-----
{1,2,3,4}
(1 row)
```

rb_xor(roaringbitmap, roaringbitmap)

Description: Calculates the XOR of two Roaring bitmaps.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_xor(rb_build('{1,2,3}'), rb_build('{2,3,4}')));
rb_to_array
-----
{1,4}
(1 row)
```

rb_andnot(roaringbitmap, roaringbitmap)

Description: Sets in the first Roaring bitmap set but not in the second Roaring bitmap set.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_andnot(rb_build('{1,2,3}'), rb_build('{2,3,4}')));
rb_to_array
-----
{1}
(1 row)
```

rb_cardinality(roaringbitmap)

Description: Calculates the cardinality of a Roaring bitmap.

Return type: int

Example:

```
postgres=#SELECT rb_cardinality(rb_build('{1,2,3}'));
rb_cardinality
-----
3
(1 row)
```

rb_and_cardinality(roaringbitmap, roaringbitmap)

Description: Calculates the cardinality of the intersection of two Roaring bitmaps.

Return type: int

Example:

```
postgres=#SELECT rb_and_cardinality(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_and_cardinality
-----
2
(1 row)
```

rb_or_cardinality(roaringbitmap, roaringbitmap)

Description: Calculates the cardinality of the union of two Roaring bitmaps.

Return type: int

Example:

```
postgres=#SELECT rb_or_cardinality(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_or_cardinality
-----
4
(1 row)
```

rb_xor_cardinality(roaringbitmap, roaringbitmap)

Description: Calculates the cardinality of two Roaring bitmaps after the XOR operation.

Return type: int

Example:

```
postgres=#SELECT rb_xor_cardinality(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_xor_cardinality
-----
2
(1 row)
```

rb_andnot_cardinality(roaringbitmap, roaringbitmap)

Description: Calculates the cardinality of two Roaring bitmaps after ANDNOT operation.

Return type: int

Example:

```
postgres=#SELECT rb_andnot_cardinality(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_andnot_cardinality
-----
1
(1 row)
```

rb_is_empty(roaringbitmap)

Description: Determines whether a Roaring bitmap is empty.

Return type: bool

Example:

```
postgres=#SELECT rb_is_empty(rb_build('{1,2,3}'));
rb_is_empty
-----
f
(1 row)
```

rb_equals(roaringbitmap, roaringbitmap)

Description: Determines whether two Roaring bitmaps are equal.

Return type: bool

Example:

```
postgres=#SELECT rb_equals(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_equals
-----
f
(1 row)
```

rb_intersect(roaringbitmap, roaringbitmap)

Description: Determines whether two Roaring bitmaps are intersected.

Return type: bool

Example:

```
postgres=#SELECT rb_intersect(rb_build('{1,2,3}'), rb_build('{2,3,4}'));
rb_intersect
-----
t
(1 row)
```

rb_min(roaringbitmap)

Description: Returns the minimum value in a Roaring bitmap.

Return type: int

Example:

```
postgres=#SELECT rb_min(rb_build('{1,2,3}'));
rb_min
-----
1
(1 row)
```

rb_max(roaringbitmap)

Description: Returns the maximum value in a Roaring bitmap.

Return type: int

Example:

```
postgres=#SELECT rb_max(rb_build('{1,2,3}'));
rb_max
-----
3
(1 row)
```

rb_add(roaringbitmap, int)

Description: Adds an element to a Roaring bitmap.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_add(rb_build('{1,3}'), 2));
rb_to_array
-----
{1,2,3}
(1 row)
```

rb_added(int, roaringbitmap)

Description: Adds an element to a Roaring bitmap.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_added(2, rb_build('{1,3}')));
rb_to_array
-----
{1,2,3}
(1 row)
```

rb_contain(roaringbitmap,int)

Description: Determines whether a Roaring bitmap contains the specified element.

Return type: bool

Example:

```
postgres=#SELECT rb_contain(rb_build('{1,3}'), 2);
rb_contain
-----
f
(1 row)
```

rb_containedby(int,roaringbitmap)

Description: Determines whether the given element is included in a given Roaring bitmap.

Example:

```
postgres=#SELECT rb_containedby(2,rb_build('{1,3}'));
rb_containedby
-----
f
(1 row)
```

rb_contain_rb(roaringbitmap,roaringbitmap)

Description: Determines whether the first Roaring bitmap contains the second Roaring bitmap.

Return type: bool

Example:

```
postgres=#SELECT rb_contain_rb(rb_build('{1,3}'), rb_build('{2,3}'));
rb_contain_rb
-----
f
(1 row)
```

rb_containedby_rb(roaringbitmap,roaringbitmap)

Description: Determines whether the second Roaring bitmap contains the first Roaring bitmap.

Return type: bool

Example:

```
postgres=#SELECT rb_containedby_rb(rb_build('{1,3}'), rb_build('{2,3}'));
rb_containedby_rb
-----
f
(1 row)
```

rb_remove(roaringbitmap,int)

Description: Removes elements from a Roaring bitmap.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT rb_to_array(rb_remove(rb_build('{1,3}'),1));
rb_to_array
-----
{3}
(1 row)
```

rb_clear(roaringbitmap,int,int)

Description: Clears elements within a specified range from roaring bitmaps.

Return type: RoaringBitmap

Example:

```
postgres=#SELECT
rb_to_array(rb_clear(rb_build('{1,2,3}'),1,2));

rb_to_array
-----
{2,3}
(1 row)
```

rb_flip(roaringbitmap,int,int)

Description: Reverses elements in a specified range.

Example:

```
postgres=#SELECT rb_to_array(rb_flip(rb_build('{1,2,3,7,9}'), 1,10));
rb_to_array
-----
{4,5,6,8,10}
(1 row)
```

rb_rank(roaringbitmap,int)

Description: Returns the cardinality of the set of values less than the specified value.

Return type: int

Example:

```
postgres=#SELECT rb_rank(rb_build('{1,10,100}'),99);
rb_rank
-----
2
(1 row)
```

21.7.19.3 Roaring Bitmap Aggregation Functions

Since 8.1.3, DWS supports efficient bitmap processing functions and operators, which can be used in user profiling and precision marketing, greatly improving query performance.

rb_build_agg(int)

Description: Aggregates int values in a group into a RoaringBitmap value.

Return type: RoaringBitmap

Example:

```
CREATE TABLE t1 (a int ,b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using round-robin as the distribution mode by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
INSERT INTO t1 SELECT generate_series(1,10),generate_series(1,20,2);
INSERT 0 10
SELECT rb_iterate(rb_build_agg(b)) FROM t1;
rb_iterate
-----
1
```

```
3
5
7
9
11
13
15
17
19
(10 rows)
```

rb_and_agg(roaringbitmap)

Description: Aggregates data of the Roaring bitmaps in a group into a Roaring bitmap set based on the INTERSECT operation.

Example:

```
CREATE TABLE r1(a int ,b roaringbitmap);
INSERT INTO r1 SELECT a, rb_build_agg(b) FROM t1 GROUP BY a;
INSERT INTO t1 SELECT generate_series(1,10),generate_series(1,20,4);
INSERT INTO r1 SELECT a, rb_build_agg(b) FROM t1 GROUP BY a;
SELECT a, rb_to_array(rb_and_agg(b)) FROM r1 GROUP BY a ORDER BY a;
a | rb_to_array
-----+-----
1 | {1}
2 | {3}
3 | {5}
4 | {7}
5 | {9}
6 | {11}
7 | {13}
8 | {15}
9 | {17}
10 | {19}
(10 rows)
```

rb_or_agg(roaringbitmap)

Description: Combines Roaring bitmaps in a group into one Roaring bitmap based on the UNION logic.

Example:

```
SELECT a, rb_to_array(rb_or_agg(b)) FROM r1 GROUP BY a ORDER BY a;
a | rb_to_array
-----+-----
1 | {1}
2 | {3,5}
3 | {5,9}
4 | {7,13}
5 | {9,17}
6 | {1,11}
7 | {5,13}
8 | {9,15}
9 | {13,17}
10 | {17,19}
(10 rows)
```

rb_xor_agg(roaringbitmap)

Description: Combines Roaring bitmaps in a group into one Roaring bitmap based on the XOR logic.

Example:

```
SELECT a, rb_to_array(rb_xor_agg(b)) FROM r1 GROUP BY a ORDER BY a;
```

| a | rb_to_array |
|----|-------------|
| 1 | {} |
| 2 | {5} |
| 3 | {9} |
| 4 | {13} |
| 5 | {17} |
| 6 | {1} |
| 7 | {5} |
| 8 | {9} |
| 9 | {13} |
| 10 | {17} |

(10 rows)

rb_and_cardinality_agg(roaringbitmap)

Description: Cardinality of Roaring bitmaps in a group calculated based on INTERSECT.

Return type: int

Example:

```
SELECT a, rb_and_cardinality_agg(b) FROM r1 GROUP BY a ORDER BY 1;
```

| a | rb_and_cardinality_agg |
|----|------------------------|
| 1 | 1 |
| 2 | 1 |
| 3 | 1 |
| 4 | 1 |
| 5 | 1 |
| 6 | 1 |
| 7 | 1 |
| 8 | 1 |
| 9 | 1 |
| 10 | 1 |

(10 rows)

rb_or_cardinality_agg(roaringbitmap)

Description: Cardinality of Roaring bitmaps in a group calculated based on UNION.

Example:

```
SELECT a, rb_or_cardinality_agg(b) FROM r1 GROUP BY a ORDER BY 1;
```

| a | rb_or_cardinality_agg |
|----|-----------------------|
| 1 | 1 |
| 2 | 2 |
| 3 | 2 |
| 4 | 2 |
| 5 | 2 |
| 6 | 2 |
| 7 | 2 |
| 8 | 2 |
| 9 | 2 |
| 10 | 2 |

(10 rows)

rb_xor_cardinality_agg(roaringbitmap)

Description: Cardinality of Roaring bitmaps in a group calculated based on XOR.

Example:

```
SELECT a, rb_xor_cardinality_agg(b) FROM r1 GROUP BY a ORDER BY 1;
a | rb_xor_cardinality_agg
-----+-----
1 | 0
2 | 1
3 | 1
4 | 1
5 | 1
6 | 1
7 | 1
8 | 1
9 | 1
10 | 1
(10 rows)
```

21.7.19.4 Use Cases

Background

Currently, real-time precision marketing is required in the Internet, education, and gaming industries. User profiling enables user search based on combined criteria. Example:

- Before launching a sales promotion, e-commerce companies need to send the promotion message to a selected batch of users with specific features.
- In education, exercise questions need to be pushed based on students' weaknesses.
- On search, video, and portal websites, different contents are pushed to users based on their interests.

These use cases have the following characteristics in common:

- The data volume is huge and the calculation workload is huge.
- There are a large number of users with a lot of labels and fields, occupying a large amount of storage space.
- The feature conditions for selection are diversified, and it is difficult to find a fixed index. If each field has an index, that will occupy too much storage space.
- High performance is required because real-time marketing requires response in seconds.
- Data update has high requirements on timeliness, and user profiles need to be updated in real time.

Roaring bitmaps in DWS can efficiently generate, compress, and parse bitmap data, and supports the most common bitmap aggregation operations (AND, OR, NOT, and XOR). This feature meets the requirements of real-time precision marketing and quick user selection in the case of a large amount of data with hundreds of millions of users and tens of millions of labels.

Using roaringbitmap

Assume that there is a web page browsing information table **userinfo**. The fields in the table are as follows:

```
CREATE TABLE userinfo
(userid int,
age int,
```

```
gender text,  
salary int,  
hobby text  
)WITH (orientation=column);
```

The data in the **userinfo** table increases with the change of user information. For example, if a user has multiple hobby attributes, there will be multiple records in the **userinfo** table.

If a user wants to filter out males with income greater than CNY10,000, age greater than 30, and a hobby of phishing, and then push specific messages to these target groups.

The traditional method is to directly query the original table. The statement is as follows:

```
SELECT distinct userid FROM userinfo WHERE salary > 10000 AND age > 30 AND gender ='m' AND hobby  
='fishing';
```

If the **userinfo** table contains a small amount of data, indexes are created in the **salary**, **age**, **gender**, and **hobby** columns to meet the query requirements. However, if the **userinfo** table contains a large amount of data and a large number of labels, the preceding statement cannot meet the requirements. The reasons are as follows:

- A large number of indexes need to be created.
- The count (distinct) performance is poor.

Roaring bitmaps perform better in this case.

1. Create a RoaringBitmap table.

```
CREATE TABLE userinfoet  
( age int,  
gender text,  
salary int,  
hobby text,  
userset roaringbitmap,  
PRIMARY KEY(age,gender,salary,hobby)  
)WITH (orientation=column);
```

2. All data in the **userinfo** table must be aggregated to the **userinfoet** table through the aggregation of the label column. You can run the following command to aggregate all data. Or you can aggregate only incremental data. To aggregate only incremental data, a set of users with the same label are put in a table record. This can be implemented by using the UPSERT function. Frequent update operations may generate a large amount of dirty data. Therefore, you are advised to create the **userinfoet** table as a row-store table to aggregate incremental data.

```
INSERT INTO userinfoet  
SELECT age, gender, salary, hobby, rb_build_agg(userid)  
FROM  
userinfo  
GROUP BY age, gender, salary, hobby;
```

3. Query the **userinfoet** table for the selected user information.

```
SELECT rb_iterate(rb_or_agg(userset)) FROM userinfoet WHERE salary > 10000 AND age > 30 AND  
gender ='m' AND hobby ='fishing';
```

After data aggregation, the data volume of the table **userinfoet** is much smaller than that of the source table, so the scanning performance of the base table is much faster. In addition, based on the advantages of Roaring bitmaps, the performance of calculating **rb_or_agg** and **rb_iterate** is better. Compared with the traditional method, the performance is significantly improved.

21.7.20 UUID Functions

UUID functions are used to generate UUID data (see [UUID Type](#)).

uuid_generate_v1()

Description: Generates a UUID sequence number.

Return type: UUID

Example:

```
SELECT uuid_generate_v1();
       uuid_generate_v1
-----
c71ceaca-a175-11e9-a920-797ff7000001
(1 row)
```

NOTE

The **uuid_generate_v1** function generates a UUID based on the time information, cluster node ID, and ID of the thread that generates the sequence. The UUID is globally unique in a single cluster, however, there is a possibility that the time information, cluster node IDs, thread IDs, and clock sequences of multiple clusters are the same at the same time. Therefore, there is a low probability that UUIDs generated among multiple clusters are duplicate.

uuid()

Description: Generates a UUID sequence number. This function is a MySQL compatibility function supported only by version 8.2.0 and later clusters.

Return type: UUID

Example:

```
SELECT uuid();
       uuid
-----
6327dc96-f0e7-0100-f2f2-6c9ff700fffe
(1 row)
```

NOTE

UUID is generated in the way the **uuid_generate_v1()** function works. The function generates a UUID based on the time information, cluster node ID, and ID of the thread that generates the sequence. The UUID is globally unique in a single cluster, however, there is a possibility that the time information, cluster node IDs, thread IDs, and clock sequences of multiple clusters are the same at the same time. Therefore, there is a low probability that UUIDs generated among multiple clusters are duplicate.

sys_guid()

Description: Generates an Oracle GUID, which is similar to the UUID. This function is compatible with Oracle.

Return type: text

Example:

```
SELECT sys_guid();
       sys_guid
-----
```

```
-----  
4EBD3C74A17A11E9A1BF797FF7000001  
(1 row)
```

NOTE

The data generation principle of the `sys_guid` function is the same as that of the `uuid_generate_v1` function.

UUID Function Application Example

A UUID is globally unique. It can be used as a primary key or a distribution column in a data table. When **`uuid_generate_v1()`** is used as the default value of the distribution column in a data table, data can be evenly distributed to each DN through hash distribution to prevent data skew.

NOTE

The obvious advantage of UUID is that it is globally unique and does not require a central node. UUIDs are generated independently on a single node. However, UUIDs occupy more storage space than INTs, the index efficiency is low, and the generated IDs are random, making them difficult to identify. Therefore, you need to select UUID or Sequence as the primary key of the data table based on the site requirements.

An example is as follows:

1. The INT type is used as the distribution column.

An example hash table **`mytable01`** is created, and the ints are used as the distribution column. After data is inserted, data skew occurs.

```
CREATE TABLE mytable01(a INT, b INT) DISTRIBUTE BY hash(a);  
CREATE TABLE  
INSERT INTO mytable01 VALUES(1, 10);  
INSERT 0 1  
INSERT INTO mytable01 VALUES(1, 10);  
INSERT 0 1  
INSERT INTO mytable01 VALUES(1, 10);  
INSERT 0 1  
INSERT INTO mytable01 VALUES(1, 10);  
INSERT 0 1  
INSERT INTO mytable01 VALUES(1, 10);  
INSERT 0 1  
SELECT * FROM mytable01;  
a | b  
---+---  
1 | 10  
1 | 10  
1 | 10  
1 | 10  
1 | 10  
(5 rows)  
  
SELECT table_skewness('mytable01');  
table_skewness  
-----  
("dn_6003_6004      ",5,100.000%)  
("dn_6001_6002      ",0,0.000%)  
("dn_6005_6006      ",0,0.000%)  
(3 rows)
```

2. The UUIDs are used as the distribution column.

Create an example hash table **`mytable02`** and use the UUIDs as the distribution column. After data is inserted, data distribution is normal.

```
CREATE TABLE mytable02(id UUID default uuid_generate_v1(), a INT, b INT) DISTRIBUTE BY hash(id);  
CREATE TABLE
```

```
INSERT INTO mytable02(a, b) VALUES(1, 10);
INSERT 0 1
INSERT INTO mytable02(a, b) VALUES(1, 10);
INSERT 0 1
INSERT INTO mytable02(a, b) VALUES(1, 10);
INSERT 0 1
INSERT INTO mytable02(a, b) VALUES(1, 10);
INSERT 0 1
INSERT INTO mytable02(a, b) VALUES(1, 10);
INSERT 0 1

SELECT * FROM mytable02;
      id      | a | b
-----+---+---
63e45c14-cc74-0e00-e9aa-0a2c3fa0fffe | 1 | 10
63e45c1f-4d18-0700-e9ab-0a2c3fa0fffe | 1 | 10
63e45c26-f859-0b00-e9ad-0a2c3fa0fffe | 1 | 10
63e45c23-9e5d-0300-e9ac-0a2c3fa0fffe | 1 | 10
63e45c2a-5825-0600-e9ae-0a2c3fa0fffe | 1 | 10
(5 rows)

SELECT table_skewness('mytable02');
      table_skewness
-----
("dn_6001_6002      ",3,60.000%)
("dn_6003_6004      ",2,40.000%)
("dn_6005_6006      ",0,0.000%)
(3 rows)
```

21.7.21 Text Search Functions and Operators

21.7.21.1 Text Search Operators

@@

Description: Specifies whether the **tsvector**-typed words match the **tsquery**-typed words.

Example:

```
SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```

@@@

Description: Synonym for @@

Example:

```
SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```

&&

Description: Performs the AND operation on two **tsquery**-typed words.

Example:

```
SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;  
result  
-----  
( 'fat' | 'rat' ) & 'cat'  
(1 row)
```

||

Description: Performs the OR operation on two **tsquery**-typed words.

Example:

```
SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;  
result  
-----  
( 'fat' | 'rat' ) | 'cat'  
(1 row)  
SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;  
result  
-----  
'a':1 'b':2,5 'c':3 'd':4  
(1 row)
```

!!

Description: **NOT** a **tsquery**

Example:

```
SELECT !! 'cat'::tsquery AS RESULT;  
result  
-----  
!'cat'  
(1 row)
```

@>

Description: Specifies whether a **tsquery**-typed word contains another **tsquery**-typed word.

Example:

```
SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;  
result  
-----  
f  
(1 row)
```

<@

Description: Specifies whether a **tsquery**-typed word is contained in another **tsquery**-typed word.

Example:

```
SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;  
result  
-----  
t  
(1 row)
```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types **tsvector** and **tsquery**.

21.7.21.2 Text Search Functions

get_current_ts_config()

Description: Gets default text search configuration.

Return type: regconfig

Example:

```
SELECT get_current_ts_config();
get_current_ts_config
-----
english
(1 row)
```

length(tsvector)

Description: Number of lexemes in a **tsvector**-typed word.

Return type: integer

Example:

```
SELECT length('fat:2,4 cat:3 rat:5A'::tsvector);
length
-----
3
(1 row)
```

numnode(tsquery)

Description: Number of lexemes plus **tsquery** operators

Return type: integer

Example:

```
SELECT numnode('(fat & rat) | cat'::tsquery);
numnode
-----
5
(1 row)
```

plainto_tsquery([config regconfig ,] query text)

Description: Generates **tsquery** lexemes without punctuation.

Return type: tsquery

Example:

```
SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery
-----
'fat' & 'rat'
(1 row)
```

querytree(query tsquery)

Description: Gets indexable part of a **tsquery**.

Return type: text

Example:

```
SELECT querytree('foo & ! bar'::tsquery);
querytree
-----
'foo'
(1 row)
```

setweight(tsvector, "char")

Description: Assigns weight to each element of **tsvector**.

Return type: tsvector

Example:

```
SELECT setweight('fat:2,4 cat:3 rat:5B'::tsvector, 'A');
setweight
-----
'cat':3A 'fat':2A,4A 'rat':5A
(1 row)
```

strip(tsvector)

Description: Removes positions and weights from **tsvector**.

Return type: tsvector

Example:

```
SELECT strip('fat:2,4 cat:3 rat:5A'::tsvector);
strip
-----
'cat' 'fat' 'rat'
(1 row)
```

to_tsquery([config regconfig ,] query text)

Description: Normalizes words and converts them to **tsquery**.

Return type: tsquery

Example:

```
SELECT to_tsquery('english', 'The & Fat & Rats');
to_tsquery
-----
'fat' & 'rat'
(1 row)
```

to_tsvector([config regconfig ,] document text)

Description: Reduces document text to **tsvector**.

Return type: tsvector

Example:

```
SELECT to_tsvector('english', 'The Fat Rats');
       to_tsvector
-----
'fat':2 'rat':3
(1 row)
```

ts_headline([config regconfig,] document text, query tsquery [, options text])

Description: Highlights a query match.

Return type: text

Example:

```
SELECT ts_headline('x y z', 'z'::tsquery);
       ts_headline
-----
x y <b>z</b>
(1 row)
```

ts_rank([weights float4[],] vector tsvector, query tsquery [, normalization integer])

Description: Ranks document for query.

Return type: float4

Example:

```
SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
       ts_rank
-----
.0607927
(1 row)
```

ts_rank_cd([weights float4[],] vector tsvector, query tsquery [, normalization integer])

Description: Ranks document for query using cover density.

Return type: float4

Example:

```
SELECT ts_rank_cd('hello world'::tsvector, 'world'::tsquery);
       ts_rank_cd
-----
0
(1 row)
```

ts_rewrite(query tsquery, target tsquery, substitute tsquery)

Description: Replaces **tsquery**-typed word.

Return type: tsquery

Example:

```
SELECT ts_rewrite('a & b'::tsquery, 'a'::tsquery, 'foo|bar'::tsquery);
       ts_rewrite
-----
```

```
'b' & ( 'foo' | 'bar' )  
(1 row)
```

ts_rewrite(query tsquery, select text)

Description: Replaces **tsquery** data in the target with the result of a **SELECT** command.

Return type: tsquery

Example:

```
SELECT ts_rewrite('world'::tsquery, 'select "world"::tsquery, "hello"::tsquery');  
ts_rewrite  
-----  
'hello'  
(1 row)
```

21.7.21.3 Text Search Debugging Functions

ts_debug([config regconfig,] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])

Description: Tests a configuration.

Return type: SETOF record

Example:

```
SELECT ts_debug('english', 'The Brightest supernovae');  
ts_debug  
-----  
(asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})  
(blank,"Space symbols"," ",{},{})  
(asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})  
(blank,"Space symbols"," ",{},{})  
(asciiword,"Word, all ASCII",supernovae,{english_stem},english_stem,{supernova})  
(5 rows)
```

ts_lexize(dict regdictionary, token text)

Description: Tests a data dictionary.

Return type: text[]

Example:

```
SELECT ts_lexize('english_stem', 'stars');  
ts_lexize  
-----  
{star}  
(1 row)
```

ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)

Description: Tests a parser.

Return type: SETOF record

Example:

```
SELECT ts_parse('default', 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)

Description: Tests a parser.

Return type: SETOF record

Example:

```
SELECT ts_parse(3722, 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text)

Description: Gets token types defined by parser.

Return type: SETOF record

Example:

```
SELECT ts_token_type('default');
ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)

Description: Gets token types defined by parser.

Return type: SETOF record

Example:

```
SELECT ts_token_type(3722);
      ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

ts_stat(sqlquery text, [weights text,] OUT word text, OUT ndoc integer, OUT nentry integer)

Description: Gets statistics of a **tsvector** column.

Return type: SETOF record

Example:

```
SELECT ts_stat('select "hello world"::tsvector');
      ts_stat
-----
(world,1,1)
(hello,1,1)
(2 rows)
```

21.7.22 HLL Functions and Operators

21.7.22.1 HLL Operators

The HLL type supports the following operators:

Table 21-48 HLL Operators

| HLL Operators | Description | Return Type | Example |
|---------------|--|-------------|---|
| = | Checks whether the values of hll and hll_hashval are equal. | bool | <ul style="list-style-type: none"> hll
 <pre>SELECT (hll_empty() hll_hash_integer(1)) = (hll_empty() hll_hash_integer(1)); ?column?</pre> <pre>----- t (1 row)</pre> hll_hashval
 <pre>SELECT hll_hash_integer(1) = hll_hash_integer(1); ?column?</pre> <pre>----- t (1 row)</pre> |
| <> or != | Checks whether the values of hll and hll_hashval are not equal. | bool | <ul style="list-style-type: none"> hll
 <pre>SELECT (hll_empty() hll_hash_integer(1)) <> (hll_empty() hll_hash_integer(2)); ?column?</pre> <pre>----- t (1 row)</pre> hll_hashval
 <pre>SELECT hll_hash_integer(1) <> hll_hash_integer(2); ?column?</pre> <pre>----- t (1 row)</pre> |
| | Represents the functions of hll_add , hll_union , and hll_add_rev . | hll | <ul style="list-style-type: none"> hll_add
 <pre>SELECT hll_empty() hll_hash_integer(1); ?column?</pre> <pre>----- \x128b7f8895a3f5af28cafe (1 row)</pre> hll_add_rev
 <pre>SELECT hll_hash_integer(1) hll_empty(); ?column?</pre> <pre>----- \x128b7f8895a3f5af28cafe (1 row)</pre> hll_union
 <pre>SELECT (hll_empty() hll_hash_integer(1)) (hll_empty() hll_hash_integer(2)); ?column?</pre> <pre>----- \x128b7f8895a3f5af28cafeda0ce907e4355b60 (1 row)</pre> |

| HLL Operators | Description | Return Type | Example |
|---------------|---|-------------|---|
| # | Calculates the distinct value of the hll , which is equivalent to the hll_cardinality function. | integer | <pre>SELECT #(hll_empty() hll_hash_integer(1)); ?column? ----- 1 (1 row)</pre> |

21.7.22.2 Hash Functions

hll_hash_boolean(bool)

Description: Hashes data of the bool type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_boolean(FALSE);
hll_hash_boolean
-----
5048724184180415669
(1 row)
```

hll_hash_boolean(bool, int32)

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the bool type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_boolean(FALSE, 10);
hll_hash_boolean
-----
391264977436098630
(1 row)
```

hll_hash_smallint(smallint)

Description: Hashes data of the smallint type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_smallint(100::smallint);
hll_hash_smallint
-----
4631120266694327276
(1 row)
```

 NOTE

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

hll_hash_smallint(smallint, int32)

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the smallint type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_smallint(100::smallint, 10);
 hll_hash_smallint
-----
8349353095166695771
(1 row)
```

hll_hash_integer(integer)

Description: Hashes data of the integer type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_integer(0);
 hll_hash_integer
-----
-3485513579396041028
(1 row)
```

hll_hash_integer(integer, int32)

Description: Hashes data of the integer type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
SELECT hll_hash_integer(0, 10);
 hll_hash_integer
-----
183371090322255134
(1 row)
```

hll_hash_bigint(bigint)

Description: Hashes data of the bigint type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_bigint(100::bigint);
 hll_hash_bigint
-----
8349353095166695771
(1 row)
```

hll_hash_bigint(bigint, int32)

Description: Hashes data of the bigint type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
SELECT hll_hash_bigint(100::bigint, 10);
 hll_hash_bigint
-----
4631120266694327276
(1 row)
```

hll_hash_bytea(bytea)

Description: Hashes data of the bytea type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_bytea(E'\\x');
 hll_hash_bytea
-----
0
(1 row)
```

hll_hash_bytea(bytea, int32)

Description: Hashes data of the bytea type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
SELECT hll_hash_bytea(E'\\x', 10);
 hll_hash_bytea
-----
6574525721897061910
(1 row)
```

hll_hash_text(text)

Description: Hashes data of the text type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_text('AB');
 hll_hash_text
-----
5365230931951287672
(1 row)
```

hll_hash_text(text, int32)

Description: Hashes data of the text type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
SELECT hll_hash_text('AB', 10);
       hll_hash_text
-----
7680762839921155903
(1 row)
```

hll_hash_any(anytype)

Description: Hashes data of any type.

Return type: hll_hashval

Example:

```
SELECT hll_hash_any(1);
       hll_hash_any
-----
-8604791237420463362
(1 row)

SELECT hll_hash_any('08:00:2b:01:02:03'::macaddr);
       hll_hash_any
-----
-4883882473551067169
(1 row)
```

hll_hash_any(anytype, int32)

Description: Hashes data of any type and configures a hash seed (that is, change the hash policy).

Return type: hll_hashval

Example:

```
SELECT hll_hash_any(1, 10);
       hll_hash_any
-----
-1478847531811254870
(1 row)
```

hll_hashval_eq(hll_hashval, hll_hashval)

Description: Compares two pieces of data of the hll_hashval type to check whether they are the same.

Return type: bool

Example:

```
SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
       hll_hashval_eq
-----
t
(1 row)
```

hll_hashval_ne(hll_hashval, hll_hashval)

Description: Compares two pieces of data of the hll_hashval type to check whether they are different.

Return type: bool

Example:

```
SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
hll_hashval_ne
-----
f
(1 row)
```

21.7.22.3 Precision Functions

HLL supports **explicit**, **sparse**, and **full** modes. **explicit** and **sparse** excel when the data scale is small, and barely produce errors in calculation results. When the number of distinct values increases, **full** becomes more suitable, but produces some errors. The following functions are used to view precision parameters in HLLs.

hll_schema_version(hll)

Description: Checks the schema version in the current HLL.

Return type: integer

Example:

```
SELECT hll_schema_version(hll_empty());
hll_schema_version
-----
1
(1 row)
```

hll_type(hll)

Description: Checks the type of the current HLL.

Return type: integer

Example:

```
SELECT hll_type(hll_empty());
hll_type
-----
1
(1 row)
```

hll_log2m(hll)

Description: Check the value of log2m of the current HLL. This value affects the error rate in calculating the number of distinct values by the HLL. The formula for calculating the error rate is as follows:

$$\pm 1.04 / \sqrt{2^{\wedge} \log 2m}$$

Return type: integer

Example:

```
SELECT hll_log2m(hll_empty());
hll_log2m
-----
```

```
11  
(1 row)
```

hll_regwidth(hll)

Description: Checks the number of bits of buckets in a hll data structure.

Return type: integer

Example:

```
SELECT hll_regwidth(hll_empty());  
hll_regwidth  
-----  
5  
(1 row)
```

hll_expthresh(hll)

Description: Obtains the size of **expthresh** in the current HLL. An HLL usually switches from the **explicit** mode to the **sparse** mode and then to the **full** mode. This process is called the promotion hierarchy policy. You can change the value of **expthresh** to change the policy. For example, if **expthresh** is **0**, an HLL will skip the **explicit** mode and directly enter the **sparse** mode. If the value of **expthresh** is explicitly set to a value ranging from 1 to 7, this function returns $2^{\text{expthresh}}$.

Return type: record

Example:

```
SELECT hll_expthresh(hll_empty());  
hll_expthresh  
-----  
(-1,160)  
(1 row)  
  
SELECT hll_expthresh(hll_empty(11,5,3));  
hll_expthresh  
-----  
(8,8)  
(1 row)
```

hll_sparseon(hll)

Description: Specifies whether to enable the **sparse** mode. **0** indicates **off** and **1** indicates **on**.

Return type: integer

Example:

```
SELECT hll_sparseon(hll_empty());  
hll_sparseon  
-----  
1  
(1 row)
```

21.7.22.4 Aggregate Functions

hll_add_agg(hll_hashval)

Description: Groups hashed data into HLL.

Return type: hll

Example:

1. Prepare data.

```
CREATE TABLE t_id(id int);
INSERT INTO t_id VALUES(generate_series(1,500));
CREATE TABLE t_data(a int, c text);
INSERT INTO t_data SELECT mod(id,2), id FROM t_id;
```
2. Create another table and specify an HLL column:

```
CREATE TABLE t_a_c_hll(a int, c hll);
```
3. Use **GROUP BY** on column **a** to group data, and insert the data to the HLL column:

```
INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;
```
4. Calculate the number of distinct values for each group in the HLL column:

```
SELECT a, #c as cardinality FROM t_a_c_hll order by a;
```

| a | cardinality |
|---|------------------|
| 0 | 250.741759091658 |
| 1 | 250.741759091658 |

(2 rows)

hll_add_agg(hll_hashval, int32 log2m)

Description: Groups hashed data into HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16.

Return type: hll

Example:

```
SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 10)) FROM t_data;
```

| hll_cardinality |
|------------------|
| 503.932348927339 |

(1 row)

hll_add_agg(hll_hashval, int32 log2m, int32 regwidth)

Description: Groups hashed data into HLL and sets the **log2m** and **regwidth** parameters in sequence. The value of **regwidth** ranges from 1 to 5.

Return type: hll

Example:

```
SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
```

| hll_cardinality |
|------------------|
| 496.628982624022 |

(1 row)

hll_add_agg(hll_hashval, int32 log2m, int32 regwidth, int64 expthresh)

Description: Groups hashed data into **hll** and sets parameters **log2m**, **regwidth**, and **expthresh** in sequence. The value of **expthresh** is an integer ranging from -1 to 7. **expthresh** is used to specify the threshold for switching from the **explicit** mode to the **sparse** mode. -1 indicates the auto mode; 0 indicates that the **explicit** mode is skipped; a value from 1 to 7 indicates that the mode is switched when the number of distinct values reaches $2^{\text{expthresh}}$.

Return type: hll

Example:

```
SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1, 4)) FROM t_data;  
hll_cardinality  
-----  
496.628982624022  
(1 row)
```

hll_add_agg(hll_hashval, int32 log2m, int32 regwidth, int64 expthresh, int32 sparseon)

Description: Groups hashed data into **hll** and sets parameters **log2m**, **regwidth**, **expthresh**, and **sparseon** in sequence. The value of **sparseon** is 0 or 1.

Return type: hll

Example:

```
SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1, 4, 0)) FROM t_data;  
hll_cardinality  
-----  
496.628982624022  
(1 row)
```

hll_union_agg(hll)

Description: Perform the **UNION** operation on multiple pieces of data of the hll type to obtain one HLL.

Return type: hll

Example:

Perform the **UNION** operation on data of the HLL type in each group to obtain one HLL, and calculate the number of distinct values:

```
SELECT #hll_union_agg(c) as cardinality FROM t_a_c_hll;  
cardinality  
-----  
496.628982624022  
(1 row)
```

NOTE

To perform **UNION** on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This restriction also applies to the `hll_union(hll, hll)` function.

21.7.22.5 Functional Functions

hll_print(hll)

Description: Prints some debugging parameters of an HLL.

Return type: cstring

Example:

```
SELECT hll_print(hll_empty());  
hll_print
```

```
-----  
EMPTY, nregs=2048, nbits=5, expthresh=-1(160), sparseon=1  
(1 row)
```

hll_empty()

Description: Creates an empty HLL.

Return type: hll

Example:

```
SELECT hll_empty();  
hll_empty  
-----  
\x118b7f  
(1 row)
```

hll_empty(int32 log2m)

Description: Creates an empty HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16.

Return type: hll

Example:

```
SELECT hll_empty(10);  
hll_empty  
-----  
\x118a7f  
(1 row)
```

hll_empty(int32 log2m, int32 regwidth)

Description: Creates an empty HLL and sets the **log2m** and **regwidth** parameters in sequence. The value of **regwidth** ranges from 1 to 5.

Return type: hll

Example:

```
SELECT hll_empty(10, 4);  
hll_empty  
-----  
\x116a7f  
(1 row)
```

hll_empty(int32 log2m, int32 regwidth, int64 expthresh)

Description: Creates an empty HLL and sets the **log2m**, **regwidth**, and **expthresh** parameters. The value of **expthresh** is an integer ranging from -1 to 7. This parameter specifies the threshold for switching from the **explicit** mode to the **sparse** mode. -1 indicates the auto mode; 0 indicates that the **explicit** mode is skipped; a value from 1 to 7 indicates that the mode is switched when the number of distinct values reaches $2^{\text{expthresh}}$.

Return type: hll

Example:

```
SELECT hll_empty(10, 4, 7);  
hll_empty
```

```
-----  
\x116a48  
(1 row)
```

hll_empty(int32 log2m, int32 regwidth, int64 expthresh, int32 sparseon)

Description: Creates an empty HLL and sets the **log2m**, **regwidth**, **expthresh**, and **sparseon** parameters. The value of **sparseon** is 0 or 1.

Return type: hll

Example:

```
SELECT hll_empty(10,4,7,0);  
hll_empty  
-----  
\x116a08  
(1 row)
```

hll_add(hll, hll_hashval)

Description: Adds hll_hashval to an HLL.

Return type: hll

Example:

```
SELECT hll_add(hll_empty(), hll_hash_integer(1));  
hll_add  
-----  
\x128b7f8895a3f5af28cafe  
(1 row)
```

hll_add_rev(hll_hashval, hll)

Description: Adds hll_hashval to an HLL. This function works the same as hll_add, except that the positions of parameters are switched.

Return type: hll

Example:

```
SELECT hll_add_rev(hll_hash_integer(1), hll_empty());  
hll_add_rev  
-----  
\x128b7f8895a3f5af28cafe  
(1 row)
```

hll_eq(hll, hll)

Description: Compares two HLLs to check whether they are the same.

Return type: bool

Example:

```
SELECT hll_eq(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(), hll_hash_integer(2)));  
hll_eq  
-----  
f  
(1 row)
```

hll_ne(hll, hll)

Description: Compares two HLLs to check whether they are different.

Return type: bool

Example:

```
SELECT hll_ne(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(), hll_hash_integer(2)));
hll_ne
-----
t
(1 row)
```

hll_cardinality(hll)

Description: Calculates the number of distinct values of an HLL.

Return type: integer

Example:

```
SELECT hll_cardinality(hll_empty() || hll_hash_integer(1));
hll_cardinality
-----
1
(1 row)
```

hll_union(hll, hll)

Description: Performs the **UNION** operation on two HLL data structures to obtain one HLL.

Return type: hll

Example:

```
SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(), hll_hash_integer(2)));
hll_union
-----
\x128b7f8895a3f5af28cafeda0ce907e4355b60
(1 row)
```

21.7.22.6 Built-in Functions

HyperLogLog (HLL) has a series of built-in functions for internal data processing. Generally, you are not advised to use these functions.

Table 21-49 HLL built-in functions

| Function | Function |
|--------------|--|
| hll_in | Receives hll data in string format. |
| hll_out | Sends hll data in string format. |
| hll_rcv | Receives hll data in bytea format. |
| hll_send | Sends hll data in bytea format. |
| hll_trans_in | Receives hll_trans_type data in string format. |

| Function | Function |
|-------------------|---|
| hll_trans_out | Sends hll_trans_type data in string format. |
| hll_trans_recv | Receives hll_trans_type data in bytea format. |
| hll_trans_send | Sends hll_trans_type data in bytea format. |
| hll_tymod_in | Receives tymod data. |
| hll_tymod_out | Sends tymod data. |
| hll_hashval_in | Receives hll_hashval data. |
| hll_hashval_out | Sends hll_hashval data. |
| hll_add_trans0 | Works similar to hll_add , and is used during the initial phase of DNs in distributed aggregation procedures. |
| hll_union_trans | Works similar to hll_union , and is used on the first phase of DNs in distributed aggregation operations. |
| hll_union_collect | Works similar to hll_union , and is used on the second phase of CNs in distributed aggregation operations to summarize the results of each DN. |
| hll_pack | Is used on the third phase of CNs in distributed aggregation operations to convert a user-defined type hll_trans_type to the hll type. |
| hll | Converts a hll type to another hll type. Input parameters can be specified. |
| hll_hashval | Converts the bigint type to the hll_hashval type. |
| hll_hashval_int4 | Converts the int4 type to the hll_hashval type. |

21.7.23 Set Returning Functions

21.7.23.1 Series Generating Functions

generate_series() returns a series-based set based on the specified start value (**start**), end value (**stop**), and step (**step**).

If **step** is a positive number and **start** is greater than **stop**, zero row is returned. If **step** is a negative number and **start** is less than **stop**, zero row is returned. If any input is NULL, zero rows are returned. If the value of **step** is **0**, an error is reported.

generate_series(start, stop)

Description: Generates a series of values, from **start** to **stop**, the default step is **1**.

Parameter type: int, bigint, or numeric

Return type: setof int, setof bigint, or setof numeric (same as the argument type)

Example:

```
SELECT * FROM generate_series(2,4);
generate_series
-----
         2
         3
         4
(3 rows)

SELECT * FROM generate_series(4,3);
generate_series
-----
(0 rows)

SELECT * FROM generate_series(1,NULL);
generate_series
-----
(0 rows)
```

generate_series(start, stop, step)

Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

Parameter type: int, bigint, or numeric

Return type: setof int, setof bigint, or setof numeric (same as the argument type)

Example:

```
SELECT * FROM generate_series(5,1,-2);
generate_series
-----
         5
         3
         1
(3 rows)

SELECT * FROM generate_series(4,6,-5);
generate_series
-----
(0 rows)

SELECT * FROM generate_series(4,3,0);
ERROR: step size cannot equal zero
```

generate_series(start, stop, step interval)

Description: Generates a series of values, from **start** to **stop** with a step size of **step**.

Parameter type: timestamp or timestamp with time zone

Return type: setof timestamp or setof timestamp with time zone (same as argument type)

Example:

```
-- this example relies on the date-plus-integer operator
SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
-----
2017-06-02
```

```
2017-06-09
2017-06-16
(3 rows)

SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10 hours');
generate_series
-----
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)
```

21.7.23.2 Subscript Generating Functions

generate_subscripts(array anyarray, dim int)

Description: Generates a series comprising the given array's subscripts.

Return type: setof int

Example:

```
SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s
---
1
2
3
4
(4 rows)
```

generate_subscripts(array anyarray, dim int, reverse boolean)

Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.

Return type: setof int

Example:

```
SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1,TRUE) AS s;
s
---
4
3
2
1
(4 rows)
```

generate_subscripts is a function that generates the set of valid subscripts for the specified dimension of a given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- unnest a 2D array
CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
FROM generate_subscripts($1,1) g1(i),
```

```
generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2
-----
 1
 2
 3
 4
(4 rows)
```

21.7.24 Geometric Functions and Operators

21.7.24.1 Geometric Operators

+

Description: The operator implements a panning function by adding the coordinates of the second point to each corresponding point of the first parameter.

Example:

```
SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
result
-----
(3,1),(2,0)
(1 row)
```

-

Description: The operator implements a panning function by subtracting the coordinates of the second point from each corresponding point of the first parameter.

Example:

```
SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
result
-----
(-1,1),(-2,0)
(1 row)
```

*

Description: Scaling out/rotation

Example:

```
SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;
result
-----
(2,2),(0,0)
(1 row)
```

/

Description: Scaling in/rotation

Example:

```
SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;  
result  
-----  
(1,1),(0,0)  
(1 row)
```

#

Description: Point or box of intersection

Example:

```
SELECT box '((1,-1),(-1,1))' # box '((1,1),(-1,-1))' AS RESULT;  
result  
-----  
(1,1),(-1,-1)  
(1 row)
```

#

Description: Number of paths or polygon vertexs

Example:

```
SELECT # path '((1,0),(0,1),(-1,0))' AS RESULT;  
result  
-----  
3  
(1 row)
```

@-@

Description: Length or circumference

Example:

```
SELECT @-@ path '((0,0),(1,0))' AS RESULT;  
result  
-----  
2  
(1 row)
```

@@

Description: Center of box

Example:

```
SELECT @@ circle '((0,0),10)' AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

##

Description: Closest point to first figure on second figure.

Example:

```
SELECT point '(0,0)' ## box '((2,0),(0,2))' AS RESULT;  
result  
-----
```

```
(0,0)
(1 row)
```

<->

Description: Distance between the two figures.

Example:

```
SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;
result
-----
      3
(1 row)
```

&&

Description: Overlaps? (One point in common makes this true.)

Example:

```
SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;
result
-----
      t
(1 row)
```

<<

Description: Is strictly left of (no common horizontal coordinate)?

Example:

```
SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;
result
-----
      t
(1 row)
```

>>

Description: Is strictly right of (no common horizontal coordinate)?

Example:

```
SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;
result
-----
      t
(1 row)
```

&<

Description: Does not extend to the right of?

Example:

```
SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;
result
-----
      t
(1 row)
```

&>

Description: Does not extend to the left of?

Example:

```
SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

<<|

Description: Is strictly below (no common horizontal coordinate)?

Example:

```
SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;
result
-----
t
(1 row)
```

|>>

Description: Is strictly above (no common horizontal coordinate)?

Example:

```
SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;
result
-----
t
(1 row)
```

&<|

Description: Does not extend above?

Example:

```
SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

|&>

Description: Does not extend below?

Example:

```
SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```

<^

Description: Is below (allows touching)?

Example:

```
SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;  
result  
-----  
t  
(1 row)
```

>^

Description: Is above (allows touching)?

Example:

```
SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))' AS RESULT;  
result  
-----  
t  
(1 row)
```

?#

Description: Intersect?

Example:

```
SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;  
result  
-----  
t  
(1 row)
```

?-

Description: Is horizontal?

Example:

```
SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;  
result  
-----  
t  
(1 row)
```

?-

Description: Are horizontally aligned?

Example:

```
SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;  
result  
-----  
t  
(1 row)
```

?|

Description: Is vertical?

Example:

```
SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;  
result
```

```
-----  
f  
(1 row)
```

?|

Description: Are vertically aligned?

Example:

```
SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;  
result  
-----  
t  
(1 row)
```

?-|

Description: Are perpendicular?

Example:

```
SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;  
result  
-----  
t  
(1 row)
```

?||

Description: Are parallel?

Example:

```
SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;  
result  
-----  
t  
(1 row)
```

@>

Description: Contains?

Example:

```
SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;  
result  
-----  
t  
(1 row)
```

<@

Description: Contained in or on?

Example:

```
SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;  
result  
-----  
t  
(1 row)
```

~=

Description: Same as?

Example:

```
SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;  
result  
-----  
t  
(1 row)
```

21.7.24.2 Geometric Functions

area(object)

Description: Area calculation

Return type: double precision

Example:

```
SELECT area(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
1  
(1 row)
```

center(object)

Description: Figure center calculation

Return type: point

Example:

```
SELECT center(box '((0,0),(1,2))') AS RESULT;  
result  
-----  
(0.5,1)  
(1 row)
```

diameter(circle)

Description: Circle diameter calculation

Return type: double precision

Example:

```
SELECT diameter(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
4  
(1 row)
```

height(box)

Description: Vertical size of box

Return type: double precision

Example:

```
SELECT height(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
1  
(1 row)
```

isclosed(path)

Description: A closed path?

Return type: boolean

Example:

```
SELECT isclosed(path '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
t  
(1 row)
```

isopen(path)

Description: An open path?

Return type: boolean

Example:

```
SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
t  
(1 row)
```

length(object)

Description: Length calculation

Return type: double precision

Example:

```
SELECT length(path '((-1,0),(1,0))') AS RESULT;  
result  
-----  
4  
(1 row)
```

npoints(path)

Description: Number of points in path

Return type: int

Example:

```
SELECT npoints(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
3  
(1 row)
```

npoints(polygon)

Description: Number of points in polygon

Return type: int

Example:

```
SELECT npoints(polygon '((1,1),(0,0))) AS RESULT;  
result  
-----  
2  
(1 row)
```

pclose(path)

Description: Converts path to closed.

Return type: path

Example:

```
SELECT pclose(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

popen(path)

Description: Converts path to open.

Return type: path

Example:

```
SELECT popen(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
[(0,0),(1,1),(2,0)]  
(1 row)
```

radius(circle)

Description: Circle diameter calculation

Return type: double precision

Example:

```
SELECT radius(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
2  
(1 row)
```

width(box)

Description: Horizontal size of box

Return type: double precision

Example:

```
SELECT width(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
1  
(1 row)
```

21.7.24.3 Geometric Type Conversion Functions

box(circle)

Description: Circle to box

Return type: box

Example:

```
SELECT box(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
(1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)  
(1 row)
```

box(point, point)

Description: Points to box

Return type: box

Example:

```
SELECT box(point '(0,0)', point '(1,1)') AS RESULT;  
result  
-----  
(1,1),(0,0)  
(1 row)
```

box(polygon)

Description: Polygon to box

Return type: box

Example:

```
SELECT box(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
(2,1),(0,0)  
(1 row)
```

circle(box)

Description: Box to circle

Return type: circle

Example:

```
SELECT circle(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
<(0.5,0.5),0.707106781186548>  
(1 row)
```

circle(point, double precision)

Description: Center and radius to circle

Return type: circle

Example:

```
SELECT circle(point '(0,0)', 2.0) AS RESULT;  
result  
-----  
<(0,0),2>  
(1 row)
```

circle(polygon)

Description: Polygon to circle

Return type: circle

Example:

```
SELECT circle(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
<(1,0.3333333333333333),0.924950591148529>  
(1 row)
```

lseg(box)

Description: Box diagonal to line segment

Return type: lseg

Example:

```
SELECT lseg(box '((-1,0),(1,0))') AS RESULT;  
result  
-----  
[(1,0),(-1,0)]  
(1 row)
```

lseg(point, point)

Description: Points to line segment

Return type: lseg

Example:

```
SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;  
result  
-----  
[(-1,0),(1,0)]  
(1 row)
```

path(polygon)

Description: Polygon to path

Return type: path

Example:

```
SELECT path(polygon '((0,0),(1,1),(2,0)))' AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

point(double precision, double precision)

Description: Points

Return type: point

Example:

```
SELECT point(23.4, -44.5) AS RESULT;  
result  
-----  
(23.4,-44.5)  
(1 row)
```

point(box)

Description: Center of box

Return type: point

Example:

```
SELECT point(box '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

point(circle)

Description: Center of circle

Return type: point

Example:

```
SELECT point(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

point(lseg)

Description: Center of line segment

Return type: point

Example:

```
SELECT point(lseg '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

point(polygon)

Description: Center of polygon

Return type: point

Example:

```
SELECT point(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
(1,0.3333333333333333)  
(1 row)
```

polygon(box)

Description: Box to 4-point polygon

Return type: polygon

Example:

```
SELECT polygon(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
((0,0),(0,1),(1,1),(1,0))  
(1 row)
```

polygon(circle)

Description: Circle to 12-point polygon

Return type: polygon

Example:

```
SELECT polygon(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),(1,1.73205080756888),  
(1.73205080756888,1),(2.244929359829471e-16),(1.73205080756888,-0.9999999999999999),  
(1,-1.73205080756888),(3.67394039744206e-16,-2),(-0.9999999999999999,-1.73205080756888),  
(-1.73205080756888,-1))  
(1 row)
```

polygon(npts, circle)

Description: Circle to **npts**-point polygon

Return type: polygon

Example:

```
SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),(1,1.73205080756888),
```

```
(1.73205080756888,1),(2,2.44929359829471e-16),(1.73205080756888,-0.999999999999999),  
(1,-1.73205080756888),(3.67394039744206e-16,-2),(-0.999999999999999,-1.73205080756888),  
(-1.73205080756888,-1))  
(1 row)
```

polygon(path)

Description: Path to polygon

Return type: polygon

Example:

```
SELECT polygon(path '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

21.7.25 Network Address Functions and Operators

21.7.25.1 cidr and inet Operators

The operators <<, <=, >>, and >= test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

<

Description: Is less than

Example:

```
SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;  
result  
-----  
t  
(1 row)
```

<=

Description: Is less than or equals

Example:

```
SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

=

Description: Equals

Example:

```
SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;  
result  
-----
```

```
t  
(1 row)
```

>=

Description: Is greater than or equals

Example:

```
SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

>

Description: Is greater than

Example:

```
SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;  
result  
-----  
t  
(1 row)
```

<>

Description: Does not equal to

Example:

```
SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;  
result  
-----  
t  
(1 row)
```

<<

Description: Is contained in

Example:

```
SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```

<<=

Description: Is contained in or equals

Example:

```
SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```

>>

Description: Contains

Example:

```
SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

>>=

Description: Contains or equals

Example:

```
SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;  
result  
-----  
t  
(1 row)
```

~

Description: Bitwise NOT

Example:

```
SELECT ~ inet '192.168.1.6' AS RESULT;  
result  
-----  
63.87.254.249  
(1 row)
```

&

Description: The AND operation is performed on each bit of the two network addresses.

Example:

```
SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;  
result  
-----  
0.0.0.0  
(1 row)
```

|

Description: The OR operation is performed on each bit of the two network addresses.

Example:

```
SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;  
result  
-----  
202.168.1.6  
(1 row)
```

+

Description: Addition

Example:

```
SELECT inet '192.168.1.6' + 25 AS RESULT;  
result  
-----  
192.168.1.31  
(1 row)
```

-

Description: Subtraction

Example:

```
SELECT inet '192.168.1.43' - 36 AS RESULT;  
result  
-----  
192.168.1.7  
(1 row)  
SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;  
result  
-----  
24  
(1 row)
```

21.7.25.2 Network Address Functions

The **abbrev**, **host**, and **text** functions are primarily intended to offer alternative display formats.

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to **inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

abbrev(inet)

Description: Abbreviated display format as text

Return type: text

Example:

```
SELECT abbrev(inet '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1.0.0/16  
(1 row)
```

abbrev(cidr)

Description: Abbreviated display format as text

Return type: text

Example:

```
SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1/16  
(1 row)
```

broadcast(inet)

Description: Broadcast address for network

Return type: inet

Example:

```
SELECT broadcast('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.255/24  
(1 row)
```

family(inet)

Description: Extracts family of address; **4** for IPv4, **6** for IPv6

Return type: int

Example:

```
SELECT family('::1') AS RESULT;  
result  
-----  
6  
(1 row)
```

host(inet)

Description: Extracts IP address as text.

Return type: text

Example:

```
SELECT host('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.5  
(1 row)
```

hostmask(inet)

Description: Constructs host mask for network.

Return type: inet

Example:

```
SELECT hostmask('192.168.23.20/30') AS RESULT;  
result  
-----  
0.0.0.3  
(1 row)
```

masklen(inet)

Description: Extracts subnet mask length.

Return type: int

Example:

```
SELECT masklen('192.168.1.5/24') AS RESULT;  
result  
-----  
24  
(1 row)
```

netmask(inet)

Description: Constructs a subnet mask for the network.

Return type: inet

Example:

```
SELECT netmask('192.168.1.5/24') AS RESULT;  
result  
-----  
255.255.255.0  
(1 row)
```

network(inet)

Description: Extracts network part of address.

Return type: cidr

Example:

```
SELECT network('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.0/24  
(1 row)
```

set_masklen(inet, int)

Description: Sets subnet mask length for **inet** value.

Return type: inet

Example:

```
SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;  
result  
-----  
192.168.1.5/16  
(1 row)
```

set_masklen(cidr, int)

Description: Sets subnet mask length for **cidr** value.

Return type: cidr

Example:

```
SELECT set_masklen('192.168.1.0/24'::cidr, 16) AS RESULT;  
result  
-----  
192.168.0.0/16  
(1 row)
```

text(inet)

Description: Extracts IP address and subnet mask length as text.

Return type: text

Example:

```
SELECT text(inet '192.168.1.5') AS RESULT;  
result  
-----  
192.168.1.5/32  
(1 row)
```

trunc(macaddr)

The function **trunc(macaddr)** returns a MAC address with the last 3 bytes set to zero.

Description: Sets last 3 bytes to zero.

Return type: macaddr

Example:

```
SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;  
result  
-----  
12:34:56:00:00:00  
(1 row)
```

The **macaddr** type also supports the standard relational operators (such as > and <=) for lexicographical ordering, and the bitwise arithmetic operators (~, & and |) for NOT, AND and OR.

21.7.26 System Information Functions

21.7.26.1 Session Information Functions

current_catalog

Description: name of the current database (called **catalog** in the SQL standard), same as **current_database()**.

Return type: name

Example:

```
SELECT current_catalog;  
current_database  
-----  
gaussdb  
(1 row)
```

current_database()

Description: Name of the current database

Return type: name

Example:

```
SELECT current_database();
current_database
-----
gaussdb
(1 row)
```

pg_client_encoding()

Description: Obtains the character encoding mode of the current client. When characters are displayed incorrectly, you can check the client encoding to quickly locate the fault.

Return type: name

Example:

```
SELECT pg_client_encoding();
pg_client_encoding
-----
UTF8
(1 row)
```

current_query()

Description: Text of the currently executing query, as submitted by the client (might contain more than one statement)

Return type: text

Example:

```
SELECT current_query();
current_query
-----
SELECT current_query();
(1 row)
```

current_schema[()]

Description: **current_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

Return type: name

Example:

```
SELECT current_schema();
current_schema
-----
public
(1 row)
```

current_schemas(boolean)

Description: **current_schemas(boolean)** returns an array of the names of all schemas presently in the search path. The Boolean option determines whether implicitly included system schemas such as **pg_catalog** are included in the returned search path.

Return type: name[]

Example:

```
SELECT current_schemas(true);
 current_schemas
-----
{pg_catalog,public}
(1 row)
```

NOTE

The search path can be altered at run time. The command is:

```
SET search_path TO schema [, schema, ...]
```

current_user

Description: Username of current execution context. **current_user** is the identifier of the user whose permission needs to be checked. It is usually used to represent a session user, but this setting can be changed according to [SET ROLE](#). It also changes during the execution of functions with the attribute **SECURITY DEFINER**.

Return type: name

Example:

```
SELECT current_user;
 current_user
-----
dbadmin
(1 row)
```

inet_client_addr()

Description: Displays the IP address of the currently connected client.

NOTE

- It is available only in remote connection mode.
- If the database is connected to the local PC, the value is empty.

Return type: inet

Example:

```
SELECT inet_client_addr();
 inet_client_addr
-----
10.10.0.50
(1 row)
```

inet_client_port()

Description: Displays the port number of the currently connected client.

 NOTE

It is available only in remote connection mode.

Return type: integer

Example:

```
SELECT inet_client_port();
inet_client_port
-----
33143
(1 row)
```

inet_server_addr()

Description: Displays the IP address of the current server.

 NOTE

- It is available only in remote connection mode.
- If the database is connected to the local PC, the value is empty.

Return type: inet

Example:

```
SELECT inet_server_addr();
inet_server_addr
-----
10.10.0.13
(1 row)
```

inet_server_port()

Description: Displays the port of the current server. All these functions return NULL if the current connection is via a Unix-domain socket.

 NOTE

It is available only in remote connection mode.

Return type: integer

Example:

```
SELECT inet_server_port();
inet_server_port
-----
8000
(1 row)
```

pg_backend_pid()

Description: Process ID of the server process attached to the current session

Return type: integer

Example:

```
SELECT pg_backend_pid();
pg_backend_pid
-----
```

```
140229352617744  
(1 row)
```

pg_conf_load_time()

Description: Configures load time. **pg_conf_load_time** returns the timestamp with time zone when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
SELECT pg_conf_load_time();  
       pg_conf_load_time  
-----  
2017-09-01 16:05:23.89868+08  
(1 row)
```

pg_my_temp_schema()

Description: **pg_my_temp_schema** returns the OID of the current session's temporary schema, or zero if it has none (because it has not created any temporary tables). **pg_is_other_temp_schema** returns true if the given OID is the OID of another session's temporary schema.

Return type: OID

Example:

```
SELECT pg_my_temp_schema();  
       pg_my_temp_schema  
-----  
0  
(1 row)
```

pg_is_other_temp_schema(oid)

Description: Whether the schema is the temporary schema of another session.

Return type: boolean

Example:

```
SELECT pg_is_other_temp_schema(25356);  
       pg_is_other_temp_schema  
-----  
f  
(1 row)
```

pg_postmaster_start_time()

Description: Specifies the start time of the database instance.

pg_postmaster_start_time returns the timestamp (with time zone) when the database instance was started.

Return type: timestamp with time zone

Example:

```
SELECT pg_postmaster_start_time();  
       pg_postmaster_start_time  
-----
```

```
2017-08-30 16:02:54.99854+08
(1 row)
```

pg_trigger_depth()

Description: Current nesting level of triggers

Return type: integer

Example:

```
SELECT pg_trigger_depth();
pg_trigger_depth
-----
0
(1 row)
```

pgxc_version()

Description: Postgres-XC version information

Return type: text

Example:

```
SELECT pgxc_version();
pgxc_version
-----
Postgres-XC 1.1 on x86_64-unknown-linux-gnu, based on PostgreSQL 9.2.4, compiled by g++ (GCC) 5.4.0,
64-bit
(1 row)
```

session_user

Description: Session user name **session_user** is usually the user who initiated the current database connection, but administrators can change this setting with [SET SESSION AUTHORIZATION](#).

Return type: name

Example:

```
SELECT session_user;
session_user
-----
dbadmin
(1 row)
```

user

Description: Is equivalent to **current_user**.

Return type: name

Example:

```
SELECT user;
current_user
-----
dbadmin
(1 row)
```

version()

Description: version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
SELECT version();
```

| version |
|---|
| PostgreSQL 9.2.4 gsqr ((GaussDB 8.2.1 build 39137c2d) compiled at 2022-09-23 15:43:11 commit 3629 last
mr 5138 release) on x86_64-unknown-linux-gnu, compiled by g++ (GCC) 5.4.0, 64-bit |

21.7.26.2 Access Privilege Inquiry Functions

has_any_column_privilege(user, table, privilege)

Description: Queries whether a specified user has permission for any column of table.

Return type: boolean

has_any_column_privilege(table, privilege)

Description: Queries whether the current user has permission for any column of table.

Return type: boolean

has_any_column_privilege checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to **has_table_privilege**, except that the desired access permission type must be some combination of SELECT, INSERT, UPDATE, or REFERENCES.

NOTE

Note that having any of these permissions at the table level implicitly grants it for each column of the table, so **has_any_column_privilege** will always return **true** if **has_table_privilege** does for the same parameters. But **has_any_column_privilege** also succeeds if there is a column-level grant of the permission for at least one column.

has_column_privilege(user, table, column, privilege)

Description: Queries whether a specified user has permission for column.

Return type: boolean

has_column_privilege(table, column, privilege)

Description: Queries whether the current user has permission for column.

Return type: boolean

has_column_privilege checks whether a user can access a column in a particular way. Its argument possibilities are analogous to **has_table_privilege**, with the

addition that the column can be specified either by name or attribute number. The desired access permission type must evaluate to some combination of **SELECT**, **INSERT**, **UPDATE**, or **REFERENCES**.

 NOTE

Note that having any of these permissions at the table level implicitly grants it for each column of the table.

has_database_privilege(user, database, privilege)

Description: Queries whether a specified user has permission for database.

Return type: boolean

has_database_privilege(database, privilege)

Description: Queries whether the current user has permission for database.

Return type: boolean

Note: **has_database_privilege** checks whether a user can access a database in a particular way. Its argument possibilities are analogous to **has_table_privilege**. The desired access permission type must evaluate to some combination of **CREATE**, **CONNECT**, **TEMPORARY**, or **TEMP** (which is equivalent to **TEMPORARY**).

has_foreign_data_wrapper_privilege(user, fdw, privilege)

Description: Queries whether a specified user has permission for foreign-data wrapper.

The **fdw** parameter indicates the name or ID of the foreign data wrapper.

Return type: boolean

has_foreign_data_wrapper_privilege(fdw, privilege)

Description: Queries whether the current user has permission for foreign-data wrapper.

Return type: boolean

Note: **has_foreign_data_wrapper_privilege** checks whether a user can access a foreign-data wrapper in a particular way. Its argument possibilities are analogous to **has_table_privilege**. The desired access permission type must evaluate to **USAGE**.

has_function_privilege(user, function, privilege)

Description: Queries whether a specified user has permission for function.

Return type: boolean

has_function_privilege(function, privilege)

Description: Queries whether the current user has permission for function.

Return type: boolean

Note: **has_function_privilege** checks whether a user can access a function in a particular way. Its argument possibilities are analogous to **has_table_privilege**. When a function is specified by a text string rather than by OID, the allowed input is the same as that for the **regprocedure** data type (see [Object Identifier Types](#)). The desired access permission type must evaluate to **EXECUTE**.

has_language_privilege(user, language, privilege)

Description: Queries whether a specified user has permission for language.

Return type: boolean

has_language_privilege(language, privilege)

Description: Queries whether the current user has permission for language.

Return type: boolean

Note: **has_language_privilege** checks whether a user can access a procedural language in a particular way. Its argument possibilities are analogous to **has_table_privilege**. The desired access permission type must evaluate to **USAGE**.

has_schema_privilege(user, schema, privilege)

Description: Queries whether a specified user has permission for schema.

Return type: boolean

has_schema_privilege(schema, privilege)

Description: Queries whether the current user has permission for schema.

Return type: boolean

Note: **has_schema_privilege** checks whether a user can access a schema in a particular way. Its argument possibilities are analogous to **has_table_privilege**. The desired access permission type must evaluate to some combination of **CREATE** or **USAGE**.

has_server_privilege(user, server, privilege)

Description: Queries whether a specified user has permission for foreign server.

Return type: boolean

has_server_privilege(server, privilege)

Description: Queries whether the current user has permission for foreign server.

Return type: boolean

Note: **has_server_privilege** checks whether a user can access a foreign server in a particular way. Its argument possibilities are analogous to **has_table_privilege**. The desired access permission type must evaluate to **USAGE**.

has_table_privilege(user, table, privilege)

Description: Queries whether a specified user has permission for table.

Return type: boolean

has_table_privilege(table, privilege)

Description: Queries whether the current user has permission for table.

Return type: boolean

has_table_privilege checks whether a user can access a table in a particular way. The user can be specified by name, by OID (**pg_authid.oid**), **public** to indicate the PUBLIC pseudo-role, or if the argument is omitted **current_user** is assumed. The table can be specified by name or by OID. When specifying by name, the name can be schema-qualified if necessary. The desired access permission type is specified by a text string, which must be one of the values **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCES**, or **TRIGGER**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with grant option. Also, multiple permission types can be listed separated by commas, in which case the result will be **true** if any of the listed permissions is held.

Example:

```
SELECT has_table_privilege('tpcds.web_site', 'select');
has_table_privilege
-----
t
(1 row)

SELECT has_table_privilege('dbadmin', 'tpcds.web_site', 'select,INSERT WITH GRANT OPTION ');
has_table_privilege
-----
t
(1 row)
```

pg_has_role(user, role, privilege)

Description: Queries whether a specified user has permission for role.

Return type: boolean

pg_has_role(role, privilege)

Description: Specifies whether the current user has permission for role.

Return type: boolean

Note: **pg_has_role** checks whether a user can access a role in a particular way. Its argument possibilities are analogous to **has_table_privilege**, except that **public** is not allowed as a user name. The desired access permission type must evaluate to some combination of **MEMBER** or **USAGE**. **MEMBER** denotes direct or indirect membership in the role (that is, the right to do **SET ROLE**), while **USAGE** denotes the permissions of the role are available without doing **SET ROLE**.

21.7.26.3 Schema Visibility Inquiry Functions

Schema visibility inquiry functions perform visibility checks on database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and argument data type(s) earlier in the path. For operator classes, both name and associated index access method are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias types (**regclass**, **regtype**, **regprocedure**, **regoperator**, **regconfig**, or **regdictionary**).

For example, a table is said to be visible if its containing schema is in the search path and no table of the same name appears earlier in the search path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. For example, to list the names of all visible tables:

```
SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

pg_collation_is_visible(collation_oid)

Description: Queries whether the collation is visible in search path.

Return type: boolean

pg_conversion_is_visible(conversion_oid)

Description: Queries whether the conversion is visible in search path.

Return type: boolean

pg_function_is_visible(function_oid)

Description: Queries whether the function is visible in search path.

Return type: boolean

pg_opclass_is_visible(opclass_oid)

Description: Queries whether the operator class is visible in search path.

Return type: boolean

pg_operator_is_visible(operator_oid)

Description: Queries whether the operator is visible in search path.

Return type: boolean

pg_opfamily_is_visible(opclass_oid)

Description: Queries whether the operator family is visible in search path.

Return type: boolean

pg_table_is_visible(table_oid)

Description: Queries whether the table is visible in search path.

Return type: boolean

pg_ts_config_is_visible(config_oid)

Description: Queries whether the text search configuration is visible in search path.

Return type: boolean

pg_ts_dict_is_visible(dict_oid)

Description: Queries whether the text search dictionary is visible in search path.

Return type: boolean

pg_ts_parser_is_visible(parser_oid)

Description: Queries whether the text search parser is visible in search path.

Return type: boolean

pg_ts_template_is_visible(template_oid)

Description: Queries whether the text search template is visible in search path.

Return type: boolean

pg_type_is_visible(type_oid)

Description: Queries whether the type (or domain) is visible in search path.

Return type: boolean

21.7.26.4 System Catalog Information Functions

format_type(type_oid, typemod)

Description: Gets SQL name of a data type.

Return type: text

Note:

format_type returns the SQL name of a data type that is identified by its type OID and possibly a type modifier. Pass NULL for the type modifier if no specific modifier is known. Certain type modifiers are passed for data types with length limitations. The SQL name returned from **format_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. So the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned from **format_type** is `character varying(6)`, indicating the length of varchar type is 6 bytes. So the actual storage length of varchar type is 10 bytes.

```
SELECT format_type((SELECT oid FROM pg_type WHERE typname='varchar'), 10);
format_type
```

```
-----  
character varying(6)  
(1 row)
```

pg_check_authid(role_oid)

Description: Check whether a role name with given OID exists.

Return type: Boolean

pg_describe_object(catalog_id, object_id, object_sub_id)

Description: Gets description of a database object.

Return type: text

Note: **pg_describe_object** returns a description of a database object specified by catalog OID, object OID and a (possibly zero) sub-object ID. This is useful to determine the identity of an object as stored in the **pg_depend** catalog.

pg_get_constraintdef(constraint_oid)

Description: Gets definition of a constraint.

Return type: text

pg_get_constraintdef(constraint_oid, pretty_bool)

Description: Gets definition of a constraint.

Return type: text

Note: **pg_get_constraintdef** and **pg_get_indexdef** respectively reconstruct the creating command for a constraint and an index.

pg_get_expr(pg_node_tree, relation_oid)

Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

Return type: text

pg_get_expr(pg_node_tree, relation_oid, pretty_bool)

Description: Decompiles internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.

Return type: text

Note: **pg_get_expr** decompiles the internal form of an individual expression, such as the default value for a column. It can be useful when examining the contents of system catalogs. If the expression might contain Vars, specify the OID of the relationship they refer to as the second parameter; if no Vars are expected, zero is sufficient.

pg_get_indexdef(index_oid)

Description: Gets **CREATE INDEX** command for index.

Return type: text

index_oid indicates the index OID, which can be queried in the **PG_STATIO_ALL_INDEXES** system view.

Example: Query the OID and CREATE INDEX command of **index ds_ship_mode_t1_index1**.

```
SELECT indexrelid FROM PG_STATIO_ALL_INDEXES WHERE indexrelname = 'ds_ship_mode_t1_index1';
indexrelid
-----
136035
(1 row)
SELECT * FROM pg_get_indexdef(136035);
pg_get_indexdef
-----
CREATE INDEX ds_ship_mode_t1_index1 ON tpceds.ship_mode_t1 USING psort (sm_ship_mode_sk)
TABLESPACE pg_default
(1 row)
```

pg_get_indexdef(index_oid, column_no, pretty_bool)

Description: Gets **CREATE INDEX** command for index, or definition of just one index column when **column_no** is not zero.

Return type: text

```
SELECT * FROM pg_get_indexdef(136035,0,false);
pg_get_indexdef
-----
CREATE INDEX ds_ship_mode_t1_index1 ON tpceds.ship_mode_t1 USING psort (sm_ship_mode_sk)
TABLESPACE pg_default
(1 row)
SELECT * FROM pg_get_indexdef(136035,1,false);
pg_get_indexdef
-----
sm_ship_mode_sk
(1 row)
```

pg_get_keywords()

Description: Gets list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg_get_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keyword. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

pg_get_ruledef(rule_oid)

Description: Gets **CREATE RULE** command for a rule.

Return type: text

pg_get_ruledef(rule_oid, pretty_bool)

Description: Gets **CREATE RULE** command for a rule.

Return type: text

pg_get_userbyid(role_oid)

Description: Gets role name with given OID.

Return type: name

Note: **pg_get_userbyid** extracts a role's name given its OID.

pg_get_viewdef(viewname text [, pretty bool [, fullflag bool]])

Description: gets underlying **SELECT** command for views.

Return type: text

Note:

- **pg_get_viewdef** reconstructs the **SELECT** query that defines a view. If the value of **pretty bool** is set to **true**, the display format is suitable for printing and more readable. The default value of **pretty bool** is **false**, and the display format is not readable. Use the default format for dump purposes whenever possible. The **pretty bool** parameter can be applied only to valid views.
- When **fullflag bool** is set to **true**, the complete definition of the view is displayed. The default value is **false**.

pg_get_viewdef(viewoid oid [, pretty bool [, fullflag bool]])

Description: gets underlying **SELECT** command for views.

Return type: text

pg_get_viewdef(view_oid, wrap_column_int)

Description: Gets underlying **SELECT** command for view, wrapping lines with columns as specified, printing is implied.

Return type: text

pg_get_tabledef(table_oid)

Description: Obtains the table definition based on the table OID.

Return type: text

Example: Obtain the OID of the table **customer_t2** from the system catalog **pg_class**, and then use this function to query the definition of **customer_t2** to obtain the table columns, storage mode (row-store or column-store), and table distribution mode configured for **customer_t2** when it is created.

```
select oid from pg_class where relname ='customer_t2';
oid
-----
17353
```

```
(1 row)

select * from pg_get_tabledef(17353);
      pg_get_tabledef
-----
SET search_path = dbadmin;          +
CREATE TABLE customer_t2 (        +
  state_id character(2),             +
  state_name character varying(40), +
  area_id numeric                    +
)                                    +
WITH (orientation=column, compression=low)+
DISTRIBUTE BY HASH(state_id)        +
TO GROUP group_version1;
(1 row)
```

pg_get_tabledef(table_name)

Description: Obtains the table definition based on the table name.

Return type: text

Remarks: **pg_get_tabledef** reconstructs the **CREATE** statement of the table definition, including the table definition, index information, and comments. Users need to create the dependent objects of the table, such as groups, schemas, tablespaces, and servers. The table definition does not include the statements for creating these dependent objects.

pg_get_tabledef(table_name/table_oid, forCreate boolean)

Description: Obtains the table definition based on the table name or OID. It is supported only by clusters of version 9.1.0.100 or later.

Return type: text

- If the **forCreate** parameter is **true**, the table definition obtained will exclude the **TO GROUP** clause.
- If the **forCreate** parameter is **false**, the table definition obtained will include the **TO GROUP** clause.

pg_get_tabledef(table_name/table_oid, forCreate boolean, withColComm boolean)

Description: Obtains the table definition based on the table name or OID. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: text

- If **withColComment** is **true**, the comment for a column field is displayed next to it,
- If **withColComment** is **false**, the comment for a column is shown at the end of the table definition.

Example:

```
SELECT pg_get_tabledef('person',false,true);
      pg_get_tabledef
-----
SET search_path = public;          +
CREATE TABLE person (             +
```

```
id integer COMMENT 'Student ID',      +
name character varying(25) COMMENT 'Name', +
address text COMMENT 'Address'      +
)                                     +
WITH (orientation=row, compression=no) +
DISTRIBUTE BY ROUNDROBIN             +
TO GROUP group_version1;
(1 row)

SELECT pg_get_tabledef('person',false,false);
pg_get_tabledef
-----
SET search_path = public;      +
CREATE TABLE person (        +
id integer,                    +
name character varying(25),    +
address text                   +
)                               +
WITH (orientation=row, compression=no) +
DISTRIBUTE BY ROUNDROBIN      +
TO GROUP group_version1;      +
COMMENT ON COLUMN person.id IS 'Student ID'; +
COMMENT ON COLUMN person.name IS 'Name'; +
COMMENT ON COLUMN person.address IS 'Address';
(1 row)
```

pg_get_stat_expressions(oid)

Description: Obtains the expressions in the extended statistics objects. Only clusters of version 8.2.1.200 or later support this function.

Return type: text[]

pg_options_to_table(reloptions)

Description: Gets the set of storage option name/value pairs.

Return type: SETOF record

Note: **pg_options_to_table** returns the set of storage option name/value pairs (**option_name/option_value**) when passing **pg_class.reloptions** or **pg_attribute.attoptions**.

Example:

```
CREATE TABLE customer_test
(
state_ID CHAR(2),
state_NAME VARCHAR2(40),
area_ID NUMBER
)
WITH (ORIENTATION = COLUMN, COMPRESSION=middle);
SELECT pg_options_to_table(reloptions) FROM pg_class WHERE relname='customer_test';
pg_options_to_table
-----
(orientation,column)
(compression,middle)
(bucketnums,16384)
(colversion,2.0)
(enable_delta,false)
(5 rows)
```

pg_typeof(any)

Description: Gets the data type of any value.

Return type: regtype

Note:

pg_typeof returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. The function is declared as returning **regtype**, which is an OID alias type (see [Object Identifier Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.

Example:

```
SELECT pg_typeof(33);
pg_typeof
-----
integer
(1 row)

SELECT typen FROM pg_type WHERE oid = pg_typeof(33);
typen
-----
4
(1 row)
```

collation for (any)

Description: Gets the collation of the parameter.

Return type: text

Note:

The expression **collation for** returns the collation of the value that is passed to it. Example:

```
SELECT collation for (description) FROM pg_description LIMIT 1;
pg_collation_for
-----
"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the argument expression, then a null value is returned. If the parameter is not of a collatable data type, then an error is thrown.

getdistributekey(table_name)

Description: Gets a distribution column for a hash table.

