| PERIOD | <p>Specifies the period of automatically creating partitions and enables the automatic partition creation function. Only row-store and column-store range partitioned tables, time series tables, and cold and hot tables are supported. The partition key must be unique and its type can only be TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE] or DATE. MAXVALUE partitions are not supported. The value of (nowTime - boundaryTime)/ PERIOD must be less than the upper limit of the number of partitions, where nowTime indicates the current time and boundaryTime indicates the earliest partition boundary time. It cannot be used on midrange computers and acceleration clusters.</p> | <p>1 hour ~ 100 years</p> <p>CAUTION</p> <ul style="list-style-type: none">• In a database compatible with Teradata or MySQL, if the partition key type is DATE, PERIOD cannot be less than 1 day.• If PERIOD is set when a partitioned table is created, you can specify only the partition key. Two default partitions are created during table creation. The time ranges of the two default partitions are both PERIOD. The boundary time of the first default partition is the first hour, day, week, month, or year past the current time. The time unit is selected based on the maximum unit of PERIOD. The boundary time of the second default partition is the boundary time of the first partition plus PERIOD. Assume that the current time is 2022-02-17 16:32:45, and the boundary of the first default partition is described in Table 21-155. For more information about the default partitions, see Example: Creating a Partitioned Table with Automatic Partition Management and No Specified Partitions. |

| Parameter | Description | Value Range |
|-----------|---|--------------------|
| TTL | <p>Specifies the partition expiration time in partition management and enables the automatic partition deletion function. This parameter cannot be set separately. You must set PERIOD in advance or at the same time. The value of this parameter must be greater than or equal to that of PERIOD.</p> <p>Time To Live (TTL) specifies the data storage period of the table. The data that exceeds the TTL period will be cleared. To do this, the function in proc_drop_partition (relname regclass, older_than interval) is automatically invoked based on the period. The PERIOD and TTL values are of the Interval type, for example, 1 hour, 1 day, 1 week, 1 month, 1 year, and 1 month 2 day 3 hour.</p> <p>PERIOD indicates that data is partitioned by time period. The partition size may affect the query performance. The proc_add_partition (relname regclass, boundaries_interval interval) function is automatically invoked to create a partition after each period.</p> | 1 hour ~ 100 years |

| Parameter | Description | Value Range |
|---------------|--|---|
| COLVERSION | Specifies the version of the column-store format. Switching between different storage formats is supported. However, the storage format of a partitioned table cannot be switched. | <ul style="list-style-type: none">• 1.0: Each column in a column-store table is stored in a separate file. The file name is relfilenode.C1.0, relfilenode.C2.0, relfilenode.C3.0, or similar.• 2.0: All columns of a column-store table are combined and stored in a file. The file is named relfilenode.C1.0. Default value: 2.0
The value of COLVERSION can only be set to 2.0 for OBS multi-temperature tables.
CAUTION
When creating a column-store table, set COLVERSION to 2.0 . Compared with the 1.0 storage format, the performance is significantly improved: <ol style="list-style-type: none">1. The time required for creating a column-store wide table is significantly reduced.2. In the Roach data backup scenario, the backup time is significantly reduced.3. The build and catch up time is greatly reduced. |
| SKIP_FPI_HINT | Indicates whether to skip the hint bits operation when the full-page writes (FPW) log needs to be written during sequential scanning. | Default value: false
CAUTION
If SKIP_FPI_HINT is set to true and the checkpoint operation is performed on a table, no Xlog will be generated when the table is sequentially scanned. This applies to intermediate tables that are queried less frequently, reducing the size of Xlogs and improving query performance. |

PARTITION BY Parameters

- **partition_less_than_item** is as follows:
`PARTITION partition_name VALUES LESS THAN ( { partition_value | MAXVALUE } )`
- **partition_start_end_item** is as follows:
`PARTITION partition_name {
 {START(partition_value) END (partition_value) EVERY (interval_value)} |
 {START(partition_value) END ({partition_value | MAXVALUE})} |
 {START(partition_value)} |
 {END({partition_value | MAXVALUE})}
}`
- **list_partition_item**:
`PARTITION partition_name VALUES ( { (partition_value) [, ...] | DEFAULT } )`

Table 21-153 PARTITION BY Parameters

| Parameter | Description | Value Range |
|-----------------------------------|---|--|
| PARTITION BY RANGE(partition_key) | The syntax specifying range partitioning. partition_key indicates the name of a partition key. | <ul style="list-style-type: none">Assume that the VALUES LESS THAN syntax is used.
CAUTION
In this case, a maximum of four partition keys are supported, and the partition key must be a column name. If there are multiple partition keys, a column name can appear only once, and two adjacent partition keys must be separated by a comma (,).

Data types supported by the partition keys are as follows:
SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, DOUBLE PRECISION, CHARACTER VARYING(n), VARCHAR(n), CHARACTER(n), CHAR(n), CHARACTER, CHAR, TEXT, NVARCHAR2, NAME, TIMESTAMP[(p)] [WITHOUT TIME ZONE], TIMESTAMP[(p)] [WITH TIME ZONE], and DATE.Assume that the START END syntax is used.
CAUTION
In this case, only one partition key is supported.

Data types supported by the partition key are as follows: SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, DOUBLE PRECISION, TIMESTAMP[(p)] [WITHOUT TIME |

| Parameter | Description | Value Range |
|---|--|---|
| | | ZONE],
TIMESTAMP[(p)]
[WITH TIME ZONE],
and DATE. |
| PARTITION BY
LIST
(partition_key,...) | The syntax specifying list partitioning. partition_key indicates the name of a partition key. | In list partitioning, partition keys support the following data types: TINYINT, SMALLINT, INTEGER, BIGINT, NUMERIC/DECIMAL, TEXT, NVARCHAR2, VARCHAR(n), CHAR, BPCHAR, TIME, TIME WITH TIMEZONE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, DATE, INTERVAL and SMALLDATETIME.
CAUTION
In list partitioning, a partition key has a maximum of four columns. |

| Parameter | Description | Value Range |
|--------------------------|---|-------------|
| partition_less_than_item | <p>Partition definition syntax in range partitioning.</p> <p>partition_name is the name of a range partition.</p> <p>partition_value is the upper limit of range partition, and the value depends on the type of partition_key. MAXVALUE can specify the upper boundary of a range partition, and it is commonly used to specify the upper boundary of the last range partition.</p> <pre>PARTITION partition_name VALUES
LESS THAN ({ partition_value
MAXVALUE })</pre> <p>CAUTION</p> <ul style="list-style-type: none">• Upper boundaries must be specified for each partition.• The types of upper boundaries must be the same as those of partition keys.• In a partition list, partitions are arranged in ascending order of upper boundary values. Therefore, a partition with a certain upper boundary value is placed before another partition with a larger upper boundary value.• If a partition key consists of multiple columns, the columns are used for partitioning in sequence. The first column is preferred to be used for partitioning. If the values of the first columns are the same, the second column is used. The subsequent columns are used in the same manner. | - |

| Parameter | Description | Value Range |
|--------------------------|--|--|
| partition_start_end_item | <p>The syntax of using the start value and interval value to define a range partition.</p> <pre>PARTITION partition_name {START (partition_value) END (partition_value) EVERY (interval_value)}
 {START (partition_value) END (partition_value) MAXVALUE}

{START(partition_value)
 {END (partition_value) MAXVALUE}}</pre> | <p>The following table describes the parameters.</p> <ul style="list-style-type: none">• partition_name: name or name prefix of a range partition. It is the name prefix only in the following cases (assuming that partition_name is p1):<ul style="list-style-type: none">– If START+END+EVERY is used, the names of partitions will be defined as p1_1, p1_2, and the like. For example, if PARTITION p1 START(1) END(4) EVERY(1) is defined, the generated partitions are [1, 2), [2, 3), and [3, 4), and their names are p1_1, p1_2, and p1_3. In this case, p1 is a name prefix.– If the defined statement is in the first place and has START specified, the range (MINVALUE, START) will be automatically used as the first actual partition, and its name will be p1_0. The other partitions are then named p1_1, p1_2, and the like. For example, if PARTITION p1 START(1), PARTITION p2 START(2) is defined, generated partitions are (MINVALUE, 1), [1, 2), and [2, MAXVALUE), and their names will be p1_0, p1_1, and p2. |

| Parameter | Description | Value Range |
|-----------|-------------|--|
| | | <p>In this case, p1 is a name prefix and p2 is a partition name. MINVALUE means the minimum value.</p> <ul style="list-style-type: none">• partition_value: start point value or end point value of a range partition. The value depends on partition_key and cannot be MAXVALUE.• interval_value: width of each partition for dividing the [START, END) range. It cannot be MAXVALUE. If the value of (END – START) divided by EVERY has a remainder, the width of only the last partition is less than the value of EVERY.• MAXVALUE: maximum value. It is usually used to set the upper boundary for the last range partition. |

| Parameter | Description | Value Range |
|-----------|-------------|--|
| | | <p>CAUTION</p> <ol style="list-style-type: none">If the defined statement is in the first place and has START specified, the range (MINVALUE, START) will be automatically used as the first actual partition.The START END syntax must comply with the following rules:<ul style="list-style-type: none">The value of START (if any, same for the following situations) in each partition_start_end_item must be smaller than that of END.In two adjacent partition_start_end_item statements, the value of the first END must be equal to that of the second START.The value of EVERY in each partition_start_end_item must be a positive number (in ascending order) and must be smaller than END minus START.Each partition includes the start value (unless it is MINVALUE) and excludes the end value. The format is as follows: [Start value, end value).Partitions created by the same partition_start_end_item belong to the same tablespace.If partition_name is a name prefix of a partition, the length must not exceed 57 bytes. If there are more than 57 bytes, the prefix will be automatically truncated.When creating or modifying a partitioned table, ensure that the total number of partitions in the table does not exceed the maximum value (32767). <ol style="list-style-type: none">In statements for creating partitioned |

| Parameter | Description | Value Range |
|---------------------|---|--|
| list_partition_item | <p>Partition definition syntax in list partitioning.</p> <p>partition_name indicates the partition name.</p> <p>partition_value is an enumerated value of the list partition boundary. The value depends on the type of partition_key. DEFAULT indicates the default partition boundary.</p> <p><code>PARTITION partition_name VALUES ({ (partition_value) [, ...] DEFAULT })</code></p> | <p>The following conventions and constraints apply to list partitioned tables:</p> <ul style="list-style-type: none">• The partition whose boundary value is DEFAULT is the default partition.• Each list partitioned table can have only one DEFAULT partition.• The number of partitions in a partitioned table cannot exceed 32767, and the number of boundary values of all partitions cannot exceed 32767.• Regardless of the number of partition keys, the boundary of the DEFAULT partition can only be DEFAULT.• If a partition key consists of multiple columns, each partition_value must contain the values of all partition keys. If a partition key contains only one column, the parentheses on both sides of partition_value can be omitted. For details, see Example: Creating a List Partitioned Table with Multiple Partition Keys.• If the partition key consists of multiple columns, compare the values in the columns one by one. If a value is different from another value, regardless of their columns, they are different values. |

| Parameter | Description | Value Range |
|-----------|-------------|---|
| | | <ul style="list-style-type: none">Each value of partition_value must be unique.When data is inserted, if its partition key and value falls into the boundary of a non-DEFAULT partition, the data is written to the partition. Otherwise, the data is written to the DEFAULT partition. |

Table 21-154 Processing of NULL values in index columns in unique indexes

| Constraint | All Index Columns Are NULL | Some Index Columns Are NULL |
|--------------------|--------------------------------|--|
| NULLS DISTINCT | Can be inserted repeatedly. | Can be inserted repeatedly. |
| NULLS NOT DISTINCT | Cannot be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |
| NULLS IGNORE | Can be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |

Table 21-155 Partition boundaries

| period | Maximum PERIOD Unit | Boundary of First Default Partition |
|---------|---------------------|-------------------------------------|
| 1hour | Hour | 2022-02-17 17:00:00 |
| 1day | Day | 2022-02-18 00:00:00 |
| 1month | Month | 2022-03-01 00:00:00 |
| 13month | Year | 2023-01-01 00:00:00 |

DISTRIBUTE BY Parameter Description

Default value: determined by the GUC parameter **default_distribution_mode**

- When **default_distribution_mode** is set to **roundrobin**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation, round-robin distribution is selected.
- When **default_distribution_mode** is set to **hash**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 - a. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 - b. If the primary key or unique constraint is not included during table creation but there are columns whose data types can be used as distribution columns, hash distribution is selected. The distribution column is the first column whose data type can be used as a distribution column.
 - c. If the primary key or unique constraint is not included during table creation and no column whose data type can be used as a distribution column exists, round-robin distribution is selected.

The following data types can be used as distribution columns:

- Integer types: **TINYINT**, **SMALLINT**, **INT**, **BIGINT**, and **NUMERIC/DECIMAL**
- Character types: **CHAR**, **BPCHAR**, **VARCHAR**, **VARCHAR2**, **NVARCHAR2**, and **TEXT**
- Date/time types: **DATE**, **TIME**, **TIMETZ**, **TIMESTAMP**, **TIMESTAMPTZ**, **INTERVAL**, and **SMALLDATETIME**

Example: Using the LESS THAN Syntax to Create a Range Partitioned Table

The range partitioned table **customer_address** has four partitions and their partition keys are of the integer type. The ranges of the partitions are as follows: **ca_address_sk < 2450815**, **2450815 <= ca_address_sk < 2451179**, **2451179 <= ca_address_sk < 2451544**, **2451544 <= ca_address_sk**.

```
CREATE TABLE customer_address
(
    ca_address_sk    INTEGER          NOT NULL ,
    ca_address_id    CHARACTER(16)    NOT NULL ,
    ca_street_number CHARACTER(10)      ,
    ca_street_name   CHARACTER varying(60) ,
    ca_street_type   CHARACTER(15)      ,
    ca_suite_number  CHARACTER(10)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE(ca_address_sk)
(
    PARTITION P1 VALUES LESS THAN(2450815),
    PARTITION P2 VALUES LESS THAN(2451179),
    PARTITION P3 VALUES LESS THAN(2451544),
    PARTITION P4 VALUES LESS THAN(MAXVALUE)
);
```

View the information of the partitioned table.

```
SELECT relname, boundaries FROM pg_partition p where p.parentid='customer_address'::regclass ORDER BY 1;
```

| relname | boundaries |
|------------------|------------|
| customer_address | |
| p1 | {2450815} |
| p2 | {2451179} |
| p3 | {2451544} |
| p4 | {NULL} |
| (5 rows) | |

Query the number of rows in the **P1** partition.

```
SELECT count(*) FROM customer_address PARTITION (P1);
SELECT count(*) FROM customer_address PARTITION FOR (2450815);
```

Examples: Enabling and Disabling ROW MOVEMENT

If **ROW MOVEMENT** is enabled, the data of a row is moved to a new partition when the partition key of the row is updated to a new value and the new value belongs to another partition.

If a partition key is frequently updated, enabling **ROW MOVEMENT** may cause extra I/O overhead. To enable it, evaluate service requirements first.

Create a table partitioned by date and enable **ROW MOVEMENT**.

```
DROP TABLE IF EXISTS sale_data;
CREATE TABLE sales_data (
  sale_id INT,
  product_name VARCHAR(100),
  sale_date DATE,
  amount DECIMAL(10, 2)
)
PARTITION BY RANGE (sale_date) (
  PARTITION p_2023q1 VALUES LESS THAN ('2023-04-01'),
  PARTITION p_2023q2 VALUES LESS THAN ('2023-07-01'),
  PARTITION p_2023q3 VALUES LESS THAN ('2023-10-01'),
  PARTITION p_2023q4 VALUES LESS THAN ('2024-01-01')
)
ENABLE ROW MOVEMENT;
```

Insert test data.

```
INSERT INTO sales_data (sale_id, product_name, sale_date, amount)
VALUES
(1, 'Product A', '2023-02-15', 1000.00), -- It belongs to p_2023q1.
(2, 'Product B', '2023-05-20', 1500.00); -- It belongs to p_2023q2.
```

Query the data distribution of each partition.

```
SELECT tableoid::regclass AS partition, * FROM sales_data ORDER BY sale_id;
```

| partition | sale_id | product_name | sale_date | amount |
|------------|---------|--------------|---------------------|---------|
| 2147617615 | 1 | Product A | 2023-02-15 00:00:00 | 1000.00 |
| 2147617616 | 2 | Product B | 2023-05-20 00:00:00 | 1500.00 |
| (2 rows) | | | | |

Update the partition key (which is moved from **p_2023q1** to **p_2023q2**).

```
UPDATE sales_data SET sale_date = '2023-05-01' WHERE sale_id = 1;
```

Query the data distribution of each partition again to confirm that the row has been moved.

```
SELECT tableoid::regclass AS partition, * FROM sales_data ORDER BY sale_id;
```

| partition | sale_id | product_name | sale_date | amount |
|------------|---------|--------------|---------------------|---------|
| 2147617616 | 1 | Product A | 2023-05-01 00:00:00 | 1000.00 |
| 2147617616 | 2 | Product B | 2023-05-20 00:00:00 | 1500.00 |

(2 rows)

Disable **ROW MOVEMENT**.

```
ALTER TABLE sales_data DISABLE ROW MOVEMENT;
```

Modify the partition key again (which is move from **p_2023q2** back to **p_2023q2**).

```
UPDATE sales_data SET sale_date = '2023-02-15' WHERE sale_id = 1;
```

View the command output. It indicates that **ROW MOVEMENT** is disabled and the partition key cannot be updated.

```
gaussdb=> UPDATE sales_data SET sale_date = '2023-02-15' WHERE sale_id = 1;
ERROR:  dn_6003_6004: fail to update partitioned table "sales_data"
DETAIL:  disable row movement
```

Example: Using the START END Syntax to Create a Column-store Range Partitioned Table

```
CREATE TABLE customer_address_SE
(
    ca_address_sk    INTEGER          NOT NULL ,
    ca_address_id    CHARACTER(16)    NOT NULL ,
    ca_street_number CHARACTER(10)      ,
    ca_street_name   CHARACTER varying(60) ,
    ca_street_type   CHARACTER(15)      ,
    ca_suite_number  CHARACTER(10)
)
WITH (ORIENTATION = COLUMN)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE(ca_address_sk)
(
    PARTITION p1 START(1) END(1000) EVERY(200),
    PARTITION p2 END(2000),
    PARTITION p3 START(2000) END(5000)
);
```

View the information of the partitioned table.

```
SELECT relname, boundaries FROM pg_partition p where p.parentid='customer_address_SE'::regclass ORDER
BY 1;
 relname | boundaries
-----+-----
customer_address_se |
p1_0      | {1}
p1_1      | {201}
p1_2      | {401}
p1_3      | {601}
p1_4      | {801}
p1_5      | {1000}
p2        | {2000}
p3        | {5000}
(9 rows)
```

Example: Using the START END Syntax to Create and Modify a Range Partitioned Table

Create a temporary schema.

```
CREATE SCHEMA tpcds;  
SET CURRENT_SCHEMA TO tpcds;
```

Create a partitioned table with the partition key of the integer type.

```
CREATE TABLE tpcds.startend_pt (c1 INT, c2 INT)  
DISTRIBUTE BY HASH (c1)  
PARTITION BY RANGE (c2) (  
    PARTITION p1 START(1) END(1000) EVERY(200),  
    PARTITION p2 END(2000),  
    PARTITION p3 START(2000) END(2500),  
    PARTITION p4 START(2500),  
    PARTITION p5 START(3000) END(5000) EVERY(1000)  
)  
ENABLE ROW MOVEMENT;
```

View the information of the partitioned table.

```
SELECT relname, boundaries FROM pg_partition p where p.parentid='tpcds.startend_pt'::regclass ORDER BY  
1;
```

| relname | boundaries |
|-------------------|------------|
| p1_0 | {1} |
| p1_1 | {201} |
| p1_2 | {401} |
| p1_3 | {601} |
| p1_4 | {801} |
| p1_5 | {1000} |
| p2 | {2000} |
| p3 | {2500} |
| p4 | {3000} |
| p5_1 | {4000} |
| p5_2 | {5000} |
| tpcds.startend_pt | |