Return type: text

Example:

```
SELECT getdistributekey('item');
getdistributekey
-----
i_item_sk
(1 row)
```

21.7.26.5 System Function Checking Function

pv_builtin_functions()

Description: Queries information about system functions.

Return type: record

pg_get_functiondef(func_oid)

Description: Gets definition of a function.

Return type: text

func_oid is the OID of the function, which can be queried in the **PG_PROC** system catalog.

Example: Query the OID and definition of the **justify_days** function.

```
SELECT oid FROM pg_proc WHERE proname = 'justify_days';
 oid
-----
 1295
(1 row)

SELECT * FROM pg_get_functiondef(1295);
headerlines | definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.justify_days(interval)+
  | RETURNS interval +
  | LANGUAGE internal +
  | IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
  | AS $function$interval_justify_days$function$ +
(1 row)
```

Note: The query result returned by **pg_get_functiondef** is in the original text format of the stored procedure. The escape character (\) is used to facilitate subsequent parsing.

pg_get_function_arguments(func_oid)

Description: Gets argument list of function's definition (with default values).

Return type: text

Note: **pg_get_function_arguments** returns the argument list of a function, in the form it would need to appear in within **CREATE FUNCTION**.

pg_get_function_identity_arguments(func_oid)

Description: Gets argument list to identify a function (without default values).

Return type: text

Note: **pg_get_function_identity_arguments** returns the argument list necessary to identify a function, in the form it would need to appear in within **ALTER FUNCTION**. This form omits default values.

pg_get_function_result(func_oid)

Description: Gets **RETURNS** clause for function.

Return type: text

Note: **pg_get_function_result** returns the appropriate **RETURNS** clause for the function.

21.7.26.6 Comment Checking Functions

col_description(table_oid, column_number)

Description: Gets comment for a table column.

Return type: text

Note: **col_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

Example: Query the **pg_class** system catalog to obtain the table OID, and query the INFORMATION_SCHEMA.COLUMNS system view to obtain **column_number**.

```
SELECT COLUMN_NAME,ORDINAL_POSITION FROM INFORMATION_SCHEMA.COLUMNS WHERE  
TABLE_NAME = 't' AND COLUMN_NAME = 'a';
```

```
column_name | ordinal_position
```

```
-----+-----  
a          |          1  
(1 row)
```

```
SELECT oid FROM pg_class WHERE relname='t';
```

```
oid
```

```
-----  
44020  
(1 row)
```

```
SELECT col_description(44020,1);  
col_description
```

```
-----  
This is a test table.  
(1 row)
```

obj_description(object_oid, catalog_name)

Description: Gets comment for a database object.

Return type: text

Note: The two-parameter form of **obj_description** returns the comment for a database object specified by its OID and the name of the containing system catalog. For example, **obj_description(123456,'pg_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj_description** requires only the object OID.

obj_description cannot be used for table columns since columns do not have OIDs of their own.

obj_description(object_oid)

Description: Gets comment for a database object.

Return type: text

shobj_description(object_oid, catalog_name)

Description: Gets comment for a shared database object.

Return type: text

Note: The functions of **shobj_description** and **obj_description** are similar. The only difference is that **shobj_description** is used for shared objects. Some system catalogs are global to all databases within each cluster, and the comments for objects in them are stored globally as well.

21.7.26.7 Transaction IDs and Snapshots

The following functions provide server transaction information in an exportable form. The main use of these functions is to determine which transactions were committed between two snapshots.

pgxc_is_committed(transaction_id)

Description: Determines whether the given XID is committed or ignored. NULL indicates the unknown status (such as running, preparing, and freezing).

Return type: Boolean

txid_current()

Description: Gets current transaction ID.

Return type: bigint

txid_current_snapshot()

Description: Gets current snapshot.

Return type: txid_snapshot

txid_snapshot_xip(txid_snapshot)

Description: Gets in-progress transaction IDs in snapshot.

Return type: setof bigint

txid_snapshot_xmax(txid_snapshot)

Description: Gets **xmax** of snapshot.

Return type: bigint

txid_snapshot_xmin(txid_snapshot)

Description: Gets **xmin** of snapshot.

Return type: bigint

txid_visible_in_snapshot(bigint, txid_snapshot)

Description: Queries whether the transaction ID is visible in snapshot. (do not use with subtransaction ids)

Return type: boolean

The internal transaction ID type (**xid**) is 32 bits wide and wraps around every 4 billion transactions. **txid_snapshot**, the data type used by these functions, stores information about transaction ID visibility at a particular moment in time. [Table 21-50](#) describes its components.

Table 21-50 Snapshot components

| Component | Description |
|-----------|--|
| xmin | Earliest transaction ID (txid) that is still active. All earlier transactions will either be committed and visible, or rolled back. |
| xmax | First as-yet-unassigned txid. All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible. |
| xip_list | Active txids at the time of the snapshot. The list includes only those active txids between xmin and xmax ; there might be active txids higher than xmax . A txid that is xmin ≤ txid < xmax and not in this list was already completed at the time of the snapshot, and is either visible or dead according to its commit status. The list does not include txids of subtransactions. |

txid_snapshot's textual representation is **xmin:xmax:xip_list**.

For example: **10:20:10,14,15** means **xmin=10**, **xmax=20**, **xip_list=10, 14, 15**.

21.7.26.8 Computing Node Group Function

pv_compute_pool_workload()

Description: Load status of a computing Node Group.

Return type: void

Example:

```
SELECT * from pv_compute_pool_workload();
nodename | rpinuse | maxrp | nodestate
-----+-----+-----+-----
datanode1 | 0 | 1000 | normal
datanode2 | 0 | 1000 | normal
(2 rows)
```

21.7.26.9 Lock Information Function

pgxc_get_lock_conflicts()

Description: Obtains information about conflicting locks in the cluster. When a lock is waiting for another lock or another lock is waiting for it, a lock conflict occurs.

Return type: SETOF record

Example:

```
SELECT * from pgxc_get_lock_conflicts();
           pgxc_get_lock_conflicts
-----
(relation,cn_5001,gaussdb,u1,test,,,,omm,648406,,, "<insufficient
privilege>",140651661784832,ExclusiveLock,f,2024-10-29 17:24:13.425672+08,)
(1 row)
```

21.7.27 System Management Functions

21.7.27.1 Configuration Settings Functions

Configuration setting functions are used for querying and modifying configuration parameters during running.

current_setting(setting_name)

Description: Specifies the current setting.

Return type: text

Note: **current_setting** obtains the current setting of **setting_name** by query. It is equivalent to the **SHOW** statement. For example:

```
SELECT current_setting('datestyle');
           current_setting
-----
ISO, MDY
(1 row)
```

read_global_var(global_setting_name)

Description: Reads the current value of a global variable.

Return type: text

Note: **read_global_var** is used query the current value of **global_setting_name**. It is equivalent to the **SHOW** statement.

Example:

```
SET my.var = 1000;
SELECT read_global_var('my.var');
           read_global_var
-----
1000
(1 row)
```

 NOTE

global_setting_name indicates a variable similar to **my.var**. The variable name contains decimal points and the left and right sides of the decimal points are not empty. Variables of this type are called global variables.

Global variables can be set only by running the **SET** command. Methods such as **gs_guc**, **ALTER DATABASE dbname SET paraname TO value**, and **ALTER USER username SET paraname TO value** are not supported. Global variables are visible to all users.

set_config(setting_name, new_value, is_local)

Description: Sets the parameter and returns a new value.

Return type: text

Note: **set_config** sets the parameter **setting_name** to **new_value**. If **is_local** is **true**, the new value will only apply to the current transaction. If you want the new value to apply for the current session, use **false** instead. The function corresponds to the **SET** statement. For example:

```
SELECT set_config('log_statement_stats', 'off', false);

set_config
-----
off
(1 row)
```

 CAUTION

If **behavior_compat_options** is set to **DISABLE_SET_GLOBAL_VAR_ON_DATANODE**, you cannot use this function to set global variables on DNs.

21.7.27.2 Universal File Access Functions

Universal file access functions provide local access interfaces for files on a database server. Only files in the database cluster directory and the **log_directory** directory can be accessed. Use a relative path for files in the cluster directory, and a path matching the **log_directory** configuration setting for log files. Only database system administrators can use these functions.

pg_ls_dir(dirname text)

Description: Lists files in a directory.

Return type: setof text

Note: **pg_ls_dir** returns all the names in the specified directory, except the special entries "." and "..".

Examples:

```
SELECT pg_ls_dir('./');

pg_ls_dir
-----
.postgresql.conf.swp
postgresql.conf
```

```
pg_tblspc
PG_VERSION
pg_ident.conf
core
server.crt
pg_serial
pg_twophase
postgresql.conf.lock
pg_stat_tmp
pg_notify
pg_subtrans
pg_ctl.lock
pg_xlog
pg_clog
base
pg_snapshots
postmaster.opts
postmaster.pid
server.key.rand
server.key.cipher
pg_multixact
pg_errorinfo
server.key
pg_hba.conf
pg_replslot
.pg_hba.conf.swp
cacert.pem
pg_hba.conf.lock
global
gaussdb.state
(32 rows)
```

pg_read_file(filename text, offset bigint, length bigint)

Description: Returns the content of a text file.

Return type: text

Note: **pg_read_file** returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If **offset** is negative, it is the length rolled back from the file end. If **offset** and **length** are omitted, the entire file is returned.

Examples:

```
SELECT pg_read_file('postmaster.pid',0,100);
       pg_read_file
-----
53078          +
/srv/BigData/hadoop/data1/coordinator+
1500022474      +
8000           +
/var/run/dws    +
localhost      +
2
(1 row)
```

pg_read_binary_file(filename text [, offset bigint, length bigint,missing_ok boolean])

Description: Returns the content of a binary file.

Return type: bytea

Note: **pg_read_binary_file** is similar to **pg_read_file**, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with

the **convert_from** function, this function can be used to read a file in a specified encoding:

```
SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```

pg_stat_file(filename text)

Description: Returns status information about a file.

Return type: record

Note: **pg_stat_file** returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a **boolean** value indicating if it is a directory. Typical use cases are as follows:

```
SELECT * FROM pg_stat_file('filename');  
SELECT (pg_stat_file('filename')).modification;
```

Examples:

```
SELECT * FROM pg_stat_file('postmaster.pid');  
  
size |      access      |      modification      |      change  
| creation | isdir  
-----+-----+-----+-----  
117 | 2017-06-05 11:06:34+08 | 2017-06-01 17:18:08+08 | 2017-06-01 17:18:08+08  
|      | f  
(1 row)  
SELECT (pg_stat_file('postmaster.pid')).modification;  
      modification  
-----  
2017-06-01 17:18:08+08  
(1 row)
```

21.7.27.3 Server Signaling Functions

Server signaling functions send control signals to other server processes. Only system administrators can use these functions.

pg_cancel_backend(pid int)

Description: Cancels a current query of the backend.

Return type: boolean

Note: **pg_cancel_backend** sends a query cancellation signal (**SIGINT**) to the backend process identified by **pid**. The PID of an active backend process can be found in the **pid** column of the **pg_stat_activity** view, or can be found by listing the database process using **ps** on the server.

Example:

```
SELECT pid FROM pg_stat_activity WHERE stmt_type = 'RESET';  
      pid  
-----  
281471222065200  
(1 row)  
  
SELECT pg_cancel_backend(281471222065200);  
      pg_cancel_backend  
-----  
t  
(1 row)
```

pg_reload_conf()

Description: Notifies the server process to reload the configuration file.

Return type: boolean

Note: **pg_reload_conf** sends a **SIGHUP** signal to the server. As a result, all server processes reload their configuration files.

Example:

```
SELECT pg_reload_conf();
pg_reload_conf
-----
t
(1 row)
```

pg_rotate_logfile()

Description: Rotates the log files of the server.

Return type: boolean

Note: **pg_rotate_logfile** instructs the log file manager to immediately switch to a new output file. This function is valid only if the built-in log collector is running.

Example:

```
SELECT pg_rotate_logfile();
pg_rotate_logfile
-----
t
(1 row)
```

pg_terminate_backend(pid int)

Description: Terminates a backend thread.

Return type: boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise.

Example:

```
SELECT pid FROM pg_stat_activity;
 pid
-----
140657876268816
140433774061312
140433587902208
140433656592128
140433723717376
140433637189376
140433552770816
140433481983744
140433349310208
(9 rows)

SELECT pg_terminate_backend(140657876268816);
pg_terminate_backend
-----
t
(1 row)
```

pg_wlm_jump_queue(pid int)

Description: Moves a task to the top of the CN queue.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise.

Example:

```
SELECT pid FROM pg_stat_activity WHERE stmt_type='RESET';
      pid
-----
281471222065200
(1 row)

SELECT pg_wlm_jump_queue(281471222065200);
 pg_wlm_jump_queue
-----
t
(1 row)
```

gs_wlm_switch_cgroup(pid int, cgroup text)

Description: Moves a job to other Cgroup to improve the job priority.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise.

pg_cancel_query(queryId int)

Description: Cancels a current query of the backend. This function is supported in 8.1.2 or later.

Return type: boolean

Note: **pg_cancel_query** sends a query cancellation signal (**SIGINT**) to the backend process identified by **query_id**. The **query_id** of an active backend process can be found in the **query_id** column of the **pg_stat_activity** view.

Example:

```
SELECT query_id FROM pgxc_stat_activity WHERE stmt_type='RESET';
      query_id
-----
0
0
(2 rows)

SELECT pg_cancel_query(0);
 pg_cancel_query
-----
f
(1 row)
```

pgxc_cancel_query(queryId int)

Description: Cancels the query that is being executed in the current cluster. This function is supported in 8.1.2 or later.

Return type: boolean

Note: If the queries of all nodes have been canceled, **true** is returned. Otherwise, **false** is returned.

Example:

```
SELECT query_id FROM pgxc_stat_activity WHERE stmt_type = 'RESET';
query_id
-----
      0
      0
(2 rows)

SELECT pgxc_cancel_query(0);
pgxc_cancel_query
-----
f
(1 row)
```

pg_terminate_query(queryId int)

Description: Terminates a current query of the backend. This function is supported in 8.1.2 or later.

Return type: boolean

Example:

```
SELECT query_id FROM pgxc_stat_activity WHERE stmt_type = 'RESET';
query_id
-----
      0
      0
(2 rows)

SELECT pg_terminate_query(0);
pg_terminate_query
-----
f
(1 row)
```

pgxc_terminate_query(queryId int)

Description: Terminates the query that is being executed in the current cluster. This function is supported in 8.1.2 or later.

Return type: boolean

Example:

```
SELECT query_id FROM pgxc_stat_activity;
query_id
-----
72339069014638631
(1 rows)

SELECT pgxc_terminate_query(72339069014638631);
pgxc_terminate_query
-----
t
(1 row)
```

21.7.27.4 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

create_wdr_snapshot()

Description: Creates a performance data snapshot.

Return type: text

NOTE

- Only the database administrator **SYSADMIN** can execute this function.
- This function can be executed only on CNs. If it is executed on DN, the following message will be returned: "WDR snapshot can only be created on coordinator."
- Before executing this function, ensure that the value of **enable_wdr_snapshot** is **on**. If its value is **off**, the following message will be returned for this function: "WDR snapshot request can't be executed, because GUC parameter 'enable_wdr_snapshot' is off."
- If the snapshot thread is not started for some reason, for example, the node is restarted, the following message will be returned for this function: "WDR snapshot request can not be accepted, please retry later."
- If this function fails to be executed, the following message will be returned: "Cannot respond to WDR snapshot request."
- If this function is successfully executed, the following message will be returned: "WDR snapshot request has been submitted." This message indicates that the snapshot creation request has been sent to the background snapshot thread, but does not mean that the snapshot has been successfully created.

kill_snapshot(scope cstring)

Description: Kills the background snapshot thread. This function sends a command to the background snapshot thread and waits for the thread to stop.

The input parameter **scope** indicates the operation scope. Its value can be **local** or **global**.

- Value **local** indicates killing the snapshot thread on the current CN.
- Value **global** indicates killing the snapshot thread on the current CN as well as those on all the other CNs in the cluster.
- If any other value is passed, error message "Scope is invalid, use "local" or "global"." is displayed.
- The input parameter can be left empty, in which case the default value **local** will be used.

Return type: none

NOTE

- Only the database administrator **SYSADMIN** can execute this function.
- This function can be executed only on CNs. If it is executed on DN, the following message will be returned: "kill_snapshot can only be executed on coordinator."
- Executing this function sends a kill signal to the background snapshot thread and waits for it to finish. If the snapshot thread is not killed within 100s, the error message "Kill snapshot thread failed" is displayed.

pg_export_snapshot()

Description: Saves the current snapshot and returns its identifier.

Return type: text

Note: **pg_export_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot_id** command is executed. Doing so is possible only when the transaction is set to the **REPEATABLE READ** isolation level. The output of the function cannot be used as the input of **set transaction snapshot**.

Example:

```
SELECT pg_export_snapshot();
pg_export_snapshot
-----
00000000000A7128-1
(1 row)
```

21.7.27.5 Advisory Lock Functions

Advisory lock functions manage advisory locks. These functions are only for internal use currently.

pg_advisory_lock(key bigint)

Description: Obtains an exclusive session-level advisory lock.

Return type: void

Note: **pg_advisory_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.

pg_advisory_lock(key1 int, key2 int)

Description: Obtains an exclusive session-level advisory lock.

Return type: void

pg_advisory_lock_shared(key bigint)

Description: Obtains a shared session-level advisory lock.

Return type: void

pg_advisory_lock_shared(key1 int, key2 int)

Description: Obtains a shared session-level advisory lock.

Return type: void

Note: **pg_advisory_lock_shared** works in the same way as **pg_advisory_lock**, except the lock can be shared with other sessions requesting shared locks. Only would-be exclusive lockers are locked out.

pg_advisory_unlock(key bigint)

Description: Releases an exclusive session-level advisory lock.

Return type: boolean

pg_advisory_unlock(key1 int, key2 int)

Description: Releases an exclusive session-level advisory lock.

Return type: boolean

Note: **pg_advisory_unlock** releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, a SQL warning will be reported by the server.

pg_advisory_unlock_shared(key bigint)

Description: Releases a shared session-level advisory lock.

Return type: boolean

pg_advisory_unlock_shared(key1 int, key2 int)

Description: Releases a shared session-level advisory lock.

Return type: boolean

Note: **pg_advisory_unlock_shared** works in the same way as **pg_advisory_unlock**, except it releases a shared session-level advisory lock.

pg_advisory_unlock_all()

Description: Releases all advisory locks owned by the current session.

Return type: void

Note: **pg_advisory_unlock_all** releases all advisory locks owned by the current session. The function is implicitly invoked when the session ends even if the client is abnormally disconnected.

pg_advisory_xact_lock(key bigint)

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

pg_advisory_xact_lock(key1 int, key2 int)

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

Note: **pg_advisory_xact_lock** works in the same way as **pg_advisory_lock**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

pg_advisory_xact_lock_shared(key bigint)

Description: Obtains a shared transaction-level advisory lock.

Return type: void

pg_advisory_xact_lock_shared(key1 int, key2 int)

Description: Obtains a shared transaction-level advisory lock.

Return type: void

Note: **pg_advisory_xact_lock_shared** works in the same way as **pg_advisory_lock_shared**, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

pg_try_advisory_lock(key bigint)

Description: Obtains an exclusive session-level advisory lock if available.

Return type: boolean

Note: **pg_try_advisory_lock** is similar to **pg_advisory_lock**, except **pg_try_advisory_lock** does not block the resource until the resource is released. **pg_try_advisory_lock** either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

pg_try_advisory_lock(key1 int, key2 int)

Description: Obtains an exclusive session-level advisory lock if available.

Return type: boolean

pg_try_advisory_lock_shared(key bigint)

Description: Obtains a shared session-level advisory lock if available.

Return type: boolean

pg_try_advisory_lock_shared(key1 int, key2 int)

Description: Obtains a shared session-level advisory lock if available.

Return type: boolean

Note: **pg_try_advisory_lock_shared** is similar to **pg_try_advisory_lock**, except **pg_try_advisory_lock_shared** attempts to obtain a shared lock instead of an exclusive lock.

pg_try_advisory_xact_lock(key bigint)

Description: Obtains an exclusive transaction-level advisory lock if available.

Return type: boolean

pg_try_advisory_xact_lock(key1 int, key2 int)

Description: Obtains an exclusive transaction-level advisory lock if available.

Return type: boolean

Note: **pg_try_advisory_xact_lock** works in the same way as **pg_try_advisory_lock**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.

pg_try_advisory_xact_lock_shared(key bigint)

Description: Obtains a shared transaction-level advisory lock if available.

Return type: boolean

pg_try_advisory_xact_lock_shared(key1 int, key2 int)

Description: Obtains a shared transaction-level advisory lock if available.

Return type: boolean

Note: **pg_try_advisory_xact_lock_shared** works in the same way as **pg_try_advisory_lock_shared**, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.

21.7.27.6 Replication Functions

A replication function synchronizes logs and data between instances. It is a statistics or operation method provided by the system to implement HA.

NOTE

Replication functions except statistics queries are internal functions. You are not advised to use them directly.

pg_create_logical_replication_slot('slot_name', 'plugin_name')

Description: Creates a logical replication slot. This is no longer used in 9.1.0.200 and later versions. It is reserved for compatibility with earlier versions.

Parameter:

- **slot_name**
Indicates the name of the streaming replication slot.
Value range: a string, supporting only letters, digits, and the following special characters: `_?-`.
- **plugin_name**
Indicates the name of the plugin.
Value range: a string, supporting only **mppdb_decoding**

Return type: name, text

Note: The first return value is the slot name, and the second is the start LSN position for decoding in the logical replication slot.

pg_create_physical_replication_slot ('slot_name', isDummyStandby)

Description: Creates a physical replication slot.

Parameter:

- **slot_name**
Indicates the name of the streaming replication slot.
Value range: a string, supporting only letters, digits, and the following special characters: _?.-
- **isDummyStandby**
Indicates whether the replication slot is the secondary one.
Value range: a boolean value, **true** or **false**

Return type: name, text

Note: The first return value is the slot name, and the second is the start LSN position for decoding in the physical replication slot.

pg_get_replication_slots()

Description: Displays information about all replication slots on the current DN.

Return type: record

The following information is returned:

Table 21-51 pg_get_replication_slots() fields

| Field | Type | Description |
|---------------|---------|---|
| slot_name | text | Replication slot name |
| plugin | name | Name of the output plug-in of the logical replication slot |
| slot_type | text | Replication slot type |
| datoid | oid | Replication slot's database OID |
| active | boolean | Whether the replication slot is active |
| xmin | xid | Transaction ID of the replication slot |
| catalog_xmin | text | ID of the earliest-decoded transaction corresponding to the logical replication slot. |
| restart_lsn | text | Xlog file information on the replication slot. |
| dummy_standby | boolean | Indicates whether the replication slot is the secondary one. |

Example:

```
SELECT * FROM pg_get_replication_slots();
 slot_name | plugin | slot_type | datoid | active | xmin | catalog_xmin | restart_lsn | dummy_standby
-----+-----+-----+-----+-----+-----+-----+-----+-----
gs_roach_common |      | physical |    0 | f      |      |      | 602861775 | FFFFFFFF/FFFFFFF | f
(1 row)
```

pg_drop_replication_slot('slot_name')

Description: Deletes a streaming replication slot.

Parameter:

slot_name: name of a streaming replication slot. Value range: a string. Only letters, digits, underscores (_), question marks (?), hyphens (-), and periods (.) are allowed.

Return type: void

pg_logical_slot_peek_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

Description: Performs decoding but does not go to the next streaming replication slot. (The decoding result will be returned again on future calls.) This is no longer used in 9.1.0.200 and later versions. It is reserved for compatibility with earlier versions.

Parameter:

- **slot_name**
Indicates the name of the streaming replication slot.
Value range: a string, supporting only letters, digits, and the following special characters: _?-.
- **LSN**
Indicates a target LSN. Decoding is performed only when an LSN is less than or equal to this value.
Value range: a string, in the format of xlogid/xrecoff, for example, '1/2AAFC60' (If this parameter is set to **NULL**, the target LSN indicating the end position of decoding is not specified.)
- **upto_nchanges**
Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto_nchanges** is **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds 4 after decoding in the first two transactions is finished.
Value range: a non-negative integer

NOTE

If any of the **LSN** and **upto_nchanges** values are reached, decoding ends.

- options (optional)
 - include-xids
Indicates whether the decoded **data** column contains XID information.
Valid value: **0** and **1**. The default value is **1**.
 - **0**: The decoded **data** column does not contain XID information.
 - **1**: The decoded **data** column contains XID information.
 - skip-empty-xacts
Indicates whether to ignore empty transaction information during decoding.
Valid value: **0** and **1**. The default value is **0**.
 - **0**: The empty transaction information is not ignored during decoding.
 - **1**: The empty transaction information is ignored during decoding.
 - include-timestamp
Indicates whether decoding information contains the **commit** timestamp.
Valid value: **0** and **1**. The default value is **0**.
 - **0**: The decoding information does not contain the **commit** timestamp.
 - **1**: The decoding information contains the **commit** timestamp.

Return type: text, uint, text

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content, respectively.

pg_logical_slot_get_changes('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value')

Description: Performs decoding and goes to the next streaming replication slot. This is no longer used in 9.1.0.200 and later versions. It is reserved for compatibility with earlier versions.

Parameter: This function has the same parameters as **pg_logical_slot_peek_changes**. For details, see [pg_logical_slot_peek_changes\('slot_name', 'LSN', upto_nchanges, 'options_name', 'options_value'\)](#).

pg_replication_slot_advance ('slot_name', 'LSN')

Description: Directly goes to the streaming replication slot for a specified LSN, without outputting any decoding result.

Parameter:

- slot_name
Indicates the name of the streaming replication slot.

Value range: a string, supporting only letters, digits, and the following special characters: _?-..

- LSN

Indicates a target LSN. Next decoding will be performed only in transactions whose commission position is greater than this value. If an input LSN is smaller than the position recorded in the current streaming replication slot, the function directly returns. If the input LSN is greater than the LSN of the current physical log, the latter LSN will be directly used for decoding.

Value range: a string, in the format of xlogid/xrecoff

Return type: name, text

Note: A return result contains the slot name and LSN that is actually used for decoding.

pg_stat_get_data_senders()

Description: Displays statistics about replication sending threads on all data page on the current DN.

Return type: record

The following information is returned:

Table 21-52 pg_stat_get_data_senders() fields

| Field | Type | Description |
|------------------|--------------------------|--|
| pid | bigint | Thread PID |
| sender_pid | integer | Current sender PID |
| local_role | text | Local role |
| peer_role | text | Peer role |
| state | text | Current sender's replication status |
| catchup_start | timestamp with time zone | Startup time of a catchup task |
| catchup_end | timestamp with time zone | End time of a catchup task |
| queue_size | text | Data queue size |
| queue_lower_tail | text | Position of data queue tail 1 |
| queue_header | text | Position of data queue header |
| queue_upper_tail | text | Position of data queue tail 2 |
| send_position | text | Sending position of the sender |
| receive_position | text | Receiving position of the receiver |
| catchup_type | text | Catchup task type, full or incremental |

| Field | Type | Description |
|------------------------|---------|--|
| catchup_bcm_filename | text | BCM file executed by the current catchup task |
| catchup_bcm_finished | integer | Number of BCM files completed by a catchup task |
| catchup_bcm_total | integer | Total number of BCM files to be operated by a catchup task |
| catchup_percent | text | Completion percentage of a catchup task |
| catchup_remaining_time | text | Estimated remaining time of a catchup task |

pg_stat_get_wal_senders()

Description: Displays statistics about replication sending threads on all WALs on the current DN.

Return type: record

The following information is returned:

Table 21-53 pg_stat_get_wal_senders() fields

| Field | Type | Description |
|-----------------------|--------------------------|--|
| pid | bigint | Thread PID |
| sender_pid | integer | Current sender PID |
| local_role | text | Local role |
| peer_role | text | Peer role |
| peer_state | text | Peer status |
| state | text | Current sender's replication status |
| catchup_start | timestamp with time zone | Startup time of a catchup task |
| catchup_end | timestamp with time zone | End time of a catchup task |
| sender_sent_location | text | Location where the sender sends LSNs |
| sender_write_location | text | Location where the sender writes LSNs |
| sender_flush_location | text | Location where the sender flushes LSNs |

| Field | Type | Description |
|----------------------------|---------|---|
| sender_replay_location | text | Location where the sender replays LSNs |
| receiver_received_location | text | Location where the receiver receives LSNs |
| receiver_write_location | text | Location where the receiver writes LSNs |
| receiver_flush_location | text | Location where the receiver flushes LSNs |
| receiver_replay_location | text | Location where the receiver replays LSNs |
| sync_percent | text | Specifies the synchronization percentage. |
| sync_state | text | Synchronization state (asynchronous duplication, synchronous duplication, or potential synchronization) |
| sync_priority | integer | Priority of synchronous duplication (0 indicates asynchronization) |
| sync_most_available | text | Whether to block the active node when the synchronization on the standby node fails |
| channel | text | WALSender channel information |

pg_stat_get_wal_receiver()

Description: Displays statistics about replication receiving threads on all WALs on the current DN.

Return type: record

The following information is returned:

Table 21-54 pg_stat_get_wal_receiver()

| Field | Type | Description |
|--------------|---------|---------------------------------------|
| receiver_pid | integer | Current receiver PID |
| local_role | text | Local role |
| peer_role | text | Peer role |
| peer_state | text | Peer status |
| state | text | Current receiver's replication status |

| Field | Type | Description |
|----------------------------|------|---|
| sender_sent_location | text | Location where the sender sends LSNs |
| sender_write_location | text | Location where the sender writes LSNs |
| sender_flush_location | text | Location where the sender flushes LSNs |
| sender_replay_location | text | Location where the sender replays LSNs |
| receiver_received_location | text | Location where the receiver receives LSNs |
| receiver_write_location | text | Location where the receiver writes LSNs |
| receiver_flush_location | text | Location where the receiver flushes LSNs |
| receiver_replay_location | text | Location where the receiver replays LSNs |
| sync_percent | text | Specifies the synchronization percentage. |
| channel | text | WALReceiver channel information |

pg_stat_get_stream_replications()

Description: Displays information about all replication statistics on the current DN.

Return type: record

The following information is returned:

Table 21-55 pg_stat_get_stream_replications()

| Field | Type | Description |
|--------------------|---------|-----------------------|
| local_role | text | Local role |
| static_connections | integer | Connection statistics |
| db_state | text | Database status |
| detail_information | text | Detail information |

Example:

```
SELECT * FROM pg_stat_get_stream_replications();  
local_role | static_connections | db_state | detail_information
```

```
-----+-----+-----+-----  
Normal |          0 | Normal | Normal  
(1 row)
```

pg_stat_xlog_space()

Description: Displays the Xlog space usage on the current DN.

Return type: record

The following information is returned:

Table 21-56 pg_stat_xlog_space()

| Column | Type | Description |
|------------|--------|---|
| xlog_files | bigint | Number of all identified xlog files in the pg_xlog directory, excluding the backup and archive_status subdirectories. |
| xlog_size | bigint | Total size (MB) of all identified xlog files in the pg_xlog directory, excluding the backup and archive_status subdirectories. |
| other_size | bigint | Total size (MB) of files in the backup and archive_status subdirectories of the pg_xlog directory. |

Example:

```
SELECT * FROM pg_stat_xlog_space();  
xlog_files | xlog_size | other_size  
-----+-----+-----  
       79 |      1264 |         0  
(1 row)
```

pgxc_stat_xlog_space()

Description: Displays the Xlog space usage on all active DNs.

Return type: record

The following information is returned:

Table 21-57 pgxc_stat_xlog_space()

| Column | Type | Description |
|-----------|------|-------------|
| node_name | name | Node name |

| Column | Type | Description |
|------------|--------|---|
| xlog_files | bigint | Number of all identified xlog files in the pg_xlog directory, excluding the backup and archive_status subdirectories. |
| xlog_size | bigint | Total size (MB) of all identified xlog files in the pg_xlog directory, excluding the backup and archive_status subdirectories. |
| other_size | bigint | Total size (MB) of files in the backup and archive_status subdirectories of the pg_xlog directory. |

Example:

```
SELECT * FROM pgxc_stat_xlog_space();
 node_name | xlog_files | xlog_size | other_size
-----+-----+-----+-----
dn_6001_6002 |      73 |    1168 |         0
dn_6003_6004 |      73 |    1168 |         0
dn_6005_6006 |      73 |    1168 |         0
cn_5003      |      79 |    1264 |         0
cn_5001      |      72 |    1152 |         0
cn_5002      |      73 |    1168 |         0
(6 rows)
```

21.7.27.7 Resource Management Functions

This section describes the functions of the resource management module.

gs_switch_respool(query_id bigint, resource_pool_name name)

Description: Job resource pool switchover function is supported by cluster versions 9.1.0 and later.

The value of **resource_pool_name** must contain less than 64 characters. Upon calling this function, the system will decide whether to start a job in the queuing phase when switching to the new resource pool. If a job is running, the system will switch to the new resource pool to start the queuing job from the original resource pool. Additionally, the CPU control of the new resource pool will limit the queuing job.

This function supports resource pool switchover in both static and dynamic management and control modes, as well as resource pool switchover using short queries.

Return type: bool

CAUTION

- Only administrators or users with administrator permissions can use this function. Common users are not authorized to use it. To use this function, the cluster's CPU control function, specifically the **Cgroup** function, must be functioning normally. You can use the **pgxc_cgroup_reload_conf()** function to check whether **Cgroup** is normal. If the command output contains non-success information, rectify the fault.
- After the resource pool is switched, the function performs management and control based on the exception rules of the new resource pool.
- If a job is in the global concurrent queue, which means it is waiting in the global queue, it will not take effect right away after the resource pool is switched. At this point, the job has not entered the resource pool queue yet.
- 1. Job CPU control switchover supports CNs and DNs. For example, if resource pool A uses 40 cores and resource pool B uses 5 cores, switching a job from pool A to pool B will execute the job on the 5 cores of pool B. This results in slower execution but isolates the job, ensuring that jobs in pool A are unaffected, thus degrading the statement.
- When switching resource pools, use similar statements to perform batch switchovers. Ensure that the jobs being switched are in the same state, such as all queuing or all running. If switching between different types of statements, it is recommended to switch them twice. Switching them together may exceed the concurrent statement limit, causing abnormal job wake-ups.

```
SELECT gs_switch_respool (queryid,'xxx') FROM xxx where xxx;
```
- The restrictions on switching the statement resource pool are as follows:
 - If jobs from resource pool A are switched to pool B, jobs at the head of the queue in pool A will be woken up. If the concurrent job limit in pool B is reached, job A1 will not run immediately.
 - Switch job A2 from queuing in pool A to pool B. If the concurrent job limit in pool B is reached, job A2 will continue to queue. If not, job A2 will wake up and run immediately.
 - During resource pool switchover, only the same lane can be switched. For example, switching the fast lane of pool A will switch the fast lane of pool B. If the short query acceleration function is not enabled in pool B, the job runs directly regardless of its status in pool B.
- This function can be used only when all nodes are normal. If a node is faulty, the function fails to be executed.

Example:

While executing the statement with ID **74590868828368101**, the administrator successfully switches it to the **poolg1** resource pool.

```
CALL gs_switch_respool(74590868828368101,'poolg1');
gs_switch_respool
-----
t
(1 row)
```

gs_increase_except_num(unique_sql_id int8)

Description: Records job exception information. The input parameter must be greater than 0. If this function is invoked, the number of job exceptions will be

increased by 1 and the latest job exception time will be updated to the current time.

Return type: bool

Example:

```
SELECT gs_increase_except_num(111);
gs_increase_except_num
-----
t
(1 row)
```

gs_increase_except_num(unique_sql_id int8, except_num int4)

Description: Records job exception information. The input parameter must be greater than 0. If this function is invoked, the number of job exceptions will be increased by **except_num** and the latest job exception time will be updated to the current time.

Return type: bool

Example:

```
SELECT gs_increase_except_num(111, 4);
gs_increase_except_num
-----
t
(1 row)
```

gs_increase_except_num(unique_sql_id int8, except_num int4, except_time int8)

Description: Records job exception information. The input parameter must be greater than 0. If this function is invoked, the number of job exceptions will be increased by **except_num** and the latest job exception time will be updated to **except_time**, a timestamp. This function is mainly invoked internally.

Return type: bool

Example:

```
SELECT gs_increase_except_num(111, 4, 714623414421256);
gs_increase_except_num
-----
t
(1 row)
```

gs_append_blocklist(unique_sql_id int8)

Description: Adds a job to the blocklist and update the blocklist information in **GS_BLOCKLIST_QUERY**.

Return type: bool

Example:

```
SELECT gs_append_blocklist(111);
gs_append_blocklist
-----
t
(1 row)
```

gs_remove_blocklist(unique_sql_id int8)

Description: Removes a job from the blocklist. and update the blocklist information in **GS_BLOCKLIST_QUERY**.

Return type: bool

Example:

```
SELECT gs_remove_blocklist(111);
gs_append_blocklist
-----
t
(1 row)
```

gs_increase_sql_except_num(sql_hash text)

Description: Records job exception information. If this function is invoked, the number of job exceptions will be increased by 1 and the latest job exception time will be updated to the current time. This function is supported only by 9.1.0.200 and later cluster versions and is used for internal calling.

Return type: bool

Example:

```
SELECT gs_increase_sql_except_num('sql_7bf6381d2a5a456a1936027198ad8b12');
gs_increase_sql_except_num
-----
t
(1 row)
```

gs_increase_sql_except_num(sql_hash text, except_num int4)

Description: Records job exception information. If this function is invoked, the number of job exceptions will be increased by **except_num** and the latest job exception time will be updated to the current time. This function is supported only by 9.1.0.200 and later cluster versions and is used for internal calling.

Return type: bool

Example:

```
SELECT gs_increase_sql_except_num('sql_7bf6381d2a5a456a1936027198ad8b12', 4);
gs_increase_sql_except_num
-----
t
(1 row)
```

gs_increase_sql_except_num(sql_hash text, except_num int4, except_time int8)

Description: Records job exception information. If this function is invoked, the number of job exceptions will be increased by **except_num** and the latest job exception time will be updated to **except_time**. **except_time** functions as a timestamp here. This function is supported only by 9.1.0.200 and later cluster versions and is used for internal calling.

Return type: bool

Example:

```
SELECT gs_increase_sql_except_num('sql_7bf6381d2a5a456a1936027198ad8b12', 4, 714623414421256);
gs_increase_sql_except_num
-----
t
(1 row)
```

gs_append_blocklist(sql_hash text)

Description: Adds a job to the blocklist and updates the blocklist information in **GS_BLOCKLIST_SQL**. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: bool

Example:

```
SELECT gs_append_blocklist('sql_7bf6381d2a5a456a1936027198ad8b12');
gs_append_blocklist
-----
t
(1 row)
```

gs_remove_blocklist(sql_hash text)

Description: Removes a job from the blocklist and updates the blocklist information in **GS_BLOCKLIST_SQL**. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: bool

Example:

```
SELECT gs_remove_blocklist('sql_7bf6381d2a5a456a1936027198ad8b12');
gs_remove_blocklist
-----
t
(1 row)
```

gs_wlm_rebuild_except_rule_hash()

Description: Rebuilds the memory hash table of exception rules on the current node. The monitoring thread obtains the exception rule thresholds from the memory hash table in real time. When the hash table is abnormal, this function can be used to rebuild the table.

Return type: bool

Example:

```
SELECT gs_wlm_rebuild_except_rule_hash();
gs_wlm_rebuild_except_rule_hash
-----
t
(1 row)
```

gs_wlm_readjust_user_space(oid)

Description: This function calibrates the permanent storage space of a user. The input parameter is the user OID. If the input parameter is set to **0**, the permanent storage space of all users is calibrated.

Return type: text

Example:

```
SELECT gs_wlm_readjust_user_space(0);  
gs_wlm_readjust_user_space  
-----  
Exec Success  
(1 row)
```

pgxc_wlm_readjust_schema_space()

Description: This function calibrates the permanent storage space of a schema.

Return type: text

Example:

```
SELECT pgxc_wlm_readjust_schema_space();  
pgxc_wlm_readjust_schema_space  
-----  
Exec Success  
(1 row)
```

pgxc_wlm_readjust_relfilenode_size_table()

Description: Space statistics calibration function. It does not recreate the **PG_RELFILENODE_SIZE** system catalog but recalibrates the user and schema space.

NOTE

Due to transaction isolation between the calibration function and other services, the calibration function is invisible to other services that are being executed. As a result, the calibration function does not involve space changes of such services. To avoid space difference errors after calibration, you are advised to use the space calibration function to perform calibration when the space is stable.

Return type: text

Example:

```
SELECT pgxc_wlm_readjust_schema_space();  
pgxc_wlm_readjust_relfilenode_size_table  
-----  
Exec Success  
(1 row)
```

pgxc_wlm_readjust_relfilenode_size_table(integer)

Description: Space statistics calibration function

NOTE

Due to transaction isolation between the calibration function and other services, the calibration function is invisible to other services that are being executed. As a result, the calibration function does not involve space changes of such services. To avoid space difference errors after calibration, you are advised to use the space calibration function to perform calibration when the space is stable.

Parameter: The value ranges from 0 to 4. Different input parameter values indicate different calibration granularities.

- If the input parameter is set to **0** (default value), the **PG_RELFILENODE_SIZE** system catalog is not rebuilt and the user and schema space are recalibrated.

- If the input parameter is set to **1**, the **PG_RELFILENODE_SIZE** system catalog is rebuilt and the user and schema space are recalibrated.
- If the input parameter is set to **2**, the **PG_RELFILENODE_SIZE** system catalog is rebuilt.
- If the input parameter is set to **3**, the schema space is recalibrated.
- If the input parameter is set to **4**, the user space is recalibrated.

Return type: text

Example:

```
SELECT * FROM pgxc_wlm_readjust_relfilenode_size_table(1);
      result
-----
Exec success
(1 row)
```

pgxc_wlm_get_schema_space(cstring)

Description: Obtains the schema space of each instance in a specified logical cluster on the CN.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|--------------|--------|--------------------------|
| schemaname | text | Schema name |
| schemaid | oid | Schema OID |
| databasename | text | Database name |
| databaseid | oid | Database OID |
| nodename | text | Instance name |
| nodegroup | text | Name of the node group |
| usedspace | bigint | Size of the used space |
| permSPACE | bigint | Upper limit of the space |

Example:

```
SELECT * FROM pgxc_wlm_get_schema_space('group1');
 schemaname | schemaid | databasename | databaseid | nodename | nodegroup | usedspace | permSPACE
-----+-----+-----+-----+-----+-----+-----+-----

pgxc_wlm_analyze_schema_space(cstring)

Description: Obtains the schema space of a specified logical cluster on the CN.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|--------------|---------|--|
| schemaname | text | Schema name |
| databasename | text | Database name |
| nodegroup | text | Name of the node group |
| total_value | bigint | Total cluster space in the current schema |
| avg_value | bigint | Average space of instances in the current schema |
| skew_percent | integer | Skew ratio |
| extend_info | text | Extended information, including the maximum space of a single instance, minimum space of a single instance, and names of the instances with the maximum space or minimum space |

Example:

```
SELECT * FROM pgxc_wlm_analyze_schema_space('group1');
  schemaname | databasename | nodegroup | total_value | avg_value | skew_percent |
extend_info

gs_wlm_set_queryband_action(cstring,cstring,int4)

Description: Sets the action and query order of **query_band**.

Return type: boolean

The following table describes the input parameters.

| Name | Type | Description |
|--------|---------|---|
| qband | cstring | Query band key-value pair. The maximum length is 63 characters. |
| action | cstring | Action associated to a query band |
| order | int4 | Query band query order. The default value is -1 . |

Example:

```
SELECT * FROM gs_wlm_set_queryband_action('a=1','respool=p1');
gs_wlm_set_queryband_action
-----
t
(1 row)

SELECT * FROM gs_wlm_set_queryband_action('a=3','respool=p1;priority=rush',1);
gs_wlm_set_queryband_action
-----
t
(1 row)
```

gs_wlm_set_queryband_order(cstring,int4)

Description: Sets the **query_band** query order.

Return type: boolean

The following table describes the input parameters.

| Name | Type | Description |
|-------|---------|--|
| qband | cstring | query_band key-value pairs |
| order | int4 | Query band query order. The default value is -1 . |

Example:

```
SELECT * FROM gs_wlm_set_queryband_order('a=1',2);
gs_wlm_set_queryband_order
-----
t
(1 row)
```

gs_wlm_get_queryband_action(cstring)

Description: Obtains the action and query order of **query_band**.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|------------|---------|---|
| qband | cstring | query_band key-value pairs |
| respool_id | Oid | OID of the resource pool associated with query_band |
| respool | text | Name of the resource pool associated with query_band |
| priority | text | Intra-queue priority associated with query_band |
| qborder | int4 | query_band query order |

Example:

```
SELECT * FROM gs_wlm_get_queryband_action('a=1');
qband | respool_id | respool | priority | qborder
-----+-----+-----+-----+-----
a=1   | 16388 | p1     | Medium   | -1
(1 row)
```

gs_cgroup_reload_conf()

Description: This function loads the Cgroup configuration file online on the current instance.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|-----------|------|--|
| node_name | text | Instance name |
| node_host | text | IP address of the node where the instance is located |
| result | text | Whether Cgroup online loading is successful |

Example:

```
SELECT * FROM gs_cgroup_reload_conf();
node_name | node_host | result
-----+-----+-----
cn_5001   | 192.168.178.35 | success
```

pgxc_cgroup_reload_conf()

Description: This function loads the Cgroup configuration file online on all instances of the system.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|-----------|------|--|
| node_name | text | Instance name |
| node_host | text | IP address of the node where the instance is located |
| result | text | Whether Cgroup online loading is successful |

Example:

```
SELECT * FROM pgxc_cgroup_reload_conf();
 node_name | node_host | result
-----+-----+-----

```

pgxc_cgroup_reload_conf(text)

Description: This function loads the Cgroup configuration file online on a node. The input parameter is the IP address of the node.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|-----------|------|--|
| node_name | text | Instance name |
| node_host | text | IP address of the node where the instance is located |
| result | text | Whether Cgroup online loading is successful |

Example:

```
SELECT * FROM pgxc_cgroup_reload_conf('192.168.178.35');
 node_name | node_host | result
-----+-----+-----
 cn_5001   | 192.168.178.35 | success
 dn_6007_6008 | 192.168.178.35 | success
 dn_6003_6004 | 192.168.178.35 | success
 dn_6001_6002 | 192.168.178.35 | success
 dn_6005_6006 | 192.168.178.35 | success
(5 rows)
```

gs_wlm_node_recover(boolean isForce)

Description: This function updates and restores job information and counts on the CCN in dynamic resource management mode. It can be executed only by administrators, and is usually used to restore a faulty CN after it was restarted. This function is called by the Cluster Manager (CM). Its usage is as follows:

- If this function is executed by CN, it instructs the CCN to clear job information and counts on the CN.
- If this function is executed by CCN, it resets job counts and obtains the latest slow lane job information from the CN.

Return type: bool

gs_wlm_node_clean(cstring nodename)

Description: On the CCN in dynamic resource management mode, clears the job information and counts of a specified CN. This function can be executed only by administrators, and is usually used to restore a faulty CN after it was restarted. This function is called by the Cluster Manager (CM). Generally, users are not advised to call it.

Return type: bool

pg_stat_get_wlm_node_resource_info(int4)

Description: This function displays the summary of all DN resources.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|-----------------|---------|-------------------------------|
| min_mem_util | integer | Minimum memory usage of a DN |
| max_mem_util | integer | Maximum memory usage of a DN |
| min_cpu_util | integer | Minimum CPU usage of a DN |
| max_cpu_util | integer | Maximum CPU usage of a DN |
| min_io_util | integer | Minimum I/O usage of a DN |
| max_io_util | integer | Maximum I/O usage of a DN |
| phy_usemem_rate | integer | Maximum physical memory usage |

pg_stat_get_workload_struct_info()

Description: Load management function for locating CCN queuing problems. This function is an internal function. To use this function, contact technical support.

Return type: record

pgxc_query_resource_info(query_id bigint)

Description: This function displays resource monitoring information about the statement with a specified query ID on all DNs. It is supported only by clusters of version 9.1.0.100 or later.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|------------|--------|--|
| node_name | text | Instance name, which contains only DNs. |
| user_id | oid | User ID. |
| queryid | bigint | Internal query ID used for statement execution. |
| used_mem | int | Memory used by the statement on the current DN. The unit is MB. |
| cpu_time | bigint | CPU time of a statement on the current DN. The unit is ms. |
| used_cpu | double | Number of CPUs used by the statement on the current DN. |
| spill_size | bigint | Amount of data spilled to disks on the current DN. The default value is 0. The unit is MB. |
| read_bytes | bigint | Number of logical read bytes used by the statement on the current DN. The unit is KB. |

| Column | Type | Description |
|-------------|--------|--|
| write_bytes | bigint | Number of logical write bytes used by the statement on the current DN. The unit is KB. |
| read_count | bigint | Number of logical reads used by the statement on the current DN. |
| write_count | bigint | Number of logical writes used by the statement on the current DN. |
| read_speed | int | Logical read rate used by the statement on the current DN. The unit is KB/s. |
| write_speed | int | Logical write rate used by the statement on the current DN. The unit is KB/s. |
| curr_iops | int | I/O operations per second of the statement on the current DN. It is recorded as a count in a column-store table and as a count of 10,000 in a row-store table. |
| send_pkg | bigint | Total number of communication packages sent by a statement across all DNs. |
| recv_pkg | bigint | Total number of communication packages received by a statement across all DNs. |
| send_bytes | bigint | Total sent data of the statement stream, in byte. |
| recv_bytes | bigint | Total received data of the statement stream, in byte. |
| send_speed | int | Network sending rate of the statement on the current DN. The unit is KB/s. |
| recv_speed | int | Network receiving rate of the statement on the current DN. The unit is KB/s. |

21.7.27.8 Memory Management Functions

This function is supported only by cluster versions 9.1.0 and later.

pg_shared_chunk_detail(contextname char(64))

Description: This function queries information about all chunks requested by the memory context in a specified shared memory.

The **contextname** parameter indicates the name of the memory context.

Before using this function, use the **pg_shared_chunk_dump(contextname char(64))** function to print related information to a file.

Return type: record

Example:

```
SELECT * FROM pg_shared_chunk_detail('pgstat file hash table');
   parent | level | file_name | line_number | chunk_size | requested_number | total_size
-----+-----+-----+-----+-----+-----+-----
pgstat file context | 2 | dynahash.cpp | 158 | 2048 | 1 | 2048
pgstat file context | 2 | dynahash.cpp | 158 | 256 | 1 | 256
pgstat file context | 2 | dynahash.cpp | 158 | 4096 | 9 | 36864
pgstat file context | 2 | dynahash.cpp | 158 | 8192 | 4 | 32768
(4 rows)
```

pv_session_chunk_detail(tid int, contextname char(64))

Description: This function queries information about all chunks applied for by a memory context created by a specified thread.

The **tid** parameter indicates the thread ID, while the **contextname** parameter indicates the memory context name.

To use this function, you need to use the **pv_session_chunk_dump(tid int, contextname char(64))** function to print related information to a file.

Return type: record

Example:

```
SELECT * FROM pv_session_chunk_detail(140178810990936, 'Timezones');
   parent | level | file_name | line_number | chunk_size | requested_number | total_size
-----+-----+-----+-----+-----+-----+-----
TopMemoryContext | 1 | dynahash.cpp | 158 | 1280 | 2 | 2560
TopMemoryContext | 1 | dynahash.cpp | 158 | 160 | 1 | 160
TopMemoryContext | 1 | dynahash.cpp | 158 | 2560 | 2 | 5120
TopMemoryContext | 1 | localtime.cpp | 1965 | 128 | 1 | 128
TopMemoryContext | 1 | localtime.cpp | 1965 | 448 | 1 | 448
(5 rows)
```

pg_shared_chunk_dump(contextname char(64))

Description: This function prints information about all chunks applied for by the memory context in the specified shared memory as a file.

The **contextname** parameter indicates the name of the memory context.

Return type: Boolean

Example:

```
SELECT * FROM pg_shared_chunk_dump('pgstat file hash table');
pg_shared_chunk_dump
-----
t
(1 row)
```

pv_session_chunk_dump(tid int, contextname char(64))

Description: This function prints information about all chunks applied for by a memory context created by a specified thread into a file.

The **tid** parameter indicates the thread ID, while the **contextname** parameter indicates the memory context name.

Return type: Boolean

Example:

```
SELECT * FROM pv_session_chunk_dump(140472797325280, 'Timezones');
pv_session_chunk_dump
-----
t
(1 row)
```

21.7.27.9 Other Functions

pgxc_pool_check()

Description: Checks whether the connection data buffered in the pool is consistent with **pgxc_node**. This parameter has been discarded in 8.3.0 and later cluster versions.

Return type: boolean

pgxc_pool_reload()

Description: Updates the connection information buffered in the pool.

Return type: boolean

pgxc_lock_for_backup()

Description: Locks the cluster before backup. Backup is performed to restore data on new nodes.

Return type: boolean

NOTE

pgxc_lock_for_backup locks a cluster before **gs_dump** or **gs_dumpall** is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.

pg_pool_validate(clear boolean, co_node_name cstring)

Description: Clears invalid backend threads on a CN. (These backend threads hold invalid pooler connections to standby DN's.)

Return type: record

pg_nodes_memory()

Description: queries the memory usage of all nodes.

Return type: record

table_skewness(text)

Description: queries the percentage of table data among all nodes.

Parameter: Indicates that the type of the name of the to-be-queried table is text.

Return type: record

table_skewness(table_name text, column_name text[, row_num text])

Description: Queries the proportion of column data distributed on each node based on the hash distribution rule. The results are sorted based on the data volumes of the nodes.

Parameters: **table_name** indicates a table name, **column_name** indicates a column name, and **row_num** indicates that all data in the current column is returned. The default value is **0**. A value other than **0** indicates the number of data records whose statistics are sampled. (Records are randomly sampled.)

Return type: record

Example:

Distribute data by hash based on the **a** column in the **tx** table. Seven records are distributed on DN 1, two records on DN 2, and one record on DN 0.

```
SELECT * FROM table_skewness('tx','a');
seqnum | num | ratio
-----+-----+-----
1      | 7   | 70.000%
2      | 2   | 20.000%
0      | 1   | 10.000%
(3 row)
```

table_data_skewness(data_row record, locatorType "char")

Description: Calculates the bucket distribution index for the records concatenated using the columns in a specified table.

Parameters: **data_row** indicates the record concatenated using columns in the specified table. **locatorType** indicates the distribution rule. You are advised to set **locatorType** to **H**, indicating hash distribution.

Return type: smallint

Example:

Calculates the bucket distribution index based on the hash distribution rule for the records combined concatenated using column **a** in the **tx** table.

```
select a, table_data_skewness(row(a), 'H') from tx;
a | table_data_skewness
--+-----+-----
3 |                    0
6 |                    2
7 |                    2
4 |                    1
5 |                    1
(5 rows)
```

table_distribution(schemaname text, tablename text)

Description: queries the storage space occupied by a specified table on each node.

Parameter: Indicates that the types of the schema name and table name for the table to be queried are both text.

Return type: record

 NOTE

- To query for the storage distribution of a specified table by using this function, you must have the **SELECT** permission for the table.
- The performance of **table_distribution** is better than that of **table_skewness**. Especially in a large cluster with a large amount of data, **table_distribution** is recommended.
- When you use **table_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

table_distribution(regclass)

Description: queries the storage space occupied by a specified table on each node.

Parameter: indicates the name or OID of the table to be queried. The table name can be defined by the schema name. Parameter type: regclass

Return type: record

 NOTE

- To query for the storage distribution of a specified table by using this function, you must have the **SELECT** permission for the table.
- The performance of **table_distribution** is better than that of **table_skewness**. Especially in a large cluster with a large amount of data, **table_distribution** is recommended.
- When you use **table_distribution** and want to view the space usage, you can use **dnsize** or **(sum(dnsize) over ())** to view the percentage.

table_distribution()

Description: queries the storage distribution of all tables in the current database.

Return type: record

 NOTE

- This function involves the query for information about all tables in the database. To execute this function, you must have the administrator rights or rights of the preset role **gs_role_read_all_stats**.
- Based on the **table_distribution()** function, DWS provides the **PGXC_GET_TABLE_SKEWNESS** view as an alternative way to query for data skew. You are advised to use this view when the number of tables in the database is less than 10000.

gs_table_distribution(schemaname text, tablename text)

Description: queries the storage space occupied by a specified table on each node.

Return type: record

Table 21-58 Fields returned by the **gs_table_distribution(schemaname text, tablename text)** function

| Name | Type | Description |
|------------|------|-------------|
| schemaname | name | Schema name |

| Name | Type | Description |
|----------------|-----------|--|
| tablename | name | Table name |
| relkind | character | Type. <ul style="list-style-type: none">• i: index• r: table |
| relpersistence | character | Type. <ul style="list-style-type: none">• t: local temporary table• g: global temporary table• u: unlogged table• p: common table |
| nodename | name | Node name |
| dnsize | bigint | Storage space of the table on the node, in bytes. |
| sessionid | bigint | For a global temporary table, the session ID of each session is displayed. |

 NOTE

- To query for the storage distribution of a specified table by using this function, you must have the **SELECT** permission for the table.
- This function is based on the physical file storage space records in the **PG_RELFILENODE_SIZE** system catalog. Ensure that the GUC parameters **use_workload_manager** and **enable_perm_space** are enabled.
- The **gs_table_distribution** function performs slower than the **table_distribution** function when querying a single table. However, when querying the entire database, the **gs_table_distribution** function shows significantly better performance. For large clusters with a substantial amount of data, it is recommended to use the **gs_table_distribution** function to query all tables in the database.
- For a global temporary table, the distribution of each session in the storage space is displayed. The **sessionid** column is used to distinguish sessions.

gs_table_distribution()

Description: quickly queries the storage distribution of all tables in the current database.

Return type: record

Table 21-59 Fields returned by the **gs_table_distribution()** function

| Name | Type | Description |
|------------|------|-------------|
| schemaname | name | Schema name |
| tablename | name | Table name |

| Name | Type | Description |
|----------------|-----------|--|
| relkind | character | Type of the table. i : index; r : table. |
| relpersistence | character | Type. <ul style="list-style-type: none">• t: local temporary table• g: global temporary table• u: unlogged table• p: common table |
| nodename | name | Node name |
| dnsize | bigint | Storage space of the table on the node, in bytes. |
| sessionid | bigint | For a global temporary table, the session ID of each session is displayed. |

 NOTE

- To query for the storage distribution of a specified table by using this function, you must have the **SELECT** permission for the table.
- This function is based on the physical file storage space records in the **PG_RELFILENODE_SIZE** system catalog. Ensure that the GUC parameters **use_workload_manager** and **enable_perm_space** are enabled.
- The **gs_table_distribution** function performs slower than the **table_distribution** function when querying a single table. However, when querying the entire database, the **gs_table_distribution** function shows significantly better performance. For large clusters with a substantial amount of data, it is recommended to use the **gs_table_distribution** function to query all tables in the database.
- Based on the **gs_table_distribution()** function, DWS 8.2.1 and later versions provide the **PGXC_WLM_TABLE_DISTRIBUTION_SKEWNESS** view for data skew query. You are advised to use this view when the number of tables in the database is small (less than 10,000).

check_foreign_key_constraint(schema.table)

Description: Checks whether data in a foreign key table meets foreign key constraints. This is supported only by clusters of version 9.1.0.200 or later.

Return type: text

Example:

```
set info_constraint_options = 'foreign_key';

CREATE TABLE ptt1 (a int,b int,e varchar(50),f varchar(50),PRIMARY KEY (a,b)) DISTRIBUTE BY HASH(a,b);
CREATE TABLE tt2 (a int , b int, c int, d int) DISTRIBUTE BY HASH(a,b);

select check_foreign_key_constraint('table_constraints.tt2');
check_foreign_key_constraint
-----
tt2 table has no foreign key constraint

ALTER TABLE tt2 ADD CONSTRAINT fk_tt1_a FOREIGN KEY (a,b) REFERENCES ptt1(a,b);
```

```
select check_foreign_key_constraint('table_constraints.tt2');
check_foreign_key_constraint
-----
tt2 satisfied all Foreign key constraints
```

plan_seed()

Description: Obtains the seed value of the previous query statement (internal use).

Return type: integer

pg_stat_get_env()

Description: Obtains the environment variable information about the current node.

Return type: record

pg_stat_get_thread()

Description: Provides information about the status of all threads under the current node.

Return type: record

pgxc_get_os_threads()

Description: Provides information about the status of threads under all normal nodes in a cluster.

Return type: record

pg_stat_get_sql_count()

Description: Provides statistics on the number of **SELECT/UPDATE/INSERT/DELETE/MERGE INTO** statements executed by all users on the current node, response time, and the number of DDL, DML, and DCL statements.

Return type: record

pgxc_get_sql_count()

Description: Provides statistics on the number of **SELECT/UPDATE/INSERT/DELETE/MERGE INTO** statements executed by all users on all nodes of the current cluster, response time, and the number of DDL, DML, and DCL statements.

Return type: record

pgxc_get_workload_sql_count()

Description: Provides statistics on the number of **SELECT/UPDATE/INSERT/DELETE** statements executed in all workload Cgroup on all CNs of the current cluster and the number of DDL, DML, and DCL statements.

Return type: record

pgxc_get_workload_sql_elapse_time()

Description: Provides statistics on response time of **SELECT/UPDATE/INSERT/DELETE** statements executed in all workload Cgroup on all CNs of the current cluster.

Return type: record

get_instr_unique_sql()

Description: Provides information about Unique SQL statistics collected on the current node. If the node is a CN, the system returns the complete information about the Unique SQL statistics collected on the CN. That is, the system collects and summarizes the information about the Unique SQL statistics on other CNs and DNs. If the node is a DN, the Unique SQL statistics on the DN is returned. For details, see the **GS_INSTR_UNIQUE_SQL** view.

Return type: record

reset_instr_unique_sql(cstring, cstring, INT8)

Description: Clears collected Unique SQL statistics. The input parameters are described as follows:

- **GLOBAL/LOCAL**: Data is cleared from all nodes or the current node.
- **ALL/BY_USERID/BY_CNID/BY_GUC**: **ALL** indicates that all data is cleared. **BY_USERID/BY_CNID** indicates that data is cleared by **USERID** or **CNID**. **BY_GUC** indicates that the clearance operation is caused by the decrease of the value of the GUC parameter **instr_unique_sql_count**.
- The third parameter corresponds to the second parameter. The parameter is invalid for **ALL/BY_GUC**.

Return type: bool

pgxc_get_instr_unique_sql()

Description: Provides complete information about Unique SQL statistics collected on all CNs in a cluster. This function can be executed only on CNs.

Return type: record

get_instr_unique_sql_remote_cns()

Description: Provides complete information about Unique SQL statements collected on all CNs in the cluster, except the CN on which the function is being executed. This function can be executed only on CNs.

Return type: record

pgxc_get_node_env()

Description: Provides the environment variable information about all nodes in a cluster.

Return type: record

gs_switch_relfilenode()

Description: Exchanges meta information of two tables or partitions. (This is only used for the redistribution tool. An error message is displayed when the function is directly used by users).

Return type: integer

copy_error_log_create()

Description: Creates the error table (**public.pgxc_copy_error_log**) required for creating the **COPY FROM** error tolerance mechanism.

Return type: boolean

NOTE

- This function attempts to create the **public.pgxc_copy_error_log** table. For details about the table, see [Table 21-60](#).
- Create the B-tree index on the **relname** column and execute **REVOKE ALL on public.pgxc_copy_error_log FROM public** to manage permissions for the error table (the permissions are the same as those of the **COPY** statement).
- **public.pgxc_copy_error_log** is a row-store table. Therefore, this function can be executed and **COPY FROM** error tolerance is available only when row-store tables can be created in the cluster. After the GUC parameter **enable_hadoop_env** is enabled, row-based tables cannot be created in the cluster. The default value for DWS is **off**.
- Same as the error table and the **COPY** statement, the function requires **sysadmin** or higher permissions.
- If the **public.pgxc_copy_error_log** table or the **copy_error_log_relname_idx** index already exists before the function creates it, the function will report an error and roll back.

Table 21-60 Error table public.pgxc_copy_error_log

| Column | Type | Description |
|-----------|--------------------------|---|
| relname | varchar | Table name in the form of <i>Schema name.Table name</i> |
| begintime | timestamp with time zone | Time when a data format error was reported |
| filename | varchar | Name of the source data file where a data format error occurs |
| rownum | bigint | Number of the row where a data format error occurs in a source data file |
| rawrecord | text | Raw record of a data format error in the source data file To prevent a field from being too long, the length of the field cannot exceed 1024 bytes. |
| detail | text | Error details |

| Column | Type | Description |
|------------|---------|---|
| columnname | varchar | Name of the column whose data format is incorrect in the data source file. Only 8.2.1.100 and later versions support this function. |
| errcode | varchar | Error code corresponding to the error information. The sqlstate error code is used. Only 8.2.1.100 and later versions support this function. |
| queryid | bigint | ID of the SQL statement for executing the Copy statement. It uniquely identifies an SQL statement. Only 8.2.1.100 and later versions support this function. |

pv_compute_pool_workload()

Description: Provides the current load information about computing Node Groups on cloud.

Return type: record

pg_stat_get_status(tid, num_node_display)

Description: Queries for the blocking and waiting status of the backend threads and auxiliary threads in the current instance. For details about the returned results, see the PG_THREAD_WAIT_STATUS view. The input parameters are described as follows:

- **tid**: thread ID, which is of the bigint type. If this parameter is null, the waiting statuses of all backend threads and auxiliary threads are returned. Otherwise, only the waiting statuses of threads with the specified IDs are returned.
- **num_node_display**: integer type. Specifies the maximum number of waiting nodes displayed in the **wait_status** column for records whose waiting status is **wait node**.
 - If this parameter is left empty or set to a value less than or equal to **0**, only one waiting node is displayed.
 - If the value is greater than **20**, a maximum number of nodes can be displayed is **20**.
 - If the value is greater than **0** and less than or equal to **20**, the smaller value between **num_node_display** and the actual number of waiting nodes is displayed. Use the **SELECT * from pg_stat_get_status(NULL, 10)** query for example. If the number of waiting nodes is greater than **10**, the names of only 10 nodes are displayed randomly. If the number of waiting nodes is less than or equal to **10**, the names of all waiting nodes are displayed. If the number of waiting nodes is greater than the number of displayed nodes, the displayed node names are randomly selected.

Return type: record

pgxc_get_thread_wait_status(num_node_display)

Description: Queries for the call hierarchy between threads generated by all SQL statements on each node in a cluster, as well as the block waiting status of each thread. For details about the returned results, see the PGXC_THREAD_WAIT_STATUS view. The type and meaning of the input parameter **num_node_display** are the same as those of the **pg_stat_get_status** function.

Return type: record

pgxc_os_run_info()

Description: Obtains the running status of the operating system on each node in a cluster. For details about the returned results, see "System Catalogs > System Views > PV_OS_RUN_INFO" in the *Developer Guide*.

Return type: record

get_instr_wait_event()

Description: obtains the waiting status and events of the current instance. For details about the returned results, see "System Catalogs > System Views > GS_WAIT_EVENTS" in the *Developer Guide*. If the GUC parameter **enable_track_wait_event** is **off**, this function returns **0**.

Return type: record

pgxc_wait_events()

Description: queries statistics about waiting status and events on each node in a cluster. For details about the returned results, see "System Catalogs > System Views > PGXC_WAIT_EVENTS" in the *Developer Guide*. If the GUC parameter **enable_track_wait_event** is **off**, this function returns **0**.

Return type: record

pgxc_stat_bgwriter()

Description: queries statistics about backend write processes on each node in a cluster. For details about the returned results, see "System Catalogs > System Views > PG_STAT_BGWRITER" in the *Developer Guide*.

Return type: record

pgxc_stat_replication()

Description: queries information about the log synchronization status on each node in a cluster, such as the location where the logs are sent and received. For details about the returned results, see "System Catalogs > System Views > PG_STAT_REPLICATION" in the *Developer Guide*.

Return type: record

pgxc_replication_slots()

Description: queries the replication status on each DN in a cluster. For details about the returned results, see "System Catalogs > System Views > PG_REPLICATION_SLOTS" in the *Developer Guide*.

Return type: record

pgxc_settings()

Description: queries information about runtime parameters on each node in a cluster. For details about the returned results, see "System Catalogs > System Views > PG_SETTINGS" in the *Developer Guide*.

Return type: record

pgxc_instance_time()

Description: queries the running time statistics of each node in a cluster and the time consumed in each execution phase. For details about the returned results, see "System Catalogs > System Views > PV_INSTANCE_TIME" in the *Developer Guide*.

Return type: record

pg_stat_get_redo_stat()

Description: queries Xlog redo statistics on the current node. For details about the returned results, see "System Catalogs > System Views > PV_REDO_STAT" in the *Developer Guide*.

Return type: record

pgxc_redo_stat()

Description: queries the Xlog redo statistics of each node in a cluster. For details about the returned results, see "System Catalogs > System Views > PV_REDO_STAT" in the *Developer Guide*.

Return type: record

get_local_rel_iostat()

Description: Obtains the disk I/O statistics of the current instance. For details about the returned results, see "System Catalogs > System Views > GS_REL_IOSTAT" in the *Developer Guide*.

Return type: record

pgxc_rel_iostat()

Description: queries the disk I/O statistics on each node in a cluster. For details about the returned result, see "System Catalogs > System Views > GS_REL_IOSTAT" in the *Developer Guide*.

Return type: record

get_node_stat_reset_time()

Description: Obtains the time when statistics of the current instance were reset.

Return type: timestampz

pgxc_node_stat_reset_time()

Description: queries the time when the statistics of each node in a cluster are reset. For details about the returned result, see "System Catalogs > System Views > GS_NODE_STAT_RESET_TIME" in the *Developer Guide*.

Return type: record

NOTE

When an instance is running, its statistics keep rising. In the following cases, the statistical values in the memory will be reset to 0:

- The instance is restarted or a cluster switchover occurs.
- The database is dropped.
- A reset operation is performed. For example, the statistics counter in the database is reset using the **pgstat_recv_resetcounter** function or the Unique SQL statements are cleared using the **reset_instr_unique_sql** function.

If any of the preceding events occurs, DWS will record the time when the statistics are reset. You can query the time using the **get_node_stat_reset_time** function.

pgxc_parallel_query(text, text)

Description: Runs a specified SQL query statement on a data instance of a specified type and returns the query result to the current CN. This function is supported in 8.1.2 or later.

The function has two parameters:

The first parameter specifies the instances on which the SQL statement is executed. Currently, the valid input parameters are **dn**, **datanode**, **cn**, **coordinator**, and **all**. Other values will cause function execution errors. **dn** and **datanode** indicate that the statement is executed on all DNs. **cn** and **coordinator** indicate that the statement is executed on all CNs. **all** indicates that the statement is executed on all CNs and DNs.

The second parameter specifies the verification of the objects queried by the SQL statement that is to be sent to a remote node for execution. User tables, distributed tables, and user-defined functions with multiple result sets are not supported.

Return type: record

 NOTE

- This function is only used by developers to efficiently collect the execution information or status of instances in a cluster. You are not advised to use it directly.
- This function contains multiple result sets, and the return data type is record. Therefore, you need to add the output column name and data type specified by the **AS** statement after the function call, as shown in the following:

```
SELECT * FROM pgxc_parallel_query('all', 'select node_name, db_name, thread_name, query_id, tid, lwtid, ptid, tlevel, smpid, wait_status, wait_event from pg_thread_wait_status') AS (node_name text, db_name text, thread_name text, query_id bigint, tid bigint, lwtid integer, ptid integer, tlevel integer, smpid integer, wait_status text, wait_event text);
```
- The data type of the output result of the SQL statement specified by the second parameter of the function must be the same as the data type specified by the **AS** statement. Otherwise, an error may be reported during execution due to type mismatch.
- The SQL statement specified by the second parameter of the function cannot trigger cross-node query. Otherwise, an error is reported.
- The SQL statement specified by the second parameter of the function can only be a **SELECT**, **UPDATE**, **DELETE**, or **INSERT** statement.
 - The **returning** statement is not supported.
 - The user who invokes the function must have the operation permission on the SQL objects.
 - For **INSERT** statements, **INSERT OVERWRITE**, **UPSERT**, and **INSERT INTO** are not supported.
 - The **UPDATE**, **DELETE**, and **INSERT** statements can be executed only by the initial user in in-place upgrade mode or by the administrator in redistribution mode. The number of records modified by the statements on each instance must be the same. Otherwise, an error will be reported during statement execution. The function outputs a column of values of the bigint type. These values indicate the number of records operated by the statement on each instance.