(12 rows)

Import data and check the data volume in the partition.

```
INSERT INTO tpcds.startend_pt VALUES (GENERATE_SERIES(0, 4999), GENERATE_SERIES(0, 4999));  
SELECT COUNT(*) FROM tpcds.startend_pt PARTITION FOR (0);
```

| count |
|-------|
| 1 |

(1 row)

```
SELECT COUNT(*) FROM tpcds.startend_pt PARTITION (p3);
```

| count |
|-------|
| 500 |

(1 row)

View the information of the partitioned table.

```
SELECT relname, boundaries FROM pg_partition p where p.parentid='tpcds.startend_pt'::regclass ORDER BY  
1;
```

| relname | boundaries |
|---------|------------|
| p1_0 | {1} |
| p1_1 | {201} |
| p1_2 | {401} |
| p1_3 | {601} |
| p1_4 | {801} |
| p1_5 | {1000} |
| p2 | {2000} |
| p3 | {2500} |
| p4 | {3000} |
| p5_1 | {4000} |
| p6_1 | {5300} |
| p6_2 | {5600} |
| p6_3 | {5900} |

```
p71      | {6000}  
q1_1     | {4250}  
q1_2     | {4500}  
q1_3     | {4750}  
q1_4     | {5000}  
tpcds.startend_pt |  
(19 rows)
```

Example: Creating a List Partitioned Table with Partition Keys

```
CREATE TABLE data_list  
(  
    id int,  
    time int,  
    salary decimal(12,2)  
)  
PARTITION BY LIST (time)  
(  
    PARTITION P1 VALUES (202209),  
    PARTITION P2 VALUES (202210,202208),  
    PARTITION P3 VALUES (202211),  
    PARTITION P4 VALUES (202212),  
    PARTITION P5 VALUES (202301)  
);
```

Example: Creating a List Partitioned Table with Multiple Partition Keys

A partitioned table has two partition keys: **period** and **city**.

```
CREATE TABLE sales_info  
(  
    sale_time timestamptz,  
    period    int,  
    city      text,  
    price     numeric(10,2),  
    remark    varchar2(100)  
)  
DISTRIBUTE BY HASH(sale_time)  
PARTITION BY LIST (period, city)  
(  
    PARTITION north_2022 VALUES (('202201', 'north1'), ('202202', 'north2')),  
    PARTITION south_2022 VALUES (('202201', 'south1'), ('202202', 'south2'), ('202203', 'south2')),  
    PARTITION rest VALUES (DEFAULT)  
);
```

Example: Creating a Partitioned Table with Automatic Partition Management and No Specified Partitions

Set **PERIOD** to **1 day** and partition key to **time**.

```
CREATE TABLE time_part  
(  
    id integer,  
    time timestamp  
) with (PERIOD='1 day')  
partition by range(time);
```

Two default partitions are created during table creation. The boundary time of the first default partition is the start of the day later than the current time, that is, 2022-12-13 00:00:00. The boundary time of the second default partition is the boundary time of the first partition plus PERIOD, that is, 2022-12-13 00:00:00+1 day=2022-12-14 00:00:00.

```
SELECT now();  
       now  
-----
```

```
2022-12-12 20:41:21.603172+08
(1 row)

SELECT relname, boundaries FROM pg_partition p where p.parentid='time_part'::regclass ORDER BY 1;
 relname | boundaries
-----+-----
default_part_1 | {"2022-12-13 00:00:00"}
default_part_2 | {"2022-12-14 00:00:00"}
time_part |
(3 rows)
```

Example: Creating a Partitioned Table with Automatic Partition Management and Specified Partitions

```
CREATE TABLE CPU(
  id integer,
  idle numeric,
  IO numeric,
  scope text,
  IP text,
  time timestamp
) with (TTL='7 days',PERIOD='1 day')
partition by range(time)
(
  PARTITION P1 VALUES LESS THAN('2022-01-05 16:32:45'),
  PARTITION P2 VALUES LESS THAN('2022-01-06 16:56:12')
);
```

Example: Creating a Partitioned Table by Month

Create partitioned table **customer_address**, which contains 13 partitions and their partition keys are of the date type.

```
CREATE TABLE customer_address
(
  ca_address_sk integer NOT NULL,
  ca_address_date date NOT NULL
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE (ca_address_date)
(
  PARTITION p202001 VALUES LESS THAN('20200101'),
  PARTITION p202002 VALUES LESS THAN('20200201'),
  PARTITION p202003 VALUES LESS THAN('20200301'),
  PARTITION p202004 VALUES LESS THAN('20200401'),
  PARTITION p202005 VALUES LESS THAN('20200501'),
  PARTITION p202006 VALUES LESS THAN('20200601'),
  PARTITION p202007 VALUES LESS THAN('20200701'),
  PARTITION p202008 VALUES LESS THAN('20200801'),
  PARTITION p202009 VALUES LESS THAN('20200901'),
  PARTITION p202010 VALUES LESS THAN('20201001'),
  PARTITION p202011 VALUES LESS THAN('20201101'),
  PARTITION p202012 VALUES LESS THAN('20201201'),
  PARTITION p202013 VALUES LESS THAN(MAXVALUE)
);
```

Insert data.

```
INSERT INTO customer_address values('1','20200215');
INSERT INTO customer_address values('7','20200805');
INSERT INTO customer_address values('9','20201111');
INSERT INTO customer_address values('4','20201231');
```

Query a partition.

```
SELECT * FROM customer_address PARTITION(p202009);
ca_address_sk | ca_address_date
-----+-----
```

```
7 | 2020-08-05 00:00:00  
(1 row)
```

Example: Using the START END Syntax to Create a Partitioned Table with Multiple Partitions at a Time

- Create a partitioned table **day_part**. Each day is a partition, and the partition key is a date.

```
CREATE table day_part(id int,d_time date)  
DISTRIBUTE BY HASH (id)  
PARTITION BY RANGE (d_time)  
(PARTITION p1 START('2022-01-01') END('2022-01-31') EVERY(interval '1 day'));  
ALTER TABLE day_part ADD PARTITION pmax VALUES LESS THAN (maxvalue);
```

- Create a partitioned table **week_part**, seven days as a partition, and the partition key is a date.

```
CREATE table week_part(id int,w_time date)  
DISTRIBUTE BY HASH (id)  
PARTITION BY RANGE (w_time)  
(PARTITION p1 START('2021-01-01') END('2022-01-01') EVERY(interval '7 day'));  
ALTER TABLE week_part ADD PARTITION pmax VALUES LESS THAN (maxvalue);
```

- Create the partitioned table **month_part**, each month as a partition, and the partition key is a date.

```
CREATE table month_part(id int,m_time date)  
DISTRIBUTE BY HASH (id)  
PARTITION BY RANGE (m_time)  
(PARTITION p1 START('2021-01-01') END('2022-01-01') EVERY(interval '1 month'));  
ALTER TABLE month_part ADD PARTITION pmax VALUES LESS THAN (maxvalue);
```

Example: Creating a Hot or Cold Table

Only a column-store partitioned table is supported. Use the default OBS tablespace. Set LMT to 30 for cold and hot switchover rules.

```
CREATE TABLE cold_hot_table  
(  
  W_WAREHOUSE_ID      CHAR(16)      NOT NULL,  
  W_WAREHOUSE_NAME     VARCHAR(20)    ,  
  W_STREET_NUMBER      CHAR(10)      ,  
  W_STREET_NAME        VARCHAR(60)   ,  
  W_STREET_ID          CHAR(15)      ,  
  W_SUITE_NUMBER       CHAR(10)      ,  
)  
WITH (ORIENTATION = COLUMN, storage_policy = 'LMT:30')  
DISTRIBUTE BY HASH (W_WAREHOUSE_ID)  
PARTITION BY RANGE(W_STREET_ID)  
(  
  PARTITION P1 VALUES LESS THAN(100000),  
  PARTITION P2 VALUES LESS THAN(200000),  
  PARTITION P3 VALUES LESS THAN(300000),  
  PARTITION P4 VALUES LESS THAN(MAXVALUE)  
)  
ENABLE ROW MOVEMENT;
```

[ALTER TABLE PARTITION, DROP TABLE](#)

21.13.4.3 CREATE TABLE AS

Function

CREATE TABLE AS creates a table based on the results of a query. It is applicable to data migration or replication scenarios.

CREATE TABLE AS creates a table and fills the table with **SELECT** query results. The table columns have the names and data types associated with the output columns of **SELECT**. Except that you can override the **SELECT** output column names by giving an explicit list of new column names.

CREATE TABLE AS queries once the source table and writes data in the new table. The query result view changes when the source table changes. In contrast, a view re-evaluates its defining **SELECT** statement whenever it is queried.

Precautions

- This command cannot be used to create a partitioned table.
- If an error occurs when you create a table, after the system is recovered, the system probably cannot automatically clear the created disk file whose size is not 0. This problem seldom occurs.
- The UNLOGGED table uses no primary/standby mechanism. In the case of system faults or abnormal breakpoints, data loss may occur. Therefore, the UNLOGGED table cannot be used to store basic data.
- The UNLOGGED table does not ensure safe data. Users can back up data before using the table; for example, users should back up the data before a system upgrade.

Syntax

```
CREATE [ [ GLOBAL | LOCAL | VOLATILE ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE table_name
    [ ( column_name [, ...] ) ]
    [ WITH ( {storage_parameter = value} [, ...] ) ]
    [ COMPRESS | NOCOMPRESS ]

    [ DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { [HASH] ( column_name ) } } ]

    [ COMMENT [=] 'text' ]
    AS query
    [ WITH [ NO ] DATA ];
```

Parameter Description

Table 21-156 CREATE TABLE AS parameters

| Parameter | Description | Value Range |
|---------------------------|--|--|
| GLOBAL LOCAL VOLATILE | Specifies the type of a temporary table. | For details, see Parameter Description . |
| TEMPORARY TEMP | If TEMP or TEMPORARY is specified, the created table is a temporary table. | - |

| Parameter | Description | Value Range |
|--|--|--|
| UNLOGGED | <p>Specifies that the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead log, which makes them considerably faster than ordinary tables. However, they are not crash-safe: an unlogged table is automatically truncated after a crash or unclean shutdown. The contents of an unlogged table are also not replicated to standby servers. Any indexes created on an unlogged table are automatically unlogged as well.</p> <p>If data is missing in the indexes of unlogged tables due to some unexpected operations such as an unclean shutdown, users should re-create the indexes with errors.</p> | <p>Starting from version 9.1.0, UNLOGGED tables are automatically saved in the pg_unlogged tablespace and cannot be moved or assigned to other tablespaces. After an earlier version is upgraded to 9.1.0, the UNLOGGED table created in the earlier version is still stored in the original tablespace.</p> <p>If the instance restarts unexpectedly, the UNLOGGED table will be reset, which can impact the instance's recovery time objective (RTO). Starting from version 9.1.0, there is a script called switch_unlogged_tablespace.py that can move unlogged tables to optimize the recovery time objective (RTO). This script works together with the GUC parameter enable_unlogged_tablepace_compat.</p> |
| table_name | Specifies the name of the table to be created. | A string, which must comply with the naming convention . |
| column_name | Specifies the name of a column to be created in the new table. | A string, which must comply with the naming convention . |
| WITH
(storage_parameter [= value] [, ...]) | The WITH clause sets the storage options for a table or its index. | For details about the parameters, see Table 21-157 . |

| Parameter | Description | Value Range |
|--------------------------|--|-------------|
| COMPRESS
NOCOMPRESS | <ul style="list-style-type: none">• If the keyword COMPRESS is specified, the compression feature is triggered when data is inserted into tables in batches. If this feature is enabled, a scan is performed for all tuple data within the page to generate a dictionary and then the tuple data is compressed and stored.• If NOCOMPRESS is specified, the table is not compressed. Default value:
NOCOMPRESS , tuple data is not compressed before storage. | - |

| Parameter | Description | Value Range |
|--------------------|--|---|
| DISTRIBUTE BY | <p>Specifies how the table is distributed or replicated between DNs.</p> <ul style="list-style-type: none">• REPLICATION: Each row in the table exists on all DNs, that is, each DN has complete table data.• ROUNDROBIN: Each row in the table is sent to each DN in sequence. This distribution policy prevents data skew. However, data distribution nodes are random. As a result, there is a higher probability that table redistribution is triggered during computing. This distribution policy is recommended for large tables with severe column skew. This value is supported only in 8.1.2 or later.• HASH (column_name): Each row of the table will be placed into all the DNs based on the hash value of the specified column. <p>Default value: determined by the GUC parameter default_distribution_mode. For details about how to select the default value of DISTRIBUTE BY, see the notice below this table.</p> | <p>The following data types can be used as distribution columns:</p> <ul style="list-style-type: none">• Integer types: TINYINT, SMALLINT, INT, BIGINT, and NUMERIC/DECIMAL• Character types: CHAR, BPCHAR, VARCHAR, VARCHAR2, NVARCHAR2, and TEXT• Date/time types: DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPPTZ, INTERVAL, and SMALLDATETIME |
| COMMENT [=] 'text' | The COMMENT clause can specify table comments during table creation. | - |

| Parameter | Description | Value Range |
|----------------------|---|-------------|
| AS query | Indicates a SELECT or VALUES command, or an EXECUTE command that runs a prepared SELECT , or VALUES query. | - |
| [WITH [NO] DATA] | Specifies whether the data produced by the query should be copied into the new table. By default, the data is copied. If the NO parameter is used, the data is not copied. | - |

NOTICE

DISTRIBUTE BY parameter description:

- When **DISTRIBUTE BY HASH (column_name)** is specified, the primary key and its unique index must contain the **column_name** column.
 - When **DISTRIBUTE BY HASH (column_name)** in a referenced table is specified, the foreign key of the reference table must contain the **column_name** column.
 - When **default_distribution_mode** is set to **roundrobin**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 1. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 2. If the primary key or unique constraint is not included during table creation, round-robin distribution is selected.
 - When **default_distribution_mode** is set to **hash**, the default value of **DISTRIBUTE BY** is selected according to the following rules:
 1. If the primary key or unique constraint is included during table creation, hash distribution is selected. The distribution column is the column corresponding to the primary key or unique constraint.
 2. If the primary key or unique constraint is not included during table creation but there are columns whose data types can be used as distribution columns, hash distribution is selected. The distribution column is the first column whose data type can be used as a distribution column.
 3. If the primary key or unique constraint is not included during table creation and no column whose data type can be used as a distribution column exists, round-robin distribution is selected.
-

Table 21-157 storage_parameter parameters

| storage_parameter
Parameter | Description | Value Range |
|--------------------------------|--|---|
| FILLFACTOR | <p>The fillfactor of a table is a percentage between 10 and 100. When a smaller fillfactor is specified, INSERT operations pack table pages only to the indicated percentage. The remaining space on each page is reserved for updating rows on that page. This gives UPDATE a chance to place the updated copy of a row on the same page, which is more efficient than placing it on a different page. For a table whose records are never updated, setting the fillfactor to 100 (complete packing) is the appropriate choice, but in heavily updated tables smaller fillfactors are appropriate.</p> <p>The default value is 100 (filled to capacity).</p> <p>The parameter is only valid for row-store tables.</p> | 10~100 |
| ORIENTATION | <p>Specifies the storage mode (row-store, column-store) for table data. This parameter cannot be modified once it is set.</p> <p>Default value: ROW (row-store)</p> | <ul style="list-style-type: none">• ROW indicates that table data is stored in rows. ROW applies to OLTP service, which has many interactive transactions. An interaction involves many columns in the table. Using ROW can improve the efficiency.• COLUMN indicates that the data is stored in columns. COLUMN applies to the data warehouse service, which has a large amount of aggregation computing, and involves a few column operations. |

| storage_parameter
Parameter | Description | Value Range |
|--------------------------------|---|--|
| COMPRESSION | <p>Specifies the compression level of the table data. It determines the compression ratio and time. Generally, the higher the level of compression, the higher the ratio, the longer the time, and the lower the level of compression, the lower the ratio, the shorter the time. The actual compression ratio depends on the distribution characteristics of loading table data.</p> <p>NOTE
Currently, row-store table compression is not supported.</p> | <p>This parameter is available only for column-store tables. Value: LOW (default value), MIDDLE, or HIGH.</p> |
| MAX_BATCHROW | <p>Specifies the maximum of a storage unit during data loading process. The parameter is only valid for column-store tables.</p> <p>Default value: 60000</p> | 10000 to 60000 |
| PARTIAL_CLUSTER_ROWS | <p>Specifies the number of records to be partial cluster stored during data loading process. The parameter is only valid for column-store tables.</p> <p>Default value: 4,200,000</p> | 600000 to 2147483647 |
| enable_delta | <p>Specifies whether to enable delta tables in column-store tables. The parameter is only valid for column-store tables.</p> <p>Using column-store tables with delta tables is not recommended. This may cause disk bloat and performance deterioration due to delayed merge.</p> <p>Default value: off</p> | on or off |

| storage_parameter
Parameter | Description | Value Range |
|--------------------------------|---|---|
| COLVERSION | <p>Specifies the version of the column-store format. You can switch between different storage formats.</p> <p>Default value: 2.0</p> <p>NOTE</p> <p>When creating a column-store table, set COLVERSION to 2.0. Compared with the 1.0 storage format, the performance is significantly improved:</p> <ol style="list-style-type: none">1. The time required for creating a column-store wide table is significantly reduced.2. In the Roach data backup scenario, the backup time is significantly reduced.3. The build and catch up time is greatly reduced. | <p>Valid value:</p> <ul style="list-style-type: none">• 1.0: Each column in a column-store table is stored in a separate file. The file name is relfilenode.C1.0, relfilenode.C2.0, relfilenode.C3.0, or similar.• 2.0: All columns of a column-store table are combined and stored in a file. The file is named relfilenode.C1.0. |
| SKIP_FPI_HINT | <p>Indicates whether to skip the hint bits operation when the full-page writes (FPW) log needs to be written during sequential scanning.</p> <p>Default value: false</p> <p>NOTE</p> <p>If SKIP_FPI_HINT is set to true and the checkpoint operation is performed on a table, no Xlog will be generated when the table is sequentially scanned. This applies to intermediate tables that are queried less frequently, reducing the size of Xlogs and improving query performance.</p> | true or false |

Examples

Create the **customer** table.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer
(
  C_CUSTKEY    BIGINT NOT NULL CONSTRAINT C_CUSTKEY_pk PRIMARY KEY ,
  C_NAME      VARCHAR(25) ,
  C_ADDRESS   VARCHAR(40) ,
  C_NATIONKEY INT NOT NULL CHECK (C_NATIONKEY > 0)
```

```
)  
DISTRIBUTE BY HASH(C_CUSTKEY);
```

Create the **store_returns_t1** table and insert numbers that are greater than 4795 in the **C_CUSTKEY** column of the **CUSTOMER** table:

```
CREATE TABLE store_returns_t1 AS SELECT * FROM CUSTOMER WHERE C_CUSTKEY > 4795;
```

Copy **store_returns_t1** to create the **store_returns_t2** table:

```
CREATE TABLE store_returns_t2 AS table store_returns_t1;
```

[CREATE TABLE, SELECT](#)

21.13.4.4 ALTER TABLE

Function

ALTER TABLE is used to modify tables, including modifying table definitions, renaming tables, renaming specified columns in tables, renaming table constraints, setting table schemas, enabling or disabling row-level access control, and adding or updating multiple columns.

Only the owner of a table, a user granted with the ALTER permission for the table, or a system administrator has the permission to run the **ALTER TABLE** statement. To change the owner or schema of a table, you must be the table owner or a system administrator and be a direct or indirect member of the new role.

Precautions

Table 21-158 Precautions for ALTER TABLE

| Constraint | Description |
|--|--|
| Storage method of tables | After a table is created, the parameter ORIENTATION (which specifies whether the table is a row-store or column-store table) cannot be modified. |
| Supported range of column-store tables | Column-store tables support PARTIAL CLUSTER KEY but do not support table-level foreign key constraints. In 8.1.1 or later, you can use the PRIMARY KEY constraint and table-level UNIQUE constraint during the column-store table creation. |
| Modification of column-store tables | <ul style="list-style-type: none">The NOT NULL constraint and PRIMARY KEY constraint can be added to existing column-store tables using ALTER. This constraint is supported only by clusters of version 8.2.0 or later.If you delete the PRIMARY KEY constraint by specifying the constraint name, the NOT NULL constraint is not deleted. You can manually delete the NOT NULL constraint as needed. |

| Constraint | Description |
|---|--|
| Columns of column-store tables | The column constraints supported by column-store tables include NULL , NOT NULL , and DEFAULT constant values. Only the DEFAULT value can be modified and deleted (SET DEFAULT and DROP DEFAULT), and only the NOT NULL constraint can be deleted. |
| Operations supported by column-store tables | <ul style="list-style-type: none">• ADD COLUMN is used to add a column. The types of new and modified columns should be the data types supported by column storage (for details, see Data Types).• ALTER TYPE is used to change the data type of a column. The USING option of ALTER TYPE supports only constant expressions and expressions involving the column.• SET STATISTICS is used to set the statistics collection target of a single column.• Table name can be modification.• DROP COLUMN is used to delete a column. |
| Modification of distribution columns | The data type of the distribution column in an existing table cannot be modified. |
| Row-store REPLICATION tables | A system column cannot be designated as a primary key in a row-store REPLICATION distributed table. |
| Auto-increment columns | Auto-increment columns cannot be added, or a column in which the DEFAULT value contains the nextval() expression cannot be added either. |
| Modification of OBS cold and hot tables | <ul style="list-style-type: none">• The cold_tablespace and storage_policy parameters of ALTER RESET cannot be used in OBS hot or cold tables, and COLVERSION cannot be changed to 1.0 for such tables.• You can change a column-store table whose COLVERSION is 2.0 to an OBS hot or cold table. The COLD_TABLESPACE and STORAGE_POLICY parameters must be added.• You can use ALTER TABLE to change the values of STORAGE_POLICY for REOPTIONS. After the cold/hot switchover policy is changed, the cold/hot attribute of the existing cold data will not change. The new policy takes effect for the next cold/hot switchover. |
| V3 tables | COLVERSION cannot be modified for V3 tables (COLVERSION is 3.0), and non-V3 tables (COLVERSION is 2.0) cannot be switched to V3 tables. |

| Constraint | Description |
|--|---|
| Operations that trigger table rebuilding | <p>When an ALTER TABLE operation is performed on a table, it triggers table rebuilding. During this process, data is dumped into a new data file. Once the process is complete, the original file is deleted. If the table is large, the process can use a significant amount of disk space. When the disk space is insufficient, exercise caution when performing the ALTER TABLE operation on large tables to prevent the cluster from being read-only.</p> <ul style="list-style-type: none">• Change the data type of a column.• Add columns (including the oid column) to a row-store table.• Modify COLVERSION for a column-store table.• Specify the DEFAULT constant values for a column added to a column-store table. If the DEFAULT values contain volatile functions or are not NULL and do not belong to a specific data type, ensure they are correctly defined. |
| Other | <ul style="list-style-type: none">• When you modify the COLVERSION or enable_delta parameter of a column-store table, other ALTER operations cannot be performed.• You cannot specify a tablespace when running ALTER TABLE for an unlogged table. When you run ALTER TABLE for a non-unlogged table, do not specify pg_unlogged as the tablespace.• Distribution columns cannot be modified for global temporary tables. |

**WARNING**

- Avoid performing **ALTER TABLE**, **ALTER TABLE PARTITION**, **DROP PARTITION**, and **TRUNCATE** operations during peak hours to prevent long SQL statements from blocking these operations or SQL services.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

ALTER TABLE Syntax Format

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
    action [, ... ];
```

action can be the following modification operations:

- Change the data type of an existing column in the table. You can modify the null constraint, default value, and comment information at the same time.

Only the type conversion of the same category (between values, strings, and time) is allowed.

```
ALTER TABLE [ IF EXISTS ] table_name
  MODIFY ( { column_name data_type | [ CONSTRAINT constraint_name ] NOT NULL [ ENABLE ] |
    [ CONSTRAINT constraint_name ] NULL | DEFAULT default_expr | COMMENT 'text' } [, ...] );
```

- Rename the table. Changing the name does not affect the stored data. Tables cannot be renamed across schemas. The new table name can contain the schema name of the original table. If **new_table_name** does not specify a schema, the new table and the original table are in the same schema.

```
ALTER TABLE [ IF EXISTS ] table_name
  RENAME TO new_table_name;
ALTER TABLE [ IF EXISTS ] table_name
  RENAME TO schema.new_table_name;
```

- Rename the specified column in the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
  RENAME [ COLUMN ] column_name TO new_column_name;
```

- Rename the constraint of the table.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
  RENAME CONSTRAINT constraint_name TO new_constraint_name;
```

- Set the schema of the table.

```
ALTER TABLE [ IF EXISTS ] table_name
  SET SCHEMA new_schema;
```

NOTE

- Currently, **SET SCHEMA** can only set schemas to user schemas. It cannot set a schema to a system internal schema.
- The schema setting moves the table into another schema. Associated indexes and constraints owned by table columns are migrated as well. Currently, the schema for sequences cannot be changed. If the table has sequences, delete the sequences, and create them again or delete the ownership between the table and sequences. In this way, the table schema can be changed.
- To change the schema of a table, you must also have CREATE privilege on the new schema. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE permission on the table's schema. These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the table. However, a system administrator can alter ownership of any table anyway.

- Add columns.

```
ALTER TABLE [ IF EXISTS ] table_name
  ADD ( { column_name data_type [ compress_mode ] [ COLLATE collation ] [ column_constraint
    [ ... ] ] } [, ...] );
```

- Update columns.

```
ALTER TABLE [ IF EXISTS ] table_name
  MODIFY ( { column_name data_type | column_name [ CONSTRAINT constraint_name ] NOT NULL
    [ ENABLE ] | column_name [ CONSTRAINT constraint_name ] NULL } [, ...] );
```

- Delete an index from a specified table.

```
ALTER TABLE table_name DROP INDEX index_name;
```

 NOTE

- All the actions except for **RENAME** and **SET SCHEMA** can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several columns or alter the type of several columns in a single command. This is useful with large tables, since only one pass over the table need be made.
- Adding a **CHECK** or **NOT NULL** constraint requires scanning the table to verify that existing rows meet the constraint.
- Adding a column with a non-null default or changing the type of an existing column will require the entire table to be rewritten. Table rebuilding may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

Clauses of action Related to Table Operations

There are several clauses of **action**:

```
column_clause
| ADD table_constraint [ NOT VALID ]
| ADD table_constraint_using_index
| VALIDATE CONSTRAINT constraint_name
| DROP CONSTRAINT [ IF EXISTS ] constraint_name [ RESTRICT | CASCADE ]
| CLUSTER ON index_name
| SET WITHOUT CLUSTER
| SET ( {storage_parameter = value} [, ... ] )
| RESET ( storage_parameter [, ... ] )
| OWNER TO new_owner
| SET TABLESPACE new_tablespace
| SET {COMPRESS|NOCOMPRESS}
| DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { HASH ( column_name [,...] ) } }
| TO { GROUP groupname | NODE ( nodename [, ... ] ) }
| ADD NODE ( nodename [, ... ] )
| DELETE NODE ( nodename [, ... ] )
| DISABLE TRIGGER [ trigger_name | ALL | USER ]
| ENABLE TRIGGER [ trigger_name | ALL | USER ]
| ENABLE REPLICA TRIGGER trigger_name
| ENABLE ALWAYS TRIGGER trigger_name
| DISABLE ROW LEVEL SECURITY
| ENABLE ROW LEVEL SECURITY
| FORCE ROW LEVEL SECURITY
| NO FORCE ROW LEVEL SECURITY
| REFRESH STORAGE
```

- **ADD table_constraint [NOT VALID]**
Adds a new table constraint. When used with the **NOT VALID** option, this constraint is valid only for foreign keys and **CHECK** constraints. If the **NOT VALID** option is added to the constraint, the check on whether the existing records in the table meet the initial constraint is skipped.
- **ADD table_constraint_using_index**
Adds primary key constraint or unique constraint based on the unique index.
- **VALIDATE CONSTRAINT constraint_name**
Validates a foreign key or check constraint that was previously created as **NOT VALID**, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid.
- **DROP CONSTRAINT [IF EXISTS] constraint_name [RESTRICT | CASCADE]**
Drops a table constraint.

- **CLUSTER ON index_name**
Selects the default index for future **CLUSTER** operations. It does not actually re-cluster the table.
- **SET WITHOUT CLUSTER**
Removes the most recently used **CLUSTER** index specification from the table. This operation affects future cluster operations that do not specify an index.
- **SET ({storage_parameter = value} [, ...])**
Changes one or more storage parameters for the table.
- **RESET (storage_parameter [, ...])**
Resets one or more storage parameters to their defaults. As with **SET**, a table rewrite might be needed to update the table entirely.
- **OWNER TO new_owner**
Changes the owner of the table, sequence, or view to the specified user.
- **SET {COMPRESS|NOCOMPRESS}**
Sets the compression feature of a table. The table compression feature affects only the storage mode of data inserted in a batch subsequently and does not affect storage of existing data. Setting the table compression feature will result in the fact that there are both compressed and uncompressed data in the table.
- **DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { HASH (column_name [,...]) } }**
Changing a table's distribution mode will physically redistribute the table data based on the new distribution mode. After the distribution mode is changed, you are advised to manually run the **ANALYZE** statement to collect new statistics about the table.

 NOTE

- This operation is a major change operation, involving table distribution information modification and physical data redistribution. During the modification, services are blocked. After the modification, the original execution plan of services will change. Perform this operation according to the standard change process.
- This operation is a resource-intensive operation. If you need to modify the distribution mode of large tables, perform the operation when the computing and storage resources are sufficient. Ensure that the remaining space of the entire cluster and the tablespace where the original table is located is sufficient to store a table that has the same size as the original table and is distributed in the new distribution mode.
- **TO { GROUP groupname | NODE (nodename [, ...]) }**
The syntax is only available in extended mode (when GUC parameter **enable_cluster_resize** is **on**). Exercise caution when enabling the mode. It is used for tools like internal dilatation tools. Common users should not use the mode.
- **ADD NODE (nodename [, ...])**
It is only available for tools like internal dilatation. General users should not use the mode.
- **DELETE NODE (nodename [, ...])**
It is only available for internal scale-in tools. Common users should not use the syntax.

- **DISABLE TRIGGER [trigger_name | ALL | USER]**

Disables a single trigger specified by **trigger_name**, disables all triggers, or disables only user triggers (excluding internally generated constraint triggers, for example, deferrable unique constraint triggers and exclusion constraints triggers).

 NOTE

Exercise caution when using this function because data integrity cannot be ensured as expected if the triggers are not executed.

- **ENABLE TRIGGER [trigger_name | ALL | USER]**

Enables a single trigger specified by **trigger_name**, enables all triggers, or enables only user triggers.

- **ENABLE REPLICA TRIGGER trigger_name**

Determines that the trigger firing mechanism is affected by the configuration variable **session_replication_role**. When the replication role is **origin** (default value) or **local**, a simple trigger is fired.

When **ENABLE REPLICA** is configured for a trigger, it is fired only when the session is in **replica** mode.

- **ENABLE ALWAYS TRIGGER trigger_name**

Determines that all triggers are fired regardless of the current replication mode.

- **DISABLE/ENABLE ROW LEVEL SECURITY**

Enables or disables row-level access control for a table.

If row-level access control is enabled for a data table but no row-level access control policy is defined, the row-level access to the data table is not affected. If row-level access control for a table is disabled, the row-level access to the table is not affected even if a row-level access control policy has been defined. For details, see [CREATE ROW LEVEL SECURITY POLICY](#).

 NOTE

Row-level access control cannot be enabled for HDFS tables, foreign tables, and temporary tables.

- **NO FORCE/FORCE ROW LEVEL SECURITY**

Forcibly enables or disables row-level access control for a table.

By default, the table owner is not affected by the row-level access control feature. However, if row-level access control is forcibly enabled, the table owner (excluding system administrators) will be affected. System administrators are not affected by any row-level access control policies.

- **REFRESH STORAGE**

Changes the local hot partitions that meet the criteria specified in the **storage_policy** parameter of an OBS multi-temperature table to the cold partitions stored in the OBS.

For example, if **storage_policy** is set to **'LMT:10'** for an OBS hot or cold table when it is created, the partitions that are not updated within the last 10 days are switched to cold partitions in the OBS.

Clauses of column_clause Related to Column Operations

There are several clauses of **column_clause**:

```
ADD [ COLUMN ] column_name data_type [ compress_mode ] [ COLLATE collation ] [ column_constraint  
[ ... ] ]  
| MODIFY [ COLUMN ] column_name data_type  
| MODIFY [ COLUMN ] column_name [ CONSTRAINT constraint_name ] NOT NULL [ ENABLE ]  
| MODIFY [ COLUMN ] column_name [ CONSTRAINT constraint_name ] NULL  
| MODIFY [ COLUMN ] column_name DEFAULT default_expr  
| MODIFY [ COLUMN ] column_name ON UPDATE on_update_expr  
| MODIFY [ COLUMN ] column_name COMMENT comment_text  
| DROP [ COLUMN ] [ IF EXISTS ] column_name [ RESTRICT | CASCADE ]  
| ALTER [ COLUMN ] column_name [ SET DATA ] TYPE data_type [ COLLATE collation ] [ USING  
expression ]  
| ALTER [ COLUMN ] column_name { SET DEFAULT expression | DROP DEFAULT }  
| ALTER [ COLUMN ] column_name { SET | DROP } NOT NULL  
| ALTER [ COLUMN ] column_name SET STATISTICS [PERCENT] integer  
| ADD STATISTICS (( column_1_name, column_2_name [, ...] ))  
| ADD { INDEX | UNIQUE [ INDEX ] } [ index_name ] ( ( { column_name | ( expression ) } [ COLLATE  
collation ] [ opclass ] [ ASC | DESC ] [ NULLS LAST ] } [, ...] ) [ USING method ] [ NULLS [ NOT ] DISTINCT  
| NULLS IGNORE ] [ COMMENT 'text' ] LOCAL [ ( { PARTITION index_partition_name } [, ...] ) ] [ WITH  
( { storage_parameter = value } [, ...] ) ]  
| ADD { INDEX | UNIQUE [ INDEX ] } [ index_name ] ( ( { column_name | ( expression ) } [ COLLATE  
collation ] [ opclass ] [ ASC | DESC ] [ NULLS { FIRST | LAST } } [, ...] ) [ USING method ] [ NULLS [ NOT ]  
DISTINCT | NULLS IGNORE ] [ COMMENT 'text' ] [ WITH ( {storage_parameter = value} [, ...] ) ] [ WHERE  
predicate ]  
| DROP { INDEX | KEY } index_name  
| CHANGE [ COLUMN ] old_column_name new_column_name data_type [ [ CONSTRAINT  
constraint_name ] NOT NULL [ ENABLE ] |  
[ CONSTRAINT constraint_name ] NULL | DEFAULT default_expr | COMMENT 'text' ]  
| DELETE STATISTICS (( column_1_name, column_2_name [, ...] ))  
| ALTER [ COLUMN ] column_name SET ( {attribute_option = value} [, ...] )  
| ALTER [ COLUMN ] column_name RESET ( attribute_option [, ...] )  
| ALTER [ COLUMN ] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
```

- **ADD [COLUMN] column_name data_type [compress_mode] [COLLATE collation] [column_constraint [...]]**
Adds a column to a table. If a column is added with **ADD COLUMN**, all existing rows in the table are initialized with the column's default value (**NULL** if no **DEFAULT** clause is specified).
- **ADD ({ column_name data_type [compress_mode] } [, ...])**
Adds columns in the table.
- **MODIFY [COLUMN] column_name data_type**
Modifies the data type of an existing field in a table. Note that the data type of the distribution column cannot be modified.
- **MODIFY [COLUMN] column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE]**
Adds a NOT NULL constraint to a column of a table. Currently, this clause is unavailable to column-store tables.
- **MODIFY [COLUMN] column_name [CONSTRAINT constraint_name] NULL**
Deletes the NOT NULL constraint to a certain column in the table.
- **MODIFY [COLUMN] column_name DEFAULT default_expr**
Changes the default value of the table.
- **MODIFY [COLUMN] column_name ON UPDATE on_update_expr**
Modifies the ON UPDATE expression of a specified column in a table. The column must be of the timestamp or timestampz type. If **on_update_expr** is **NULL**, the **ON UPDATE** clause is deleted.

- **MODIFY [COLUMN] column_name COMMENT comment_text**
Modifies the comment of the table.
- **DROP [COLUMN] [IF EXISTS] column_name [RESTRICT | CASCADE]**
Drops a column from a table. Index and constraint related to the column are automatically dropped. If an object not belonging to the table depends on the column, **CASCADE** must be specified, such as foreign key reference and view.
The **DROP COLUMN** form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a **NULL** value for the column. Therefore, column deletion takes a short period of time but does not immediately release the table space on the disks, because the space occupied by the deleted column is not reclaimed. The space will be reclaimed when **VACUUM** is executed.
- **ALTER [COLUMN] column_name [SET DATA] TYPE data_type [COLLATE collation] [USING expression]**
Change the data type of a field in the table. Only the type conversion of the same category (between values, character strings, and time) is allowed. Indexes and simple table constraints on the column will automatically use the new data type by reparsing the originally supplied expression.
ALTER TYPE requires an entire table be rewritten. This is an advantage sometimes, because it frees up unnecessary space from a table. For example, to reclaim the space occupied by a deleted column, the fastest method is to use the command.

```
ALTER TABLE table ALTER COLUMN anycol TYPE anytype;
```

In this command, **anycol** indicates any column existing in the table and **anytype** indicates the type of the prototype of the column. **ALTER TYPE** does not change the table except that the table is forcibly rewritten. In this way, the data that is no longer used is deleted.
USING in **ALTER TYPE** can specify any expression involving the old values of the row; that is, it can refer to any columns other than the one being converted. This allows very general conversions to be done with the **ALTER TYPE** syntax. Because of this flexibility, the **USING** expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, **ALTER TYPE** might fail to convert the default even though a **USING** clause is supplied. In such cases, drop the default with **DROP DEFAULT**, perform the **ALTER TYPE**, and then use **SET DEFAULT** to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.
- **ALTER [COLUMN] column_name { SET DEFAULT expression | DROP DEFAULT }**
Sets or removes the default value for a column. The default values only apply to subsequent **INSERT** commands; they do not cause rows already in the table to change. Defaults can also be created for views, in which case they are inserted into **INSERT** statements on the view before the view's **ON INSERT** rule is applied.
- **ALTER [COLUMN] column_name { SET | DROP } NOT NULL**
Changes whether a column is marked to allow **NULL** values or to reject **NULL** values. You can only use **SET NOT NULL** when the column contains no **NULL** values.

- **ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer**
Specifies the per-column statistics-gathering target for subsequent **ANALYZE** operations. The value ranges from **0** to **10000**. Set it to **-1** to revert to using the default system statistics target.
- **ADD { INDEX | UNIQUE [INDEX] } [index_name] ({ { column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS LAST] } [, ...]) [USING method] [NULLS [NOT] DISTINCT | NULLS IGNORE] [COMMENT 'text'] LOCAL [({ PARTITION index_partition_name } [, ...])] [WITH ({ storage_parameter = value } [, ...])]**
Create an index for the partitioned table. For details about the parameters, see [CREATE INDEX](#).
- **ADD { INDEX | UNIQUE [INDEX] } [index_name] ({ { column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS { FIRST | LAST }] } [, ...]) [USING method] [NULLS [NOT] DISTINCT | NULLS IGNORE] [COMMENT 'text'] [WITH ({storage_parameter = value} [, ...])] [WHERE predicate]**
Create an index on the table. For details about the parameters, see [CREATE INDEX](#).
- **DROP { INDEX | KEY } index_name**
Deletes an index from a table.
- **CHANGE [COLUMN] old_column_name new_column_name data_type [[CONSTRAINT constraint_name] NOT NULL [ENABLE] | [CONSTRAINT constraint_name] NULL | DEFAULT default_expr | COMMENT 'text']**
Modifies the column information in the table, such as column names and column field information.
- **{ADD | DELETE} STATISTICS ((column_1_name, column_2_name [, ...]))**
Adds or deletes the declaration of collecting multi-column statistics to collect multi-column statistics as needed when **ANALYZE** is performed for a table or a database. The statistics about a maximum of 32 columns can be collected at a time. You are not allowed to add or delete the declaration for system tables or foreign tables
- **ALTER [COLUMN] column_name SET ({attribute_option = value} [, ...])**
ALTER [COLUMN] column_name RESET (attribute_option [, ...])
Sets or resets per-attribute options.
The attribute option parameters are **n_distinct**, **n_distinct_inherited**, and **cstore_cu_sample_ratio**. **n_distinct** specifies and fixes the statistics of a table's distinct values. **n_distinct_inherited** specifies and inherits the distinct value statistics. **cstore_cu_sample_ratio** specifies the CU ratio for **ANALYZE** on a column-store table. Currently, the **n_distinct_inherited** parameter cannot be set or reset.
 - **n_distinct**
Sets the distinct value statistics of the column.
Value range: -1.0 to INT_MAX
Default value: **0**, indicating that this parameter is not set.