```
SELECT * FROM pgxc_parallel_query('cn', 'UPDATE pg_partition SET relpages = 0') AS (updated bigint);
```

create_wdr_snapshot()

Description: Creates a performance data snapshot.

Return type: text

 NOTE

- Only the database administrator **SYSADMIN** can execute this function.
- This function can be executed only on CNs. If it is executed on DN, the following message will be returned: "WDR snapshot can only be created on coordinator."
- Before executing this function, ensure that the value of **enable_wdr_snapshot** is **on**. If its value is **off**, the following message will be returned for this function: "WDR snapshot request cannot be executed, because GUC parameter 'enable_wdr_snapshot' is off."
- If the snapshot thread is not started for some reason, for example, the node is restarted, the following message will be returned for this function: "WDR snapshot request cannot be accepted, please retry later."
- If this function fails to be executed, the following message will be returned: "Cannot respond to WDR snapshot request."
- If this function is successfully executed, the following message will be returned: "WDR snapshot request has been submitted." This message indicates that the snapshot creation request has been sent to the background snapshot thread, but does not mean that the snapshot has been successfully created.

kill_snapshot(scope cstring)

Description: kills the background snapshot thread. This function sends a command to the background snapshot thread and waits for the thread to stop.

The input parameter **scope** indicates the operation scope. Its value can be **local** or **global**.

- Value **local** indicates killing the snapshot thread on the current CN.
- Value **global** indicates killing the snapshot thread on the current CN as well as those on all the other CNs in the cluster.
- If any other value is passed, error message "Scope is invalid, use "local" or "global"." is displayed.
- The input parameter can be left empty, in which case the default value **local** will be used.

Return type: none

NOTE

- Only the database administrator **SYSADMIN** can execute this function.
- This function can be executed only on CNs. If it is executed on DN, the following message will be returned: "kill_snapshot can only be executed on coordinator."
- Executing this function sends a kill signal to the background snapshot thread and waits for it to finish. If the snapshot thread is not killed within 100s, the error message "Kill snapshot thread failed" is displayed.

generate_wdr_report(begin_snap_id bigint, end_snap_id bigint, report_type cstring, report_scope cstring, node_name cstring)

Description: Creates a load analysis report.

The input parameters are described as follows:

- **begin_snap_id** and **end_snap_id**: IDs of the start and end snapshots, respectively. The IDs are of the bigint type. The value of **begin_snap_id** must be less than that of **end_snap_id**, and the time for the start and end snapshots cannot overlap. You can check whether the snapshot time overlaps by querying **select s1.end_ts < s2.start_ts from (select * from dbms_om.snapshot where snapshot_id=end_snap_id) as s2;** in the **dbms_om.snapshot** table. If **true** is returned, the snapshot time does not overlap. Otherwise, the snapshot time overlaps.
- **report_type**: report type. The value is a cstring and can be **summary**, **detail**, or **all**.
- **report_scope**: report scope. The value is a cstring and can be **cluster** or **node**.
- **node_name**: node name. The value is a cstring. If **report_scope** is **node**, the value of this parameter must be **pg_catalog**, which indicates the CN or DN name in the **node_name** column of the **pgxc_node** table.

Return type: text

 NOTE

- Only the database administrator **SYSADMIN** can execute this function.
- This function can be executed only on CNs. If it is executed on DN, the following message will be returned: "WDR report can only be created on coordinator."
- If the report is created successfully, message "Report %s has been generated" will be returned.
- The statistics cannot be reset between the time the start snapshot is taken and the time the end snapshot is taken. Otherwise, error message "Instance reset time is different" will be displayed. For details about the events that cause a statistics reset, see the [pgxc_node_stat_reset_time](#) function.

wdr_xdb_query(db_name text, snapshot_id bigint, view_name text)

Description: Queries a specified view in a specified database. The query results of some views vary depending on databases. For example, the **global_table_stat** view is used to query the statistics of a table. The results of querying this view vary because tables in different databases are different. The **wdr_xdb_query** function can access the database specified by **db_name** in the current connection and query the view specified by **view_name** in the database. The input parameters are described as follows:

- **db_name**: specifies the name of a database. The value is of the text type.
- **snapshot_id**: specifies the snapshot ID. The value is of the bigint type. For details, see section "Performance View Snapshot" in *Data Warehouse Service (DWS) Developer Guide*.
- **view_name**: specifies the name of a view. The value is of the text type. The view name must be in the following whitelist:
 - global_table_stat
 - global_table_change_stat
 - global_column_table_io_stat
 - global_row_table_io_stat

The return value type is record. The first column is **snapshot_id bigint**, and the second column is **db_name text**. The names, types, and sequences of other columns are the same as those of the views specified by **view_name**.

Example:

```
select snapshot_id, db_name, schemaname, relname, distribute_mode,
seq_scan ,seq_tuple_read ,index_scan ,index_tuple_read ,tuple_inserted
,tuple_updated ,tuple_deleted ,tuple_hot_updated ,live_tuples ,dead_tuples from
wdr_xdb_query('postgres':text, 1, 'global_table_stat':text) as i(snapshot_id bigint, db_name text,
schemaname name, relname name, distribute_mode char, seq_scan bigint, seq_tuple_read
bigint, index_scan bigint, index_tuple_read bigint, tuple_inserted bigint, tuple_updated bigint,
tuple_deleted bigint, tuple_hot_updated bigint, live_tuples bigint, dead_tuples bigint);
```

 NOTE

- This function is supported only in 8.1.2 or later.
- Only the database administrator **SYSADMIN** can execute this function.
- This function can be used to query only the views in the whitelist. If you use this function to query other views, the error message **Input view name is invalid.** will be displayed.

vac_fileclear_relation(oid)

Description: Forcibly clears VACUUM rewritten files in a specified column-store table to reclaim space.

Parameter: OID of a column-store table.

Return type: integer

NOTE

- Before using this function, set **colvacuum_threshold_scale_factor** and ensure that the files are cleared and space reclaimed only after the VACUUM process has rewritten the files of the specified column-store table.
- This function exclusively locks a specified column-store table.
- This function cannot be used after DDL delay is enabled.

vac_fileclear_all_relation()

Description: Forcibly clears VACUUM rewritten files in all specified column-store tables to reclaim space.

Return type: record

NOTE

This function cannot be used after DDL delay is enabled.

get_col_file_info(table_name)

Description: Queries the number of empty CU files and the total number of CU files in a specified column-store table. This function is supported only in cluster 8.2.0 and later versions.

Parameter: Name of a column-store table.

Return type: int

Fields in the returned value:

- **total_file_num int**: total number of CU files. The value ranges from **-1** to **INT_MAX**. **-1** indicates a failure, which could be caused by unsupported table types. The values in the range **0** to **INT_MAX** indicates the total number of files.
- **empty_file_num int**: number of empty CU files. The value ranges from **-1** to **INT_MAX**. **-1** indicates a failure, which could be caused by unsupported table types. The values in the range **0** to **INT_MAX** indicates the total number of empty files.

Example:

```
call get_col_file_info('t4');
total_file_num | empty_file_num
-----+-----
10 | 7
(1 row)
```

get_all_col_file_info()

Description: Queries the number of empty CU files and the total number of CU files in all column-store tables. This function is supported only in cluster 8.2.0 and later versions.

Return type: record

Fields in the returned value:

- **space_name text**: schema to which the column-store tables belong
- **table_name text**: name of a column-store table
- **total_file_num int**: total number of CU files. The value ranges from **-1** to **INT_MAX**. **-1** indicates a failure, which could be caused by unsupported table types. The values in the range **0** to **INT_MAX** indicates the total number of files.
- **empty_file_num int**: number of empty CU files. The value ranges from **-1** to **INT_MAX**. **-1** indicates a failure, which could be caused by unsupported table types. The values in the range **0** to **INT_MAX** indicates the total number of empty files.

Example:

```
call get_all_col_file_info();
space_name | table_name | total_file_num | empty_file_num
-----+-----+-----+-----
public    | t4        | 10             | 7
public    | t2        | 1              | 1
public    | t1        | 3              | 0
(3 rows)
```

pg_get_bucket_epoch(relid)

Description: Queries the **epoch** value of the **v3** table on the current node. To print the **epoch** values of all subpartitions in a partitioned table, you must provide the OID of the parent table. This function can be executed only in VW write scenarios. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: record

Fields in the returned value:

- **relfilenode oid**: column-store **relfilenode** of a non-partitioned table. For a partitioned table, the value is **0**.
- **partfilenode oid**: **relfilenode** of a column-store partitioned table. For a non-partitioned table, the value is **0**.
- **epoch xid**: **epoch** value corresponding to the table on the current node.

Example:

```
select * from pg_get_bucket_epoch(2147483732);
relfilenode | partfilenode | epoch
-----+-----+-----
2137383742 | 0            | 1000001
(1 row)
```

pg_get_bucket_epoch(tablespaceid, databaseid, relfilenode)

Description: Queries the **epoch** value of the **v3** table on the current node. Enter the OID of the tablespace where the **v3** table is located, the OID of the database,

and the **relfilenode** corresponding to the table. This function can be executed in both VW write and read scenarios. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: xid

Fields in the returned value:

epoch xid: **epoch** value corresponding to the table on the current node.

Example:

```
select * from pg_get_bucket_epoch(2147483729, 16792, 2147483732);
epoch
-----
1000001
(1 row)
```

pgxc_get_bucket_epoch(tablespaceid, databaseid, relfilenode)

Description: Queries the **epoch** values of the **v3** table on all DN. Enter the OID of the tablespace where the **v3** table is located, the OID of the database, and the **relfilenode** corresponding to the table. This function can be executed in both VW write and read scenarios. This function is supported only by clusters of version 9.1.0.200 or later.

Return type: record

Fields in the returned value:

- **nodename text:** node name
- **epoch xid:** **epoch** value corresponding to the table on the current node.

Example:

```
select * from pgxc_get_bucket_epoch(2147483729, 16792, 2147483732);
nodename | epoch
-----+-----
datanode3 | 1000001
datanode1 |      0
datanode2 |      0
(1 row)
```

current_temp_schema()

Description: Returns the temporary schema of the current session. If the current session does not have a temporary schema, null is returned. This function is supported by clusters of version 8.2.1.220 or later.

Return type: name

Example:

```
select current_temp_schema();
current_temp_schema
-----
(1 row)
create temp table tmp1(a int,b int) distribute by hash(a);
CREATE TABLE
select current_temp_schema();
current_temp_schema
-----
```

```
pg_temp_coordinator1_2_2_140718823485088
(1 row)
```

get_volatile_pg_class()

Description: Obtains the **pg_class** metadata related to all volatile temporary tables in the current session. This parameter is supported by version 8.2.0 or later clusters.

Return type: record

Fields in the returned value:

- **oid**: OID of the volatile temporary table.
- Other fields: same as the fields (excluding hidden fields) in the **pg_class system catalog**.

get_volatile_pg_class(relname text)

Description: Obtains the **pg_class** metadata related to a specified volatile temporary table in the current session. This parameter is supported by version 8.2.0 or later clusters.

Parameter: name of the **volatile** temporary table in the current session.

Return type: record

Fields in the returned value:

- **oid**: OID of the volatile temporary table.
- Other fields: same as the fields (excluding hidden fields) in the **pg_class system catalog**.

Example:

```
SELECT * FROM get_volatile_pg_class('tx1');
 oid | relname | relnamespace | reltype | reloftype | relowner | relam | relfilenode | reltablespace | relpages |
 reltuples | relallvisible | reltoastrelid | reltoastidxid | reldeltarelid |
 reldeltaidx | relcudescrid | relcudescidx | relhasindex | relisshared | relpersistence | relkind | relnatts |
 relchecks | relhasoids | relhaspkey | relhasrules | relhastriggers | relhassub
 class | relcmprr | relhasclusterkey | relrowmovement | parttype | relfrozenxid | relacl |
 reloptions | relreplident | relfrozenxid64
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
16772 | tx1 | 16770 | 16774 | 0 | 10 | 0 | 16772 | 1665 | 0 | 0
| 0 | 16775 | 0 | 0 |
| 0 | 0 | 0 | f | f | v | r | 2 | 0 | f | f |
f | f | f | f | n | 11815 | | {orientation=row,compression=no} |
d | 11815
(1 row)
```

get_volatile_pg_attribute()

Description: Obtains the **pg_attribute** metadata related to all volatile temporary tables in the current session. This parameter is supported by version 8.2.0 or later clusters.

Return type: record

Fields in the returned value:

- **oid**: OID of the column.
- Other fields: same as the fields (excluding hidden fields) in the **pg_attribute** catalog.

get_volatile_pg_attribute(relname text, attrname text)

Description: Obtains the **pg_attribute** metadata related to a specified volatile temporary table in the current session. This parameter is supported by version 8.2.0 or later clusters.

Parameter:

- **relname**: table name (must be in the current session).
- **attrname**: column name.

Return type: record

Fields in the returned value:

- **oid**: OID of the column.
- Other fields: same as the fields (excluding hidden fields) in the **pg_attribute** catalog.

Example:

```
SELECT * FROM get_volatile_pg_attribute('tx1', 'b');
 attrelid | attname | atttypid | attstattarget | attlen | attnum | attndims | attcacheoff | atttypmod | attbyval |
 attstorage | attalign | attnotnull | atthasdef | attisdropped | attislocal |
 attcmprmode | attinhcount | attcollation | attacl | attoptions | attfdwoptions | attinitdefval | attkvtype
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 16772 | b       | f         |      25       |    -1   |     -1   |     2     |     0        |    -1     |    -1     | f         | x         | i         |
 127   |         |           |      0        |    100  |          |           |             |           |           | 0         |           |           |
(1 row)
```

pg_get_publication_tables(pubname text)

Description: Returns the relid list of tables to be published based on the publication name. This function is supported by version 8.2.0.100 or later clusters.

Parameter: **pubname**

Return type: set of OID

Example:

```
SELECT * FROM pg_get_publication_tables('mypub');
 relid
-----
 16757
 16776
(2 rows)
```

pg_relation_is_publishable(relname regclass)

Description: Checks whether a table can be published. This function is supported by version 8.2.0.100 or later clusters.

Parameter: **relname**

Return type: Boolean

Example:

```
SELECT * FROM pg_relation_is_publishable('t1');
pg_relation_is_publishable
-----
t
(1 row)
```

get_col_cu_info(schema_name text, table_name text, row_count int8, dirty_percent int8)

Description: Queries the CU information of a column-store table. The CU information of each partition is collected separately. This function is supported by version 8.2.0.100 or later clusters.

Parameters: schema name (mandatory), table name (mandatory), threshold for the number of rows in a small CU (optional, 200 by default, ranging from 1 to 60000, and percentage threshold for deleting dirty CUs (optional, 70 by default, ranging from 1 to 100)

Return type: record

Fields in the returned value:

node_name: DN name.

part_name: partition name. This column is empty for a common table.

zero_size_cu_count: number of CUs whose **cuSize** is **0** and number of rows is less than or equal to **row_count**.

small_cu_count: number of CUs whose **cuSize** is **ALIGNOF_CUSIZE(8192)** and number of rows is less than or equal to **row_count**.

dirty_cu_count: number of CUs whose deadtupe percentage exceeds **dirty_percent** due to deletion.

total_cu_count: total number of CUs.

small_cu_size: total size of 8 KB CUs.

total_cu_size: total CU size.

Example:

```
SELECT * FROM get_col_cu_info('public','hs_part');
node_name | part_name | zero_size_cu_count | small_cu_count | dirty_cu_count | total_cu_count |
small_cu_size | total_cu_size
-----+-----+-----+-----+-----+-----+-----+-----
dn_1      | p1        | 3 | 0 | 0 | 3 | 0 bytes | 0 bytes
dn_1      | p2        | 3 | 0 | 0 | 3 | 0 bytes | 0 bytes
dn_1      | p3        | 3 | 0 | 0 | 3 | 0 bytes | 0 bytes
(3 rows)
```

```
SELECT * FROM get_col_cu_info('public','hs_part', 200, 90);
node_name | part_name | zero_size_cu_count | small_cu_count | dirty_cu_count | total_cu_count |
small_cu_size | total_cu_size
-----+-----+-----+-----+-----+-----+-----+-----
dn_1      | p1        |          3         |          0      |          0      |          3      | 0 bytes | 0 bytes
dn_1      | p2        |          3         |          0      |          0      |          3      | 0 bytes | 0 bytes
dn_1      | p3        |          3         |          0      |          0      |          3      | 0 bytes | 0 bytes
(3 rows)
```

get_col_file_vacuum_info(schema_name text, table_name text, force_get_rewritten_file_num bool)

Description: Queries the vacuum information of a column-store table. The vacuum information of each partition is collected separately. This function is supported by version 8.2.0.100 or later clusters.

Parameters: schema name (mandatory), table name (mandatory), and whether to forcibly obtain the precise number of files that can be cleared (mandatory, **false** by default)

Return type: record

Fields in the returned value:

node_name: DN name.

part_name: partition name. This column is empty for a common table.

total_file_num: total number of CU files.

rewritable_file_num: number of files that can be rewritten but have not been rewritten.

rewritten_file_num: number of files that have been rewritten but have not been cleared. The value is obtained from data in the memory. If the memory data is lost due to reasons such as restart, you can set **force_get_rewritten_file_num=true** to forcibly obtain the accurate number of files that can be cleared.

empty_file_num: number of cleared files.

Example:

```
SELECT * FROM get_col_file_vacuum_info('public','pa',false);
node_name | part_name | total_file_num | rewritable_file_num | rewritten_file_num | empty_file_num
-----+-----+-----+-----+-----+-----
datanode1 | pa1       |          1     |          0          |          0          |          0
datanode1 | pa2       |          1     |          0          |          0          |          0
datanode2 | pa1       |          1     |          0          |          0          |          0
datanode2 | pa2       |          1     |          0          |          0          |          0
datanode3 | pa1       |          1     |          0          |          0          |          0
datanode3 | pa2       |          1     |          0          |          0          |          0

```

get_col_file_vacuum_info(schema_name text, table_name text, colvacuum_threshold_scale_factor int)

Description: Queries the vacuum information of a column-store table. The vacuum information of each partition is collected separately. This function is supported by version 8.2.0.100 or later clusters.

Parameters: schema name (mandatory), table name (mandatory), and **colvacuum_threshold_scale_factor** (mandatory. The value range is 0 to 100, indicating the ratio of dead tuples.)

Return type: record

Return value:

node_name: DN name.

part_name: partition name. This column is empty for a common table.

total_file_num: total number of CU files.

rewritable_file_num: number of files that can be rewritten but have not been rewritten.

rewritten_file_num: number of files that have been rewritten but have not been cleared. The value is obtained from data in the memory. If the memory data is lost due to reasons such as restart, you can set **force_get_rewritten_file_num=true** to forcibly obtain the accurate number of files that can be cleared.

empty_file_num: number of cleared files.

Example:

```
SELECT * FROM get_col_file_vacuum_info('public','pa',10);
```

| node_name | part_name | total_file_num | rewritable_file_num | rewritten_file_num | empty_file_num |
|-----------|-----------|----------------|---------------------|--------------------|----------------|
| datanode1 | pa1 | 1 | 0 | 0 | 0 |
| datanode1 | pa2 | 1 | 0 | 0 | 0 |
| datanode2 | pa1 | 1 | 0 | 0 | 0 |
| datanode2 | pa2 | 1 | 0 | 0 | 0 |
| datanode3 | pa1 | 1 | 0 | 0 | 0 |
| datanode3 | pa2 | 1 | 0 | 0 | 0 |

(6 rows)

get_all_col_cu_info(row_count int8)

Description: Queries the CU information of all column-store tables in the database. This function is supported by version 8.2.0.100 or later clusters.

Parameter: threshold for the number of rows in a small CU (optional, **200** by default, and ranging from **1** to **60000**)

Return type: record

Fields in the returned value:

node_name: DN name.

schema_name: schema name.

table_name: table name.

zero_size_cu_count: number of CUs whose **cuSize** is **0** and number of rows is less than or equal to **row_count**.

small_cu_count: number of CUs whose **cuSize** is **ALIGNOF_CUSIZE(8192)** and number of rows is less than or equal to **row_count**.

total_cu_count: total number of CUs.

small_cu_size: total size of 8 KB CUs.

total_cu_size: total CU size.

Example:

```
SELECT * FROM get_all_col_cu_info(200);
```

| node_name | schema_name | table_name | zero_size_cu_count | small_cu_count | total_cu_count | small_cu_size | total_cu_size |
|-----------|-------------|------------|--------------------|----------------|----------------|---------------|---------------|
| datanode1 | public | udi_48076 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |
| datanode1 | public | udi_48077 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |
| datanode2 | public | udi_48076 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |
| datanode2 | public | udi_48077 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |
| datanode3 | public | udi_48076 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |
| datanode3 | public | udi_48077 | 5 | 1 | 6 | 8192 bytes | 8192 bytes |

(6 rows)

get_all_col_file_vacuum_info(force_get_rewritten_file_num bool)

Description: Queries the vacuum information of all column-store tables in the database. This function is supported by version 8.2.0.100 or later clusters.

Parameter: whether to forcibly obtain the accurate number of files that can be cleared (mandatory. It can be **true** or **false**.)

Return type: record

Fields in the returned value:

node_name: DN name.

schema_name: schema name.

table_name: table name.

total_file_num: total number of CU files.

rewritable_file_num: number of files that can be rewritten but have not been rewritten.

rewritten_file_num: number of files that have been rewritten but have not been cleared. The value is obtained from data in the memory. If the memory data is lost due to reasons such as restart, you can set **force_get_rewritten_file_num=true** to forcibly obtain the accurate number of files that can be cleared.

empty_file_num: number of cleared files.

Example:

```
SELECT * FROM get_all_col_file_vacuum_info(false);
```

| node_name | schema_name | table_name | total_file_num | rewritable_file_num | rewritten_file_num | empty_file_num |
|-----------|-------------|------------|----------------|---------------------|--------------------|----------------|
| datanode1 | public | udi_57373 | 2 | 0 | 0 | 1 |
| datanode1 | public | udi_57374 | 2 | 0 | 0 | 1 |
| datanode2 | public | udi_57373 | 2 | 0 | 0 | 1 |
| datanode2 | public | udi_57374 | 2 | 0 | 0 | 1 |
| datanode3 | public | udi_57373 | 2 | 0 | 0 | 1 |
| datanode3 | public | udi_57374 | 2 | 0 | 0 | 1 |

show_tsc_info()

Description: Queries the TimeStamp-Counter (TSC) information obtained from the current database node. This function is supported by version 8.2.1 or later clusters.

Return type: record

Table 21-61 Parameter

| Name | Type | Description |
|-----------------------|---------|---|
| node_name | text | Node name |
| tsc_mult | bigint | TSC conversion multiplier |
| tsc_shift | bigint | TSC conversion shifts |
| tsc_frequency | float8 | TSC frequency. |
| tsc_use_frequency | boolean | Indicates whether to use the TSC frequency for time conversion. |
| tsc_ready | boolean | Indicates whether the TSC frequency can be used for time conversion |
| tsc_scalar_error_info | text | Error information about obtaining TSC conversion information |
| tsc_freq_error_info | text | Error information about obtaining TSC frequency information |

Example:

```
SELECT * FROM show_tsc_info();
 node_name | tsc_mult | tsc_shift | tsc_frequency | tsc_use_frequency | tsc_ready |
 tsc_scalar_error_info | tsc_freq_error_info
-----+-----+-----+-----+-----+-----+-----
 coordinator1 |          |          | 2400 | t          | t          | TSC scalar is not initialized |
```

get_tsc_info()

Description: Re-obtains the TimeStamp-Counter (TSC) information of the current database node. This function is supported by version 8.2.1 or later clusters.

Return type: record

Table 21-62 show_tsc_info() return columns

| Column | Type | Description |
|-----------|--------|---------------------------|
| node_name | text | Node name |
| tsc_mult | bigint | TSC conversion multiplier |
| tsc_shift | bigint | TSC conversion shifts |

| Column | Type | Description |
|-----------------------|---------|---|
| tsc_frequency | float8 | TSC frequency |
| tsc_use_frequency | boolean | Indicates whether to use the TSC frequency for time conversion. |
| tsc_ready | boolean | Indicates whether the TSC frequency can be used for time conversion |
| tsc_scalar_error_info | text | Error information about obtaining TSC conversion information |
| tsc_freq_error_info | text | Error information about obtaining TSC frequency information |

Example:

```
SELECT * FROM get_tsc_info();
 node_name | tsc_mult | tsc_shift | tsc_frequency | tsc_use_frequency | tsc_ready |
 tsc_scalar_error_info | tsc_freq_error_info
-----+-----+-----+-----+-----+-----+-----
 coordinator1 |          |          | 2400 | t          | t          | TSC scalar is not initialized |
```

test_tsc_info(time float8, loops int)

Description: Tests the accuracy of the time converted using the TimeStamp-Counter (TSC) on the current node. This function is supported by version 8.2.1 or later clusters.

The input parameters are described as follows:

- **time**: indicates the test time difference (unit: s). The test duration must be less than or equal to 60s.
- **loops**: indicates the number of tests. The value ranges from 1 to 10.

Return type: record

Fields in the returned value:

- **id**: number of cycles.
- **real_time_diff**: time difference obtained using **gettimeofday** (unit: us).
- **est_time_scalar**: time difference (unit: μ s) converted using TSC conversion information.
- **est_time_frequency**: time difference (unit: μ s) converted using the TSC frequency.

Example:

```
SELECT * FROM test_tsc_info(0.01,10);
 id | real_time_diff | est_time_scalar | est_time_frequency
-----+-----+-----+-----
 1 | 10057 | 10056.9
 2 | 10057 | 10057.4816666667
 3 | 10056 | 10055.2841666667
 4 | 10054 | 10054.4908333333
```

| | | | | | | |
|----|--|-------|--|--|--|------------------|
| 5 | | 10055 | | | | 10054.2875 |
| 6 | | 10055 | | | | 10054.7483333333 |
| 7 | | 10055 | | | | 10054.4725 |
| 8 | | 10054 | | | | 10054.0766666667 |
| 9 | | 10058 | | | | 10058.1016666667 |
| 10 | | 10057 | | | | 10056.3733333333 |

(10 rows)

pgxc_recyclebin_purge

Description: This function traverses and clears objects in the recycle bin. It is supported only by 9.1.0.200 and later cluster versions.

Return type: void

Example:

```
SELECT * FROM pgxc_recyclebin_purge();
pgxc_recyclebin_purge
-----
(1 row)
```

21.7.28 Backup and Restoration Control Functions

21.7.28.1 Backup Control Functions

Backup control functions help online backup.

pg_create_restore_point(name text)

Description: Creates a named point for performing the restore operation (restricted to system administrators).

Return type: text

Note: **pg_create_restore_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery_target_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

pg_current_xlog_location()

Description: Obtains the write position of the current transaction log.

Return type: text

Note: **pg_current_xlog_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require rights of the system administrator.

Example:

```
SELECT pg_current_xlog_location();
pg_current_xlog_location
-----
0/4310D5D8
(1 row)
```

pg_current_xlog_insert_location()

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **pg_current_xlog_insert_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require rights of the system administrator.

Example:

```
SELECT pg_current_xlog_insert_location();
pg_current_xlog_insert_location
-----
0/4316AD50
(1 row)
```

pg_start_backup(label text [, fast boolean])

Description: Starts executing online backup (restricted to system administrators or replication roles).

Return type: text

Note: **pg_start_backup** receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database cluster and then returns the starting position of backed up transaction logs in text mode.

```
SELECT pg_start_backup('label_goes_here');
pg_start_backup
-----
0/3000020
(1 row)
```

pg_stop_backup()

Description: Completes online backup (restricted to system administrators or replication roles).

Return type: text

Note: **pg_stop_backup** deletes the label file created by **pg_start_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg_start_backup**, the starting and ending transaction log locations for the backup, and the starting and ending times of the backup. The return value is the backup's ending transaction log location. After the ending position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. This way, the ended transaction log file can be immediately archived so that backup is complete.

Example:

```
SELECT pg_stop_backup();
pg_stop_backup
```

```
-----  
0/4401E610  
(1 row)
```

pg_switch_xlog()

Description: Switches to a new transaction log file (restricted to system administrators).

Return type: text

Note: **pg_switch_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, **pg_switch_xlog** will do nothing but return the start location of the transaction log file currently in use.

Example:

```
SELECT pg_switch_xlog();  
pg_switch_xlog  
-----  
0/45017978  
(1 row)
```

pg_xlogfile_name(location text)

Description: Converts the position string in a transaction log to a file name.

Return type: text

Note: **pg_xlogfile_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

pg_xlogfile_name_offset(location text)

Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

Return type: text, integer

Note: **pg_xlogfile_name_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());  
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived  
NOTICE: pg_stop_backup complete, all required WAL segments have been archived  
  file_name      | file_offset  
-----+-----  
000000010000000000000003 |      272  
(1 row)
```

pg_xlog_location_diff(location text, location text)

Description: **pg_xlog_location_diff** calculates the difference in bytes between two transaction log locations.

Return type: numeric

`pg_cbm_tracked_location()`

Description: Queries for the LSN location parsed by CBM.

Return type: text

`pg_cbm_get_merged_file(startLSNArg text, endLSNArg text)`

Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

Return type: text

`pg_cbm_get_changed_block(startLSNArg text, endLSNArg text)`

Description: Combines CBM files within the specified LSN range into a table and return records of this table.

Return type: record

Note: The table columns include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of No. of modified pages.

`pg_cbm_recycle_file(slotName name, targetLSNArg text)`

Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion. If **slotName** is empty, **targetLSNArg** is used as the recycling point. During backup and DR, you need to specify a slot name due to parallelism. Record the **targetLSNArg** value of the task to the slot, traverse all backup slots, and find the smallest LSN as the recycling point.

Return type: text

`pg_cbm_force_track(targetLSNArg text,timeOut int)`

Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.

Return type: text

`pg_enable_delay_ddl_recycle()`

Description: Enables DDL delay and returns the Xlog position of the enabling point.

Return type: text

Example:

```
SELECT pg_enable_delay_ddl_recycle();
pg_enable_delay_ddl_recycle
-----
00000000/4607B250
(1 row)
```

pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)

Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect.

Return type: record

pg_enable_delay_xlog_recycle()

Description: Enables Xlog recycle delay.

Return type: void

Example:

```
SELECT pg_enable_delay_xlog_recycle();
pg_enable_delay_xlog_recycle
-----
(1 row)
```

pg_disable_delay_xlog_recycle()

Description: Disables Xlog recycle delay.

Return type: void

Example:

```
SELECT pg_disable_delay_xlog_recycle();
pg_disable_delay_xlog_recycle
-----
(1 row)
```

pgxc_get_senders_catchup_time()

Description: Displays the catchup information of the currently active primary/standby instance sending thread on all DN's.

Return type: record

The following information is returned:

Table 21-63 pgxc_get_senders_catchup_time() columns

| Column | Type | Description |
|------------|---------|-------------------------------------|
| node_name | text | Node name |
| lwpid | integer | Current sender lwpid |
| local_role | text | Local role |
| peer_role | text | Peer role |
| state | text | Current sender's replication status |
| sender | text | Current sender type |

| Column | Type | Description |
|------------------------|--------------------------|--|
| catchup_start | timestamp with time zone | Startup time of a catchup task |
| catchup_end | timestamp with time zone | End time of a catchup task |
| catchup_type | text | Catchup task type, full or incremental |
| catchup_bcm_filename | text | BCM file executed by the current catchup task |
| catchup_bcm_finished | integer | Number of BCM files completed by a catchup task |
| catchup_bcm_total | integer | Total number of BCM files to be operated by a catchup task |
| catchup_percent | text | Completion percentage of a catchup task |
| catchup_remaining_time | text | Estimated remaining time of a catchup task |

pgxc_lock_for_backup()

Description: Locks the cluster before backup. Backup is performed to restore data on new nodes.

Return type: boolean

NOTE

pgxc_lock_for_backup locks a cluster before **gs_dump** or **gs_dumpall** is used to back up the cluster. After a cluster is locked, operations changing the system structure are not allowed. This function does not affect DML statements.

Example:

```
SELECT pgxc_lock_for_backup();
pgxc_lock_for_backup
-----
t
(1 row)
```

21.7.28.2 Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions can be executed during restoration or when the database is running properly.

pg_is_in_recovery()

Description: Returns **true** if restoration is still in progress.

Return type: bool

Example:

```
SELECT pg_is_in_recovery();
pg_is_in_recovery
-----
f
(1 row)
```

pg_last_xlog_receive_location()

Description: This function gets the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if not yet started, the function return will return **NULL**.

Return type: text

Example:

```
SELECT pg_last_xlog_receive_location();
pg_last_xlog_receive_location
-----
(1 row)
```

pg_last_xlog_replay_location()

Description: Gets last transaction log location replayed during restoration. When the recovery is still in progress, the transaction log keeps increasing. If restoration has completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns **NULL**.

Return type: text

Example:

```
SELECT pg_last_xlog_replay_location();
pg_last_xlog_replay_location
-----
0/2B16530
(1 row)
```

pg_last_xact_replay_timestamp()

Description: Gets the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return **NULL**. Otherwise, if restoration is still in progress, this will increase monotonically. If restoration has completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return **NULL**.

Return type: timestamp with time zone

Restoration control functions control restoration processes. These functions may be executed only during restoration.

Example:

```
SELECT pg_last_xact_replay_timestamp();
pg_last_xact_replay_timestamp
-----
2023-01-04 07:03:08.098024+00
(1 row)
```

pg_is_xlog_replay_paused()

Description: Returns **true** if restoration is paused.

Return type: bool

pg_xlog_replay_pause()

Description: Pauses restoration immediately.

Return type: void

pg_xlog_replay_resume()

Description: Restarts restoration if it was paused.

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

Return type: void

pg_xlog_replay_completion()

Description: Displays the progress of xlog redo on the current DN.

Return type: record

Example:

```
SELECT * FROM pg_xlog_replay_completion();
replay_start | replay_current | replay_end | replay_percent
-----+-----+-----+-----
0/2ACAB80   | 0/2B16530     | 0/4F62B090 | 0%
(1 row)
```

The following information is returned:

Table 21-64 pg_xlog_replay_completion() columns

| Column | Type | Description |
|----------------|---------|--|
| replay_start | integer | Start LSN of xlog redo |
| replay_current | integer | LSN of the current replay of xlog redo |
| replay_end | integer | Maximum LSN that requires xlog redo |
| replay_percent | integer | Completion percentage of xlog redo |

pg_data_sync_from_dummy_completion()

Description: Displays the progress of data page file synchronization during the failover on the current DN.

Return type: record

Example:

```
SELECT * FROM pg_data_sync_from_dummy_completion();
start_index | current_index | total_index | sync_percent
-----+-----+-----+-----
0 | 0 | 0 | 100%
(1 row)
```

The following information is returned:

Table 21-65 pg_data_sync_from_dummy_completion() columns

| Column | Type | Description |
|---------------|---------|---|
| start_index | integer | Start LSN of data page file synchronization |
| current_index | integer | Current LSN of data page file synchronization |
| total_index | integer | Maximum LSN of data page file synchronization |
| sync_percent | integer | Completion percentage of data page files |

gs_roach_stop_backup(backupid text)

Description: Stops a backup started by the internal backup tool GaussRoach and returns the position where the current log is inserted. This function is similar to **pg_stop_backup**, but is more lightweight.

Return type: text

gs_roach_enable_delay_ddl_recycle(backupid name)

Description: Enables DDL delay and returns the log position of the enabling point. This function is similar to **pg_enable_delay_ddl_recycle**, but is more lightweight. In addition, this function allows you to enable DDL delay for multiple backups.

Return type: text

gs_roach_disable_delay_ddl_recycle(backupid text)

Description: Disables DDL delay, returns the logs for which DDL delay takes effect, and deletes the physical files of the column-store tables that have been deleted by the user. This function is similar to **pg_enable_delay_ddl_recycle**, but is more lightweight. In addition, this function allows you to disable DDL delay for multiple backups.

Return type: record

gs_roach_switch_xlog(request_ckpt bool)

Description: Switches the currently used log segment file and returns the position of the segment log. If the value of **request_ckpt** is **true**, a full check point is triggered.

Return type: text

pg_resume_bkp_flag(backupid name)

Description: This function resumes the **delay xlog** flag from a specified backup and returns **start_backup_flag boolean**, **to_delay boolean**, **ddl_delay_recycle_ptr text**, and **rewind_time text**.

Return type: record

pg_update_reloptions_in_newcluster

Description: This function writes the storage path in the file specified by the **obs-store-path-list** parameter to the **reloptions** field in the **pg_class** table during full restoration of V3 tables to a new cluster. This function is supported only by clusters of version 9.1.0 or later.

Return type: bool

21.7.29 Database Object Functions

21.7.29.1 Database Object Size Functions

Database object size functions calculate and return the actual disk space used by database objects in bytes.

pg_column_size(any)

Description: Specifies the number of bytes used to store a particular value (possibly compressed).

Return type: integer

Note: **pg_column_size** displays the space for storing an independent data value.

```
postgres=#SELECT pg_column_size(1);
pg_column_size
-----
         4
(1 row)
```

pg_database_size(oid)

Description: Specifies the disk space used by the database with the specified OID.

Return type: bigint

pg_database_size(name)

Description: Specifies the disk space used by the database with the specified name.

Return type: bigint

Note: **pg_database_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

Example:

```
postgres=#SELECT pg_database_size('gaussdb');
pg_database_size
-----
      51590112
(1 row)
```

pg_relation_size(oid)

Description: Specifies the disk space used by the table with a specified OID or index.

Return type: bigint

get_db_source_datasize()

Description: Estimates the total size of non-compressed data in the current database.

Return type: bigint

Note: (1) **ANALYZE** must be performed before this function is called. (2) Calculate the total size of non-compressed data by estimating the compression rate of column-store tables.

Example:

```
postgres=#analyze;
ANALYZE
postgres=#SELECT get_db_source_datasize();
get_db_source_datasize
-----
      35384925667
(1 row)
```

pg_relation_size(text)

Description: Specifies the disk space used by the table with a specified name or index. The table name can be schema-qualified.

Return type: bigint

pg_relation_size(relation regclass, fork text)

Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.

Return type: bigint

pg_relation_size(relation regclass)

Description: Is an abbreviation of **pg_relation_size(..., 'main')**.

Return type: bigint

Note: **pg_relation_size** returns the size in bytes of the table, index, or compressed table with the specified OID or name.

pg_partition_size(oid,oid)

Description: Specifies the disk space used by the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

Return type: bigint

pg_partition_size(text, text)

Description: Specifies the disk space used by the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

Return type: bigint

pg_partition_indexes_size(oid,oid)

Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

Return type: bigint

pg_partition_indexes_size(text,text)

Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

Return type: bigint

pg_indexes_size(regclass)

Description: Specifies the total disk space used by the index appended to the specified table.

Return type: bigint

pg_size_pretty(bigint)

Description: Converts the calculated byte size into a size readable to human beings.

Return type: text

pg_size_pretty(numeric)

Description: Converts the calculated byte size indicated by a numeral into a size readable to human beings.

Return type: text

Note: **pg_size_pretty** formats the results of other functions into a human-readable format. KB/MB/GB/TB can be used.

pg_table_size(regclass)

Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).

Return type: bigint

pg_total_relation_size(oid)

Description: Specifies the disk space used by the table with a specified OID, including the index and the compressed data.

Return type: bigint

pg_total_relation_size(regclass)

Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.

Return type: bigint

pg_total_relation_size(text)

Description: This function specifies the disk space used by the table with the specified name, including the index and compressed data. The table name can be schema-qualified.

Return type: bigint

Note: **pg_total_relation_size** can specify the OID or name of a table or compressed table, and then return the data in bytes and the sizes of all related indexes and compressed tables.

pg_obs_file_size(regclass)

Description: This function obtains the CU file size, file name, and bucket ID stored on OBS by specifying the OID or name of a V3 column-store table. This function is supported only by clusters of version 9.1.0 or later.

Parameter: The input parameter can be the table OID or table name.

Return type: record

Table 21-66 Return fields

| Field | Type | Description |
|----------|---------|--|
| bucketid | integer | ID of the bucket for storing CU files. |
| filename | text | CU file name. |
| size | bigint | CU file size, in bytes. |

Example:

```
SELECT * FROM pg_obs_file_size('t3_col_part_dif_partition');
 bucketid | filename | size
-----+-----+-----
      9 | 23488119324673.0 | 512
     22 | 23488102760449.0 | 512
     21 | 23488119521281.0 | 512
     16 | 23488102662145.0 | 512
(4 rows)
```

pg_obs_file_size(text, text)

Description: This function specifies a partition of a column-store V3 table (primary table name or partitioned table) and returns the size, file name, and bucket ID of the CU file stored on OBS. This function is supported only by clusters of version 9.1.0 or later.

Parameter: The input parameter can be the table OID or table name. The partition name is used as the partition name.

Return type: record

| Field | Type | Description |
|----------|---------|--|
| bucketid | integer | ID of the bucket for storing CU files. |
| filename | text | CU file name. |
| size | bigint | CU file size, in bytes. |

21.7.29.2 Database Object Position Functions

pg_relation_filenode(relation regclass)

Description: Specifies the ID of a filenode with the specified relationship.

Return type: OID

Description: **pg_relation_filenode** receives the OID or name of a table, index, sequence, or compressed table, and returns the filenode number allocated to it. The filenode is the basic component of the file name used by the relationship. For most tables, the result is the same as that of **pg_class.relfilenode**. For the specified system directory, **relfilenode** is **0** and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns **NULL**.

pg_relation_filepath(relation regclass)

Description: Specifies the name of a file path with the specified relationship.

Return type: text

Description: **pg_relation_filepath** is similar to **pg_relation_filenode**, except that **pg_relation_filepath** returns the whole file path name for the relationship (relative to the data directory **PGDATA** of the database cluster).

21.7.29.3 Partition Management Function

proc_add_partition (relname regclass, boundaries_interval interval)

Description: Adds partitions to a table with the automatic partition creation function enabled.

Return type: void

Note: When the function is executed, multiple partitions with time range as **boundaries_interval** are created based on the existing partition boundary until **new_part_boundary - now_time >= 29 * boundaries_interval**. Then, an extra partition is created to ensure that at least a new partition is created when the function is executed.

Example:

```
call proc_add_partition('my_schema.my_table', interval '1 day');
proc_add_partition
-----
(1 row)
```

proc_drop_partition (relname regclass, older_than interval)

Description: Deletes partitions from a table with the automatic partition deletion function enabled.

Return type: void

Note: When this function is executed, all partitions in the table are traversed and the partitions whose boundary is smaller than **now_time - older_than** are

deleted. If all partitions meet the deletion condition, the table is truncated with one partition kept.

Example:

```
call proc_drop_partition('my_schema.my_table', interval '7 day');
proc_drop_partition
-----
(1 row)
```

pg_partition_management_time(table_name, time)

Description: Modifies the execution time of the partition scheduling task that automatically adds or removes partitions. The default time is when the auto-increment partition table was created. This function is supported only by 8.3.0 and later versions.

Return value: **SUCCESS**, which indicates that the time is successfully modified.

Parameter:

- **table_name** indicates the name of the auto-increment partitioned table. The type is Name.
- **time** indicates the time when the data switching task is scheduled. The type is Time.

Example:

```
call pg_partition_management_time('partition_management_time','3:00');
pg_partition_management_time
-----
SUCCESS
(1 row)
```

21.7.29.4 Collation Version Function

pg_collation_actual_version (oid)

Description: Returns the actual version of the collation object currently installed in the operating system. Currently, this parameter is valid only for case_insensitive collations.

Return type: text

Example:

```
SELECT oid FROM pg_collation WHERE collname = 'case_insensitive';
oid
-----
3300
(1 row)

SELECT pg_collation_actual_version(3300);
pg_collation_actual_version
-----
153.14
(1 row)
```

21.7.29.5 Hot and Cold Table Functions

pg_obs_cold_refresh_time(table_name, time)

Description: Modifies the time when cold data in a hot and cold table is migrated to OBS. The default value is 00:00 every day.

table_name indicates the name of the hot and cold table, and the type is Name.
time indicates the time when the data switchover task is scheduled, and the type is Time.

Return value: **SUCCESS**, which indicates that the time is successfully modified.

Example:

```
SELECT * FROM pg_obs_cold_refresh_time('lifecycle_table', '06:30:00');
pg_obs_cold_refresh_time
-----
SUCCESS
(1 row)
```

pg_refresh_storage()

Description: Switches hot data to cold data on all hot and cold tables (in OBS).

Return type: int

Columns in the returned value:

- **success_count int**: indicates the number of tables that are successfully switched.
- **failed_count int**: indicates the number of tables that fail to be switched.

Example:

```
SELECT * FROM pg_refresh_storage();
success_count | failed_count
-----+-----
1 | 0
(1 row)
```

pg_lifecycle_table_data_distribute(table_name)

Description: Views the data distribution of a cold and hot table.

table_name indicates the table name and cannot be left blank.

Return value: record

Example: Multiple records are generated based on the number of nodes. The following example shows the data distribution in the **w1** table when there is only one DN node.

```
SELECT * FROM pg_catalog.pg_lifecycle_table_data_distribute('w1');
schemaname | tablename | nodename | hotpartition | coldpartition | switchablepartition | hotdatasize | colddatasize | switchabledatasize
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | w1 | dn_1 | p2 | p1 | | 80 KB | 0 bytes | 0 bytes
(1 row)
```

pg_lifecycle_node_data_distribute()

Description: Views the data distribution of all hot and cold tables.

Return value: record

Example: There are two cold and hot tables in the database. The data distribution is as follows:

```
SELECT * FROM pg_catalog.pg_lifecycle_node_data_distribute();
 schemaname | tablename | nodename | hotpartition | coldpartition | switchablepartition | hotdatasize |
colddatasize | switchabledatasize
-----+-----+-----+-----+-----+-----+-----+-----
public      | w1        | dn_1     | p2           | p1            |                     | 81920      |
public      | w2        | dn_1     | p2           | p1            |                     | 81920      |
(2 rows)
```

refresh_hot_storage(relname text)

Description: Flushes all partition data of a specified cold and hot table to OBS. The returned value is the number of switched partitions. This function is supported only in 8.2.1.100 or later.

Parameter:

relname: table name (name of a cold and hot table. If the name of a non-cold and hot table is used, no error is reported and **0** is returned.)

Return type: integer

```
SELECT refresh_hot_storage('multi_temper_table');
 refresh_hot_storage
-----
4
(1 row)
```

refresh_hot_storage(relname text, partname text)

Description: Synchronizes partition data of a specified hot and cold table to OBS. The returned value is the number of switched partitions. This function is supported only in 8.2.1.100 or later.

Parameter:

- **relname:** table name (name of a cold and hot table. If the name of a non-cold and hot table is used, no error is reported and **0** is returned.)
- **partname:** partition name (specifies a partition name of a cold and hot table)

Return type: integer

```
SELECT refresh_hot_storage('multi_temper_table','p1');
 refresh_hot_storage
-----
1
(1 row)
```

reload_cold_partition(relname text)

Description: This function converts all cold partitions to hot ones. The returned value is the number of switched partitions. This function is supported only by 8.3.0 and later versions.

Parameter:

relname: table name (name of a cold and hot table. If the name of a non-cold and hot table is used, no error is reported and **0** is returned.)

Return type: integer

```
SELECT reload_cold_partition('multi_temper_table');
reload_cold_partition
-----
4
(1 row)
```

reload_cold_partition(relname text, partname text)

Description: This function converts specific cold partitions to hot ones. The returned value is the number of switched partitions. This function is supported only by 8.3.0 and later versions.

Parameter:

- **relname:** table name (name of a cold and hot table. If the name of a non-cold and hot table is used, no error is reported and **0** is returned.)
- **partname:** partition name (specifies a partition name of a cold and hot table)

Return type: integer

```
SELECT reload_cold_partition('multi_temper_table','p1');
reload_cold_partition
-----
1
(1 row)
```

21.7.30 Residual File Management Functions

21.7.30.1 Functions for Obtaining the Residual File List

pg_get_residualfiles()

Description: Obtains all residual file records of the current node. This function is an instance-level function and is irrelevant to the current database. It can run on any instance.

Return type: record

The following information is displayed:

Table 21-67 pg_get_residualfiles () return fields

| Column | Type | Description |
|--------------|------|-----------------|
| isverified | bool | Verified or not |
| isdeleted | bool | Deleted or not |
| dbname | text | Database name |
| residualfile | text | Data file path |

| Column | Type | Description |
|----------|------|--------------------|
| filepath | text | Residual file path |
| notes | text | Notes |

Example:

```
SELECT * FROM pg_get_residualfiles();
isverified | isdeleted | dbname | residualfile | filepath | notes
-----+-----+-----+-----+-----+-----
f          | f        | db2    | base/49155/114691 | pgrf_20200908160211441546 |
f          | f        | db2    | base/49155/114694 | pgrf_20200908160211441546 |
f          | f        | db2    | base/49155/114696 | pgrf_20200908160211441546 |
(3 rows)
```

pgxc_get_residualfiles()

Description: Unified CN query function of `pg_get_residualfiles()`. This function is a cluster-level function and is irrelevant to the current database. It runs on CNs.

Return type: record

The following information is displayed:

Table 21-68 `pgxc_get_residualfiles()` return fields

| Column | Type | Description |
|--------------|------|--------------------|
| nodename | text | Node name |
| isverified | bool | Verified or not |
| isdeleted | bool | Deleted or not |
| dbname | text | Database name |
| residualfile | text | Data file path |
| filepath | text | Residual file path |
| notes | text | Notes |

Example:

```
SELECT * FROM pgxc_get_residualfiles();
nodename | isverified | isdeleted | dbname | residualfile | filepath | notes
-----+-----+-----+-----+-----+-----+-----
cn_5001  | f          |          | postgres | base/15092/32803 | pgrf_20200910170129360401 |
dn_6001_6002 | f        | f        | db2    | base/49155/114691 | pgrf_20200908160211441546 |
dn_6001_6002 | f        | f        | db2    | base/49155/114694 | pgrf_20200908160211441546 |
dn_6001_6002 | f        | f        | db2    | base/49155/114696 | pgrf_20200908160211441546 |
(4 rows)
```

21.7.30.2 Functions for Scanning Residual Files

Only cluster 8.3.0 and later versions support the function of scanning residual files. All functions described in this section can be invoked only by the **sysadmin** role.

pg_scan_residualfiles()

Description: This function scans all residual file records in the database connected to the current node. It is an instance-level function and is related to the current database, and it can run on any instance.

- When it is executed on a CN, it scans the database of the CN and OBS for residual files.
- When it is executed on a CN, it scans the database of the DN for residual files.

Return type: record

The following information is displayed:

Table 21-69 Return fields

| Field | Type | Description |
|---------|------|---|
| pgscrfl | text | Local path of the metadata file that records residual file information. |

Example:

```
SELECT * FROM pg_scan_residualfiles();
pgscrfl
-----
pg_residualfiles/pgscrfl_meta_1663_16323_20231027143716005244
pg_residualfiles/pgscrfl_meta_2147484281_16323_20231027143716005713
(2 rows)
```

NOTE

The restrictions on using this function are as follows:

- Only the current database can be scanned for residual files. Currently, only the default tablespace, OBS tablespace, and user-defined tablespace are scanned.
- This function is a heavy-load operation and cannot be used concurrently on a single node. You should avoid using this function when the service is overloaded or the resource is scarce.
- Only hot partitions in cold-hot-partition-separated tables are supported. Cold partitions are not supported.
- Do not use this function during the upgrade observation period.
- Residual files in the deleted database cannot be scanned.
- Inconsistent cluster metadata information can cause this function incorrectly scan valid data files.

pgxc_scan_residualfiles(query_flag)

Description: Unified CN execution function of **pg_scan_residualfiles()** This function is a cluster-level function and is related to the current database. It runs on CNs.

Parameter description: **query_flag**. The parameter type is int, indicating the execution range. **1** indicates the CN, **2** indicates the primary DN, and **4** indicates the standby DN. The query union set can be obtained through the OR operation. For example, **1|2=3** indicates the CN and primary DN, and **1|2|4=7** indicates the CN, primary DN, and standby DN. The default value is **7**.

Return type: record

The command output is as follows.

Table 21-70 Return fields

| Field | Type | Description |
|-------------|------|---|
| nodename | name | Node name. |
| instance_id | text | Instance name. |
| pgscrfs | text | Local path of the metadata file that records residual file information. |

Example:

```
SELECT * FROM pgxc_scan_residualfiles();
 node_name | instance_id | pgscrfs
-----+-----+-----
dn_6001_6002 | dn_6001 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144103839354
dn_6001_6002 | dn_6001 | pg_residualfiles/pgscrfs_meta_2147484281_16323_20231027144103839826
cn_5001 | cn_5001 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144103946217
dn_6007_6008 | dn_6008 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144104171311
(4 rows)

SELECT * FROM pgxc_scan_residualfiles(1);
 node_name | instance_id | pgscrfs
-----+-----+-----
cn_5001 | cn_5001 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144421861628
(1 row)

SELECT * FROM pgxc_scan_residualfiles(2);
 node_name | instance_id | pgscrfs
-----+-----+-----
dn_6001_6002 | dn_6001 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144424210395
dn_6001_6002 | dn_6001 | pg_residualfiles/pgscrfs_meta_2147484281_16323_20231027144424210855
(2 rows)

SELECT * FROM pgxc_scan_residualfiles(4);
 node_name | instance_id | pgscrfs
-----+-----+-----
dn_6007_6008 | dn_6008 | pg_residualfiles/pgscrfs_meta_1663_16323_20231027144427492060
(1 row)
```

 NOTE

The restrictions on using this function are as follows:

- Only the current database can be scanned for residual files. Currently, only the default tablespace, OBS tablespace, and user-defined tablespace are scanned.
- This function is a heavy-load operation and cannot be used concurrently on a single node. You should avoid using this function when the service is overloaded or the resource is scarce.
- Only hot partitions in cold-hot-partition-separated tables are supported. Cold partitions are not supported.
- Do not use this function during the upgrade observation period.
- Residual files in the deleted database cannot be scanned.
- Inconsistent cluster metadata information can cause this function incorrectly scan valid data files.

pg_get_scan_residualfiles()

Description: Obtains all residual file records scanned on the current node. This function is an instance-level function and is irrelevant to the current database. It can run on any instance.

Return type: record

The command output is as follows.

Table 21-71 Return fields

| Field | Type | Description |
|--------------|------------|---|
| handled | bool | Whether residual files have been processed, moved, or modified. |
| dbname | text | Database name |
| residualfile | text | Path of the residual file |
| size | bigint | File size, in bytes. For residual files in the OBS path, the value of this parameter is 0 . |
| inode | bigint | Inode in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is 0 . |
| atime | timestampz | Access time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |
| mtime | timestampz | Modify time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |
| ctime | timestampz | Change time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |

| Field | Type | Description |
|----------|------|--|
| filepath | text | Local path of the metadata file that records residual file information, corresponding to the pgscrfl_meta file. |
| notes | text | Notes |

pgxc_get_scan_residualfiles(query_flag)

Description: Unified CN execution function of **pg_get_scan_residualfiles()** This function is a cluster-level function and is irrelevant to the current database. It runs on CNs.

The **query_flag** parameter is of the int type and indicates the execution range. **1** indicates the CN, **2** indicates the primary DN, and **4** indicates the standby DN. The query union set can be obtained through the OR operation. For example, **1|2=3** indicates the CN and primary DN, and **1|2|4=7** indicates the CN, primary DN, and standby DN. The default value is **7**.

Return type: record

The command output is as follows.

Table 21-72 Return fields

| Field | Type | Description |
|--------------|------------|---|
| nodename | name | Node name |
| instance_id | text | Instance name |
| handled | bool | Whether residual files have been processed, moved, or modified. |
| dbname | text | Database name |
| residualfile | text | Path of the residual file |
| size | bigint | File size, in bytes. For residual files in the OBS path, the value of this parameter is 0 . |
| inode | bigint | Inode in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is 0 . |
| atime | timestampz | Access time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |
| mtime | timestampz | Modify time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |

| Field | Type | Description |
|----------|------------|--|
| ctime | timestampz | Change time in the stat information of the residual file. For residual files in the OBS path, the value of this parameter is empty. |
| filepath | text | Local path of the metadata file that records residual file information, corresponding to the pgscrfl_meta file. |
| notes | text | Notes |

pg_archive_scan_residualfiles()

Description: Archives all residual file records scanned on the database connected to the current node. This function is an instance-level function and is related to the current database. It can run on any instance.

Return type: record

The command output is as follows.

Table 21-73 Return fields

| Field | Type | Description |
|---------|--------|--|
| archive | text | Path of the local folder after archiving. Residual files in the OBS path are archived in the corresponding OBS database directory. |
| count | bigint | Number of archived residual files. |
| size | bigint | Total size of archived residual files, in bytes. |

Example:

```
SELECT * FROM pg_archive_scan_residualfiles();
      archive      | count | size
-----+-----+-----
pg_residualfiles/archive/pgscrfl_archive_20231027144613791801 |    4 | 81920
(1 row)
```

 NOTE

- This function can archive only the residual files recorded in the current login database. During archiving, the residual files are verified. The verification results are as follows:
 - Verification passed: After the verification is passed, the residual files are archived and marked as handled.
 - Verification failed: If the verification fails, the residual files are not archived and marked as handled.
 - Verification delayed: If the verification is delayed, it indicates that verification is not possible at the moment, and archiving is skipped. The verification delay is related to the transaction completion status and the standby node's redo progress.
- The actual archive directory and the corresponding tablespace are in the same file system. Deleting the tablespace also deletes the archived residual files.
- This function cannot be used after DDL delay is enabled.
- This function is a heavy-load operation and cannot be used concurrently on a single node. You should avoid using this function when the service is overloaded or the resource is scarce.

pgxc_archive_scan_residualfiles(query_flag)

Description: Unified CN execution function of **pg_archive_scan_residualfiles()**

This function is a cluster-level function and is related to the current database. It runs on CNs.

The **query_flag** parameter is of the int type and indicates the execution range. **1** indicates the CN, **2** indicates the primary DN, and **4** indicates the standby DN. The query union set can be obtained through the OR operation. For example, **1|2=3** indicates the CN and primary DN, and **1|2|4=7** indicates the CN, primary DN, and standby DN. The default value is **7**.

Return type: record

The command output is as follows.

Table 21-74 Return fields

| Field | Type | Description |
|-------------|--------|--|
| nodename | name | Node name. |
| instance_id | text | Instance name. |
| archive | text | Path of the local folder after archiving. Residual files in the OBS path are archived in the corresponding OBS database directory. |
| count | bigint | Number of archived residual files. |
| size | bigint | Total size of archived residual files, in bytes. |

Example:

```
SELECT * FROM pgxc_archive_scan_residualfiles();
```

```
node_name | instance_id | archive | count | size
```

```
cn_5001 | cn_5001 | pg_residualfiles/archive/pgscrif_archive_20231027145050896440 | 1 | 40960  
dn_6007_6008 | dn_6008 | pg_residualfiles/archive/pgscrif_archive_20231027145051018138 | 1 | 24576  
(2 rows)
```

NOTE

- This function can archive only the residual files recorded in the current login database. During archiving, the residual files are verified. The verification results are as follows:
 - Verification passed: After the verification is passed, the residual files are archived and marked as handled.
 - Verification failed: If the verification fails, the residual files are not archived and marked as handled.
 - Verification delayed: If the verification is delayed, it indicates that verification is not possible at the moment, and archiving is skipped. The verification delay is related to the transaction completion status and the standby node's redo progress.
- The actual archive directory and the corresponding tablespace are in the same file system. Deleting the tablespace also deletes the archived residual files.
- This function cannot be used after DDL delay is enabled.
- This function is a heavy-load operation and cannot be used concurrently on a single node. You should avoid using this function when the service is overloaded or the resource is scarce.

pg_rm_scan_residualfiles_archive()

Description: Deletes all archived residual file records on the current node. This function is an instance-level function and is irrelevant to the current database. It can run on any instance.

Return type: record

The command output is as follows.

Table 21-75 Return fields

| Field | Type | Description |
|-------|--------|---|
| count | bigint | Number of residual files that have been deleted from the archive. For residual files in the local path, the number of deleted files is counted. For residual files in the OBS path, the number of deleted table directories is counted. |
| size | bigint | Total size of residual files that have been deleted from the archive, in bytes. For residual files in the OBS path, the value of this parameter is 0 . |

Example:

```
SELECT * FROM pg_rm_scan_residualfiles_archive();  
count | size  
-----+-----  
4 | 81920  
(1 row)
```

pgxc_rm_scan_residualfiles_archive(query_flag)

Description: Unified CN execution function of **pg_rm_scan_residualfiles_archive()**. This function is a cluster-level function and is irrelevant to the current database. It runs on CNs.

The **query_flag** parameter is of the int type and indicates the execution range. **1** indicates the CN, **2** indicates the primary DN, and **4** indicates the standby DN. The query union set can be obtained through the OR operation. For example, **1|2=3** indicates the CN and primary DN, and **1|2|4=7** indicates the CN, primary DN, and standby DN. The default value is **7**.

Return type: record

The command output is as follows.

Table 21-76 Return fields

| Field | Type | Description |
|-------------|--------|---|
| nodename | name | Node name. |
| instance_id | text | Instance name. |
| count | bigint | Number of residual files that have been deleted from the archive. For residual files in the local path, the number of deleted files is counted. For residual files in the OBS path, the number of deleted table directories is counted. |
| size | bigint | Total size of residual files that have been deleted from the archive, in bytes. For residual files in the OBS path, the value of this parameter is 0 . |

Example:

```
SELECT * FROM pgxc_rm_scan_residualfiles_archive();
 node_name | instance_id | count | size
-----+-----+-----+-----
dn_6001_6002 | dn_6001 | 4 | 81920
cn_5001 | cn_5001 | 1 | 40960
dn_6007_6008 | dn_6008 | 1 | 24576
coordinator1 | coordinator1 | 1 | 0
(4 rows)
```

21.7.30.3 Functions for Verifying Residual Files

pg_verify_residualfiles(filepath)

Description: Verifies whether the file recorded in the parameter specified file is a residual file. This function is an instance-level function and is related to the current database. It can run on any instance.

Parameter type: text

Return type: bool

The following table describes return columns.

Table 21-77 pg_verify_residualfiles (filepath) return fields

| Column | Type | Description |
|------------|------|---------------------------------------|
| isverified | bool | Whether the verification is complete. |

Example:

```
postgres=#SELECT * FROM pg_verify_residualfiles('pgrf_20200908160211441546');
isverified
-----
t
(1 row)
```

 NOTE

This function only verifies whether the recorded file is a residual file in the current database. If the recorded file is not in the current database, the verification is not applicable.

pg_verify_residualfiles()

Description: Verifies whether recorded files on all residual file lists of the current instance are residual files. This function is an instance-level function and is related to the current database. It can run on any instance.

Parameter type: none

Return type: record

The following table describes return columns.

Table 21-78 pg_verify_residualfiles () return fields

| Column | Type | Description |
|----------|------|---------------------------------------|
| result | bool | Whether the verification is complete. |
| filepath | text | Residual file path. |
| notes | text | Notes. |

Example:

```
postgres=#SELECT * FROM pg_verify_residualfiles();
result |      filepath      | notes
-----+-----+-----
t      | pgrf_20200908160211441546 |
(1 row)
```

 NOTE

This function only verifies whether the recorded file is a residual file in the current database. If the recorded file is not in the current database, the verification is not applicable.

pgxc_verify_residualfiles()

Description: Unified CN query function of pg_verify_residualfiles() This function is a cluster-level function and is related to the current database. It runs on CNs.

Parameter type: none

Return type: record

The following table describes return columns.

Table 21-79 pgxc_verify_residualfiles () return fields

| Column | Type | Description |
|----------|------|---------------------------------------|
| nodename | text | Node name. |
| result | bool | Whether the verification is complete. |
| filepath | text | Residual file path. |
| notes | text | Notes. |

Example:

```
postgres=#SELECT * FROM pgxc_verify_residualfiles();
 nodename | result |      filepath      | notes
-----+-----+-----+-----
  cn_5001 |    t   | pgrf_20200910170129360401 |
dn_6001_6002 | t     | pgrf_20200908160211441546 |
(2 rows)
```

NOTE

This function only verifies whether the recorded file is a residual file in the current database. If the recorded file is not in the current database, the verification is not applicable.

pg_is_residualfiles(residualfile)

Description: Queries whether a specified **relfilenode** is a residual file in the current database. This function is an instance-level function and is related to the current database. It can run on any instance.

Parameter type: text

Return type: bool

The following table describes return columns.

Table 21-80 pg_is_residualfiles (residualfile) return fields

| Column | Type | Description |
|--------|------|------------------------------------|
| result | bool | Whether a file is a residual file. |

Example:

```
postgres=#SELECT * FROM pg_is_residualfiles('base/49155/114691');
result
-----
t
(1 row)
```

NOTE

This function only verifies whether the recorded file is a residual file in the current database. If the recorded file is not in the current database, it is verified as a residual file.

For example, the file **base/15092/14790** is not regarded as a residual file in a **gaussdb** database, but it is regarded as a residual file in other databases.

```
postgres=#SELECT * FROM pg_is_residualfiles('base/15092/14790');
result
-----
f
(1 row)

postgres=#\c db2
db2=# SELECT * FROM pg_is_residualfiles('base/15092/14790');
result
-----
t
(1 row)
```

21.7.30.4 Functions for Deleting Residual Files

pg_rm_residualfiles(filepath)

Description: Deletes files from a specified residual file list on the current instance. This function is an instance-level function and is irrelevant to the current database. It can run on any instance.

Parameter type: text

Return type: record

The following table describes return columns.

Table 21-81 pg_rm_residualfiles (filepath) return fields

| Column | Type | Description |
|--------|------|---------------------------|
| result | bool | Deletion completed or not |

Example:

```
postgres=#SELECT * FROM pg_rm_residualfiles('pgrf_20200908160211441599');
result
-----
t
(1 row)
```

 NOTE

- Residual files can be deleted only after verification using the `pg_verify_residualfiles()` function.
- All verified files, regardless which database they are in, will be deleted.
- If all files recorded in the specified file have been deleted, the specified file will be removed and backed up in the `$PGDATA/pg_residualfile/backup` directory.

`pg_rm_residualfiles()`

Description: Deletes all files recorded on all residual file lists on the current instance. This function is an instance-level function and is irrelevant to the current database. It can run on any instance.

Parameter type: none

Return type: record

The following table describes return columns.

Table 21-82 `pg_rm_residualfiles ()` return fields

| Column | Type | Description |
|----------|------|---------------------------|
| result | bool | Deletion completed or not |
| filepath | text | Residual file path |
| notes | text | Notes |

Example:

```
postgres=#SELECT * FROM pg_rm_residualfiles();
result |      filepath      | notes
-----+-----+-----
t      | pg_rf_20200908160211441546 |
(1 row)
```

 NOTE

- Residual files can be deleted only after verification using the `pg_verify_residualfiles()` function.
- All verified files, regardless which database they are in, will be deleted.
- If all files recorded in the specified file have been deleted, the specified file will be removed and backed up in the `$PGDATA/pg_residualfile/backup` directory.

`pgxc_rm_residualfiles()`

Description: Unified CN query function of `pgxc_rm_residualfiles`. This function is a cluster-level function and is irrelevant to the current database. It runs on CNs.

Parameter type: none

Return type: record

The following table describes return columns.

Table 21-83 pgxc_rm_residualfiles () return fields

| Column | Type | Description |
|----------|------|---------------------------|
| nodename | text | Node name |
| result | bool | Deletion completed or not |
| filepath | text | Residual file path |
| notes | text | Notes |

Example:

```
postgres=#SELECT * FROM pgxc_rm_residualfiles();
 nodename | result |      filepath      | notes
-----+-----+-----+-----
  cn_5001 |    t   | pgrf_20200910170129360401 |
 dn_6001_6002 | t     | pgrf_20200908160211441546 |
(2 rows)
```

pgxc_clear_disk_cache()

Description: This function deletes all disk cache files. This function is supported only by clusters of version 9.0.2 or later.

Return type: void

Example:

```
SELECT pgxc_clear_disk_cache();
pgxc_clear_disk_cache
-----
(1 row)
```

21.7.30.5 Using Residual File Management Functions

Procedure

- Step 1** Call the **pgxc_get_residualfiles()** function to obtain the name of the database that has residual files.
- Step 2** Go to the databases where residual files exist and call the **pgxc_verify_residualfiles()** function to verify the residual files recorded in the current database.
- Step 3** Call the **pgxc_rm_residualfiles()** function to delete all the verified residual files.

----End

NOTE

The pgxc residual file management function only operates on the CN and the current primary DN, and does not verify or clear residual files on the standby DN. Therefore, after the primary DN is cleared, you need to clear residual files on the standby DN or build the standby DN in a timely manner. This prevents residual files on the standby DN from being copied back to the primary DN due to incremental build after a primary/standby switchover.

Examples

The following example uses two user-created databases, **db1** and **db2**.

```
postgres=# \l
```

| Name | Owner | Encoding | Collate | Ctype | Access privileges |
|-----------|--------|-----------|---------|-------|-------------------|
| db1 | fpi810 | SQL_ASCII | C | C | |
| db2 | fpi810 | SQL_ASCII | C | C | |
| postgres | fpi810 | SQL_ASCII | C | C | |
| template0 | fpi810 | SQL_ASCII | C | C | =c/fpi810 + |
| | | | | | fpi810=CTc/fpi810 |
| template1 | fpi810 | SQL_ASCII | C | C | =c/fpi810 + |
| | | | | | fpi810=CTc/fpi810 |

(5 rows)

- Run the following command to obtain all residual file records of the cluster on the CNs:

```
db1=# select * from pgxc_get_residualfiles() order by 4, 6; -- order by is optional.
```

```
db1=# select * from pgxc_get_residualfiles() order by 4, 6;
```

| nodename | isverified | isdeleted | dbname | residualfile | filepath | notes |
|--------------|------------|-----------|--------|------------------|---------------------------|-------|
| dn_6001_6002 | f | f | db1 | base/16390/16395 | pgrf_20200921153355979438 | |
| dn_6001_6002 | f | f | db1 | base/16390/24592 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24579 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24582 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24584 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24585 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24588 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24589 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24591 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24576 | pgrf_20200921153612088342 | |

(10 rows)

In the current cluster:

- Residual file records exist in the **db1** and **db2** databases on the **dn_6001_6002** node (active node instance).
 - Residual files are displayed in the **residualfile** column.
 - The **filepath** column lists the files that record residual files. These files are stored in the **pg_residualfiles** directory under the instance data directory.
- Call the **pgxc_verify_residualfiles()** function to verify the **db1** database.

```
db1=# SELECT * FROM pgxc_verify_residualfiles();
```

```
postgres=# \c db1
```

Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "db1" as user "fpi810".

```
db1=# select * from pgxc_verify_residualfiles();
```

| nodename | result | filepath | notes |
|--------------|--------|---------------------------|-------|
| dn_6001_6002 | t | pgrf_20200921153355979438 | |
| dn_6001_6002 | t | pgrf_20200921153612088342 | |

(2 rows)

Verification functions are at the database level. Therefore, when a verification function is called in the **db1** database, it only verifies residual files in **db1**.

You can call the **get** function again to check whether the verification is complete.

```
db1=# SELECT * FROM pgxc_get_residualfiles() order by 4, 6;
```

```
db1=# select * from pgxc_get_residualfiles() order by 4, 6;
```

| nodename | isverified | isdeleted | dbname | residualfile | filepath | notes |
|--------------|------------|-----------|--------|------------------|---------------------------|-------|
| dn_6001_6002 | t | f | db1 | base/16390/16395 | pgrf_20200921153355979438 | |
| dn_6001_6002 | t | f | db1 | base/16390/24592 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24579 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24582 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24584 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24585 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24588 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24589 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24591 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24576 | pgrf_20200921153612088342 | |

(10 rows)

As shown in the preceding figure, the residual files in the **db1** database have been verified, and the residual files in the **db2** database are not verified.

3. Call the **pgxc_rm_residualfiles()** function to delete residual files.

```
db1=# SELECT * FROM pgxc_rm_residualfiles();
```

```
db1=# select * from pgxc_rm_residualfiles();
```

| nodename | result | filepath | notes |
|--------------|--------|---------------------------|-------|
| dn_6001_6002 | t | pgrf_20200921153355979438 | |
| dn_6001_6002 | t | pgrf_20200921153612088342 | |

(2 rows)

4. Call the **pgxc_get_residualfiles()** function again to check the deletion result.

```
db1=# select * from pgxc_get_residualfiles() order by 4, 6;
```

| nodename | isverified | isdeleted | dbname | residualfile | filepath | notes |
|--------------|------------|-----------|--------|------------------|---------------------------|-------|
| dn_6001_6002 | t | t | db1 | base/16390/24592 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24579 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24582 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24584 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24576 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24588 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24589 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24591 | pgrf_20200921153612088342 | |
| dn_6001_6002 | f | f | db2 | base/16391/24585 | pgrf_20200921153612088342 | |

(9 rows)

The result shows that the residual files in the **db1** database are deleted (**isdeleted** is marked as **t**) and the residual files in the **db2** database are not deleted.

In addition, nine query results are displayed. Compared with the previous query results, a record for the residual file ending with **9438** is missing. This is because the record file that records the residual file ending with **9438** contains only one record, which is deleted in step 3. If all residual files in a record file are deleted, the record file is also deleted. Deleted files are backed up in the **pg_residualfiles/backup** directory.

```
[fpi810@host-192-168-244-162 pg_residualfiles]$ ls
backup pendingdeletesfile pgrf_20200921153612088342
[fpi810@host-192-168-244-162 pg_residualfiles]$ ls backup/
pgrf_20200921153355979438_bak
```

5. To delete files from the **db2** database, you need to call the **verify** function in the **db2** database and then call the **rm** function.
 - a. Go to the **db2** database and call the verification function.

```

db1=# \c db2
Non-SSL connection (SSL connection is recommended when requiring high-security)
You are now connected to database "db2" as user "fpi810".
db2=# select * from pgxc_verify_residualfiles();
  nodename | result | filepath | notes
-----+-----+-----+-----
 dn_6001_6002 | t      | pgrf_20200921153612088342 |
(1 row)

```

Query the verification result:

```

db2=# select * from pgxc_get_residualfiles() order by 4, 6;
  nodename | isverified | isdeleted | dbname | residualfile | filepath | notes
-----+-----+-----+-----+-----+-----+-----
 dn_6001_6002 | t          | t         | db1     | base/16390/24592 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24579 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24582 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24584 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24576 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24588 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24589 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24591 | pgrf_20200921153612088342 |
 dn_6001_6002 | t          | f         | db2     | base/16391/24585 | pgrf_20200921153612088342 |
(9 rows)

```

- b. Call the deletion function:

```

db2=# select * from pgxc_rm_residualfiles();
  nodename | result | filepath | notes
-----+-----+-----+-----
 dn_6001_6002 | t      | pgrf_20200921153612088342 |
(1 row)

```

- c. Query the deletion result:

```

db2=# select * from pgxc_get_residualfiles() order by 4, 6;
  nodename | isverified | isdeleted | dbname | residualfile | filepath | notes
-----+-----+-----+-----+-----+-----+-----
(0 rows)

```

All residual files recorded in the record file whose name ends with **8342** have been deleted, so the record file is deleted and backed up in the **backup** directory. As a result, no records are found.

```

[fpi810@host-192-168-244-162 pg_residualfiles]$ ls
backup pendingdeletesfile
[fpi810@host-192-168-244-162 pg_residualfiles]$ ls backup/
pgrf_20200921153355979438_bak pgrf_20200921153612088342_bak

```

21.7.31 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access databases, using the OID of each table or index in a database to mark the database for which statistics are generated; functions that access servers, identified by the server process ID, whose value ranges from 1 to the number of currently active servers.

For a global temporary table, the input parameter of the function is the OID of the table in **pg_class**. The function returns the statistics of the current session. The results of querying the same global temporary table in different sessions may be different.

pg_stat_get_db_numbackends(oid)

Description: Obtains the number of active server threads of a specified database on the current instance.

Return type: integer

pg_stat_get_db_total_numbackends(oid)

Description: Obtains the total number of active server threads of a specified database on all CNs in a cluster (if this function is executed on a CN), or obtains the number of active server threads of a specified database on the current instance (if this function is executed on a DN).

Return type: integer

pg_stat_get_db_xact_commit(oid)

Description: Obtains the number of committed transactions in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_xact_commit(oid)

Description: Obtains the total number of committed transactions in a specified database on all CNs in a cluster (if this function is executed on a CN), or obtains the number of committed transactions in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_xact_rollback(oid)

Description: Obtains the number of rollback transactions in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_xact_rollback(oid)

Description: Obtains the total number of rollback transactions in a specified database on all CNs in a cluster (if this function is executed on a CN), or obtains the number of rollback transactions in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_blocks_fetched(oid)

Description: Obtains the number of disk block fetch requests in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_blocks_fetched(oid)

Description: Obtains the total number of disk block fetch requests in a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of disk block fetch requests in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_blocks_hit(oid)

Description: Obtains the number of requested disk blocks found in the cache in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_blocks_hit(oid)

Description: Obtains the total number of requested disk blocks found in the cache in a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of requested disk blocks found in the cache in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_tuples_returned(oid)

Description: This function obtains the number of tuples returned for a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_tuples_returned(oid)

Description: Obtains the total number of tuples returned for a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of tuples returned for a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_tuples_fetched(oid)

Description: Obtains the number of tuples read from a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_tuples_fetched(oid)

Description: Obtains the total number of tuples read from a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of tuples read from a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_tuples_inserted(oid)

Description: Obtains the number of tuples inserted into a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_tuples_inserted(oid)

Description: Obtains the total number of tuples inserted into a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of tuples inserted into a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_tuples_updated(oid)

Description: Obtains the number of updated tuples in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_tuples_updated(oid)

Description: Obtains the total number of updated tuples in a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of updated tuples in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_tuples_deleted(oid)

Description: Obtains the number of tuples deleted from a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_tuples_deleted(oid)

Description: Obtains the total number of tuples deleted from a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of tuples deleted from a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_conflict_lock(oid)

Description: Obtains the total number of conflicting locks in a specified database on all CNs and DNs in a cluster (if this function is executed on a CN), or obtains the number of conflicting locks in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_deadlocks(oid)

Description: Obtains the number of deadlocks in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_deadlocks(oid)

Description: Obtains the total number of deadlocks in a specified database on all CNs and DN in a cluster (if this function is executed on a CN), or obtains the number of deadlocks in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_conflict_all(oid)

Description: Obtains the number of conflict recoveries in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_conflict_all(oid)

Description: Obtains the total number of conflict recoveries in a specified database on all CNs and DN in a cluster (if this function is executed on a CN), or obtains the number of conflict recoveries in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_temp_files(oid)

Description: Obtains the number of temporary files created in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_temp_files(oid)

Description: Obtains the total number of temporary files created in a specified database on all DN in a cluster (if this function is executed on a CN), or obtains the number of temporary files created in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_temp_bytes(oid)

Description: Obtains the number of bytes of the temporary files created in a specified database on the current instance.

Return type: bigint

pg_stat_get_db_total_temp_bytes(oid)

Description: Obtains the total number of bytes of the temporary files created in a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the number of bytes of the temporary files created in a specified database on the current instance (if this function is executed on a DN).

Return type: bigint

pg_stat_get_db_blk_read_time(oid)

Description: Obtains the time required for reading data blocks from a specified database on the current instance.

Return type: double

pg_stat_get_db_total_blk_read_time(oid)

Description: Obtains the total time required for reading data blocks from a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the time required for reading data blocks from a specified database on the current instance (if this function is executed on a DN).

Return type: double

pg_stat_get_db_blk_write_time(oid)

Description: Obtains the time required for writing data blocks to a specified database on the current instance.

Return type: double

pg_stat_get_db_total_blk_write_time(oid)

Description: Obtains the total time required for writing data blocks to a specified database on all DNs in a cluster (if this function is executed on a CN), or obtains the time required for writing data blocks to a specified database on the current instance (if this function is executed on a DN).

Return type: double

pg_stat_get_numscans(oid)

Description: Number of sequential row scans done if parameters are in a table or number of index scans done if parameters are in an index

Return type: bigint

pg_stat_get_tuple()

Description: This function can be executed on both CNs and DNs. This function is supported only by version 8.1.3 or later clusters.

If no parameters are specified, this function queries the statistics of all system catalogs on CNs, the dirty page rate of the tables on each CN, the statistics of all

system catalogs and user catalogs on DNs, and the dirty page rate of the tables on each DN.

If the schema name and table name are specified, this function queries the statistics and dirty page rate of the specified table.

 NOTE

The statistics of this function depend on the **ANALYZE** operation. To obtain the most accurate information, perform the **ANALYZE** operation on the table first.

Return type: record

The following table describes return columns.

| Column | Type | Description |
|-------------------|--------------------------|--|
| nodename | text | Node name |
| tableid | oid | Table OID |
| partid | oid | Partition OID of the partitioned table |
| last_vacuum | timestamp with time zone | Time of the last manual VACUUM |
| last_autovacuum | timestamp with time zone | Time of the last AUTOVACUUM |
| last_analyze | timestamp with time zone | Time of the last manual ANALYZE |
| last_autoanalyze | timestamp with time zone | Time of the last AUTOANALYZE |
| vacuum_count | bigint | Number of VACUUM operations |
| autovacuum_count | bigint | Number of AUTOVACUUM operations |
| analyze_count | bigint | Number of ANALYZE operations |
| autoanalyze_count | bigint | Number of times of automatically performing the ANALYZE operation |
| n_tup_ins | bigint | Number of rows inserted |
| n_tup_upd | bigint | Number of rows updated |
| n_tup_del | bigint | Number of rows deleted |
| n_tup_hot_upd | bigint | Number of rows with HOT updates |
| n_tup_change | bigint | Number of changed rows after ANALYZE |
| n_live_tup | bigint | Estimated number of live rows |
| n_dead_tup | bigint | Estimated number of dead rows |
| dirty_rate | bigint | Dirty page rate of a single CN or DN |

| Column | Type | Description |
|-------------------|--------------------------|--|
| last_data_changed | timestamp with time zone | Time when a table was last modified. This column is left empty in 8.2.0 and later versions. You are advised to query the value using pg_stat_get_last_data_changed_time(oid) . |

pg_stat_get_tuples_returned(oid)

Description: Number of sequential row scans done if parameters are in a table or number of index entries returned if parameters are in an index

Return type: bigint

pg_stat_get_tuples_fetched(oid)

Description: Number of table rows fetched by bitmap scans if parameters are in a table,

or table rows fetched by simple index scan using the index if parameters are in an index

Return type: bigint

pg_stat_get_tuples_inserted(oid)

Description: Number of rows inserted into table

Return type: bigint

pg_stat_get_local_tuples_inserted(oid)

Description: Number of rows inserted into the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_tuples_updated(oid)

Description: Number of rows updated in table

Return type: bigint

pg_stat_get_local_tuples_updated(oid)

Description: Number of rows updated in the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_tuples_deleted(oid)

Description: Number of rows deleted from table

Return type: bigint

pg_stat_get_local_tuples_deleted(oid)

Description: Number of rows deleted from the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_tuples_changed(oid)

Description: Queries the function on a CN and returns the total number of inserted, updated, and deleted rows in the table since the last **ANALYZE** or **AUTOANALYZE** operation. Queries the function on a DN and returns the total number of inserted, updated, and deleted rows in the table since the last **ANALYZE** or **AUTOANALYZE** operation on the current node.

Return type: bigint

pg_stat_get_local_tuples_changed(oid)

Description: Number of inserted, updated, and deleted rows in the table since the last **ANALYZE** or **AUTOANALYZE** operation on the current node.

Return type: bigint

pg_stat_get_tuples_hot_updated(oid)

Description: Number of rows HOT-updated in table

Return type: bigint

pg_stat_get_local_tuples_hot_updated(oid)

Description: Number of rows with HOT updates in the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_live_tuples(oid)

Description: Number of live tuples in the table.

Return type: bigint

pg_stat_get_local_live_tuples(oid)

Description: Number of live tuples in the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_dead_tuples(oid)

Description: Number of dead tuples in the table.

Return type: bigint

pg_stat_get_local_dead_tuples(oid)

Description: Number of dead tuples in the table on the current node. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_blocks_fetched(oid)

Description: Number of disk block fetch requests for table or index

Return type: bigint

pg_stat_get_blocks_hit(oid)

Description: Number of disk block requests found in cache for table or index

Return type: bigint

pg_stat_get_partition_tuples_inserted(oid)

Description: Number of rows in the corresponding table partition

Return type: bigint

pg_stat_get_partition_tuples_updated(oid)

Description: Number of rows that have been updated in the corresponding table partition

Return type: bigint

pg_stat_get_partition_tuples_deleted(oid)

Description: Number of rows deleted from the corresponding table partition

Return type: bigint

pg_stat_get_partition_tuples_changed(oid)

Description: Total number of inserted, updated, and deleted rows after the table partition was last analyzed or autoanalyzed

Return type: bigint

pg_stat_get_partition_live_tuples(oid)

Description: Number of live rows in a table partition

Return type: bigint

pg_stat_get_partition_dead_tuples(oid)

Description: Number of dead rows in a table partition

Return type: bigint

pg_stat_get_xact_tuples_inserted(oid)

Description: Number of tuple inserted into the active subtransactions related to the table.

Return type: bigint

pg_stat_get_xact_tuples_deleted(oid)

Description: Number of deleted tuples in the active subtransactions related to a table

Return type: bigint

pg_stat_get_xact_tuples_hot_updated(oid)

Description: Number of hot updated tuples in the active subtransactions related to a table

Return type: bigint

pg_stat_get_xact_tuples_updated(oid)

Description: Number of updated tuples in the active subtransactions related to a table

Return type: bigint

pg_stat_get_xact_partition_tuples_inserted(oid)

Description: Number of inserted tuples in the active subtransactions related to a table partition

Return type: bigint

pg_stat_get_xact_partition_tuples_deleted(oid)

Description: Number of deleted tuples in the active subtransactions related to a table partition

Return type: bigint

pg_stat_get_xact_partition_tuples_hot_updated(oid)

Description: Number of hot updated tuples in the active subtransactions related to a table partition

Return type: bigint

pg_stat_get_xact_partition_tuples_updated(oid)

Description: Number of updated tuples in the active subtransactions related to a table partition

Return type: bigint

pg_stat_get_last_vacuum_time(oid)

Description: Last time when the autovacuum thread is manually started to clear a table

Return type: timestamptz

pg_stat_get_last_autovacuum_time(oid)

Description: Time of the last vacuum initiated by the autovacuum thread on this table

Return type: timestamptz

pg_stat_get_local_last_autovacuum_time(oid)

Description: Time of the last vacuum initiated by the autovacuum thread of the current node on this table. This function is supported only in 8.1.2 or later.

Return type: timestamptz

pg_stat_get_vacuum_count(oid)

Description: Number of times a table is manually cleared

Return type: bigint

pg_stat_get_autovacuum_count(oid)

Description: Number of times of vacuum initiated by the autovacuum thread on this table

Return type: bigint

pg_stat_get_local_autovacuum_count(oid)

Description: Number of times of vacuum initiated by the autovacuum thread of the current node on this table. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_last_analyze_time(oid)

Description: Last time when a table starts to be analyzed manually or by the autovacuum thread

Return type: timestamptz

pg_stat_get_last_autoanalyze_time(oid)

Description: Time of the last analysis initiated by the autovacuum thread on this table

Return type: timestamptz

pg_stat_get_local_last_autoanalyze_time(oid)

Description: Time of the last analysis initiated by the autovacuum thread of the current node on this table. This function is supported only in 8.1.2 or later.

Return type: timestamptz

pg_stat_get_analyze_count(oid)

Description: Number of times a table is manually analyzed

Return type: bigint

pg_stat_get_autoanalyze_count(oid)

Description: Number of times the autovacuum daemon analyzes a table

Return type: bigint

pg_stat_get_local_autoanalyze_count(oid)

Description: Number of times that the autovacuum daemon of the current node starts analysis on this table. This function is supported only in 8.1.2 or later.

Return type: bigint

pg_stat_get_local_analyze_status(oid)

Description: Specifies whether to analyze the status of a table on the current node. This parameter is valid only for CNs. This function is supported only in 8.1.2 or later.

- If the number of modified rows in the table exceeds the ANALYZE threshold (calculated based on `autovacuum_analyze_threshold` + `autovacuum_analyze_scale_factor` x `reltuples`, where **reltuples** is the estimated number of rows in the table recorded in `pg_class`), **Analyze needed** is returned.
- If the number of modified rows in the table does not exceed the threshold of **analyze**, the message **Analyze not needed** is returned.

Return type: text

pg_stat_get_runtime_relstats(oid)

Description: Returns memory table-level statistics generated by lightweight autoanalyze.

Return type: SETOF record

pg_stat_get_runtime_attstats(oid)

Description: Returns memory table- and column- level statistics generated by lightweight autoanalyze.

Return type: SETOF record

pg_stat_get_runtime_partstats(oid)

Description: Returns memory partition level statistics generated by lightweight autoanalyze. Only 8.2.1.200 and later cluster versions support this function.

Return type: SETOF record

pg_stat_get_runtime_part_attstats(oid)

Description: Returns memory partition-column level statistics generated by lightweight autoanalyze. Only 8.2.1.200 and later cluster versions support this function.

Return type: SETOF record

pg_stat_get_runtime_exprstats(oid)

Description: Returns memory expression statistics generated by lightweight autoanalyze. Only 8.2.1.200 and later cluster versions support this function.

Return type: SETOF record

pg_stat_get_predicate_columns(oid)

Description: This function returns the predicate column information collected by a table. Only clusters of 9.1.0.100 and later versions support this function.

Return type: setof smallint

pg_stat_delete_predicate_columns(oid)

Description: This function clears the predicate column information of a table. Only clusters of 9.1.0.100 and later versions support this function.

Return type: void

pg_total_autovac_tuples(bool)

Description: Gets the tuple records related to **total autovac**, such as **nodename**, **nspname**, **relname**, and the IUD information of tuples.

Return type: SETOF record

pg_autovac_status(oid)

Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds of **analyze** and **vacuum**, and the number of analyzed or vacuumed tuples.

Return type: SETOF record

pg_autovac_timeout(oid)

Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.

Return type: bigint

pg_autovac_coordinator(oid)

Description: Returns the name of the CN performing the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.

Return type: text

pg_stat_get_all(regclass)

Description: This function retrieves a tuple record from the **pg_stat_object** table on the current CN. The record includes 29 columns, ranging from **databaseid** to **autovac_vacuum_count**. The input parameter is the table OID. Only 8.2.1.210 and later cluster versions support this function.

Return type: SETOF record

Example: Query the last access time of the **t1** table in the public schema on the current node.

```
SELECT data_access_timestamp FROM pg_stat_get_all('public.t1'::regclass);
data_access_timestamp
-----
2024-06-27 16:16:26.643132+08
(1 row)
```

pgxc_stat_get_all(relnamespace text, relname text)

Description: This function retrieves tuple records from the **pg_stat_object** table on all CNs. The record includes 29 columns, ranging from **databaseid** to **autovac_vacuum_count**. Only 8.2.1.210 and later cluster versions support this function.

Return type: SETOF record

Example: Query the last access time of the **t1** table in the public schema on all CNs.

```
SELECT relid,data_access_timestamp FROM pgxc_stat_get_all('public','t1');
relid  | data_access_timestamp
-----+-----
2147516676 | 2000-01-01 08:00:00+08
2147516674 | 2000-01-01 08:00:00+08
2147516655 | 2024-06-27 16:16:26.643132+08
(3 rows)
```

pgxc_stat_get_last_data_access_timestamp(relnamespace text, relname text)

Description: This function returns the last access time of a specified table on all nodes. Clusters of 9.1.0.100 and later versions support this function.

Return type: timestamptz

Example: Query the last access time of table **t1** in the public schema on all nodes.

```
SELECT * FROM pgxc_stat_get_last_data_access_timestamp('public','t1');
pgxc_stat_get_last_data_access_timestamp
-----
2024-06-27 16:16:26.643132+08
(1 row)
```

pgxc_stat_flush_object_data()

Description: This function enables manual persistence, where each node writes statistics on all tables in local databases to the **pg_stat_object** system catalog. The statistics include 29 columns from **databaseid** to **autovac_vacuum_count** in **pg_stat_object**. Only the system administrator can execute this function. Clusters of 9.1.0.100 and later versions support this function.

Return type: Boolean

Example: The system administrator performs persistence.

```
SELECT pgxc_stat_flush_object_data();
pgxc_stat_flush_object_data
-----
t
(1 row)
```

NOTE

This function cannot be executed concurrently.

pgxc_get_wlm_session_info_bytime(text, timestamp without time zone, timestamp without time zone, int)

Description: The query performance of the PGXC_WLM_SESSION_INFO view is poor if the view contains a large number of records. In this case, you are advised to use this function to filter the query. The input parameters are *time column* (**start_time** or **finish_time**), *start time*, *end time*, and *maximum number of records returned for each CN*. The return result is a subset of records in the **GS_WLM_SESSION_HISTORY** view.

Return type: SETOF record

pgxc_get_wlm_current_instance_info(text, int default null)

Description: Queries the current resource usage of each node in the cluster on the CN and reads the data that is not stored in the GS_WLM_INSTANCE_HISTORY system catalog in the memory. The input parameters are the node name (**ALL**, **C**, **D**, or *instance name*) and the maximum number of records returned by each node. The returned value is **GS_WLM_INSTANCE_HISTORY**.

Return type: SETOF record

pgxc_get_wlm_history_instance_info(text, TIMESTAMP, TIMESTAMP, int default null)

Description: Queries the historical resource usage of each cluster node on the CN node and reads data from the **GS_WLM_INSTANCE_HISTORY** system catalog. The input parameters are as follows: node name (**ALL**, **C**, **D**, or *instance name*), start time, end time, and maximum number of records returned for each instance. The returned value is **GS_WLM_INSTANCE_HISTORY**.

Return type: SETOF record

pg_stat_get_last_data_changed_time(oid)

Description: Returns the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** was performed last time on a table. The data in the **last_data_changed** column of the PG_STAT_ALL_TABLES view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use the function.

Return type: timestampz

pg_stat_set_last_data_changed_time(oid)

Description: Manually changes the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** was performed last time.

Return type: void

pg_stat_set_last_data_changed_num(oid)

Description: Sets the history modification times of a table node.

Return type: void

pv_session_time()

Description: Collects statistics on the running time of each session thread on the current node and the time consumed in each execution phase.

Return type: record

pv_instance_time()

Description: Collects statistics on the running time of the current node and the time consumed in each execution phase.

Return type: record

pg_stat_get_activity(integer)

Description: Returns a record about the backend with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The return result is a subset of records (excluding the **connection_info** column) in the PG_STAT_ACTIVITY view.

Return type: SETOF record

pg_stat_get_activity_with_conninfo(integer)

Description: Returns a record about the backend with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The return result is a subset of records in the **PG_STAT_ACTIVITY** view.

Return type: SETOF record

pg_user_iostat(text)

Description: This function has been deprecated in version 8.1.2 and is invalid when used in queries in the current version. In cluster versions 8.2.0 and later, you can use the **PGXC_TOTAL_USER_RESOURCE_INFO** view to query the real-time resource consumption of users on instances.

Return type: record

| Name | Type | Description |
|---------------|------|---|
| userid | oid | User ID. |
| min_curr_iops | int4 | Minimum I/O of the current user across DNs. |
| max_curr_iops | int4 | Maximum I/O of the current user across DNs. |
| min_peak_iops | int4 | Minimum peak I/O of the current user across DNs. |
| max_peak_iops | int4 | Maximum peak I/O of the current user across DNs. |
| io_limits | int4 | io_limits set for the resource pool specified by the user. |
| io_priority | text | io_priority set for the user. |

pg_stat_get_function_calls(oid)

Description: Number of times the function has been called

Return type: bigint

pg_stat_get_function_total_time(oid)

Description: Gets the total wall-clock time spent on a function, in microseconds. The time spent on calling this function is included.

Return type: double precision

pg_stat_get_function_self_time(oid)

Description: Gets the time spent only on this function in the current transaction. The time spent on calling this function is not included.

Return type: double precision

pg_stat_get_backend_idset()

Description: Set of currently active server process numbers (from 1 to the number of active server processes)

Return type: setofinteger

pg_stat_get_backend_pid(integer)

Description: Thread ID of the given server thread

Return type: bigint

```
SELECT pg_stat_get_backend_pid(1);
pg_stat_get_backend_pid
-----
139706243217168
(1 row)
```

pg_stat_get_backend_dbid(integer)

Description: ID of the database connected to the given server process

Return type: OID

pg_stat_get_backend_userid(integer)

Description: User ID of the given server process

Return type: OID

pg_stat_get_backend_activity(integer)

Description: Active command of the given server process, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is on

Return type: text

pg_stat_get_backend_waiting(integer)

Description: True if the given server process is waiting for a lock, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is on

Return type: boolean

pg_stat_get_backend_activity_start(integer)

Description: The time at which the given server process's currently executing query was started, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is on

Return type: timestamp with time zone

pg_stat_get_backend_xact_start(integer)

Description: The time at which the given server process's currently executing transaction was started, but only if the current user is a system administrator or the same user as that of the session being queried and **track_activities** is on

Return type: timestamp with time zone

pg_stat_get_backend_start(integer)

Description: The time at which the given server process was started, or **NULL** if the current user is neither a system administrator nor the same user as that of the session being queried

Return type: timestamp with time zone

pg_stat_get_backend_client_addr(integer)

Description: IP address of the client connected to the given server process.

If the connection is over a Unix domain socket, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

Return type: inet

Note: An IP address used as an input parameter of this function cannot contain periods (.). For example, **192.168.100.128** should be written as **192168100128**.

pg_stat_get_backend_client_port(integer)

Description: TCP port number of the client connected to the given server process

If the connection is over a Unix domain socket, **-1** will be returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

Return type: integer

pg_stat_get_bgwriter_timed_checkpoints()

Description: The number of times the background writer has started timed checkpoints (because the **checkpoint_timeout** time has expired)

Return type: bigint

pg_stat_get_bgwriter_requested_checkpoints()

Description: The number of times the background writer has started checkpoints based on requests from the backend because **checkpoint_segments** has been exceeded or the **CHECKPOINT** command has been executed

Return type: bigint

pg_stat_get_bgwriter_buf_written_checkpoints()

Description: The number of buffers written by the background writer during checkpoints

Return type: bigint

pg_stat_get_bgwriter_buf_written_clean()

Description: The number of buffers written by the background writer for routine cleaning of dirty pages

Return type: bigint

pg_stat_get_bgwriter_maxwritten_clean()

Description: The number of times the background writer has stopped its cleaning scan because it has written more buffers than specified in the **bgwriter_lru_maxpages** parameter

Return type: bigint

pg_stat_get_buf_written_backend()

Description: The number of buffers written by the backend because they needed to allocate a new buffer

Return type: bigint

pg_stat_get_buf_alloc()

Description: The total number of buffer allocations

Return type: bigint

pg_stat_clear_snapshot()

Description: Discards the current statistics snapshot.

Return type: void

pg_stat_reset()

Description: Resets all statistics counters for the current database to zero (requires system administrator permissions).

Return type: void

pg_stat_reset_shared(text)

Description: Resets all statistics counters for the current database in each node in a shared cluster to zero (requires system administrator permissions).

Return type: void

pg_stat_reset_single_table_counters(oid)

Description: Resets statistics for a single table or index in the current database to zero (requires system administrator permissions).

Return type: void

pg_stat_reset_single_function_counters(oid)

Description: Resets statistics for a single function in the current database to zero (requires system administrator permissions).

Return type: void

pg_stat_session_cu(int, int, int)

Description: Obtains the compression unit (CU) hit statistics of sessions running on the current node.

Return type: record

gs_get_stat_session_cu(text, int, int, int)

Description: Obtains the CU hit statistics of all sessions running in a cluster.

Return type: record

gs_get_stat_db_cu(text, text, bigint, bigint, bigint)

Description: Obtains the CU hit statistics of a database in a cluster.

Return type: record

pg_stat_get_cu_mem_hit(oid)

Description: Obtains the number of CU memory hits of a column storage table in the current database of the current node.

Return type: bigint

pg_stat_get_cu_hdd_sync(oid)

Description: Obtains the number of times CU is synchronously read from a disk by a column-store table in the current database of the current node.

Return type: bigint

pg_stat_get_cu_hdd_asyn(oid)

Description: Obtains the number of times CU is asynchronously read from a disk by a column-store table in the current database of the current node.

Return type: bigint

pg_stat_get_db_cu_mem_hit(oid)

Description: Obtains the CU memory hit in a database of the current node.

Return type: bigint

pg_stat_get_db_cu_hdd_sync(oid)

Description: Obtains the times CU is synchronously read from a disk by a database of the current node.

Return type: bigint

pg_stat_get_db_cu_hdd_asyn(oid)

Description: Obtains the times CU is asynchronously read from a disk by a database of the current node.

Return type: bigint

pgxc_fenced_udf_process()

Description: Shows the number of UDF Master and Work processes.

Return type: record

pgxc_terminate_all_fenced_udf_process()

Description: Kills all UDF Work processes.

Return type: bool

gs_all_nodegroup_control_group_info(text)

Description: Provides Cgroup information for all logical clusters. Before invoking this function, you need to specify the name of a logical cluster to be queried. For example, to query the Cgroup information of the **installation** logical cluster, run the following statement:

```
SELECT * FROM gs_all_nodegroup_control_group_info('installation');
```

Return type: record

The following table describes return columns.

| Name | Type | Description |
|----------|--------|--|
| name | text | Name of a Cgroup |
| type | text | Type of the Cgroup |
| gid | bigint | Cgroup ID |
| classgid | bigint | ID of the Class Cgroup where a Workload Cgroup belongs |
| class | text | Class Cgroup |

| Name | Type | Description |
|----------|--------|-------------------------------------|
| workload | text | Workload Cgroup |
| shares | bigint | CPU quota allocated to a Cgroup |
| limits | bigint | Limit of CPUs allocated to a Cgroup |
| wdlevel | bigint | Workload Cgroup level |
| cpucores | text | Usage of CPU cores in a Cgroup |

gs_get_nodegroup_tablecount(name)

Description: Total number of user tables in all the databases in a logical cluster

Return type: integer

pgxc_max_datanode_size(name)

Description: Maximum disk space occupied by database files in all the DNs of a logical cluster. The unit is byte.

Return type: bigint

gs_check_logic_cluster_consistency()

Description: Checks whether the system information of all logical clusters in the system is consistent. If no record is returned, the information is consistent. Otherwise, the Node Group information on CNs and DNs in the logical cluster is inconsistent. This function cannot be invoked during redistribution in a scale-in or scale-out.

Return type: record

gs_check_tables_distribution()

Description: Checks whether the user table distribution in the system is consistent. If no record is returned, table distribution is consistent. This function cannot be invoked during redistribution in a scale-in or scale-out.

Return type: record

pg_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)

Description: Obtains damage information about pages or CUs after the current node is started.

Return type: record

pgxc_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)

Description: Obtains damage information about pages or CUs after all the nodes in the cluster are started.

Return type: record

pg_stat_bad_block_clear()

Description: Deletes the page and CU damage information that is read and recorded on the node. (System administrator rights are required.)

Return type: void

pgxc_stat_bad_block_clear()

Description: Deletes the page and CU damage information that is read and recorded on all the nodes in the cluster. (System administrator rights are required.)

Return type: void

gs_respool_exception_info(pool text)

Description: Queries for the query rule of a specified resource pool.

Return type: record

gs_control_group_info(pool text)

Description: Queries for information about Cgroups associated with a resource pool.

Return type: record

The following information is displayed:

| Attribute | Value | Description |
|-----------|---------------------|---|
| name | class_a:workload_a1 | Class name and workload name |
| class | class_a | Class Cgroup name |
| workload | workload_a1 | Workload Cgroup name |
| type | DEFWD | Cgroup type (Top, CLASS, BAKWD, DEFWD, and TSWD) |
| gid | 87 | Cgroup ID |
| shares | 30 | Percentage of CPU resources to those on the parent node |
| limits | 0 | Percentage of CPU cores to those on the parent node |
| rate | 0 | Allocation ratio in Timeshare |

| Attribute | Value | Description |
|-----------|-------|---------------------|
| cpucores | 0-3 | Number of CPU cores |

gs_wlm_user_resource_info(name text)

Description: Queries for a user's resource quota and resource usage.

Return type: record

pgxc_stat_single_table(schema, tablename)

Description: Executed on CNs, with the schema name and table name passed. This function queries the statistics of a single table in the entire database and the dirty page rate of the table on each DN.

This function is supported only by version 8.1.3 or later clusters.

NOTE

The statistics of this function depend on the **ANALYZE** operation. To obtain the most accurate information, perform the **ANALYZE** operation on the table first.

Return type: record

The return value fields are the same as those of the [pg_stat_get_tuple\(\)](#) function.

```
SELECT * FROM pgxc_stat_single_table('public','t1');
 nodeid | tableid | partid | last_vacuum | last_autovacuum | last_analyze |
 last_autoanalyze | vacuum_count | autovacuum_count | analyze_count | autoanalyze_count | n_tup_ins | n_
 tup_upd | n_tup_del | n_tup_hot_upd | n_tup_change | n_live_tup | n_dead_tup | dirty_rate |
 last_data_changed
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 datanode1 | 1270075 |      | 2000-01-01 08:00:00+08 | 2000-01-01 08:00:00+08 | 2023-01-09
 09:38:43.220876+08 | 2000-01-01 08:00:00+08 |      0 |      0 |      1 |      0 |      0 |
      0 |      0 |      0 |      0 |      0 |      0 |
(1 row)
```

pgxc_stat_wal_write()

Description: Records information about DN threads that interact with CNs, and collects statistics on WAL logs and data page import volume and rate. This function is executed on all CNs. This parameter is supported by version 8.2.0 or later clusters.

Return type: bigint

Fields in the returned value:

- **node_name**: instance name.
- **application_name**: application name.
- **query_start**: start time of the statement that is being executed.
- **datapage_write**: total size of data pages generated by the current query, in bytes

- **datapage_write_speed**: data page import speed, in bytes/s.
- **wal_write**: total size WAL logs imported by the current query, in bytes.
- **wal_write_speed**: WAL log import speed, in bytes/s.
- **total_datapage_write**: total size of data pages generated by the current thread, in bytes.
- **total_wal_write**: total size of WAL logs, in bytes.

```
SELECT * FROM pgxc_stat_wal_write();
node_name | datid | pid | lwtid | usesysid | application_name | state | query_start
| backend_start | query_id | datapage_write | datapage_write_speed | wal_write |
wal_write_speed | total_datapage_write | total_wal_write
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

NOTE

When row-store data is imported in batches without indexes, the Xlogs related to logical new pages are generated during data page copy. If the volume of Xlogs is greater than the default value, flow control will be triggered.

pg_stat_wal_write()

Description: This function is executed on a CN or DN to record thread information on it and collect statistics on WAL logs and the volume and rate of imported data pages. The following uses a CN as an example.

This parameter is supported by version 8.2.0 or later clusters.

Return type: bigint

Fields in the returned value:

- **node_name**: instance name.
- **application_name**: application name.
- **query_start**: start time of the statement that is being executed.
- **datapage_write**: total size of data pages generated by the current query, in bytes
- **datapage_write_speed**: data page import speed, in bytes/s.
- **wal_write**: total size WAL logs imported by the current query, in bytes.
- **wal_write_speed**: WAL log import speed, in bytes/s.
- **total_datapage_write**: total size of data pages generated by the current thread, in bytes.

- **total_wal_write**: total size of WAL logs, in bytes.

```
SELECT * FROM pg_stat_wal_write();
```

| node_name | datid | pid | lwtid | usesysid | application_name | state | query_start | backend_start | query_id | datapage_write | datapage_write_speed | wal_write | wal_write_speed | total_datapage_write | total_wal_write |

(16 rows)

NOTE

When row-store data is imported in batches without indexes, the Xlogs related to logical new pages are generated during data page copy. If the volume of Xlogs is greater than the default value, flow control will be triggered.

gs_stack()

Description: Obtains the stack information of CN or DN processes. The input parameter **tid** needs to be obtained from views. **lwtid** is not supported. This function is supported by version 8.2.1 or later clusters.

gs_stack() provides a more flexible and quicker method to obtain the stack than **gdb** and **gstack** commands. It is recommended for administrators to use during problem analysis and locating. It is not recommended that this tool be used as a routine monitoring tool.

Fields in the returned value:

- **tid**: thread ID.
- **lwtid**: lightweight thread ID.
- **stack**: stack information corresponding to the **tid** or **lwtid** thread.

The **gs_stack()** function can be used in the following four ways:

- Method 1: If the input parameter value of the **gs_stack(tid)** function is 0, stacks of all threads in the CN or DN process connected to gsql are printed.

NOTE

- This statement can be executed by connecting to a CN or DN using gsql.
- The process of obtaining the running stacks of all threads in a CN or DN takes a long time, which affects normal service running. Therefore, you are advised not to run this command frequently.

```
SELECT * FROM gs_stack(0);
```

```

0x66 | | ThreadStarterFunc(void*) +
```

- Method 2: If the input parameter of the **gs_stack(tid)** function is set to a specified tid, the stack information of the tid thread in the CN or DN process connected using gsql is printed.

NOTE

- This statement can be executed by connecting to a CN or DN using gsql.
- tid** must be the ID of an existing thread on the connected CN or DN process. Otherwise, the error message "invalid thread id" is displayed.
- tid** is obtained from other views. **lwtid** is not supported.
- The process of obtaining the running stack of a specified thread in a specified CN or DN process takes a short time, which does not affect services. Therefore, this method is recommended.

```
SELECT * FROM gs_stack(140185903826656);
tid      | lwtid | stack
-----+-----
140185903826656 | 95275 | __poll + 0x2d +
          |      | GsWaiter::wait(void*, long) + 0x11a +
          |      | CheckpointerMain() + 0x8bb +
          |      | AuxiliaryThreadUnderPm(AuxProcType) + 0x210 +
          |      | SubPostmasterMain(tag_gs_thread_args*) + 0x7e0+
          |      | MainStarterThreadFunc(void*) + 0x6a +
          |      | ThreadStarterFunc(void*) + 0x66 +
          |      | start_thread + 0xc5 +
          |      | clone + 0x6d +
(1 row)
```

- Method 3: If the **gs_stack()** function is set to **gs_stack('nodename', 0)**, stacks of all threads in the process specified by **nodename** are printed.

NOTE

- The underlying implementation uses **execute direct on**. Therefore, you must use gsql to connect to the CN to run the command.
- The first parameter **nodename** must be enclosed in single quotation marks.
- The process of obtaining the running stacks of all threads in a CN or DN takes a long time, which affects normal service running. Therefore, you are advised not to run this command frequently.

```
SELECT * FROM gs_stack('datanode2', 0);

| | LibcommEpollWait(int, int) + 0x38 +
| | RecvDataThreadMain(void*) + 0x8e +
| | LibcommThreadRoutine(void*) + 0x41+
| | start_thread + 0xc5 +
| | clone + 0x6d +
(1 row)
```

pgxc_get_xlog_stats()

Description: Collects statistics on the number of Xlogs of different types from the time when each DN is started to the current time. This command is executed on CNs. This function is supported only by clusters of version 8.3.0 or later.

Return type: record

The following information is displayed:

| Name | Type | Description |
|--------------|--------|----------------|
| node_name | text | Node name |
| rmgr_name | text | Xlog main type |
| record_info | text | xlog info |
| record_count | bigint | Quantity |

| Name | Type | Description |
|---------------|--------|---------------------------------------|
| count_pct | text | Count (%) |
| record_size | bigint | Record size, in bytes. |
| record_pct | text | Percentage of the record size. |
| fpi_size | bigint | Full page image (FPI) size, in bytes. |
| fpi_pct | text | Percentage of the FPI size. |
| combined_size | bigint | Total size of Xlogs, in bytes. |
| combined_pct | text | Percentage of the total Xlog size. |

 NOTE

- This function collects statistics only on the number and size of Xlogs of different types since the last DN startup.
- The xlog size calculated by this function does not consider the xlog spilling. As a result, the xlog size is different from the actual xlog file size.

```
SELECT * FROM pgxc_get_xlog_stats();
```

| node_name | rmgr_name | record_info | record_count | count_pct | record_size | record_pct | fpi_size | fpi_pct | combined_size | combined_pct |

pgxc_get_wal_speed()

Description: Obtains the WAL generation rate of each DN and the receive, write, flush, and redo rates of standby DNs. This function is supported only by clusters of version 8.3.0 or later.

Return type: record

The following information is displayed:

| Name | Type | Description |
|----------------|--------|---|
| node_name | text | Node name. |
| pid | bigint | PID of a thread. |
| local_role | text | Role of the current node |
| peer_role | text | Role of the recipient |
| peer_state | text | Status of the recipient |
| state | text | Transmission status |
| generate_speed | bigint | Generation rate of the primary DN wal, in byte/s. |

| Name | Type | Description |
|---------------|--------|---|
| receive_speed | bigint | Receiving rate of the standby DN. The unit is byte/s. |
| write_speed | bigint | Write speed of the standby DN. The unit is byte/s. |
| flush_speed | bigint | Disk flushing rate of the standby DN. The unit is byte/s. |
| redo_speed | bigint | Redo speed of the standby DN. The unit is byte/s. |

pg_xlog_display_one_lsn(start_lsn)

Description: This command can be executed on CNs or DNs to completely parse Xlogs in the current location based on the start LSN. This function is supported only by clusters of version 8.3.0 or later.

Input parameter: **start_lsn**, indicating the start LSN. Ensure that the entered start LSN is the beginning of an Xlog.

Return type: record

The following information is displayed:

| Name | Type | Description |
|-----------|------|---------------------------------|
| node_name | text | Current instance name. |
| start_lsn | text | Start LSN. |
| end_lsn | text | End LSN. |
| startlsn | text | Start LSN of the Xlog. |
| endlsn | text | End LSN of the Xlog. |
| prelsn | text | Start LSN of the previous Xlog. |

| Name | Type | Description |
|----------|------|---------------------------------------|
| xid | xid | Xlog transaction ID. |
| datalen | int4 | Xlog data length, in bytes. |
| totallen | int4 | Xlog length, in bytes. |
| type | text | Xlog type. |
| desc | text | Xlog content. |
| blkref | text | Relfilenode associated with the Xlog. |

Example:

```
SELECT * FROM pg_xlog_display_one_lsn('0/101CA00');
node_name | startlsn | endlsn | prelsn | xlog_tid | datalen | totallen | xlogtype |
xlogdescribe
          | blkref
-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----

```

pg_xlogdump (tablename)

Description: Parses and filters Xlog files based on table names on CNs or DN. This function is supported only by clusters of version 8.3.0 or later.

Return type: record

The following information is displayed:

| Name | Type | Description |
|-----------|------|---------------------------------|
| node_name | text | Node name. |
| start_lsn | text | Start LSN. |
| end_lsn | text | End LSN. |
| startlsn | text | Start LSN of the Xlog. |
| endlsn | text | End LSN of the Xlog. |
| prelsn | text | Start LSN of the previous Xlog. |
| xid | xid | Xlog transaction ID. |

| Name | Type | Description |
|---------|------|---------------------------------------|
| datalen | int4 | Xlog data length, in bytes. |
| totalen | int4 | Xlog length, in bytes. |
| type | text | Xlog type. |
| desc | text | Xlog content. |
| blkref | text | Relfilenode associated with the Xlog. |

 NOTE

- The length of the **xlogdescribe** field varies depending on the Xlog type. The **pg_xlogdump()** function truncates the field and retains only the first 64 bytes.
- You can find the target Xlog and use the **pg_xlog_display_one_lsn()** function to view the complete Xlog content.

Example:

```
SELECT * FROM pg_xlogdump(pg_class);
node_name | startlsn | endlsn | prelsn | xlog_tid | datalen | totalen | xlogtype | xlogdescribe
|          |         |         |         |          |         |         |          |

pg_xlogdump (xid)

Description: Parses and filters Xlogs based on transaction IDs. This statement can be executed on CNs or DN. This function is supported only by clusters of version 8.3.0 or later.

Return type: record

The following information is displayed:

| Name | Type | Description |
|-----------|------|---------------------------------------|
| node_name | text | Node name. |
| start_lsn | text | Start LSN. |
| end_lsn | text | End LSN. |
| startlsn | text | Start LSN of the Xlog. |
| endlsn | text | End LSN of the Xlog. |
| prelsn | text | Start LSN of the previous Xlog. |
| xid | xid | Xlog transaction ID. |
| datalen | int4 | Xlog data length, in bytes. |
| totalen | int4 | Xlog length, in bytes. |
| type | text | Xlog type. |
| desc | text | Xlog content. |
| blkref | text | Relfilenode associated with the Xlog. |

NOTE

- The length of the **xlogdescribe** field varies depending on the Xlog type. The **pg_xlogdump()** function truncates the field and retains only the first 64 bytes.
- You can find the target Xlog and use the **pg_xlog_display_one_lsn()** function to view the complete Xlog content.

Example:

```
SELECT * FROM pg_xlogdump(1);

pg_xlogdump (start_lsn, end_lsn)

Description: Parses Xlog files based on the start and end LSNs. This command can be executed on CNs or DN. This function is supported only by clusters of version 8.3.0 or later.

Input parameters: **start_lsn** indicates the start LSN, and **end_lsn** indicates the end LSN. You do not need to ensure that the start LSN is the first Xlog. The parsing starts from the first valid Xlog after the start LSN.

Return type: record

The following information is displayed:

| Field | Type | Description |
|-----------|------|---------------------------------------|
| node_name | text | Node name. |
| start_lsn | text | Start LSN. |
| end_lsn | text | End LSN. |
| startlsn | text | Start LSN of the Xlog. |
| endlsn | text | End LSN of the Xlog. |
| prelsn | text | Start LSN of the previous Xlog. |
| xid | xid | Xlog transaction ID. |
| datalen | int4 | Xlog data length, in bytes. |
| totallen | int4 | Xlog length, in bytes. |
| type | text | Xlog type. |
| desc | text | Xlog content. |
| blkref | text | Relfilenode associated with the Xlog. |

 NOTE

- The length of the **xlogdescribe** field varies depending on the Xlog type. The **pg_xlogdump()** function truncates the field and retains only the first 64 bytes.
- You can find the target Xlog and use the **pg_xlog_display_one_lsn()** function to view the complete Xlog content.

Example:

```
SELECT * FROM pg_xlogdump('0/101EF70','0/101F590');

21.7.32 Trigger Functions

pg_get_triggerdef(oid)

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried

Return type: text

Example:

```
SELECT pg_get_triggerdef(oid) FROM pg_trigger;
          pg_get_triggerdef
-----
CREATE TRIGGER insert_trigger BEFORE INSERT ON test_trigger_src_tbl FOR EACH ROW EXECUTE
PROCEDURE tri_insert_func()
(1 row)
```

pg_get_triggerdef(oid, boolean)

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

Return type: text

NOTE

The Boolean parameters take effect only when the WHEN condition is specified during trigger creation.

Example:

```
SELECT pg_get_triggerdef(oid,true) FROM pg_trigger;
          pg_get_triggerdef
-----
CREATE TRIGGER insert_trigger BEFORE INSERT ON test_trigger_src_tbl FOR EACH ROW EXECUTE
PROCEDURE tri_insert_func()
(1 row)

SELECT pg_get_triggerdef(oid,false) FROM pg_trigger;
          pg_get_triggerdef
-----
CREATE TRIGGER insert_trigger BEFORE INSERT ON test_trigger_src_tbl FOR EACH ROW EXECUTE
PROCEDURE tri_insert_func()
(1 row)
```

21.7.33 XML Functions

21.7.33.1 Generating XML Content

Expressions of functions and class functions in this section can be used to generate XML content from SQL data. This method is used to format query results into XML documents for processing in client applications.

XMLPARSE ({ DOCUMENT | CONTENT } *value*)

Description: Generates an XML value from character data.

Return type: XML

Example:

```
SELECT xmlparse(document '<foo>bar</foo>');
      xmlparse
-----
<foo>bar</foo>
(1 row)
```

XMLSERIALIZE ({ DOCUMENT | CONTENT } *value AS type*

Description: Generates a string from XML values.

Return type: type, which can be character, character varying, or text (or its alias)

Example:

```
SELECT xmlserialize(content 'good' AS CHAR(10));
xmlserialize
-----
good
(1 row)
```

xmlcomment(text)

Description: Creates an XML note that uses the specified text as the content. The text cannot contain (--) or end with a hyphen (-). If the parameter is null, the result is also null.

Return type: XML

Example:

```
SELECT xmlcomment('hello');
xmlcomment
-----
<!--hello-->
(1 row)
```

xmlconcat(xml[, ...])

Description: Concatenates a list of XML values into a single value. Null values are ignored. If all parameters are null, the result is also null.

Return type: XML

Example:

```
SELECT xmlconcat('<abc/>', '<bar>foo</bar>');
xmlconcat
-----
<abc/><bar>foo</bar>
(1 row)
```

Note: If XML declarations exist and they are the same XML version, the result will use the version. Otherwise, the result does not use any version. If all XML values have the **standalone** attribute whose status is **yes**, the **standalone** attribute in the result is **yes**. If at least one XML value's **standalone** attribute is **no**, the **standalone** attribute in the result is **no**. Otherwise, the result does not contain the **standalone** attribute.

Example:

```
SELECT xmlconcat('<?xml version="1.1"?><foo/>', '<?xml version="1.1" standalone="no"?><bar/>');
xmlconcat
-----
<?xml version="1.1"?><foo/><bar/>
(1 row)
```

xmlelement(name name [, xmlattributes(value [AS attname] [, ...])] [, content, ...])

Description: Generates an XML element with the given name, attribute, and content.

Return type: XML

Example:

```
SELECT xmlelement(name foo);
xmlelement
-----
<foo/>
(1 row)

SELECT xmlelement(name foo, xmlattributes('xyz' as bar));
xmlelement
-----
<foo bar="xyz"/>
(1 row)

SELECT xmlelement(name foo, xmlattributes(current_date as bar), 'cont', 'ent');
xmlelement
-----
<foo bar="2023-08-16">content</foo>
(1 row)
```

Element and attribute names without valid XML names are escaped by replacing invalid characters with the sequence **_xHHHH_**, where **HHHH** is the Unicode code points of the character expressed in hexadecimal format. Example:

```
SELECT xmlelement(name "foo$bar", xmlattributes('xyz' as "a&b"));
xmlelement
-----
<foo_x0024_bar a_x0026_b="xyz"/>
```

If the attribute value is a column reference, you do not need to specify an explicit attribute name, and the column name is used as the attribute name by default. In other cases, the attribute must be given an explicit name. So this example is legal:

```
CREATE TABLE test (a xml, b xml);
SELECT xmlelement(name test, xmlattributes(a, b)) FROM test;
```

But these are illegal:

```
SELECT xmlelement(name test, xmlattributes('constant'), a, b) FROM test;
SELECT xmlelement(name test, xmlattributes(func(a, b))) FROM test;
```

The element content, if specified, will be formatted based on its data type. If the content itself is of the XML type, a complex XML document will be constructed.

Example:

```
SELECT xmlelement(name foo, xmlattributes('xyz' as bar), xmlelement(name
abc), xmlcomment('test'), xmlelement(name xyz));
xmlelement
-----
<foo bar="xyz"><abc/><!--test--><xyz/></foo>
```

Other types of content will be formatted into valid XML character data. This means that special characters **<**, **>**, and **&** will be converted to entities. Binary data (data type **bytea**) is represented as Base64 or hexadecimal code, depending on the configuration parameter **xmlbinary**.

xmlforest(content [AS name] [, ...])

Description: Generates an XML forest (sequence) of an element with a given name and content.

Return type: XML

Example:

```
SELECT xmlforest('abc' AS foo, 123 AS bar);
       xmlforest
-----
<foo>abc</foo><bar>123</bar>
(1 row)

SELECT xmlforest(table_name, column_name) FROM ALL_TAB_COLUMNS WHERE schema = 'pg_catalog';
       xmlforest
-----
<table_name>pg_authid</table_name><column_name>rolsuper</column_name>
<table_name>pg_authid</table_name><column_name>rolinherit</column_name>
<table_name>pg_authid</table_name><column_name>rolcreatorole</column_name>
```

xmlpi(name target [, content])

Description: Creates an XML processing instruction. The content cannot contain the character sequence of ?>.

Return type: XML

Example:

```
SELECT xmlpi(name php, 'echo "hello world";');
       xmlpi
-----
<?php echo "hello world";?>
(1 row)
```

xmlroot(xml, version text | no value [, standalone yes|no|no value])

Description: Modifies the attributes of the root node of an XML value. If a version is specified, it replaces the value in the version declaration of the root node. If a **standalone** value is specified, it replaces the **standalone** value in the root node.

Return type: XML

Example:

```
SELECT xmlroot(xmlparse(document '<?xml version="1.0" standalone="no"?><content>abc</content>'),
              version '1.1', standalone yes);
       xmlroot
-----
<?xml version="1.1" standalone="yes"?><content>abc</content>
(1 row)
```

xmlagg(xml)

Description: The **xmlagg** function is an aggregate function that concatenates input values.

Return type: XML

Example:

```
CREATE TABLE test (y int, x xml);
INSERT INTO test VALUES (1, '<foo>abc</foo>');
INSERT INTO test VALUES (2, '<bar/>');

SELECT xmlagg(x) FROM test;
      xmlagg
-----
<bar/><foo>abc</foo>
(1 row)
```

Add an **ORDER BY** clause to an aggregate call to determine the concatenation sequence. For example:

```
SELECT xmlagg(x ORDER BY y DESC) FROM test;
      xmlagg
-----
<bar/><foo>abc</foo>
(1 row)
```

21.7.33.2 XML Predicates

The functions in this section check the attributes of an XML value.

xml IS DOCUMENT

Description: IS DOCUMENT returns true if the XML value of the parameter is a correct XML document; if the XML document is incorrect, false is returned. If the parameter is null, a null value is returned.

Return type: bool

```
SELECT '<abc/>' is document;
?column?
-----
t
(1 row)
```

xml IS NOT DOCUMENT

Description: Returns **true** if the XML value of the parameter is not a correct XML document. If the XML document is correct, **false** is returned. If the parameter is null, a null value is returned.

Return type: bool

```
SELECT 'abc' is document;
?column?
-----
f
(1 row)
```

XMLEXISTS(text PASSING [BY REF] xml [BY REF])

Description: If the **xpath** expression in the first parameter returns any node, the **XMLEXISTS** function returns true. Otherwise, the function returns false. (If any parameter is null, the result is null.) The BY REF clause is invalid and is used to maintain SQL compatibility.

Return type: bool

Example:

```
SELECT xmlexists('//*[text() = "TScity"]' PASSING BY REF '<towns><town>TScity</town><town>TOcity</town></towns>');
xmlexists
-----
t
(1 row)
```

xml_is_well_formed(text)

Description: Checks whether a text string is a well-formatted XML value and returns a Boolean result. If the **xmloption** parameter is set to **DOCUMENT**, the document is checked. If the **xmloption** parameter is set to **CONTENT**, the content is checked.

Return type: bool

Example:

```
SET xmloption TO DOCUMENT;
SET

SELECT xml_is_well_formed('<>');
xml_is_well_formed
-----
f
(1 row)

SELECT xml_is_well_formed('<abc/>');
xml_is_well_formed
-----
t
(1 row)

SET xmloption TO CONTENT;
SELECT xml_is_well_formed('abc');
xml_is_well_formed
-----
t
(1 row)
```

xml_is_well_formed_document(text)

Description: Checks whether a text string is a well-formatted text and returns a Boolean result.

Return type: bool

Example:

```
SELECT xml_is_well_formed_document('<test:foo xmlns:test="http://test.com/test">bar</test:foo>');
xml_is_well_formed_document
-----
t
(1 row)

SELECT xml_is_well_formed_document('<test:foo xmlns:test="http://test.com/test">bar</my:foo>');
xml_is_well_formed_document
-----
f
(1 row)
```

xml_is_well_formed_content(text)

Description: Checks whether a text string is a well-formatted content and returns a Boolean result.

Return type: bool

Example:

```
SELECT xml_is_well_formed_content('content');
xml_is_well_formed_content
-----
t
(1 row)

SELECT xml_is_well_formed_content('<content');
xml_is_well_formed_content
-----
f
(1 row)
```

21.7.33.3 Processing XML

To process values of the XML data type, DWS provides the **xpath** and **xpath_exists** functions, as well as the **XMLTABLE** table function.

xpath(xpath, xml [, nsarray])

Description: Returns an array of XML values corresponding to the set of nodes produced by the **xpath** expression. If the **xpath** expression returns a scalar value instead of a set of nodes, an array of individual elements is returned.

The second parameter **xml** must be a complete XML document, which must have a root node element.

The third parameter is optional and is an array mapping of a namespace. The array should be a two-dimensional text array, and the length of the second dimension should be 2. (It should be an array of arrays, each containing exactly two elements). The first element of each array item is the alias of the namespace name, and the second element is the namespace URI. The alias provided in this array does not have to be the same as the alias used in the XML document itself. In other words, in the context of both XML documents and **xpath** functions, aliases are local.

Return type: XML value array

Example:

```
SELECT xpath('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>', ARRAY[ARRAY['my',
'http://example.com']]);
xpath
-----
{test}
(1 row)
```

Process the default (anonymous) namespace:

```
SELECT xpath('/mydefns:b/text()', '<a xmlns="http://example.com"><b>test</b></a>', ARRAY[ARRAY['mydefns', 'http://example.com']]);
xpath
-----
{test}
(1 row)
```

xpath_exists(xpath, xml [, nsarray])

Description: The **xpath_exists** function is a special form of the **xpath** function. This function does not return an XML value that satisfies the **xpath** function; it

returns a Boolean value indicating whether the query is satisfied. This function is equivalent to the standard **XMLEXISTS** predicate, but it also provides support for a namespace mapping parameter.

Return type: bool

Example:

```
SELECT xpath_exists('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>',  
ARRAY[ARRAY['my', 'http://example.com']]);  
xpath_exists  
-----  
t  
(1 row)
```

xmltable

Description: Generates a table based on the input XML data, **XPath** expression, and column definition. An **xmltable** is similar to a function in syntax, but it can appear only as a table in the FROM clause of a query.

Return value: setof record

Syntax:

```
XMLTABLE ( [ XMLNAMESPACES ( namespace_uri AS namespace_name [, ...] ), ]  
          row_expression PASSING [ BY { REF | VALUE } ]  
          document_expression [ BY { REF | VALUE } ]  
          COLUMNS name { type [ PATH column_expression ] [ DEFAULT default_expression ] [ NOT NULL |  
NULL ] | FOR ORDINALITY }  
          [, ...]  
          )
```

Parameter:

- The optional XMLNAMESPACES clause is a comma-separated list of namespace definitions, where each **namespace_uri** is a text-type expression and each **namespace_name** is a simple identifier. XMLNAMESPACES specifies the XML namespaces used in the document and their aliases. The default namespace declaration is not supported.
- The mandatory parameter **row_expression** is an **XPath** 1.0 expression. This expression calculates the sequence of XML nodes based on the provided XML document **document_expression**. The sequence is the sequence of converting **xmltable** to output lines. If the **document_expression** value is **NULL** or an empty node set generated by **row_expression**, no line is returned.
- The **document_expression** parameter is used to input an XML document. The input document must be in the XML format. XML segment data or XML documents in incorrect formats are not supported. The BY REF and BY VALUE clauses do not take effect. They are used only to implement SQL standard compatibility.
- The COLUMNS clause specifies the column list definition in the output table. The column name and column data type are mandatory, and the path, default value, and whether the clause is empty are optional.
 - **column_expression** of a column is an **XPath** 1.0 expression used to calculate the value of the column extracted from the current row based on **row_expression**. If **column_expression** is not specified, the field name is used as an implicit path.

- A column can be marked as **NOT NULL**. If **column_expression** in the **NOT NULL** column does not return any data, and there is no **DEFAULT** clause or the calculation result of **default_expression** is **NULL**, an error is reported.
- The columns marked as **FOR ORDINALITY** are filled with row numbers starting from 1. The sequence is the node sequence retrieved from the **row_expression** result set. A maximum of one column can be marked as **FOR ORDINALITY**.

NOTICE

XPath 1.0 does not specify the order for nodes, so the order in which results are returned depends on the order in which data is obtained.

Example:

```
SELECT * FROM XMLTABLE('/ROWS/ROW'  
PASSING '<ROWS><ROW id="1"><CITY_ID>1002a</CITY_ID><CITY_NAME>snowcity</CITY_NAME></  
ROW><ROW id="2"><CITY_ID>1003b</CITY_ID><CITY_NAME>icecity</CITY_NAME></ROW><ROW  
id="3"><CITY_ID>1004c</CITY_ID><CITY_NAME>windcity</CITY_NAME></ROW></ROWS>'  
COLUMNS id INT PATH '@id',  
ordinality FOR ORDINALITY,  
CITY_id TEXT PATH 'CITY_ID',CITY_name TEXT PATH 'CITY_NAME' NOT NULL);  
id | ordinality | city_id | city_name  
-----  
1 | 1 | 1002a | snowcity  
2 | 2 | 1003b | icecity  
3 | 3 | 1004c | windcity  
(3 rows)
```

21.7.33.4 Mapping a Table to XML

table_to_xml(tbl regclass, nulls boolean, tableforest boolean, targetns text)

Description: Maps the contents of a table to XML values.

Return type: XML

table_to_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)

Description: Maps a relational table schema to an XML schema document.

Return type: XML

table_to_xml_and_xmlschema(tbl regclass, nulls boolean, tableforest boolean, targetns text)

Description: Maps a relational table to XML values and schema documents.

Return type: XML

query_to_xml(query text, nulls boolean, tableforest boolean, targetns text)

Description: Maps the contents of an SQL query to XML values.

Return type: XML

query_to_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)

Description: Maps an SQL query into an XML schema document.

Return type: XML

query_to_xml_and_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)

Description: Maps SQL queries to XML values and schema documents.

Return type: XML

cursor_to_xml(cursor refcursor, count int, nulls boolean, tableforest boolean, targetns text)

Description: Maps a cursor query to an XML value.

Return type: XML

cursor_to_xmlschema(cursor refcursor, nulls boolean, tableforest boolean, targetns text)

Description: Maps a cursor query to an XML schema document.

Return type: XML

schema_to_xml(schema name, nulls boolean, tableforest boolean, targetns text)

Description: Maps a table in a schema to an XML value.

Return type: XML

schema_to_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)

Description: Maps a table in a schema to an XML schema document.

Return type: XML

schema_to_xml_and_xmlschema(schema name, nulls boolean, tableforest boolean, targetns text)

Description: Maps a table in a schema to an XML value and a schema document.

Return type: XML

database_to_xml(nulls boolean, tableforest boolean, targetns text)

Description: Maps a database table to an XML value.

Return type: XML

database_to_xmlschema(nulls boolean, tableforest boolean, targetns text)

Description: Maps a database table to an XML schema document.

Return type: XML

database_to_xml_and_xmlschema(nulls boolean, tableforest boolean, targetns text)

Description: Maps database tables to XML values and schema documents.

Return type: XML

NOTE

The parameters for mapping a table to an XML value are described as follows:

- **tbl**: table name.
- **nulls**: indicates whether the output contains null values. If the value is **true**, the null value in the column is `<columnname xsi:nil="true"/>`. If the value is **false**, the columns containing null values are omitted from the output.
- **tableforest**: If this parameter is set to **true**, XML fragments are generated. If this parameter is set to **false**, XML files are generated.
- **targetns**: specifies the XML namespace of the desired result. If this parameter is not specified, an empty string is passed.
- **query**: SQL query statement
- **cursor**: cursor name
- **count**: amount of data obtained from the cursor
- **schema**: schema name

21.7.34 Call Stack Recording Functions

The **pv_memory_profiling(type int)** and environment variable **MALLOC_CONF** are used by DWS to control the enabling and disabling of the memory allocation call stack recording module and the output of the process-level memory call stack. The following figure illustrates the process.

MALLOC_CONF

The environment variable **MALLOC_CONF** is used to enable the monitoring module. It is in the `${BIGDATA_HOME}/mppdb/.mppdbgs_profile` file and is enabled by default. Note the following points:

- Restart the database after modifying this environment variable.

- If **om_monitor** is enabled in the cluster, restart the **om_monitor** process and then the database after setting this environment variable, so that the setting can take effect.
- This environment variable can be set on all servers in the cluster or on some servers where the module needs to be enabled. For the GaussDB process, each process determines whether to enable the module based on the **MALLOC_CONF** environment variable.

Commands for enabling and disabling **MALLOC_CONF**:

- Enabling the monitoring module:
`export MALLOC_CONF=prof:true`
- Disabling the monitoring module:
`export MALLOC_CONF=prof:false`

pv_memory_profiling (type int)

Parameter description: Controls the backtrace recording and output of memory allocation functions such as **malloc** in the gaussdb process.

Value range: a positive integer from 0 to 3.

Table 21-84 Values and descriptions of **pv_memory_profile**

| pv_memory_profiling Value | Description |
|----------------------------------|--|
| 0 | Disables the memory trace function and does not record information of call stacks such as malloc . |
| 1 | Enables the memory trace function to record information of call stacks such as malloc . |
| 2 | Outputs trace logs of call stacks such as malloc . <ul style="list-style-type: none">• Output path: /proc/pid/cwd directory. <i>pid</i> indicates the ID of the GaussDB process.• Output log name format: jeprof.<pid>.*.heap, where <i>pid</i> indicates the ID of the GaussDB process and * indicates the unique sequence number of the output trace log, for example, jeprof.195473.0.u0.heap. |
| 3 | Outputs memory statistics. <ul style="list-style-type: none">• Output path: /proc/pid/cwd directory. <i>pid</i> indicates the ID of the GaussDB process.• Log name format: <i>Node name + Process ID + Time + heap_stats + .out</i>. You can use vim to open the file. |

Return type: Boolean

Note:

- If the function is called successfully, **true** is returned. Otherwise, **false** is returned.
- If **Memory profiling failed, check if \$MALLOC_CONF contain 'prof:true'**. is displayed, it indicates that the module is used when **MALLOC_CONF=prof:true** is not set. In this case, you need to set the environment variable.
- If **Type %d is not supported. The valid range is 0-3.** is displayed, the parameter value is incorrect. The correct values are **0, 1, 2, and 3**.
- If "Memory profiling failed, input type is %d, failed number is %d." is displayed, contact technical support.

Outputting Memory Call Stack Information

Procedure:

- Step 1** Execute the following statement to output the memory call stack information and output the **trace** file in the directory where the GaussDB process is located:

```
SELECT * FROM pv_memory_profiling(2);
```

- Step 2** Use the jeprof tool provided by jemalloc to parse log information.

Method 1: Output in text format.

```
jeprof --text --show_bytes $GAUSSHOME/bin/gaussdb trace file 1 >prof.txt
```

Method 2: Export the report in PDF format.

```
jeprof --pdf --show_bytes $GAUSSHOME/bin/gaussdb trace file 1 > prof.pdf
```

NOTE

- To parse the memory call stack information, you need to use the GaussDB source code for analysis. You need to send the **trace** file to R&D engineers for analysis.
- To analyze the **trace** file, you need to use the jeprof tool, which is generated by jemalloc. The Perl environment is required for using the tool. To generate PDF calling diagrams, you need to install the GraphViz tool that matches the OS.

----End

Example

Log in as the system administrator, set environment variables, and start the database.

```
export MALLOC_CONF=prof:true
```

Disable the memory trace recording function when the database is running.

```
postgres=#SELECT pv_memory_profiling(0);
pv_memory_profiling
-----
t
(1 row)
```

Enable the memory trace recording function when the database is running.

```
postgres=#SELECT pv_memory_profiling(1);
pv_memory_profiling
-----
t
(1 row)
```

Output memory trace records.

```
postgres=#SELECT pv_memory_profiling(2);
pv_memory_profiling
-----
t
```

(1 row)

Generate the trace file in text or PDF format in the directory where the GaussDB process is located.

```
jeprof --text --show_bytes $GAUSSHOME/bin/gaussdb trace file 1 >prof.txt
jeprof --pdf --show_bytes $GAUSSHOME/bin/gaussdb trace file 1 > prof.pdf
```

Outputs memory statistics. Execute the following statement to generate the memory statistics file in the directory where the GaussDB process is located. The file can be directly read.

```
postgres=#SELECT pv_memory_profiling(3);
pv_memory_profiling
-----
t
(1 row)
```

21.7.35 Hudi System Functions

Hudi system functions are supported only by 9.1.0.100 and later cluster versions.

pg_show_custom_settings()

Description: Queries details about Hudi foreign table parameter settings.

Return type: SETOF record

Example:

```
SELECT * FROM pg_show_custom_settings();
      name      | setting | unit | category | short_desc |
extra_desc | context | vartype | source | min_val | max_val |
enumvals | boot_val | reset_val | sourcefile | sourceline
-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
hoodie.public.hudi_mor_ft.consume.ending.timestamp | 20230404172329544 | | Customized Options |
GUC placeholder variable | | user | string | session | | |
| | | | | | | | | | | | |
hoodie.public.hudi_mor_ft.consume.mode | incremental | | Customized Options | GUC
placeholder variable | | user | string | session | | |
| | | | | | | | | | | | |
hoodie.public.hudi_mor_ft.consume.start.timestamp | 20230404172329543 | | Customized Options |
GUC placeholder variable | | user | string | session | | |
| | | | | | | | | | | | |
(3 rows)
```

hudi_get_options(regclass)

Description: Queries the properties of a Hudi foreign table (hoodie.properties). It is represented by a key-value pair.

Return type: SETOF record

Example:

```
select * from hudi_get_options('public.hudi_mor_ft');
      key                | value
-----+-----
hoodie.table.precombine.field | col_int
hoodie.datasource.write.drop.partition.columns | false
hoodie.table.partition.fields | 
hoodie.table.type | MERGE_ON_READ
hoodie.archive.log.folder | archived
hoodie.compaction.payload.class | 
org.apache.hudi.common.model.OverwriteWithLatestAvroPayload
hoodie.timeline.layout.version | 1
hoodie.table.version | 4
hoodie.table.recordkey.fields | col_bigint
hoodie.database.name | default
hoodie.datasource.write.partitionpath.urlencode | false
hoodie.table.name | lt_test_mor_014
hoodie.table.keygenerator.class | org.apache.hudi.keygen.ComplexKeyGenerator
hoodie.datasource.write.hive_style_partitioning | true
hoodie.table.create.schema | 
{"type": "record", "name": "lt_test_mor_014_record", "namespace": "hoodie.lt_test_mor_014", "fields": [
  {"name": "_hoodie_commit_time", "type": [
    "string", "null"]}, {"name": "_hoodie_commit_seqno", "type": ["string", "null"]},
  {"name": "_hoodie_record_key", "type": ["string", "null"]}, {"name": "_hoodie_partition_path", "type": [
    "string", "null"]}, {"name": "_hoodie_file_name", "type": ["string", "null"]}, {"name": "col_bigint", "type": ["long", "null"]},
  {"name": "col_int", "type": ["int", "null"]}, {"name": "col_text", "type": ["string", "null"]}, {"name": "col_text2", "type": ["string", "null"]}]}
hoodie.table.checksum | 515660817
(16 rows)
```

hudi_get_max_commit(regclass)

Description: This function retrieves the most recent commit timestamp and data write time for the current Hudi external table.

Return type: record

Example:

```
SELECT * FROM hudi_get_max_commit('public.hudi_mor_ft');
max_commit | write_time
-----+-----
20221207141822 | 2022-12-07 14:18:30+08
(1 row)
```

hudi_get_commit(regclass, cstring, int)

Description: This function retrieves the timestamp and write time of the commit data for the current Hudi foreign table, starting from the specified commit and up to the *M*th commit. If the *M*th commit does not exist, the latest commit and the corresponding data write time are returned.

Return type: record

Example:

```
SELECT * FROM hudi_get_commit('public.hudi_mor_ft', '20230329174744657', 3);
   end_commit |      write_time
-----+-----
20230329174808908 | 2023-08-31 15:43:08+08
(1 row)
```

hudi_sync_task_submit(regclass, regclass)

Description: Submits an automatic Hudi synchronization task. The first input parameter is the synchronization target table, and the second input parameter is the Hudi foreign table. If the task is submitted successfully, the task ID is returned.

Return type: text

NOTE

- The synchronization target table must contain a primary key, which must be the same as the value of **hudi recordkey**.
- If the hudi table contains the **precombine** field, the synchronization target table must also contain the corresponding field.
- If the synchronization target table contains only the primary key (no other fields except the primary key), the synchronization task cannot be submitted normally.
- The user must have the **INSERT** and **UPDATE** permissions on the target table and the **SELECT** permission on the Hudi foreign table. Otherwise, the synchronization task cannot be submitted.

Example:

```
SELECT hudi_sync_task_submit('public.hudi_sync_i','public.hudi_mor_ft');
   hudi_sync_task_submit
-----
6465efe2-3ea1-0b00-dde5-b57dfb30fffe
(1 row)
```

hudi_sync_task_submit(regclass, regclass, interval)

Description: The function is the same as that of **hudi_sync_task_submit(regclass, regclass)**. The difference is that, in this function, you can specify an input parameter of the interval type to specify the task scheduling period. The value ranges from 5 seconds to 24 hours. If the task is submitted successfully, the task ID is returned.

Return type: text

NOTE

- The synchronization target table must contain a primary key, which must be the same as the value of **hudi recordkey**.
- If the hudi table contains the **precombine** field, the synchronization target table must also contain the corresponding field.
- If the synchronization target table contains only the primary key (no other fields except the primary key), the synchronization task cannot be submitted normally.
- The user must have the **INSERT** and **UPDATE** permissions on the target table and the **SELECT** permission on the Hudi foreign table. Otherwise, the synchronization task cannot be submitted.

Example:

```
SELECT hudi_sync_task_submit('public.hudi_sync_i','public.hudi_mor_ft','1 hour');
   hudi_sync_task_submit
```

```
-----  
6465efe2-3ea1-0b00-dde5-b57dfb30ffe  
(1 row)
```

hudi_sync_task_submit(regclass, regclass, text, text)

Description: The function is the same as that of **hudi_sync_task_submit(regclass, regclass)**. The difference is that you can specify two additional text input parameters to indicate the fields that you expect to be synchronized. The fields are separated by commas (,). Quotation marks and escape characters can be parsed. The number and sequence of fields in the two text parameters must be the same, because the synchronization will be performed based on the mapping between the fields in the two text parameters. If the task is submitted successfully, the task ID is returned.

Return type: text

NOTE

- The synchronization target table must contain a primary key, which must be the same as the value of **hudi recordkey**.
- If the hudi table contains the **precombine** field, the synchronization target table must also contain the corresponding field.
- If the synchronization target table contains only the primary key (no other fields except the primary key), the synchronization task cannot be submitted normally.
- The user must have the **INSERT** and **UPDATE** permissions on the target table and the **SELECT** permission on the Hudi foreign table. Otherwise, the synchronization task cannot be submitted.

Example:

```
SELECT hudi_sync_task_submit('public.hudi_sync_i','public.hudi_mor_ft','_hoodie_commit_time, col_bigint,  
col_text', '_hoodie_commit_time, col_bigint, col_text');  
hudi_sync_task_submit  
-----  
646610bc-cdd1-0d00-d07d-b57e89a0ffe  
(1 row)
```

hudi_sync_task_submit(regclass, regclass, text, text, interval)

Description: The function is the same as that of **hudi_sync_task_submit(regclass, regclass, text, text)**. The difference is that you can specify an additional input parameter of the interval type to specify the task scheduling period. The value ranges from 5 seconds to 24 hours.

Return type: text

NOTE

- The synchronization target table must contain a primary key, which must be the same as the value of **hudi recordkey**.
- If the hudi table contains the **precombine** field, the synchronization target table must also contain the corresponding field.
- If the synchronization target table contains only the primary key (no other fields except the primary key), the synchronization task cannot be submitted normally.
- The user must have the **INSERT** and **UPDATE** permissions on the target table and the **SELECT** permission on the Hudi foreign table. Otherwise, the synchronization task cannot be submitted.

Example:

```
SELECT hudi_sync_task_submit('public.hudi_sync_i','public.hudi_mor_ft','_hoodie_commit_time, col_bigint, col_text', '_hoodie_commit_time, col_bigint, col_text', '10 minute 30second');
      hudi_sync_task_submit
-----
646610bc-cdd1-0d00-d07d-b57e89a0fffe
(1 row)
```

hudi_show_sync_state()

Description: Obtains the synchronization status of the Hudi automatic synchronization task.

Return type: SETOF record

Example:

```
SELECT * FROM hudi_show_sync_state();
 target_tbl | source_ftbl | payload_type | precombine_key | latest_commit
-----+-----+-----+-----+-----
public.hudi_sync_i | public.hudi_mor_ft | org.apache.hudi.common.model.OverwriteWithLatestAvroPayload | col_int | 20230511114021573
(1 row)
```

hudi_sync(regclass, regclass)

Description: Stored procedure, which is invoked by the Hudi automatic synchronization task. Tasks submitted using **pg_catalog.hudi_sync_task_submit(regclass, regclass)** will execute the stored procedure. Upon successful execution of the command, the number of synchronized rows and timestamp will be displayed.

Return type: text

Example:

```
CALL hudi_sync('public.hudi_sync_i', 'public.hudi_mor_ft');
NOTICE: execute full sync
CONTEXT: PL/pgSQL function hudi_sync(regclass,regclass) line 11 at RETURN
      hudi_sync
-----
sync 1 rows up to 20230511114021573.
(1 row)
```

hudi_sync_custom(regclass, regclass, text)

Description: A stored procedure, which is the entry for invoking the Hudi automatic synchronization task. Users can customize the mapping between the fields in the target table and those in the data source table. Tasks submitted using **pg_catalog.hudi_sync_task_submit(regclass, regclass, text, text)** will execute the stored procedure. In the preceding information, **text** is a JSON string, indicating the synchronization mapping between two table fields. Upon successful execution of the command, the number of synchronized rows and timestamp will be displayed.

Return type: text

Example:

```
CALL hudi_sync_custom('public.hudi_sync_i', 'public.hudi_mor_ft', '{"_hoodie_commit_time" :
"_hoodie_commit_time", "col_bigint" : "col_bigint", "col_text" : "col_text"}');
NOTICE: execute full sync
CONTEXT: PL/pgSQL function hudi_sync_custom(regclass,regclass,text) line 14 at RETURN
        hudi_sync_custom
-----
sync 1 rows up to 20230511114021573.
(1 row)
```

hudi_set_sync_commit(regclass, regclass, text)

Description: Sets the start timestamp of the first synchronization of the Hudi automatic synchronization task to prevent resynchronization. The first parameter is the synchronization target table, the second parameter is the Hudi foreign table, and the third parameter is the expected synchronization start point. This function must be used before a synchronization task is submitted.

Return type: text

Example:

```
select hudi_set_sync_commit('public.hudi_sync_i', 'public.hudi_mor_ft', '20230511114021573');
NOTICE: set sync commit successfully, the next synchronization will start from 20230511114021573
CONTEXT: referenced column: hudi_set_sync_commit
        hudi_set_sync_commit
-----
20230511114021573
(1 row)
```

NOTE

You must have the **INSERT** and **UPDATE** permissions on the target table and the **SELECT** permission on the Hudi foreign table. Otherwise, you cannot set the synchronization progress.

hudi_set_sync_commit(text, text)

Description: Sets the start timestamp of the next synchronization of a Hudi automatic synchronization task. You can use it to sync historical data again or to skip some data. The first parameter is the task ID, and the second parameter is the expected start time of the next synchronization. This function can be used only after a synchronization task is submitted. Before using this function, you need to pause the task.

Return type: text

Example:

```
select hudi_set_sync_commit('6524c8e3-aae9-0000-5a14-be8ec000ffe', '20230511114021573');
NOTICE: set sync commit successfully, the next synchronization will start from 20230511114021573
CONTEXT: referenced column: hudi_set_sync_commit
        hudi_set_sync_commit
-----
20230511114021573
(1 row)
```

NOTE

- Only users who have the permission on the target task can invoke this function.
- Before invoking this function, ensure that the target task is paused and has been successfully executed at least once.

pg_task_show(text)

Description: Queries the information about the current automatic scheduling task. For a Hudi synchronization task, the input parameter should be **SQLonHudi**.

Return type: SETOF record

Example:

```
SELECT * FROM pg_task_show('SQLonHudi');
      task_id      |
-----+-----
what               | category_id | userid | is_broken |
interval | time_cons | start_time | end_time | parameter | task_rank | next_start_time
| next_end_time | last_log | failure_times
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+
64d257e9-1e9b-0d00-3ce3-7e61b5e0ffe | call pg_catalog.hudi_sync_custom('public.hudi_read_target',
'public.hudi_read101', '{"_hoodie_commit_seqno": "_hoodie_commit_seqno", "id": "id", "ts": "ts",
"long_field": "ts"}'); | SQLonHudi | 10 | f | '00:00:10' | 2023-08-08 22:58:15.846903+08
| 0 | 5 | 2023-08-08 22:58:15.846903+08 | 2023-08-08 22:58:24.846903+08 |
(1 row)
```

NOTE

The **last_log** and **failure_times** fields are used to record the status of the last task.

- The value of **last_log** is updated when the task is complete. If the task is successful, the content is cleared. If the task fails, the task failure log is recorded.
- The value of **failure_times** is updated at the end of each time window. It is set to **0** if the task is successful, incremented by 1 if the task fails, and unchanged if the task is not started in that round. This value helps identify when the first failure happens.

pg_task_remove(text)

Description: Deletes an automatic scheduling task. The input parameter is a task ID. The function returns the number of deleted tasks.

Return type: integer

Example:

```
SELECT pg_task_remove('64661705-8ada-0100-d07f-b57e89a0ffe');
pg_task_remove
-----
1
(1 row)
```

pg_task_pause(text)

Description: Suspend an automatic scheduling task. The input parameter is a task ID. The function returns the number of suspended tasks.

Return type: integer

Example:

```
SELECT pg_task_pause('64661705-8ada-0100-d07f-b57e89a0ffe');
pg_task_pause
-----
1
(1 row)
```

pg_task_resume(text)

Description: Resumes an automatic scheduling task. The input parameter is the ID of a suspended task. The function returns the number of resumed tasks.

Return type: integer

Example:

```
SELECT pg_task_resume('64661705-8ada-0100-d07f-b57e89a0fffe');
pg_task_resume
-----
1
(1 row)
```

pg_task_reset_interval(text, interval)

Description: Modifies the scheduling period of a synchronization task. The first input parameter is **task_id**, and the second input parameter the scheduling period, of which the value ranges from 5 seconds to 24 hours. The function returns the number of tasks whose periods are modified.

Return type: integer

Example:

```
select pg_task_reset_interval('64bfd69c-a016-0000-120e-1e802978fffe', '10 hours 30 minutes');
pg_task_reset_interval
-----
1
(1 row)
```

21.7.36 Funnel and Retention Functions

Funnel and retention functions are supported only in cluster 8.3.0 and later versions.

Context

Both funnel functions and retention functions are widely used tools for analyzing user behavior in product and data analysis. They are particularly useful for product managers, data scientists, and marketing personnel. These functions assist in analyzing the customer journey, comprehending user churn and conversion problems, and assessing the product's ability to consistently attract and retain customers.

- **Funnel analysis:** examines each step a customer takes from initial contact to final purchase. It helps product teams and marketers understand how users interact with products or services, as well as the conversion and churn rates at each step. The funnel analysis involves designating stages of the customer's journey from first hearing about a product to making a purchase. The whole process may include visiting a website, registering an account, and purchasing a product.
- **Retention analysis:** focuses on the percentage of users who continue using a product after a specified period of time. It calculates the number of users who remain active after a certain time point, such as user registration, first order placement, or initial use. Common retention analysis functions include daily,

weekly, and monthly retention rates, which help analyze whether users continue using the product after initially hearing about it.

WINDOW_FUNNEL

The **WINDOW_FUNNEL** function searches for an event chain in the sliding time window and counts the maximum number of consecutive events in the event chain.

Given a list of user-defined events, DWS finds the longest sequential match starting from the first event and returns the length of the match. Once the matching fails, the entire matching ends. Example:

Assume that the window is large enough:

- The condition events are c1, c2, and c3, but the user data is c1, c2, c3, and c4. So, c1, c2, and c3 are matched, and the return value of the function is 3.
- The condition events are c1, c2, and c3, but the user data is c4, c3, c2, and c1. So, c1 is matched, and the return value of the function is 1.
- The condition events are c1, c2, and c3, but the user data is c4 and c3. So, no event is matched, and the return value of the function is 0.

Function syntax

```
windowFunnel(window, mode, timestamp, cond1, cond2, ..., condN)
```

Input parameters

- **window**: bigint type. It indicates the size of the sliding time window. The unit is second.
- **mode**: text type. Currently, only the **Default** mode is supported. For other modes, an error is reported. In the **Default** mode, it matches as many events as possible, starting from the first event in the window.
- **timestamp**: time range when an event occurs. The **timestamp without time zone**, **timestamp with time zone**, **date**, **int** and **bigint** types are supported.
- **cond**: variable-length Boolean array. It indicates the condition. DWS supports only 1 to 32 conditions. If the number of conditions is not within the range, an error is reported.

Return values

level: int type. It indicates the maximum length of the event list that matches the condition.

Retention Functions

The retention function evaluates if an event meets each condition, starting from the first one.

Function syntax

```
retention(cond1, cond2, ..., cond32);
```

Input parameters

cond: variable-length Boolean array with a maximum length of 32 characters, indicating whether an event meets specific conditions. DWS supports only 1 to 32

conditions. If the number of conditions is not within the range, an error is reported.

Return values

retention condition: tinyint array type. It indicates the expression of the returned result, which is the same as the length of the input parameter **cond**. If the **cond1** and **condi** conditions are met, the *ith* value of the returned result is **1**. Otherwise, the *ith* value is **0**.

Other Retention-Related Functions

DWS supports functions **range_retention_count** and **range_retention_sum** as supplements to the retention function for better customer retention analysis.

- **range_retention_count**

range_retention_count calculates the retention rate of each user. This function returns an array, which can be used as the input parameter of the **range_retention_sum** function.

Function syntax

```
range_retention_count(is_first, is_active, dt, retention_interval, retention_granularity, output_format)
```

Input parameters

- **is_first**: indicates whether it is an initial behavior. The value is of the Boolean type. The value **true** indicates that it is an initial behavior, and the value **false** indicates that it is not an initial behavior.
- **is_active**: indicates whether it is a retention behavior. The value is of the Boolean type. The value **true** indicates that it is a retention behavior, and the value **false** indicates that it is not a retention behavior.
- **dt**: indicates the date when the behavior happens. The value is of the date type.
- **retention_interval**: indicates the storage interval. The value is of the array type. A maximum of 15 storage intervals are supported. For example, ARRAY[1,3,5,7,15,30].
- **retention_granularity**: indicates the retention granularity, which can be day, week, or month. The value is of the text type.
- **output_format**: indicates the output format. The value is of the text type and can be **normal** (default) or **expand** (daily retention details can be obtained).

Return value: BIGINT array of user retention information.

- **range_retention_sum**

range_retention_sum summarizes and calculates the daily (weekly/monthly) retention rate of all users.

Function syntax

```
range_retention_sum(range_retention_count_result)
```

Input parameter: return value of the **range_retention_count** function.

Return value: text array of user retention statistics.