- **n_distinct_inherited**
Sets the distinct value statistics of the column in an inherited table.
Value range: -1.0 to INT_MAX
Default value: **0**, indicating that this parameter is not set.
- **cstore_cu_sample_ratio**
Specifies the expansion multiple in the calculation of CUs to be sampled during ANALYZE on a column-store table.
Value range: 1.0-10000.0
Default value: **1.0**
- **ALTER [COLUMN] column_name SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }**
Sets the storage mode for a column. This clause specifies whether this column is held inline or in a secondary TOAST table, and whether the data should be compressed. This statement can only be used for row-based tables. **SET STORAGE** only sets the strategy to be used for future table operations.

Options of Other Parameters

- **column_constraint** is as follows:
[CONSTRAINT constraint_name]
{ NOT NULL |
NULL |
CHECK (expression) |
DEFAULT default_expr |
UNIQUE [NULLS [NOT] DISTINCT | NULLS IGNORE] index_parameters |
PRIMARY KEY index_parameters }
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]
- **compress_mode** of a column is as follows:
[DELTA | PREFIX | DICTIONARY | NUMSTR | NOCOMPRESS]
- **table_constraint_using_index** used to add the primary key constraint or unique constraint based on the unique index is as follows:
[CONSTRAINT constraint_name]
{ UNIQUE | PRIMARY KEY } USING INDEX index_name
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]
- Add foreign key constraint **REFERENCES**.
[CONSTRAINT constraint_name]
FOREIGN KEY (column_name [, ...]) REFERENCES reftable [(refcolumn [, ...])]
- **table_constraint** is as follows:
[CONSTRAINT constraint_name]
{ CHECK (expression) |
UNIQUE [NULLS [NOT] DISTINCT | NULLS IGNORE] (column_name [, ...]) index_parameters |
PRIMARY KEY (column_name [, ...]) index_parameters }
[DEFERRABLE | NOT DEFERRABLE | INITIALLY DEFERRED | INITIALLY IMMEDIATE]
- **index_parameters** is as follows:
[WITH ({storage_parameter = value} [, ...])]
[USING INDEX TABLESPACE tablespace_name]

Parameter Description

Table 21-159 ALTER TABLE parameters

| Parameter | Description | Value Range |
|---|--|---|
| IF EXISTS | Sends a prompt instead of an error if the table name does not exist. | - |
| ONLY | Performs operations only on the specified table name. If ONLY is not specified:

The table and all subtables will be modified.

Note that you can only add or delete columns to or from a parent or child table, or change the type of a column. The parent table and its subsequent representatives must always have the same columns and types. | - |
| table_name | Specifies the name of the table to be modified.

You can add the asterisk (*) option following the table name to specify that all subtables are scanned, which is the default operation. | Valid table name. |
| new_table_name | New name of a table. | A string compliant with the identifier naming rules . |
| column_name, column_1_name, and column_2_name | Specifies the name of an existing or new field. | Valid column name. |
| new_column_name | Specifies the new name of a column. | A string compliant with the identifier naming rules . |
| constraint_name | Specifies the name of a constraint. | Valid constraint name. |
| new_constraint_name | Specifies the new name of a table constraint. | A string compliant with the identifier naming rules . |
| schema_name | Specifies the schema name of a table. | Valid schema name. |
| new_schema | Specifies the new schema name. | Valid schema name. |
| index_name | Specifies the index name. | Valid index name. |

| Parameter | Description | Value Range |
|-------------------|---|---|
| new_owner | Specifies the name of the new owner of the table. | Valid username or role name. |
| new_tablespace | Specifies the name of the new tablespace to which the table belongs. | Valid tablespace name. |
| data_type | Specifies the type of a new column or a new type of an existing column. | A string compliant with the identifier naming rules . |
| storage_parameter | Specifies the storage parameters of a table. | For details, see Table 21-160 . |
| compress_mode | Specifies the compression option of the table column. Currently, this parameter is valid only for row-store tables. The clause specifies the algorithm preferentially used by the column. | - |
| collation | Specifies the collation rule name of a column. The optional COLLATE clause specifies a collation for the new column; if omitted, the collation is the default for the new column. | - |
| USING expression | A USING clause specifies how to compute the new column value from the old; if omitted, the default conversion is an assignment cast from old data type to new. A USING clause must be provided if there is no implicit or assignment cast from the old to new type. | - |
| NOT NULL NULL | Sets whether the column allows null values. | - |
| integer | Specifies the constant value of an integer with a sign. When PERCENT is used, statistics are collected based on the percentage of table data. | 0~100 |
| attribute_option | Specifies an attribute option. | - |

| Parameter | Description | Value Range |
|---------------------------------------|---|-------------|
| PLAIN EXTERNAL
EXTENDED MAIN | <p>Specifies a column storage mode.</p> <ul style="list-style-type: none">• PLAIN must be used for fixed-length values (such as integers). It must be inline and uncompressed.• MAIN is for inline, compressible data.• EXTERNAL is for external, uncompressed data. Use of EXTERNAL will make substring operations on text and bytea values run faster, at the penalty of increased storage space.• EXTENDED is for external, compressed data. EXTENDED is the default for most data types that support non-PLAIN storage. | - |
| CHECK
(expression) | <p>New or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to TRUE succeed. If any row of an insert or update operation produces a FALSE result, an error exception is raised and the insert or update does not alter the database.</p> <p>A check constraint specified as a column constraint should reference only the column's values, while an expression appearing in a table constraint can reference multiple columns.</p> <p>Currently, CHECK expression does not include subqueries and cannot use variables apart from the current column.</p> | - |

| Parameter | Description | Value Range |
|---|--|-------------|
| DEFAULT
default_expr | <p>Assigns a default data value for a column.</p> <p>The data type of the default expression must match the data type of the column.</p> <p>The default expression will be used in any insert operation that does not specify a value for the column. If there is no default value for a column, then the default value is NULL.</p> <p>If a suffix operator, such as (!). is used in default_expr, enclose the operator in parentheses.</p> | - |
| UNIQUE [NULLS
[NOT] DISTINCT
NULLS IGNORE]
index_parameters

UNIQUE
(column_name
[, ...]) [NULLS
[NOT] DISTINCT
NULLS IGNORE]
index_parameters | <p>The UNIQUE constraint specifies that a group of one or more columns of a table can contain only unique values.</p> <p>The [NULLS [NOT] DISTINCT NULLS IGNORE] field is used to specify how to process null values in the index column of the Unique index. For details, see Table 21-161.</p> <p>Default value: This parameter is left empty by default. NULL values can be inserted repeatedly.</p> | - |
| PRIMARY KEY
index_parameters

PRIMARY KEY
(column_name
[, ...])
index_parameters | <p>The primary key constraint specifies that a column or columns of a table can contain only unique (non-duplicate) and non-null values.</p> | - |

| Parameter | Description | Value Range |
|--|---|-------------|
| DEFERRABLE NOT DEFERRABLE INITIALLY DEFERRED INITIALLY IMMEDIATE | Sets whether the constraint is deferrable. This option is unavailable to column-store tables. <ul style="list-style-type: none">• DEFERRABLE: deferrable can be postponed until the end of the transaction using the SET CONSTRAINTS command.• NOT DEFERRABLE: checks immediately after the execution of each command.• INITIALLY IMMEDIATE: checks immediately after the execution of each statement.• INITIALLY DEFERRED: checks when the transaction ends. | - |
| WITH
({storage_parameter = value} [, ...]) | Specifies an optional storage parameter for a table or an index. | - |
| COMPRESS
NOCOMPRESS | <ul style="list-style-type: none">• NOCOMPRESS: If the NOCOMPRESS keyword is specified, the existing compression feature of the table is not changed.• COMPRESS: If the COMPRESS keyword is specified, the table compression feature is triggered if tuples are inserted in a batch. | - |
| CASCADE | Automatically drops objects that depend on the dropped column or constraint (for example, views referencing the column). | - |
| RESTRICT | Refuses to drop the column or constraint if there are any dependent objects. This is the default behavior. | - |

| Parameter | Description | Value Range |
|--------------|---|---|
| cache_policy | <p>Specifies the table cache policy. This parameter is supported only in storage-compute decoupled 3.0 clusters.</p> <p>Default value: ALL</p> | <ul style="list-style-type: none">• ALL: Hot cache is used for the entire table.• NONE: Cold cache is used for the entire table.• HPN: The first <i>N</i> partitions in a partitioned table use hot cache. The rest of the partitions use cold cache.• HPL: <i>P1, P2,</i> In a partitioned table, the specified partitions use hot cache. The rest of the partitions use cold cache. <p>NOTE</p> <ul style="list-style-type: none">• For foreign tables and non-partitioned tables, only the ALL and NONE cache policies are supported.• Only range-partitioned and list-partitioned internal tables support HPN and HPL cache policies. |

Table 21-160 storage_parameter parameters

| Parameter Type | Parameter | Description | Value Range |
|---|-----------|---|---|
| Partition management parameters (newly added) | PERIOD | <p>Sets the period for automatically creating partitions in partition management.</p> <p>NOTE</p> <ul style="list-style-type: none">If this parameter is not configured when you create a table, you can run the set statements to configure this parameter and enable automatic partition creation. If this parameter has been configured before, you can run the set statements to modify this parameter.You can run the reset command to disable the automatic partition creation function. However, if the automatic partition deletion function is enabled, the automatic partition creation function cannot be disabled. | <p>Interval type.</p> <p>For details about the value range of PERIOD and the constraints on enabling this function, see the PERIOD parameter in WITH Clause Parameters.</p> |
| | TTL | <p>Sets the partition expiration time for automatically deleting partitions in partition management.</p> <p>NOTE</p> <ul style="list-style-type: none">If this parameter is not configured when you create a table, you can run the set statements to configure this parameter and enable automatic partition deletion. If this parameter has been configured before, you can run the set statements to modify this parameter.You can run the reset command to disable the automatic partition deletion. | <p>Interval type.</p> <p>For details about the value range of TTL and restrictions on enabling this function, see the TTL parameters in WITH Clause Parameters.</p> |

| Parameter Type | Parameter | Description | Value Range |
|---|--------------------|---|-------------|
| Parameters related to column-store tables in Turbo storage format (newly added) | enable_turbo_store | <p>Specifies whether the column-store table is in the turbo storage format. This is supported only by 9.1.0.100 and later cluster versions.</p> <p>NOTE</p> <ul style="list-style-type: none">Common column-store tables in version 3.0 do not support the turbo storage format, while HStore Opt tables in version 3.0 only support the turbo storage format.In version 2.0, there is no restriction on column-store tables. | - |

The NULL value of the index column in the unique index is processed as follows:

Use the **[NULLS [NOT] DISTINCT | NULLS IGNORE]** field to set how null values are handled in the unique index column.

When the inserted data is compared with the original data in the table, the NULL value can be processed in any of the following ways:

- **NULLS DISTINCT:** NULL values are unequal and can be inserted repeatedly.
- **NULLS NOT DISTINCT:** NULL values are equal. If all index columns are NULL, NULL values cannot be inserted repeatedly. If some index columns are NULL, data can be inserted only when non-null values are different.
- **NULLS IGNORE:** NULL values are skipped during the equivalent comparison. If all index columns are NULL, NULL values can be inserted repeatedly. If some index columns are NULL, data can be inserted only when non-null values are different.

Table 21-161 Processing of NULL values in index columns in unique indexes

| Constraint | All Index Columns Are NULL | Some Index Columns Are NULL. |
|--------------------|--------------------------------|--|
| NULLS DISTINCT | Can be inserted repeatedly. | Can be inserted repeatedly. |
| NULLS NOT DISTINCT | Cannot be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |

| Constraint | All Index Columns Are NULL | Some Index Columns Are NULL. |
|--------------|-----------------------------|--|
| NULLS IGNORE | Can be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |

Table Operation Examples

Create the sample table **customer**.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer
(
  C_CUSTKEY    BIGINT      ,
  C_NAME      VARCHAR(25) ,
  C_ADDRESS   VARCHAR(40) ,
  C_NATIONKEY INT          ,
  C_PHONE     CHAR(15)    ,
  C_ACCTBAL   DECIMAL(15,2)
)
DISTRIBUTE BY HASH(C_CUSTKEY);
```

Create the column-store table **customer_address**.

```
DROP TABLE IF EXISTS customer_address;
CREATE TABLE customer_address
(
  ca_address_sk    INTEGER          NOT NULL ,
  ca_address_id    CHARACTER(16)    NOT NULL ,
  ca_street_number CHARACTER(10)      ,
  ca_street_name   CHARACTER varying(60) ,
  ca_street_type   CHARACTER(15)      ,
  ca_suite_number  CHARACTER(10)
)
WITH (ORIENTATION = COLUMN, COMPRESSION=HIGH,COLVERSION=2.0)
DISTRIBUTE BY HASH (ca_address_sk);
```

- Change the schema of a table.
Set the schema of the **customer** table to **myschema**.

```
ALTER TABLE customer SET SCHEMA myschema;
```
- Add a primary key constraint or unique constraint based on the unique index.
Create a unique index **customer_constraint1** for the customer table, add a primary key constraint based on the existing unique index, and rename the index.

```
CREATE UNIQUE INDEX customer_constraint1 ON customer(C_CUSTKEY);
ALTER TABLE customer ADD CONSTRAINT customer_constraint2 PRIMARY KEY USING INDEX customer_constraint1;
```
- Rename a table constraint.

```
ALTER TABLE customer RENAME CONSTRAINT customer_constraint2 TO customer_constraint;
```
- Delete a table constraint.

```
ALTER TABLE customer DROP CONSTRAINT customer_constraint;
```
- Add a primary key constraint to a table.

```
ALTER TABLE CUSTOMER ADD PRIMARY KEY(C_CUSTKEY);
```
- Add a partial cluster column to the column-store table **customer_address**.

```
ALTER TABLE customer_address ADD CONSTRAINT customer_address_cluster PARTIAL CLUSTER KEY(ca_address_sk);
```

- Delete the partial cluster column from the column-store table **customer_address**.
`ALTER TABLE customer_address DROP CONSTRAINT customer_address_cluster;`
- Modify the storage format of a column-store table.
`ALTER TABLE customer_address SET (COLVERSION = 1.0);`
- Change the distribution mode of a table.
`ALTER TABLE customer_address DISTRIBUTE BY REPLICATION;`
- Rename a table.
`ALTER TABLE CUSTOMER RENAME TO CUSTOMER_t;`
- Modify the table cache policy (supported only in storage-compute decoupled 3.0 clusters).
`ALTER TABLE orders SET (cache_policy = 'NONE');`
- Disable the automatic partition deletion function of a table. For details about how to create a table, see [Example: Creating a Partitioned Table with Automatic Partition Management and Specified Partitions](#).
`ALTER TABLE CPU RESET (ttl);`

Index Operation Example

- Add an index to a table.
`ALTER TABLE customer ADD INDEX customer_index(C_CUSTKEY);`
- Delete a table index.
`ALTER TABLE customer DROP INDEX customer_index;`
`ALTER TABLE customer DROP KEY customer_index;`
- Adds an index to a column in a table.
`ALTER TABLE CUSTOMER ADD c_address_id varchar(20) CONSTRAINT ca_address_index CHECK (c_address_id > 0);`

Hot and Cold Table Operation Example

- Do a cold or hot switchover for a single table.
`ALTER TABLE cold_hot_table REFRESH STORAGE;`
- Change a column-store partitioned table to a hot and cold table.
`CREATE table test_1(id int,d_time date)
WITH(ORIENTATION=COLUMN)
DISTRIBUTE BY HASH (id)
PARTITION BY RANGE (d_time)
(PARTITION p1 START('2022-01-01') END('2022-01-31') EVERY(interval '1 day'))

ALTER TABLE test_1 SET (storage_policy = 'LMT:100');`

Column Operation Example

Create the sample table **warehouse_t**.

```
DROP TABLE IF EXISTS warehouse_t;  
CREATE TABLE warehouse_t  
(  
    W_WAREHOUSE_SK      INTEGER          NOT NULL,  
    W_WAREHOUSE_ID      CHAR(16)         NOT NULL,  
    W_WAREHOUSE_NAME     VARCHAR(20)     UNIQUE DEFERRABLE,  
    W_WAREHOUSE_SQ_FT    INTEGER          ,  
    W_COUNTY            VARCHAR(30)      ,  
    W_STATE              CHAR(2)         DEFAULT 'GA',  
    W_ZIP               CHAR(10)  
);
```

- Adds a column.
Adds a column to the **warehouse_t** table.
`ALTER TABLE warehouse_t ADD W_GOODS_CATEGORY int;`

Adds multiple columns to the **warehouse_t** table.

```
ALTER TABLE warehouse_t ADD (W_COMMENT VARCHAR(117) NOT NULL, W_COUNT int);
```

- Delete a column.

Delete a column from the **warehouse_t** table.

```
ALTER TABLE warehouse_t DROP COLUMN W_STATE;
```

- Rename a column.

Change the column name **W_ZIP** of the **warehouse_t** table to **new_W_ZIP**.

```
ALTER TABLE warehouse_t RENAME W_ZIP TO new_W_ZIP;
```

- Change the column name and column field information.

Change the column name **W_GOODS_CATEGORY** of the **warehouse_t** table to **W_GOODS_CATEGORY2**, change the data type of the **W_GOODS_CATEGORY2** column to **DECIMAL**, and set the column constraint to **NOT NULL**.

```
ALTER TABLE warehouse_t CHANGE W_GOODS_CATEGORY W_GOODS_CATEGORY2 DECIMAL NOT NULL COMMENT 'W_GOODS_CATEGORY';
```

- Change the comment of a column.

```
ALTER TABLE warehouse_t MODIFY W_GOODS_CATEGORY2 COMMENT 'W_GOODS_CATEGORY';
```

- Change the data type of a column.

Change the data type of the **warehouse_t** column and set the column constraint to **NOT NULL**.

```
ALTER TABLE warehouse_t MODIFY W_WAREHOUSE_SQ_FT varchar(20) NOT NULL;
```

- Add the **NOT NULL** constraint to a column.

```
ALTER TABLE warehouse_t ALTER COLUMN W_COUNTY SET NOT NULL;
```

- Add a primary key to the **warehouse_t** table.

```
ALTER TABLE warehouse_t ADD PRIMARY KEY(w_warehouse_name);
```

- Modify the **ON UPDATE** expression of a specified column in a table.

Add a timestamp column with the **ON UPDATE** expression to the **warehouse_t** table. The timestamp of the column is automatically updated when an **UPDATE** operation is performed on the table.

```
ALTER TABLE warehouse_t ADD COLUMN C_TIME timestamp on update current_timestamp;
```

Delete the timestamp column with the **ON UPDATE** expression from the **warehouse_t** table.

```
ALTER TABLE warehouse_t MODIFY COLUMN C_TIME timestamp on update NULL;
```

21.13.4.5 ALTER TABLE PARTITION

Function

ALTER TABLE PARTITION is used to modify table partitions, including adding, deleting, splitting, merging partitions, migrating data from ordinary tables to partitioned tables, and modifying partition attributes.

A partitioned table is a logical table that is divided into segments, called partitions whose data is stored on different physical blocks.

Common partitioning strategies define data ranges based on one or more columns. Each partition stores data within a range. These columns are called partition keys.

Currently, DWS row-store and column-store tables support range partitioning and list partitioning.

- Range partitioning

A table is partitioned into ranges defined by a key column or set of columns, with no overlap between the ranges of values assigned to different partitions. Each range has a dedicated partition for data storage.

 - Core feature: Data is distributed by consecutive intervals. It is used in scenarios where data is ordered and retrieved by range.
 - Scenario: Partition keys increase linearly or have continuous intervals. Data query is usually performed around a certain range, and new data naturally falls into a new range. For example, data about orders is partitioned by time range, and data about user levels is partitioned by value range.
 - Range partitioning maps data to partitions based on ranges of values of the partitioning key that you establish for each partition. This is the most commonly used partitioning policy. Currently, range partitioning only allows the use of the range partitioning policy.
- List partitioning

List partitioning allocates records to partitions based on the key values in each partition. The key values do not overlap in different partitions. Each set of key values gets its own partition for storing related data. List partitioning is supported only by clusters of version 8.1.3 or later.

 - Core feature: Data is divided based on discrete enumerated values, which are used as fixed classification category or high-frequency filter criteria.
 - Scenario: Partition key values are fixed and discrete. Data query is usually based on a certain category, and key values do not increase irregularly. For example, the user information table is partitioned by province, and each province corresponds to a partition.
 - In list partitioning, data is mapped to a created partition based on the partition key value. If the data can be mapped to, it is inserted into the specific partition. If it cannot be mapped to, error messages are returned.

Precautions

- The name of the partition to be added cannot be the same as that of an existing partition in the partitioned table.
- For a range partitioned table, the boundary value of the added partition must be the same type as the partition key of the partitioned table. The key value of the added partition must exceed the upper limit of the last partition.
- For a list partitioned table, if the DEFAULT partition has been defined, no new partition can be added.
- Unless otherwise specified, the syntax of range partitioned tables is the same as that of column-store partitioned tables.
- If the number of partitions in the target partitioned table has reached the maximum (32767), partitions cannot be added.
- If a partitioned table has only one partition, the partition cannot be deleted.
- When you run the **DROP PARTITION** command to delete a partition, the data in the partition is also deleted.

- Use **PARTITION FOR()** to choose partitions. The number of specified values in the brackets should be the same as the column number in customized partition, and they must be consistent.
- The **Value** partitioned table does not support the **Alter Partition** operation.
- For OBS hot and cold tables:
 - They do not support specifying the partition table's tablespace as the OBS tablespace for **MOVE**, **EXCHANGE**, **MERGE**, and **SPLIT** operations.
 - When an **ALTER** statement is executed, the data in the cold partition should stay in the cold partition, and the data in the hot partition should remain in the hot partition. It is not allowed to move cold partition data to the local tablespace.
 - Only the default tablespace is supported for cold partitions.
 - Cold and hot partitions cannot be merged.
 - Cold partition switching is not supported during the **EXCHANGE** operation.

**WARNING**

- Avoid performing **ALTER TABLE**, **ALTER TABLE PARTITION**, **DROP PARTITION**, and **TRUNCATE** operations during peak hours to prevent long SQL statements from blocking these operations or SQL services.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

Modify the syntax of the table partition.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
action [, ... ];
```

action indicates the following clauses for maintaining partitions. For the partition continuity when multiple clauses are used for partition maintenance, DWS does **DROP PARTITION** and then **ADD PARTITION**, and finally runs the rest clauses in sequence.

- **MODIFY PARTITION: Setting Whether a Partitioned Index Is Available**
- **REBUILD PARTITION syntax: Rebuilding a Partitioned Index**
- **EXCHANGE PARTITION: Moving the Data from an Ordinary Table to a Specified Partition**
- **ROW MOVEMENT: Setting the Row Movement Switch of a Partitioned Table**
- **MERGE PARTITIONS: Merging Partitions Into One**
- **SPLIT PARTITION: Splitting One Partition into Multiple Ones**
- **ADD PARTITION Sub-syntax: Adding One or More Partitions to a Specified Partitioned Table**
- **DROP PARTITION Sub-syntax: Deleting a Specified Partition or Multiple Partitions from a Partitioned Table**

- **TRUNCATE PARTITION: Clearing Data in a Table Partition**

ALTER TABLE PARTITION Main Clause Parameters

Table 21-162 ALTER TABLE PARTITION main clause parameters

| Parameter | Description | Value Range |
|-----------------|--|--|
| table_name | Specifies the name of the partitioned table to be modified. | Name of an existing partitioned table. |
| action [, ...] | Specifies clauses for maintaining partitions. For the partition continuity when multiple clauses are used for partition maintenance, DWS does DROP PARTITION and then ADD PARTITION , and finally runs the rest clauses in sequence. | For details, see the following clauses. |
| partition_name | Specifies the name of the partition to be modified. | Name of an existing partition. |
| partition_value | Specifies the key value of a partition.
The value specified by PARTITION FOR (partition_value [, ...]) can uniquely identify a partition. | Value range of the partition key of the partition to be renamed. |

MODIFY PARTITION: Setting Whether a Partitioned Index Is Available

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
MODIFY PARTITION partition_name { UNUSABLE LOCAL INDEXES | REBUILD UNUSABLE LOCAL INDEXES }
```

Table 21-163 modify_clause parameters

| Parameter | Description | Value Range |
|--------------------------------|---|--------------------------------|
| partition_name | Specifies the name of the partition to be modified. | Name of an existing partition. |
| UNUSABLE LOCAL INDEXES | Sets all the indexes unusable in the partition. | - |
| REBUILD UNUSABLE LOCAL INDEXES | Rebuilds all the indexes in the partition. | - |

REBUILD PARTITION syntax: Rebuilding a Partitioned Index

REBUILD PARTITION can rebuild indexes in a partitioned table. It is mainly used to restore the unusable partitioned indexes caused by abnormal operations (such

as a large number of partition data changes and index damage) or optimize the partitioned index performance. Compared with rebuilding indexes in an entire table, rebuilding indexes in a partitioned table takes less resources and shorter time.

Typical application scenarios

- **Repairing invalid partitioned indexes:** After a partition executes a large number of DML operations (such as batch deletion and update) or is interrupted unexpectedly, the partitioned indexes may become unusable. In this case, you need to rebuild the indexes.
- **Performance optimization:** For a partitioned table that has been running for a long time, indexes may have fragments. Rebuilding the indexes can optimize the index structure and improve the query efficiency.
- **Partition data exchange:** After partition data is exchanged using EXCHANGE PARTITION, indexes may need to be rebuilt to ensure consistency.

This syntax is supported only by clusters of version 8.3.0.100 or later.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
REBUILD PARTITION partition_name [ WITHOUT UNUSABLE ]
```

Table 21-164 rebuild_clause parameters

| Parameter | Description | Value Range |
|------------------|---|-------------|
| WITHOUT UNUSABLE | Ignores indexes in the UNUSABLE state when indexes on a partition are rebuilt. | - |

EXCHANGE PARTITION: Moving the Data from an Ordinary Table to a Specified Partition

EXCHANGE PARTITION is a key operation for efficiently managing partitioned tables in DWS. It can exchange metadata between a partition in a partitioned table and an ordinary table, instead of physically moving data. This means that the ownership of data blocks can be quickly switched, avoiding large-scale I/O operations and greatly improving performance.

Application scenarios:

1. **Batch data loading:** It can load pre-processed data to a temporary table and then replace the data in the target partition, reducing the write pressure on the production table during peak hours.
2. **Historical data archiving:** It can exchange partitions that are not frequently accessed to independent tables, facilitating migration to low-cost storage.
3. **Partition data repair:** It can exchange the data of a faulty partition to a temporary table for correction and then exchange the data back to the partitioned table, reducing lock contention during the repair.
4. **Data migration:** It can exchange the data of a specific partition across tables or databases to avoid inserting data one by one.

Syntax:

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
EXCHANGE PARTITION { ( partition_name ) | FOR ( partition_value [, ...] ) }  
    WITH TABLE {[ ONLY ] ordinary_table_name | ordinary_table_name * | ONLY ( ordinary_table_name )}  
    [ { WITH | WITHOUT } VALIDATION ] [ VERBOSE ]
```

Table 21-165 exchange_clause parameters

| Parameter | Description | Value Range |
|----------------------------------|--|--|
| partition_value | Specifies the key value of a partition.
The value specified by PARTITION FOR (partition_value [, ...]) can uniquely identify a partition. | Value range of the partition key of the partition to be renamed. |
| ordinary_table_name | Specifies the name of the ordinary table whose data is to be migrated. | Name of an existing common table. |
| { WITH WITHOUT }
VALIDATION | Checks whether the ordinary table data meets the specified partition key range of the partition to be exchanged. The default value is WITH .
The check is time consuming, especially when the data volume is large. Therefore, use WITHOUT when you are sure that the current ordinary table data meets the partition key range of the partition to be exchanged. | <ul style="list-style-type: none">● WITH: checks whether the ordinary table data meets the partition key range of the partition to be exchanged. If any data does not meet the required range, an error is reported.● WITHOUT: does not check whether the ordinary table data meets the partition key range of the partition to be exchanged. |
| VERBOSE | When VALIDATION is WITH , if the ordinary table contains data that is out of the partition key range, insert the data to the correct partition. If there is no correct partition where the data can be route to, an error is reported.
CAUTION
Only when VALIDATION is WITH , VERBOSE can be specified. | - |

The ordinary table and the partitioned table whose data is to be exchanged must meet the following requirements:

- The number of columns of the ordinary table is the same as that of the partitioned table, and their information should be consistent, including the column name, data type, constraint, collation, storage parameter, compression, and data type of a deleted column.
- The compression information of the ordinary table and partitioned table should be consistent.
- The distribution column information of the ordinary table and the partitioned table should be consistent.
- The number and information of indexes of the ordinary table and the partitioned table should be consistent.
- The number and information of constraints of the ordinary table and the partitioned table should be consistent.
- The ordinary table cannot be a temporary table or unlogged table.
- Exchanging partitions between an ordinary table and a partitioned table requires them to be in the same logical cluster or node group to avoid slow data insertion. Otherwise, the exchange operation becomes a slow data copy process, especially with large tables.
- In online scale-out and redistribution scenarios, the exchange partition statement may interfere with the redistribution of ordinary tables and partitioned tables (if there are lock conflicts between the partition exchange and redistribution statement). Usually, the redistribution of ordinary tables and partitioned tables is retried twice after being interrupted, but if a table is exchanged too often, the redistribution may fail for multiple times. If the redistribution process of an ordinary table is interrupted by the partition exchange operation, the data has been replaced with the data in the original partitioned table during the redistribution retry. In this case, full redistribution will be performed again.
- If other columns following the last valid column in the partitioned table are deleted and the deleted columns are not considered, the partitioned table can be exchanged with the ordinary table as long as the columns of the two tables are the same.
- The table-level parameter **colversion** must be consistent between the column-store ordinary table and the column-store partitioned table. The colversion 2.0 and colversion 1.0 cannot be exchanged.

When the exchange is done, the data and tablespace of the ordinary table and partitioned table are exchanged. In this case, statistics about the ordinary table and the partitioned table become unreliable. Both tables should be analyzed again.

ROW MOVEMENT: Setting the Row Movement Switch of a Partitioned Table

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
{ ENABLE | DISABLE } ROW MOVEMENT
```

Table 21-166 row_clause parameters

| Parameter | Description | Value Range |
|-----------------------------|---|---|
| ENABLE/DISABLE ROW MOVEMENT | <p>Specifies whether to relocate a row within a table. If the new value of a partition key in a row belongs to another partition, an error message is displayed or the row is moved to the corresponding partition.</p> <ul style="list-style-type: none">• ENABLE: The row is moved to the corresponding partition. If partition keys are frequently updated, enable this parameter.• DISABLE: The row is not moved to the corresponding partition. If partition keys are updated, an error is reported. If data cross-partition update is strictly prohibited, disable this parameter. <p>The default value is DISABLE.</p> <p>CAUTION
To enable cross-partition update, you need to enable row movement. However, if SELECT FOR UPDATE is executed concurrently to query the partitioned table, the query results may be inconsistent. Therefore, exercise caution when performing this operation.</p> | <p>The date column (partition key) of a partitioned table is partitioned by quarter into p_2023q1 and p_2023q2. The value 2023-02-15 of a row belongs to the partition p_2023q1 in the first quarter. After the value is updated to 2023-05-15, you can configure ROW MOVEMENT to determine whether to move the data in this row.</p> <ul style="list-style-type: none">• ENABLE: The row movement is enabled. The data is moved to the new partition p_2023q2.• DISABLE: The row movement is disabled. The system reports an error. <p>For details, see Examples: Enabling and Disabling ROW MOVEMENT.</p> |

MERGE PARTITIONS: Merging Partitions Into One

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
MERGE PARTITIONS { partition_name } [, ...] INTO PARTITION partition_name
```

- The partition before the keyword **INTO** is called the source partition, and the partition after the **INTO** is called the target partition.
- The number of source partitions cannot be less than 2.
- The source partition name must be unique.
- The source partition cannot have unusable indexes. Otherwise, an error will be reported.
- The target partition name must either be the same as the name of the last source partition or different from all partition names of the table.

- The boundaries of the target partition are the union of the boundaries of all the source partitions.
- For a range partitioned table, all source partitions must have contiguous boundaries.
- For list partitioning, if the source partition contains a DEFAULT partition, the boundary of the target partition is also DEFAULT.

SPLIT PARTITION: Splitting One Partition into Multiple Ones

split_clause specifies range partitioning.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }
SPLIT PARTITION { partition_name | FOR ( partition_value [, ...] ) } { split_point_clause |
no_split_point_clause }
```

- **split_point_clause:**

```
AT ( partition_value ) INTO ( PARTITION partition_name , PARTITION partition_name )
```

CAUTION

The size of split point should be in the range of splitting partition key. The split point can only split one partition into two.

- **no_split_point_clause:**

```
INTO { ( partition_less_than_item [, ...] ) | ( partition_start_end_item [, ...] ) }
```

CAUTION

- The first new partition key specified by **partition_less_than_item** must be larger than that of the former partition (if any), and the last partition key specified by **partition_less_than_item** must be equal to that of the splitting partition.
 - The start point (if any) of the first new partition specified by **partition_start_end_item** must be equal to the partition key (if any) of the previous partition. The end point (if any) of the last partition specified by **partition_start_end_item** must be equal to the partition key of the splitting partition.
 - **partition_less_than_item** supports a maximum of four partition keys and **partition_start_end_item** supports only one partition key. For details about the supported data types, see the **PARTITION BY RANGE(partition_key)** parameter in [Table 21-150](#).
 - **partition_less_than_item** and **partition_start_end_item** cannot be used in the same statement. There is no restriction on different SPLIT statements.
- **partition_less_than_item:**
PARTITION partition_name VALUES LESS THAN ({ partition_value | MAXVALUE } [, ...])
 - **partition_start_end_item** (For details about the restrictions, see the **partition_start_end_item** parameter in [Table 21-150](#)).
PARTITION partition_name {
 {START(partition_value) END (partition_value) EVERY (interval_value)} |

```
{START(partition_value) END ({partition_value | MAXVALUE})} |  
{START(partition_value)} |  
{END({partition_value | MAXVALUE})}  
}
```

split_clause specifies list partitioning.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
SPLIT PARTITION { partition_name | FOR ( partition_value [, ...] ) } { split_values_clause |  
split_no_values_clause }
```

- **split_values_clause** specifies a split point.

```
VALUES ( { (partition_value) [, ...] } | DEFAULT ) INTO ( PARTITION partition_name , PARTITION  
partition_name )
```

CAUTION

- If the source partition is not a **DEFAULT partition**, the boundary specified by the cut point is a non-null true subset of the source partition boundary. If the source partition is a **DEFAULT** partition, the boundary specified by the cut point cannot overlap with the boundaries of other non-**DEFAULT** partitions.
- The boundary specified by the split point is the boundary of the first partition after the keyword **INTO**. The difference between the boundary of the source partition and the specified boundary of the split point is the boundary of the second partition.
- If the source partition is the **DEFAULT** partition, the boundary of the second partition is still **DEFAULT**.

-
- **split_no_values_clause** specifies no split point is specified.

```
INTO ( list_partition_item [, ...], PARTITION partition_name )
```

CAUTION

- The syntax of **list_partition_item** is the same as that of specifying the partition when creating a list partitioned table, except that the boundary value in the partition definition cannot be **DEFAULT**.
 - Except for the last partition, the boundaries of other partitions must be explicitly defined. The defined boundary cannot be **DEFAULT** and must be a non-empty proper subset of the source partition boundary. The boundary of the last partition is the difference set between the source partition boundary and other partition boundaries, and the boundary of the last partition is empty (that is, the difference set cannot be empty).
 - If the source partition is a **DEFAULT** partition, the boundary of the last partition is **DEFAULT**.
-

ADD PARTITION Sub-syntax: Adding One or More Partitions to a Specified Partitioned Table

add_clause specifies range partitioning.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
ADD { partition_less_than_item... | partition_start_end_item }
```

 CAUTION

- The **partition_less_than_item** syntax can only be used for range partitioned tables. Otherwise, an error will be reported.
- The syntax of **partition_less_than_item** is the same as the syntax specifying partitions in creating a range partitioned table.
- If the boundary value of the last partition is a MAXVALUE, new partitions cannot be added. Otherwise, an error will be reported.

add_clause specifies list partitioning.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
ADD list_partition_item
```

 CAUTION

- The **list_partition_item** syntax can only be used for a list partitioned table. Otherwise, an error will be reported.
- The **list_partition_item** syntax is the same as the syntax for specifying partitions when creating a list partitioned table.
- If the current partitioned table contains DEFAULT partitions, no new partitions can be added. Otherwise, an error will be reported.

DROP PARTITION Sub-syntax: Deleting a Specified Partition or Multiple Partitions from a Partitioned Table

Delete a specified partition.

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
DROP PARTITION { partition_name | FOR ( partition_value [, ...] ) }
```

Delete multiple partitions. (This feature is supported by clusters of version 8.1.3.100 or later.)

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
DROP PARTITION { partition_name [, ...] }
```

TRUNCATE PARTITION: Clearing Data in a Table Partition

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
TRUNCATE PARTITION { partition_name | FOR ( partition_value [, ...] ) };
```

- **partition_value** indicates the partition key value. Multiple partition key values can be specified. Use commas (,) to separate multiple partition key values.
- When the **PARTITION FOR** clause is used, the entire partition where **partition_value** is located is cleared.