Examples

Create the **funnel_test** table.

```
CREATE TABLE IF NOT EXISTS funnel_test
(
    user_id INT,
    event_type TEXT,
    event_time TIMESTAMP,
    event_timez TIMESTAMP WITH TIME ZONE,
    event_time_int BIGINT
);
```

Insert data.

```
INSERT INTO funnel_test VALUES
(1,'Browse','2021-01-31 11:00:00', '2021-01-31 11:00:00+08', 10),
(1,'Click','2021-01-31 11:10:00', '2021-01-31 11:10:00+07', 20),
(1,'Order','2021-01-31 11:20:00', '2021-01-31 11:20:00+06', 30),
(1,'Pay','2021-01-31 11:30:00', '2021-01-31 11:30:00+05', 40),
(2,'Order','2021-01-31 11:00:00', '2021-01-31 11:00:00+08', 11),
(2,'Pay','2021-01-31 11:10:00', '2021-01-31 11:10:00+08', 12),
(1,'Browse','2021-01-31 11:00:00', '2021-01-31 11:00:00+01', 50),
(3,'Browse','2021-01-31 11:20:00', '2021-01-31 11:20:00-04', 30),
(3,'Click','2021-01-31 12:00:00', '2021-01-31 12:00:00-04', 80),
(4,'Browse','2021-01-31 11:50:00', '2021-01-31 11:50:00-01', 1000),
(4,'Pay','2021-01-31 12:00:00', '2021-01-31 12:00:00-02', 900),
(4,'Order','2021-01-31 12:00:00', '2021-01-31 12:00:00-03', 1001),
(4,'Click','2021-01-31 12:00:00', '2021-01-31 12:00:00-04', 1001),
(5,'Browse','2021-01-31 11:50:00', '2021-01-31 11:50:00+08', NULL),
(5,'Click','2021-01-31 12:00:00', '2021-01-31 12:00:00+08', 776),
(5,'Order','2021-01-31 11:10:00', '2021-01-31 11:10:00+08', 999),
(6,'Browse','2021-01-31 11:50:00', '2021-01-31 11:50:00+01', -1),
(6,'Click','2021-01-31 12:00:00', '2021-01-31 12:00:00+02', -2),
(6,'Order','2021-01-31 12:10:00', '2021-01-31 12:00:00+03', -3);
```

Calculate the funnel for each user. In the **level** column of the following command output, **0** means that there were no events in the window period and **1** means that there was one event in the window period.

```
SELECT
    user_id,
    windowFunnel(
        0, 'default', event_timez,
        event_type = 'Browse', event_type = 'Click', event_type = 'Order', event_type = 'Pay'
    ) AS level
FROM funnel_test
GROUP BY user_id
ORDER BY user_id;
```

| user_id | level |
|---------|-------|
| 1 | 1 |
| 2 | 0 |
| 3 | 1 |
| 4 | 1 |
| 5 | 1 |
| 6 | 1 |

(6 rows)

Calculate the funnel of each user and specify the length of the sliding time window as **NULL**. An error is reported.

```
SELECT
    user_id,
    windowFunnel(
        NULL, 'default', event_time,
        event_type = 'Browse', event_type = 'Click', event_type = 'Order', event_type = 'Pay'
    ) AS level
FROM funnel_test
GROUP BY user_id
ORDER BY user_id;
ERROR: Invalid parameter : window length or mode is null.
```

Calculate the funnel of each user and specify multiple conditions.

```
SELECT
  user_id,
  windowFunnel(
    40, 'default', date(event_time),
    true, true, false, true
  ) AS level

21.7.37 EXTERNAL SCHEMA System Functions

System functions related to EXTERNAL SCHEMA are supported only by clusters of version 8.3.0 or later.

pg_get_external_schema_table_options(text, text)

Description: Obtains the options of an external schema table.

Input parameter: The first input parameter is the external schema name, and the second input parameter is the table name.

Return type: SETOF record

Example:

```
SELECT * FROM pg_get_external_schema_table_options('ex_lf', 'test_lf');
option_name | option_value
-----+-----
encoding    | utf8
format       | parquet
foldername   | /**/ /**/ /**/
(3 rows)
```

pg_get_external_schema_table_col(text, text)

Description: Obtains the column information of an external schema table.

Input parameter: The first input parameter is the external schema name, and the second input parameter is the table name.

Return type: SETOF record

Example:

```
SELECT * FROM pg_get_external_schema_table_col('ex_lf', 'test_lf');
col_name | col_type | part_col
-----+-----+-----
field_smallint | smallint | f
field_int | int | f
field_integer | int | f
field_bigint | bigint | f
field_float | float | f
field_double | double | f
field_double_precision | double | f
field_decimal | decimal(10,0) | f
field_numeric | decimal(10,0) | f
field_timestamp | timestamp | f
field_date | date | f
field_varchar | varchar(5) | f
field_char | char(5) | f
field_boolean | boolean | f
field_string | string | f
(15 rows)
```

21.7.38 Storage-Compute Decoupling Functions

21.7.38.1 Data Sharing Functions

pgxc_group_add_subscription(src_vw_name, target_vw_name)

Description: In a storage-compute decoupling architecture, a KV subscription relationship is established between logical clusters (Virtual Warehouses, VWs). Once established, the KV cache of the consumer VW periodically synchronizes the SST file incrementally from the OBS cudesc snapshot directory of the producer to the local host. This allows tables in the producer VW to be queried across VWs in the consumer VM. The created subscription relationship can be found in the **pgxc_group_subscription** table. This function is supported only by clusters of version 9.0.3 or later.

Return type: void

The following information is displayed:

Table 21-85 Columns returned by pgxc_group_add_subscription(src_vw_name, target_vw_name)

| Column | Type | Description |
|----------------|------|---|
| src_vw_name | text | Producer VW name, which is usually used as the VW to which data is written. |
| target_vw_name | text | Consumer VW name, which is usually used as the VW for reading data. |

Example:

```
SELECT pgxc_group_add_subscription('write_group', 'single_read_group');
pgxc_group_add_subscription
-----
(1 row)
```

pgxc_group_drop_subscription(src_vw_name, target_vw_name)

Description: To delete an established KV subscription relationship in a storage and compute separation architecture, remove the records from the **pgxc_group_subscription** table. After deletion, the consumer VW can no longer query tables in the producer VW across VWs. This function is supported only by clusters of version 9.0.3 or later.

Return type: void

The following information is displayed:

Table 21-86 Columns returned by pgxc_group_drop_subscription(src_vw_name, target_vw_name)

| Column | Type | Description |
|----------------|------|---|
| src_vw_name | text | Producer VW name, which is usually used as the VW to which data is written. |
| target_vw_name | text | Consumer VW name, which is usually used as the VW for reading data. |

Example:

```
SELECT pgxc_group_drop_subscription('write_group', 'single_read_group');
pgxc_group_drop_subscription
-----
(1 row)
```

21.7.38.2 Function for Obtaining File Information of Tablespaces in the Trash Directory

pgxc_tablespace_trash_info()

Description: Obtains the file statistics of the tablespaces whose filesystem is OBS in the trash directory in a storage-compute decoupling architecture. The information includes the number of files, total file size, and whether the automatic cleanup lifecycle policy is enabled for the trash directory. This function is available only for clusters of version 9.1.0.222 or later.

Return type: record

Return columns:

| Column | Type | Description |
|------------|------|--|
| spcname | text | Tablespace name. |
| file_count | int | Number of tablespace-related files in the trash directory. |
| total_size | int | Total size of tablespace files in the trash directory. |
| lifecycle | text | Whether the expiration policy for lifecycle is added to the trash directory. This field does not take effect in the current version. <ul style="list-style-type: none">● active: The policy is added.● inactive: The policy is not added. |

Example:

```
select * from pgxc_tablespace_trash_info();
spcname | file_count | total_size | lifecycle
-----+-----+-----+-----
cu_obs_tbs|      0    |      0    | inactive
(1 row)
```

21.7.39 Time Series Functions

[Table 21-87](#) lists the time series calculation functions supported by DWS.

Table 21-87 Time series calculation functions

| Time Series Calculation Function | Description |
|--------------------------------------|--|
| delta(field numeric) | Calculates the difference between two rows sorted by time. |

| Time Series Calculation Function | Description |
|--|--|
| spread(field numeric) | Calculates the difference between the maximum value and the minimum value in a specified period. |
| mode() within group (order by value anyelement) | Returns the value with the highest occurrence frequency for a given column. If multiple values have the same frequency, this function returns the smallest value among these values. |
| value_of_percentile(column float, percentile float, compression float) | Calculates the percentile. This is the approximation algorithm of percentile_cont . |
| percentile_of_value(column float, percentilevalue float, compression float) | Calculates a value based on a given percentile. This is the inverse function of value_of_percentile . |
| first(column1, column2) | Compares the values of column2 in a group, finds the minimum value, and outputs the value of column1 . |
| last(column1, column2) | Compares the values of column2 in a group, finds the maximum value, and outputs the corresponding value of column1 . |

delta(field numeric)

Description: Calculates the difference between two adjacent rows sorted by time in time series scenarios. It is used to monitor metrics such as traffic and speed.

Parameter: **field** indicates the column to be calculated.

CAUTION

The **delta** window function needs to be used together with the **over** window function. The **rows** statement in the **over** statement does not change the result of the **delta** function. For example, the results returned by **delta(value) over(order by time rows 1 preceding)** and **delta(value) over(order by time rows 3 preceding)** are the same.

Example:

```
SELECT
  delta(value) over (rows 1 preceding)
FROM
  (VALUES ('2019-07-12 00:00:00'::timestampz, 1),
    ('2019-07-12 00:01:00'::timestampz, 3),
    ('2019-07-12 00:02:00'::timestampz, 7))
  v(time,value) order by 1;
delta
-----
0
```

```
2
4
(3 rows)
```

spread(field numeric)

Description: Calculates the increment of each metric in a group. Generally, the increment is calculated after the metric is sorted by time.

Parameter: **field** indicates the column to be calculated.

CAUTION

If there are less than two tuples in each group, the returned result is **0**. Do not use this function with the **over** window function.

Example:

```
SELECT
  time, SPREAD(value)
FROM
  (VALUES ('2019-07-12 00:00:00'::timestampz, 1), ('2019-07-12 00:00:00'::timestampz, 3),
    ('2019-07-12 00:01:00'::timestampz, 3), ('2019-07-12 00:01:00'::timestampz, 6),
    ('2019-07-12 00:02:00'::timestampz, 7), ('2019-07-12 00:02:00'::timestampz, 9))
  v(time,value) group by time order by time;
  time      | spread
-----+-----
2019-07-12 00:00:00+08 |    2
2019-07-12 00:01:00+08 |    3
2019-07-12 00:02:00+08 |    2
(3 rows)
```

mode() within group (order by value anyelement)

Description: Returns the value with the highest occurrence frequency for a given column. If multiple values have the same frequency, this function returns the smallest value among these values.

Parameter: **value** indicates the column to be queried.

CAUTION

- This function must be used together with the **WITHIN GROUP** statement, or an error will be reported. The parameter of this function is placed after **ORDER BY** of the group.
- This function cannot be used together with the **over** clause.

Example:

```
SELECT
  mode() within group (order by value)
FROM
  (VALUES ('2019-07-12 00:00:00'::timestampz, 1),
    ('2019-07-12 00:01:00'::timestampz, 1),
    ('2019-07-12 00:02:00'::timestampz, 7))
  v(time,value);
mode
-----
```

```
1  
(1 row)
```

value_of_percentile(column float, percentile float, compression float)

Description: Returns an approximate percentile value for a given column in ascending order. It is an approximate result of **percentile_cont**, but the performance is better than that of **percentile_cont**.

Table 21-88 Parameters

| Parameter | Type | Description |
|-------------|-------|---|
| column | float | Column whose percentile is to be calculated |
| percentile | float | Percentile value. Value range: 0 to 1 |
| compression | float | Compression coefficient. The value ranges from 0 to 500 . The default value is 300 . A larger value indicates that more memory is occupied during function calculation and the result precision is higher. If the specified value is not within the value range, the value is regarded as 300. |

Example:

```
SELECT value_of_percentile(values, 0.8, 0) from TABLE;
```

percentile_of_value(column float, percentilevalue float, compression float)

Description: Returns the percentile of a given column in ascending order. This function is the inverse function of **value_of_percentile**.

Table 21-89 Parameters

| Parameter | Type | Description |
|-----------------|-------|---|
| column | float | Column whose percentile is to be calculated |
| percentilevalue | float | Value whose percentile is to be calculated |
| compression | float | Compression coefficient. The value ranges from 0 to 500 . The default value is 300 . A larger value indicates that more memory is occupied during function calculation and the result precision is higher. If the specified value is not within the value range, the value is regarded as 300. |

Example:

```
SELECT percentile_of_value(values, 80, 0) from TABLE;
```

first(column1, column2)

Description: Compares the values of **column2** in a group, finds the minimum value, and outputs the value of **column1**. It is an aggregation function.

Table 21-90 Parameters

| Parameter | Type | Description |
|-----------|-------------------------------|-------------------|
| column1 | bigint/text/double/numeric | Output column |
| column2 | timestamp/timestamptz/numeric | Comparison column |

Example: For details about the sample data, see the table definition and data in the [time_fill\(\)](#) expression.

Obtain the first idle value in each group sorted by time based on **scope_name**.

```
select first(idle, time_string) from dcs_cpu group by scope_name;
first
-----
  1
  3
(2 rows)
```

last(column1, column2)

Description: Compares the values of **column2** in a group, finds the maximum value, and outputs the value of **column1**. It is an aggregation function.

Table 21-91 Parameters

| Parameter | Type | Description |
|-----------|-------------------------------|-------------------|
| column1 | bigint/text/double/numeric | Output column |
| column2 | timestamp/timestamptz/numeric | Comparison column |

Example: For details about the sample data, see the table definition and data in the [time_fill\(\)](#) expression.

Obtain the last idle value in each group sorted by time based on **scope_name**.

```
select last(idle, time_string) from dcs_cpu group by scope_name;
last
-----
  3
  2
(2 rows)
```

Time Series Filling Functions

Table 21-92 lists the time series filling functions supported by DWS.

Table 21-92 Time series filling functions

| Time Series Filling Expression | Description |
|---|--|
| <code>time_fill(interval, time_column, start_time, end_time),
fill_last(agg_function(agg_column))</code> | Adds missing time data (aggregation result) after sorting by time column.
Uses the former value sorted by time to fill the latter value. |
| <code>time_fill(interval, time_column, start_time, end_time),
fill_first(agg_function(agg_column))</code> | Adds missing time data (aggregation result) after sorting by time column.
Uses the latter value sorted by time to fill the former value. |
| <code>time_fill(interval, time_column, start_time, end_time),
fill_avg(agg_function(agg_column))</code> | Adds missing time data (aggregation result) after sorting by time column.
Uses the former and latter values sorted by time to fill the current value. |

CAUTION

- The **time_fill** function needs to be used as an aggregation function. The **GROUP BY** clause needs to reference its own calculation result and cannot be nested with itself. The clause cannot be called multiple times in a single query, used as a lower-layer computing node, or used with the **WITHIN GROUP** clause.
- **time_fill** must be used together with **fill_avg**, **fill_first**, **fill_last**, or the **Agg** function.
- **time_fill** can only be used in **GROUP BY**. A **GROUP BY** clause that contains **time_fill** cannot contain other columns.
- **time_fill** cannot be used in other positions following **SELECT**, for example, after **WHERE** or other join conditions.
- The **start** timestamp must be smaller than the **finish** timestamp, and their interval must be greater than the value of **window_width**.
- All parameters cannot be null. Values of **start** and **finish** must be specified.

Table 21-93 Parameters

| Parameter | Type | Description |
|-----------|---|--------------------------|
| interval | INTERVAL. The minimum interval is 1 second. | Interval grouped by time |

| Parameter | Type | Description |
|--------------------------|---|---|
| time_column | TIMESTAMP or TIMESTAMPTZ | Interval grouped by a specified column |
| start_time | TIMESTAMP or TIMESTAMPTZ | Start time of a group |
| end_time | TIMESTAMP or TIMESTAMPTZ | End time of a group |
| agg_function(agg_column) | Specifies the agg function to aggregate specified columns, for example, max(col) . | Fills the agg result according to the specified filling method. |

time_fill(interval, time_column, start_time, end_time), fill_last(agg_function(agg_column))

Description: Uses the former value sorted by time to fill in the latter value.

Create the sample table **dc_s_cpu** and insert data into the table.

```
create table dcs_cpu(  
idle real,  
vcpu_num int,  
node text,  
scope_name text,  
server_ip text,  
iowait numeric,  
time_string timestamp  
)with (orientation=column) distribute by hash(node);  
insert into dcs_cpu VALUES(1.0,1,'node_a','scope_a','1.1.1.1',1.0,'2019-07-12 00:10:10');  
insert into dcs_cpu VALUES(2.0,2,'node_b','scope_a','1.1.1.2',2.0,'2019-07-12 00:12:10');  
insert into dcs_cpu VALUES(3.0,3,'node_c','scope_b','1.1.1.3',3.0,'2019-07-12 00:13:10');
```

Calculate the average value in a group at the interval of 1 min. Use the value of the former time segment to fill in the value of the latter time segment.

```
select time_fill(interval '1 min',time_string,'2019-07-12 00:09:00','2019-07-12 00:14:00'), fill_last(avg(idle))  
from dcs_cpu group by time_fill order by time_fill;  
   time_fill      | fill_last  
-----+-----  
2019-07-12 00:09:00 |  
2019-07-12 00:10:00 |      1  
2019-07-12 00:11:00 |      1  
2019-07-12 00:12:00 |      2  
2019-07-12 00:13:00 |      3  
2019-07-12 00:14:00 |      3  
(6 rows)
```

time_fill(interval, time_column, start_time, end_time), fill_first(agg_function(agg_column))

Description: Uses the latter value sorted by time to fill in the former value.

Example:

Calculate the average value in a group at the interval of 1 min. Use the value of the latter time segment to fill in the value of former time segment. (For details

about the sample data, see the table definition and data in [time_fill\(interval, time_column, start_time, end_time\), fill_last\(agg_function\(agg_column\)\).](#))

```
select time_fill(interval '1 min',time_string,'2019-07-12 00:09:00','2019-07-12 00:14:00'), fill_first(avg(idle))
from dcs_cpu group by time_fill order by time_fill;
   time_fill      | fill_first
-----+-----
2019-07-12 00:09:00 |      1
2019-07-12 00:10:00 |      1
2019-07-12 00:11:00 |      2
2019-07-12 00:12:00 |      2
2019-07-12 00:13:00 |      3
2019-07-12 00:14:00 |
(6 rows)
```

time_fill(interval, time_column, start_time, end_time), fill_avg(agg_function(agg_column))

Description: Uses the former and latter values sorted by time to fill in the current value.

Example:

Calculate the average value in a group at the interval of 1 min. Use the weighted average value of the former and latter values to fill in the current value. (For details about the sample data, see the table definition and data in [time_fill\(interval, time_column, start_time, end_time\), fill_last\(agg_function\(agg_column\)\).](#))

```
select time_fill(interval '1 min',time_string,'2019-07-12 00:09:00','2019-07-12 00:14:00'), fill_avg(avg(idle))
from dcs_cpu group by time_fill order by time_fill;
   time_fill      | fill_avg
-----+-----
2019-07-12 00:09:00 |      1
2019-07-12 00:10:00 |      1
2019-07-12 00:11:00 |     1.5
2019-07-12 00:12:00 |      2
2019-07-12 00:13:00 |      3
2019-07-12 00:14:00 |      3
(6 rows)
```

21.8 Expressions

21.8.1 Simple Expressions

Logical Expressions

[Logical Operators](#) lists the operators and calculation rules of logical expressions.

Comparative Expressions

[Comparison Operators](#) lists the common comparative operators.

In addition to comparative operators, you can also use the following sentence structure:

- BETWEEN operator
a BETWEEN x AND y is equivalent to **a >= x AND a <= y**.

a NOT BETWEEN x AND y is equivalent to **a < x OR a > y**.

- To check whether a value is null, use:
expression IS NULL
expression IS NOT NULL
or an equivalent (non-standard) sentence structure:
expression ISNULL
expression NOTNULL

NOTICE

Do not write **expression=NULL** or **expression<>(!=)NULL**, because **NULL** represents an unknown value, and these expressions cannot determine whether two unknown values are equal.

Examples

```
SELECT 2 BETWEEN 1 AND 3 AS RESULT;  
result  
-----  
t  
(1 row)  
  
SELECT 2 >= 1 AND 2 <= 3 AS RESULT;  
result  
-----  
t  
(1 row)  
  
SELECT 2 NOT BETWEEN 1 AND 3 AS RESULT;  
result  
-----  
f  
(1 row)  
  
SELECT 2 < 1 OR 2 > 3 AS RESULT;  
result  
-----  
f  
(1 row)  
  
SELECT 2+2 IS NULL AS RESULT;  
result  
-----  
f  
(1 row)  
  
SELECT 2+2 IS NOT NULL AS RESULT;  
result  
-----  
t  
(1 row)  
  
SELECT 2+2 ISNULL AS RESULT;  
result  
-----  
f  
(1 row)  
  
SELECT 2+2 NOTNULL AS RESULT;  
result
```

```
-----  
t  
(1 row)  
  
SELECT 2+2 IS DISTINCT FROM NULL AS RESULT;  
result  
-----  
t  
(1 row)  
  
SELECT 2+2 IS NOT DISTINCT FROM NULL AS RESULT;  
result  
-----  
f  
(1 row)
```

21.8.2 Conditional Expressions

Data that meets the requirements specified by conditional expressions are filtered during SQL statement execution.

Conditional expressions include the following types:

- CASE

CASE expressions are similar to the **CASE** statements in other coding languages.

Figure 21-3 shows the syntax of a **CASE** expression.

Figure 21-3 case::=

A **CASE** clause can be used in a valid expression. **condition** is an expression that returns a value of Boolean type.

- If the result is **true**, the result of the **CASE** expression is the required result.
- If the result is false, the following **WHEN** or **ELSE** clauses are processed in the same way.
- If every **WHEN condition** is false, the result of the expression is the result of the **ELSE** clause. If the **ELSE** clause is omitted and has no match condition, the result is NULL.

CAUTION

- Keep the number of nested **case when** layers at 3 or fewer. The parser must expand all related fields during parsing. Deep recursion can lead to high memory usage.
- For complex **case when** statements, use a subquery instead. For details, see [Subquery Expressions](#).

Example:

```
CREATE TABLE tpcds.case_when_t1(CW_COL1 INT) DISTRIBUTE BY HASH (CW_COL1);

INSERT INTO tpcds.case_when_t1 VALUES (1), (2), (3);

SELECT * FROM tpcds.case_when_t1;
cw_col1
-----
      3
      1
      2
(3 rows)

SELECT CW_COL1, CASE WHEN CW_COL1=1 THEN 'one' WHEN CW_COL1=2 THEN 'two' ELSE 'other'
END FROM tpcds.case_when_t1;
cw_col1 | case
-----+-----
      3 | other
      1 | one
      2 | two
(3 rows)

DROP TABLE tpcds.case_when_t1;
```

- **DECODE**

[Figure 21-4](#) shows the syntax of a **DECODE** expression.

Figure 21-4 decode::=

Compare each following **compare(n)** with **base_expr**, **value(n)** is returned if a **compare(n)** matches the **base_expr** expression. If **base_expr** does not match each **compare(n)**, the default value is returned.

[Conditional Expression Functions](#) describes the examples.

```
SELECT DECODE('A','A',1,'B',2,0);
case
-----
      1
(1 row)
```

- **COALESCE**

[Figure 21-5](#) shows the syntax of a **COALESCE** expression.

Figure 21-5 coalesce::=

COALESCE returns its first non-NULL value. If all the arguments are NULL, return **NULL**. This value is replaced by the default value when data is displayed. Like a **CASE** expression, **COALESCE** only evaluates the parameters

that are needed to determine the result. That is, parameters to the right of the first non-null parameter are not evaluated.

Example:

```
CREATE TABLE tpcds.c_tabl(description varchar(10), short_description varchar(10), last_value
varchar(10))
DISTRIBUTE BY HASH (last_value);

INSERT INTO tpcds.c_tabl VALUES('abc', 'efg', '123');
INSERT INTO tpcds.c_tabl VALUES(NULL, 'efg', '123');

INSERT INTO tpcds.c_tabl VALUES(NULL, NULL, '123');

SELECT description, short_description, last_value, COALESCE(description, short_description, last_value)
FROM tpcds.c_tabl ORDER BY 1, 2, 3, 4;
description | short_description | last_value | coalesce
-----+-----+-----+-----
abc         | efg              | 123        | abc
           | efg              | 123        | efg
           |                  | 123        | 123
(3 rows)

DROP TABLE tpcds.c_tabl;
```

If **description** is not **NULL**, the value of **description** is returned. Otherwise, parameter **short_description** is calculated. If **short_description** is not **NULL**, the value of **short_description** is returned. Otherwise, parameter **last_value** is calculated. If **last_value** is not **NULL**, the value of **last_value** is returned. Otherwise, **none** is returned.

```
SELECT COALESCE(NULL, 'Hello World');
coalesce
-----
Hello World
(1 row)
```

- **NULLIF**

Figure 21-6 shows the syntax of a **NULLIF** expression.

Figure 21-6 nullif::=

Only if **value1** is equal to **value2** can **NULLIF** return the **NULL** value. Otherwise, **value1** is returned.

Example:

```
CREATE TABLE tpcds.null_if_t1 (
  NI_VALUE1 VARCHAR(10),
  NI_VALUE2 VARCHAR(10)
) DISTRIBUTE BY HASH (NI_VALUE1);

INSERT INTO tpcds.null_if_t1 VALUES('abc', 'abc');
INSERT INTO tpcds.null_if_t1 VALUES('abc', 'efg');

SELECT NI_VALUE1, NI_VALUE2, NULLIF(NI_VALUE1, NI_VALUE2) FROM tpcds.null_if_t1 ORDER BY 1,
2, 3;
ni_value1 | ni_value2 | nullif
-----+-----+-----
abc       | abc       |
abc       | efg       | abc
```

(2 rows)

```
DROP TABLE tpcds.null_if_t1;
```

If **value1** is equal to **value2**, **NULL** is returned. Otherwise, **value1** is returned.

```
SELECT NULLIF('Hello','Hello World');
```

```
nullif
```

```
-----
```

```
Hello
```

```
(1 row)
```

- GREATEST (maximum value) and LEAST (minimum value)

Figure 21-7 shows the syntax of a **GREATEST** expression.

Figure 21-7 greatest::=

You can select the maximum value from any numerical expression list.

```
SELECT greatest(9000,155555,2.01);
```

```
greatest
```

```
-----
```

```
155555
```

```
(1 row)
```

Figure 21-8 shows the syntax of a **LEAST** expression.

Figure 21-8 least::=

You can select the minimum value from any numerical expression list.

Each of the preceding numeric expressions can be converted into a common data type, which will be the data type of the result.

The NULL values in the list will be ignored. The result is **NULL** only if the results of all expressions are **NULL**.

```
SELECT least(9000,2);
```

```
least
```

```
-----
```

```
2
```

```
(1 row)
```

Conditional Expression Functions describes the examples.

- NVL

Figure 21-9 shows the syntax of an **NVL** expression.

Figure 21-9 nvl::=

If the value of **value1** is **NULL**, **value2** is returned. Otherwise, **value1** is returned.

Example:

```
SELECT nvl(null,1);
nvl
-----
1
(1 row)
SELECT nvl ('Hello World' ,1);
nvl
-----
Hello World
(1 row)
```

- IF

Figure 21-10 shows the syntax of an **IF** expression.

Figure 21-10 if::=

If the value of **bool_expr** is **true**, **expr1** is returned. Otherwise, **expr2** is returned.

Conditional Expression Functions describes the examples.

- IFNULL

Figure 21-11 shows the syntax of an **IFNULL** expression.

Figure 21-11 ifnull::=

It returns **expr1** or **expr2**. If **expr1** is not **NULL**, **expr1** is returned. Otherwise, **expr2** is returned.

Conditional Expression Functions describes the examples.

21.8.3 Subquery Expressions

Subquery expressions include the following types:

- EXISTS/NOT EXISTS

Figure 21-12 shows the syntax of an **EXISTS/NOT EXISTS** expression.

Figure 21-12 EXISTS/NOT EXISTS::=

The parameter of an **EXISTS** expression is an arbitrary **SELECT** statement, or subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of **EXISTS** is "true". If the subquery returns no rows, the result of **EXISTS** is "false".

The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion.

Example:

```
SELECT sr_reason_sk,sr_customer_sk FROM tpcds.store_returns WHERE EXISTS (SELECT d_dom FROM  
tpcds.date_dim WHERE d_dom = store_returns.sr_reason_sk and sr_customer_sk <10);  
sr_reason_sk | sr_customer_sk
```

| | |
|----|---|
| 13 | 2 |
| 22 | 5 |
| 17 | 7 |
| 25 | 7 |
| 3 | 7 |
| 31 | 5 |
| 7 | 7 |
| 14 | 6 |
| 20 | 4 |
| 5 | 6 |
| 10 | 3 |
| 1 | 5 |
| 15 | 2 |
| 4 | 1 |
| 26 | 3 |

(15 rows)

- IN/NOT IN

Figure 21-13 shows the syntax of an **IN/NOT IN** expression.

Figure 21-13 IN/NOT IN::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of **IN** is "true" if any equal subquery row is found. The result is "false" if no equal row is found (including the case where the subquery returns no rows).

This is in accordance with SQL's normal rules for Boolean combinations of null values. If the columns corresponding to two rows equal and are not empty, the two rows are equal to each other. If any columns corresponding to the two rows do not equal and are not empty, the two rows are not equal to each other. Otherwise, the result is **NULL**. If there are no equal right-hand

values and at least one right-hand row yields null, the result of **IN** will be null, not false.

Example:

```
SELECT sr_reason_sk,sr_customer_sk FROM tpcds.store_returns WHERE sr_customer_sk IN (SELECT  
d_dom FROM tpcds.date_dim WHERE d_dom < 10);
```

sr_reason_sk | sr_customer_sk

| -----+----- | |

- ANY/SOME

Figure 21-14 shows the syntax of an **ANY/SOME** expression.

Figure 21-14 any/some::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of **ANY** is "true" if any true result is obtained. The result is "false" if no true result is found (including the case where the subquery returns no rows). **SOME** is a synonym of **ANY**. **IN** can be equivalently replaced with **ANY**.

Example:

```
SELECT sr_reason_sk,sr_customer_sk FROM tpcds.store_returns WHERE sr_customer_sk < ANY  
(SELECT d_dom FROM tpcds.date_dim WHERE d_dom < 10);
```

sr_reason_sk | sr_customer_sk

| -----+----- | |
|-------------|---|
| 26 | 3 |
| 17 | 7 |
| 32 | 5 |
| 32 | 5 |
| 13 | 2 |
| 31 | 5 |
| 25 | 7 |
| 5 | 6 |
| 7 | 7 |
| 10 | 3 |
| 1 | 5 |

| 22 | 5 |
| 33 | 4 |
| 20 | 4 |
| 33 | 8 |
| 15 | 2 |

(19 rows)

- ALL

Figure 21-15 shows the syntax of an **ALL** expression.

Figure 21-15 all::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of **ALL** is "true" if all rows yield true (including the case where the subquery returns no rows). The result is "false" if any false result is found.

Example:

```
SELECT sr_reason_sk,sr_customer_sk FROM tpcds.store_returns WHERE sr_customer_sk < all(SELECT
d_dom FROM tpcds.date_dim WHERE d_dom < 10);
sr_reason_sk | sr_customer_sk
-----+-----
(0 rows)
```

21.8.4 Array Expressions

IN

expression **IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list meets the expression result on the left, the result of **IN** is **true**. If no result meets the requirements, the result of **IN** is **false**.

Example:

```
SELECT 8000+500 IN (10000, 9000) AS RESULT;
result
-----
f
(1 row)
```

NOTE

If the expression result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **IN** is **null** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.

NOT IN

expression **NOT IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list does not meet the expression result on the left, the result of **NOT IN** is **true**. If any content meets the expression result, the result of **NOT IN** is **false**.

Example:

```
SELECT 8000+500 NOT IN (10000, 9000) AS RESULT;  
result  
-----  
t  
(1 row)
```

NOTE

If the query statement result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **NOT IN** is **null** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.

In all situations, **X NOT IN Y** equals to **NOT(X IN Y)**.

ANY/SOME (array)

expression operator **ANY** (*array expression*)

expression operator **SOME** (*array expression*)

```
SELECT 8000+500 < SOME (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)  
SELECT 8000+500 < ANY (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)
```

The parentheses on the right contain an array expression, which must generate an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- If at least one comparison result is true, the result of **ANY** is **true**.
- If no comparison result is true, the result of **ANY** is false.

NOTE

If no comparison result is true and the array expression generates at least one null value, the value of **ANY** is **NULL**, rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.

SOME is a synonym of **ANY**.

ALL (array)

expression operator **ALL** (*array expression*)

The parentheses on the right contain an array expression, which must generate an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- The result of **ALL** is "true" if all comparisons yield **true** (including the case where the array has zero elements).
- The result is **false** if any false result is found.

If the array expression yields a null array, the result of **ALL** will be null. If the left-hand expression yields null, the result of **ALL** is ordinarily null (though a non-strict comparison operator could possibly yield a different result). Also, if the right-hand array contains any null elements and no false comparison result is obtained, the result of **ALL** will be null, not true (again, assuming a strict comparison operator). This method is consistent with the Boolean rules used when SQL statements return empty values.

```
SELECT 8000+500 < ALL (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)
```

21.8.5 Row Expressions

Syntax:

row_constructor operator row_constructor

Both sides of the row expression are row constructors. The values of both rows must have the same number of fields and they are compared with each other. The row comparison allows operators including =, <>, <, <=, and >= or a similar operator.

The use of operators =<> is slightly different from other operators. If all fields of two rows are not empty and equal, the two rows are equal. If any field in two rows is not empty and not equal, the two rows are not equal. Otherwise, the comparison result is null.

For operators <, <=, >, and >=, the fields in rows are compared from left to right until a pair of fields that are not equal or are empty are detected. If the pair of fields contains at least one null value, the comparison result is null. Otherwise, the comparison result of this pair of fields is the final result.

Example:

```
SELECT ROW(1,2,NULL) < ROW(1,3,0) AS RESULT;  
result  
-----  
t  
(1 row)
```

21.9 Type Conversion

21.9.1 Overview

Context

SQL is a typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. DWS has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behavior in DWS is governed by general rules. This allows the use of mixed-type expressions.

The DWS scanner/parser divides lexical elements into five fundamental categories: integers, floating-point numbers, strings, identifiers, and keywords. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with constant strings. For example, the query:

```
SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
label | value
-----+-----
Origin | (0,0)
(1 row)
```

has two literal constants, of type **text** and **point**. If a type is not specified for a string literal, then the placeholder type **unknown** is assigned initially.

There are four fundamental SQL constructs requiring distinct type conversion rules in the DWS parser:

- **Function calls**
Much of the SQL type system is built around a rich set of functions. Functions can have one or more arguments. Since SQL permits function overloading, the function name alone does not uniquely identify the function to be called. The parser must select the right function based on the data types of the supplied arguments.
- **Operators**
SQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.
- **Value Storage**
SQL **INSERT** and **UPDATE** statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.
- **UNION, CASE, and related constructs**
Since all query results from a unionized **SELECT** statement must appear in a single set of columns, the types of the results of each **SELECT** clause must be matched up and converted to a uniform set. Similarly, the result expressions of a **CASE** construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for **ARRAY** constructs, and for the **GREATEST** and **LEAST** functions.

The system catalog **PG_CAST** stores information about the conversion between data types and how to perform the conversion. For details, see section "PG_CAST" in the *Data Warehouse Service (DWS) Developer Guide*.

The return type and conversion behavior of an expression are determined during semantic analysis. Data types are divided into several basic type categories, including **boolean**, **numeric**, **string**, **bitstring**, **datetime**, **timespan**, **geometric**, and **network**. Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed based on the following principles:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.
- Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function.

Converting Empty Strings to Numeric Values in TD-Compatible Mode

- Different from the Oracle database, which processes an empty string as NULL, Teradata database converts an empty string to **0** by default. Therefore, when an empty string is queried, value **0** is found. Similarly, in TD-compatible mode, the empty string is converted to **0** of the corresponding numeric type by default. In addition, '-', '+', and ' ' are converted to **0** by default in TD-compatible mode, but an error is reported for a decimal point string. Example:

```
create table t1(no int,col varchar);
insert into t1 values(1,'');
insert into t1 values(2,null);
select * from t1 where col is null;
no | col
----+-----
2 | 
(1 row)
select * from t1 where col="";
no | col
----+-----
1 | 
(1 row)
```
- The method of converting an empty string into a numeric value in MySQL-compatible mode is the same as that in TD-compatible mode.

21.9.2 Operators

Operator Type Resolution

1. Select the operators to be considered from the **pg_operator** system catalog. Considered operators are those with the matching name and argument count. If the search path finds multiple available operators, only the most suitable one is considered.
2. Look for the best match.
 - a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown**

literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.

- b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if there are no exact matches. If only one candidate remains, use it; else continue to the next step.
- c. Review all available candidate operators and select the one that supports the most preferred position types, which fall under the input data type's category, when type conversion is needed. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
- d. If any input arguments are of **unknown** types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
- e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, an error is reported.

Examples

Example 1: factorial operator type resolution. There is only one factorial operator (postfix !) defined in the system catalog, and it takes an argument of type **bigint**. The scanner assigns an initial type of **bigint** to the argument in this query expression:

```
SELECT 40 ! AS "40 factorial";
      40 factorial
-----
8159152832478977343456112695961158942720000000000
(1 row)
```

So the parser does a type conversion on the operand and the query is equivalent to:

```
SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 2: string concatenation operator type resolution. A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates. An example with one unspecified argument:

```
SELECT text 'abc' || 'def' AS "text and unknown";
text and unknown
-----
```

```
abcdef  
(1 row)
```

In this example, the parser looks for an operator whose parameters are of the text type. Such an operator is found.

Here is a concatenation of two values of unspecified types:

```
SELECT 'abc' || 'def' AS "unspecified";  
unspecified  
-----  
abcdef  
(1 row)
```

NOTE

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, **text**, is used as the specific type to resolve the unknown-type literals.

Example 3: absolute-value and negation operator type resolution. The DWS operator catalog has several entries for the prefix operator @. All the entries implement absolute-value operations for various numeric data types. One of these entries is for type **float8**, which is the preferred type in the numeric category. Therefore, DWS will use that entry when faced with an **unknown** input:

```
SELECT @ '-4.5' AS "abs";  
abs  
-----  
4.5  
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as type **float8** before applying the chosen operator.

Example 4: array inclusion operator type resolution. The following is an example of resolving an operator with one known and one unknown input:

```
SELECT array[1,2] <@ '{1,2,3}' as "is subset";  
is subset  
-----  
t  
(1 row)
```

NOTE

In the **pg_operator** table of DWS, several entries correspond to the infix operator <@, but the only two that may accept an integer array on the left-hand side are array inclusion (**anyarray <@ anyarray**) and range inclusion (**anyelement <@ anyrange**). Because none of these polymorphic pseudo-types (see [Pseudo-Types](#)) is considered preferred, the parser cannot resolve the ambiguity on that basis. However, [2.e](#) tells it to assume that the unknown-type literal is of the same type as the other input, that is, integer array. Now only one of the two operators can match, so array inclusion is selected. (If you select range inclusion, an error will be reported because the string does not have the right format to be a range literal.)

21.9.3 Functions

Function Type Resolution

1. Select the functions to be considered from the **pg_proc** system catalog. If a non-schema-qualified function name was used, the functions in the current

search path are considered. If a qualified function name was given, only functions in the specified schema are considered.

If the search path finds multiple functions of different argument types, a proper function in the path is considered.

2. Check for a function accepting exactly the input argument types. If the function exists, use it. Cases involving **unknown** will never find a match at this step.
3. If no exact match is found, see if the function call appears to be a special type conversion request.
4. Look for the best match.
 - a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown** literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
 - b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none has exact matches. If only one candidate remains, use it; else continue to the next step.
 - c. Run through all candidates and keep those that accept preferred types at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
 - d. If any input arguments are of **unknown** types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
 - e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the **unknown**-argument positions. If exactly one candidate passes this test, use it. Otherwise, fail.

Examples

Example 1: Use the rounding function argument type resolution as the first example. There is only one **round** function that takes two arguments; it takes a first argument of type **numeric** and a second argument of type **integer**. So the following query automatically converts the first argument of type **integer** to **numeric**:

```
SELECT round(4, 4);
round
-----
```

```
4.0000  
(1 row)
```

That query is converted by the parser to:

```
SELECT round(CAST (4 AS numeric), 4);
```

Since numeric constants with decimal points are initially assigned the type **numeric**, the following query will require no type conversion and therefore might be slightly more efficient:

```
SELECT round(4.0, 4);
```

Example 2: Use the substring function type resolution as the second example. There are several **substr** functions, one of which takes types **text** and **integer**. If called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category **string** (namely of type **text**).

```
SELECT substr('1234', 3);  
substr  
-----  
34  
(1 row)
```

If the string is declared to be of type **varchar**, as might be the case if it comes from a table, then the parser will try to convert it to become **text**:

```
SELECT substr(varchar '1234', 3);  
substr  
-----  
34  
(1 row)
```

This is transformed by the parser to effectively become:

```
SELECT substr(CAST (varchar '1234' AS text), 3);
```

NOTE

The parser learns from the **pg_cast** catalog that **text** and **varchar** are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion is inserted in this case.

And, if the function is called with an argument of type **integer**, the parser will try to convert that to **text**:

```
SELECT substr(1234, 3);  
substr  
-----  
34  
(1 row)
```

This is transformed by the parser to effectively become:

```
SELECT substr(CAST (1234 AS text), 3);  
substr  
-----  
34  
(1 row)
```

21.9.4 Value Storage

Value Storage Type Resolution

1. Search for an exact match with the target column.
2. Try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the content of the literal string will be fed to the input conversion routine for the target type.
3. Check whether there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the **pg_cast** catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type **integer**. The parameter receives the destination column's **atttypmod** value (typically its declared length, although the interpretation of **atttypmod** varies for different data types), and may take a third boolean parameter that says whether the cast is explicit or implicit. The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

Examples

Use the **character** storage type conversion as an example. For a target column declared as **character(20)** the following statement shows that the stored value is sized correctly:

```
CREATE TABLE x1
(
  customer_sk      integer,
  customer_id      char(20),
  first_name       char(6),
  last_name        char(8)
)
with (orientation = column,compression=middle)
distribute by hash (last_name);

INSERT INTO x1(customer_sk, customer_id, first_name) VALUES (3769, 'abcdef', 'Grace');

SELECT customer_id, octet_length(customer_id) FROM x1;
  customer_id | octet_length
-----+-----
  abcdef      |           20
(1 row)
DROP TABLE x1;
```

NOTE

What has really happened here is that the two unknown literals are resolved to **text** by default, allowing the || operator to be resolved as **text** concatenation. Then the **text** result of the operator is converted to **bpchar** ("blank-padded char", the internal name of the **character** data type) to match the target column type. Since the conversion from **text** to **bpchar** is binary-coercible, this conversion does not insert any real function call. Finally, the sizing function **bpchar(bpchar, integer, boolean)** is found in the system catalog and used for the operator's result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

21.9.5 UNION, CASE, and Related Constructs

SQL UNION constructs must match up possibly dissimilar types to become a single result set. Since all query results from a **SELECT UNION** statement must appear in

a single set of columns, the types of the results of each **SELECT** clause must be matched up and converted to a uniform set. Similarly, the result expressions of a **CASE** construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for **ARRAY** constructs, and for the **GREATEST** and **LEAST** functions.

Type Resolution for UNION, CASE, and Related Constructs

- If all inputs are of the same type, and it is not unknown, resolve as that type.
- If all inputs are of type **unknown**, resolve as type **text** (the preferred type of the string category). Otherwise, **unknown** inputs are ignored.
- If the entered values are not the same type, the query fails (except for the **unknown** type).
- When input types fall under the same category, the preferred type of that category is chosen, unless the union operation selects the type of the first branch as the chosen type.

NOTE

typcategory in the **pg_type** system catalog indicates the data type category.
typispreferred indicates whether a type is preferred in **typcategory**.

- All the input is converted to the selected type. (The original length of a string is retained). Fail if there is not an implicit conversion from a given input to the selected type.
- If the input contains the json, txid_snapshot, sys_refcursor, or geometry type, **UNION** cannot be performed.

Type Resolution for CASE, COALESCE, IF, and IFNULL in TD-Compatible Mode

- If all inputs are of the same type, and it is not unknown, resolve as that type.
- If all inputs are of type **unknown**, resolve as type **text**.
- If inputs are of string type (including **unknown** which is resolved as type **text**) and digit type, resolve as the string type. If the inputs are not of the two types, fail.
- If the non-unknown inputs are all of the same type category, choose the input type which is a preferred type in that category, if there is one.
- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

Type Resolution for CASE, COALESCE, IF, and IFNULL in MySQL-Compatible Mode

- If all inputs are of the same type, and it is not unknown, resolve as that type.
- If all inputs are of type **unknown**, resolve as type **text**.
- If some inputs are of type **unknown** and the others are of a non-**unknown** type, resolve as that non-**unknown** type.
- If the inputs are of different non-**unknown** types, treat type **enum** as type **text** for comparison.
- If the non-**unknown** inputs are all of the same type, choose a preferred type, if there is one. If the inputs are of different types, resolve as type **text**.

- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

Examples

Example 1: Use type resolution with unknown types in a union as the first example. Here, the unknown-type literal **'b'** will be resolved to type **text**.

```
SELECT text 'a' AS "text" UNION SELECT 'b';
text
-----
a
b
(2 rows)
```

Example 2: Use type resolution in a simple union as the second example. The literal **1.2** is of type **numeric**, and the **integer** value **1** can be cast implicitly to **numeric**, so that type is used.

```
SELECT 1.2 AS "numeric" UNION SELECT 1;
numeric
-----
1
1.2
(2 rows)
```

Example 3: Use type resolution in a transposed union as the third example. Here, since type **real** cannot be implicitly cast to **integer**, but **integer** can be implicitly cast to **real**, the union result type is resolved as **real**.

```
SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
real
-----
1
2.2
(2 rows)
```

Example 4: Use type resolution in the **COALESCE** function with input values of types **int** and **varchar** as the fourth example. Type resolution fails in ORA-compatible mode. The types are resolved as type **varchar** in TD-compatible mode, and as type **text** in MySQL-compatible mode.

```
-- Create the ora_db, td_db, and mysql_db databases by setting dbcompatibility to ORA, TD, and MySQL,
-- respectively:
CREATE DATABASE ora_db dbcompatibility = 'ORA';
CREATE DATABASE td_db dbcompatibility = 'TD';
CREATE DATABASE mysql_db dbcompatibility = 'MySQL';

-- Switch to the ora_db database:
\c ora_db

-- Create the t1 table:
ora_db=# CREATE TABLE t1(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for
-- COALESCE:
ora_db=# EXPLAIN SELECT coalesce(a, b) FROM t1;
ERROR: COALESCE types integer and character varying cannot be matched
CONTEXT: referenced column: coalesce

-- Delete the table:
ora_db=# DROP TABLE t1;

-- Switch to the td_db database:
ora_db=# \c td_db
```

```
-- Create the t2 table:
td_db=# CREATE TABLE t2(a int, b varchar(10));

-- Show the execution plan of a statement for querying the types int and varchar of input parameters for COALESCE:
td_db=# EXPLAIN VERBOSE select coalesce(a, b) from t2;
          QUERY PLAN
-----
id |          operation          | E-rows | E-distinct | E-width | E-costs

21.10 Full Text Search

21.10.1 Introduction

21.10.1.1 Full-Text Retrieval

Textual search operators have been used in databases for years. The DWS has `~`, `~*`, `LIKE`, and `ILIKE` operators for textual data types, but they lack many essential properties required by modern information systems. This problem can be solved by using indexes and dictionaries.

Text search lacks the following essential properties required by information systems:

- There is no linguistic support, even for English.
Regular expressions are not sufficient because they cannot easily handle derived words. For example, you might miss documents that contain **satisfies**, although you probably would like to find them when searching for **satisfy**. It is possible to use **OR** to search for multiple derived forms, but this is tedious and error-prone, because some words can have several thousand derivatives.
- They provide no ordering (ranking) of search results, which makes them ineffective when thousands of matching documents are found.
- They tend to be slow because there is no index support, so they must process all documents for every search.

Full text indexing allows documents to be preprocessed and an index is saved for later rapid searching. Preprocessing includes:

- Parsing documents into tokens
It is useful to identify various classes of tokens, for example, numbers, words, complex words, and email addresses, so that they can be processed differently. In principle, token classes depend on the specific application, but for most purposes it is adequate to use a predefined set of classes.
- Converting tokens into lexemes
A lexeme is a string, just like a token, but it has been normalized so that different forms of the same word are made alike. For example, normalization almost always includes folding upper-case letters to lower-case, and often involves removal of suffixes (such as **s** or **es** in English). This allows searches to find variant forms of the same word, without tediously entering all the possible variants. Also, this step typically eliminates stop words, which are words that are so common that they are useless for searching. (In short, tokens are raw fragments of the document text, while lexemes are words that are believed useful for indexing and searching.) DWS uses dictionaries to perform this step and provides various standard dictionaries.
- Storing preprocessed documents optimized for searching
For example, each document can be represented as a sorted array of normalized lexemes. Along with the lexemes, it is often desirable to store positional information for proximity ranking. Therefore, a document that contains a more "dense" region of query words is assigned with a higher rank than the one with scattered query words.

Dictionaries allow fine-grained control over how tokens are normalized. With appropriate dictionaries, you can define stop words that should not be indexed.

A data type **tsvector** is provided for storing preprocessed documents, along with a type **tsquery** for storing query conditions. For details, see [Text Search Types](#). For details about the functions and operators provided for the **tsvector** data type, see

Text Search Functions and Operators. The matching operator @@ is the most important. For details, see [Basic Text Matching](#).

21.10.1.2 What Is a Document?

A document is the unit of searching in a full text search system; for example, a magazine article or email message. The text search engine must be able to parse documents and store associations of lexemes (keywords) with their parent document. Later, these associations are used to search for documents that contain query words.

For searches within DWS, a document is normally a textual column within a row of a database table, or possibly a combination (concatenation) of such columns, perhaps stored in several tables or obtained dynamically. In other words, a document can be constructed from different parts for indexing and it might not be stored anywhere as a whole. For example:

```
SELECT d_dow || '-' || d_dom || '-' || d_fy_week_seq AS identify_serials FROM tpeds.date_dim WHERE
d_fy_week_seq = 1;
identify_serials
-----
5-6-1
0-8-1
2-3-1
3-4-1
4-5-1
1-2-1
6-7-1
(7 rows)
```

NOTICE

Actually, in these example queries, **coalesce** should be used to prevent a single **NULL** attribute from causing a **NULL** result for the whole document.

Another possibility is to store the documents as simple text files in the file system. In this case, the database can be used to store the full text index and to execute searches, and some unique identifier can be used to retrieve the document from the file system. However, retrieving files from outside the database requires system administrator permissions or special function support, so this is less convenient than keeping all the data inside the database. Also, keeping everything inside the database allows easy access to document metadata to assist in indexing and display.

For text search purposes, each document must be reduced to the preprocessed **tsvector** format. Searching and relevance-based ranking are performed entirely on the **tsvector** representation of a document. The original text is retrieved only when the document has been selected for display to a user. We therefore often speak of the **tsvector** as being the document, but it is only a compact representation of the full document.

21.10.1.3 Basic Text Matching

Full text search in DWS is based on the match operator @@, which returns **true** if a **tsvector** (document) matches a **tsquery** (query). It does not matter which data type is written first:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector @@ 'cat & rat'::tsquery AS RESULT;
result
-----
t
(1 row)
SELECT 'fat & cow'::tsquery @@ 'a fat cat sat on a mat and ate a fat rat'::tsvector AS RESULT;
result
-----
f
(1 row)
```

As the above example suggests, a **tsquery** is not raw text, any more than a **tsvector** is. A **tsquery** contains search terms, which must be already-normalized lexemes, and may combine multiple terms using **AND**, **OR**, and **NOT** operators. For details, see [Text Search Types](#). There are functions **to_tsquery** and **plainto_tsquery** that are helpful in converting user-written text into a proper **tsquery**, for example by normalizing words appearing in the text. Similarly, **to_tsvector** is used to parse and normalize a document string. So in practice a text search match would look more like this:

```
SELECT to_tsvector('fat cats ate fat rats') @@ to_tsquery('fat & rat') AS RESULT;
result
-----
t
(1 row)
```

Observe that this match would not succeed if written as follows:

```
SELECT 'fat cats ate fat rats'::tsvector @@ to_tsquery('fat & rat') AS RESULT;
result
-----
f
(1 row)
```

In the preceding match, no normalization of the word **rats** will occur. Therefore, **rats** does not match **rat**.

The @@ operator also supports text input, allowing explicit conversion of a text string to **tsvector** or **tsquery** to be skipped in simple cases. The variants available are:

```
tsvector @@ tsquery
tsquery  @@ tsvector
text     @@ tsquery
text     @@ text
```

The form **text @@ tsquery** is equivalent to **to_tsvector(text) @@ tsquery**. The form **text @@ text** is equivalent to **to_tsvector(text) @@ plainto_tsquery(text)**.

21.10.1.4 Configurations

Full text search functionality includes the ability to do many more things: skip indexing certain words (stop words), process synonyms, and use sophisticated parsing, for example, parse based on more than just white space. This functionality is controlled by text search configurations. DWS comes with predefined configurations for many languages, and you can easily create your own configurations. (The **\dF** command of **gsql** shows all available configurations.)

During installation an appropriate configuration is selected and **default_text_search_config** is set accordingly in **postgresql.conf**. If you are using the same text search configuration for the entire cluster you can use the value in **postgresql.conf**. To use different configurations throughout the cluster but the

same configuration within any one database, use `ALTER DATABASE ... SET`. Otherwise, you can set **default_text_search_config** in each session.

Each text search function that depends on a configuration has an optional argument, so that the configuration to use can be specified explicitly. **default_text_search_config** is used only when this argument is omitted.

To make it easier to build custom text search configurations, a configuration is built up from simpler database objects. DWS's text search facility provides the following types of configuration-related database objects:

- Text search parsers break documents into tokens and classify each token (for example, as words or numbers).
- Text search dictionaries convert tokens to normalized form and reject stop words.
- Text search templates provide the functions underlying dictionaries. (A dictionary simply specifies a template and a set of parameters for the template.)
- Text search configurations select a parser and a set of dictionaries to use to normalize the tokens produced by the parser.

21.10.2 Tables and Indexes

21.10.2.1 Searching a Table

It is possible to do a full text search without an index.

- A simple query to print each row that contains the word **science** in its **body** column is as follows:

```
DROP SCHEMA IF EXISTS tsearch CASCADE;

CREATE SCHEMA tsearch;

CREATE TABLE tsearch.pgweb(id int, body text, title text, last_mod_date date);

INSERT INTO tsearch.pgweb VALUES(1, 'Philology is the study of words, especially the history and development of the words in a particular language or group of languages.', 'Philology', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(2, 'Mathematics is the science that deals with the logic of shape, quantity and arrangement.', 'Mathematics', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(3, 'Computer science is the study of processes that interact with data and that can be represented as data in the form of programs.', 'Computer science', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(4, 'Chemistry is the scientific discipline involved with elements and compounds composed of atoms, molecules and ions.', 'Chemistry', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(5, 'Geography is a field of science devoted to the study of the lands, features, inhabitants, and phenomena of the Earth and planets.', 'Geography', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(6, 'History is a subject studied in schools, colleges, and universities that deals with events that have happened in the past.', 'History', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(7, 'Medical science is the science of dealing with the maintenance of health and the prevention and treatment of disease.', 'Medical science', '2010-1-1');

INSERT INTO tsearch.pgweb VALUES(8, 'Physics is one of the most fundamental scientific disciplines, and its main goal is to understand how the universe behaves.', 'Physics', '2010-1-1');
```

```
SELECT id, body, title FROM tsearch.pgweb WHERE to_tsvector('english', body) @@
to_tsquery('english', 'science');
id | body | title
----+-----+-----
2 | Mathematics is the science that deals with the logic of shape, quantity and
    arrangement. | Mathematics
3 | Computer science is the study of processes that interact with data and that can be represented as
    data in the form of programs. | Computer science
5 | Geography is a field of science devoted to the study of the lands, features, inhabitants, and
    phenomena of the Earth and planets. | Geography
7 | Medical science is the science of dealing with the maintenance of health and the prevention and
    treatment of disease. | Medical science
(4 rows)
```

This will also find related words, such as **science**, since all these are reduced to the same normalized lexeme.

The query above specifies that the **english** configuration is to be used to parse and normalize the strings. Alternatively, you can omit the configuration parameters, and use the configuration set by **default_text_search_config**.

```
SHOW default_text_search_config;
default_text_search_config
-----
pg_catalog.english
(1 row)

SELECT id, body, title FROM tsearch.pgweb WHERE to_tsvector(body) @@ to_tsquery('science');
id | body | title
----+-----+-----
2 | Mathematics is the science that deals with the logic of shape, quantity and
    arrangement. | Mathematics
3 | Computer science is the study of processes that interact with data and that can be represented as
    data in the form of programs. | Computer science
5 | Geography is a field of science devoted to the study of the lands, features, inhabitants, and
    phenomena of the Earth and planets. | Geography
7 | Medical science is the science of dealing with the maintenance of health and the prevention and
    treatment of disease. | Medical science
(4 rows)
```

- A more complex example to select the ten most recent documents that contain **treatment** and **science** in the **title** or **body** column is as follows:

```
SELECT title FROM tsearch.pgweb WHERE to_tsvector(title || ' ' || body) @@ to_tsquery('treatment &
science') ORDER BY last_mod_date DESC LIMIT 10;
title
-----
Medical science
(1 rows)
```

For clarity we omitted the **coalesce** function calls which would be needed to find rows that contain **NULL** in one of the two columns.

The preceding examples show queries without using indexes. Most applications will find this approach too slow. Therefore, practical use of text searching usually requires creating an index, except perhaps for occasional ad-hoc searches.

21.10.2.2 Creating an Index

You can create a **GIN** index to speed up text searches:

```
CREATE INDEX pgweb_idx_1 ON tsearch.pgweb USING gin(to_tsvector('english', body));
```

The `to_tsvector()` function accepts one or two arguments.

If the one-argument version of the index is used, the system will use the configuration specified by **default_text_search_config** by default.

To create an index, the two-argument version must be used, or the index content may be inconsistent. Only text search functions that specify a configuration name can be used in expression indexes. Index content is not affected by **default_text_search_config**, because different entries could contain **tsvector**s that were created with different text search configurations, and there would be no way to guess which was which. It would be impossible to dump and restore such an index correctly.

Because the two-argument version of **to_tsvector** was used in the index above, only a query reference that uses the two-argument version of **to_tsvector** with the same configuration name will use that index. That is, **WHERE to_tsvector('english', body) @@ 'a & b'** can use the index, but **WHERE to_tsvector(body) @@ 'a & b'** cannot. This ensures that an index will be used only with the same configuration used to create the index entries.

More complex expression indexes can be set up when the configuration name of the index is specified by another column. For example:

```
CREATE INDEX pgweb_idx_2 ON tsearch.pgweb USING gin(to_tsvector('zhparser', body));
```

NOTE

In this example, `zhparser` supports only the UTF-8 or GBK database encoding format. If the `SQL_ASCII` encoding is used, an error will be reported.

where **body** is a column in the **pgweb** table. This allows mixed configurations in the same index while recording which configuration was used for each index entry. This would be useful, for example, if the document collection contained documents in different languages. Again, queries that are meant to use the index must be phrased to match, for example, **WHERE to_tsvector(config_name, body) @@ 'a & b'** must match **to_tsvector** in the index.

Indexes can even concatenate columns:

```
CREATE INDEX pgweb_idx_3 ON tsearch.pgweb USING gin(to_tsvector('english', title || ' ' || body));
```

Another approach is to create a separate **tsvector** column to hold the output of **to_tsvector**. This example is a concatenation of **title** and **body**, using **coalesce** to ensure that one column will still be indexed when the other is **NULL**:

```
ALTER TABLE tsearch.pgweb ADD COLUMN textsearchable_index_col tsvector;  
UPDATE tsearch.pgweb SET textsearchable_index_col = to_tsvector('english', coalesce(title, '') || ' ' || coalesce(body, ''));
```

Then, create a GIN index to speed up the search:

```
CREATE INDEX textsearch_idx_4 ON tsearch.pgweb USING gin(textsearchable_index_col);
```

Now you are ready to perform a fast full text search:

```
SELECT title  
FROM tsearch.pgweb  
WHERE textsearchable_index_col @@ to_tsquery('science & Computer')  
ORDER BY last_mod_date DESC  
LIMIT 10;
```

```
title
-----
Computer science
(1 rows)
```

One advantage of the separate-column approach over an expression index is that it is unnecessary to explicitly specify the text search configuration in queries in order to use the index. As shown in the preceding example, the query can depend on **default_text_search_config**. Another advantage is that searches will be faster, since it will not be necessary to redo the **to_tsvector** calls to verify index matches. The expression-index approach is simpler to set up, however, and it requires less disk space since the **tsvector** representation is not stored explicitly.

21.10.2.3 Constraints on Index Use

The following is an example of using an index:

```
create table table1 (c_int int,c_bigint bigint,c_varchar varchar,c_text text) with(orientation=row);

create text search configuration ts_conf_1(parser=POUND);
create text search configuration ts_conf_2(parser=POUND) with(split_flag='%');

set default_text_search_config='ts_conf_1';
create index idx1 on table1 using gin(to_tsvector(c_text));

set default_text_search_config='ts_conf_2';
create index idx2 on table1 using gin(to_tsvector(c_text));

select c_varchar,to_tsvector(c_varchar) from table1 where to_tsvector(c_text) @@ plainto_tsquery('#@.....
&**) and to_tsvector(c_text) @@ plainto_tsquery('company') and c_varchar is not null order by 1 desc limit
3;
```

In this example, **table1** has two GIN indexes created on the same column **c_text**, **idx1** and **idx2**, but these two indexes are created under different settings of **default_text_search_config**. Differences between this example and the scenario where one table has common indexes created on the same column are as follows:

- GIN indexes use different parsers (that is, different delimiters). In this case, the index data of **idx1** is different from that of **idx2**.
- In the specified scenario, the index data of multiple common indexes created on the same column is the same.

As a result, using **idx1** and **idx2** for the same query returns different results.

Constraints

Still use the above example. When:

- Multiple GIN indexes are created on the same column of the same table.
- The GIN indexes use different parsers (that is, different delimiters).
- The column is used in a query, and an index scan is used in the execution plan.

To avoid different query results caused by different GINs, ensure that only one GIN is available on a column of a physical table.

21.10.3 Controlling Text Search

21.10.3.1 Parsing Documents

DWS provides function **to_tsvector** for converting a document to the **tsvector** data type.

to_tsvector([*config regconfig*,] *document text*) returns **tsvector**

to_tsvector parses a textual document into tokens, reduces the tokens to lexemes, and returns a **tsvector**, which lists the lexemes together with their positions in the document. The document is processed according to the specified or default text search configuration. Here is a simple example:

```
SELECT to_tsvector('english', 'a fat cat sat on a mat - it ate a fat rats');
       to_tsvector
-----
'ate':9 'cat':3 'fat':2,11 'mat':7 'rat':12 'sat':4
```

In the preceding example we see that the resulting **tsvector** does not contain the words **a**, **on**, or **it**, the word **rats** became **rat**, and the punctuation sign (-) was ignored.

The **to_tsvector** function internally calls a parser which breaks the document text into tokens and assigns a type to each token. For each token, a list of dictionaries is consulted. where the list can vary depending on the token type. The first dictionary that recognizes the token emits one or more normalized lexemes to represent the token. For example:

- **rats** became **rat** because one of the dictionaries recognized that the word **rats** is a plural form of **rat**.
- Some words are recognized as stop words (see [Stop Words](#)), which causes them to be ignored since they occur too frequently to be useful in searching. In our example these are **a**, **on**, and **it**.
- If no dictionary in the list recognizes the token then it is also ignored. In this example that happened to the punctuation sign (-) because there are in fact no dictionaries assigned for its token type (**space symbols**), meaning space tokens will never be indexed.

The choices of parser, dictionaries and which types of tokens to index are determined by the selected text search configuration. It is possible to have many different configurations in the same database, and predefined configurations are available for various languages. In our example we used the default configuration **english** for the English language.

The function **setweight** can be used to label the entries of a **tsvector** with a given weight, where a weight is one of the letters **A**, **B**, **C**, or **D**. This is typically used to mark entries coming from different parts of a document, such as title versus body. Later, this information can be used for ranking of search results.

Because **to_tsvector(NULL)** will return **NULL**, you are advised to use **coalesce** whenever a column might be **NULL**. Here is the recommended method for creating a **tsvector** from a structured document:

```
CREATE TABLE tsearch.tt (id int, title text, keyword text, abstract text, body text, ti tsvector);

INSERT INTO tsearch.tt(id, title, keyword, abstract, body) VALUES (1, 'book', 'literature', 'Ancient poetry', 'Tang poem Song jambic verse');

UPDATE tsearch.tt SET ti =
    setweight(to_tsvector(coalesce(title, '')), 'A') ||
```

```
setweight(to_tsvector(coalesce(keyword,'')), 'B') ||  
setweight(to_tsvector(coalesce(abstract,'')), 'C') ||  
setweight(to_tsvector(coalesce(body,'')), 'D');  
DROP TABLE tsearch.tt;
```

Here we have used **setweight** to label the source of each lexeme in the finished **tsvector**, and then merged the labeled **tsvector** values using the **tsvector** concatenation operator **||**. For details about these operations, see [Manipulating tsvector](#).

21.10.3.2 Parsing Queries

DWS provides functions **to_tsquery** and **plainto_tsquery** for converting a query to the **tsquery** data type. **to_tsquery** offers access to more features than **plainto_tsquery**, but is less forgiving about its input.

to_tsquery([config regconfig,] querytext text) returns tsquery

to_tsquery creates a **tsquery** value from **querytext**, which must consist of single tokens separated by the Boolean operators **&** (AND), **|** (OR), and **!** (NOT). These operators can be grouped using parentheses. In other words, the input to **to_tsquery** must already follow the general rules for **tsquery** input, as described in [Text Search Types](#). The difference is that while basic **tsquery** input takes the tokens at face value, **to_tsquery** normalizes each token to a lexeme using the specified or default configuration, and discards any tokens that are stop words according to the configuration. For example:

```
SELECT to_tsquery('english', 'The & Fat & Rats');  
to_tsquery  
-----  
'fat' & 'rat'  
(1 row)
```

As in basic **tsquery** input, **weight(s)** can be attached to each lexeme to restrict it to match only **tsvector** lexemes of those **weight(s)**. For example:

```
SELECT to_tsquery('english', 'Fat | Rats:AB');  
to_tsquery  
-----  
'fat' | 'rat':AB  
(1 row)
```

Also, the asterisk (*****) can be attached to a lexeme to specify prefix matching:

```
SELECT to_tsquery('supern:*A & star:A*B');  
to_tsquery  
-----  
'supern':*A & 'star':*AB  
(1 row)
```

Such a lexeme will match any word having the specified string and weight in a **tsquery**.

plainto_tsquery([config regconfig,] querytext text) returns tsquery

plainto_tsquery transforms unformatted text **querytext** to **tsquery**. The text is parsed and normalized much as for **to_tsvector**, then the **&** (AND) Boolean operator is inserted between surviving words.

For example:

```
SELECT plainto_tsquery('english', 'The Fat Rats');  
plainto_tsquery  
-----
```

```
'fat' & 'rat'  
(1 row)
```

Note that **plainto_tsquery** cannot recognize Boolean operators, weight labels, or prefix-match labels in its input:

```
SELECT plainto_tsquery('english', 'The Fat & Rats:C');  
plainto_tsquery  
-----  
'fat' & 'rat' & 'c'  
(1 row)
```

Here, all the input punctuation was discarded as being space symbols.

21.10.3.3 Ranking Search Results

Ranking attempts to measure how relevant documents are to a particular query, so that when there are many matches the most relevant ones can be shown first. DWS provides two predefined ranking functions. They take into account lexical, proximity, and structural information; that is, they consider how often the query terms appear in the document, how close together the terms are in the document, and how important is the part of the document where they occur. However, the concept of relevancy is vague and application-specific. Different applications might require additional information for ranking, for example, document modification time. The built-in ranking functions are only examples. You can write your own ranking functions and/or combine their results with additional factors to fit your specific needs.

The two ranking functions currently available are:

```
ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4
```

Ranks vectors based on the frequency of their matching lexemes.

```
ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ]) returns float4
```

This function requires positional information in its input. Therefore, it will not work on "stripped" **tsvector** values. It will always return zero.

For both these functions, the optional **weights** argument offers the ability to weigh word instances more or less heavily depending on how they are labeled. The weight arrays specify how heavily to weigh each category of word, in the order:

```
{D-weight, C-weight, B-weight, A-weight}
```

If no **weights** are provided, then these defaults are used: {0.1, 0.2, 0.4, 1.0}

Typically weights are used to mark words from special areas of the document, like the title or an initial abstract, so they can be treated with more or less importance than words in the document body.

Since a longer document has a greater chance of containing a query term it is reasonable to take into account document size. For example, a hundred-word document with five instances of a search word is probably more relevant than a thousand-word document with five instances. Both ranking functions take an integer **normalization** option that specifies whether and how a document's length should impact its rank. The integer option controls several behaviors, so it is a bit mask: you can specify one or more behaviors using a vertical bar (|) (for example, 2|4).

- 0 (the default) ignores the document length
- 1 divides the rank by (1 + Logarithm of the document length)
- 2 divides the rank by the document length
- 4 divides the rank by the mean harmonic distance between extents (this is implemented only by ts_rank_cd)
- 8 divides the rank by the number of unique words in document
- 16 divides the rank by (1 + Logarithm of the number of unique words in document)
- 32 divides the rank by (itself + 1)

If more than one flag bit is specified, the transformations are applied in the order listed.

It is important to note that the ranking functions do not use any global information, so it is impossible to produce a fair normalization to 1% or 100% as sometimes desired. Normalization option 32 (**rank/(rank+1)**) can be used to scale all ranks into the range zero to one. This is just a cosmetic change, and it will not affect the ordering of the search results.

Here is an example that selects only the ten highest-ranked matches:

Run the following statements in a database that uses the UTF-8 or GBK encoding:

```
SELECT id, title, ts_rank_cd(to_tsvector(body), query) AS rank
FROM tsearch.pgweb, to_tsquery('science') query
WHERE query @@ to_tsvector(body)
ORDER BY rank DESC
LIMIT 10;
id | title | rank
---+-----+-----
11 | Philology | .2
2 | Mathematics | .1
12 | Geography | .1
13 | Computer science | .1
(4 rows)
```

This is the same example using normalized ranking:

```
SELECT id, title, ts_rank_cd(to_tsvector(body), query, 32 /* rank/(rank+1) */) AS rank
FROM tsearch.pgweb, to_tsquery('science') query
WHERE query @@ to_tsvector(body)
ORDER BY rank DESC
LIMIT 10;
id | title | rank
---+-----+-----
11 | Philology | .166667
2 | Mathematics | .0909091
12 | Geography | .0909091
13 | Computer science | .0909091
(4 rows)
```

The following example sorts query by Chinese word segmentation:

```
CREATE TABLE tsearch.ts_zhparser(id int, body text);
INSERT INTO tsearch.ts_zhparser VALUES (1, 'sort');
INSERT INTO tsearch.ts_zhparser VALUES(2, 'sort query');
INSERT INTO tsearch.ts_zhparser VALUES(3, 'query sort');
-- Accurate match
SELECT id, body, ts_rank_cd (to_tsvector('zhparser', body), query) AS rank FROM tsearch.ts_zhparser,
to_tsquery('sort') query WHERE query @@ to_tsvector (body);
id | body | rank
---+-----+-----
1 | sort | .1
```

```
(1 row)

-- Fuzzy match
SELECT id, body, ts_rank_cd (to_tsvector ('zhparser', body), query) AS rank FROM tsearch.ts_zhparser,
to_tsquery ('sort') query WHERE query @@ to_tsvector ('zhparser', body);
 id |  body  | rank 
-----+-----
  3 | query sort | .1
  1 | sort   | .1
  2 | sort query | .1
(3 rows)
```

Ranking can be expensive since it requires consulting the **tsvector** of each matching document, which can be I/O bound and therefore slow. Unfortunately, it is almost impossible to avoid since practical queries often result in large numbers of matches.

21.10.3.4 Highlighting Results

To present search results it is ideal to show a part of each document and how it is related to the query. Usually, search engines show fragments of the document with marked search terms. DWS provides function **ts_headline** that implements this functionality.

ts_headline([config regconfig,] document text, query tsquery [, options text]) returns text

ts_headline accepts a document along with a query, and returns an excerpt from the document in which terms from the query are highlighted. The configuration to be used to parse the document can be specified by **config**. If **config** is omitted, the **default_text_search_config** configuration is used.

If an options string is specified it must consist of a comma-separated list of one or more **option=value** pairs. The available options are:

- **StartSel, StopSel**: The strings with which to delimit query words appearing in the document, to distinguish them from other excerpted words. You must double-quote these strings if they contain spaces or commas.
- **MaxWords, MinWords**: These numbers determine the longest and shortest headlines to output.
- **ShortWord**: Words of this length or less will be dropped at the start and end of a headline. The default value of three eliminates common English articles.
- **HighlightAll**: Boolean flag. If **true** the whole document will be used as the headline, ignoring the preceding three parameters.
- **MaxFragments**: Maximum number of text excerpts or fragments to display. The default value of zero selects a non-fragment-oriented headline generation method. A value greater than zero selects fragment-based headline generation. This method finds text fragments with as many query words as possible and stretches those fragments around the query words. As a result query words are close to the middle of each fragment and have words on each side. Each fragment will be of at most **MaxWords** and words of length **ShortWord** or less are dropped at the start and end of each fragment. If not all query words are found in the document, then a single fragment of the first **MinWords** in the document will be displayed.
- **FragmentDelimiter**: When more than one fragment is displayed, the fragments will be separated by this string.

Any unspecified options receive these defaults:

```
StartSel=<b>, StopSel=</b>,  
MaxWords=35, MinWords=15, ShortWord=3, HighlightAll=FALSE,  
MaxFragments=0, FragmentDelimiter=" ... "
```

For example:

```
SELECT ts_headline('english',  
'The most common type of search  
is to find all documents containing given query terms  
and return them in order of their similarity to the  
query.',  
to_tsquery('english', 'query & similarity'));  
      ts_headline  
-----  
containing given <b>query</b> terms  
and return them in order of their <b>similarity</b> to the  
<b>query</b>.  
(1 row)  
  
SELECT ts_headline('english',  
'The most common type of search  
is to find all documents containing given query terms  
and return them in order of their similarity to the  
query.',  
to_tsquery('english', 'query & similarity'),  
'StartSel = <, StopSel = >');  
      ts_headline  
-----  
containing given <query> terms  
and return them in order of their <similarity> to the  
<query>.  
(1 row)
```

ts_headline uses the original document, not a **tsvector** summary, so it can be slow and should be used with care.

21.10.4 Additional Features

21.10.4.1 Manipulating tsvector

DWS provides functions and operators that can be used to manipulate documents that are already in **tsvector** type.

- **tsvector || tsvector**

The **tsvector** concatenation operator returns a new **tsvector** which combines the lexemes and positional information of the two **tsvectors** given as arguments. Positions and weight labels are retained during the concatenation. Positions appearing in the right-hand **tsvector** are offset by the largest position mentioned in the left-hand **tsvector**, so that the result is nearly equivalent to the result of performing **to_tsvector** on the concatenation of the two original document strings. (The equivalence is not exact, because any stop-words removed from the end of the left-hand argument will not affect the result, whereas they would have affected the positions of the lexemes in the right-hand argument if textual concatenation were used.)

One advantage of using concatenation in the **tsvector** form, rather than concatenating text before applying **to_tsvector**, is that you can use different configurations to parse different sections of the document. Also, because the **setweight** function marks all lexemes of the given **tsvector** the same way, it is necessary to parse the text and do **setweight** before concatenating if you want to label different parts of the document with different weights.

- `setweight(vector tsvector, weight "char")` returns `tsvector`
setweight returns a copy of the input `tsvector` in which every position has been labeled with the given weight, either **A**, **B**, **C**, or **D**. (**D** is the default for new `tsvectors` and as such is not displayed on output.) These labels are retained when `tsvectors` are concatenated, allowing words from different parts of a document to be weighted differently by ranking functions.

NOTICE

Note that weight labels apply to positions, not lexemes. If the input `tsvector` has been stripped of positions then **setweight** does nothing.

- `length(vector tsvector)` returns integer
Returns the number of lexemes stored in the vector.
- `strip(vector tsvector)` returns `tsvector`
Returns a `tsvector` which lists the same lexemes as the given `tsvector`, but which lacks any position or weight information. While the returned `tsvector` is much less useful than an unstripped `tsvector` for relevance ranking, it will usually be much smaller.

21.10.4.2 Manipulating Queries

DWS provides functions and operators that can be used to manipulate queries that are already in `tsquery` type.

- `tsquery && tsquery`
Returns the AND-combination of the two given `tsqueries`.
- `tsquery || tsquery`
Returns the OR-combination of the two given `tsqueries`.
- `!! tsquery`
Returns the negation (NOT) of the given `tsquery`.
- `numnode(query tsquery)` returns integer
Returns the number of nodes (lexemes plus operators) in a **tsquery**. This function is useful to determine if the query is meaningful (returns > 0), or contains only stop words (returns 0). For example:

```
SELECT numnode(plainto_tsquery('the any'));
NOTICE: text-search query contains only stop words or doesn't contain lexemes, ignored
CONTEXT: referenced column: numnode
numnode
-----
      0

SELECT numnode('foo & bar'::tsquery);
numnode
-----
      3
```

- `querytree(query tsquery)` returns text
Returns the portion of a **tsquery** that can be used for searching an index. This function is useful for detecting unindexable queries, for example those containing only stop words or only negated terms. For example:

```
SELECT querytree(to_tsquery('!defined'));
querytree
-----
T
(1 row)
```

21.10.4.3 Rewriting Queries

The **ts_rewrite** family of functions searches a given **tsquery** for occurrences of a target subquery, and replace each occurrence with a substitute subquery. In essence this operation is a **tsquery** specific version of substring replacement. A target and substitute combination can be thought of as a query rewrite rule. A collection of such rewrite rules can be a powerful search aid. For example, you can expand the search using synonyms (that is, new york, big apple, nyc, gotham) or narrow the search to direct the user to some hot topic.

- **ts_rewrite** (query tsquery, target tsquery, substitute tsquery) returns tsquery
This form of **ts_rewrite** simply applies a single rewrite rule: **target** is replaced by **substitute** wherever it appears in query. For example:

```
SELECT ts_rewrite('a & b':tsquery, 'a':tsquery, 'c':tsquery);
ts_rewrite
-----
'b' & 'c'
```

- **ts_rewrite** (query tsquery, select text) returns tsquery
This form of **ts_rewrite** accepts a starting query and a SQL select command, which is given as a text string. The **select** must yield two columns of **tsquery** type. For each row of the select result, occurrences of the first column value (the target) are replaced by the second column value (the substitute) within the current **query** value.

NOTE

Note that when multiple rewrite rules are applied in this way, the order of application can be important; so in practice you will want the source query to **ORDER BY** some ordering key.

Consider a real-life astronomical example. We will expand query supernovae using table-driven rewriting rules:

```
CREATE TABLE tsearch.aliaes (id int, t tsquery, s tsquery);

INSERT INTO tsearch.aliaes VALUES(1, to_tsquery('supernovae'), to_tsquery('supernovae|sn'));

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM tsearch.aliaes');

ts_rewrite
-----
'crab' & ( 'supernova' | 'sn' )
```

We can change the rewriting rules just by updating the table:

```
UPDATE tsearch.aliaes
SET s = to_tsquery('supernovae|sn & !nebulae')
WHERE t = to_tsquery('supernovae');

SELECT ts_rewrite(to_tsquery('supernovae & crab'), 'SELECT t, s FROM tsearch.aliaes');

ts_rewrite
-----
'crab' & ( 'supernova' | 'sn' & '!nebula' )
```

Rewriting can be slow when there are many rewriting rules, since it checks every rule for a possible match. To filter out obvious non-candidate rules we

can use the containment operators for the **tsquery** type. In the example below, we select only those rules which might match the original query:

```
SELECT ts_rewrite('a & b'::tsquery, 'SELECT t,s FROM tsearch.aliaes WHERE "a & b"::tsquery @> t');
ts_rewrite
-----
'b' & 'a'
(1 row)
DROP TABLE ts_rewrite;
```

21.10.4.4 Gathering Document Statistics

The function **ts_stat** is useful for checking your configuration and for finding stop-word candidates.