Syntax for Modifying a Partition Name

```
ALTER TABLE [ IF EXISTS ] { table_name [*] | ONLY table_name | ONLY ( table_name ) }  
RENAME PARTITION { partition_name | FOR ( partition_value [, ...] ) } TO partition_new_name;
```

Table 21-167 Parameters for modifying a partition name

| Parameter | Description | Value Range |
|--------------------|--|---|
| partition_new_name | Specifies the new name of the partition. | A string compliant with the identifier naming rules . |

Example: Create a Range Partitioned Table `customer_address`

```
DROP TABLE IF EXISTS customer_address;
CREATE TABLE customer_address
(
  ca_address_sk    INTEGER          NOT NULL ,
  ca_address_id    CHARACTER(16)    NOT NULL ,
  ca_street_number CHARACTER(10)      ,
  ca_street_name   CHARACTER varying(60) ,
  ca_street_type   CHARACTER(15)      ,
  ca_suite_number  CHARACTER(10)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE(ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(100),
  PARTITION P2 VALUES LESS THAN(200),
  PARTITION P3 VALUES LESS THAN(300)
);
```

Example: Create a List Partitioned Table

```
DROP TABLE IF EXISTS data_list;
CREATE TABLE data_list(
  id int,
  time int,
  salary decimal(12,2)
)PARTITION BY LIST (time)(
  PARTITION P1 VALUES (202209),
  PARTITION P2 VALUES (202210,202208),
  PARTITION P3 VALUES (202211),
  PARTITION P4 VALUES (202212),
  PARTITION P5 VALUES (202301)
);
```

Example: Use **MODIFY PARTITION** to Set Whether a Partitioned Index Is Usable

Create the local index **student_grade_index** for the partitioned table **customer_address** and set partition index names.

```
CREATE INDEX customer_address_index ON customer_address(ca_address_id) LOCAL
(
  PARTITION P1_index,
  PARTITION P2_index,
  PARTITION P3_index
);
```

Rebuild all indexes on partition **P1** in the partitioned table **customer_address**.

```
ALTER TABLE customer_address MODIFY PARTITION P1 REBUILD UNUSABLE LOCAL INDEXES;
```

Set all indexes in partition **P3** of the partitioned table **customer_address** to be unusable.

```
ALTER TABLE customer_address MODIFY PARTITION P3 UNUSABLE LOCAL INDEXES;
```

Example: Use REBUILD PARTITION to Rebuild a Partitioned Index into Which Data Has Been Inserted

Step 1 Creates a partitioned table.

```
DROP TABLE IF EXISTS sales;
CREATE TABLE sales (
  id      INT,
  sale_date DATE,
  amount  DECIMAL(10,2)
)
PARTITION BY RANGE (sale_date)
(
  PARTITION p202310 VALUES LESS THAN ('2023-11-01'),
  PARTITION p202311 VALUES LESS THAN ('2023-12-01')
);
```

Step 2 Create an index.

```
CREATE INDEX idx_sale_date ON sales (sale_date) LOCAL;
```

Step 3 Insert partition data of October and November.

```
INSERT INTO sales PARTITION (p202310)
VALUES
(1, '2023-10-05', 100.50),
(2, '2023-10-10', 200.75);
INSERT INTO sales PARTITION (p202311)
VALUES
(3, '2023-11-15', 300.00);
```

Step 4 Rebuild indexes of the specific partition **p202310**.

```
ALTER TABLE sales REBUILD PARTITION p202310 WITHOUT UNUSABLE;
```

----End

Example: Use ADD PARTITION to Add One or More Partitions to a Specified Partitioned Table

Add a partition to the range partitioned table **customer_address**.

```
ALTER TABLE customer_address ADD PARTITION P5 VALUES LESS THAN (500);
```

Add the following partitions to the range partitioned table **customer_address**:
[500, 600), [600, 700).

```
ALTER TABLE customer_address ADD PARTITION p6 START(500) END(700) EVERY(100);
```

Add the **MAXVALUE** partition **p7** to the range partitioned table **customer_address**.

```
ALTER TABLE customer_address ADD PARTITION p7 END(MAXVALUE);
```

Add partition **P6** to a list partitioned table.

```
ALTER TABLE data_list ADD PARTITION P6 VALUES (202302,202303);
```

Example: Use SPLIT PARTITION to Split a Partition into Multiple Partitions

Split partition **P7** in the range partitioned table **customer_address** at **800**.

```
ALTER TABLE customer_address SPLIT PARTITION P7 AT(800) INTO (PARTITION P6a,PARTITION P6b);
```

Split the partition at **400** in the range partitioned table **customer_address** into multiple partitions.

```
ALTER TABLE customer_address SPLIT PARTITION FOR(400) INTO(PARTITION p_part START(300) END(500) EVERY(100));
```

Split partition **P2** in the list partitioned table **data_list** into two partitions: **p2a** and **p2b**.

```
ALTER TABLE data_list SPLIT PARTITION P2 VALUES(202210) INTO (PARTITION p2a,PARTITION p2b);
```

Example: Use EXCHANGE PARTITION to Migrate Data from a Common Table to a Specified Partition

The following example demonstrates how to migrate data from table **math_grade** to partition **math** in partitioned table **student_grade**.

1. Create the partitioned table **student_grade**.

```
CREATE TABLE student_grade (  
    stu_name    char(5),  
    stu_no     integer,  
    grade      integer,  
    subject    varchar(30)  
)  
PARTITION BY LIST(subject)  
(  
    PARTITION gym VALUES('gymnastics'),  
    PARTITION phys VALUES('physics'),  
    PARTITION history VALUES('history'),  
    PARTITION math VALUES('math')  
);
```

2. Add data to the partitioned table **student_grade**.

```
INSERT INTO student_grade VALUES  
( 'Ann', 20220101, 75, 'gymnastics'),  
( 'Jack', 20220103, 60, 'math'),  
( 'Anna', 20220108, 56, 'history'),  
( 'Jann', 20220107, 82, 'physics'),  
( 'Molly', 20220104, 91, 'physics'),  
( 'Sam', 20220105, 72, 'math');
```

3. Query the records of partition **math** in **student_grade**.

```
SELECT * FROM student_grade PARTITION (math);
```

The query result is as follows:

| stu_name | stu_no | grade | subject |
|----------|----------|-------|---------|
| Jack | 20220103 | 60 | math |
| Sam | 20220105 | 72 | math |

(2 rows)

4. Create an ordinary table **math_grade** that matches the definition of the partitioned table **student_grade**.

```
CREATE TABLE math_grade  
(  
    stu_name    char(5),  
    stu_no     integer,  
    grade      integer,  
    subject    varchar(30)  
);
```

5. Insert data to the **math_grade** table. The data in the **student_grade** partitioned table conforms to the partition rule of partition **math**.

```
INSERT INTO math_grade VALUES  
( 'Ann', 20220101, 75, 'math'),  
( 'Jack', 20220103, 60, 'math'),
```

```
('Anna', 20220108, 56, 'math'),  
('Jann', 20220107, 82, 'math');
```

6. Migrate data from the ordinary table **math_grade** to partition **math** in the partitioned table **student_grade**.

```
ALTER TABLE student_grade EXCHANGE PARTITION (math) WITH TABLE math_grade;
```

7. Query the **student_grade** partitioned table. The results show that data in the **math_grade** table has exchanged with data in the **math** partition of the **student_grade** table.

```
SELECT * FROM student_grade PARTITION (math);  
stu_name | stu_no | grade | subject
```

```
-----+-----+-----+-----  
Anna    | 20220108 | 56 | math  
Jeck    | 20220103 | 60 | math  
Ann     | 20220101 | 75 | math  
Jann    | 20220107 | 82 | math  
(4 rows)
```

8. Query the **math_grade** table. The result shows that the data stored in the **math** partition of the **student_grade** partitioned table has been exchanged to the **math_grade** table.

```
SELECT * FROM math_grade;  
stu_name | stu_no | grade | subject
```

```
-----+-----+-----+-----  
Jeck    | 20220103 | 60 | math  
Sam     | 20220105 | 72 | math  
(2 rows)
```

Example: Use TRUNCATE PARTITION to Clear Data in a Table Partition

Clear the **p1** partition of the **customer_address** table.

```
ALTER TABLE customer_address TRUNCATE PARTITION p1;
```

Examples: Enabling and Disabling ROW MOVEMENT

If **ROW MOVEMENT** is enabled, the data of a row is moved to a new partition when the partition key of the row is updated to a new value and the new value belongs to another partition.

If a partition key is frequently updated, enabling **ROW MOVEMENT** may cause extra I/O overhead. To enable it, evaluate service requirements first.

Create a table partitioned by date and enable **ROW MOVEMENT**.

```
DROP TABLE IF EXISTS sale_data;  
CREATE TABLE sales_data (  
  sale_id INT,  
  product_name VARCHAR(100),  
  sale_date DATE,  
  amount DECIMAL(10, 2)  
)  
PARTITION BY RANGE (sale_date) (  
  PARTITION p_2023q1 VALUES LESS THAN ('2023-04-01'),  
  PARTITION p_2023q2 VALUES LESS THAN ('2023-07-01'),  
  PARTITION p_2023q3 VALUES LESS THAN ('2023-10-01'),  
  PARTITION p_2023q4 VALUES LESS THAN ('2024-01-01')  
)  
ENABLE ROW MOVEMENT;
```

Insert test data.

```
INSERT INTO sales_data (sale_id, product_name, sale_date, amount)  
VALUES
```

```
(1, 'Product A', '2023-02-15', 1000.00), -- It belongs to p_2023q1.  
(2, 'Product B', '2023-05-20', 1500.00); -- It belongs to p_2023q2.
```

Query the data distribution of each partition.

```
SELECT tableoid::regclass AS partition, * FROM sales_data ORDER BY sale_id;
```

| partition | sale_id | product_name | sale_date | amount |
|------------|---------|--------------|---------------------|---------|
| 2147617615 | 1 | Product A | 2023-02-15 00:00:00 | 1000.00 |
| 2147617616 | 2 | Product B | 2023-05-20 00:00:00 | 1500.00 |
| (2 rows) | | | | |

Update the partition key (which is moved from **p_2023q1** to **p_2023q2**).

```
UPDATE sales_data SET sale_date = '2023-05-01' WHERE sale_id = 1;
```

Query the data distribution of each partition again to confirm that the row has been moved.

```
SELECT tableoid::regclass AS partition, * FROM sales_data ORDER BY sale_id;
```

| partition | sale_id | product_name | sale_date | amount |
|------------|---------|--------------|---------------------|---------|
| 2147617616 | 1 | Product A | 2023-05-01 00:00:00 | 1000.00 |
| 2147617616 | 2 | Product B | 2023-05-20 00:00:00 | 1500.00 |
| (2 rows) | | | | |

Disable **ROW MOVEMENT**.

```
ALTER TABLE sales_data DISABLE ROW MOVEMENT;
```

Modify the partition key again (which is move from **p_2023q2** back to **p_2023q1**).

```
UPDATE sales_data SET sale_date = '2023-02-15' WHERE sale_id = 1;
```

View the command output. It indicates that **ROW MOVEMENT** is disabled and the partition key cannot be updated.

```
gaussdb=> UPDATE sales_data SET sale_date = '2023-02-15' WHERE sale_id = 1;  
ERROR:  dn_6003_6004: fail to update partitioned table "sales_data"  
DETAIL:  disable row movement
```

Example: Use **MERGE PARTITIONS** to Merge Multiple Partitions into One

Merge partitions **P2** and **P3** in the range partitioned table **customer_address** into one.

```
ALTER TABLE customer_address MERGE PARTITIONS P2, P3 INTO PARTITION P_M;
```

Example: Use **DROP PARTITION** to Delete a Specified Partition from a Partitioned Table

Delete partitions **P6a** and **P6b** from partitioned table **customer_address**.

```
ALTER TABLE customer_address DROP PARTITION P6a, P6b;
```

[CREATE TABLE PARTITION](#) and [DROP TABLE](#)

21.13.4.6 RENAME TABLE

Function

RENAME TABLE renames a specified table.

RENAME TABLE has the same function as the following command:

```
ALTER TABLE table_name RENAME to new_table_name
```

Precautions

Tables cannot be renamed across schemas.

Syntax

```
RENAME TABLE  
{[schema.]table_name TO new_table_name} [, ...];
```

Parameter Description

Table 21-168 RENAME TABLE parameters

| Parameter | Description | Value Range |
|----------------|---|---|
| schema | Specifies the schema name. | Valid schema name |
| table_name | Specifies the name of the table to be modified. | Name of an existing table |
| new_table_name | Specifies the new table name. | A string that must comply with the rules in Identifier Naming Conventions . |

Examples

Create a column-store table and specify the storage format and compression mode.

```
DROP TABLE IF EXISTS customer_address;  
CREATE TABLE customer_address  
(  
  ca_address_sk    INTEGER          NOT NULL ,  
  ca_address_id    CHARACTER(16)     NOT NULL ,  
  ca_street_number CHARACTER(10)      ,  
  ca_street_name   CHARACTER varying(60) ,  
  ca_street_type   CHARACTER(15)      ,  
  ca_suite_number  CHARACTER(10)  
)  
WITH (ORIENTATION = COLUMN, COMPRESSION=HIGH,COLVERSION=2.0)  
DISTRIBUTE BY HASH (ca_address_sk);
```

Rename a table.

```
RENAME TABLE customer_address TO new_customer_address;
```

Helpful Links

[CREATE TABLE](#), [ALTER TABLE](#), [DROP TABLE](#)

21.13.4.7 DROP TABLE

Function

DROP TABLE deletes a specified table.

Precautions

- **DROP TABLE** forcibly deletes a specified table. After a table is deleted, any indexes that exist for the table will be deleted; any functions or stored procedures that use this table cannot be run. Deleting a partitioned table also deletes all partitions in the table.
- Only the table owner, schema owner, or a user granted with the DROP permission can run **DROP TABLE** on a table. A system administrator has this permission by default. To delete all the rows in a table but retain the table definition, use **TRUNCATE** or **DELETE**.

DANGER

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE**, **USER/ROLE**, **SCHEMA**, **TABLE**, **VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

Syntax

```
DROP TABLE [ IF EXISTS ]  
{ [schema.]table_name } [, ...] [ CASCADE | RESTRICT ] ;
```

Parameter Description

Table 21-169 DROP TABLE parameters

| Parameter | Description | Value Range |
|-----------|---|-------------|
| IF EXISTS | Reports a notice instead of an error if the specified table does not exist. | - |
| schema | Name of the schema to which the table to be deleted belongs. | - |

| Parameter | Description | Value Range |
|--------------------|---|--|
| table_name | Specifies the name of the table to be deleted. | An existing table name. |
| CASCADE RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none">• CASCADE: automatically deletes objects (such as views) that depend on the table to be deleted.• RESTRICT (default): refuses to delete the table if any objects depend on it. This is the default. |
| PURGE | If the Purge parameter is specified, data is directly deleted regardless of whether the recycle bin feature is enabled. This is supported only by clusters of version 9.1.0.200 or later. | - |
| KEEP ttl
HOUR | <p>In V3 tables, enabling the recycle bin feature and setting a TTL allows physical files to be moved to the recycle bin for potential restoration. However, once the TTL expires, the background process automatically clears the objects in the recycle bin. This is supported only by clusters of version 9.1.0.200 or later.</p> <p>NOTICE
You are advised to use this parameter in scenarios where the DROP and TRUNCATE operations are not frequently performed.</p> | - |

Examples

Delete **warehouse_t1** table.

```
DROP TABLE tpcds.warehouse_t1;
```

[ALTER TABLE](#), [12.101-RENAME TABLE](#), and [CREATE TABLE](#)

21.13.4.8 CREATE FOREIGN TABLE (SQL on OBS or Hadoop)

Function

CREATE FOREIGN TABLE creates an HDFS or OBS foreign table in the current database to access structured data stored in the HDFS or OBS distributed cluster

file system. You can also use the HDFS or OBS foreign table to export data in ORC and Parquet formats to HDFS or OBS.

A foreign table is a virtual table within a database or big data platform that does not physically store data. Instead, it serves as a mapping to data residing in external storage systems, such as HDFS or OBS. This mapping is established using metadata, which includes the table structure, the location of the data, and its file format. It enables users to directly access or operate external data using standard SQL statements. A foreign table serves as a data proxy that logically maps data in external file systems to table structures that can be identified by databases.

Foreign tables are designed to break data silos. Foreign tables allow database users to access external system data in a familiar way through metadata mapping and export data to external systems. In this way, data can be efficiently collaborated, analyzed, and shared across systems, especially in big data scenarios, significantly reducing data movement costs and improving collaboration efficiency.

When DWS accesses external data sources through foreign tables, the access performance varies according to data sources.

- Data stored in OBS: Data storage is decoupled from compute. The cluster storage cost is low, and storage capacity is not limited. Clusters can be deleted at any time. However, the compute performance depends on the OBS access performance and is lower than that of HDFS. OBS is recommended when data computing is infrequent.
- Data stored in HDFS: Data storage is not decoupled from compute. The cluster storage cost is high, and storage capacity is limited. The compute performance is high. You must export data before you delete clusters. HDFS is recommended for computing-intensive scenarios.

NOTE

The following read and write foreign tables are supported only in the storage-compute decoupling 3.0 version.

Precautions

- When using an OBS foreign table to access data in an OBS bucket, you need to ensure that your DWS cluster and OBS bucket are in the same region.
- Only the system administrator **dbadmin** or a common user who has been granted the USEFT permission can perform foreign table operations.

```
ALTER USER user_name USEFT;
```
- The HDFS foreign table and OBS foreign table are classified into read-only, write-only, and read-write foreign tables. Read-only foreign tables are used for query. Write-only foreign tables can be used to export data from DWS to the distributed file system. Read-write foreign tables can be used for query and data export. Only 9.1.0.100 and later versions support read-write foreign tables.
- Supported formats:
 - Importing data: Only data in ORC, TEXT, CSV, CARBONDATA, PARQUET, and JSON formats can be imported for query.
 - Exporting data: For OBS foreign tables, data in ORC and PARQUET (supported only in storage-compute decoupling 3.0 version) can be exported. For HDFS foreign tables, data in ORC and PARQUET can be exported.

- Before using a foreign table, you need to manually create a foreign server, which is a virtual object configured in the database and used to define parameters (such as the address, protocol, and authentication information) for connecting to an external data source. Through the foreign servers, the local database can directly query and insert external data, just like operating local tables. (The syntax is similar, but may be restricted by performance or functions.) For details, see [CREATE SERVER](#).
- If the foreign data wrapper is set to **HDFS_FDW** or **DFS_FDW** when you manually create a foreign server, you need to configure the **DISTRIBUTE BY** clause to specify the distribution mode when creating a read-only foreign table.

Table 21-170 Read and write formats supported by OBS foreign tables

| Data Type | DFS_FDW/HDFS_FDW | | |
|------------|------------------|------------|------------|
| | READ ONLY | WRITE ONLY | READ WRITE |
| - | | | |
| ORC | √ | √ | √ |
| PARQUET | √ | √ | √ |
| CARBONDATA | √ | × | × |
| TEXT | √ | × | × |
| CSV | √ | × | × |
| JSON | √ | × | × |

Syntax

Create an HDFS foreign table.

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] table_name
( [ { column_name type_name
  [ { [CONSTRAINT constraint_name] NULL |
    [CONSTRAINT constraint_name] NOT NULL |
    column_constraint [...] } ] |
  table_constraint [, ...] [, ...] ] )
SERVER server_name
OPTIONS ( { option_name 'value ' [, ...] )
[ {WRITE ONLY | READ ONLY | READ WRITE} ]
DISTRIBUTE BY {ROUNDROBIN | REPLICATION}

[ PARTITION BY ( column_name ) [ AUTOMAPPED ] ] ;
```

- **column_constraint** is as follows:
[CONSTRAINT constraint_name]
{PRIMARY KEY | UNIQUE}
[NOT ENFORCED [ENABLE QUERY OPTIMIZATION | DISABLE QUERY OPTIMIZATION] | ENFORCED]
- **table_constraint** is as follows:
[CONSTRAINT constraint_name]
{PRIMARY KEY | UNIQUE} (column_name)
[NOT ENFORCED [ENABLE QUERY OPTIMIZATION | DISABLE QUERY OPTIMIZATION] | ENFORCED]

Parameter Description

Table 21-171 CREATE FOREIGN TABLE (SQL on OBS or Hadoop) parameters

| Parameter | Description | Value Range |
|---------------|---|--|
| IF NOT EXISTS | Sends a notice, but does not throw an error, if a table with the same name exists. | - |
| table_name | Specifies the name of the foreign table. | A string, which must comply with the naming convention. For details, see Identifier Naming Conventions . |
| column_name | Specifies the name of a column in the foreign table. Columns are separated by commas (,). | <p>A string, which must comply with the naming convention. For details, see Identifier Naming Conventions.</p> <p>A JSON object consists of nested or parallel name-value pairs, which are irrelevant to the sequence. When data in JSON format is imported, the mapping between fields and values is determined based on the automatic mapping between field names and names of name-value pairs. You need to define proper field names. Otherwise, you may not get the expected result. The rules for automatic mapping between field names and names of name-value pairs are as follows:</p> <ul style="list-style-type: none">• If there are no nesting or arrays, the field names must be the same as the names of name-value pairs, case insensitive.• Use underscores (_) to concatenate two names to identify the nesting relationship.• A field name uses the number sign (#) and a decimal non-negative integer (n) to identify the nth element (starting from 0) of an array. <p>For example, to import each element of the <code>{"A": "simple", "B": {"C": "nesting"}, "D": ["array", 2, {"E": "complicated"}]}</code> object, the field names in the foreign table must be defined as <code>a</code>, <code>b</code>, <code>b_c</code>, <code>d</code>, <code>d#0</code>, <code>d#1</code>, <code>d#2</code> and <code>d#2_e</code>. The sequence in which the fields are defined does not affect the import result.</p> |
| type_name | Specifies the data type of the column. | - |

| Parameter | Description | Value Range |
|---------------------|--|--|
| constraint_name | Specifies the name of a constraint for the foreign table. | - |
| { NULL NOT NULL } | <p>Specifies whether the column allows NULL.</p> <p>When you create a table, whether the data in HDFS is NULL or NOT NULL cannot be guaranteed. The consistency of data is guaranteed by users. Users must decide whether the column is NULL or NOT NULL. (The optimizer optimizes the NULL/NOT NULL and generates a better plan.)</p> | - |
| SERVER server_name | Specifies the server name of the foreign table. Users can customize its name. | A string indicating an existing server. It must comply with the naming convention. |

| Parameter | Description | Value Range |
|-------------------------------------|--|---|
| OPTIONS | Specifies parameters of foreign table data. | <p>The OPTIONS parameters to be specified vary depending on the scenario. The options are as follows:</p> <ul style="list-style-type: none">• Data format parameters. For details, see Table 21-172.• Error-tolerance parameters. For details, see Table 21-173.• Parameters that need to be specified only when the server type is DLI. For details, see Table 21-174.• Parameters that need to be specified only when format is set to hudi. For details, see OPTIONS parameters (only when format is set to hudi).• OBS foreign table. Different data source formats support different OPTIONS parameters. For details, see Table 21-176.• HDFS foreign table. Different data source formats support different OPTIONS parameters. For details, see Table 21-177. |
| WRITE ONLY READ ONLY READ WRITE | Specifies the type of the foreign table to be created. | <ul style="list-style-type: none">• WRITE ONLY creates a write-only HDFS/OBS foreign table.• READ ONLY creates a read-only HDFS/OBS foreign table.• READ WRITE creates a read/write HDFS/OBS foreign table. <p>If the foreign table type is not specified, a read-only foreign table is created by default.</p> |
| DISTRIBUTE BY ROUND ROBIN | Specifies ROUNDROBIN as the distribution mode for the HDFS/OBS foreign table. Each row of the table is sent to each DN in turn. Therefore, data is evenly distributed on each DN. | - |

| Parameter | Description | Value Range |
|---------------------------|--|-------------|
| DISTRIBUTE BY REPLICATION | Specifies REPLICATION as the distribution mode for the HDFS foreign table. Each row in the table exists on all DN. That is, full table data is stored on each DN. | - |

| Parameter | Description | Value Range |
|---------------------------------------|--|--|
| PARTITION BY (column_name) AUTOMAPPED | column_name specifies the partition column. AUTOMAPPED means the partition column specified by the HDFS partitioned foreign table is automatically mapped with the partition directory information in HDFS. The prerequisite is that the sequences of partition columns specified in the HDFS foreign table and in the directory are the same. This function is applicable only to read-only foreign tables. | <ul style="list-style-type: none">• A write-only partitioned foreign table can have up to four levels of partitions, meaning that you can specify a maximum of four columns as partition columns. At least one column must be reserved as a non-partition column.• HDFS read-only foreign tables support partition tables in text, CSV, CarbonData, ORC, and Parquet formats.• HDFS write-only foreign tables support ORC and Parquet partitioned tables.• HDFS read and write foreign tables support ORC and Parquet partitioned tables.• OBS read-only, write-only, and read-write foreign tables support ORC and Parquet partitioned tables.• Columns of the floating point or Boolean type cannot be used as partition columns.• The maximum length of a partition field can be specified by the GUC parameter dfs_partition_directory_length.• A partition directory name is in the format <i>Partition column name=Partition column value</i>. Special characters in the name will be escaped. To ensure that the total length of the name after escaping does not exceed dfs_partition_directory_length, it is advisable to keep the name length before escaping less than or equal to $(\text{dfs_partition_directory_length} + 1)/3$.• Do not use a column containing too many Chinese characters as a partition column. You may encounter errors when calculating the final partition directory name's length due to the different space requirements of Chinese and English characters. This is particularly true when the partition directory name exceeds the dfs_partition_directory_length length limit. |
| CONSTRAINT constraint_name | Specifies the name of informational constraint of the foreign table. | A string, which must comply with the naming convention. |

| Parameter | Description | Value Range |
|-------------|--|-------------|
| PRIMARY KEY | The primary key constraint specifies that one or more columns of a table must contain unique (non-duplicate) and non-null values. Only one primary key can be specified for a table. | - |
| UNIQUE | Specifies that a group of one or more columns of a table must contain unique values. For the purpose of a unique constraint, NULL is not considered equal. | - |

| Parameter | Description | Value Range |
|--------------|---|--|
| NOT ENFORCED | <p>Specifies that the created constraint is an informational constraint, which is not forcibly verified by the database. This parameter is used with ENABLE QUERY OPTIMIZATION.</p> <ul style="list-style-type: none">• Informational rather than mandatory: You still need to specify a unique constraint for a column using PRIMARY KEY or UNIQUE to optimize the query execution plan.• No mandatory verification: The database does not check whether the data in the external data source actually meets constraint conditions (for example, whether duplicate values exist).• Performance optimization: The query optimizer is allowed to use an informational constraint to generate a more efficient execution plan. However, you need to ensure | <p>For example, the primary key is declared, but the verification is not mandatory.</p> <pre>CREATE FOREIGN TABLE hdfs_users (user_id INT PRIMARY KEY NOT ENFORCED,
...</pre> |

| Parameter | Description | Value Range |
|---------------------------|--|---|
| | <p>that the data meets constraint conditions, or the query result may be incorrect.</p> <ul style="list-style-type: none">• Risk: If the actual data violates constraint conditions (for example, duplicate values exist), the query result may be incorrect (for example, the aggregation result is abnormal or redundant records are generated during JOIN operations). <p>For more information, see Informational Constraints.</p> | |
| ENFORCED | Specifies that the created constraint is an enforced constraint that is forcibly validated by the database. This parameter is reserved. Currently, DWS does not support ENFORCED . | - |
| PRIMARY KEY (column_name) | Specifies the informational constraint on column_name . | A string indicating an existing column_name. It must comply with the naming convention. |

| Parameter | Description | Value Range |
|----------------------------|--|--|
| ENABLE QUERY OPTIMIZATION | Enables the query optimizer to use informational constraints to generate a more efficient execution plan. This parameter is used together with NOT ENFORCED . | Create a foreign table, add a unique constraint to the p_partkey int column, do not enforce the constraint, and allow the optimizer to use the informational constraint to generate a better execution plan.
CREATE FOREIGN TABLE ft_part
(
p_partkey int UNIQUE NOT ENFORCED ENABLE QUERY OPTIMIZATION,
...
) |
| DISABLE QUERY OPTIMIZATION | Disables the query optimizer to use informational constraints to generate an efficient execution plan. | - |

Table 21-172 OPTIONS parameters of the data format

| Parameter | Description | Value Range |
|-----------|---|---|
| header | Specifies whether a data file contains a table header. header is available only for CSV files. | <ul style="list-style-type: none">• true or on: The first row of the data file will be identified as the header and ignored during export.• false or off: The first row is identified as data. The default value is false or off . |
| quote | Specifies the quotation mark for the CSV format. The default value is a double quotation mark ("). | The quote value cannot be the same as the delimiter or null value.
The quote value must be a single-byte character.
Invisible characters are recommended as quote values, such as 0x07, 0x08, and 0x1b. |

| Parameter | Description | Value Range |
|-----------|---|-------------|
| escape | <p>Specifies an escape character for a CSV file. The value must be a single-byte character.</p> <p>In a database, an escape character is a special character used to escape other characters. It enables the database system to identify and correctly process characters that have special meanings and may conflict with SQL syntax (such as quotation marks and special characters) as common characters. Common escape characters include backslashes (\) and double quotation marks (").</p> <p>The default value is a double quotation mark ("). If it is the same as the value of quote, it will be replaced with \0.</p> | - |

| Parameter | Description | Value Range |
|-----------|---|---|
| location | <p>Specifies the file path on OBS. This is an OBS foreign table parameter. The data sources of multiple buckets are separated by vertical bars (), for example, LOCATION 'obs://bucket1/folder/ obs://bucket2/'.</p> <p>The database scans all objects in the specified folders.</p> <p>When accessing a DLI multi-version table, you do not need to specify the location parameter.</p> | - |
| format | <p>Specifies the format of the source data file in a foreign table.</p> | <p>The HDFS foreign table can read data in ORC, TEXT, JSON, CSV, Parquet, and Hudi file formats when in READ ONLY mode. But if you are using the WRITE ONLY/READ WRITE foreign table, you can only work with data in ORC and Parquet file formats.</p> <p>OBS foreign tables allow you to read data in ORC, TEXT, JSON, CSV, CarbonData, Parquet, and Hudi file formats in read-only mode. But if you are using write-only mode, you can only work with data in ORC and Parquet file formats.</p> <p>CAUTION</p> <ul style="list-style-type: none">Only JSON objects (embraced in {}) can be imported. JSON arrays (embraced in []) cannot be imported. However, arrays inside a JSON object can be imported.Apache Hudi is a transactional data lake platform. In the current version, you can set the format parameter of the OBS foreign table to Hudi to access the corresponding Hudi table data sets. This version also provides the method of accessing the incremental or real-time view of the Hudi table. |

| Parameter | Description | Value Range |
|------------|--|---|
| foldername | <p>The directory of the data source file in the foreign table, that is, the corresponding file directory in HDFS or on OBS. This is mandatory for WRITE ONLY and READ WRITE writable foreign tables and optional for READ ONLY foreign tables.</p> <p>When accessing a DLI multi-version table, you do not need to specify the foldername parameter.</p> <ul style="list-style-type: none">• OBS foreign table. The format is <i>/OBS bucket name/folder name/</i>. Ensure that the OBS bucket and DWS cluster are in the same region. Cross-region access to OBS bucket data is not supported.• HDFS foreign table. The format is the directory where data files in the remote HDFS are stored. For an MRS cluster, log in to the MRS console, go to the cluster basic information page, click Files, select HDFS File List, and find the | <p>Example of an OBS foreign table</p> <pre>OPTIONS (
 foldername '/obs-demo01/obs-dws/',
 format 'parquet',
 encoding 'utf8')</pre> <p>Example of an HDFS foreign table:</p> <pre>OPTIONS (
 foldername '/user/hive/warehouse/demo.db/
 product_info_orc/',
 format 'orc',
 encoding 'utf8')</pre> |

| Parameter | Description | Value Range |
|-----------|---|-------------|
| | directory where data is stored. | |
| encoding | It specifies the encoding format of a source data file in the foreign table. Its default value is utf8 . This parameter is optional. | - |
| totalrows | (Optional)
Estimated number of rows in a table. This parameter is used only for OBS foreign tables. Because OBS may store many files, it is slow to analyze data. This parameter allows you to set an estimated value so that the optimizer can estimate the table size according to the value. Generally, query efficiency is high when the estimated value is close to the actual value. | - |

| Parameter | Description | Value Range |
|-----------|--|---|
| filenames | Data source files specified in the foreign table. Multiple files are separated by commas (,). | <ul style="list-style-type: none">You are advised to use the foldername parameter to specify the location of the data source. For a read-only foreign table, either filenames or foldername must be specified. For a write-only foreign table or read-write foreign table, only foldername can be specified.If foldername is an absolute directory, it should be enclosed by slashes (/). Multiple paths are separated by commas (,).When you query a partitioned table, data is pruned based on partition information, and data files that meet the requirement are queried. Pruning involves scanning HDFS directory contents many times. Therefore, do not use columns with low repetition as partition column.OBS read-only foreign tables and read/write foreign tables are not supported. |
| delimiter | Specifies the column delimiter of data, and uses the default delimiter if it is not set. The default delimiter of TEXT is a tab. | <p>The value of delimiter can be a multi-character delimiter whose length is less than or equal to 10 bytes.</p> <ul style="list-style-type: none">A delimiter cannot be \r or \n.A delimiter cannot be the same as the null parameter.A separator cannot contain (\), (.), digits, or letters.The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.You are advised to use a multi-character, such as the combination of the dollar sign (\$), caret (^), ampersand (&), or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.delimiter is available only for TEXT and CSV source data files. |

| Parameter | Description | Value Range |
|-------------|---|---|
| eol | Specifies the newline character style of the imported data file. | <p>Multi-character newline characters are supported, but the newline character cannot exceed 10 bytes. Common newline characters include \r (0x0D), \n (0x0A), and \r\n (0x0D0A). Special newline characters include \$ and #.</p> <ul style="list-style-type: none">• The eol parameter applies only to TEXT files.• The value of the eol parameter cannot be the same as that of DELIMITER or NULL.• The value of the eol parameter cannot contain digits, letters, or periods (.). |
| null | Specifies the string that represents a null value. | <p>The default value is \N for the TEXT format.</p> <ul style="list-style-type: none">• The null value cannot be \r or \n. The maximum length is 100 characters.• The null parameter cannot be the same as the delimiter.• null is available only for TEXT and CSV source data files. |
| noescaping | Specifies in TEXT format, whether to escape the backslash (\) and its following characters. | <p>noescaping is available only for the TEXT format. true/on or false/off. The default value is false or off.</p> |
| date_format | Specifies the DATE format for data import. This parameter is valid only for READ ONLY foreign tables. | <p>The value must be in a valid DATE format. For details, see Date and Time Processing Functions and Operators.</p> <ul style="list-style-type: none">• If ORACLE is specified as the compatible database, the DATE format is TIMESTAMP. For details, see timestamp_format below.• date_format is available only for TEXT and CSV source data files. |
| time_format | Specifies the TIME format for data import. This parameter is valid only for READ ONLY foreign tables. | <p>This parameter is available only for TEXT and CSV source data files.</p> <p>Value range: Valid TIME. Time zones cannot be used. For details, see Date and Time Processing Functions and Operators.</p> |

| Parameter | Description | Value Range |
|--------------------------|--|---|
| timestamp_format | Specifies the TIMESTAMP format for data import. This parameter is valid only for READ ONLY foreign tables. | This parameter is available only for TEXT and CSV source data files.
Value range: any valid TIMESTAMP value. Time zones are not supported. For details, see Date and Time Processing Functions and Operators . |
| smalldatetimetime_format | Specifies the SMALLDATETIME format for data import. This parameter is valid only for READ ONLY foreign tables. | This parameter is available only for TEXT and CSV source data files.
Value range: any valid SMALLDATETIME value. For details, see Date and Time Processing Functions and Operators . |
| dataencoding | This parameter specifies the data code of the data table to be exported when the database code is different from the data code of the data table. For example, the database code is Latin-1, but the data in the exported data table is in UTF-8 format. This parameter is optional. If this parameter is not specified, the database encoding format is used by default. This syntax is valid only for the WRITE ONLY/READ WRITE foreign table of HDFS. | The parameter is available only for HDFS foreign tables in ORC format with WRITE ONLY or READ WRITE.
Value range: data code types supported by the database encoding |

| Parameter | Description | Value Range |
|-------------|---|--|
| filesize | Specifies the file size of a write-only foreign table. This parameter is optional. If this parameter is not specified, the file size in the distributed file system configuration is used by default. This syntax is valid only for WRITE ONLY/READ WRITE writable foreign tables. | The parameter is available only for HDFS foreign tables in ORC format with WRITE ONLY or READ WRITE.
Value range: an integer ranging from 1 to 1024 |
| compression | Specifies the file compression mode. This parameter is optional and is supported only by cluster versions 8.2.0 and later.

For a write only/read-write foreign table, it specifies the compression mode for ORC files.

For a READ ONLY foreign table, it specifies the compression mode for TEXT, CSV, or JSON files. | <ul style="list-style-type: none">For ORC files: the value can be zlib (default), snappy, and lz4.For Parquet files: zlib, snappy (default), lz4, lz4_hadoop.For TEXT, CSV, and JSON files: the value is gzip. CAUTION <ul style="list-style-type: none">In versions earlier than 8.2.0, the parameter cannot be specified for READ ONLY foreign tables.The lz4_hadoop compression option is designed to work with the Hive LZ4 algorithm. By setting the compression format for a parquet foreign table, both the parquet foreign table and Hive can seamlessly exchange data. |
| version | Specifies the ORC version number. This parameter is optional. This syntax is available only for WRITE ONLY/READ WRITE foreign tables. | Value range: Only 0.12 is supported. The default value is 0.12 . |

| Parameter | Description | Value Range |
|---------------|---|---|
| julian_adjust | <p>Specifies whether to correct the Julian day in the data. This parameter is optional and is supported only by cluster versions 8.3.0 and later.</p> <p>Spark 2.X uses the Julian day, and Spark 3.0 and later versions use the Proleptic Gregorian calendar. As a result, some dates before parquet 1582 are different. Correct the dates based on the site requirements.</p> | The value can be true or false . Default value: true |
| cache_policy | <p>Specifies the disk cache policy for foreign tables. This parameter is supported only in the storage-compute decoupling 3.0 version.</p> | <p>Value range: For foreign tables, this parameter can be set to ALL or NONE. ALL indicates that the hot cache in the disk cache is used, and NONE indicates that the cold cache is used. Hot cache occupies more space than cold cache and uses more complex replacement algorithms.</p> |

Table 21-173 OPTIONS fault tolerance parameters

| Parameter | Description | Value Range |
|---------------------|---|---|
| fill_missing_fields | Specifies whether to generate an error message when the last column in a row in the source file is lost during data loading. | true/on or false/off . The default value is false or off . <ul style="list-style-type: none">If this parameter is set to true or on and the last column of a data row in a data source file is lost, the column is replaced with NULL and no error message will be generated.If this parameter is set to false or off and the last column is missing, the following error information will be displayed:
missing data for column "tt" CAUTION <ul style="list-style-type: none">Because SELECT COUNT(*) does not parse columns in text format, it does not report missing columns.fill_missing_fields is available only for TEXT and CSV source data files. |
| ignore_extra_data | Specifies whether to ignore excessive columns when the number of data source files exceeds the number of foreign table columns. This parameter is available only during data importing. | true/on or false/off . The default value is false or off . <ul style="list-style-type: none">If this parameter is set to true or on and the number of data source files exceeds the number of foreign table columns, excessive columns will be ignored.If this parameter is set to false or off and the number of data source files exceeds the number of foreign table columns, the following error information will be displayed:
extra data after last expected column CAUTION <ul style="list-style-type: none">If the newline character at the end of the row is lost, setting the parameter to true will ignore data in the next row.Because SELECT COUNT(*) does not parse columns in text format, it does not report missing columns.ignore_extra_data is available only for TEXT and CSV source data files. |

| Parameter | Description | Value Range |
|---------------|--|--|
| checkencoding | Specifies whether to check the character encoding. | <p>Value range: no, low, and high The default value is low.</p> <p>In TEXT format, the rule of error tolerance for invalid characters imported is as follows:</p> <ul style="list-style-type: none">• \0 is converted to a space.• Other invalid characters are converted to question marks.• Setting checkencoding to low enables invalid characters toleration. If NULL and DELIMITER are set to spaces or question marks (?), errors like "illegal chars conversion may confuse null 0x20" will be displayed, prompting you to modify parameters that may cause confusion and preventing importing errors. <p>In ORC format, the rule of error tolerance for invalid characters imported is as follows:</p> <ul style="list-style-type: none">• If checkencoding is set to no, invalid characters are not checked during data import. If you confirm that there are no invalid characters, this option can shorten the import time.• If checkencoding is low, an imported field containing invalid characters will be replaced with a quotation mark string of the same length.• If checkencoding is high, data import stops when an invalid character is detected. |

| Parameter | Description | Value Range |
|---------------|---|---|
| force_mapping | Indicates the handling method used when no correct name-value pairs are matched for the foreign table columns in JSON format. | <p>The options include true and false. Default value: true</p> <ul style="list-style-type: none">• If force_mapping is true, null is entered in the corresponding column. The meaning of null is the same as that defined in JSON.• If force_mapping is false, an error is reported, indicating that the column does not exist. <p>CAUTION
There are no restrictions on JSON objects. While the definition of foreign table fields must comply with DWS identifier specifications (such as length and character restrictions). This import method may cause exceptions. For example, a JSON name cannot be correctly identified or a field is repeatedly defined. You are advised to use the fault tolerance option force_mapping or JSON operators (for details, see JSON/JSONB Functions and Operators).</p> <p>For JSON format, SELECT COUNT(*) does not parse specific fields. Therefore, no error is reported when a field is missing or the format is incorrect.</p> |

Table 21-174 OPTIONS parameters (only when the server type is DLI)

| Parameter | Description | Value Range |
|-------------------|---|-------------|
| dli_project_id | Specifies the project ID corresponding to DLI. You can obtain the project ID from the management console. This parameter is available only when the server type is DLI. This parameter is supported only in 8.1.1 or later. | - |
| dli_database_name | Specifies the name of the database where the DLI multi-version table to be accessed is located. This parameter is available only when the server type is DLI. This parameter is supported only in 8.1.1 or later. | - |
| dli_table_name | Specifies the name of the DLI multi-version table to be accessed. This parameter is available only when the server type is DLI. This parameter is supported only in 8.1.1 or later. | - |

Table 21-175 OPTIONS parameters (available only when **format** is set to **hudi**. The following parameters are supported only in clusters of version 9.1.0.100 or later.)

| Parameter | Description | Value Range |
|-------------|--|---|
| auth_server | Specifies a server, which is used for user identity authentication when KMS is used to encrypt data in the Hudi foreign table. This parameter can be specified only when format is set to Hudi . | Value range: name of an available HDFS server.

MRS provides the column-level encryption capability for Hudi data. RangerKMS is used to manage users and key IDs and control encryption and decryption permissions. You can specify the auth_server parameter when creating a foreign table to bind user RangerKMS to the table. In this way, you can be authorized and obtain keys to read encrypted data. |
| kms_url | Specifies the IP address and port number of the KMS service. This parameter can be specified only when format is set to hudi and auth_server is specified. | Value range: a valid string in ip:port format.

Generally, if auth_server is specified, the IP address and port number of the KMS service can be automatically parsed. If this parameter is specified, the address is forcibly used to access the KMS service. |
| cow_improve | Optimization parameter for the COPY_ON_WRITE table. When this parameter is enabled, DNs replace the dws-bigdata component to directly read data from OBS.

This parameter can be specified only when format is set to Hudi and cannot be specified together with auth_server . | Value range: true/on and false/off .
The default value is false or off .
NOTE
This parameter is invalid for MERGE_ON_READ tables. |

 NOTE

chunksize indicates the cache size of each OBS reading thread on a DN. The format can be text, CSV, or JSON. The default size is 4 MB.

Informational Constraints

In DWS, the use of data constraints depend on users. If users can make data sources strictly comply with certain constraints, the query on data with such constraints can be accelerated. Foreign tables do not support Index. Informational constraint is used for optimizing query plans.

The constraints of creating informational constraints for an HDFS foreign table are as follows:

- You can create an informational constraint only if the values in a NOT NULL column in your table are unique. Otherwise, the query result will be different from expected.
- Currently, the informational constraint of DWS supports only PRIMARY KEY and UNIQUE constraints.
- The informational constraints of DWS support the NOT ENFORCED attribute.
- UNIQUE informational constraints can be created for multiple columns in a table, but only one PRIMARY KEY constraint can be created in a table.
- Multiple informational constraints can be established in a column of a table (because the function that establishing a column or multiple constraints in a column is the same.) Therefore, you are not advised to set up multiple informational constraints in a column, and only one Primary Key type can be set up.
- Table-level COMMENT is not supported.
- Multi-column combination constraints are not supported.
- Different CNs in the same cluster cannot concurrently export data to the same write-only ORC foreign table.
- The catalog of a write-only foreign table in ORC format can only be used as the export catalog of a single foreign table of DWS. It cannot be used for multiple foreign tables, and other components cannot write other files to this catalog.

Example: Creating an HDFS Foreign Table

In HDFS, import the TPC-H benchmark test tables **part** and **region** using Hive. The path of the **part** table is **/user/hive/warehouse/partition.db/part_4**, and that of the **region** table is **/user/hive/warehouse/mppdb.db/region_orc11_64stripe/**.

1. Establish HDFS_Server, with HDFS_FDW or DFS_FDW as the foreign data wrapper.