```
ts_stat(sqlquery text, [ weights text, ]
      OUT word text, OUT ndoc integer,
      OUT nentry integer) returns setof record
```

sqlquery is a text value containing an SQL query which must return a single **tsvector** column. **ts_stat** executes the query and returns statistics about each distinct lexeme (word) contained in the **tsvector** data. The columns returned are:

- **word text**: the value of a lexeme.
- **ndoc integer**: number of documents (**tsvectors**) the word occurred in.
- **nentry integer**: total number of occurrences of the word.

If **weights** are supplied, only occurrences having one of those weights are counted. For example, to find the ten most frequent words in a document collection:

```
SELECT * FROM ts_stat('SELECT to_tsvector("english", sr_reason_sk) FROM tpccs.store_returns WHERE
sr_customer_sk < 10') ORDER BY nentry DESC, ndoc DESC, word LIMIT 10;;
 word | ndoc | nentry
-----+-----+-----
 32  |    2 |      2
 33  |    2 |      2
  1  |    1 |      1
 10  |    1 |      1
 13  |    1 |      1
 14  |    1 |      1
 15  |    1 |      1
 17  |    1 |      1
 20  |    1 |      1
 22  |    1 |      1
(10 rows)
```

The same, but counting only word occurrences with weight **A** or **B**:

```
SELECT * FROM ts_stat('SELECT to_tsvector("english", sr_reason_sk) FROM tpccs.store_returns WHERE
sr_customer_sk < 10', 'a') ORDER BY nentry DESC, ndoc DESC, word LIMIT 10;
 word | ndoc | nentry
-----+-----+-----
(0 rows)
```

21.10.5 Parsers

Text search parsers are responsible for splitting raw document text into tokens and identifying each token's type, where the set of types is defined by the parser itself. Note that a parser does not modify the text at all — it simply identifies plausible word boundaries. Because of this limited scope, there is less need for application-specific custom parsers than there is for custom dictionaries.

Currently, DWS provides the following built-in parsers: `pg_catalog.default` for English configuration, and `pg_catalog.ngram`, `pg_catalog.zhparser`, and `pg_catalog.pound` for full text search in texts containing Chinese, or both Chinese and English.

The built-in parser is named **`pg_catalog.default`**. It recognizes 23 token types, shown in [Table 21-94](#).

Table 21-94 Default parser's token types

| Alias | Description | Examples |
|------------------------------|--|--|
| <code>asciiword</code> | Word, all ASCII letters | elephant |
| <code>word</code> | Word, all letters | mañana |
| <code>numword</code> | Word, letters and digits | beta1 |
| <code>asciihword</code> | Hyphenated word, all ASCII | up-to-date |
| <code>hword</code> | Hyphenated word, all letters | lógico-matemática |
| <code>numhword</code> | Hyphenated word, letters and digits | postgresql-beta1 |
| <code>hword_asciipart</code> | Hyphenated word part, all ASCII | postgresql in the context
postgresql-beta1 |
| <code>hword_part</code> | Hyphenated word part, all letters | lógico or matemática in the
context lógico-matemática |
| <code>hword_numpart</code> | Hyphenated word part, letters and digits | beta1 in the context
postgresql-beta1 |
| <code>email</code> | Email address | foo@example.com |
| <code>protocol</code> | Protocol head | http:// |
| <code>url</code> | URL | example.com/stuff/index.html |
| <code>host</code> | Host | example.com |
| <code>url_path</code> | URL path | /stuff/index.html, in the
context of a URL |
| <code>file</code> | File or path name | /usr/local/foo.txt, if not
within a URL |
| <code>sfloat</code> | Scientific notation | -1.23E+56 |
| <code>float</code> | Decimal notation | -1.234 |
| <code>int</code> | Signed integer | -1234 |
| <code>uint</code> | Unsigned integer | 1234 |
| <code>version</code> | Version number | 8.3.0 |

| Alias | Description | Examples |
|--------|---------------|--|
| tag | XML tag | |
| entity | XML entity | & |
| blank | Space symbols | (any whitespace or punctuation not otherwise recognized) |

Note: The parser's notion of a "letter" is determined by the database's locale setting, specifically **lc_ctype**. Words containing only the basic ASCII letters are reported as a separate token type, since it is sometimes useful to distinguish them. In most European languages, token types **word** and **asciiword** should be treated alike.

email does not support all valid email characters as defined by RFC 5322. Specifically, the only non-alphanumeric characters supported for email user names are period, dash, and underscore.

It is possible for the parser to identify overlapping tokens in the same piece of text. As an example, a hyphenated word will be reported both as the entire word and as each component:

```
SELECT alias, description, token FROM ts_debug('english','foo-bar-beta1');
  alias | description | token
-----+-----+-----
numhword | Hyphenated word, letters and digits | foo-bar-beta1
hword_asciipart | Hyphenated word part, all ASCII | foo
blank | Space symbols | -
hword_asciipart | Hyphenated word part, all ASCII | bar
blank | Space symbols | -
hword_numpart | Hyphenated word part, letters and digits | beta1
```

This behavior is desirable since it allows searches to work for both the whole compound word and for components. Here is another instructive example:

```
SELECT alias, description, token FROM ts_debug('english','http://example.com/stuff/index.html');
  alias | description | token
-----+-----+-----
protocol | Protocol head | http://
url | URL | example.com/stuff/index.html
host | Host | example.com
url_path | URL path | /stuff/index.html
```

N-gram is a mechanical word segmentation method, and applies to no semantic Chinese segmentation scenarios. The N-gram segmentation method ensures the completeness of the segmentation. However, to cover all the possibilities, it adds unnecessary words to the index, resulting in a large number of index items. N-gram supports Chinese coding, including GBK and UTF-8. Six built-in token types are shown in [Table 21-95](#).

Table 21-95 Token types

| Alias | Description |
|----------|---------------|
| zh_words | chinese words |

| Alias | Description |
|-------------|-----------------|
| en_word | english word |
| numeric | numeric data |
| alnum | alnum string |
| grapsymbol | graphic symbol |
| multisymbol | multiple symbol |

Zhparser is a dictionary-based semantic word segmentation method. The bottom-layer calls the Simple Chinese Word Segmentation (SCWS) algorithm (<https://github.com/hightman/scws>), which applies to Chinese segmentation scenarios. SCWS is a term frequency and dictionary-based mechanical Chinese words engine. It can split a whole paragraph Chinese text into words. The two Chinese coding formats, GBK and UTF-8, are supported. The 26 built-in token types are shown in [Table 21-96](#).

Table 21-96 Token types

| Alias | Description |
|-------|----------------------------|
| A | Adjective |
| B | Differentiation |
| C | Conjunction |
| D | Adverb |
| E | Exclamation |
| F | Position |
| G | Lexeme |
| H | Preceding element |
| I | Idiom |
| J | Acronyms and abbreviations |
| K | Subsequent element |
| L | Common words |
| M | Numeral |
| N | Noun |
| O | Onomatopoeia |
| P | Preposition |
| Q | Quantifiers |

| Alias | Description |
|-------|----------------|
| R | Pronoun |
| S | Space |
| T | Time |
| U | Auxiliary word |
| V | Verb |
| W | Punctuation |
| X | Unknown |
| Y | Interjection |
| Z | Status words |

Pound segments words in a fixed format. It is used to segment to-be-parsed nonsense Chinese and English words that are separated by fixed separators. It supports Chinese encoding (including GBK and UTF8) and English encoding (including ASCII). Pound has six pre-configured token types (as listed in [Table 21-97](#)) and supports five separators (as listed in [Table 21-98](#)). By default, the separator is #. Pound The maximum length of a token is 256 characters.

Table 21-97 Token types

| Alias | Description |
|-------------|-----------------|
| zh_words | chinese words |
| en_word | english word |
| numeric | numeric data |
| alnum | alnum string |
| grapsymbol | graphic symbol |
| multisymbol | multiple symbol |

Table 21-98 Separator types

| Delimiter | Description |
|-----------|-------------------|
| @ | Special character |
| # | Special character |
| \$ | Special character |
| % | Special character |

| Delimiter | Description |
|-----------|-------------------|
| / | Special character |

21.10.6 Dictionaries

21.10.6.1 Overview

A dictionary is used to define stop words, that is, words to be ignored in full-text retrieval.

A dictionary can also be used to normalize words so that different derived forms of the same word will match. A normalized word is called a lexeme.

In addition to improving retrieval quality, normalization and removal of stop words can reduce the size of the **tsvector** representation of a document, thereby improving performance. Normalization and removal of stop words do not always have linguistic meaning. Users can define normalization and removal rules in dictionary definition files based on application environments.

A dictionary is a program that receives a token as input and returns:

- An array of lexemes if the input token is known to the dictionary (note that one token can produce more than one lexeme).
- A single lexeme to replace the original token with a new token to be passed to subsequent dictionaries (a dictionary that does this is called a filtering dictionary).
- An empty array if the input token is known to the dictionary but is a stop word.
- **NULL** if the dictionary does not recognize the token.

DWS provides predefined dictionaries for many languages and also provides five predefined dictionary templates, **Simple**, **Synonym**, **Thesaurus**, **Ispell**, and **Snowball**. These templates can be used to create new dictionaries with custom parameters.

When using full-text retrieval, you are advised to:

- In the text search configuration, configure a parser together with a set of dictionaries to process the parser's output tokens. For each token type that the parser can return, a separate list of dictionaries is specified by the configuration. When a token of that type is found by the parser, each dictionary in the list is consulted in turn, until a dictionary recognizes it as a known word. If it is identified as a stop word, or no dictionary recognizes the token, it will be discarded and not indexed or searched for. Generally, the first dictionary that returns a non-**NULL** output determines the result, and any remaining dictionaries are not consulted. However, a filtering dictionary can replace the input token with a modified one, which is then passed to subsequent dictionaries.
- The general rule for configuring a list of dictionaries is to place first the most narrow, most specific dictionary, then the more general dictionaries, finishing

with a very general dictionary, like a **Snowball** stemmer dictionary or a **Simple** dictionary, which recognizes everything. In the following example, for an astronomy-specific search (**astro_en** configuration), you can configure the token type **asciiword** (ASCII word) with a **Synonym** dictionary of astronomical terms, a general English **Ispell** dictionary, and a **Snowball** English stemmer dictionary:

```
ALTER TEXT SEARCH CONFIGURATION astro_en
ADD MAPPING FOR asciiword WITH astro_syn, english_isspell, english_stem;
```

A filtering dictionary can be placed anywhere in the list, except at the end where it would be useless. Filtering dictionaries are useful to partially normalize words to simplify the task of later dictionaries.

21.10.6.2 Stop Words

Stop words are words that are very common, appear in almost every document, and have no discrimination value. Therefore, they can be ignored in the context of full text searching. Each type of dictionaries treats stop words in different ways. For example, **Ispell** dictionaries first normalize words and then check the list of stop words, while **Snowball** dictionaries first check the list of stop words.

For example, every English text contains words like **a** and **the**, so it is useless to store them in an index. However, stop words affect the positions in **tsvector**, which in turn affect ranking.

```
SELECT to_tsvector('english','in the list of stop words');
to_tsvector
-----
'list':3 'stop':5 'word':6
```

The missing positions 1, 2, and 4 are because of stop words. Ranks calculated for documents with and without stop words are quite different:

```
SELECT ts_rank_cd (to_tsvector('english','in the list of stop words'), to_tsquery('list & stop'));
ts_rank_cd
-----
.05

SELECT ts_rank_cd (to_tsvector('english','list stop words'), to_tsquery('list & stop'));
ts_rank_cd
-----
.1
```

21.10.6.3 Simple Dictionary

A **Simple** dictionary operates by converting the input token to lower case and checking it against a list of stop words. If the token is found in the list, an empty array will be returned, causing the token to be discarded. If it is not found, the lower-cased form of the word is returned as the normalized lexeme. In addition, you can set **Accept** to **false** for **Simple** dictionaries (default: **true**) to report non-stop-words as unrecognized, allowing them to be passed on to the next dictionary in the list.

Precautions

- Most types of dictionaries rely on dictionary configuration files. The name of a configuration file can only be lowercase letters, digits, and underscores (_).
- A dictionary cannot be created in **pg_temp** mode.

- Dictionary configuration files must be stored in UTF-8 encoding. They will be translated to the actual database encoding, if that is different, when they are read into the server.
- Generally, a session will read a dictionary configuration file only once, when it is first used within the session. To modify a configuration file, run the **ALTER TEXT SEARCH DICTIONARY** statement to update and reload the file.

Procedure

Step 1 Create a **Simple** dictionary.

```
CREATE TEXT SEARCH DICTIONARY public.simple_dict (  
    TEMPLATE = pg_catalog.simple,  
    STOPWORDS = english  
);
```

english.stop is the full name of a file of stop words. For details about the syntax and parameters for creating a **Simple** dictionary, see [CREATE TEXT SEARCH DICTIONARY](#).

Step 2 Use the **Simple** dictionary.

```
SELECT ts_lexize('public.simple_dict','Yes');  
ts_lexize  
-----  
{yes}  
(1 row)  
  
SELECT ts_lexize('public.simple_dict','The');  
ts_lexize  
-----  
{}  
(1 row)
```

Step 3 Set **Accept=false** so that the **Simple** dictionary returns **NULL** instead of a lower-cased non-stop word.

```
ALTER TEXT SEARCH DICTIONARY public.simple_dict ( Accept = false );  
SELECT ts_lexize('public.simple_dict','Yes');  
ts_lexize  
-----  
  
(1 row)  
  
SELECT ts_lexize('public.simple_dict','The');  
ts_lexize  
-----  
{}  
(1 row)
```

----End

21.10.6.4 Synonym Dictionary

A synonym dictionary is used to define, identify, and convert synonyms of tokens. Phrases are not supported (use the thesaurus dictionary in [Thesaurus Dictionary](#)).

Examples

- A synonym dictionary can be used to overcome linguistic problems, for example, to prevent an English stemmer dictionary from reducing the word "Paris" to "pari". It is enough to have a **Paris paris** line in the synonym dictionary and put it before the **english_stem** dictionary.

```

SELECT * FROM ts_debug('english', 'Paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {english_stem} | english_stem | {pari}
(1 row)

CREATE TEXT SEARCH DICTIONARY my_synonym (
  TEMPLATE = synonym,
  SYNONYMS = my_synonyms,
  FILEPATH = 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'
);

ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR asciiword
    WITH my_synonym, english_stem;

SELECT * FROM ts_debug('english', 'Paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {paris}
(1 row)

SELECT * FROM ts_debug('english', 'paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {paris}
(1 row)

ALTER TEXT SEARCH DICTIONARY my_synonym ( CASESENSITIVE=true);

SELECT * FROM ts_debug('english', 'Paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {paris}
(1 row)

SELECT * FROM ts_debug('english', 'paris');
  alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | Paris | {my_synonym,english_stem} | my_synonym | {pari}
(1 row)

```

The full name of the synonym dictionary file is **my_synonyms.syn**, and the dictionary is stored in 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'. For details about the syntax and parameters for creating a synonym dictionary, see [CREATE TEXT SEARCH DICTIONARY](#).

- An asterisk (*) can be placed at the end of a synonym in the configuration file. This indicates that the synonym is a prefix. The asterisk is ignored when the entry is used in `to_tsvector()`, but when it is used in `to_tsquery()`, the result will be a query item with the prefix match marker (see [Manipulating Queries](#)).

Assume that the content in the dictionary file **synonym_sample.syn** is as follows:

```

postgres  pgsql
postgresql  pgsql
postgre pgsql
gogle  googl
indices index*

```

Create and use a dictionary.

```

CREATE TEXT SEARCH DICTIONARY syn (
  TEMPLATE = synonym,
  SYNONYMS = synonym_sample
);

SELECT ts_lexize('syn','indices');

```

```
ts_lexize
-----
{index}
(1 row)

CREATE TEXT SEARCH CONFIGURATION tst (copy=simple);

21.10.6.5 Thesaurus Dictionary

A thesaurus dictionary (sometimes abbreviated as TZ) is a collection of words that include relationships between words and phrases, such as broader terms (BT), narrower terms (NT), preferred terms, non-preferred terms, and related terms. A thesaurus dictionary replaces all non-preferred terms by one preferred term and, optionally, preserves the original terms for indexing as well. A thesaurus dictionary is an extension of the synonym dictionary with added phrase support.

Precautions

- A thesaurus dictionary has the capability to recognize phrases. Therefore, it must remember its state and interact with the parser to check whether it should handle the next token or stop accumulation. The thesaurus dictionary must be configured carefully. For example, if the thesaurus dictionary is assigned to handle only the **asciiword** token, then a thesaurus dictionary definition like **one 7** will not work because token type **uint** is not assigned to the thesaurus dictionary.
- Thesauruses are used during indexing. Any change in the thesaurus dictionary's parameters requires reindexing. For most other dictionary types, small changes such as adding or removing stop words does not force reindexing.

Procedure

Step 1 Create a TZ named **thesaurus_astro**.

thesaurus_astro is a simple astronomical TZ that defines two astronomical word combinations (word+synonym).

```
supernovae stars : sn  
crab nebulae : crab
```

Run the following statement to create the TZ:

```
CREATE TEXT SEARCH DICTIONARY thesaurus_astro (  
  TEMPLATE = thesaurus,  
  DictFile = thesaurus_astro,  
  Dictionary = pg_catalog.english_stem,  
  FILEPATH = 'obs://bucket_name/path accesskey=ak secretkey=sk region=rg'  
);
```

The full name of the thesaurus dictionary file is **thesaurus_astro.ths**, and the dictionary is stored in the **obs://bucket_name/path accesskey=ak secretkey=sk region=rg** directory. **pg_catalog.english_stem** is the subdictionary (a **Snowball** English stemmer) used for input normalization. The subdictionary has its own configuration (for example, stop words), which is not shown here. For details about the syntax and parameters for creating a TZ, see [CREATE TEXT SEARCH DICTIONARY](#).

Step 2 Bind the TZ to the desired token types in the text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION english  
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart  
  WITH thesaurus_astro, english_stem;
```

Step 3 Use the TZ.

- Test the TZ.

The **ts_lexize** function is not very useful for testing the TZ because the function processes its input as a single token. Instead, you can use the **plainto_tsquery**, **to_tsvector**, or **to_tsquery** function which will break their input strings into multiple tokens.

```
SELECT plainto_tsquery('english','supernova star');  
plainto_tsquery  
-----  
'sn'  
(1 row)  
  
SELECT to_tsvector('english','supernova star');  
to_tsvector  
-----  
'sn':1  
(1 row)  
  
SELECT to_tsquery('english','"supernova star"');  
to_tsquery  
-----  
'sn'  
(1 row)
```

supernova star matches **supernovae stars** in **thesaurus_astro** because the **english_stem** stemmer of the Snowball type is specified in the **thesaurus_astro** definition. The stemmer removed **e** and **s**.

- To index the original phrase, include it in the right-hand part of the definition.

```
supernovae stars : sn supernovae stars  
  
ALTER TEXT SEARCH DICTIONARY thesaurus_astro (  
  DictFile = thesaurus_astro,  
  FILEPATH = 'file:///home/dicts/');  
  
SELECT plainto_tsquery('english','supernova star');  
plainto_tsquery
```

```
-----  
'sn' & 'supernova' & 'star'  
(1 row)
```

----End

21.10.6.6 Ispell Dictionary

The Ispell dictionary template supports morphological dictionaries, which can normalize many different linguistic forms of a word into the same lexeme. For example, an English Ispell dictionary can match all declensions and conjugations of the search term **bank**, such as **banking**, **banked**, **banks**, **banks'**, and **bank's**.

DWS does not provide any predefined Ispell dictionaries or dictionary files. The **.dict** files and **.affix** files support multiple open-source dictionary formats, including **Ispell**, **MySpell**, and **Hunspell**.

Procedure

Step 1 Obtain the dictionary definition file (.dict) and affix file (.affix).

You can use an open-source dictionary. The name extensions of the open-source dictionary may be **.aff** and **.dic**. In this case, you need to change them to **.affix** and **.dict**. In addition, for some dictionary files (for example, Norwegian dictionary files), you need to run the following commands to convert the character encoding to UTF-8:

```
iconv -f ISO_8859-1 -t UTF-8 -o nn_no.affix nn_NO.aff  
iconv -f ISO_8859-1 -t UTF-8 -o nn_no.dict nn_NO.dic
```

Step 2 Create an Ispell dictionary.

```
CREATE TEXT SEARCH DICTIONARY norwegian_ispell (  
  TEMPLATE = ispell,  
  DictFile = nn_no,  
  AffFile = nn_no,  
  FilePath = 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'  
);
```

The full name of the Ispell dictionary file is **nn_no.dict** and **nn_no.affix**, and the dictionary is stored in 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'. For details about the syntax and parameters for creating an Ispell dictionary, see [CREATE TEXT SEARCH DICTIONARY](#).

Step 3 Use the Ispell dictionary to split compound words.

```
SELECT ts_lexize('norwegian_ispell', 'sjokoladefabrikk');  
      ts_lexize  
-----  
{sjokolade,fabrikk}  
(1 row)
```

MySpell does not support compound words. **Hunspell** supports compound words. DWS supports only the basic compound word operations of **Hunspell**. Generally, an Ispell dictionary recognizes a limited set of words, so they should be followed by another broader dictionary, for example, a Snowball dictionary, which recognizes everything.

----End

21.10.6.7 Snowball Dictionary

A **Snowball** dictionary is based on a project by Martin Porter and is used for stem analysis, providing stemming algorithms for many languages. DWS provides predefined **Snowball** dictionaries of many languages. You can query the **PG_TS_DICT** system catalog to view the predefined **Snowball** dictionaries and supported stemming algorithms.

Snowball dictionaries identify all inputs as recognized, whether simplified or not, so they should be placed at the end of the dictionary list. It is useless to place it before any other dictionary because a token will never pass it through to the next dictionary.

For details about the syntax of **Snowball** dictionaries, see [CREATE TEXT SEARCH DICTIONARY](#).

21.10.7 Configuration Examples

Text search configuration specifies the following components required for converting a document into a **tsvector**:

- A parser, decomposes a text into tokens.
- Dictionary list, converts each token into a lexeme.

Each time when the **to_tsvector** or **to_tsquery** function is invoked, a text search configuration is required to specify a processing procedure. The GUC parameter **default_text_search_config** specifies the default text search configuration, which will be used if the text search function does not explicitly specify a text search configuration.

DWS provides some predefined text search configurations. You can also create user-defined text search configurations. In addition, to facilitate the management of text search objects, multiple **gsql** meta-commands are provided to display related information. For details, see "Meta-Command Reference" in the Data Warehouse Service (DWS) *Tool Guide*.

Procedure

- Step 1** Create a text search configuration **ts_conf** by copying the predefined text search configuration **english**.

```
CREATE TEXT SEARCH CONFIGURATION ts_conf ( COPY = pg_catalog.english );  
CREATE TEXT SEARCH CONFIGURATION
```

- Step 2** Create a **Synonym** dictionary.

Assume that the definition file **pg_dict.syn** of the **Synonym** dictionary contains the following contents:

```
postgres pg  
pgsql pg  
postgresql pg
```

Run the following statement to create the **Synonym** dictionary:

```
CREATE TEXT SEARCH DICTIONARY pg_dict (  
    TEMPLATE = synonym,  
    SYNONYMS = pg_dict,  
    FILEPATH = 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'  
);
```

- Step 3** Create an **Ispell** dictionary **english_ispell** (the dictionary definition file is from the open source dictionary).

```
CREATE TEXT SEARCH DICTIONARY english_ispell (  
    TEMPLATE = ispell,  
    DictFile = english,  
    AffFile = english,  
    StopWords = english,  
    FILEPATH = 'obs://bucket01/obs.example.com accesskey=xxxxx secretkey=xxxxx region=xx-xx-xx'  
);
```

- Step 4** Modify the text search configuration **ts_conf** and change the dictionary list for tokens of certain types. For details about token types, see [Parsers](#).

```
ALTER TEXT SEARCH CONFIGURATION ts_conf  
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,  
        word, hword, hword_part  
    WITH pg_dict, english_ispell, english_stem;
```

- Step 5** In the text search configuration, set non-index or set the search for tokens of certain types.

```
ALTER TEXT SEARCH CONFIGURATION ts_conf  
    DROP MAPPING FOR email, url, url_path, sfloat, float;
```

- Step 6** Use the text retrieval commissioning function **ts_debug()** to test the text search configuration **ts_conf**.

```
SELECT * FROM ts_debug('ts_conf', '  
PostgreSQL, the highly scalable, SQL compliant, open source object-relational  
database management system, is now undergoing beta testing of the next  
version of our software.  
' );
```

- Step 7** You can set the default text search configuration of the current session to **ts_conf**. This setting is valid only for the current session.

```
\dF+ ts_conf  
    Text search configuration "public.ts_conf"  
Parser: "pg_catalog.default"  
    Token      |      Dictionaries  
-----+-----  
asciihword    | pg_dict,english_ispell,english_stem  
asciiword     | pg_dict,english_ispell,english_stem  
file          | simple  
host          | simple  
hword         | pg_dict,english_ispell,english_stem  
hword_asciipart | pg_dict,english_ispell,english_stem  
hword_numpart | simple  
hword_part    | pg_dict,english_ispell,english_stem  
int           | simple  
numhword      | simple  
numword       | simple  
uint          | simple  
version       | simple  
word          | pg_dict,english_ispell,english_stem  
  
SET default_text_search_config = 'public.ts_conf';  
SET  
SHOW default_text_search_config;  
default_text_search_config  
-----  
public.ts_conf  
(1 row)
```

----End

21.10.8 Testing and Debugging Text Search

21.10.8.1 Testing a Configuration

The function `ts_debug` allows easy testing of a text search configuration.

```
ts_debug([ config regconfig, ] document text,
        OUT alias text,
        OUT description text,
        OUT token text,
        OUT dictionaries regdictionary[],
        OUT dictionary regdictionary,
        OUT lexemes text[])
returns setof record
```

ts_debug displays information about every token of document as produced by the parser and processed by the configured dictionaries. It uses the configuration specified by **config**, or **default_text_search_config** if that argument is omitted.

ts_debug returns one row for each token identified in the text by the parser. The columns returned are:

- alias text — short name of the token type
- description text — description of the token type
- token text — text of the token
- **dictionaries regdictionary[]** — the dictionaries selected by the configuration for this token type
- **dictionary regdictionary**: the dictionary that recognized the token, or NULL if none did
- **lexemes text[]**: the lexeme(s) produced by the dictionary that recognized the token, or NULL if none did; an empty array ({}) means the token was recognized as a stop word

Here is a simple example:

```
SELECT * FROM ts_debug('english','a fat cat sat on a mat - it ate a fat rats');
 alias | description | token | dictionaries | dictionary | lexemes
-----+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | a | {english_stem} | english_stem | {}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | fat | {english_stem} | english_stem | {fat}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | cat | {english_stem} | english_stem | {cat}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | sat | {english_stem} | english_stem | {sat}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | on | {english_stem} | english_stem | {}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | a | {english_stem} | english_stem | {}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | mat | {english_stem} | english_stem | {mat}
blank | Space symbols | | {} | | 
blank | Space symbols | - | {} | | 
asciiword | Word, all ASCII | it | {english_stem} | english_stem | {}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | ate | {english_stem} | english_stem | {ate}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | a | {english_stem} | english_stem | {}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | fat | {english_stem} | english_stem | {fat}
blank | Space symbols | | {} | | 
asciiword | Word, all ASCII | rats | {english_stem} | english_stem | {rat}
(24 rows)
```

21.10.8.2 Testing a Parser

The **ts_parse** function allows direct testing of a text search parser.

```
ts_parse(parser_name text, document text,  
OUT tokid integer, OUT token text) returns setof record
```

ts_parse parses the given **document** and returns a series of records, one for each token produced by parsing. Each record includes a **tokid** showing the assigned token type and a **token** which is the text of the token. For example:

```
SELECT * FROM ts_parse('default', '123 - a number');  
tokid | token  
-----+-----  
22 | 123  
12 |  
12 | -  
1 | a  
12 |  
1 | number  
(6 rows)  
ts_token_type(parser_name text, OUT tokid integer,  
OUT alias text, OUT description text) returns setof record
```

ts_token_type returns a table which describes each type of token the specified parser can recognize. For each token type, the table gives the integer **tokid** that the parser uses to label a token of that type, the **alias** that names the token type in configuration commands, and a short description. For example:

```
SELECT * FROM ts_token_type('default');  
tokid | alias | description  
-----+-----  
1 | asciiword | Word, all ASCII  
2 | word | Word, all letters  
3 | numword | Word, letters and digits  
4 | email | Email address  
5 | url | URL  
6 | host | Host  
7 | sfloat | Scientific notation  
8 | version | Version number  
9 | hword_numpart | Hyphenated word part, letters and digits  
10 | hword_part | Hyphenated word part, all letters  
11 | hword_asciipart | Hyphenated word part, all ASCII  
12 | blank | Space symbols  
13 | tag | XML tag  
14 | protocol | Protocol head  
15 | numhword | Hyphenated word, letters and digits  
16 | asciihword | Hyphenated word, all ASCII  
17 | hword | Hyphenated word, all letters  
18 | url_path | URL path  
19 | file | File or path name  
20 | float | Decimal notation  
21 | int | Signed integer  
22 | uint | Unsigned integer  
23 | entity | XML entity  
(23 rows)
```

21.10.8.3 Testing a Dictionary

The **ts_lexize** function facilitates dictionary testing.

ts_lexize(dict regdictionary, token text) returns text[]: **ts_lexize** returns an array of lexemes if the input **token** is known to the dictionary, or an empty array if the token is known to the dictionary but it is a stop word, or **NULL** if it is an unknown word.

For example:

```
SELECT ts_lexize('english_stem', 'stars');
ts_lexize
-----
{star}

SELECT ts_lexize('english_stem', 'a');
ts_lexize
-----
{}
```

NOTICE

The **ts_lexize** function expects a single **token**, not text.

21.10.9 Limitations

The current limitations of DWS's full text search are:

- The length of each lexeme must be less than 2 KB.
- The length of a **tsvector** (lexemes + positions) must be less than 1 megabyte.
- Position values in **tsvector** must be greater than 0 and no more than 16,383.
- No more than 256 positions per lexeme. Excessive positions, if any, will be discarded.
- The number of nodes (lexemes + operators) in a tsquery must be less than 32,768.

21.11 System Operation

DWS runs SQL statements to perform different system operations, such as setting variables, displaying the execution plan, and collecting garbage data.

Setting Variables

For details about how to set various parameters for a session or transaction, see [SET](#).

Displaying the Execution Plan

For details about how to display the execution plan that DWS makes for SQL statements, see [EXPLAIN](#).

Specifying a Checkpoint in Transaction Logs

By default, WALs periodically specify checkpoints in a transaction log. **CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system. For details, see [CHECKPOINT](#).

Collecting Unnecessary Data

For details about how to collect garbage data and analyze a database as required,
For details, see [VACUUM](#).

Collecting statistics

For details about how to collect statistics on tables in databases, For details, see
[ANALYZE](#) | [ANALYSE](#).

Setting the Constraint Check Mode for the Current Transaction

For details about how to set the constraint check mode for the current transaction,
For details, see [SET CONSTRAINTS](#).

21.12 Transaction Management

DWS supports the ACID properties of database transactions. It provides the **READ COMMITTED** and **REPEATABLE READ** isolation levels of transactions.

WARNING

- In scenarios where the client explicitly starts a transaction or manually disables "autocommit", you must manually execute a commit command to commit the transaction.
 - You are advised to optimize the statements that take longer than 30 minutes to execute.
 - Avoid business operations that take longer than 2 hours to execute to prevent issues such as long transactions and long locks.
 - For more information about development design proposal, see "DWS Development Design Proposal" in the *Data Warehouse Service Developer Guide*.
-

Concepts

- A transaction refers to an operation that consists of multiple steps, either all successful or all failed.
- A database transaction is a logical unit in the execution process of DBMS. It consists of a limited number of database operations in a certain sequence (generally all the operations between **BEGIN TRANSACTION** and **END TRANSACTION**). These operations are either fully completed or not performed at all.

Purposes

The purposes of database transactions are as follows:

- To provide a method for restoring the database operation sequence from a failure while keeping database consistency even in case of system failure.

- To provide isolation between programs accessing a database concurrently, so that they do not interfere one another in this process.

Transaction Execution Process

After a transaction is committed in DBMS, DBMS needs to ensure that all operations in the transaction are successfully completed and the results are permanently stored in the database. If an operation in the transaction fails, all the operations in the transaction must be rolled back to the status before the transaction is executed. Transactions run independently and do not interfere with each other or affect database running.

Transaction Properties

A transaction has atomicity, consistency, isolation, and durability (ACID) properties.

- **Atomicity:** All the operations in a transaction are inseparable. They are either fully completed or not executed at all.
For example, if account A transfers an amount of money to account B, \$500 are deducted from account A and \$500 added to account B. If the amount fails to be added to account B, it cannot be deducted from account A. If atomicity is not guaranteed, the account balances will be inconsistent.
- **Consistency:** A transaction can only bring the database from one valid state to another, maintaining database invariants. Any data written to the database must be valid according to all defined rules, including data accuracy, concatenation, and spontaneous execution of scheduled tasks.
For example, if account A transfers \$500 to account B, \$500 is deducted from account A and added to account B. The sum of the deducted amount (-\$500) and the added amount (+500) should be 0. The total account balance of accounts A and B remains unchanged, no matter whether the money is transferred.
- **Isolation:** The execution of a transaction cannot be interfered by other transactions. Isolation means that the operations inside a transaction and data used are isolated from other concurrent transactions. The concurrent transactions do not affect each other.
Transactions are often executed concurrently. Isolation ensures that concurrent execution of transactions leaves the database in the same state that would have been obtained if the transactions were executed sequentially. Transaction isolation is divided into different levels, including **READ UNCOMMITTED**, **READ COMMITTED**, **REPEATABLE READ**, and **SERIALIZABLE**.
- **Durability:** Once a transaction is committed, its modifications are permanently saved to the database. Even if the system is faulty, committed modifications will not be lost.

Table 21-99 ACID usage

| ACID | Purpose |
|-----------|--|
| Atomicity | Concurrency control and fault recovery |

| ACID | Purpose |
|-------------|---|
| Consistency | SQL integrity constraints (primary key and foreign key constraints) |
| Isolation | Concurrency control |
| Durability | Fault recovery |

Common concurrency control technologies include lock-based and timestamp-based concurrency control. DWS uses the two-phase lock technology for DDL statements and uses multi-version concurrency control (MVCC) for DML statements. DWS databases fault recovery is based on WAL logs. MVCC mainly uses redo logs to ensure transaction read/write consistency.

Redo logs are critical components in database systems that ensure data durability and enable fault recovery. These logs record the modification operations—not the data before or after—performed by transactions. In the event of a failure, such as a system breakdown or crash, the database can replay these operations to restore data to a consistent state before the fault occurred.

Redo log recovery process: After a crash and subsequent restart, the database performs recovery using the redo log, which is known as Write-Ahead Log (WAL). It scans log entries from the last checkpoint—representing committed transactions that were not yet written to disk—and re-executes these operations to restore lost in-memory changes. Simultaneously, uncommitted transactions are rolled back using undo operations to reverse partial modifications. This ensures data is restored to a consistent and complete state, preserving durability of committed transactions and atomicity of incomplete ones. This mechanism is the core basis for databases to enable high reliability.

Isolation Levels

Isolation prevents data inconsistency during the execution of concurrent transactions. A transaction isolation level specifies how concurrent transactions process the same object.

In DWS, transaction isolation levels are controlled by the GUC parameter **transaction_isolation** or the **SET TRANSACTION** syntax. The following isolation levels are supported. The default isolation level is **READ COMMITTED**.

- **READ COMMITTED:** Only committed data is read.
- **READ UNCOMMITTED:** DWS does not support **READ UNCOMMITTED**. If **READ UNCOMMITTED** is set, **READ COMMITTED** is used instead.
- **REPEATABLE READ:** Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.
- **SERIALIZABLE:** DWS does not support **SERIALIZABLE**. If **SERIALIZABLE** is set, **REPEATABLE READ** is used instead.

Transaction Control Syntax

- Starting a transaction

DWS starts a transaction using **START TRANSACTION** and **BEGIN**. For details, see [START TRANSACTION](#) and [BEGIN](#).

- Setting a transaction

DWS sets a transaction using **SET TRANSACTION** or **SET LOCAL TRANSACTION**. For details, see [SET TRANSACTION](#).

- Committing a transaction

DWS commits all operations of a transaction using **COMMIT** or **END**. For details, see [COMMIT | END](#).

- Rolling back a transaction

If a fault occurs during a transaction and the transaction cannot proceed, the system performs rollback to cancel all the completed database operations related to the transaction. For details, see [ROLLBACK](#).

NOTE

If an execution request (not in a transaction block) received in the database contains multiple statements, the statements will be packed into a transaction. If one of the statements fails, the entire request will be rolled back.

- Other operations on transactions

- **SAVEPOINT** establishes a new savepoint within the current transaction. The transaction can be rolled back to the savepoint. You can roll back the commands executed after a savepoint but retain the commands executed before the savepoint. For details, see [SAVEPOINT](#).
- **ROLLBACK TO SAVEPOINT** rolls back a transaction to a savepoint. It implicitly deletes all the savepoints established after that savepoint. For details, see [ROLLBACK TO SAVEPOINT](#).
- **RELEASE SAVEPOINT** deletes a savepoint in a transaction. For details, see [RELEASE SAVEPOINT](#).

Transaction Example

A customer buys a \$100 item in a store using an e-payment account. At least two operations are involved: 1. \$100 is deducted from the customer's account. 2. \$100 is added to the store's account. In DBMS, the two operations must be both completed or not executed at all.

- Create sample data.

Create an account balance table and insert data. (Assume the store's and the customer's accounts each have \$500.)

```
CREATE TABLE customer_info (  
  NAME VARCHAR(32) PRIMARY KEY,  
  MONEY INTEGER  
);  
INSERT INTO customer_info (name, money) VALUES ('buyer', 500), ('shop', 500);
```

The table data shows that the store and customer each have \$500.

```
SELECT * FROM customer_info;
```

| name | money |
|----------|-------|
| buyer | 500 |
| shop | 500 |
| (2 rows) | |

2. Simulate a successful transaction.

Deduct \$100 from the customer's account and add \$100 to the store's account.

```
UPDATE customer_info SET money = money-100 WHERE name IN (SELECT name FROM
customer_info WHERE name = 'buyer');
UPDATE customer_info SET money = money+100 WHERE name IN (SELECT name FROM
customer_info WHERE name = 'shop');

SELECT * FROM customer_info;
```

| name | money |
|----------|-------|
| buyer | 400 |
| shop | 600 |
| (2 rows) | |

3. Restore initial values.

```
UPDATE customer_info SET money=500;
select * from customer_info;
```

| name | money |
|----------|-------|
| shop | 500 |
| buyer | 500 |
| (2 rows) | |

4. Simulate a transaction failure.

\$100 is deducted from the customer's account but fails to be added to the store's account.

a. Deduct \$100 from the customer's account.

```
UPDATE customer_info SET money = money-100 WHERE name IN (SELECT name FROM
customer_info WHERE name = 'buyer');
```

b. The store finds a payment problem and terminates subsequent operations. An error is reported when the amount of money is added to the store's account. The execution of the following statement is terminated. (Only the store thinks that there is a problem with payment.)

```
UPDATE customer_info SET money = money+100 WHERE name IN (SELECT name FROM
customer_info WHERE name = 'shop');
```

c. Query the account balances. The consumer has paid \$100 but store does not receive it.

```
SELECT * FROM customer_info;
```

| name | money |
|----------|-------|
| buyer | 400 |
| shop | 500 |
| (2 rows) | |

Without ACID properties, the account balances will be incorrect once an error occurs during SQL statement execution..

Simulate the rollback of an abnormal database transaction.

1. Restore initial values.

```
UPDATE customer_info SET money=500;
```

2. Deduct \$100 from the customer's account.

```
BEGIN TRANSACTION;  
UPDATE customer_info SET money = money-100 WHERE name IN (SELECT name FROM  
customer_info WHERE name = 'buyer');
```

3. An error is reported when the amount of money is added to the store's account. The execution of the following statement is terminated.

```
UPDATE customer_info SET money = money+100 WHERE name IN (SELECT name FROM  
customer_info WHERE name = 'shop');
```

4. Roll back the transaction. All the completed database operations related to the transaction are canceled.

```
ERROR: syntax error at or near "shop"  
LINE 1: ...e IN (SELECT name FROM customer_info WHERE name = ''shop'');  
END TRANSACTION;  
ROLLBACK
```

5. Query the account balances. The query result shows that the account balances remain unchanged. If an error occurs during transaction execution, the database is rolled back to the state before the transaction starts. The integrity of the database is not damaged.

```
SELECT * FROM customer_info;
```

| name | money |
|----------|-------|
| buyer | 500 |
| shop | 500 |
| (2 rows) | |

Two-Phase Transaction

DWS uses the distributed shared nothing architecture. Table data is distributed on different nodes. One or more statements on the client may modify data on multiple nodes at the same time. In this case, a distributed transaction is generated. DWS uses two-phase commit transactions to ensure data consistency and atomicity in distributed transactions. Two-phase commit divides transaction commit into two phases, usually for transactions that contain write operations. When data is written to different nodes, the atomicity requirement of the transaction must be met, that is, either all data is committed or all data is rolled back.

Two-phase commit is not supported in the following scenarios:

- Explicit two-phase commit of **PREPARE TRANSACTION** is not supported.

```
BEGIN;  
PREPARE TRANSACTION 'p1';
```

```
ERROR: Explicit prepare transaction is not supported.
```

- The file mappings of system catalogs cannot be modified in a two-phase transaction.

```
REINDEX TABLE pg_class;
```

```
ERROR: cannot PREPARE a transaction that modified relation mapping.
```

- Transaction snapshots cannot be committed and exported in cross-node transactions.

```
BEGIN;  
CREATE TABLE t1(a int);  
SELECT pg_export_snapshot();  
END;
```

```
ERROR: cannot PREPARE a transaction that has exported snapshots.
```

21.13 DDL Syntax

21.13.1 DDL Syntax Overview

Data definition language (DDL) is used to define or modify an object in a database, such as a table, index, or view.

NOTE

DWS does not support DDL if its CN is unavailable. For example, if a CN in the cluster is faulty, creating a database or table will fail.

Defining a Database

A database is the warehouse for organizing, storing, and managing data. Defining a database includes: creating a database, altering the database attributes, and dropping the database. The following table lists the related SQL statements.

Table 21-100 SQL statements for defining a database

| Function | SQL Statement |
|---------------------------|------------------------|
| Create a database | CREATE DATABASE |
| Alter database attributes | ALTER DATABASE |
| Delete a database | DROP DATABASE |

Defining a Schema

A schema is the set of a group of database objects and is used to control the access to the database objects. The following table lists the related SQL statements.

Table 21-101 SQL statements for defining a schema

| Function | SQL Statement |
|-------------------------|----------------------|
| Create a schema | CREATE SCHEMA |
| Alter schema attributes | ALTER SCHEMA |
| Delete a schema | DROP SCHEMA |

Defining a Table

A table is a special data structure in a database and is used to store data objects and the relationship between data objects. The following table lists the related SQL statements.

Table 21-102 SQL statements for defining a table

| Function | SQL Statement |
|----------------------------------|---------------------|
| Create a table | CREATE TABLE |
| Alter table attributes | ALTER TABLE |
| Alter a table name | RENAME TABLE |
| Delete a table | DROP TABLE |
| Delete all the data from a table | TRUNCATE |

Defining a Partitioned Table

A partitioned table is a special data structure in a database and is used to store data objects and the relationship between data objects. The following table lists the related SQL statements.

Table 21-103 SQL statements for defining a partitioned table

| Function | SQL Statement |
|------------------------------------|-------------------------------|
| Create a partitioned table | CREATE TABLE PARTITION |
| Editing a partition | ALTER TABLE PARTITION |
| Alter partitioned table attributes | ALTER TABLE PARTITION |
| Delete a partition | ALTER TABLE PARTITION |
| Delete a partitioned table | DROP TABLE |

Defining an Index

An index indicates the sequence of values in one or more columns in the database table. The database index is a data structure that improves the speed of data access to specific information in a database table. The following table lists the related SQL statements.

Table 21-104 SQL statements for defining an index

| Function | SQL Statement |
|------------------------|---------------------|
| Create an index | CREATE INDEX |
| Alter index attributes | ALTER INDEX |
| Delete an index | DROP INDEX |
| Rebuild an index | REINDEX |

Defining a Role

A role is used to manage rights. For database security, all management and operation rights can be assigned to different roles. The following table lists the related SQL statements.

Table 21-105 SQL statements for defining a role

| Function | SQL Statement |
|-----------------------|--------------------|
| Create a role | CREATE ROLE |
| Alter role attributes | ALTER ROLE |
| Delete a role | DROP ROLE |

Defining a User

A user is used to log in to a database. Different rights can be assigned to users for managing data accesses and operations of users. The following table lists the related SQL statements.

Table 21-106 SQL statements for defining a user

| Function | SQL Statement |
|-----------------------|--------------------|
| Create a user | CREATE USER |
| Alter user attributes | ALTER USER |
| Delete a user | DROP USER |

Defining a Redaction Policy

Data redaction is to protect sensitive data by masking or changing data. You can create a data redaction policy for a specific table object and specify the effective scope of the policy. You can also add, modify, and delete redaction columns. The following table lists the related SQL statements.

Table 21-107 SQL statements for managing redaction policies

| Function | SQL Statement |
|---|--------------------------------|
| Create a data redaction policy | CREATE REDACTION POLICY |
| Modify a data redaction policy applied to a specified table | ALTER REDACTION POLICY |
| Delete a data redaction policy applied to a specified table | DROP REDACTION POLICY |

Defining Row-Level Access Control

Row-level access control policies control the visibility of rows in database tables. In this way, the same SQL query may return different results for different users. The following table lists the related SQL statements.

Table 21-108 SQL statements for row-level access control

| Function | SQL Statement |
|---|---|
| Create a row-level access control policy | CREATE ROW LEVEL SECURITY POLICY |
| Modify an existing row-level access control policy | ALTER ROW LEVEL SECURITY POLICY |
| Delete a row-level access control policy from a table | DROP ROW LEVEL SECURITY POLICY |

Defining a Stored Procedure

A stored procedure is a set of SQL statements for achieving specific functions and is stored in the database after compiling. Users can specify a name and provide parameters (if necessary) to execute the stored procedure. The following table lists the related SQL statements.

Table 21-109 SQL statements for defining a stored procedure

| Function | SQL Statement |
|---------------------------|-------------------------|
| Create a stored procedure | CREATE PROCEDURE |

| Function | SQL Statement |
|---------------------------|-----------------------|
| Delete a stored procedure | DROP PROCEDURE |

Defining a Function

In DWS, a function is similar to a stored procedure, which is a set of SQL statements. The function and stored procedure are used the same. The following table lists the related SQL statements.

Table 21-110 SQL statements for defining a function

| Function | SQL Statement |
|---------------------------|------------------------|
| Create a function | CREATE FUNCTION |
| Alter function attributes | ALTER FUNCTION |
| Delete a function | DROP FUNCTION |

Defining a View

A view is a virtual table exported from one or several basic tables. The view is used to control data accesses for users. The following table lists the related SQL statements.

Table 21-111 SQL statements for defining a view

| Function | SQL Statement |
|---------------|--------------------|
| Create a view | CREATE VIEW |
| Delete a view | DROP VIEW |

Defining a Cursor

To process SQL statements, the stored procedure process assigns a memory segment to store context association. Cursors are handles or pointers to context regions. With a cursor, the stored procedure can control alterations in context areas.

Table 21-112 SQL statements for defining a cursor

| Function | SQL Statement |
|-----------------|---------------|
| Create a cursor | CURSOR |
| Move a cursor | MOVE |

| Function | SQL Statement |
|----------------------------|---------------|
| Extract data from a cursor | FETCH |
| Close a cursor | CLOSE |

Altering or Ending a Session

A session is a connection established between the user and the database. The following table lists the related SQL statements.

Table 21-113 SQL statements related to sessions

| Function | SQL Statement |
|-----------------|----------------------------------|
| Alter a session | ALTER SESSION |
| End a session | ALTER SYSTEM KILL SESSION |

Defining a Resource Pool

A resource pool is a system catalog used by the resource load management module to specify attributes related to resource management, such as Cgroups. The following table lists the related SQL statements.

Table 21-114 SQL statements for defining a resource pool

| Function | SQL Statement |
|----------------------------|-----------------------------|
| Create a resource pool | CREATE RESOURCE POOL |
| Change resource attributes | ALTER RESOURCE POOL |
| Delete a resource pool | DROP RESOURCE POOL |

Defining Synonyms

A synonym is a special database object compatible with Oracle. It is used to store the mapping between a database object and another. Currently, only synonyms can be used to associate the following database objects: tables, views, functions, and stored procedures. The following table lists the related SQL statements.

Table 21-115 SQL statements for managing synonyms

| Function | SQL Statement |
|---------------------|-----------------------|
| Creating a synonym | CREATE SYNONYM |
| Modifying a synonym | ALTER SYNONYM |

| Function | SQL Statement |
|--------------------|---------------------|
| Deleting a synonym | DROP SYNONYM |

Defining Text Search Configuration

A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching. The following table lists the related SQL statements.

Table 21-116 SQL statements for configuring text search

| Function | SQL Statement |
|------------------------------------|---|
| Create a text search configuration | CREATE TEXT SEARCH CONFIGURATION |
| Modify a text search configuration | ALTER TEXT SEARCH CONFIGURATION |
| Delete a text search configuration | DROP TEXT SEARCH CONFIGURATION |

Defining a Full-text Retrieval Dictionary

A dictionary is used to identify and process specific words during full-text retrieval. Dictionaries are created by using predefined templates (defined in the **PG_TS_TEMPLATE** system catalog). Five types of dictionaries can be created, **Simple**, **Ispell**, **Synonym**, **Thesaurus**, and **Snowball**. Each type of dictionaries is used to handle different tasks. The following table lists the related SQL statements.

Table 21-117 SQL statements for a full-text search dictionary

| Function | SQL Statement |
|---|--------------------------------------|
| Create a full-text retrieval dictionary | CREATE TEXT SEARCH DICTIONARY |
| Modify a full-text retrieval dictionary | ALTER TEXT SEARCH DICTIONARY |
| Delete a full-text retrieval dictionary | DROP TEXT SEARCH DICTIONARY |

Defining Query Filtering Rules

You can create query filter rules to block slow SQL statements identified in advance. The following table lists the related SQL statements.

Table 21-118 SQL statements for querying filtering rules

| Function | SQL Statement |
|----------------------------------|--------------------------|
| Creating a Query Filtering Rule | CREATE BLOCK RULE |
| Modifying a Query Filtering Rule | ALTER BLOCK RULE |
| Deleting a Query Filtering Rule | DROP BLOCK RULE |

21.13.2 Databases, Tablespaces, Schemas, and Data Types

21.13.2.1 CREATE DATABASE

Function

CREATE DATABASE creates a database.

DWS creates a database by copying a database template. DWS has two default template databases **template0** and **template1** and a default user database **gaussdb**. By default, a new database is created based on **template1**. The character encoding of **template1** cannot be changed. If you want to change it, you can set the **template** parameter to **template0**.

Precautions

- A user that has the **CREATEDB** permission or a sysadmin can create a database.
- **CREATE DATABASE** cannot be executed within a transaction block.
- Errors along the line of "could not initialize database directory" are most likely related to insufficient permissions on the data directory, a full disk, or other file system problems.

Syntax

```
CREATE DATABASE database_name
[ [ WITH ] { [ OWNER [=] user_name ] |
  [ TEMPLATE [=] template ] |
  [ ENCODING [=] encoding ] |
  [ LC_COLLATE [=] lc_collate ] |
  [ LC_CTYPE [=] lc_ctype ] |
  [ DBCOMPATIBILITY [=] compatibility_type ] |
  [ DBCOMPATIBILITY_BEHAVIOR [=] opt_compat_behavior ] |
  [ CONNECTION LIMIT [=] connlimit ] }[...];
```

Parameter Description

Table 21-119 CREATE DATABASE parameters

| Parameter | Description | Value Range |
|---------------|--|---|
| database_name | Name of the database to be created | A string, which must comply with the naming convention . |
| user_name | Specifies the owner of the new database. By default, the owner of the database is the current user. | An existing user name. |
| template | Specifies the name of the template used to create a database. If it is not specified, the system uses template1 by default. | Value range:
template0 or template1 . <ul style="list-style-type: none">• template0: The character set encoding can be specified if template0 is used.• template1 (default value): The character set encoding cannot be specified if template1 is used. |
| encoding | Specifies the character set encoding used by the new database. The value can be a string (for example, SQL_ASCII) or an integer. By default, the encoding format of the template database is used.

The encoding formats of the template databases template0 and template1 vary based on OS environments by default. | Common values: GBK , UTF8 , Latin1 , and SQL_ASCII . |

| Parameter | Description | Value Range |
|---------------------|--|---|
| lc_collate | <p>Specifies the collation order to use in the new database. For example, this parameter can be set using <code>lc_collate = 'zh_CN.gbk'</code>.</p> <p>The use of this parameter affects the sort order applied to strings, for example, in queries with ORDER BY, as well as the order used in indexes on text columns. The default is to use the collation order of the template database. For other restrictions, see Character Set Encoding Description.</p> | Valid collation order |
| lc_ctype | <p>Specifies the character classification to use in the new database. For example, this parameter can be set using <code>lc_ctype = 'zh_CN.gbk'</code>.</p> <p>The use of this parameter affects the categorization of characters, for example, lower, upper and digit. The default is to use the character classification of the template database.</p> | Valid character classification |
| compatibility_type | Specifies the compatible database type. If this parameter is not specified, the default value ORA is used. | The value can be ORA , TD , or MySQL , indicating Oracle, Teradata, or MySQL database, respectively. |
| opt_compat_behavior | <p>Specifies the compatibility behavior of the database. This parameter is supported only by clusters of version 9.1.0 or later.</p> <p>If this parameter is not specified, the default value NO_BEHAVIOR is used, indicating no special behavior.</p> | <p>The value can be td_rtrim or pg_char.</p> <ul style="list-style-type: none">• td_rtrim: removes the trailing part of a variable-length character string in Teradata compatibility mode.• pg_char: converts the varchar type to the nvarchar2 type in PostgreSQL compatibility mode. |

| Parameter | Description | Value Range |
|-----------|---|--|
| conlimit | <p>Number of concurrent connections to a database. The default value -1 means no limit.</p> <ul style="list-style-type: none">• This limit does not apply to system administrators.• To ensure that a cluster runs properly, the minimum value of CONNECTION LIMIT is the number of CNs in the cluster. because when a cluster runs ANALYZE on a CN, other CNs will connect to the running CN for metadata synchronization. For example, if there are three CNs in the cluster, set CONNECTION LIMIT to 3 or a larger value. | An integer greater than or equal to -1 |

Character Set Encoding Description

- To view the character encoding of the current database, run the **show server_encoding;** command.
- To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- The character set encoding of the new database must be compatible with the language settings (**LC_COLLATE** and **LC_CTYPE**).
- If the language is **C** (or equivalently **POSIX**), then all encoding modes are allowed, but for other language settings only the encoding mode for character sets consistent with that of the locale will work properly.
- The encoding and locale settings must match those of the template database, except when template0 is used as template. This is because other databases might contain data that does not match the specified encoding, or might contain indexes whose sort ordering is affected by **LC_COLLATE** and **LC_CTYPE**. Copying such data would result in a database that is corrupt according to the new settings. template0, however, is known to not contain any data or indexes that would be affected.
- Supported encoding depends on the environment. If the message "invalid locale name" is displayed, run the **locale -a** command to check the encoding set supported by the environment.
- When the specified character encoding set is **GBK**, some uncommon Chinese characters cannot be directly used as object names. This is because when the encoding range of the second byte of GBK is between 0x40 and 0x7E, the byte encoding overlaps with the ASCII character @A-Z[]^_`a-z{ }. @[]^_{ } is an operator in the database. If it is directly used as an object name, a syntax error will be reported. For example, the GBK hexadecimal code is **0x8240**, and the second byte is **0x40**, which is the same as the ASCII character @. Therefore, the character cannot be used as an object name. If you really want

to use it, you can avoid this problem by adding double quotation marks when creating and accessing objects.

- In the current version, the GBK character set supports the character €, which is represented as **0x80** in hexadecimal code. You can use the € character in the GBK library, and the GBK character set of DWS is compatible with the CP936 character set. Note that the GBK character set is approximately equal to the CP936 character set, but the GBK character set does not contain the definition of the character €.

Examples

Create database **music** using GBK (the local encoding type is also GBK).

```
CREATE DATABASE music ENCODING 'GBK' template = template0;
```

Create database **music2** and specify **jim** as its owner.

```
CREATE USER jim PASSWORD "{Password}";  
CREATE DATABASE music2 OWNER jim;
```

Create database **music3** using template **template0** and specify **jim** as its owner.

```
CREATE DATABASE music3 OWNER jim TEMPLATE template0;
```

Create a database compatible with Oracle and set the connection limit to **10**.

```
CREATE DATABASE ora_compatible_db DBCOMPATIBILITY 'ORA' CONNECTION LIMIT = 10;
```

FAQs

For details, see "FAQs" > "Database Use" > "How Do I View and Set the Character Set Encoding Format of a DWS Database?" in *Data Warehouse Service (DWS) User Guide*.

21.13.2.2 ALTER DATABASE

Function

This command is used to modify the attributes of a database, including the database name, owner, maximum number of connections, and object isolation attribute.

Precautions

- Only the owner of a database or a system administrator has the permission to run the **ALTER DATABASE** statement. Users other than system administrators may have the following permission constraints depending on the attributes to be modified:
 - To modify the database name, you must have the CREATEDB permission.
 - To modify a database owner, you must be a database owner and a member of the new owner, and have the CREATEDB permission.

- To change the default tablespace, you must be a database owner or a system administrator, and must have the CREATE permission on the new tablespace. This statement physically migrates tables and indexes in a default tablespace to a new tablespace. Note that tables and indexes outside the default tablespace are not affected.
- Only a database owner or a system administrator can modify GUC parameters for the database.
- Only database owners and system administrators can modify the object isolation attribute of a database.
- You are not allowed to rename a database in use. To rename it, connect to another database.
- The compatibility mode of an existing database cannot be changed. You can only specify the compatibility mode when creating a database. For details, see [CREATE DATABASE](#).

Syntax

- Modify the maximum number of connections of the database.

```
ALTER DATABASE database_name  
[ [ WITH ] CONNECTION LIMIT connlimit ];
```

- Rename the database.

```
ALTER DATABASE database_name  
RENAME TO new_name;
```

NOTE

If the database contains OBS multi-temperature tables, the database name cannot be changed.

- Change the database owner.

```
ALTER DATABASE database_name  
OWNER TO new_owner;
```

- Modify the session parameter value of the database.

```
ALTER DATABASE database_name  
SET configuration_parameter { { TO | = } { value | DEFAULT } | FROM CURRENT };
```

- Reset the database configuration parameter.

```
ALTER DATABASE database_name RESET  
{ configuration_parameter | ALL };
```

- Modify the object isolation attribute of a database.

```
ALTER DATABASE database_name [ WITH ] { ENABLE | DISABLE } PRIVATE OBJECT;
```

NOTE

- To modify the object isolation attribute of a database, the database must be connected. Otherwise, the modification will fail.
- For a new database, the object isolation attribute is disabled by default. After this attribute is enabled, common users can view only the objects (such as tables, functions, views, and columns) that they have the permission to access. This attribute does not take effect for administrators. After this attribute is enabled, administrators can still view all database objects.

Parameter Description

Table 21-120 ALTER DATABASE parameters

| Parameter | Description | Value Range |
|-------------------------------|---|--|
| database_name | Specifies the name of the database whose attributes are to be modified. | A string compliant with the identifier naming rules . |
| connlimit | Specifies the maximum number of concurrent connections that can be made to this database (excluding administrators' connections). | An integer ranging from 1 to 50 is recommended.
The default value -1 indicates no restrictions. |
| new_name | Specifies the new name of a database. | A string compliant with the identifier naming rules . |
| new_owner | Specifies the new owner of a database. | A string that indicates a valid username. |
| configuration_parameter value | Sets a specified database session parameter to a specified value. | The value should be a string. <ul style="list-style-type: none">• DEFAULT indicates that the default settings of the system are used in a new session.• RESET indicates that the default settings of the system are used in a new session.• OFF indicates that the setting is disabled. |
| FROM CURRENT | Sets the value based on the database connected to the current session. | - |
| RESET configuration_parameter | Resets the specified database session parameter. | - |
| RESET ALL | Resets all database session parameters.
The modified database session parameter values will take effect in the next session. | - |

Examples

Create the **testdb** database and the **user1** user.

```
CREATE DATABASE testdb ENCODING 'UTF8' template = template0;  
DROP USER IF EXISTS user1;  
CREATE USER user1 PASSWORD '{Password}';
```

Set the number of connections of the **testdb** database to **10**.

```
ALTER DATABASE testdb CONNECTION LIMIT= 10;
```

Change the database name from **testdb** to **testdb_1**.

```
ALTER DATABASE testdb RENAME TO testdb_1;
```

Change the owner of the **testdb_1** database to **user1**.

```
ALTER DATABASE testdb_1 OWNER TO user1;
```

Disable the default index scan on the **testdb_1** database.

```
ALTER DATABASE testdb_1 SET enable_indexscan TO off;
```

Reset parameter **enable_indexscan**.

```
ALTER DATABASE testdb_1 RESET enable_indexscan;
```

Links

[CREATE DATABASE](#) and [DROP DATABASE](#)

21.13.2.3 DROP DATABASE

Function

Delete the database.

Precautions

- Only the owner of a database or a system administrator has the permission to run the **DROP DATABASE** command.
- **DROP DATABASE** does not take effect for the three preinstalled system databases (**gaussdb**, **TEMPLATE0**, and **TEMPLATE1**) because they are protected. To check databases in the current service, run the **\l** command of **gsql**.
- This command cannot be run while the database to be deleted is associated with a user. You can check the current database connections in the **v\$session** view.
- **DROP DATABASE** cannot be run inside a transaction block.
- If **DROP DATABASE** fails to be run and is rolled back, run **DROP DATABASE IF EXISTS**.
- If a "database is being accessed by other users" error is displayed when you run **DROP DATABASE**, it might be that threads cannot respond to signals in a timely manner during the **CLEAN CONNECTION** process. As a result, connections are not completely cleared. In this case, you need to run **CLEAN CONNECTION** again.

⚠ DANGER

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE, USER/ROLE, SCHEMA, TABLE, VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

```
DROP DATABASE [ IF EXISTS ] database_name ;
```

Parameter Description

Table 21-121 Parameter Description

| Parameter | Description | Value Range |
|---------------|---|--------------------------------------|
| IF EXISTS | Sends a message instead of an error if the specified database does not exist. | - |
| database_name | Specifies the name of the database to be deleted. | Specifies an existing database name. |

Examples

Delete the database named **music**.

```
DROP DATABASE music;
```

Links

[CREATE DATABASE, ALTER DATABASE](#)

FAQs

If you see this error while running the **DROP DATABASE** command, another user is connected to the database.

database "mysql_compatible_db" is being accessed by other users Detail: There are 2 other sessions using the database.

Disconnect all users from the database.

```
CLEAN CONNECTION TO ALL FORCE FOR DATABASE mysql_compatible_db;
```

Retry the **DROP DATABASE** command—it should work. If it does not, perform **CLEAN CONNECTION** and attempt again.

```
DROP DATABASE mysql_compatible_db;
```

21.13.2.4 CREATE SCHEMA

Function

CREATE SCHEMA creates a schema.

Named objects are accessed either by "qualifying" their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). When creating named objects, you can also use the schema name as a prefix.

Optionally, **CREATE SCHEMA** can include sub-commands to create objects within the new schema. The sub-commands are treated essentially the same as separate commands issued after creating the schema. If the **AUTHORIZATION** clause is used, all the created objects are owned by this user.

Precautions

- As long as the current user has the CREATE permission, the user can create a schema.
- The owner of an object created by a system administrator in a schema with the same name as a common user is the common user, not the system administrator.

Syntax

- Create a schema based on a specified name:

```
CREATE SCHEMA schema_name  
  [ AUTHORIZATION user_name ] [ WITH PERM SPACE 'space_limit' ] [ schema_element [ ... ] ];  
CREATE SCHEMA IF NOT EXISTS schema_name  
  [ AUTHORIZATION user_name ] [ WITH PERM SPACE 'space_limit' ] ;
```
- Create a schema based on a user name:

```
CREATE SCHEMA AUTHORIZATION user_name [ WITH PERM SPACE 'space_limit' ] [ schema_element  
  [ ... ] ];  
CREATE SCHEMA IF NOT EXISTS AUTHORIZATION user_name [ WITH PERM SPACE 'space_limit' ] ;
```

Parameter Description

Table 21-122 CREATE SCHEMA parameters

| Parameter | Description | Value Range |
|-------------|---|---|
| schema_name | Indicates the name of the schema to be created.
NOTICE <ul style="list-style-type: none">• The name must be unique,• and cannot start with pg_. | A string, which must comply with the identifier naming convention. For details, see Identifier Naming Conventions . |

| Parameter | Description | Value Range |
|-------------------------------------|--|--|
| AUTHORIZATION
user_name | Indicates the name of the user who will own this schema. If schema_name is not specified, user_name will be used as the schema name. In this case, user_name can only be a role name. | Name of an existing user or role. |
| WITH PERM
SPACE
'space_limit' | Indicates the storage upper limit of the permanent table in the specified schema. If space_limit is not specified, the space is not limited. | A string consists of an integer and unit. The unit can be K/M/G/T/P currently. The unit of parsed value is K and cannot exceed the range that can be expressed in 64 bits, which is 1 KB to 9007199254740991 KB. |
| schema_element | Indicates an SQL statement defining an object to be created within the schema. Currently, only CREATE TABLE , CREATE VIEW , CREATE INDEX , CREATE PARTITION , and GRANT are accepted as clauses within CREATE SCHEMA . Objects created by sub-commands are owned by the user specified by AUTHORIZATION . | - |

| Parameter | Description | Value Range |
|---------------|--|---|
| IF NOT EXISTS | <p>If IF NOT EXISTS is specified and no schema with the same name exists, a schema can be created. If a schema with the same name already exists during schema creation, the system will not report an error but will display a message indicating that the schema already exists and no further operations will be performed. When this parameter is used, the Schema_element subcommand cannot be included.</p> <p>The IF NOT EXISTS parameter is supported only in 9.1.0 and later versions.</p> | <p>If objects in the schema on the current search path are with the same name, specify the schemas different objects are in. You can run the SHOW SEARCH_PATH command to check the schemas on the current search path.</p> |

Examples

Create the role **role1**.

```
CREATE ROLE role1 IDENTIFIED BY '{password}';
```

-- Create the schema **role1** for the role **role1**. The owner of the **films** and **winners** tables created by the clause is **role1**.

```
CREATE SCHEMA AUTHORIZATION role1
  CREATE TABLE films (title text, release date, awards text[])
  CREATE VIEW winners AS
  SELECT title, release FROM films WHERE awards IS NOT NULL;
```

Helpful Links

[ALTER SCHEMA](#), [DROP SCHEMA](#)

21.13.2.5 ALTER SCHEMA

Function

ALTER SCHEMA changes the attributes of a schema.

Precautions

- Only the owner of a schema or users with the **ALTER** permission for the schema can run the **ALTER SCHEMA** statement. System administrators have this permission by default.
- To change the owner of a schema or its storage limit, a non-admin user must be directly or indirectly part of the new role and have **CREATE** permission on the database.

Syntax

- Rename a schema.

```
ALTER SCHEMA schema_name  
  RENAME TO new_name;
```
- Changes the owner of a schema.

```
ALTER SCHEMA schema_name  
  OWNER TO new_owner;
```
- Changes the storage space limit of the permanent table in the schema.

```
ALTER SCHEMA schema_name  
  WITH PERM SPACE 'space_limit';
```

Parameter Description

Table 21-123 ALTER SCHEMA parameters

| Parameter | Description | Value Range |
|-------------------------------|---|--|
| schema_name | Specifies the name of the schema to be modified. | Name of an existing schema. |
| new_name | Specifies the new schema name. | A string compliant with the identifier naming rules . |
| new_owner | Specifies the new schema owner. | Name of an existing user or role. |
| WITH PERM SPACE 'space_limit' | The upper limit of the permanent table storage space of the schema. | A string consists of an integer and unit. The unit can be K/M/G/T/P. The parsed value is in kilobytes (K) and must stay within the 1 KB to 9,007,199,254,740,991 KB range. |

Examples

Create an example schema **schema_test** and a user **user_a**.

```
CREATE SCHEMA schema_test;  
CREATE USER user_a PASSWORD '{Password}';
```

Rename **schema_test** to **schema_test1**.

```
ALTER SCHEMA schema_test RENAME TO schema_test1;
```

Change the owner of **schema_test1** to **user_a**.

```
ALTER SCHEMA schema_test1 OWNER TO user_a;
```

[CREATE SCHEMA](#) and [DROP SCHEMA](#)

21.13.2.6 DROP SCHEMA

Function

DROP SCHEMA deletes a schema in a database.

Precautions

- Only the owner of a schema or a user granted with the DROP permission for the schema or a system administrator has the permission to execute the **Drop SCHEMA** statement.

DANGER

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE, USER/ROLE, SCHEMA, TABLE, VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

```
DROP SCHEMA [ IF EXISTS ] schema_name [, ...] [ CASCADE | RESTRICT ];
```

Parameter Description

Table 21-124 DROP SCHEMA parameters

| Parameter | Description | Value Range |
|-------------|--|--------------------------|
| IF EXISTS | Sends a notice instead of an error if the specified schema does not exist. | - |
| schema_name | Specifies the name of the schema to be deleted. | An existing schema name. |

| Parameter | Description | Value Range |
|--------------------|---|---|
| CASCADE RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none">• CASCADE: automatically deletes all objects that are contained in the schema to be deleted.• RESTRICT: refuses to delete the schema that contains any objects. This is the default. |

NOTICE

- Do not delete the schemas with the beginning of **pg_temp** or **pg_toast_temp**. They are internal system schemas, and deleting them may cause unexpected errors.
- A user cannot delete the schema in use. To delete the schema in use, switch to another schema.

Example

Delete **ds_new** schema.

```
DROP SCHEMA ds_new;
```

[ALTER SCHEMA](#), [CREATE SCHEMA](#)

21.13.2.7 CREATE EXTERNAL SCHEMA

Function

Creates an EXTERNAL schema. This syntax is supported only in 8.3.0 and later versions.

You can create an external schema to access the LakeFormation, DLI, and Hive MetaStore tables. You can use an external schema name as the prefix for access. If there is no schema name prefix, you can access the named objects in the current schema.

Precautions

- A user who has the CREATE permission on the current database can create a foreign schema.
- When creating a named object, do not use EXTERNAL SCHEMA as the prefix. Objects cannot be created in EXTERNAL SCHEMA.
- **CREATE EXTERNAL SCHEMA** does not support subcommands for creating objects in the new schema.

Syntax

- Create an external schema with a specified name.

```
CREATE EXTERNAL SCHEMA schema_name
WITH SOURCE source_name
    DATABASE 'database_name'
    SERVER server_name
    [ CATALOG 'catalog_name' ]
    [ OPTIONS ( { option_name 'value ' } [, ...] ) ]
    [METAADDRESS 'address']
    [CONFIGURATION 'confpath'];
```

Parameter Description

Table 21-125 CREATE EXTERNAL SCHEMA parameters

| Parameter | Description | Value Range |
|-------------|---|--|
| schema_name | Name of an external schema. <ul style="list-style-type: none">The name must be unique.The name cannot start with pg_. | A string, which must comply with Identifier Naming Conventions . |
| SOURCE | Type of the external metadata storage engine. | Currently, only dli , lakeformation , and hive are supported. |
| DATABASE | Database corresponding to the external schema. | - |
| SERVER | Name of the external server associated with the external schema. External data can be accessed after the association. | Servers whose type is lf , obs , dli , or hdfs can be associated. For details, see CREATE SERVER . |
| CATALOG | Catalog to be accessed in LakeFormation. This parameter is mandatory only when server type is set to lf . | - |

| Parameter | Description | Value Range |
|-------------------|---|--|
| OPTIONS | Specifies the parameters for a foreign table are listed in the right column. This function is supported only by 8.3.0 and later versions. | dli_project_id: Specifies the project ID corresponding to DLI. You can obtain the project ID from the management console. This parameter is available only when the server type is DLI. |
| METASTORE ADDRESS | Hive Metastore communication interface. This parameter is supported only by 9.1.0 and later versions. | - |
| CONFIGURATION | Path for storing Hive Metastore configuration files. This parameter is supported only by 9.1.0 and later versions. | If objects in the schema on the current search path are with the same name, specify the schemas different objects are in. You can run the SHOW SEARCH_PATH command to check the schemas on the current search path. |

Example: Read the LakeFormation Table Using the External Schema

Read the LakeFormation table using the external schema.

1. Create **lf_server**. The corresponding foreign data wrapper is **DFS_FDW**.

NOTE

For details about how to create **lf_server**, see section "Managing LakeFormation Data Sources" in *Data Warehouse Service (DWS) User Guide*.

2. Create an external schema.

Set **SOURCE** to **lakeformation**, the DLI server associated with the table to **lf_server**, and **DATABASE** to the corresponding LakeFormation database.

Set **CATALOG** to the catalog of LakeFormation to be accessed. Replace it as needed.

```
CREATE EXTERNAL SCHEMA ex_lf
WITH SOURCE lakeformation
DATABASE 'demo'
SERVER lf_server
CATALOG 'hive';
```

3. Grant permissions to a role.

- a. Query the current user.

```
SELECT current_user;
```

- b. Create a role that matches the current role on the LakeFormation management plane and assign it the table access permissions.
4. Query data in the LakeFormation table using the external schema. **test_lf** indicates the LakeFormation table to be accessed.

```
SELECT COUNT(*) FROM ex_dli.test_lf;
count
-----
      20
(1 row)
```

Reading the Hive Metastore Table Using the External Schema

Read the Hive Metastore table using the external schema. Only 9.1.0 and later versions support this function.

1. Create **obs/hdfs server**, with **DFS_FDW** as the foreign data wrapper.

```
CREATE SERVER hdfs_server
FOREIGN DATA WRAPPER HDFS_FDW
OPTIONS (
  address '***.***.***.***.9000',
  type'HDFS');

CREATE SERVER obs_server
FOREIGN DATA WRAPPER dfs_fdw
OPTIONS (
  address 'obs.example.com',
  ACCESS_KEY 'access_key_value_to_be_replaced',
  SECRET_ACCESS_KEY 'secret_access_key_value_to_be_replaced',
  encrypt 'on',
  type 'obs');
```

2. Create an external schema. Set **SOURCE** to **hive** and the server associated with the table to **obs/hdfs server**. **DATABASE** indicates the HMS database, **METAADDRESS** indicates the Hive Metastore communication interface, and **CONFIGURATION** is an absolute path for storing Hive Metastore configuration files. Adjust these parameters as needed.

Before manually creating an external schema to interconnect with Hive Metastore, you need to:

- a. Obtain the **hive-site.xml** and **hivemetastore-site.xml** configuration files from the cluster management page or the Hive installation directory, and upload them to the **CONFIGURATION** directory.
- b. Add the **elk-site.xml** configuration file and configuration items (or add configuration items to the original **elk-site.xml** configuration file). Replace the username, domain name, and keytab file name as required.

```
<property>
  <name>hive.kerberos.principal</name>
  <value>user/hadoop.hadoop.com@HADOOP.COM</value> //User for connecting to
Hadoop@Domain name
</property>
<property>
  <name>hive.kerberos.keytab</name>
  <value>{Configuration directory}/user.keytab</value> // Absolute path of the keytab
file of the user for connecting to Hadoop
</property>
```

```
CREATE EXTERNAL SCHEMA ex_hms
WITH SOURCE source_type
DATABASE 'db_name'
SERVER srv_name
METAADDRESS 'address'
CONFIGURATION 'confpath';
```

- Query data in the HMS table using the external schema. **test_hms** indicates the HMS table to be accessed. Replace it as needed.

```
SELECT COUNT(*) FROM ex_hms.test_hms;
count
-----
      20
(1 row)
```

Helpful Links

[ALTER EXTERNAL SCHEMA](#)

21.13.2.8 ALTER EXTERNAL SCHEMA

Function

Modifies EXTERNAL SCHEMA. This syntax is supported only in 8.3.0 and later versions.

Syntax

Modify an external schema based on the specified name.

```
ALTER EXTERNAL SCHEMA schema_name
WITH [ SOURCE source_name ]
    [ DATABASE 'database_name' ]
    [ SERVER server_name ]
    [ CATALOG 'catalog_name' ]
    [ OPTIONS ( { option_name 'value ' } [, ...] ) ]
    [ METAADDRESS 'address']
    [ CONFIGURATION 'confpath'];
```

Parameter Description

Table 21-126 ALTER EXTERNAL SCHEMA parameters

| Parameter | Description | Value Range |
|-------------|---|---|
| schema_name | Specifies the name of the external schema to be modified. | Name of an existing schema. |
| SOURCE | Specifies the type of the external metadata storage engine. | Currently, source_type can only be set to dli , lakeformation , or hive . |
| DATABASE | Specifies the database to be accessed by the external schema. | - |
| SERVER | You can associate an external schema with a foreign server to access external data. | An existing foreign server whose type is lf , obs , dli , or hdfs . |
| CATALOG | Catalog to be accessed in LakeFormation. | - |

| Parameter | Description | Value Range |
|---------------|--|---|
| OPTIONS | Specifies parameters of foreign table data. This is supported only by 8.3.0 and later versions. | dli_project_id : project ID of DLI. You can obtain the project ID from the management console. This parameter can be set only when the server type is DLI. |
| METAADDRESS | Specifies the Hive Metastore communication port. This is supported only by 9.1.0 and later versions. | - |
| CONFIGURATION | Specifies the path for storing Hive Metastore configuration files. This parameter is supported only by clusters of version 9.1.0 or later.

If objects in the schema on the current search path are with the same name, specify the schemas different objects are in. You can run the SHOW SEARCH_PATH command to check the schemas on the current search path. | - |

Examples

Modify the database and **FOREIGN SERVER** corresponding to the **EXTERNAL SCHEMA** whose name is **ex1**.

```
ALTER EXTERNAL SCHEMA ex1
  WITH DATABASE 'demo'
  SERVER my_server;
```

21.13.2.9 CREATE TYPE

Function

CREATE TYPE defines new data types in the current database. The user who defines a new data type becomes its owner. Types are designed only for row-store tables.

Four types of data can be created by using **CREATE TYPE**: composite data, base data, a shell data, and enumerated data.

- Composite types

A composite type is specified by a list of attribute names and data types. If the data type of an attribute is collatable, the attribute's collation rule can also be specified. A composite type is essentially the same as the row type of a table. However, using **CREATE TYPE** avoids the need to create an actual

table when only a type needs to be defined. In addition, a standalone composite type is useful, for example, as the parameter or return type of a function.

To create a composite type, you must have the **USAGE** permission for all its attribute types.

- Base types

You can customize a new base type (scalar type). Generally, functions required for base types must be coded in C or another low-level language.

- Shell types

With this parameter, you can create a shell type, which is a type name without a definition. To create a shell type, use **CREATE TYPE** with only the type name. Shell types are needed as forward references when base types are created.

- Enumerated types

An enumerated type is a list of enumerated values. Each value is a non-empty string with the maximum length of 64 bytes.

Precautions

- If a schema name is given, the type will be created in the specified schema. Otherwise, it will be created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. (Because tables have associated data types, the type name must also be distinct from the name of any existing table in the same schema.)
- When creating a base type, you can place parameters in any order. The **input_function** and **output_function** parameters are mandatory, and other parameters are optional.
- The **category** and **preferred** parameters can be used to help determine which implicit cast excels in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either preferred or not within its category. If this rule is helpful in resolving overloaded functions or operators, the parser will prefer casting to preferred types (but only from other types within the same category). For types that have no implicit casts to or from any other types, it is sufficient to leave these parameters at their default values. However, for a group of types that have implicit casts, mark them all as belonging to a category and select one or two of the most general types as being preferred within the category. The **category** parameter is helpful in adding a user-defined type to an existing built-in category, such as the numeric or string type. However, you can also create new entirely-user-defined type categories. Select any ASCII character other than an uppercase letter to name such a category.
- **type_modifier_input_function** and **type_modifier_output_function** are needed if a type supports modifiers, that is, optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. DWS allows user-defined types to take one or more simple constants or identifiers as modifiers. However, this information must be capable of being packed into a single non-negative integer value for storage in system catalogs. Declared modifiers are passed to **type_modifier_input_function** in the cstring array format. The parameter must check values for validity, throwing an error if they are wrong. If they are correct, the parameter will return a single non-negative integer

value, which will be stored as `typmod` in a column. If the type does not have **type_modifier_input_function**, type modifiers will be rejected.

type_modifier_output_function converts the internal integer `typmod` value back to a correct format for user display. It must return a `cstring` value, which is the exact string appending to the type name. For example, a numeric function may return (30,2). If the default display format is enclosing a stored `typmod` integer value in parentheses, you can omit **type_modifier_output_function**.

- Input and output functions can be declared to have the results or parameters of a new type because they have to be created before the new type is created. The new type should first be defined as a shell type, which is a placeholder type that has no attributes except a name and an owner. This can be done by delivering the **CREATE TYPE** *name* statement, with no additional parameters. Then, the C I/O functions can be defined as referencing the shell type. Finally, **CREATE TYPE** with a full definition replaces the shell type with a complete, valid type definition. After that, the new type can be used normally.

Syntax

```
CREATE TYPE name AS
    ( [ attribute_name data_type [ COLLATE collation ] [, ... ] ] )

CREATE TYPE name (
    INPUT = input_function,
    OUTPUT = output_function
    [ , RECEIVE = receive_function ]
    [ , SEND = send_function ]
    [ , TYPMOD_IN = type_modifier_input_function ]
    [ , TYPMOD_OUT = type_modifier_output_function ]
    [ , ANALYZE = analyze_function ]
    [ , INTERNALLENGTH = { internallength | VARIABLE } ]
    [ , PASSEDBYVALUE ]
    [ , ALIGNMENT = alignment ]
    [ , STORAGE = storage ]
    [ , LIKE = like_type ]
    [ , CATEGORY = category ]
    [ , PREFERRED = preferred ]
    [ , DEFAULT = default ]
    [ , ELEMENT = element ]
    [ , DELIMITER = delimiter ]
    [ , COLLATABLE = collatable ]
)

CREATE TYPE name

CREATE TYPE name AS ENUM
    ( [ 'label' [, ... ] ] )
```

Parameter Description

Table 21-127 CREATE TYPE parameters

| Parameter | Description | Value Range |
|----------------|---|---|
| name | Specifies the name (optionally schema-qualified) of the type to be created. | It must comply with the naming convention . |
| attribute_name | Specifies the name of an attribute (column) for the composite type. | - |
| data_type | Specifies the name of an existing data type to become a column of the composite type. | - |
| collation | Specifies the name of an existing collation associated with a column of the composite type. | - |

| Parameter | Description | Value Range |
|-----------------|--|-------------|
| input_function | <p>Specifies the name of a function that converts data from the external text format of a type to its internal format.</p> <p>An input function can be declared as taking one parameter of the cstring type or taking three parameters of the cstring, oid, and integer types.</p> <ul style="list-style-type: none">• The cstring-type parameter is the input text as a C string.• The oid-type parameter is the OID of the type (except for array types, where the parameter is the element type OID of an array type).• The integer-type parameter is typmod of the destination column, if known (-1 will be passed if not known). <p>An input function must return a value of the data type itself. Generally, an input function must be declared as STRICT. If it is not, it will be called with a NULL parameter coming first when the system reads a NULL input value. In this case, the function must still return NULL unless an error raises. (This mechanism is designed for supporting domain input functions, which may need to reject NULL input values.)</p> | - |
| output_function | <p>Specifies the name of a function that converts data from the internal format of a type to its external text format.</p> <p>An output function must be declared as taking one parameter of a new data type. It must return data of the cstring type. Output functions are not invoked for NULL values.</p> | - |

| Parameter | Description | Value Range |
|---|---|-------------|
| receive_function (optional) | <p>Specifies the name of a function that converts data from the external binary format of a type to its internal format.</p> <p>If this function is not used, the type cannot participate in binary input. It costs lower to convert the binary format to the internal format, more portable. (For example, the standard integer data types use the network byte order as an external binary representation, whereas the internal representation is in the machine's native byte order.) This function should perform adequate checks to ensure a valid value.</p> <p>Also, this function can be declared as taking one parameter of the internal type or taking three parameters of the internal, oid, and integer types.</p> <ul style="list-style-type: none">• The internal-type parameter is a pointer to a StringInfo buffer holding received byte strings.• The oid- and integer-type parameters are the same as those of the text input function. <p>A receive function must return a value of the data type itself. Generally, a receive function must be declared as STRICT. If it is not, it will be called with a NULL parameter coming first when the system reads a NULL input value. In this case, the function must still return NULL unless an error raises. (This mechanism is designed for supporting domain receive functions, which may need to reject NULL input values.)</p> | - |
| send_function (optional) | <p>Specifies the name of a function that converts data from the internal format of a type to its external binary format.</p> <p>If this function is not used, the type cannot participate in binary output. A send function must be declared as taking one parameter of a new data type. It must return data of the bytea type. Send functions are not invoked for NULL values.</p> | - |
| type_modifier_input_function (optional) | <p>Specifies the name of a function that converts an array of modifiers for a type to its internal format.</p> | - |

| Parameter | Description | Value Range |
|--|--|-------------|
| type_modifier_output_function (optional) | Specifies the name of a function that converts the internal format of modifiers for a type to its external text format. | - |
| analyze_function (optional) | Specifies the name of a function that performs statistical analysis for a data type.

By default, if there is a default B-tree operator class for a type, ANALYZE will attempt to gather statistics by using the "equals" and "less-than" operators of the type. This behavior is inappropriate for non-scalar types, and can be overridden by specifying a custom analysis function. The analysis function must be declared to take one parameter of the internal type and return a boolean result. | - |
| internallength (optional) | Specifies a numeric constant for specifying the length in bytes of the internal representation of a new type. By default, it is variable-length.

Although the details of the new type's internal representation are only known to I/O functions and other functions that you create to work with the type, there are still some attributes of the internal representation that must be declared to DWS. The most important one is internallength . Base data types can be fixed-length (when internallength is a positive integer) or variable-length (when internallength is set to VARIABLE ; internally, this is represented by setting typlen to -1). The internal representation of all variable-length types must start with a 4-byte integer. internallength defines the total length. | - |
| PASSEDBYVALUE (optional) | Specifies that values of a data type are passed by value, rather than by reference. Types passed by value must be fixed-length, and their internal representation cannot be larger than the size of the Datum type (4 bytes on some machines, and 8 bytes on others). | - |
| alignment (optional) | Specifies the storage alignment required for a data type. It supports values char , int2 , int4 , and double . The default value is int4 .

The allowed values equate to alignment on 1-, 2-, 4-, or 8-byte boundaries. Note that variable-length types must have an alignment of at least 4 since they must contain an int4 value as their first component. | - |

| Parameter | Description | Value Range |
|----------------------|---|-------------|
| storage (optional) | <p>Specifies the storage strategy for a data type. It supports values plain, external, extended, and main. The default value is plain.</p> <ul style="list-style-type: none">• plain specifies that data of a type will always be stored in-line and not compressed. (Only plain is allowed for fixed-length types.)• extended specifies that the system will first try to compress a long data value and will then move the value out of the main table row if it is still too long.• external allows a value to be moved out of the main table, but the system will not try to compress it.• main allows for compression, but discourages moving a value out of the main table. (Data items with this storage strategy might still be moved out of the main table if there is no other way to make a row fit. However, they will be kept in the main table preferentially over extended and external items.) <p>All storage values except plain imply that the functions of the data type can handle values that have been toasted. A specified value determines the default TOAST storage strategy for columns of data types that support TOAST. Users can select different strategies for individual columns using ALTER TABLE SET STORAGE.</p> | - |
| like_type (optional) | <p>Specifies the name of an existing data type that has the same representation as a new type. The values of internallength, passedbyvalue, alignment, and storage are copied from this type, unless they are overridden by explicit specifications elsewhere in the CREATE TYPE command.</p> <p>Specifying representation in this way is especially useful when the low-level implementation of a new type references an existing type.</p> | - |

| Parameter | Description | Value Range |
|-----------------------|--|-------------|
| category (optional) | Specifies the category code (a single ASCII character) for a type. The default value is U, indicating the user-defined type. You can also choose other ASCII characters to create custom categories. | - |
| preferred (optional) | Specifies whether a type is preferred within its type category. If it is, the value will be TRUE , else FALSE . The default value is FALSE . Be cautious when creating a new preferred type within an existing type category because this could cause great changes in behavior. | - |
| default (optional) | <p>Specifies the default value for a data type. If this parameter is omitted, the default value will be NULL.</p> <p>A default value can be specified if you expect the columns of a data type to default to something other than the NULL value. You can also specify a default value using the DEFAULT keyword. (Such a default value can be overridden by an explicit DEFAULT clause attached to a particular column.)</p> | - |
| element (optional) | Specifies the type of an array element when an array type is created. For example, to define an array of 4-byte integers (int4), set ELEMENT to int4 . | - |
| delimiter (optional) | <p>Specifies the delimiter character to be used between values in arrays made of a type.</p> <p>delimiter can be set to a specific character. The default delimiter is a comma (,). Note that a delimiter is associated with the array element type, instead of the array type itself.</p> | - |
| collatable (optional) | <p>Specifies whether a type's operations can use collation information. If they can, the value will be TRUE, else FALSE (default).</p> <p>If collatable is TRUE, column definitions and expressions of a type may carry collation information by using the COLLATE clause. It is the implementations of functions operating on the type that actually use the collation information. This use cannot be achieved merely by marking the type collatable.</p> | - |

| Parameter | Description | Value Range |
|------------------|--|-------------|
| label (optional) | Specifies a text label associated with an enumerated value. It is a non-empty string of up to 64 characters. | - |

Examples

Example 1: Create a composite type, create a table, insert data, and make a query.

```
CREATE TYPE compfoo AS (f1 int, f2 text);
CREATE TABLE t1_compfoo(a int, b compfoo);
CREATE TABLE t2_compfoo(a int, b compfoo);
INSERT INTO t1_compfoo values(1,(1,'demo'));
INSERT INTO t2_compfoo select * from t1_compfoo;
SELECT (b).f1 FROM t1_compfoo;
SELECT * FROM t1_compfoo t1 join t2_compfoo t2 on (t1.b).f1=(t1.b).f1;
```

Example 2: Create an enumeration type and use it in the table definition.

```
CREATE TYPE bugstatus AS ENUM ('create', 'modify', 'closed');
CREATE TABLE customer (name text,current_bugstatus bugstatus);
INSERT INTO customer VALUES ('type','create');
SELECT * FROM customer WHERE current_bugstatus = 'create';
```

Example 3: Compile a .so file and create the shell type.

```
CREATE TYPE complex;
```

This statement creates a placeholder for the type to be created, which can then be referenced when defining its I/O functions. Now you can define an I/O function. Note that the function must be declared in NOT FENCED mode when it is created.

```
CREATE FUNCTION
complex_in(cstring)
  RETURNS complex
  AS 'filename'
  LANGUAGE C IMMUTABLE STRICT not fenced;

CREATE FUNCTION
complex_out(complex)
  RETURNS cstring
  AS 'filename'
  LANGUAGE C IMMUTABLE STRICT not fenced;

CREATE FUNCTION
complex_rcv(internal)
  RETURNS complex
  AS 'filename'
  LANGUAGE C IMMUTABLE STRICT not fenced;

CREATE FUNCTION
complex_send(complex)
  RETURNS bytea
  AS 'filename'
  LANGUAGE C IMMUTABLE STRICT not fenced;
```

Provide a complete definition of the data type.

```
CREATE TYPE complex (
internallength = 16,
```

```
input = complex_in,  
output = complex_out,  
receive = complex_rcv,  
send = complex_send,  
alignment = double  
);
```

The C functions corresponding to the input, output, receive, and send functions are defined as follows:

```
-- Define a structure body Complex:  
typedef struct Complex {  
    double    x;  
    double    y;  
} Complex;  
  
-- Define an input function:  
PG_FUNCTION_INFO_V1(complex_in);  
  
Datum  
complex_in(PG_FUNCTION_ARGS)  
{  
    char      *str = PG_GETARG_CSTRING(0);  
    double    x,  
             y;  
    Complex   *result;  
  
    if (sscanf(str, " ( %lf , %lf )", &x, &y) != 2)  
        ereport(ERROR,  
                (errmsg(ERRCODE_INVALID_TEXT_REPRESENTATION),  
                 errmsg("invalid input syntax for complex: \"%s\"",  
                        str)));  
  
    result = (Complex *) palloc(sizeof(Complex));  
    result->x = x;  
    result->y = y;  
    PG_RETURN_POINTER(result);  
}  
  
-- Define an output function:  
PG_FUNCTION_INFO_V1(complex_out);  
  
Datum  
complex_out(PG_FUNCTION_ARGS)  
{  
    Complex   *complex = (Complex *) PG_GETARG_POINTER(0);  
    char      *result;  
  
    result = (char *) palloc(100);  
    snprintf(result, 100, "(%g,%g)", complex->x, complex->y);  
    PG_RETURN_CSTRING(result);  
}  
  
-- Define a receive function:  
PG_FUNCTION_INFO_V1(complex_rcv);  
  
Datum

Helpful Links

[ALTER TYPE, DROP TYPE](#)

21.13.2.10 ALTER TYPE

Function

ALTER TYPE modifies the definition of a type.

Precautions

- Only type owners can run **ALTER TYPE**.
- To modify the schema of a type, you must also have the **CREATE** permission for the new schema.
- To change the owner, you must belong directly or indirectly to the new owner's role. You also need the **CREATE** permission on the schema of the type.
- System administrators can change the ownership of any type as needed.
- To add an attribute or modify the type of an attribute, you must have the **USAGE** permission on the attribute type.

Syntax

- **Modify a type.**

```
ALTER TYPE name action [ ... ];
ALTER TYPE name OWNER TO { new_owner | CURRENT_USER | SESSION_USER };
ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name [ CASCADE | RESTRICT ];
ALTER TYPE name RENAME TO new_name;
ALTER TYPE name SET SCHEMA new_schema;
ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE | AFTER } neighbor_enum_value ];
ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value;
```

where action is one of:

```
ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ] [ CASCADE | RESTRICT ];
DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ];
ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type [ COLLATE collation ] [ CASCADE | RESTRICT ];
```
- **Add a new attribute to a composite type.**

```
ALTER TYPE name ADD ATTRIBUTE attribute_name data_type [ COLLATE collation ] [ CASCADE | RESTRICT ];
```
- **Delete an attribute from a composite type.**

```
ALTER TYPE name DROP ATTRIBUTE [ IF EXISTS ] attribute_name [ CASCADE | RESTRICT ];
```

- Change the type of an attribute in a composite type.
`ALTER TYPE name ALTER ATTRIBUTE attribute_name [ SET DATA ] TYPE data_type [ COLLATE collation ] [ CASCADE | RESTRICT ];`

NOTE

ADD ATTRIBUTE, DROP ATTRIBUTE, and ALTER ATTRIBUTE can be combined for execution. For example, you can add multiple attributes to a command or change the types of multiple attributes.

- Change the owner of a type.
`ALTER TYPE name OWNER TO { new_owner | CURRENT_USER | SESSION_USER };`
- Change the name of a type or the name of an attribute in a composite type.
`ALTER TYPE name RENAME TO new_name;`
`ALTER TYPE name RENAME ATTRIBUTE attribute_name TO new_attribute_name [ CASCADE | RESTRICT ];`
- Move a type to a new schema.
`ALTER TYPE name SET SCHEMA new_schema;`
- Add a new value to an enumerated type.
`ALTER TYPE name ADD VALUE [ IF NOT EXISTS ] new_enum_value [ { BEFORE | AFTER } neighbor_enum_value ];`
- Change an enumerated value in the value list.
`ALTER TYPE name RENAME VALUE existing_enum_value TO new_enum_value;`

Parameter Description

Table 21-128 ALTER TYPE parameters

| Parameter | Description | Value Range |
|--------------------|---|--------------------|
| name | Specifies the name of an existing type to be modified, which can include a schema. | Valid type name. |
| new_name | Specifies the new name of a type. | A string. |
| new_owner | Specifies the username of the new owner of the type. | Valid username. |
| new_schema | Specifies the new schema of the type. | Valid schema name. |
| attribute_name | Specifies the name of the attribute to be added, changed, or deleted. | - |
| new_attribute_name | Specifies the new name of the property to be renamed. | - |
| data_type | Specifies the data type of the attribute to be added or the new type name of the attribute to be changed. | - |

| Parameter | Description | Value Range |
|---------------------|--|---|
| new_enum_value | Specifies the new tag value of the enumeration type. | A string. The value cannot be empty and contains a maximum of 64 bytes. |
| neighbor_enum_value | Specifies an existing enumerated value before or after which a new enumerated value will be added. | - |
| existing_enum_value | Specifies the existing enumeration value to be renamed. | A string. The value cannot be empty and contains a maximum of 64 bytes. |
| CASCADE | Determines that the type to be modified, its associated records, and subtables that inherit the type will all be updated. | - |
| RESTRICT | Refuses the update if the type of the association to be updated is an updated type. RESTRICT is the default option. | - |

Examples

Create an example composite type **test**, enumeration type **testdata**, and user **user_t**.

```
CREATE TYPE test AS (col1 int, col text);  
CREATE TYPE testdata AS ENUM ('create', 'modify', 'closed');  
CREATE USER user_t PASSWORD '{Password}';
```

Rename data type **test** to **test1**.

```
ALTER TYPE test RENAME TO test1;
```

Change the owner of the user-defined type **test1** to **user_t**.

```
ALTER TYPE test1 OWNER TO user_t;
```

Change the schema of the user-defined type **test1** to **user_t**.

```
ALTER TYPE test1 SET SCHEMA user_t;
```

Add a new attribute **col3** to the user-defined type **test1**.

```
ALTER TYPE user_t.test1 ADD ATTRIBUTE col3 int;
```

Add a tag value to the enumeration type **testdata**.

```
ALTER TYPE testdata ADD VALUE IF NOT EXISTS 'regress' BEFORE 'closed';
```

Rename a tag value of the enumeration type **testdata**.

```
ALTER TYPE testdata RENAME VALUE 'create' TO 'new';
```

Helpful Links

[CREATE TYPE](#) and [DROP TYPE](#)

21.13.2.11 DROP TYPE

Function

DROP TYPE deletes a user-defined data type. Only the type owner has permission to run this statement.

Syntax

```
DROP TYPE [ IF EXISTS ] name [, ...] [ CASCADE | RESTRICT ]
```

Parameter Description

Table 21-129 DROP TYPE parameters

| Parameter | Description | Value Range |
|--------------------|---|--|
| IF EXISTS | Sends a notice instead of an error if the specified type does not exist. | - |
| name | Specifies the name of the type to be deleted (schema-qualified). | Specifies an existing domain type. |
| CASCADE RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none">• CASCADE: Deletes objects (such as columns, functions, and operators) that depend on the type.• RESTRICT: Refuses to delete the type if any objects depend on it. This is the default. |

Examples

Delete **compfoo** type.

```
DROP TYPE compfoo cascade;
```

Helpful Links

[ALTER TYPE](#), [CREATE TYPE](#)

21.13.3 Users and Roles

21.13.3.1 CREATE USER

Function

Create a database user.

Precautions

- A user created using the **CREATE USER** statement has the **LOGIN** permission by default.
- A schema named after the user is automatically created in the database where the statement is executed, but not in other databases. You can run the **CREATE SCHEMA** statement to create such a schema for the user in other databases.
- The owner of an object created by a system administrator in a schema with the same name as a common user is the common user, not a system administrator.
- Users who are not system administrators and are granted with all schema permissions cannot create objects in a schema named after a user, unless the users are granted with the role permissions of that schema. For details, see **After the all Permission Is Granted to the Schema of a User, the Error Message "ERROR: current user does not have privilege to role tom" Persists During Table Creation** in *Troubleshooting*.

CAUTION

- Avoid having all business operations run under a single database user. Instead, plan different database users according to the business modules.
 - For better access control of different business modules, it is better to use multiple users and permissions instead of depending on the system administrator user to run business operations.
 - For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.
-

Syntax

```
CREATE USER user_name [ [ WITH ] option [ ... ] ] [ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' | DISABLE };
```

The **option** clause is used for setting information including permissions and attributes.

```
{SYSADMIN | NOSYSADMIN}  
| {AUDITADMIN | NOAUDITADMIN}  
| {CREATEDB | NOCREATEDB}  
| {USEFT | NOUSEFT}  
| {CREATEROLE | NOCREATEROLE}  
| {INHERIT | NOINHERIT}  
| {LOGIN | NOLOGIN}  
| {REPLICATION | NOREPLICATION}  
| {INDEPENDENT | NOINDEPENDENT}  
| {VCADMIN | NOVCADMIN}  
| CONNECTION LIMIT connlimit
```

```
| VALID BEGIN 'timestamp'  
| VALID UNTIL 'timestamp'  
| RESOURCE POOL 'respool'  
| USER GROUP 'groupuser'  
| PERM SPACE 'spacelimit'  
| TEMP SPACE 'tmpspacelimit'  
| SPILL SPACE 'spillspacelimit'  
| NODE GROUP logic_cluster_name  
| IN ROLE role_name [, ...]  
| IN GROUP role_name [, ...]  
| ROLE role_name [, ...]  
| ADMIN role_name [, ...]  
| USER role_name [, ...]  
| SYSID uid  
| DEFAULT TABLESPACE tablespace_name  
| PROFILE DEFAULT  
| PROFILE profile_name  
| PGUSER  
| AUTHINFO 'authinfo'  
| PASSWORD EXPIRATION period
```

Parameter Description

Table 21-130 CREATE USER parameters

| Parameter | Description | Value Range/
Default Value |
|-----------|---|---|
| user_name | Name of the user to be created. | A string. It must comply with the naming conventions and can contain a maximum of 63 characters. For details, see Identifier Naming Conventions . |
| password | Specifies the login password.
A password must: <ul style="list-style-type: none">Contain at least eight characters. This is the default length.Differ from the user name or the user name spelled backwards.Contains at least three of the following four character types: uppercase letters, lowercase letters, digits, and special characters, including: ~!@#\$\$%^&*()-_+=\[\{\}\];;<.>/?. If you use characters other than the four types, a warning is displayed, but you can still create the password. | A string |

| Parameter | Description | Value Range/
Default Value |
|------------------------------|---|---------------------------------------|
| DISABLE | By default, you can change your password unless it is disabled. Use this parameter to disable the password of a user. After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, IAM authentication, Kerberos authentication, or LDAP authentication. Only administrators can enable or disable a password. Common users cannot disable the password of an initial user. To enable a password, run ALTER USER and specify the password. | - |
| ENCRYPTED
UNENCRYPTED | Determines whether the password stored in the system will be encrypted. (If neither is specified, the password status is determined by password_encryption_type .) According to product security requirements, the password must be stored encrypted. Therefore, UNENCRYPTED is forbidden in DWS. If the password is encrypted using SHA256, it will be stored as it is, regardless of whether it is specified as ENCRYPTED or UNENCRYPTED . This is because the system cannot decrypt the specified encrypted password. This allows reloading of the encrypted password during dump/restore. | - |
| SYSADMIN
NOSYSADMIN | Determines whether a new user is a system administrator. A user with the SYSADMIN attribute has the highest permission in the system. | Default value:
NOSYSADMIN |
| AUDITADMIN
NOAUDITADMIN | Defines whether a user has the audit administrator attribute. | Default value:
NOAUDITADMIN |
| CREATEDB
NOCREATEDB | Controls whether a new user can create a database.

A new user does not have the permission to create a database by default. | Default value:
NOCREATEDB |

| Parameter | Description | Value Range/
Default Value |
|-----------------------------------|---|--|
| USEFT
NOUSEFT | Determines whether a new role can perform operations on foreign tables, such as creating, deleting, modifying, and reading/writing foreign tables.

The default value is NOUSEFT , indicating that new users cannot perform operations on foreign tables by default.

The new user does not have the permission to perform operations on foreign tables. | - |
| CREATEROLE

NOCREATEROLE | Controls whether a user can create a role or user (that is, execute CREATE ROLE and CREATE USER). A user with the CREATEROLE permission can also modify and delete other users or roles. | Value range: If not specified, NOCREATEROLE is the default. |
| INHERIT
NOINHERIT | Controls whether a user can inherit the permissions of its group. You are not advised to use them. | - |
| LOGIN
NOLOGIN | Controls whether a user can log in to the database. Only users with the LOGIN attribute can log in to the database. | Default value:
LOGIN |
| REPLICATION

NOREPLICATION | Controls whether a user is allowed to initiate streaming replication or put the system in and out of backup mode. A user with the REPLICATION attribute is only used for replication. | Default value:
NOREPLICATION |

| Parameter | Description | Value Range/
Default Value |
|-----------------------------|--|-------------------------------|
| INDEPENDENT NOINDEPENDENT | <p>Defines private and independent users. For a user with the INDEPENDENT attribute, administrators' rights to control and access this role are separated. Specific rules are as follows:</p> <ul style="list-style-type: none">Administrators have no rights to add, delete, query, modify, copy, or authorize the corresponding table objects without the authorization from the INDEPENDENT user.Without the authorization of the INDEPENDENT user, the administrator has no right to modify its inheritance relationship.The administrator does not have the permission to change the owner of the table object of an INDEPENDENT user.The administrator does not have the permission to remove the INDEPENDENT attribute of an INDEPENDENT user.The administrator does not have the permission to change the database password of an INDEPENDENT user. An INDEPENDENT must manage its own password. If the password is lost, it cannot be reset.The SYSADMIN attribute of a user cannot be changed to the INDEPENDENT attribute. | - |
| VCADMIN NOVCADMIN | <p>Defines a logical cluster administrator. A logical cluster administrator has the following more permissions than common users:</p> <ul style="list-style-type: none">Create, modify, and delete resource pools in the associated logical cluster.Grant the access permission for the associated logical cluster to other users or roles, or reclaim the access permission from those users or roles. | - |

| Parameter | Description | Value Range/
Default Value |
|---------------------------|--|--|
| CONNECTION
LIMIT | <p>Specifies the number of concurrent connections that can be used by a user on a single CN.</p> <p>To ensure that a cluster runs properly, the minimum value of connlimit is the number of CNs in the cluster, because when a cluster runs ANALYZE on a CN, other CNs will connect to the running CN for metadata synchronization. For example, if there are three CNs in the cluster, set CONNECTION LIMIT to 3 or a larger value.</p> | <p>Integers no less than -1.</p> <p>The default value -1 means no limit.</p> |
| VALID BEGIN | Sets the timestamp when a user takes effect. If this clause is omitted, there is no restriction on when the user takes effect. | - |
| VALID UNTIL | Sets an expiration timestamp for an account. After the specified time, the account cannot be used. If this clause is omitted, there is no restriction on when the user expires. | - |
| RESOURCE
POOL | Sets the name of resource pool used by a user, and the name belongs to the system catalog: pg_resource_pool . | - |
| USER GROUP
'groupuser' | Create a sub-user. | - |
| PERM SPACE | <p>Sets the storage space of the user permanent table.</p> <p>space_limit: specifies the upper limit of the storage space of the permanent table.</p> | <p>space_limit: A string consists of an integer and unit. The unit can be K/M/G/T/P currently.</p> <p>0 indicates no limits.</p> |
| TEMP SPACE | <p>Sets the storage space of the user temporary table.</p> <p>tmpspacelimit: specifies the storage space limit of the temporary table.</p> | <p>tmpspacelimit: A string consists of an integer and unit. The unit can be K/M/G/T/P currently.</p> <p>0 indicates no limits.</p> |

| Parameter | Description | Value Range/
Default Value |
|--------------------|--|--|
| SPILL SPACE | Sets the operator disk flushing space of the user.
spillspacelimit : specifies the operator spilling space limit. | spillspacelimit : A string consists of an integer and unit. The unit can be K/M/G/T/P currently.
0 indicates no limits. |
| NODE GROUP | Specifies the name of the logical cluster associated with a user. If the name contains uppercase characters or special characters, enclose the name with double quotation marks. | - |
| IN ROLE | The new user immediately has the permissions of users listed in the IN ROLE clause. You are not advised to use them. | - |
| IN GROUP | Indicates an obsolete spelling of IN ROLE . You are not advised to execute them. | - |
| ROLE | The ROLE clause lists one or more existing users. They are automatically added as members of the new user and have all the permissions of the new user. | - |
| ADMIN | The ADMIN clause is similar to the ROLE clause. The difference is that the user after ADMIN can grant the permissions of the new user to other users. | - |
| USER | Indicates an obsolete spelling of the ROLE clause. | - |
| SYSID | The SYSID clause is ignored. | - |
| DEFAULT TABLESPACE | The DEFAULT TABLESPACE clause is ignored. | - |
| PROFILE | The PROFILE clause is ignored. | - |

| Parameter | Description | Value Range/
Default Value |
|------------------------|---|-------------------------------|
| PGUSER | <p>This attribute is used to be compatible with open-source Postgres communication. An open-source Postgres client interface (Postgres 9.2.19 is recommended) can use a database user having this attribute to connect to the database.</p> <p>This attribute only ensures compatibility with the connection process. Incompatibility caused by kernel differences between this product and Postgres cannot be solved using this attribute.</p> | - |
| AUTHINFO
'authinfo' | <p>This attribute is used to specify the user authentication type. authinfo is the description character string, which is case sensitive.</p> <p>Only the LDAP type is supported. Its description character string is ldap. LDAP authentication is an external authentication mode. Therefore, PASSWORD DISABLE must be specified.</p> <ul style="list-style-type: none">Additional information about LDAP authentication can be added to authinfo, for example, fulluser in LDAP authentication, which is equivalent to ldapprefix+username+ldapsuffix. If authinfo is ldap, the user authentication type is LDAP. In this case, the ldapprefix and ldapsuffix information is provided by the corresponding record in the pg_hba.conf file.When executing the ALTER ROLE command, users are not allowed to change the authentication type. Only LDAP users are allowed to modify LDAP attributes. | - |

| Parameter | Description | Value Range/
Default Value |
|----------------------------|--|--|
| PASSWORD EXPIRATION period | Number of days before the login password of the role expires. The user needs to change the password in time before the login password expires. If the login password expires, the user cannot log in to the system. In this case, the user needs to ask the administrator to set a new login password. | The value is an integer ranging from -1 to 999. <ul style="list-style-type: none">• The default value -1 indicates no restrictions.• 0: indicates that the login password expires immediately. |

Examples

Create user **new_u1**.

```
CREATE USER new_u1 PASSWORD '{password}';
```

The following statements are equivalent to the above.

```
CREATE USER new_u1 IDENTIFIED BY '{password}';
```

For a user having the **CREATE DATABASE** permission, specify the **CREATEDB** keyword.

```
CREATE USER new_u1 CREATEDB PASSWORD '{password}';
```

| AUTHINFO 'authinfo'  
| PASSWORD EXPIRATION period
```

- Change the user name.
ALTER USER user_name
RENAME TO new_name;
- Change the value of a specified parameter associated with the user.
ALTER USER user_name
SET configuration_parameter { { TO | = } { value | DEFAULT } | FROM CURRENT };
- Reset the value of a specified parameter associated with the user.
ALTER USER user_name
RESET { configuration_parameter | ALL };

Parameter Description

Table 21-131 ALTER USER parameters

| Parameter | Description | Value Range/Default Value |
|---------------------------|--|---|
| user_name | Specifies the username to be changed. | Valid username. |
| new_name | Specifies the new name of a user. | A string compliant with the identifier naming rules . |
| CREATEDB NOCREATEDB | Controls whether a new user can create a database.

A new user does not have the permission to create a database by default. | Default value:
NOCREATEDB |
| CREATEROLE NOCREATEROLE | Controls whether a user can create new users or roles using CREATE ROLE and CREATE USER . A user with the CREATEROLE permission can also modify and delete other users. | Default value:
NOCREATEROLE |

| Parameter | Description | Value Range/Default Value |
|--------------------------------|---|--|
| INHERIT
NOINHERIT | Controls whether a user can inherit the permissions of its group. You are not advised to use it. | - |
| AUDITADMIN
NOAUDITADMIN | Defines whether a user has the audit administrator attribute. | Default value:
NOAUDITADMIN |
| SYSADMIN
NOSYSADMIN | Controls whether a user is a system administrator. A user with the SYSADMIN attribute has the highest permission in the system. | Default value:
NOSYSADMIN |
| USEFT
NOUSEFT | Controls whether a user can perform operations on foreign tables, such as creating, deleting, modifying, and reading/writing foreign tables.

The default value is NOUSEFT , indicating that new users cannot perform operations on foreign tables by default.

The new user does not have the permission to perform operations on foreign tables. | - |
| LOGIN
NOLOGIN | Controls whether a user can log in to the database. Only users with the LOGIN attribute can log in to the database. | Default value: LOGIN |
| REPLICATION
NOREPLICATION | Controls whether a user is allowed to initiate streaming replication or put the system in and out of backup mode. A user with the REPLICATION attribute is only used for replication. | Default value:
NOREPLICATION |

| Parameter | Description | Value Range/Default Value |
|-----------------------------|--|---------------------------|
| INDEPENDENT NOINDEPENDENT | <p>Defines private and independent users. For a user with the INDEPENDENT attribute, administrators' rights to control and access this role are separated. | Parameter | Description | Value Range/Default Value |
|-------------------------|--|---|
| CONNECTION LIMIT | <p>Specifies the number of concurrent connections that can be used by a user on a single CN.</p> <p>To ensure that a cluster can run normally, the minimum value of CONNECTION LIMIT is the number of CNs in the cluster, because when you run ANALYZE on a CN of the cluster, other CNs will connect to the running CN for metadata synchronization. For example, if there are three CNs in a cluster, set CONNECTION LIMIT to 3 or a larger value.</p> | <p>Value range: integers no less than -1.</p> <p>Default value: -1, indicating there is no limit.</p> |
| ENCRYPTED UNENCRYPTED | <p>Determines whether the password stored in the system will be encrypted. (If neither is specified, the password status is determined by password_encryption_type.) According to product security requirements, the password must be stored encrypted. Therefore, UNENCRYPTED is forbidden in DWS. If the password is encrypted using SHA256, it will be stored as it is, regardless of whether it is specified as ENCRYPTED or UNENCRYPTED. This is because the system cannot decrypt the specified encrypted password. This allows reloading of the encrypted password during dump/restore.</p> <ul style="list-style-type: none">• password: login password.• DISABLE: Users can change their own passwords unless the passwords are disabled. You can use DISABLE to disable the password of a user. After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, IAM authentication, Kerberos authentication, or LDAP authentication. Only administrators can enable or disable passwords. Common users cannot disable the password of an initial user. To enable a password, run ALTER USER and specify the password. | <p>The password must:</p> <ul style="list-style-type: none">• Contain at least eight characters.• Differ from the username or it in reverse order.• Contain at least three types of the following characters: uppercase letters (A-Z), lowercase letters (a-z), digits (0-9), and special characters such as ~!@#\$%^&*()-_+=\ []{};,:<.>/? (If you use a character that is not in the specified range, an alarm is generated, but the character can still be created.) |

| Parameter | Description | Value Range/Default Value |
|-------------------------------|---|--|
| VALID BEGIN | Sets the timestamp when a user takes effect. If this clause is omitted, there is no restriction on when the user takes effect. | - |
| VALID UNTIL | Sets an expiration timestamp for an account. After the specified time, the account cannot be used. If this clause is omitted, it means the account will never expire | - |
| RESOURCE POOL | Sets the name of the resource pool used by a user. The name is from the system catalog pg_resource_pool . | - |
| USER GROUP 'groupuser' | Creates a subuser. | - |
| PERM SPACE | Sets the storage space of the user permanent table.
space_limit : specifies the upper limit of the storage space of the permanent table. | space_limit : A string consists of an integer and unit. The unit can be K/M/G/T/P.
0 indicates no limits. |
| TEMP SPACE | Sets the storage space of the user temporary table.
tmpspacelimit : specifies the storage space limit of the temporary table. | tmpspacelimit : A string consists of an integer and unit. The unit can be K/M/G/T/P.
0 indicates no limits. |
| SPILL SPACE | Sets the operator disk flushing space of the user.
spillspacelimit : specifies the operator spilling space limit. | spillspacelimit : A string consists of an integer and unit. The unit can be K/M/G/T/P.
0 indicates no limits. |
| NODE GROUP | Specifies the name of the logical cluster associated with a user. If the name contains uppercase characters or special characters, enclose the name with double quotation marks. | - |
| ACCOUNT LOCK ACCOUNT UNLOCK | Locks or unlocks an account. <ul style="list-style-type: none">• ACCOUNT LOCK: locks an account to forbid login to databases.• ACCOUNT UNLOCK: unlocks an account to allow login to databases. | - |

| Parameter | Description | Value Range/Default Value |
|------------------------|--|---------------------------|
| PGUSER | <p>This attribute is used to be compatible with open-source Postgres communication. An open-source Postgres client interface (Postgres 9.2.19 is recommended) can use a database user having this attribute to connect to the database.</p> <p>PGUSER of a user cannot be modified in the current version. For details, see PGUSER Parameter Setting Suggestions.</p> | - |
| AUTHINFO
'authinfo' | <p>This attribute is used to specify the user authentication type. authinfo is the description character string, which is case sensitive.</p> <p>Only the LDAP type is supported. Its description character string is ldap. LDAP authentication is an external authentication mode. Therefore, PASSWORD DISABLE must be specified.</p> <ul style="list-style-type: none">Additional information about LDAP authentication can be added to authinfo, for example, fulluser in LDAP authentication, which is equivalent to ldapprefix+username+ldapsuffix. If the content of authinfo is ldap, the user authentication type is LDAP. In this case, the ldapprefix and ldapsuffix information is provided by the corresponding record in the pg_hba.conf file.When executing ALTER ROLE, users are not allowed to change the authentication type. Only LDAP users are allowed to modify LDAP attributes. | - |

| Parameter | Description | Value Range/Default Value |
|-----------------------------------|--|---|
| PASSWORD EXPIRATION period | Number of days before the login password of the role expires. The user needs to change the password in time before the login password expires. If the login password expires, the user cannot log in to the system. In this case, the user needs to ask the administrator to set a new login password. | The value is an integer ranging from -1 to 999. <ul style="list-style-type: none">• Default value -1 indicates that there is no restriction.• 0 indicates that the login password expires immediately. |
| SET configuration_parameter | Sets the session parameters of a user. The session parameters modified by running the ALTER USER command apply only to the specified user and are valid in the next session started by the user. <ul style="list-style-type: none">• DEFAULT clears the value of configuration_parameter. The value of the configuration_parameter parameter inherits the default value of the new session of the role.• FROM CURRENT uses the value of configuration_parameter of the current session. | For details about the values of configuration_parameter and value , see SET . |
| RESET configuration_parameter/ALL | The effect of clearing the configuration_parameter value is the same as setting it to DEFAULT .
ALL indicates that all parameter values are cleared. | - |

PGUSER Parameter Setting Suggestions

The **PGUSER** attribute is for compatibility with the connection process. It does not handle incompatibilities due to kernel differences between the product and Postgres.

Users with the **PGUSER** attribute have a different authentication method. Open-source clients might reveal the **PGUSER** attribute through error messages. You are advised to use the client provided with the product. Example:

```
# normaluser is a user that does not have the PGUSER attribute. psql is the Postgres client tool.
pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U normaluser
psql: authentication method 10 not supported

# pguser is a user having the PGUSER attribute.
pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U pguser
Password for user pguser:
```

Examples

Create example user **u1**.

```
DROP USER IF EXISTS u1 CASCADE;  
CREATE USER u1 PASSWORD '{Password}';
```

Change the login password of user **u1**.

```
ALTER USER u1 IDENTIFIED BY '{new_Password}' REPLACE '{Password}';
```

Add the **CREATEROLE** permission to user **u1**.

```
ALTER USER u1 CREATEROLE;
```

Set the maximum number of database connections of user **u1** to **10**.

```
ALTER USER u1 with CONNECTION LIMIT 10;
```

Set the **enable_seqscan** parameter of the session associated with user **u1** to **on**. The setting takes effect in the next session.

```
ALTER USER u1 SET enable_seqscan TO on;
```

Reset the **enable_seqscan** parameter for user **u1**.

```
ALTER USER u1 RESET enable_seqscan;
```

Lock the **u1** account.

```
ALTER USER u1 ACCOUNT LOCK;
```

Links

[CREATE ROLE](#), [CREATE USER](#), and [DROP USER](#)

21.13.3.3 DROP USER

Function

Deleting a user will also delete the schema having the same name as the user.

Precautions

- **CASCADE** is used to delete objects (excluding databases) that depend on the user. **CASCADE** cannot delete locked objects unless the locked objects are unlocked or the processes that lock the objects are stopped.
- When deleting a user in the database, if the object that the user depends on is in another database or the object of the dependent user is another database, you need to manually delete the dependent objects in other databases or delete the dependent database. Then, delete the user. Cross-database cascading deletion cannot be performed.
- In a multi-tenant scenario, the service user will also be deleted when you delete a user group. If the specified **CASCADE** concatenation is deleted, **CASCADE** will be specified upon the deletion of the service user. If you fail to delete a user, an error is reported, and you cannot delete other users either.
- If the error table specified by the GDS foreign table created by user A is under the schema of user B, user B cannot be deleted by specifying the **CASCADE** keyword in **DROP USER**.

- If a "role is being used by other users" error is displayed when you run **DROP USER**, it might be that threads cannot respond to signals in a timely manner during the **CLEAN CONNECTION** process. As a result, connections are not completely cleared. In this case, you need to run **CLEAN CONNECTION** again.

⚠ DANGER

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE, USER/ROLE, SCHEMA, TABLE, VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

```
DROP USER [ IF EXISTS ] user_name [, ...] [ CASCADE | RESTRICT ];
```

Parameter Description

Table 21-132 DROP USER parameters

| Parameter | Description | Value Range |
|--------------------|---|--|
| IF EXISTS | Sends a notice instead of an error if the specified user does not exist. | - |
| user_name | Specifies the name of a user to be deleted. | Name of an existing user. |
| CASCADE RESTRICT | <p>Specifies how to process related data in the dependent object when a delete operation is performed.</p> <p>NOTE
In DWS, the postgresql.conf file contains the enable_kill_query parameter. This parameter affects the action of deleting user objects using CASCADE.</p> <ul style="list-style-type: none">• If enable_kill_query is on and CASCADE is used to delete user objects, the processes will be automatically killed and the user will be deleted at the same time.• If enable_kill_query is off and CASCADE is used to delete user objects, the user will be deleted after the processes are automatically killed. | <ul style="list-style-type: none">• CASCADE: automatically deletes all objects (such as tables) that depend on the user to be deleted. When a user is deleted in CASCADE mode, objects owner by the user and the user's permissions for objects will be deleted.• RESTRICT: refuses to delete the user if any objects depend on it. This is the default. |

Examples

Delete user **jim**.

```
DROP USER jim CASCADE;
```

[ALTER USER](#), [CREATE USER](#)

21.13.3.4 CREATE ROLE

Function

Create a role.

A role is an entity that has own database objects and permissions. In different environments, a role can be considered a user, a group, or both.

Precautions

- **CREATE ROLE** adds a role to a database. The role does not have the login permission.
- Only the user who has the **CREATE ROLE** permission or a system administrator is allowed to create roles.

Syntax

```
CREATE ROLE role_name [ [ WITH ] option [ ... ] ] [ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' | DISABLE };
```

The syntax of role information configuration clause **option** is as follows:

```
{SYSADMIN | NOSYSADMIN}  
| {AUDITADMIN | NOAUDITADMIN}  
| {CREATEDB | NOCREATEDB}  
| {USEFT | NOUSEFT}  
| {CREATEROLE | NOCREATEROLE}  
| {INHERIT | NOINHERIT}  
| {LOGIN | NOLOGIN}  
| {REPLICATION | NOREPLICATION}  
| {INDEPENDENT | NOINDEPENDENT}  
| {VCADMIN | NOVCADMIN}  
| CONNECTION LIMIT connlimit  
| VALID BEGIN 'timestamp'  
| VALID UNTIL 'timestamp'  
| RESOURCE POOL 'respool'  
| USER GROUP 'groupuser'  
| PERM SPACE 'spacelimit'  
| TEMP SPACE 'tmpspacelimit'  
| SPILL SPACE 'spillspacelimit'  
| NODE GROUP logic_cluster_name  
| IN ROLE role_name [, ...]  
| IN GROUP role_name [, ...]  
| ROLE role_name [, ...]  
| ADMIN role_name [, ...]  
| USER role_name [, ...]  
| SYSID uid  
| DEFAULT TABLESPACE tablespace_name  
| PROFILE DEFAULT  
| PROFILE profile_name  
| PGUSER  
| AUTHINFO 'authinfo'  
| PASSWORD EXPIRATION period
```

Parameter Description

Table 21-133 CREATE ROLE parameters

| Parameter | Description | Value Range |
|-----------|---|--|
| role_name | Role name | A string. It must comply with the naming convention and can contain a maximum of 63 characters. For details, see Identifier Naming Conventions . |
| password | Specifies the login password. | <p>A password must:</p> <ul style="list-style-type: none">Contain at least eight characters. This is the default length.Differ from the user name or the user name spelled backwards.Contains at least three of the following four character types: uppercase letters, lowercase letters, digits, and special characters, including: ~!@#\$%^&*()-_+=+ [{ }];,;<.>/?. If you use characters other than the four types, a warning is displayed, but you can still create the password. <p>Value range: a string</p> |
| DISABLE | By default, you can change your password unless it is disabled. Use this parameter to disable the password of a user. | After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, IAM, Kerberos, LDAP, or oneaccess. Only administrators can enable or disable a password. Common users cannot disable the password of an initial user. To enable a password, run ALTER USER and specify the password. |

| Parameter | Description | Value Range |
|---------------------------|--|---|
| ENCRYPTED UNENCRYPTED | Determines whether the password stored in the system will be encrypted. | (If neither is specified, the password status is determined by password_encryption_type .) According to product security requirements, the password must be stored encrypted. Therefore, UNENCRYPTED is forbidden in DWS. If the password is encrypted using SHA256, it will be stored as it is, regardless of whether it is specified as ENCRYPTED or UNENCRYPTED . This is because the system cannot decrypt the specified encrypted password. This allows reloading of the encrypted password during dump/restore. |
| SYSADMIN NOSYSADMIN | Determines whether a new role is a system administrator. Roles having the SYSADMIN attribute have the highest permission. | The default value is NOSYSADMIN. |
| AUDITADMIN NOAUDITADMIN | Determines whether a role has the audit and management attributes. | The default value is NOAUDITADMIN. |
| CREATEDB NOCREATEDB | Defines a role's ability to create databases. A new role does not have the permission to create databases. | The default value is NOCREATEDB. |
| USEFT NOUSEFT | Determines whether a new role can perform operations on foreign tables, such as creating, deleting, modifying, and reading/writing foreign tables.

A new role does not have permissions for these operations. | The default value is NOUSEFT .
NOTE
In cluster 8.2.0 or later, if foreign_table_options of the GUC parameter security_enable_options is enabled, foreign table operations are permitted and the useft permission does not need to be granted to users. |

| Parameter | Description | Value Range |
|-----------------------------|--|-------------------------------------|
| CREATEROLE NOCREATEROLE | Determines whether a role will be permitted to create new roles (that is, execute CREATE ROLE and CREATE USER). A role with the CREATEROLE permission can also modify and delete other roles. | The default value is NOCREATEROLE. |
| INHERIT NOINHERIT | Determines whether a role "inherits" the permissions of roles it is a member of. You are not advised to execute them. | - |
| LOGIN NOLOGIN | Determines whether a role is allowed to log in to a database. A role having the LOGIN attribute can be thought of as a user. | The default value is NOLOGIN. |
| REPLICATION NOREPLICATION | Determines whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the REPLICATION attribute is a highly privileged role, and should only be used on roles used for replication. | The default value is NOREPLICATION. |

| Parameter | Description | Value Range |
|-----------------------------|--|---|
| INDEPENDENT NOINDEPENDENT | It defines a private and independent role. For a role with the INDEPENDENT attribute, administrators' rights to control and access this role are separated. | <p>The procedure is as follows:</p> <ul style="list-style-type: none">• Administrators have no rights to add, delete, query, modify, copy, or authorize the corresponding table objects without the authorization from the INDEPENDENT role.• Administrators have no rights to modify the inheritance relationship of the INDEPENDENT role without the authorization from this role.• Administrators have no rights to modify the owner of the table objects for the INDEPENDENT role.• Administrators have no rights to delete the INDEPENDENT attribute of the INDEPENDENT role.• Administrators have no rights to change the database password of the INDEPENDENT role. The INDEPENDENT role must manage its own password, which cannot be reset if lost.• The SYSADMIN attribute of a user cannot be changed to the INDEPENDENT attribute. |

| Parameter | Description | Value Range |
|------------------------|---|---|
| VCADMIN
NOVCADMIN | Defines the role of a logical cluster administrator. A logical cluster administrator has the following more permissions than common users: <ul style="list-style-type: none">• Create, modify, and delete resource pools in the associated logical cluster.• Grant the access permission for the associated logical cluster to other users or roles, or reclaim the access permission from those users or roles. | - |
| CONNECTION
LIMIT | Indicates how many concurrent connections the role can use on a single CN. | An integer that is greater than or equal to -1 . Default value: -1 , indicating there is no limit.
NOTICE
To ensure the proper running of a cluster, the minimum value of CONNECTION LIMIT is the number of CNs in the cluster, because when a cluster runs ANALYZE on a CN, other CNs will connect to the running CN for metadata synchronization. For example, if there are three CNs in the cluster, set CONNECTION LIMIT to 3 or a larger value. |
| VALID BEGIN | Sets a date and time when the role's password becomes valid. If this clause is omitted, the password will be valid for all time. | - |
| VALID UNTIL | Sets a date and time after which the role's password is no longer valid. If this clause is omitted, the password will be valid for all time. | - |

| Parameter | Description | Value Range |
|---------------------------|--|--|
| RESOURCE POOL | Sets the name of resource pool used by the role, and the name belongs to the system catalog:
pg_resource_pool. | - |
| USER GROUP
'groupuser' | Creates a sub-user. | - |
| PERM SPACE | Sets the storage space of the user permanent table. | space_limit: specifies the upper limit of the storage space of the permanent table. Value range: A string consists of an integer and unit. The unit can be K/M/G/T/P currently. 0 indicates no limits. |
| TEMP SPACE | Sets the storage space of the user temporary table. | tmpspacelimit: specifies the storage space limit of the temporary table. Value range: A string consists of an integer and unit. The unit can be K/M/G/T/P currently. 0 indicates no limits. |
| SPILL SPACE | Sets the operator disk flushing space of the user. | spillspacelimit: specifies the operator spilling space limit. Value range: A string consists of an integer and unit. The unit can be K/M/G/T/P currently. 0 indicates no limits. |
| NODE GROUP | Specifies the name of the logical cluster associated with a user. If the name contains uppercase characters or special characters, enclose the name with double quotation marks. | - |
| IN ROLE | Lists one or more existing roles whose permissions will be inherited by a new role. You are not advised to use them. | - |
| IN GROUP | Indicates an obsolete spelling of IN ROLE . You are not advised to use them. | - |

| Parameter | Description | Value Range |
|--------------------|--|---|
| ROLE | Lists one or more existing roles which are automatically added as members of the new role. | - |
| ADMIN | Is similar to ROLE . However, the roles after ADMIN can grant rights of new roles to other roles. | - |
| USER | Indicates an obsolete spelling of the ROLE clause. | - |
| SYSID | The SYSID clause is ignored. | - |
| DEFAULT TABLESPACE | The DEFAULT TABLESPACE clause is ignored. | - |
| PROFILE | The PROFILE clause is ignored. | - |
| PGUSER | This attribute is used to be compatible with open-source Postgres communication. An open-source Postgres client interface (Postgres 9.2.19 is recommended) can use a database user having this attribute to connect to the database. | <p>This attribute only ensures compatibility with the connection process. Incompatibility caused by kernel differences between this product and Postgres cannot be solved using this attribute.</p> <p>Users having the PGUSER attribute are authenticated in a way different from other users. Error information reported by the open-source client may cause the attribute to be enumerated. Therefore, you are advised to use a client of this product. Example:</p> <pre># normaluser is a user that does not have the PGUSER attribute. psql is the Postgres client tool. pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U normaluser psql: authentication method 10 not supported # pguser is a user having the PGUSER attribute. pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U pguser Password for user pguser:</pre> |

| Parameter | Description | Value Range |
|------------------------|---|---|
| AUTHINFO
'authinfo' | This attribute is used to specify the role authentication type. authinfo is the description character string, which is case sensitive. Currently, only the LDAP and OneAccess type is supported. Its description character string is ldap and oneaccess . LDAP and OneAccess are external authentication modes. Therefore, PASSWORD DISABLE must be specified. | <ul style="list-style-type: none">• Additional information about LDAP authentication can be added to authinfo, for example, fulluser in LDAP authentication, which is equivalent to ldapprefix+username+ldapsuffix. If the content of authinfo is ldap, the role authentication type is LDAP. In this case, the ldapprefix and ldapsuffix information is provided by the corresponding record in the pg_hba.conf file.• When the OneAccess authentication mode is supported, authinfo must contain oneaccessClientId and domain information in the 'oneaccessClientId=xxxx, domain=xxxx' format. oneaccessClientId indicates the ID of the oneaccess user and contains a maximum of 256 characters. domain indicates the access domain name of the oneaccess user and contains a maximum of 64 characters.• When executing the ALTER ROLE command, users are not allowed to change the authentication type. Only LDAP or OneAccess users are allowed to modify the LDAP or OneAccess attributes.• OneAccess is identified by internal code logic and does not need to be configured in pg_hba.conf. The authentication information is provided by authinfo. |

| Parameter | Description | Value Range |
|----------------------------|--|---|
| PASSWORD EXPIRATION period | Number of days before the login password of the role expires. The user needs to change the password in time before the login password expires. If the login password expires, the user cannot log in to the system. In this case, the user needs to ask the administrator to set a new login password. | An integer ranging from -1 to 999 . The default value is -1 , indicating that there is no restriction. The value 0 indicates that the login password expires immediately. |

Examples

Create the role **manager**.

```
CREATE ROLE manager IDENTIFIED BY '{password}';
```

Create a role with a validity period from January 1, 2015 to January 1, 2026.

```
CREATE ROLE miriam WITH LOGIN PASSWORD '{password}' VALID BEGIN '2015-01-01' VALID UNTIL '2026-01-01';
```

Create a role. The authentication type is LDAP. Other LDAP authentication information is provided by **pg_hba.conf**:

```
CREATE ROLE role1 WITH LOGIN AUTHINFO 'ldap' PASSWORD DISABLE;
```

Create a role. The authentication type is LDAP. The **fulluser** information for LDAP authentication is specified during the role creation. In this case, LDAP is case sensitive and must be enclosed in single quotation marks.

```
CREATE ROLE role2 WITH LOGIN AUTHINFO 'ldapcn=role2,cn=user,dc=lework,dc=com' PASSWORD DISABLE;
```

Create a role and set the authentication type to **OneAccess**. The authinfo information of OneAccess authentication is specified during the role creation. In this case, **oneaccess** is case sensitive and must be enclosed in single quotation marks.

```
CREATE ROLE role3 WITH LOGIN AUTHINFO 'oneaccessClientId=AbCd123,domain=example.exampleoneaccess.com' PASSWORD DISABLE;
```

Create a role and set the validity period of its login password to 30 days.

```
CREATE ROLE role4 WITH LOGIN PASSWORD '{password}' PASSWORD EXPIRATION 30;
```

21.13.3.5 ALTER ROLE

Function

ALTER ROLE changes the attributes of a role.

Precautions

None

Syntax

- Modifying the Rights of a Role

```
ALTER ROLE role_name [ [ WITH ] option [ ... ] ];
```

The **option** clause for granting rights is as follows:

```
{CREATEDB | NOCREATEDB}  
| {CREATEROLE | NOCREATEROLE}  
| {INHERIT | NOINHERIT}  
| {AUDITADMIN | NOAUDITADMIN}  
| {SYSADMIN | NOSYSADMIN}  
| {USEFT | NOUSEFT}  
| {LOGIN | NOLOGIN}  
| {REPLICATION | NOREPLICATION}  
| {INDEPENDENT | NOINDEPENDENT}  
| {VCADMIN | NOVCADMIN}  
| CONNECTION LIMIT connlimit  
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD 'password'  
| [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY 'password' [ REPLACE 'old_password' ]  
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD { 'password' | DISABLE }  
| [ ENCRYPTED | UNENCRYPTED ] IDENTIFIED BY { 'password' [ REPLACE 'old_password' ] |  
DISABLE }  
| VALID BEGIN 'timestamp'  
| VALID UNTIL 'timestamp'  
| RESOURCE POOL 'respool'  
| USER GROUP 'groupuser'  
| PERM SPACE 'spacelimit'  
| TEMP SPACE 'tmpspacelimit'  
| SPILL SPACE 'spillspacelimit'  
| NODE GROUP logic_cluster_name  
| ACCOUNT { LOCK | UNLOCK }  
| PGUSER  
| AUTHINFO 'authinfo'  
| PASSWORD EXPIRATION period
```

- Rename a role.

```
ALTER ROLE role_name  
  RENAME TO new_name;
```

- Set parameters for a role.

```
ALTER ROLE role_name [ IN DATABASE database_name ]  
  SET configuration_parameter [{ TO | = } { value | DEFAULT } | FROM CURRENT];
```

- Reset parameters for a role.

```
ALTER ROLE role_name  
  [ IN DATABASE database_name ] RESET {configuration_parameter|ALL};
```

Parameter Description

Table 21-134 ALTER ROLE parameters

| Parameter | Description | Value Range |
|---------------------------|---|---|
| role_name | Specifies the name of the role to be modified. | Name of an existing role. |
| new_name | Indicates the new name of a role. | A string compliant with the identifier naming rules . |
| CREATEDB NOCREATEDB | Defines a role's ability to create databases. If not specified, NOCREATEDB is the default value.
A new role does not have the permission to create databases. | - |
| CREATEROLE NOCREATEROLE | Determines whether a role will be permitted to create new roles (that is, execute CREATE ROLE and CREATE USER). If not specified, NOCREATEROLE is the default value.
A role with the CREATEROLE permission can also modify and delete other roles. | - |
| INHERIT NOINHERIT | Determines whether the role can inherit permissions of its group. You are not advised to execute them. | - |
| AUDITADMIN NOAUDITADMIN | Determines whether a role has the audit and management attributes.
If not specified, NOAUDITADMIN is the default. | - |
| SYSADMIN NOSYSADMIN | Determines whether a new role is a system administrator. Roles having the SYSADMIN attribute have the highest permission.
If not specified, NOSYSADMIN is the default value. | - |
| USEFT NOUSEFT | Determines whether a new role can perform operations on foreign tables, such as creating, deleting, modifying, and reading/writing foreign tables.
A new role does not have permissions for these operations.
Default value NOUSEFT indicates that a new role cannot perform operations on foreign tables. | - |

| Parameter | Description | Value Range |
|-----------------------------|--|-------------|
| LOGIN NOLOGIN | Indicates whether a user can log in to the database. Only roles with the LOGIN attribute can log in to the database. A role having the LOGIN attribute can be thought of as a user.
Value range: If not specified, NOLOGIN is the default. | - |
| REPLICATION NOREPLICATION | Determines whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the REPLICATION attribute is a highly privileged role, and should only be used on roles used for replication.
If not specified, NOREPLICATION is the default. | - |

| Parameter | Description | Value Range |
|-----------------------------|---|-------------|
| INDEPENDENT NOINDEPENDENT | <p>Defines private and independent roles. For a role with the INDEPENDENT attribute, administrators' rights to control and access this role are separated. Specific rules are as follows:</p> <ul style="list-style-type: none">• Administrators have no rights to add, delete, query, modify, copy, or authorize the corresponding table objects without the authorization from the INDEPENDENT role.• Administrators have no rights to modify the inheritance relationship of the INDEPENDENT role without the authorization from this role.• Administrators have no rights to modify the owner of the table objects for the INDEPENDENT role.• Administrators have no rights to delete the INDEPENDENT attribute of the INDEPENDENT role.• Administrators have no rights to change the database password of the INDEPENDENT role. The INDEPENDENT role must manage its own password, which cannot be reset if lost.• The SYSADMIN attribute of a user cannot be changed to the INDEPENDENT attribute. | - |
| VCADMIN NOVCADMIN | <p>Defines the role of a logical cluster administrator. A logical cluster administrator has the following more permissions than common users:</p> <ul style="list-style-type: none">• Create, modify, and delete resource pools in the associated logical cluster.• Grant the access permission for the associated logical cluster to other users or roles, or reclaim the access permission from those users or roles. | - |

| Parameter | Description | Value Range |
|---------------------|---|--|
| CONNECTION
LIMIT | <p>Indicates the number of concurrent connections that a role can use on a single CN.</p> <p>To ensure the proper running of a cluster, the minimum value of CONNECTION LIMIT is the number of CNs in the cluster, because when a cluster runs ANALYZE on a CN, other CNs will connect to the running CN for metadata synchronization. For example, if there are three CNs in the cluster, set CONNECTION LIMIT to 3 or a larger value.</p> | <p>Integers no less than -1.</p> <p>The default value -1 means no limit.</p> |

| Parameter | Description | Value Range |
|-------------------------|---|--|
| ENCRYPTED UNENCRYPTED | <p>Determines whether the password stored in the system will be encrypted. (If neither is specified, the password status is determined by password_encryption_type.) According to product security requirements, the password must be stored encrypted. Therefore, UNENCRYPTED is forbidden in DWS. If the password is encrypted using SHA256, it will be stored as it is, regardless of whether it is specified as ENCRYPTED or UNENCRYPTED. This is because the system cannot decrypt the specified encrypted password. This allows reloading of the encrypted password during dump/restore.</p> <ul style="list-style-type: none">password
Specifies the login password.DISABLE
By default, you can change your password unless it is disabled. Use this parameter to disable the password of a user. After the password of a user is disabled, the password will be deleted from the system. The user can connect to the database only through external authentication, for example, IAM authentication, Kerberos authentication, or LDAP authentication. Only administrators can enable or disable a password. Common users cannot disable the password of an initial user. To enable a password, run ALTER USER and specify the password. | <p>The password must:</p> <ul style="list-style-type: none">Contain at least eight characters.Differ from the username or it in reverse order.Contain at least three types of the following characters:
uppercase letters (A-Z), lowercase letters (a-z), digits (0-9), and special characters such as ~!@#\$%^&*()-_+=+\\[{}];,;<.>/? (If you use a character that is not in the specified range, an alarm is generated, but the character can still be created.) |
| VALID BEGIN | Sets a date and time when the role's password becomes valid. If this clause is omitted, the password will be valid for all time. | - |
| VALID UNTIL | Sets a date and time after which the role's password is no longer valid. If this clause is omitted, the password will be valid for all time. | - |

| Parameter | Description | Value Range |
|-------------------------------------|--|---|
| RESOURCE POOL | Sets the name of resource pool used by a role, and the name belongs to the system catalog:
pg_resource_pool . | - |
| USER GROUP
'groupuser' | Creates a sub-user. | - |
| PERM SPACE | Sets the storage space of the user permanent table.
space_limit specifies the upper limit of the storage space of the permanent table. | space_limit : A string consists of an integer and unit. The unit can be K/M/G/T/P. 0 indicates no limits. |
| TEMP SPACE | Sets the storage space of the user temporary table.
tmpspacelimit specifies the storage space limit of the temporary table. | tmpspacelimit : A string consists of an integer and unit. The unit can be K/M/G/T/P. 0 indicates no limits. |
| SPILL SPACE | Sets the operator disk flushing space of the user.
spillspacelimit specifies the operator spilling space limit. | spillspacelimit : A string consists of an integer and unit. The unit can be K/M/G/T/P. 0 indicates no limits. |
| NODE GROUP | Specifies the name of the logical cluster associated with a user. If the name contains uppercase characters or special characters, enclose the name with double quotation marks. | - |
| ACCOUNT LOCK
ACCOUNT
UNLOCK | <ul style="list-style-type: none">● ACCOUNT LOCK: locks an account to forbid login to databases.● ACCOUNT UNLOCK: unlocks an account to allow login to databases. | - |

| Parameter | Description | Value Range |
|----------------------------------|---|---|
| PGUSER | <p>This attribute is used to be compatible with open-source Postgres communication. An open-source Postgres client interface (Postgres 9.2.19 is recommended) can use a database user having this attribute to connect to the database.</p> <p>PGUSER of a role cannot be modified in the current version. For details, see PGUSER Parameter Setting Suggestions.</p> | - |
| AUTHINFO
'authinfo' | <p>Specifies the role authentication type. authinfo is the description character string, which is case sensitive. Only the LDAP type is supported. Its description character string is ldap. LDAP authentication is an external authentication mode. Therefore, PASSWORD DISABLE must be specified.</p> <ul style="list-style-type: none">• Additional information about LDAP authentication can be added to authinfo, for example, fulluser in LDAP authentication, which is equivalent to ldapprefix+username+ldapsuffix. If the content of authinfo is ldap, the role authentication type is LDAP. In this case, the ldapprefix and ldapsuffix information is provided by the corresponding record in the pg_hba.conf file.• When executing the ALTER ROLE command, users are not allowed to change the authentication type. Only LDAP users are allowed to modify LDAP attributes. | - |
| PASSWORD
EXPIRATION
period | <p>Specifies the number of days before the login password of the role expires. You need to change the password before the password expires. If your login password expires, you cannot log in. Ask the administrator for a new password.</p> | <p>An integer ranging from -1 to 999.</p> <ul style="list-style-type: none">• Default value -1 indicates that there is no restriction.• 0 indicates that the login password expires immediately. |

| Parameter | Description | Value Range |
|--------------------------------------|--|--|
| IN DATABASE
database_name | Modifies the parameters of a role in a specified database. | - |
| SET
configuration_parameter | Sets parameters for a role. The session parameters modified using the ALTER ROLE command is only for a specific role and is valid in the next session triggered by the role. <ul style="list-style-type: none">• DEFAULT clears the value of configuration_parameter. The value of the configuration_parameter parameter inherits the default value of the new session of the role.• FROM CURRENT uses the value of configuration_parameter of the current session. | Values of configuration_parameter and value are listed in SET . |
| RESET
configuration_parameter/ALL | The effect of clearing the configuration_parameter value is the same as setting it to DEFAULT . ALL indicates that all parameter values are cleared. | - |

PGUSER Parameter Setting Suggestions

The **PGUSER** attribute is for compatibility with the connection process. It does not handle incompatibilities due to kernel differences between the product and Postgres.

Users having the **PGUSER** attribute are authenticated in a way different from other users. Error information reported by the open-source client may cause the attribute to be enumerated. Therefore, you are advised to use a client of this product. Example:

```
# normaluser is a user that does not have the PGUSER attribute. psql is the Postgres client tool.
pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U normaluser
psql: authentication method 10 not supported

# pguser is a user having the PGUSER attribute.
pg@dws04:~> psql -d postgres -p 8000 -h 10.11.12.13 -U pguser
Password for user pguser:
```

Examples

Create example roles **r1**, **r2**, and **r3**.

```
CREATE ROLE r1 IDENTIFIED BY '{Password}';
CREATE ROLE r2 WITH LOGIN AUTHINFO 'ldapcn=r2,cn=user,dc=lework,dc=com' PASSWORD DISABLE;
CREATE ROLE r3 WITH LOGIN PASSWORD '{Password}' PASSWORD EXPIRATION 30;
```

Modify the login permission of role **r1**.

```
ALTER ROLE r1 login;
```

Change the password of role **r1**.

```
ALTER ROLE r1 IDENTIFIED BY '{new_Password}' REPLACE '{Password}';
```

Change the **manager** role to the system administrator.

```
ALTER ROLE r1 SYSADMIN;
```

Modify the **fulluser** information of the LDAP authentication role.

```
ALTER ROLE r2 WITH LOGIN AUTHINFO 'ldapcn=role2,cn=user2,dc=func,dc=com' PASSWORD DISABLE;
```

Change the validity period of the login password of the role to 90 days.

```
ALTER ROLE r3 PASSWORD EXPIRATION 90;
```

Links

[CREATE ROLE](#), [DROP ROLE](#), and [SET](#).

21.13.3.6 SET ROLE

Function

SET ROLE sets the current user identifier of the current session.

Precautions

- Users of the current session must be members of specified **rolename**, but the system administrator can choose any roles.
- Executing this command may add rights of a user or restrict rights of a user. If the role of a session user has the **INHERITS** attribute, it automatically has all rights of roles that **SET ROLE** enables the role to be. In this case, **SET ROLE** physically deletes all rights directly granted to session users and rights of its belonging roles and only leaves rights of the specified roles. If the role of the session user has the **NOINHERITS** attribute, **SET ROLE** deletes rights directly granted to the session user and obtains rights of the specified role.

Syntax

- Set the current user identifier of the current session.

```
SET [ SESSION | LOCAL ] ROLE role_name PASSWORD '{password}';
```
- Reset the current user identifier to that of the current session.

```
RESET ROLE;
```

Parameter Description

Table 21-135 SET ROLE parameters

| Parameter | Description | Value Range |
|------------|--|---|
| SESSION | Specifies that the command takes effect only for the current session. This parameter is used by default. | The value is a string and must comply with the rules in Identifier Naming Conventions . |
| LOCALE | Indicates that the specified command takes effect only for the current transaction. | - |
| role_name | Specifies the role name. | The value is a string and must comply with the rules in Identifier Naming Conventions . |
| password | Specifies the password of a role. It must comply with the password convention. | - |
| RESET ROLE | Resets the current user identifier. | - |

Examples

Create the role **manager**.

```
CREATE ROLE paul IDENTIFIED BY '{Password}';
```

Set the current user to **paul**.

```
SET ROLE paul PASSWORD '{password}';
```

View the current session user and the current user.

```
SELECT SESSION_USER, CURRENT_USER;
```

Reset the current user.

```
RESET role;
```

21.13.3.7 DROP ROLE

Function

DROP ROLE deletes a specified role.

Precautions

If a "role is being used by other users" error is displayed when you run **DROP ROLE**, it might be that threads cannot respond to signals in a timely manner

during the **CLEAN CONNECTION** process. As a result, connections are not completely cleared. In this case, you need to run **CLEAN CONNECTION** again.

** DANGER**

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE, USER/ROLE, SCHEMA, TABLE, VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
 - For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.
-

Syntax

```
DROP ROLE [ IF EXISTS ] role_name [, ...];
```

Parameter Description

Table 21-136 DROP ROLE parameters

| Parameter | Description | Value Range |
|-----------|--|-------------------|
| IF EXISTS | Sends a notice instead of an error if the specified role does not exist. | - |
| role_name | Specifies the name of the role to be deleted. | An existing role. |

Examples

Delete **manager** role.

```
DROP ROLE manager;
```

Helpful Links

[CREATE ROLE](#), [ALTER ROLE](#), [SET ROLE](#)

21.13.3.8 CREATE GROUP

Function

CREATE GROUP creates a user group.

Precautions

CREATE GROUP is an alias for **CREATE ROLE**, and it is not a standard SQL command and not recommended. Users can use **CREATE ROLE** directly.

Syntax

```
CREATE GROUP group_name [ [ WITH ] option [ ... ] ]  
[ ENCRYPTED | UNENCRYPTED ] { PASSWORD | IDENTIFIED BY } { 'password' | DISABLE };
```

The syntax of optional **action** clause is as follows:

```
where option can be:  
{SYSADMIN | NOSYSADMIN}  
| {AUDITADMIN | NOAUDITADMIN}  
| {CREATEDB | NOCREATEDB}  
| {USEFT | NOUSEFT}  
| {CREATEROLE | NOCREATEROLE}  
| {INHERIT | NOINHERIT}  
| {LOGIN | NOLOGIN}  
| {REPLICATION | NOREPLICATION}  
| {INDEPENDENT | NOINDEPENDENT}  
| {VCADMIN | NOVADMIN}  
| CONNECTION LIMIT connlimit  
| VALID BEGIN 'timestamp'  
| VALID UNTIL 'timestamp'  
| RESOURCE POOL 'respool'  
| USER GROUP 'groupuser'  
| PERM SPACE 'spacelimit'  
| NODE GROUP logic_group_name  
| IN ROLE role_name [, ...]  
| IN GROUP role_name [, ...]  
| ROLE role_name [, ...]  
| ADMIN role_name [, ...]  
| USER role_name [, ...]  
| SYSID uid  
| DEFAULT TABLESPACE tablespace_name  
| PROFILE DEFAULT  
| PROFILE profile_name  
| PGUSER
```

Parameter Description

See [Parameter Description](#) in **CREATE ROLE**.

Helpful Links

[ALTER GROUP](#), [DROP GROUP](#), and [CREATE ROLE](#)

21.13.3.9 ALTER GROUP

Function

This syntax modifies the attributes of a user group.

Precautions

ALTER GROUP is an alias for **ALTER ROLE**, and it is not a standard SQL command and not recommended. Users can use **ALTER ROLE** directly.

Syntax

- Add users to a group.

```
ALTER GROUP group_name  
ADD USER user_name [, ... ];
```
- Remove users from a group.

```
ALTER GROUP group_name  
DROP USER user_name [, ... ];
```

- Change the name of the group.

```
ALTER GROUP group_name  
RENAME TO new_name;
```

Parameter Description

For details about more parameters, see [Parameter Description](#) in **ALTER ROLE**.

Table 21-137 ALTER GROUP parameters

| Parameter | Description | Value Range |
|------------|--|---|
| group_name | Specifies the name of the user group to be modified. | A string that indicates the name of an existing group. |
| user_name | Specifies the user to be added to or removed from the group. | Name of an existing user. |
| new_name | Specifies the new name of a group. | A string compliant with the identifier naming rules . |

Helpful Links

[CREATE GROUP](#), [DROP GROUP](#), and [ALTER ROLE](#)

21.13.3.10 DROP GROUP

Function

DROP GROUP deletes a user group.

DROP GROUP is the alias for **DROP ROLE**.

Precautions

DROP GROUP is the internal interface encapsulated in the **gs_om** tool. You are not advised to use this interface, because doing so affects the cluster.

Syntax

```
DROP GROUP [ IF EXISTS ] group_name [, ...];
```

Parameter Description

See [Parameter Description](#) in **DROP ROLE**.

Helpful Links

[CREATE GROUP](#), [ALTER GROUP](#), [DROP ROLE](#)

21.13.3.11 DROP OWNED

Function

DROP OWNED deletes the database objects of a database role.

Precautions

The role's permissions on all the database objects in the current database and shared objects (databases and tablespaces) are revoked.

Syntax

```
DROP OWNED BY name [, ...] [ CASCADE | RESTRICT ];
```

Parameter Description

Table 21-138 DROP OWNED parameters

| Parameter | Description | Value Range |
|--------------------|---|---|
| name | Name of the role whose objects are to be deleted and whose permissions are to be revoked. | An existing role name. |
| CASCADE RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none">• CASCADE: automatically deletes objects that depend on the affected objects.• RESTRICT (default): refuses to delete objects with dependent objects. |

Example

Remove all database objects owned by role **u1**.

```
DROP OWNED BY u1;
```

21.13.4 Tables and External Data Sources

21.13.4.1 CREATE TABLE

Function

Creates a new empty table in the current database.

This table is owned by the user who executes the command. However, if the system administrator creates a table in the schema with the same name as a common user, the owner of the table is the user (not the system administrator).

Precautions

Table 21-139 Precautions for CREATE TABLE

| Constraint | Description |
|--|---|
| Number of column-store and HDFS partitioned tables that can be created | For better performance, keep this value at or below 1,000. |
| Data types supported by column-store tables | For details, see Data Types Supported by Column-Store Tables . |
| Primary key and unique constraint requirements | The primary key and unique constraints in a table must contain distribution columns. |
| Modification of distribution columns | The data type of the distribution column in an existing table cannot be modified. |
| Row-store REPLICATION tables | A system column cannot be designated as a primary key in a row-store REPLICATION distributed table. |
| Supported range of column-store tables | Column-store tables support the PARTIAL CLUSTER KEY and table-level primary key and unique constraints, but do not support table-level foreign key constraints. |
| Columns of column-store tables | Only the NULL , NOT NULL , and DEFAULT constant values are supported. |
| Hot and cold tables | <ul style="list-style-type: none">Hot and cold tables support only column-store partitioned tables and depend on the available OBS.Hot and cold tables support only the default tablespace default_obs_tbs. If you need to add an OBS tablespace, contact technical support. |
| Delta tables supported by column-store tables | Whether column-store tables support a delta table is specified by the enable_delta parameter. The threshold for storing data into a delta table is specified by the deltarow_threshold parameter. Column-store tables with delta tables are not recommended. If delta tables are used, disk bloat and performance deterioration may occur due to insufficient merge time. Delta tables in column-store tables are no longer supported in versions later than 9.1.0.200 due to the preceding problems. HStore tables are used instead. For details about HStore tables, see "Hybrid Data Warehouse" in <i>Data Warehouse Service (DWS) Developer Guide</i> . |

| Constraint | Description |
|---------------|--|
| HStore tables | <ul style="list-style-type: none">When creating an HStore table, ensure that the database GUC parameter settings meet the following requirements:<ul style="list-style-type: none">autovacuum is set to on.The value of autovacuum_max_workers_hstore is greater than 0.The value of autovacuum_max_workers is greater than that of autovacuum_max_workers_hstore. |
| V3 tables | <ul style="list-style-type: none">Once a table is created, it cannot be switched from a non-V3 table to a V3 table using the ALTER TABLE syntax. In other words, a non-V3 table (colversion is 2.0) cannot be converted to a V3 table (colversion is 3.0).Delta tables and column-store level-2 partitions cannot be set for V3 tables (colversion is 3.0, storage-compute decoupling).V3 tables cannot be configured as HStore tables, cold and hot tables, or time sequence tables.Global temporary tables and temporary tables cannot be created for V3 tables. Any created temporary tables are automatically converted to temporary tables with colversion 2.0. |
| Other | If an error occurs during table creation, the system may not be able to clear the created, empty disk file automatically after the system is recovered. This problem rarely occurs and does not affect the normal running of the database system. |

WARNING

- Do not specify a custom tablespace when creating an ordinary table.
- Do not specify the **COMPRESS** compression attribute when creating a row-store table.
- When creating a hash-distributed table object, ensure that data is evenly distributed. (For a table with more than 10 GB data, the skew rate must be less than 10%.)
- When creating a replication-distributed table object, ensure that there are less than 1 million rows in a table.
- For a large table (with more than 50 million rows of data) that contains the time field, ensure that the table is designed as a partitioned table and the partition interval is properly designed based on the query characteristics.
- For a table that has a large amount of data to be added, deleted, or modified, keep the number of indexes within 3 (maximum value: 5).
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

```
CREATE [ [ GLOBAL | LOCAL | VOLATILE ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE [ IF NOT EXISTS ]
table_name
{ ( { column_name data_type [ compress_mode ] [ COLLATE collation ] [ column_constraint [ ... ] ]
  | table_constraint
  | LIKE source_table [ like_option [...] ] }
  [, ... ] )
  LIKE source_table [ like_option [...] ] }
[ WITH ( { storage_parameter = value } [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS } ]
[ COMPRESS | NOCOMPRESS ]
[ DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { HASH ( column_name [...] ) } } ]
[ TO { GROUP groupname | NODE ( nodename [, ... ] ) } ]
[ COMMENT [=] 'text' ];
```

- **column_constraint** is as follows:

```
[ CONSTRAINT constraint_name ]
{ NOT NULL |
  NULL |
  CHECK ( expression ) |
  DEFAULT default_expr |
  ON UPDATE on_update_expr |
  COMMENT 'text' |
  UNIQUE [ NULLS [NOT] DISTINCT | NULLS IGNORE ] index_parameters |
  PRIMARY KEY index_parameters |
  REFERENCES reftable [ ( refcolumn ) ] }
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **compress_mode** of a column is as follows:

```
{ DELTA | PREFIX | DICTIONARY | NUMSTR | NOCOMPRESS }
```

- **table_constraint** is as follows:

```
[ CONSTRAINT constraint_name ]
{ CHECK ( expression ) |
  UNIQUE [ NULLS [NOT] DISTINCT | NULLS IGNORE ] ( column_name [, ... ] ) index_parameters |
  PRIMARY KEY ( column_name [, ... ] ) index_parameters |
  PARTIAL CLUSTER KEY ( column_name [, ... ] ) }
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

- **like_option** is as follows:

```
{ INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |  
PARTITION | REOPTIONS | DISTRIBUTION | DROPCOLUMNS | ALL }
```

- **index_parameters** is as follows:
[WITH ({storage_parameter = value} [, ...])]

Table Design Reference

DWS is compatible with the PostgreSQL ecosystem. Row storage and its B-tree index are similar to those of PostgreSQL. Column storage and its index are self-developed. When creating a table, it is crucial to choose the right storage method, distribution column, partition key, and index. This ensures efficient data access during SQL execution, reducing I/O consumption. The following figure illustrates the process from SQL statement initiation to data acquisition, helping you understand the function of each technical method for performance optimization.

1. When the SQL statement is executed, the partitioned table is optimized using the Partition Column to pinpoint the specific partition.
2. The Distribute Column is used in a distributed hash table to quickly identify the data shard where the data resides. The data shard is located on a DN in a storage-compute coupled architecture, while in a storage-compute decoupled architecture, it is located on a bucket.
3. In row-store mode, the B-tree index is used to quickly locate the data page. In column-store mode, the **min-max** index is used to quickly locate the CU data block that may contain relevant data. This index is particularly effective when filtering on the PCK column.
4. The system automatically maintains the **min-max** index for all columns in the column-store mode. There is no need for manual index definition. The **min-max** index is used for coarse filtering. CU data blocks meeting the min-max condition may not contain data rows that meet the filter condition. If a bitmap column is defined, the bitmap index can quickly locate the row number of data that meets the filter condition in the CU. For ordered CUs, binary search is also used to quickly locate the row number of data.
5. Column storage supports B-tree and GIN indexes, which can quickly locate the CU and row number of data that meets the conditions. However, due to high index maintenance costs, you are advised to use bitmap indexes instead, unless there are high performance requirements for point queries.

Table 21-140 lists the existing optimization methods of DWS.

Table 21-140 Optimization methods

| No. | Method | Usage | Example SQL | Modifiable After Creation |
|-----|-----------------------|--|---|--|
| 1 | String | <ol style="list-style-type: none">1. The string type has slower performance compared to the fixed-length type, so it is not recommended for scenarios where the fixed-length type is more suitable.2. If the specified length is less than 16, performance will be significantly improved. | - | Yes (The existing data can be rewritten.) |
| 2 | Numeric | Specifying precision for the numeric type is essential for improving performance. It is not advisable to use the numeric type without specifying precision. | - | Yes (The existing data can be rewritten.) |
| 3 | Partition by Column | <ol style="list-style-type: none">1. This requires user-defined settings and is designed for partitioned tables. Pruning is possible using partition keys and partition-wise joins are supported. This method is suitable for equality and range queries.2. Having more than 1000 partitions is not recommended, and it is advisable to limit the number of partition columns to two. | <pre>SELECT * FROM t1 WHERE t1.c1='p1';</pre> | No (You need to create a new table to make modifications.) |
| 4 | secondary_part_column | <ol style="list-style-type: none">1. This requires user-defined settings and is applicable only to column-store tables and equality queries.2. Specify a level-2 partition on the most commonly used equivalent filter. | <pre>SELECT * FROM t1 WHERE t1.c1='p1';</pre> | No (You need to create a new table to make modifications.) |

| No. | Method | Usage | Example SQL | Modifiable After Creation |
|-----|----------------------|--|--|---|
| 5 | Distribute by Column | This requires user-defined settings and is suitable for join fields that require frequent GROUP BY or multi-table joins. It reduces data shuffling through local joins and is ideal for equality queries. | <pre>SELECT * FROM t1 join t2 on t1.c3 = t2.c1;</pre> | No (You need to create a new table to make modifications.) |
| 6 | Bitmap column | Define the bitmap index (cardinality ≤ 32) or bloom filter (cardinality > 32) based on the repeated values in the CU. This method is applicable to equivalent queries of varchar or text type columns. It is advised to create indexes on columns involved in the WHERE condition. | <pre>SELECT * FROM t1 WHERE t1.c4='hello';</pre> | Yes (Modification does not rewrite existing data. Only the new data is affected.) |
| 7 | min-max index | <ol style="list-style-type: none">1. The min-max index is automatically generated and can be used for both equality and range queries.2. The min-max filtering effect depends on the data order. Specifying the PCK column enhances the filtering effect. | <pre>SELECT * FROM t1 WHERE c3 > 100 and c3 < 200;</pre> | Yes (The PCK columns can be modified. Modification does not rewrite existing data and only the new data is affected.) |

| No. | Method | Usage | Example SQL | Modifiable After Creation |
|-----|----------------------------|---|---|--|
| 8 | Primary key (B-tree index) | <ol style="list-style-type: none">1. UPSERT data import strongly depends on the primary key and needs to be customized. It is applicable to equality and range queries. We suggest limiting the number of columns to five or fewer.2. If service requirements are met, it is better to use fixed-length type columns. During definition, place columns with more distinct values at the beginning. | <pre>SELECT * FROM t1 WHERE c3 > 100 and c3 < 200;</pre> | Yes (The index can be modified and re-created.) |
| 9 | GIN index | <ol style="list-style-type: none">1. This requires user-defined settings and is suitable for multi-condition equality queries. Avoid using columns with more than 1 million distinct values.2. It is recommended when the data volume after filtering is less than 1000. If the data volume remains large after filtering, it is not recommended. | <pre>SELECT * FROM t1 WHERE c1 = 100 and c3 = 200 and c2 = 105;</pre> | Yes (The index can be modified and re-created.) |
| 10 | Orientation=column/row | This method specifies whether a table is stored in rows or columns. Row-store tables cannot be compressed and are best suited for point queries and frequent updates. Column-store tables can be compressed and are ideal for analysis purposes. | - | No (You need to create a new table to make modifications.) |

Parameter Description

Table 21-141 CREATE TABLE parameters

| Parameter | Description | Value Range or Example |
|-----------|---|--|
| UNLOGGED | If UNLOGGED is specified, the created table is an unlogged table. Data written to unlogged tables is not written to the write-ahead log, which makes them considerably faster than ordinary tables. However, an unlogged table is automatically truncated after a crash or unclean shutdown, incurring data loss risks. The contents of an unlogged table are also not replicated to standby servers. Any indexes created on an unlogged table are not automatically logged as well. | <p>Usage scenario: Unlogged tables do not ensure safe data. You can back up data before using unlogged tables; for example, you should back up the data before a system upgrade.</p> <p>Troubleshooting: If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, you should re-create the indexes with errors.</p> <p>Example:</p> <pre>CREATE UNLOGGED TABLE table_unlog (col1 VARCHAR(50) , col2 TEXT);</pre> |

| Parameter | Description | Value Range or Example |
|-----------|--|------------------------|
| | <p>NOTICE</p> <ol style="list-style-type: none">1. The UNLOGGED table uses no primary/standby mechanism. In the case of system faults or abnormal breakpoints, data loss may occur. Therefore, the UNLOGGED table cannot be used to store basic data.2. Starting from version 9.1.0, UNLOGGED tables are automatically saved in the pg_unlogged tablespace and cannot be moved or assigned to other tablespaces.3. After an earlier version is upgraded to 9.1.0, the UNLOGGED table created in the earlier version is still stored in the original tablespace.4. If the instance restarts unexpectedly, the UNLOGGED table will be reset, which can impact the instance's recovery time objective (RTO). In version 9.1.0, switch_unlogged_tablespace.py can be used to move unlogged tables to optimize the recovery time objective (RTO). This script works together with the GUC parameter enable_unlogged_tablespace_compat. | |

| Parameter | Description | Value Range or Example |
|---------------------------|--|--|
| GLOBAL LOCAL VOLATILE | <p>Specify the keywords GLOBAL, LOCAL, and VOLATILE before TEMP or TEMPORARY to create temporary tables with different attributes. Global temporary tables are supported only by 8.2.1.220 and later cluster versions.</p> <ul style="list-style-type: none">• If LOCAL is specified, a local temporary table is created.• If keyword GLOBAL is specified, the attributes of the temporary table depend on the GUC parameter enable_global_temp_table. The default value of this parameter is ON.
If enable_global_temp_table is set to on, a global temporary table GLOBAL is created.
If enable_global_temp_table is set to off, a local temporary table LOCAL is created. You can also specify keyword LOCAL to reach the same effect.• If VOLATILE is specified, a temporary volatile table is created.
If default temptable_type is set to local, temporary tables created without keywords are local temporary tables. If default temptable_type is set to volatile, temporary tables created without keywords are volatile temporary tables. | <p>Example:</p> <pre>CREATE LOCAL TEMP TABLE temp_test (col1 INT, col2 DECIMAL(10,2));</pre> |

| Parameter | Description | Value Range or Example |
|------------------|--|---|
| TEMPORARY TEMP | <p>If TEMP or TEMPORARY is specified, the created table is a temporary table.</p> <p>Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction. Therefore, apart from CN and other CN errors connected by the current session, you can still create and use temporary table in the current session.</p> <p>Temporary tables are created only in the current session. If a DDL statement involves operations on temporary tables, a DDL error will be generated. Therefore, you are not advised to perform operations on temporary tables in DDL statements. TEMP is equivalent to TEMPORARY.</p> | For other restrictions of this parameter, see TEMPORARY TEMP Parameter Description . |
| IF NOT EXISTS | <p>If IF NOT EXISTS is specified, a table will be created if there is no table using the specified name. If there is already a table using the specified name, no error will be reported. A message will be displayed indicating that the table already exists, and the database will skip table creation.</p> | <p>Example:</p> <p>Use IF NOT EXISTS to prevent duplicate table creation.</p> <pre>CREATE TABLE IF NOT EXISTS test_t1 (col1 INT,col2 VARCHAR(30));</pre> |

| Parameter | Description | Value Range or Example |
|-------------|--|--|
| table_name | Specifies the name of the table to be created. | <ul style="list-style-type: none">• The table name must start with a letter or underscore (_) and can contain up to 63 characters. Only letters, digits, underscores (_), dollar signs (\$), and number signs (#) are allowed.• Chinese table names are supported. The number of supported characters depends on the database's character set encoding. For details, see "DWS Database Object Naming Rules" in the <i>Data Warehouse Service (DWS) Developer Guide</i>.• You are not advised to use a keyword as a table name. For details, see Keyword.• A table name enclosed in double quotation marks can contain spaces and special characters. However, you are not advised to use these characters in a table name because they may make it difficult to reference and use. In addition, they may be processed differently under different database compatibility modes. |
| column_name | Specifies the name of a column to be created in the new table. | The column name can contain a maximum of 63 characters, including letters, digits, underscores (_), dollar signs (\$), and number signs (#). It must start with a letter or underscore (_). |

| Parameter | Description | Value Range or Example |
|--|--|--|
| data_type | Specifies the data type of the column. | In a database compatible with Teradata or MySQL syntax, if the data type of a column is set to DATE, the DATE type is returned. Otherwise, the TIMESTAMP type is returned. |
| compress_mode | Specifies the compress option of the table, only available for row-store table. The option specifies the algorithm preferentially used by table columns. | DELTA, PREFIX, DICTIONARY, NUMSTR, or NOCOMPRESS |
| COLLATE collation | Assigns a collation to the column (which must be of a collatable data type). | If no collation is specified, the default collation is used. |
| LIKE source_table
[like_option ...] | Specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints. | For details about LIKE constraints, see LIKE Parameter Description . |

| Parameter | Description | Value Range or Example |
|--|---|---|
| WITH | <p>Specifies an optional storage parameter for a table or an index.</p> <p>NOTE
Using Numeric of any precision to define column, specifies precision p and scale s. When precision and scale are not specified, the input will be displayed.</p> | <p>WITH contains many sub-parameters, which are classified as follows by scenario. You only need to pay attention to the parameters in specific scenarios.</p> <ul style="list-style-type: none">• For details about storage class parameters, see Table 21-142.• For details about parameters related to the partitioned table, see Table 21-143.• For details about the parameters related to the Delta table, see Table 21-144.• Parameters related to the Hstore table. For details, see Table 21-145.• For details about performance-related parameters, see Table 21-146. |
| ON COMMIT
{ PRESERVE
ROWS DELETE
ROWS } | <p>ON COMMIT determines what to do when you commit a temporary table creation operation. Global temporary tables support only the PRESERVE ROWS option.</p> | <ul style="list-style-type: none">• PRESERVE ROWS (Default): No special action is taken at the ends of transactions. The temporary table and its table data are unchanged.• DELETE ROWS: All rows in the temporary table will be deleted at the end of each transaction block. |

| Parameter | Description | Value Range or Example |
|-----------------------|--|---|
| COMPRESS NOCOMPRESS | If you specify COMPRESS in the CREATE TABLE statement, the compression feature is triggered in the case of a bulk INSERT operation. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored. If NOCOMPRESS is specified, the table is not compressed. | Default value:
NOCOMPRESS , tuple data is not compressed before storage. |
| DISTRIBUTE BY | <p>Specifies how the table is distributed or replicated between DNs.</p> <ul style="list-style-type: none">● REPLICATION: Each row in the table exists on all DNs, that is, each DN has complete table data.● ROUNDROBIN: Each row in the table is sent to each DN in turn. Therefore, data is evenly distributed on each DN. This value is supported only in 8.1.2 or later.● HASH (column_name): Each row of the table will be placed into all the DNs based on the hash value of the specified column. <p>For details about other restrictions, see DISTRIBUTE BY Parameter Description.</p> | <p>Example:
Create a hash-distributed table.</p> <pre>CREATE TABLE test_t2(col1
INT,col2
VARCHAR(30))DISTRIBUTE BY
HASH(col1);</pre> |

| Parameter | Description | Value Range or Example |
|---|--|---|
| TO { GROUP
groupname
NODE
(nodename
[, ...]) } | TO GROUP specifies the Node Group in which the table is created. Currently, it cannot be used for HDFS tables. TO NODE is used for internal scale-out tools. | <p>In logical cluster mode, if TO GROUP is not specified, the table is created in the node group associated with the logical cluster user by default. If the user, such as the administrator or a common user, does not manage the logical cluster, by default the table is created in the first logical cluster, which is the logical cluster with the smallest OID in pgxc_group.</p> <p>If the node group specified by TO GROUP is a replication table node group, the table is created on all CNs and DN, but the replication table data is distributed only on the DN in the replication table node group.</p> <p>The Storage-compute decoupling 3.0 supports read-only logical clusters. If a user is not bound to any read-only logical clusters but sets TO GROUP to a logical cluster in a table creation statement, an error will be reported during table creation. If a user bound to a read-only logical cluster creates a table, the table will be created in the logical cluster specified by the GUC parameter default_storage_nodegroup. If default_storage_nodegroup is set to installation, tables will be created in the first logical cluster.</p> |

| Parameter | Description | Value Range or Example |
|-------------------------------|--|--|
| COMMENT [=]
'text' | The COMMENT clause can specify table comments during table creation. | Example:
Add a comment for a table.
<pre>CREATE TABLE table_user(user_id INT,username VARCHAR(50))
COMMENT 'user Information';</pre> |
| COMMENT 'text' | The COMMENT clause can specify a comment for a column. | Example:
Add a comment for a specified column.
<pre>CREATE TABLE table_users(user_id INT COMMENT 'employee id',username VARCHAR(50));</pre> |
| CONSTRAINT
constraint_name | <p>Specifies a name for a column or table constraint. The optional constraint clauses specify constraints that new or updated rows must satisfy for an insert or update operation to succeed.</p> <p>There are two ways to define constraints:</p> <ul style="list-style-type: none">• A column constraint is defined as part of a column definition, and it is bound to a particular column.• A table constraint is not bound to any particular columns but can apply to more than one column. | Example:
Create the table_c_products table and define the primary key constraint. The primary key of the table consists of C_CUSTKEY and C_NAME .
<pre>CREATE TABLE table_c_products
(
 C_CUSTKEY BIGINT,
 C_NAME VARCHAR(25) ,
 C_ADDRESS VARCHAR(40),
 C_NATIONKEY INT,
 C_PHONE CHAR(15) ,
 C_ACCTBAL DECIMAL(15,2),
 CONSTRAINT C_CUSTKEY_KEY
 PRIMARY
 KEY(C_CUSTKEY,C_NAME)
)
DISTRIBUTE BY
HASH(C_CUSTKEY,C_NAME);</pre> |
| NOT NULL | Indicates that the column is not allowed to contain NULL values. | - |
| NULL | <p>The column is allowed to contain NULL values. This is the default setting.</p> <p>This clause is only provided for compatibility with non-standard SQL databases. You are advised not to use this clause.</p> | - |

| Parameter | Description | Value Range or Example |
|-------------------------|--|---|
| CHECK
(expression) | <p>Specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed. If any row of an insert or update operation produces a FALSE result, an error exception is raised and the insert or update does not alter the database.</p> <p>A check constraint specified as a column constraint should reference only the column's values, while an expression appearing in a table constraint can reference multiple columns.</p> | <p><>NULL and !=NULL are invalid in an expression. Change them to IS NOT NULL.</p> |
| DEFAULT
default_expr | <p>Assigns a default data value for a column.</p> | <p>The value can be any variable-free expressions (Subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.</p> <p>The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is NULL.</p> |

| Parameter | Description | Value Range or Example |
|-----------------------------|--|---|
| ON UPDATE
on_update_expr | <p>The ON UPDATE clause specifies a timestamp function for a column. Ensure that the data type of the column for which the ON UPDATE clause specifies a timestamp function is timestamp or timestamptz.</p> <p>When an SQL statement containing the UPDATE operation is executed, this column is automatically updated to the time specified by the timestamp function.</p> | <p>on_update_expr supports only CURRENT_TIMESTAMP, CURRENT_TIME, CURRENT_DATE, LOCALTIME, and LOCALTIMESTAMP.</p> |

| Parameter | Description | Value Range or Example |
|---|--|---|
| UNIQUE [NULLS
[NOT] DISTINCT
 NULLS IGNORE]
index_parameters

UNIQUE [NULLS
[NOT] DISTINCT
 NULLS IGNORE]
(column_name
[, ...])
index_parameters | <p>Specifies that a group of one or more columns of a table can contain only unique values.</p> <p>The [NULLS [NOT] DISTINCT NULLS IGNORE] field is used to specify how to process null values in the index column of the Unique index.</p> | <p>Default value: This parameter is left empty by default. NULL values can be inserted repeatedly.</p> <p>When the inserted data is compared with the original data in the table, the NULL value can be processed in any of the following ways:</p> <ul style="list-style-type: none">• NULLS DISTINCT: NULL values are unequal and can be inserted repeatedly.• NULLS NOT DISTINCT: NULL values are equal. If all index columns are NULL, NULL values cannot be inserted repeatedly. If some index columns are NULL, data can be inserted only when non-null values are different.• NULLS IGNORE: NULL values are skipped during the equivalent comparison. If all index columns are NULL, NULL values can be inserted repeatedly. If some index columns are NULL, data can be inserted only when non-null values are different. <p>The following table Table 21-148 lists the behaviors of the three processing modes.</p> <p>NOTE
If DISTRIBUTE BY REPLICATION is not specified, the column table that contains only unique values must contain distribution columns.</p> |

| Parameter | Description | Value Range or Example |
|---|--|--|
| PRIMARY KEY
index_parameters
PRIMARY KEY
(column_name
[, ...])
index_parameters | <p>Specifies the primary key constraint specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.</p> <p>Only one primary key can be specified for a table.</p> <p>CAUTION
If DISTRIBUTE BY REPLICATION is not specified, the column set with a primary key constraint must contain distributed columns.</p> | <p>Example:</p> <p>Create the products table, set the data type of product_no to integer and set it as the primary key.</p> <pre>CREATE TABLE products
(product_no integer PRIMARY
KEY,
name text,
price numeric
)
DISTRIBUTE BY
HASH(product_no);</pre> |
| REFERENCES
reftable
[(refcolumn)] | <p>The foreign key constraint requires that the group consisting of one or more columns in the new table should contain and match only the referenced column values in the referenced table. The referenced column should be the only column or primary key in the referenced table.</p> <p>DWS does not check foreign key constraints. When using foreign key constraints, you need to use the check_foreign_key_constraint function to check whether the data in the foreign key table meets the foreign key constraints.</p> | - |
| DEFERRABLE
NOT DEFERRABLE | <p>Controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction using the SET CONSTRAINTS command.</p> | <p>NOT DEFERRABLE is the default value. Currently, only UNIQUE and PRIMARY KEY constraints of row-store tables accept this clause. All the other constraints are not deferrable.</p> |

| Parameter | Description | Value Range or Example |
|--|---|---|
| PARTIAL CLUSTER KEY | Specifies a partial cluster key for storage. When importing data to a column-store table, you can perform local data sorting by specified columns (single or multiple). | Example:
Create the products_new table and define the partial cluster key on the product_no column.
<pre>CREATE TABLE products_new
(
 product_no integer,
 name text,
 price numeric,
 PARTIAL CLUSTER
 KEY(product_no)
) WITH (ORIENTATION =
COLUMN);</pre> |
| INITIALLY IMMEDIATE INITIALLY DEFERRED | If a constraint is deferrable, this clause specifies the default time to check the constraint. | <ul style="list-style-type: none">• If the constraint is INITIALLY IMMEDIATE (default value), it is checked after each statement.• If the constraint is INITIALLY DEFERRED, it is checked only at the end of the transaction.• The constraint check time can be altered using the SET CONSTRAINTS command. |

Table 21-142 WITH parameters (storage-related)

| Parameter | Description | Value Range |
|-------------|--|--|
| ORIENTATION | <p>Specifies the storage mode (row-store, column-store) for table data. This parameter cannot be modified once it is set.</p> <ul style="list-style-type: none">Row-store tables are suitable for OLTP workloads. There are many interactive transactions in such tables. An interaction involves multiple columns in a table.Column-store tables are suitable for data warehouse workloads. There are a large amount of aggregation calculation and few column operations on these tables. | <ul style="list-style-type: none">ROW indicates that table data is stored in rows.COLUMN indicates that the data is stored in columns. <p>Default value: ROW (row-store)</p> <p>NOTE
To create a column-store table, explicitly set orientation to column. When creating a local table in the storage-compute decoupling edition with all data stored on EVS disks, explicitly set colversion to 2.0.</p> |

| Parameter | Description | Value Range |
|---------------|--|--|
| COMPRESSION | Specifies the compression level of the table data. It determines the compression ratio and time. Generally, the higher the level of compression, the higher the ratio, the longer the time, and the lower the level of compression, the lower the ratio, the shorter the time. The actual compression ratio depends on the distribution characteristics of loading table data. | <p>This parameter is available only for column-store tables. Value: LOW (default value), MIDDLE, or HIGH.</p> <p>For details about the compression algorithms provided by DWS, see Table 21-147.</p> <p>NOTE</p> <ul style="list-style-type: none">Currently, row-store table compression is not supported.When migrating data from ORC to DWS column-store tables, low-level compression increases the backup size by 1.5 to 2 times compared to ORC, whereas high-level compression results in a similar backup size. It is crucial to take the conversion relationship into account while setting up a DWS cluster.The middle compression of column-stores uses dictionary compression. For data not suitable for dictionary compression, the file size after middle compression may be greater than that of after low compression. |
| COMPRESSLEVEL | <p>Specifies the compression level of the table data. It determines the compression ratio and time.</p> <p>This divides a compression level into sublevels, providing you with more choices for compression rate and duration. As the value becomes greater, the compression rate becomes higher and duration longer at the same compression level. The parameter is only valid for column-store tables.</p> | <p>0~3</p> <p>Default value: 0</p> |

| Parameter | Description | Value Range |
|----------------------|--|---|
| MAX_BATCHROW | Specifies the maximum of a storage unit during data loading process. The parameter is only valid for column-store tables. | 10000 to 60000
Default value: 60,000 |
| PARTIAL_CLUSTER_ROWS | Specifies the number of records to be partial cluster stored during data loading process. The parameter is only valid for column-store tables. | 600000 to 2147483647
Default value: 4,200,000 |

| Parameter | Description | Value Range |
|------------|---|---|
| COLVERSION | Specifies the version of the column-store format. You can switch between different storage formats. | <ul style="list-style-type: none">• 1.0: Each column in a column-store table is stored in a separate file. The file name is relfilenode.C1.0, relfilenode.C2.0, relfilenode.C3.0, or similar.• 2.0: All columns of a column-store table are combined and stored in a file. The file is named relfilenode.C1.0.• 3.0: Each column of a column-store table is stored in a file. The file is stored in the OBS file system and named C1_fileid.0. <p>Default value: The default value for the storage-compute coupled version is 2.0, while for the storage-compute decoupling version, it is 3.0.</p> <p>The value of COLVERSION can only be set to 2.0 for OBS multi-temperature tables.</p> |

| Parameter | Description | Value Range |
|-----------|-------------|--|
| | | <p>NOTE</p> <ul style="list-style-type: none">For clusters of version 8.1.0, the default value of this parameter is 1.0. For clusters of version 8.1.1 or later, the default value of this parameter is 2.0. If the cluster version is upgraded from 8.1.0 to 8.1.1 or later, the default value of this parameter changes from 1.0 to 2.0.When creating a column-store table, set COLVERSION to 2.0. Compared with the 1.0 storage format, the performance is significantly improved:<ul style="list-style-type: none">The time required for creating a column-store wide table is significantly reduced.In the Roach data backup scenario, the backup time is significantly reduced.The build and catch up time is greatly reduced.The storage-compute decoupling version is compatible with all column-store versions. When creating a table, you need to explicitly set colversion to 1.0, 2.0, or 3.0. If colversion is set to 3.0, a table in decoupled storage and computing mode is created. If colversion is not explicitly specified, a column-store table of version 3.0 is created by default. When creating a table with decoupled storage and compute nodes, set colversion to 3.0 and set orientation to column.V3 storage-compute decoupling tables do not support colversion switching using ALTER TABLE, for example, from 2.0 to 3.0. |

| Parameter | Description | Value Range |
|--|---|---|
| cache_policy
(This parameter is supported only in 9.0.2 and later versions where the storage and compute nodes are decoupled.) | Specifies the cache mode of tables or partitioned tables (disks). If one of the following values is specified in the cache policy, hot cache is used. Otherwise, cold cache is used. Hot cache occupies more space than cold cache and uses more complex replacement policies. | <ul style="list-style-type: none">• ALL: Hot cache is used for the entire table.• NONE: Cold cache is used for the entire table.• HPN: The first <i>N</i> partitions in a partitioned table use hot cache. The rest of the partitions use cold cache.• HPL: <i>P1, P2,</i> In a partitioned table, the specified partitions use hot cache. The rest of the partitions use cold cache. <p>The default value is ALL.</p> <p>NOTE</p> <ul style="list-style-type: none">• For foreign tables and non-partitioned tables, only the ALL and NONE cache policies are supported.• Only range-partitioned and list-partitioned internal tables support HPN and HPL cache policies. |
| enable_disaster_cs_tore | Specifies whether fine-grained DR will be enabled for column-store tables. This parameter is available only for common column-store tables whose COLVERSION is 2.0. It is unavailable for HStore tables, row-store tables, temporary tables, unlogged tables, foreign tables, time series tables, cold and hot tables, materialized views, and delta tables, and cannot be enabled together with enable_hstore and enable_delta . This parameter is supported by version 8.2.0.100 or later clusters. | - |

| Parameter | Description | Value Range |
|---------------------------------------|---|---|
| <code>fine_disaster_table_role</code> | <p>This parameter has been discarded in version 8.2.1 and is reserved for compatibility with earlier versions. This parameter is invalid in the current version.</p> <p>Specifies whether the fine-grained DR table will be set as a primary or secondary table. This parameter can be true only when the enable_disaster_cstore parameter has been set to true.</p> | <ul style="list-style-type: none">• primary: Specifies the primary fine-grained DR table.• standby: Specifies the standby fine-grained DR table. |
| <code>on_commit_preserve_rows</code> | <p>It is similar to ON COMMIT { PRESERVE ROWS DELETE ROWS }. The two parameters cannot be specified at the same time. This parameter is used only for global temporary tables.</p> | The default value is true . |

Table 21-143 WITH parameters (related to partition tables)

| Parameter | Description | Value Range |
|---------------------|---|--|
| <code>TTL</code> | Schedules the partition deletion tasks in a partitioned table. By default, no partition deletion task is created. | 1 hour ~ 100 years |
| <code>PERIOD</code> | Schedules the partition creation tasks in a partitioned table. If TTL has been configured, PERIOD cannot be greater than TTL . | 1 hour ~ 100 years
Default value: 1 day |

| Parameter | Description | Value Range |
|-------------|--|---|
| time_format | You can use auto-increment and decrement partitions for INT4 , INT8 , VARCHAR , and TEXT columns, which are commonly used for storing time-related data. The time_format option is applicable only when the partition key is INT4 , INT8 , VARCHAR , or TEXT and a period is specified. This is supported only by clusters of version 9.1.0.200 or later. | <ol style="list-style-type: none">1. The value of time_format must comply with the PostgreSQL specifications, for example, yyyymmdd.2. Restrictions on time_format differ by partition key type.
VARCHAR/TEXT:<ul style="list-style-type: none">• The precision can be accurate to seconds.• The value cannot contain letters, for example, month, am, and pm.• The time must be arranged in descending order, for example, year, month, day, hour, minute, and second.INT4/INT8:<ul style="list-style-type: none">• The precision can be accurate to hours.• The value can contain only Y, M, D, and HH24.• The time must be arranged in descending order, for example, year, month, day, and hour.3. ALTER restrictions:<ul style="list-style-type: none">• The set operation is not supported.• When period is reset (indicating that automatic partitioning is disabled and a message is displayed), you can reset this option. |

Table 21-144 WITH parameters (related to the Delta table)

| Parameter | Description | Value Range |
|------------------------|--|---|
| enable_delta | Specifies whether to enable delta tables in column-store tables. The parameter is only valid for column-store tables. If COLVERSION is set to 3.0 , enable_delta cannot be turned on because this parameter is not supported by V3 tables.

Using column-store tables with delta tables is not recommended. This may cause disk bloat and performance deterioration due to delayed merge. | Default value: off |
| DELTAROW_THRE
SHOLD | Specifies the upper limit of to-be-imported rows for triggering the data import to a delta table when data is to be imported to a column-store table. This parameter takes effect only if the enable_delta table parameter is set to on . The parameter is only valid for column-store tables. | 0 to 60000
Default value: 6000 |

Table 21-145 WITH parameters (related to Hstore tables)

| Parameter | Description | Value Range |
|---------------|--|--|
| enable_hstore | Specifies whether an HStore table will be created (based on column-store tables). The parameter is only valid for column-store tables. This parameter is supported by version 8.2.0.100 or later clusters. If COLVERSION is set to 3.0 , enable_delta cannot be turned on because this parameter is not supported by V3 tables. | Default value: off
NOTE
If this parameter is enabled, the following GUC parameters must be set to ensure that H-Store tables are cleared.

Set autovacuum to on , autovacuum_max_workers to 6 , and autovacuum_max_workers_hstore to 3 . |

| Parameter | Description | Value Range |
|-----------------------|--|--|
| enable_hstore_opt | If the enable_hstore_opt table-level parameter is enabled, the enable_hstore table-level parameter is also enabled by default. This parameter is supported only in cluster 8.3.0 and later versions. | Default value: false |
| secondary_part_column | Specifies the name of a level-2 partition column in a column-store table. Only one column can be specified as the level-2 partition column. This parameter applies only to HStore column-store tables. This parameter is supported only by clusters of version 8.3.0 or later. | <ul style="list-style-type: none">• The column specified as a level-2 partition column cannot be deleted or modified.• The level-2 partition column can be specified only when a table is created. After a table is created, the level-2 partition column cannot be modified.• You are not advised to specify a distribution column as a level-2 partition column.• The level-2 partition column determines how the table is logically split into hash partitions on DNs, which enhances the query performance for that column. |
| secondary_part_num | Specifies the number of level-2 partitions in a column-store table. This parameter applies only to HStore column-store tables. This parameter is supported only by clusters of version 8.3.0 or later. | 1~32
Default value: 8
NOTICE <ul style="list-style-type: none">• This parameter can be specified only when secondary_part_column is specified.• The number of level-2 partitions can be specified only when a table is created and cannot be modified after the table is created.• You are not advised to change the default value, which may affect the import and query performance. |

| Parameter | Description | Value Range |
|----------------|---|-------------|
| bitmap_columns | The bitmap index is only applicable to the new HStore (hstore_opt) tables. To generate the bitmap index mapping, you need to enable the enable_hstore_opt table-level parameter and set bitmap_columns to Specified Columns . This parameter is supported only by clusters of version 8.3.0 or later. | - |

Table 21-146 WITH parameters (other performance-related parameters)

| Parameter | Description | Value Range |
|------------|---|-------------|
| FILLFACTOR | The fillfactor of a table is a percentage between 10 and 100. 100 (complete packing) is the default value. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose records are never updated, setting the fillfactor to 100 (complete packing) is the appropriate choice, but in heavily updated tables smaller fillfactors are appropriate. The parameter has no meaning for column-store tables. | 10~100 |

| Parameter | Description | Value Range |
|---------------------|---|--|
| analyze_mode | Specifies the mode of table-level auto-analyze. | <ul style="list-style-type: none">• frozen: disables all ANALYZE operations (dynamic sampling can still be triggered when no statistics are collected).• backend: allows only ANALYZE triggered by AUTOVACUUM polling.• runtime: allows only runtime ANALYZE triggered by the optimizer.• all: Both backend and runtime AUTO-ANALYZE can be triggered. Default value: all |
| incremental_analyze | Specifies whether to enable the incremental analyze mode for partitioned tables. This parameter is valid only for partitioned tables and cannot be set for replicated tables. This is supported only by clusters of version 9.1.0.100 or later. | Default value: false |

| Parameter | Description | Value Range |
|--------------------|--|--|
| enable_turbo_store | <p>Determines whether to create a turbo table (column-store tables). The parameter is only valid for column-store tables. It is available only for clusters of versions 9.1.0.100 and later.</p> <p>NOTE</p> <ul style="list-style-type: none">Common column-store tables in version 3.0 do not support the turbo storage format, while HStore Opt tables in version 3.0 only support the turbo storage format.In version 2.0, there is no restriction on column-store tables.Currently, turbo tables do not support time series tables, delta tables, or lightweight update. | <p>Default value: off</p> <p>NOTE</p> <p>Turbo tables enhance the storage efficiency of numeric and varchar data types using the integers, leading to accelerated processing speeds for these types.</p> <ul style="list-style-type: none">For enhanced performance, it is advised to define the numeric type with precision and scale (p, s). The storage allocation is as follows:
For $p \leq 9$, 4-byte integers are used for storage. For $p \leq 18$, 8-byte integers are used. For $p \leq 37$, 16-byte integers are used. If $p > 37$ or remain unspecified, a variable-length format is used, which is less space-efficient and yields suboptimal performance.If the maximum length (n) of the varchar type is less than or equal to 2 bytes, 2-byte integers are used for storage. If the maximum length (n) of the varchar type is less than or equal to 4 bytes, 4-byte integers are used for storage. If the maximum length (n) of the varchar type is less than or equal to 16 bytes, 16-byte integers are used for storage. Limit VARCHAR columns in GROUP BY or HASH JOIN operations to 16 bytes or less to enable faster integer-based storage and improve performance. |

| Parameter | Description | Value Range |
|----------------------------------|--|---|
| SKIP_FPI_HINT | Indicates whether to skip the hint bits operation when the full-page writes (FPW) log needs to be written during sequential scanning. | Default value: false
NOTE
If SKIP_FPI_HINT is set to true and the checkpoint operation is performed on a table, no Xlog will be generated when the table is sequentially scanned. This applies to intermediate tables that are queried less frequently, reducing the size of Xlogs and improving query performance. |
| enable_column_autovacuum_garbage | Determines whether to enable CU rewriting logic for column-store tables using AUTOVACUUM. This parameter is supported only by clusters of version 8.2.1.100 or later.

There is a low probability that an error is reported when lightweight UPDATE and AUTOVACUUM are executed concurrently. You can set the table-level parameter to off to avoid this problem. | Default value: true |

Table 21-147 Compression algorithms for column-based storage

| COMPRESSION | NUMERIC | STRING | INT |
|-------------|--|--------------------------------------|---|
| LOW | Delta compression + RLE compression | LZ4 compression | Delta compression (RLE is optional.) |
| MIDDLE | Delta compression + RLE compression + LZ4 compression | dict compression or LZ4 compression | Delta compression or LZ4 compression (RLE is optional) |
| HIGH | Delta compression + RLE compression + zlib compression | dict compression or zlib compression | Delta compression or zlib compression (RLE is optional) |

Table 21-148 Processing of NULL values in index columns in unique indexes

| Constraint | All Index Columns Are NULL | Some Index Columns Are NULL. |
|--------------------|--------------------------------|--|
| NULLS DISTINCT | Can be inserted repeatedly. | Can be inserted repeatedly. |
| NULLS NOT DISTINCT | Cannot be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |
| NULLS IGNORE | Can be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |

TEMPORARY | TEMP Parameter Description

- Local or volatile temporary tables are visible to the current session through schema of the **pg_temp** start. Users should not delete schema started with **pg_temp**, **pg_toast_temp**.
- If **TEMPORARY** or **TEMP** is not specified when you create a table and the schema of the specified table starts with **pg_temp_**, the table is created as a temporary table.
- Similar to common tables, all metadata of local temporary tables is stored in system catalogs. Volatile temporary tables store table structure metadata in memory, except the schema metadata. Compared with local temporary tables, volatile temporary tables have the following constraints:
 - After a CN or DN is restarted, data in its memory will be lost, and accordingly, volatile temporary tables on it will become invalid.
 - Currently, volatile temporary tables do not support table structure modification, such as **ALTER** and **GRANT**.
 - Volatile temporary tables and local temporary tables share temporary schemas. Therefore, in the same session, the **VOLATILE** temporary table and local temporary table cannot have the same name.
 - Volatile temporary table information is not stored in system catalogs. Therefore, Volatile metadata cannot be queried by running DML statements in system catalogs.
 - Volatile temporary tables support only common row-store and column-store tables. Delta tables, time series tables, and cold and hot tables are not supported.
 - Views cannot be created based on volatile temporary tables.
 - A tablespace cannot be specified when a temporary table is created. The default tablespace of a volatile temporary table is **pg_volatile**.

- The following constraints cannot be specified when a volatile temporary table is created: CHECK, UNIQUE, PRIMARY KEY, TRIGGER, EXCLUDE, and PARTIAL CLUSTER.
- Similar to common tables, all metadata in global temporary tables is stored in system catalogs.
 - The difference between a global temporary table and a local temporary table is that in a global temporary table, the metadata is not deleted when a session exits, but the session data is deleted. Data of different sessions is independent but shares the metadata of the same global temporary table.
 - A global temporary table has a schema that is similar to a regular table, unlike a local or volatile temporary table which has a schema starting with **pg_temp**. This means that a global temporary table can have the same name as a local or volatile temporary table.
 - Global temporary tables support only common row-store and column-store tables. Delta tables, time series tables, and cold and hot tables are not supported.
 - Operations cannot be performed on global temporary tables of other logical clusters.

LIKE Parameter Description

The new table and the source table are decoupled after creation is complete. Changes to the source table will not be applied to the new table, and it is not possible to include data of the new table in scans of the source table.

Columns and constraints copied by **LIKE** are not merged with the same name. If the same name is specified explicitly or in another **LIKE** clause, an error is reported.

- The default expressions or the **ON UPDATE** expressions are copied from the source table to the new table only if **INCLUDING DEFAULTS** is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having default values **NULL**.
- The **CHECK** constraints are copied from the source table to the new table only when **INCLUDING CONSTRAINTS** is specified. Other types of constraints are never copied to the new table. **NOT NULL** constraints are always copied to the new table. These rules also apply to column constraints and table constraints.
- Any indexes on the source table will not be created on the new table, unless the **INCLUDING INDEXES** clause is specified.
- **STORAGE** settings for the copied column definitions are copied only if **INCLUDING STORAGE** is specified. The default behavior is to exclude **STORAGE** settings.
- If **INCLUDING COMMENTS** is specified, comments for the copied columns, constraints, and indexes are copied. The default behavior is to exclude comments.
- If **INCLUDING PARTITION** is specified, the partition definitions of the source table are copied to the new table, and the new table no longer uses the **PARTITION BY** clause. The default behavior is to exclude partition definition of the source table.

- If **INCLUDING REOPTIONS** is specified, the storage parameter (**WITH** clause of the source table) of the source table is copied to the new table. The default behavior is to exclude partition definition of the storage parameter of the source table.

 NOTE

PERIOD and **TTL** in the **WITH** clause are partition-related parameters. **LIKE INCLUDING REOPTIONS** will not be copied to the new table. To copy **LIKE INCLUDING REOPTIONS**, use **INCLUDING PARTITION**.

- If **INCLUDING DISTRIBUTION** is specified, the distribution information of the source table is copied to the new table, including distribution type and column, and the new table no longer use the **DISTRIBUTE BY** clause. The default behavior is to exclude distribution information of the source table.
- If **INCLUDING DROPCOLUMNS** is specified, the deleted column information in the source table is copied to the new table. By default, the deleted column information of the source table is not copied.
- **INCLUDING ALL** contains the meaning of **INCLUDING DEFAULTS**, **INCLUDING CONSTRAINTS**, **INCLUDING INDEXES**, **INCLUDING STORAGE**, **INCLUDING COMMENTS**, **INCLUDING PARTITION**, **INCLUDING REOPTIONS**, **INCLUDING DISTRIBUTION**, and **INCLUDING DROPCOLUMNS**.
- If **EXCLUDING** is specified, the specified parameters are not included.
- For an OBS multi-temperature table, all partitions of the new table are local hot partitions after **INCLUDING PARTITION** is specified.
- If **ALTER TABLE...ADD PARTITION** and **CREATE TABLE** are both executed for the source table, the number of partitions on different nodes may be inconsistent occasionally. As a result, an error is reported during the execution of **CREATE TABLE**. You are advised to execute **CREATE TABLE** again.

NOTICE

- If the source table contains a sequence with the **SERIAL**, **BIGSERIAL**, or **SMALLSERIAL** data type, or a column in the source table is a sequence by default and the sequence is created for this table by using **CREATE SEQUENCE... OWNED BY**, these sequences will not be copied to the new table, and another sequence specific to the new table will be created. This is different from earlier versions. To share a sequence between the source table and new table, create a shared sequence (do not use **OWNED BY**) and set a column in the source table to this sequence.
 - You are not advised to set a column in the source table to the sequence specific to another table especially when the table is distributed in specific node groups, because doing so may result in **CREATE TABLE ... LIKE** execution failures. In addition, doing so may cause the sequence to become invalid in the source sequence because the sequence will also be deleted from the source table when it is deleted from the table that the sequence is specific to. To share a sequence among multiple tables, you are advised to create a shared sequence for them.
-

DISTRIBUTE BY Parameter Description

Specifies how the table is distributed or replicated between DN.

Valid value:

- **REPLICATION**: Each row in the table exists on all DN, that is, each DN has complete table data.
- **ROUNDROBIN**: Each row in the table is sent to each DN in turn. Therefore, data is evenly distributed on each DN. This value is supported only in 8.1.2 or later.
- **HASH (column_name)**: Each row of the table will be placed into all the DN based on the hash value of the specified column.

NOTE

- When **DISTRIBUTE BY HASH (column_name)** is specified, the primary key and its unique index must contain the **column_name** column.
- When **DISTRIBUTE BY HASH (column_name)** in a referenced table is specified, the foreign key of the reference table must contain the **column_name** column.
- If **TO GROUP** is set to a replication table node group (supported in 8.1.2 or later), **DISTRIBUTE BY** must be set to **REPLICATION**. If **DISTRIBUTE BY** is not specified, the created table is automatically set as a replication table.

Default value: determined by the GUC parameter **default_distribution_mode**

- When **default_distribution_mode** is set to **roundrobin**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation, round-robin distribution is selected.
- When **default_distribution_mode** is set to **hash**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation but there are columns whose data types can be used as distribution columns, hash distribution is selected. The distribution column is the first column whose data type can be used as a distribution column.
 - c. If the primary key or unique constraint is not included during table creation and no column whose data type can be used as a distribution column exists, round-robin distribution is selected.

The following data types can be used as distribution columns:

- Integer types: **TINYINT**, **SMALLINT**, **INT**, **BIGINT**, and **NUMERIC/DECIMAL**
- Character types: **CHAR**, **BPCHAR**, **VARCHAR**, **VARCHAR2**, **NVARCHAR2**, and **TEXT**
- Date/time types: **DATE**, **TIME**, **TIMETZ**, **TIMESTAMP**, **TIMESTAMPTZ**, **INTERVAL**, and **SMALLDATETIME**

 NOTE

When you create a table, the choices of distribution keys and partition keys have major impact on SQL query performance. Therefore, choosing proper distribution column and partition key with strategies.

- Selecting an Appropriate Distribution Column

In the data distributed table using Hash, an appropriate distributed array should be used to distribute and store data on multiple DNs evenly, preventing data skew (uneven data distribution across several DNs). Determine the proper distribution column based on the following principles:

1. Determine whether data is skewed.

Connect to the database and run the following statements to check the number of tuples on each DN: Replace *tablename* with the actual name of the table to be analyzed.

```
SELECT a.count,b.node_name FROM (SELECT count(*) AS count,xc_node_id FROM
tablename GROUP BY xc_node_id) a, pgxc_node b WHERE a.xc_node_id=b.node_id ORDER
BY a.count DESC;
```

If tuple numbers vary greatly (several times or tenfold) in each DN, a data skew occurs. Change the data distribution key based on the following principles:

2. Run the ALTER TABLE statement to adjust the distribution column. The rules for selecting a distribution column are as follows:

The column value of the distribution column should be discrete so that data can be evenly distributed on each DN. For example, you are advised to select the primary key of a table as the distribution column, and the ID card number as the distribution column in a personnel information table.

With the above principles met, you can select join conditions as distribution keys so that join tasks can be pushed down to DNs, reducing the amount of data transferred between the DNs.

3. If a proper distribution column cannot be found to make data evenly distributed on each DN, you can use the **REPLICATION** or **ROUNDROBIN** data distribution mode. The **REPLICATION** data distribution mode stores complete data on each DN. Therefore, if a table is large and no proper distribution column can be found, the **ROUNDROBIN** data distribution mode is recommended. The **ROUNDROBIN** data distribution mode is supported in 8.1.2 or later.

- Selecting appropriate partition keys

In range partitioning, the table is partitioned into ranges defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. Each range has a dedicated partition for data storage.

Modify partition keys to make the query result stored in the same or least partitions (partition pruning). Obtaining consecutive I/O to improve the query performance.

In actual services, time is used to filter query objects. Therefore, you can use time as a partition key, and change the key value based on the total data volume and single data query volume.

Example: Creating a Storage-Compute Coupled Table

Create the **test_t4** table.

```
CREATE TABLE IF NOT EXISTS test_t4 ( ---Create a table when there are no test_t4 tables in the database.
col_id INT PRIMARY KEY, ---Define an INTEGER column and set it as the primary key.
col_number INT NOT NULL, ---Define an INTEGER column and set it to not null.
col_date DATE NOT NULL, --- Define a DATE column and set it to non-null.
col_price NUMERIC(10,2), ---Define a NUMERIC column. The maximum number of integer digits is 10,
and the maximum number of decimal places is 2.
col_status TEXT ---Define a TEXT column.
)
WITH (ORIENTATION = COLUMN,COLVERSION=2.0,COMPRESSION=middle) --- Set the storage method of
a table to column storage and the compression level to MIDDLE.
```

```
DISTRIBUTE BY HASH (col_id)      ---Use hash distribution.  
COMMENT 'order information for test_table4'; ---Comment a table.
```

Example: Creating a Storage-Compute Decoupled V3 Table

Create a V3 table (**test_t5**) with decoupled storage and compute (supported only in the storage-compute decoupling 3.0 version).

```
CREATE TABLE test_t5  
(  
  id integer not null,  
  data integer,  
  age integer  
)  
WITH (ORIENTATION =COLUMN, COLVERSION =3.0)  
DISTRIBUTE BY ROUNDROBIN;
```

Specify the cache policy when creating a table (supported only in the storage-compute decoupling 3.0 version).

```
CREATE TABLE sports  
(  
  N_NATIONKEY INT NOT NULL  
  , N_NAME CHAR(25) NOT NULL  
  , N_REGIONKEY INT NOT NULL  
  , N_COMMENT VARCHAR(152)  
) WITH (orientation = column, colversion = 3.0, cache_policy = 'HPL: Balls, Basketball')  
tablespace cu_obs_tbs  
DISTRIBUTE BY ROUNDROBIN  
partition by list(N_NAME)  
(  
  partition Balls values ('Basketball', 'football', 'badminton'),  
  partition Athletics values ('High jump', 'long jump', 'javelin'),  
  partition Water_Sports values ('Surfing', 'diving', 'swimming'),  
  partition Shooting values ('air guns', 'Rifles', 'archery'),  
  partition rest values (DEFAULT)  
);
```

Example: Defining Constraints When Creating a Table

Define **PRIMARY KEY** constraints for one or more columns of a table.

```
CREATE TABLE CUSTOMER  
(  
  C_CUSTKEY BIGINT ,  
  C_NAME VARCHAR(25) ,  
  C_ADDRESS VARCHAR(40) ,  
  C_NATIONKEY INT ,  
  C_PHONE CHAR(15) ,  
  C_ACCTBAL DECIMAL(15,2) ,  
  CONSTRAINT C_CUSTKEY_KEY PRIMARY KEY(C_CUSTKEY,C_NAME)  
)  
DISTRIBUTE BY HASH(C_CUSTKEY,C_NAME);
```

Define a **UNIQUE** constraint for a table.

```
CREATE TABLE CUSTOMER  
(  
  C_CUSTKEY BIGINT NOT NULL CONSTRAINT C_CUSTKEY_pk PRIMARY KEY,  
  C_NAME VARCHAR(25) ,  
  C_ADDRESS VARCHAR(40) ,  
  C_NATIONKEY INT ,  
  C_PHONE CHAR(15) ,  
  C_ACCTBAL DECIMAL(15,2)  
)  
DISTRIBUTE BY HASH(C_CUSTKEY);
```

Define a **CHECK** constraint for a table.

```
CREATE TABLE CUSTOMER
(
  C_CUSTKEY BIGINT NOT NULL CONSTRAINT C_CUSTKEY_pk PRIMARY KEY,
  C_NAME VARCHAR(25) ,
  C_ADDRESS VARCHAR(40) ,
  C_NATIONKEY INT ,
  CONSTRAINT C_CUSTKEY_KEY2 CHECK(C_CUSTKEY > 0 AND C_NAME <> '')
)
DISTRIBUTE BY HASH(C_CUSTKEY);
```

Define a **CHECK** constraint for a column.

```
CREATE TABLE CUSTOMER
(
  C_CUSTKEY BIGINT NOT NULL CONSTRAINT C_CUSTKEY_pk PRIMARY KEY ,
  C_NAME VARCHAR(25) ,
  C_ADDRESS VARCHAR(40) ,
  C_NATIONKEY INT NOT NULL CHECK (C_NATIONKEY > 0)
)
DISTRIBUTE BY HASH(C_CUSTKEY);
```

Use **DEFAULT** to declare the default value **GA** for the column **col_STATE**.

```
CREATE TABLE test_t5
(
  col_SK INTEGER NOT NULL,
  col_ID CHAR(16) NOT NULL,
  colE_NAME VARCHAR(20) UNIQUE DEFERRABLE,
  col_WAREHOUSE INTEGER,
  col_COUNTY VARCHAR(30),
  col_STATE CHAR(2) DEFAULT 'GA',
  col_ZIP CHAR(10)
);
```

Example: Creating a Column-Store Table and Specifying the Compression Level

Create the column-store table **customer_address** and set the data compression level to **HIGH**.

```
CREATE TABLE customer_address
(
  ca_address_sk INTEGER NOT NULL ,
  ca_address_id CHARACTER(16) NOT NULL ,
  ca_street_number CHARACTER(10) ,
  ca_street_name CHARACTER varying(60) ,
  ca_street_type CHARACTER(15) ,
  ca_suite_number CHARACTER(10)
)
WITH (ORIENTATION = COLUMN, COMPRESSION=HIGH,COLVERSION=2.0)
DISTRIBUTE BY HASH (ca_address_sk);
```

Example: Using CREATE TABLE LIKE to Create a Table

Use CREATE TABLE LIKE to quickly copy the schema of the existing table **test_t6** and create the table **test_t7**.

```
CREATE TABLE IF NOT EXISTS test_t6
(
  col_id INT PRIMARY KEY,
  col_number INT NOT NULL,
  col_date DATE NOT NULL,
  col_price NUMERIC(10,2),
  col_status TEXT
)
WITH (ORIENTATION = COLUMN, COMPRESSION=middle)
```

```
DISTRIBUTE BY HASH (col_id);  
CREATE TABLE test_t7 (LIKE test_t6 INCLUDING ALL);
```

21.13.4.2 CREATE TABLE PARTITION

Function

CREATE TABLE PARTITION creates a partitioned table. A partitioned table is a logical table that is divided into segments, called partitions whose data is stored on different physical blocks.

Common partitioning strategies define data ranges based on one or more columns. Each partition stores data within a range. These columns are called partition keys.

Currently, DWS row-store and column-store tables support range partitioning and list partitioning.

- Range partitioning
A table is partitioned into ranges defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. Each range has a dedicated partition for data storage.
 - Core feature: Data is distributed by consecutive intervals. It is used in scenarios where data is ordered and retrieved by range.
 - Scenario: Partition keys increase linearly or have continuous intervals. Data query is usually performed around a certain range, and new data naturally falls into a new range. For example, data about orders is partitioned by time range, and data about user levels is partitioned by value range.
 - Range partitioning maps data to partitions based on ranges of values of the partitioning key that you establish for each partition. This is the most commonly used partitioning policy. Currently, range partitioning only allows the use of the range partitioning policy.
- List partitioning
List partitioning allocates records to partitions based on the key values in each partition. The key values do not overlap in different partitions. Each set of key values gets its own partition for storing related data. List partitioning is supported only by clusters of version 8.1.3 or later.
 - Core feature: Data is divided based on discrete enumerated values, which are used as fixed classification category or high-frequency filter criteria.
 - Scenario: Partition key values are fixed and discrete. Data query is usually based on a certain category, and key values do not increase irregularly. For example, the user information table is partitioned by province, and each province corresponds to a partition.
 - In list partitioning, data is mapped to a created partition based on the partition key value. If the data can be mapped to, it is inserted into the specific partition. If it cannot be mapped to, error messages are returned.

Major Differences Between Range Partitioning and List Partitioning

Table 21-149 Range partitioning and list partitioning

| Dimension | Range Partitioning | List Partitioning |
|--------------------|---|---|
| Data distribution | Continuous range (time and value) | Discrete enumerations values (classification and status) |
| Query optimization | Range filter (BETWEEN, >, <) | Exact match (= and IN) |
| Scenario | Ranges need to be added or deleted regularly (for example, rolling by month). | Fixed categories need to be maintained (such as regions and types). |
| Typical Case | Log, time series, and numeric archiving | Regional division, status isolation, and multi-tenant data |

Advantages of Partitioning

- The performance of some types of queries can be greatly improved, especially when rows with high access rates in a table are located in a single partition or a few partitions. Partitioning narrows the range of data search and improves data access efficiency.
- When queries or updates access a large percentage of a single partition, performance can be improved by taking advantage of sequential scan of that partition instead of reads scattered across the whole table.
- Bulk loads and deletion can be performed by adding or removing partitions, if that requirement is planned into the partitioning design. It also entirely avoids the **VACUUM** overhead caused by a bulk **DELETE** (only for range partitioning).
- Generally, if there are more than 10 million rows of data on a single DN, you are advised to create a partitioned table and ensure that the data volume on a single DN ranges from 1 million to 10 million.

Precautions

- A single table can have up to 32,767 partitions with a total of 32,767 boundary values. For better performance, keep this value at or below 1,000.
- A partitioned table supports unique and primary key constraints. The constraint keys of these constraints contain all partition keys.

Syntax

```
CREATE TABLE [ IF NOT EXISTS ] partition_table_name  
( [  
    { column_name data_type [ COLLATE collation ] [ column_constraint [ ... ] ]  
    | table_constraint
```

```
| LIKE source_table [ like_option [...] ] [, ... ]  
] )  
[ WITH ( {storage_parameter = value} [, ...] ) ]  
[ COMPRESS | NOCOMPRESS ]  
[ DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { [ HASH ] ( column_name ) } } ]  
[ TO { GROUP groupname | NODE ( nodename [, ...] ) } ]  
PARTITION BY {  
    {VALUES (partition_key)} |  
    {RANGE (partition_key) ( partition_less_than_item [, ...] ) } |  
    {RANGE (partition_key) ( partition_start_end_item [, ...] ) } |  
    {LIST (partition_key) (list_partition_item [, ...])}  
} [ { ENABLE | DISABLE } ROW MOVEMENT ];
```

CREATE TABLE PARTITION Main Clause Parameters

Table 21-150 CREATE TABLE PARTITION main clause parameters

| Parameter | Description | Value Range or Example |
|----------------------|--|--|
| IF NOT EXISTS | Does not throw an error if a table with the same name exists. A notice is issued in this case. | - |
| partition_table_name | Name of the partitioned table | A string, which must comply with the naming convention. For details, see Identifier Naming Conventions . |
| column_name | Specifies the name of a column to be created in the new table. | A string, which must comply with the naming convention. For details, see Identifier Naming Conventions . |
| data_type | Specifies the data type of the column. | - |

| Parameter | Description | Value Range or Example |
|-------------------|---|--|
| COLLATE collation | <p>The COLLATE clause defines the collation rule of a column. The supported data types include char, varchar, text, nchar, and nvarchar. The collation rule significantly impacts the sequence of query results, particularly when using SELECT ... ORDER BY. If no collation rule is specified, the default collation rule C (case-sensitive) is used.</p> <p>Common collation rules:</p> <ul style="list-style-type: none">• C: The collation uses the byte order of the binary code and is sensitive to case, accents, and special characters. Data can indeed be compared based on its ASCII code values.• case_insensitive: The collation is case-insensitive. It is supported by clusters of version 8.1.3.x or later.• en_US.utf8: The collation uses the American English with a UTF-8 encoding and is case insensitive. <p>You can query collation rules supported by DWS from the PG_COLLATION system catalog.</p> <pre>SELECT * FROM pg_collation;</pre> <p>To check the default collation rule of the current database, run the following statement:</p> <pre>SELECT pg_database.datcollate AS current_collation FROM pg_catalog.pg_database WHERE pg_database.datname = pg_catalog.current_database();</pre> | <p>A case-insensitive collation rule for the values of a column</p> <pre>CREATE TABLE t1 (a text collate case_insensitive); INSERT INTO t1 values('a'),('A'), ('b'),('B'); SELECT a, a='a' FROM t1;</pre> <p>The following figure shows that A and a are equivalent.</p>  |

| Parameter | Description | Value Range or Example |
|--|--|---|
| CONSTRAINT
constraint_name | <p>Specifies a name for a column or table constraint. The optional constraint clauses specify constraints that new or updated rows must satisfy for an insert or update operation to succeed.</p> <p>There are two ways to define constraints:</p> <ul style="list-style-type: none">• A column constraint is defined as part of a column definition, and it is bound to a particular column.• A table constraint is not bound to any particular columns but can apply to more than one column. | For details about the supported constraints, see Table 21-151 . |
| LIKE source_table
[like_option ...] | Specifies a table from which the new table automatically copies all column names, their data types, and their not-null constraints. | For details about the supported constraints, see LIKE Parameters . |
| WITH | Specifies an optional storage parameter for a table or an index. | For details about the supported WITH parameters, see Table 21-152 . |
| COMPRESS /
NOCOMPRESS | Specifies the keyword COMPRESS during the creation of a table, so that the compression feature is triggered in the case of a bulk INSERT operation. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored. If NOCOMPRESS is specified, the table is not compressed. | Default value: NOCOMPRESS , tuple data is not compressed before storage. |

| Parameter | Description | Value Range or Example |
|---|--|---|
| DISTRIBUTE BY | Specifies how the table is distributed or replicated between DNs. | <ul style="list-style-type: none">• REPLICATION: Each row in the table exists on all DNs, that is, each DN has complete table data.• ROUNDROBIN: Each row in the table is sent to each DN in turn. Therefore, data is evenly distributed on each DN. This value is supported only in 8.1.2 or later.• HASH (column_name): Each row of the table will be placed into all the DNs based on the hash value of the specified column. <p>For details about other restrictions, see DISTRIBUTE BY Parameter Description.</p> <p>CAUTION</p> <ul style="list-style-type: none">• When DISTRIBUTE BY HASH (column_name) is specified, the primary key and its unique index must contain the column_name column.• When DISTRIBUTE BY HASH (column_name) in a referenced table is specified, the foreign key of the reference table must contain the column_name column. |
| TO { GROUP groupname NODE (nodename [, ...]) } | TO GROUP specifies the Node Group in which the table is created. Currently, it cannot be used for HDFS tables. TO NODE is used for internal scale-out tools. | - |

| Parameter | Description | Value Range or Example |
|-----------------------------------|--|--|
| { ENABLE DISABLE } ROW MOVEMENT | <p>Specifies whether to relocate a row within a table. If the new value of a partition key in a row belongs to another partition, an error message is displayed or the row is moved to the corresponding partition.</p> <ul style="list-style-type: none">• ENABLE: The row is moved to the corresponding partition. If partition keys are frequently updated, enable this parameter.• DISABLE: The row is not moved to the corresponding partition. If partition keys are updated, an error is reported. If data cross-partition update is strictly prohibited, disable this parameter. <p>The default value is DISABLE.</p> <p>Suggestions:</p> <ul style="list-style-type: none">• Scenario: To enable row movement, you need to change partition key values through UPDATE operations and can accept its impact on performance.• Performance: Enabling row movement will increase the overhead of UPDATE operations. Exercise caution when enabling this parameter in high-concurrency scenarios.• Alternative solution: If you need to frequently adjust the partition ownership, delete the original row and then insert a new row, or exchange partitions. | <p>The date column (partition key) of a partitioned table is partitioned by quarter into p_2023q1 and p_2023q2. The value 2023-02-15 of a row belongs to the partition p_2023q1 in the first quarter. After the value is updated to 2023-05-15, you can configure ROW MOVEMENT to determine whether to move the data in this row.</p> <ul style="list-style-type: none">• ENABLE: The row movement is enabled. The data is moved to the new partition p_2023q2.• DISABLE: The row movement is disabled. The system reports an error. <p>For details about examples, see Examples: Enabling and Disabling ROW MOVEMENT.</p> |

| Parameter | Description | Value Range or Example |
|-----------|---|------------------------|
| | CAUTION
To enable cross-partition update, you need to enable row movement. However, if SELECT FOR UPDATE is executed concurrently to query the partitioned table, the query results may be inconsistent. Therefore, exercise caution when performing this operation. | |

CONSTRAINT constraint_name Parameter

```
{ NOT NULL |  
  NULL |  
  CHECK ( expression ) |  
  DEFAULT default_expr |  
  UNIQUE [ NULLS [NOT] DISTINCT | NULLS IGNORE ] index_parameters |  
  PRIMARY KEY index_parameters }  
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

Table 21-151 CONSTRAINT constraint_name parameters

| Parameter | Description | Value Range or Example |
|-----------|--|------------------------|
| NOT NULL | Specifies that the column is not allowed to contain NULL values. | - |
| NULL | Specifies that the column can store NULL values. This is the default. This clause is only provided for compatibility with non-standard SQL databases. You are advised not to use this clause. | - |

| Parameter | Description | Value Range or Example |
|--|--|---|
| CHECK
(condition) [NO
INHERIT] | <p>Specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE or UNKNOWN succeed, or an error is reported and the execution fails.</p> <p>A check constraint specified as a column constraint should reference only the column's values, while an expression appearing in a table constraint can reference multiple columns.</p> <p>A constraint marked with NO INHERIT will not propagate to child tables.</p> | <p>Single-column constraints:</p> <p>The price must be a positive number.</p> <pre>CREATE TABLE products (
 product_id INT,
 price DECIMAL(10,2) CHECK
 (price > 0),
 discount DECIMAL(3,2));</pre> <p>Insert a data record where the price is a negative number.</p> <pre>INSERT INTO products
(product_id, price, discount)
VALUES (2, -10.00, 1.1);</pre> <p>The constraint is violated, so an error is reported and the insertion fails.</p> <pre>ERROR: dn_6003_6004: new row
for relation "products" violates
check constraint
"products_price_check"</pre> <p>Table constraints (on multiple columns):</p> <p>Create an inventory table with two columns available and reserved. One column indicates available quantity and the other column indicates reserved quantity. The available quantity must be greater than or equal to the reserved quantity.</p> <pre>CREATE TABLE inventory (
 item_id INT PRIMARY KEY,
 quantity_on_hand INT,
 quantity_reserved INT,
 CHECK (quantity_on_hand >=
 quantity_reserved));</pre> |

| Parameter | Description | Value Range or Example |
|-------------------------|--|------------------------|
| DEFAULT
default_expr | <p>Assigns a default data value for a column. The value can be any variable-free expressions (Subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column.</p> <p>The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is NULL.</p> | - |

| Parameter | Description | Value Range or Example |
|--|--|---|
| UNIQUE [NULLS [NOT] DISTINCT NULLS IGNORE]
index_parameters

UNIQUE [NULLS [NOT] DISTINCT NULLS IGNORE]
(column_name [, ...])
index_parameters | <p>Specifies that a group of one or more columns of a table can contain only unique values.</p> <p>The [NULLS [NOT] DISTINCT NULLS IGNORE] field is used to specify how to process null values in the index column of the Unique index.</p> | <p>Default value: NULL can be inserted repeatedly.</p> <p>When the inserted data is compared with the original data in the table, the NULL value can be processed in any of the following ways:</p> <ul style="list-style-type: none">• NULLS DISTINCT: Each NULL value is regarded as a different value, that is, NULL values can be inserted repeatedly.• NULLS NOT DISTINCT: All NULL values are regarded as the same value. That is, only one NULL value entry is retained in the index. NULL values cannot be inserted repeatedly. Only distinct non-NULL values can be inserted.• NULLS IGNORE: NULL values are skipped during the equivalent comparison. If all index columns are NULL, NULL values can be inserted repeatedly. If some index columns are NULL, data can be inserted only when Not NULL values are different. <p>Table 21-154 lists the behaviors of the three processing modes.</p> <p>For details, see Application Differences Among NULLS DISTINCT, NULLS NOT DISTINCT, and NULLS IGNORE.</p> |

| Parameter | Description | Value Range or Example |
|---|---|--|
| | | CAUTION
If DISTRIBUTE BY REPLICATION is not specified, the column table that contains only unique values must contain distribution columns. |
| PRIMARY KEY
index_parameters
PRIMARY KEY
(column_name
[, ...])
index_parameters | <p>Specifies the primary key constraint specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.</p> <p>Only one primary key can be specified for a table.</p> <p>CAUTION
If DISTRIBUTE BY REPLICATION is not specified, the column set with a primary key constraint must contain distributed columns.</p> | - |
| DEFERRABLE
NOT DEFERRABLE | <p>Sets whether the constraint can be deferrable. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction using the SET CONSTRAINTS command. NOT DEFERRABLE is the default value. Currently, only UNIQUE and PRIMARY KEY constraints of row-store tables accept this clause. All the other constraints are not deferrable.</p> | - |

| Parameter | Description | Value Range or Example |
|---|--|------------------------|
| INITIALLY
IMMEDIATE
INITIALLY
DEFERRED | <p>If a constraint is deferrable, this clause specifies the default time to check the constraint.</p> <ul style="list-style-type: none">• If the constraint is INITIALLY IMMEDIATE (default value), it is checked after each statement.• If the constraint is INITIALLY DEFERRED, it is checked only at the end of the transaction. <p>The constraint check time can be altered using the SET CONSTRAINTS command.</p> | - |

table_constraint Parameters

Table constraints are similar to that of column constraints. For details, see [CONSTRAINT constraint_name Parameter](#).

```
{ CHECK ( expression ) |  
  UNIQUE [ NULLS [NOT] DISTINCT | NULLS IGNORE ] ( column_name [, ... ] ) index_parameters |  
  PRIMARY KEY ( column_name [, ... ] ) index_parameters }  
[ DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE ]
```

LIKE Parameters

like_option is as follows:

```
{ INCLUDING | EXCLUDING } { DEFAULTS | CONSTRAINTS | INDEXES | STORAGE | COMMENTS |  
  REOPTIONS | DISTRIBUTION | ALL }
```

The new table and original table are decoupled after creation is complete. Changes to the original table will not be applied to the new table, and it is not possible to include data of the new table in scans of the original table.

Default expressions for the copied column definitions will only be copied if **INCLUDING DEFAULTS** is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having default values **NULL**.

NOT NULL constraints are always copied to the new table. **CHECK** constraints will only be copied if **INCLUDING CONSTRAINTS** is specified; other types of constraints will never be copied. These rules also apply to column constraints and table constraints.

Columns and constraints copied by **LIKE** are not merged with the same name. If the same name is specified explicitly or in another **LIKE** clause, an error is reported.

- Any indexes on the source table will not be created on the new table, unless the **INCLUDING INDEXES** clause is specified.

- STORAGE settings for the copied column definitions will only be copied if **INCLUDING STORAGE** is specified. The default behavior is to exclude **STORAGE** settings.
- Comments for the copied columns, constraints, and indexes will only be copied if **INCLUDING COMMENTS** is specified. The default behavior is to exclude comments.
- If **INCLUDING REOPTIONS** is specified, the new table will copy the storage parameter (**WITH** clause of the source table) of the source table. The default behavior is to exclude partition definition of the storage parameter of the source table.
- If **INCLUDING DISTRIBUTION** is specified, the new table will copy the distribution information of the source table, including distribution type and column, and the new table cannot use **DISTRIBUTE BY** clause. The default behavior is to exclude distribution information of the source table.
- **INCLUDING ALL** is an abbreviated form of **INCLUDING DEFAULTS INCLUDING CONSTRAINTS INCLUDING INDEXES INCLUDING STORAGE INCLUDING COMMENTS INCLUDING REOPTIONS INCLUDING DISTRIBUTION**.

WITH Clause Parameters

Table 21-152 WITH parameters

| Parameter | Description | Value Range |
|------------|---|-------------|
| FILLFACTOR | The fillfactor of a table is a percentage between 10 and 100. 100 (complete packing) is the default value. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose records are never updated, setting the fillfactor to 100 (complete packing) is the appropriate choice, but in heavily updated tables smaller fillfactors are appropriate. The parameter has no meaning for column-store tables. | 10~100 |

| Parameter | Description | Value Range |
|----------------------|---|---|
| ORIENTATION | Determines the storage mode of the data in the table.
CAUTION
orientation cannot be modified. | <ul style="list-style-type: none">• COLUMN: The data will be stored in columns.• ROW (default value): The data will be stored in rows.• ORC: The data of the table will be stored in ORC format (only HDFS table). |
| COMPRESSION | This parameter is available only for column-store tables. Value: LOW (default value), MIDDLE , or HIGH .
NOTE
Currently, row-store table compression is not supported. | - |
| MAX_BATCHROW | Specifies the maximum of a storage unit during data loading process. The parameter is only valid for column-store tables. | 10000 to 60000
Default value: 60000 |
| PARTIAL_CLUSTER_ROWS | Specifies the number of records to be partial cluster stored during data loading process. The parameter is only valid for column-store tables. | The value is no less than 100,000. The value is the multiple of MAX_BATCHROW . |
| enable_delta | Specifies whether to enable delta tables in column-store tables. The parameter is only valid for column-store tables. Using column-store tables with delta tables is not recommended. This may cause disk bloat and performance deterioration due to delayed merge. | Default value: off |
| DELTAROW_THRESHOLD | A reserved parameter. The parameter is only valid for column-store tables. | 0 to 60000
Default value: 6000 |

| Parameter | Description | Value Range |
|-----------------|--|----------------------------|
| COLD_TABLESPACE | Specifies the OBS tablespace for the cold partitions in a hot or cold table. This parameter is available only to column-store partitioned tables and cannot be modified. It must be used together with STORAGE_POLICY . The parameter STORAGE_POLICY can be left unconfigured. In this case, the default value default_obs_tbs is used. | Valid OBS tablespace name. |

| Parameter | Description | Value Range |
|----------------|--|--|
| STORAGE_POLICY | Specifies the rule for switching between hot and cold partitions. This parameter is used only for multi-temperature tables. This parameter must be used together with COLD_TABLESPACE . | <p>Value range: <i>Cold and hot switchover policy name</i>. <i>Cold and hot switchover threshold</i>. Currently, only LMT and HPN policies are supported. LMT indicates that the switchover is performed based on the last update time of partitions. HPN indicates the switchover is performed based on a fixed number of reserved hot partitions.</p> <ul style="list-style-type: none">• LMT:<i>[day]</i>: Switch the hot partition data that is not updated in the last <i>[day]</i> days to the OBS tablespace as cold partition data. <i>[day]</i> is an integer ranging from 0 to 36500, in days.• HPN:
<i>[hot_partition_num]</i>: <i>[hot_partition_num]</i> indicates the number of hot partitions (with data) to be retained. The rule is to find the maximum sequence ID of the partitions with data. The partitions without data whose sequence ID is greater than the maximum sequence ID are hot partitions, and <i>[hot_partition_num]</i> partitions are retained as hot partitions in descending order according to the sequence ID. A partition whose sequence ID is smaller than the minimum sequence ID of the |

| Parameter | Description | Value Range |
|---------------------------------|--|--|
| | | <p>retained hot partition is a cold partition. During hot and cold partition switchover, data needs to be migrated to the OBS tablespace.</p> <p><i>[hot_partition_num]</i> is an integer ranging from 0 to 1600.</p> <p>CAUTION</p> <ul style="list-style-type: none">For a LIST partition, you are advised to use the HPN policy with caution. Otherwise, the new partition may not be a hot partition. |
| ENABLE_MULTI_T
EMP_DISKCACHE | This parameter improves the performance of tables that separate cold and hot data. It is only applicable to tables that support this feature and is supported in versions 9.1.0 and later. | on or off
Default value: on/true |

| Parameter | Description | Value Range |
|-----------|--|--|