```
CREATE SERVER hdfs_server FOREIGN DATA WRAPPER HDFS_FDW OPTIONS
(address '10.10.0.100:25000,10.10.0.101:25000',
hdfsconfigpath '/opt/hadoop_client/HDFS/hadoop/etc/hadoop',
type'HDFS');
```

NOTE

- The IP addresses and port numbers of HDFS NameNodes are specified in **OPTIONS**. For details about the port number, search for **dfs.namenode.rpc.port** in the MRS-HDFS service configuration. In this example the port number is 25000.
 - **10.10.0.100:25000,10.10.0.101:25000** indicates the IP addresses and port numbers of the primary and standby HDFS NameNodes. It is the recommended format. Two groups of parameters are separated by commas (,).
2. Create an HDFS foreign table. The HDFS server associated with the table is **hdfs_server**, the corresponding file format of the **ft_region** table on the HDFS server is **'orc'**, and the file directory in the HDFS file system is **'/user/hive/warehouse/mppdb.db/region_orc11_64stripe/'**.

- Create an HDFS foreign table without partition keys.

```
CREATE FOREIGN TABLE ft_region
(
    R_REGIONKEY INT4,
    R_NAME TEXT,
    R_COMMENT TEXT
)
SERVER
    hdfs_server
OPTIONS
(
    FORMAT 'orc',
    encoding 'utf8',
    FOLDERNAME '/user/hive/warehouse/mppdb.db/region_orc11_64stripe/'
)
DISTRIBUTE BY
    roundrobin;
```

- Create an HDFS foreign table with partition keys.

```
CREATE FOREIGN TABLE ft_part
(
    p_partkey int,
    p_name text,
    p_mfgr text,
    p_brand text,
    p_type text,
    p_size int,
    p_container text,
    p_retailprice float8,
    p_comment text
)
SERVER
    hdfs_server
OPTIONS
(
    FORMAT 'orc',
    encoding 'utf8',
    FOLDERNAME '/user/hive/warehouse/partition.db/part_4'
)
DISTRIBUTE BY
```

```
roundrobin
PARTITION BY
(p_mfgr) AUTOMAPPED;
```

NOTE

DWS allows you to specify files using the keyword **filenames** or **foldername**. The latter is recommended. The key word **distribute** specifies the storage distribution mode of the **ft_region** table.

3. View the created server and foreign table.

```
SELECT * FROM pg_foreign_table WHERE ftrelid='ft_region'::regclass;
ftrelid | ftserver | ftwriteonly |          ftoptions
-----+-----+-----+-----
16510 | 16509 | f | {format=orc,foldername=/user/hive/warehouse/mppdb.db/
region_orc11_64stripe/}
(1 row)

select * from pg_foreign_table where ftrelid='ft_part'::regclass;
ftrelid | ftserver | ftwriteonly |          ftoptions
-----+-----+-----+-----
16513 | 16509 | f | {format=orc,foldername=/user/hive/warehouse/partition.db/part_4}
(1 row)
```

Example: Creating an HDFS Write-Only Foreign Table

Export data from the TPC-H benchmark test table **region** to the **/user/hive/warehouse/mppdb.db/region_orc/** directory of the HDFS file system through the HDFS write-only foreign table.

1. Create an HDFS foreign table. The corresponding foreign data wrapper is **HDFS_FDW** or **DFS_FDW**, which is the same as that in [Example 1](#).
2. Create a write-only HDFS foreign table.

```
CREATE FOREIGN TABLE ft_wo_region
(
  R_REGIONKEY INT4,
  R_NAME TEXT,
  R_COMMENT TEXT
)
SERVER
  hdfs_server
OPTIONS
(
  FORMAT 'orc',
  encoding 'utf8',
  FOLDERNAME '/user/hive/warehouse/mppdb.db/region_orc/'
)
WRITE ONLY;
```

3. Writes data to the HDFS file system through a write-only foreign table.
- ```
INSERT INTO ft_wo_region SELECT * FROM region;
```

**Example: Creating an HDFS Write-Only Partitioned Foreign Table (Supported Only by Storage-Compute Decoupling 3.0 Version)**

Export data from the TPC-H benchmark test table **region** table to the **/user/hive/warehouse/mppdb.db/region\_orc/** directory of the HDFS file system through the write-only, multi-level partitioned HDFS foreign table.

1. Create an HDFS foreign table. The corresponding foreign data wrapper is **HDFS\_FDW** or **DFS\_FDW**, which is the same as that in [Example: Creating an HDFS Foreign Table](#).

2. Create a write-only foreign table for HDFS multi-level partitions.

```
CREATE FOREIGN TABLE ft_wo_region_partition
(
 R_REGIONKEY INT4,
 R_NAME TEXT,
 R_COMMENT TEXT
)
SERVER
 hdfs_server
OPTIONS
(
 FORMAT 'orc',
 encoding 'utf8',
 FOLDERNAME '/user/hive/warehouse/mppdb.db/region_orc/'
)
WRITE ONLY
PARTITION BY (R_REGIONKEY, R_NAME);
```

3. Writes data to the HDFS file system through a write-only foreign table.  
INSERT INTO ft\_wo\_region\_partition SELECT \* FROM region;

## Example: Creating an OBS Read-Only Foreign Table (Supported Only by Storage-Compute Decoupling 3.0 version)

Read data from the OBS file system through the foreign table **partsupp**.

1. Create an OBS server.

### NOTICE

- Hard-coded or plaintext AK and SK are risky. For security purposes, encrypt your AK and SK and store them in the configuration file or environment variables.
- For details about the syntax for creating a server, see [CREATE SERVER](#).

```
CREATE SERVER obs_srv FOREIGN DATA WRAPPER dfs_fdw OPTIONS (
 address 'obs.example.com',
 type 'obs',
 access_key 'xxx',
 secret_access_key 'xxx'
);
```

2. Create an OBS foreign table **partsupp** and use the cold cache in the disk cache.

```
CREATE FOREIGN TABLE PARTSUPP
(
 PS_PARTKEY BIGINT NOT NULL,
 PS_SUPPKEY BIGINT NOT NULL,
 PS_AVAILQTY BIGINT NOT NULL,
 PS_SUPPLYCOST DECIMAL(15,2) NOT NULL,
 PS_COMMENT VARCHAR(199) NOT NULL
) SERVER obs_srv options (
 encoding 'utf-8',
 format 'parquet',
 foldername 'xxx',
 cache_policy 'NONE'
) READ ONLY DISTRIBUTE BY ROUNDROBIN;
```

3. Read data from OBS through the foreign table **partsupp**.  
SELECT \* FROM PARTSUPP;

## Example: Creating an HDFS Foreign Table Containing an Informational Constraint (NOT ENFORCED configured)

Perform operations on an HDFS foreign table that includes informational constraints.

- Create an HDFS foreign table with informational constraints.

```
CREATE FOREIGN TABLE ft_region (
 R_REGIONKEY int,
 R_NAME TEXT,
 R_COMMENT TEXT
 , primary key (R_REGIONKEY) not enforced)
SERVER hdfs_server
OPTIONS(format 'orc',
 encoding 'utf8',
 foldername '/user/hive/warehouse/mppdb.db/region_orc11_64stripe')
DISTRIBUTE BY roundrobin;
```

- Check whether the region table has an informational constraint index:

```
SELECT relname,relhasindex FROM pg_class WHERE oid='ft_region'::regclass;
```

| relname   | relhasindex |
|-----------|-------------|
| ft_region | f           |

(1 row)

```
SELECT conname, contype, consoft, conopt, conindid, conkey FROM pg_constraint WHERE conname
='ft_region_pkey';
```

| conname        | contype | consoft | conopt | conindid | conkey |
|----------------|---------|---------|--------|----------|--------|
| ft_region_pkey | p       | t       | t      | 0        | {1}    |

(1 row)

- Delete the informational constraint:

```
ALTER FOREIGN TABLE ft_region DROP CONSTRAINT ft_region_pkey RESTRICT;
```

```
SELECT conname, contype, consoft, conindid, conkey FROM pg_constraint WHERE conname
='ft_region_pkey';
```

| conname | contype | consoft | conindid | conkey |
|---------|---------|---------|----------|--------|
|---------|---------|---------|----------|--------|

(0 rows)

- Add a unique informational constraint for the foreign table:

```
ALTER FOREIGN TABLE ft_region ADD CONSTRAINT constr_unique UNIQUE(R_REGIONKEY) NOT
ENFORCED;
```

Delete the unique informational constraint:

```
ALTER FOREIGN TABLE ft_region DROP CONSTRAINT constr_unique RESTRICT;
```

```
SELECT conname, contype, consoft, conindid, conkey FROM pg_constraint WHERE conname
='constr_unique';
```

| conname | contype | consoft | conindid | conkey |
|---------|---------|---------|----------|--------|
|---------|---------|---------|----------|--------|

(0 rows)

- Add a unique informational constraint for the foreign table:

```
ALTER FOREIGN TABLE ft_region ADD CONSTRAINT constr_unique UNIQUE(R_REGIONKEY) NOT
ENFORCED disable query optimization;
```

```
SELECT relname,relhasindex FROM pg_class WHERE oid='ft_region'::regclass;
```

| relname   | relhasindex |
|-----------|-------------|
| ft_region | f           |

(1 row)

Delete the unique informational constraint:

```
ALTER FOREIGN TABLE ft_region DROP CONSTRAINT constr_unique CASCADE;
```

## Example: Reading OBS JSON Data Using an OBS Foreign Table

Read json data stored in OBS using a foreign table.

1. The following JSON files are on OBS. The JSON objects contain nesting and arrays. Some objects have lost columns, and some object names are duplicate.

```
{"A": "simple1", "B": {"C": "nesting1"}, "D": ["array", 2, {"E": "complicated"}]}
{"A": "simple2", "D": ["array", 2, {"E": "complicated"}]}
{"A": "simple3", "B": {"C": "nesting3"}, "D": ["array", 2, {"E": "complicated3"}]}
{"B": {"C": "nesting4"}, "A": "simple4", "D": ["array", 2, {"E": "complicated4"}]}
{"A": "simple5", "B": {"C": "nesting5"}, "D": ["array", 2, {"E": "complicated5"}]}
```

2. Create **obs\_server**, with **DFS\_FDW** as the foreign data wrapper.

```
CREATE SERVER obs_server FOREIGN DATA WRAPPER DFS_FDW OPTIONS (
 ADDRESS 'obs.example.com',
 ACCESS_KEY 'xxxxxxxxx',
 SECRET_ACCESS_KEY 'yyyyyyyyyyyyyy',
 TYPE 'OBS'
);
```

### NOTE

- **ADDRESS** is the endpoint of OBS. Replace it with the actual endpoint. You can find the domain name by searching for the value of **regionCode** in the **region\_map** file.
  - **ACCESS\_KEY** and **SECRET\_ACCESS\_KEY** are access keys for the cloud account system. Replace the values as needed.
  - **TYPE** indicates the server type. Retain the value **OBS**.
3. Create the OBS foreign table **json\_f** and define the column names. For example, **d#2\_e** indicates that the column is object **e** nested in the 2nd element of array **d**. The OBS server associated with the table is **obs\_server**. **foldername** indicates the data source directory of the foreign table, that is, the OBS directory.

### NOTICE

// Hard-coded or plaintext AK and SK are risky. For security purposes, encrypt your AK and SK and store them in the configuration file or environment variables.

```
CREATE FOREIGN TABLE json_f (
 a VARCHAR(10),
 b_c TEXT,
 d#1 INTEGER,
 d#2_e VARCHAR(30)
)SERVER obs_server OPTIONS (
 foldername '/xxx/xxx/',
 format 'json',
 encoding 'utf8',
 force_mapping 'true'
)distribute by roundrobin;
```

4. Query the foreign table **json\_f**. The fault tolerance parameter **force\_mapping** is enabled by default. If a column is missing in a JSON object, NULL is filled in. If a JSON object name is duplicate, the last name prevails.

```
SELECT * FROM json_f;
 a | b_c | d#1 | d#2_e
-----+-----+-----+-----
simple1 | nesting1 | 2 | complicated1
simple2 | | 2 | complicated2
simple3 | nesting3 | 2 | complicated3
```

```
simple4 | nesting4 | 2 | complicated4
repeat | nesting5 | 2 | complicated5
(5 rows)
```

## Example: Accessing Data on DLI Through a DLI Foreign Table

Read a DLI multi-version foreign table using a foreign table. Only DLI 8.1.1 and later support the multi-version foreign table example.

1. Create **dli\_server**, with **DFS\_FDW** as the foreign data wrapper.

```
CREATE SERVER dli_server FOREIGN DATA WRAPPER DFS_FDW OPTIONS (
 ADDRESS 'obs.example.com',
 ACCESS_KEY 'xxxxxxxxx',
 SECRET_ACCESS_KEY 'yyyyyyyyyyyyyy',
 TYPE 'DLI',
 DLI_ADDRESS 'dli.example.com',
 DLI_ACCESS_KEY 'xxxxxxxxx',
 DLI_SECRET_ACCESS_KEY 'yyyyyyyyyyyyyy'
);
```

### NOTE

- **ADDRESS** is the endpoint of OBS. **DLI\_ADDRESS** is the endpoint of DLI. Replace it with the actual endpoint.
  - **ACCESS\_KEY** and **SECRET\_ACCESS\_KEY** are access keys for the cloud account system to access OBS. Use the actual value.
  - **DLI\_ACCESS\_KEY** and **DLI\_SECRET\_ACCESS\_KEY** are access keys for the cloud account system to access DLI. Use the actual value.
  - **TYPE** indicates the server type. Retain the value **DLI**.
2. Create the OBS foreign table **customer\_address** for accessing DLI. The table does not contain partition columns, and the DLI server associated with the table is **dli\_server**. Where, the **project\_id** is **xxxxxxxxxxxxxxxxxx**, the **database\_name** on DLI is **database123**, and the **table\_name** of the table to be accessed is **table456**. Replace them based on the actual requirements.

### NOTICE

// Hard-coded or plaintext AK and SK are risky. For security purposes, encrypt your AK and SK and store them in the configuration file or environment variables.

```
CREATE FOREIGN TABLE customer_address
(
 ca_address_sk integer not null,
 ca_address_id char(16) not null,
 ca_street_number char(10) ,
 ca_street_name varchar(60) ,
 ca_street_type char(15) ,
 ca_suite_number char(10) ,
 ca_city varchar(60) ,
 ca_county varchar(30) ,
 ca_state char(2) ,
 ca_zip char(10) ,
 ca_country varchar(20) ,
 ca_gmt_offset decimal(36,33) ,
 ca_location_type char(20) ,
)
SERVER dli_server OPTIONS (
 FORMAT 'ORC',
 ENCODING 'utf8',
```

```
DLI_PROJECT_ID 'xxxxxxxxxxxxxx',
DLI_DATABASE_NAME 'database123',
DLI_TABLE_NAME 'table456'
)
DISTRIBUTE BY roundrobin;
```

3. Query data in a DLI multi-version table using a foreign table.

```
SELECT COUNT(*) FROM customer_address;
count

20
(1 row)
```

## Helpful Links

- For details about the syntax for modifying and deleting a foreign table, see [ALTER FOREIGN TABLE \(for HDFS or OBS\)](#) and [DROP FOREIGN TABLE](#).

### 21.13.4.9 CREATE FOREIGN TABLE (for OBS Import and Export)

#### Function

**CREATE FOREIGN TABLE** creates an OBS foreign table in the current database for parallel data import and export of OBS data. You do not need to create an external server. The **gsmpp\_server** created by the database by default can be used.

This syntax supports only TEXT and CSV data on OBS buckets. If you need to process ORC, CARBONDATA, and PARQUET data, see [CREATE FOREIGN TABLE \(SQL on OBS or Hadoop\)](#) and create an external server.

A foreign table is a virtual table within a database or big data platform that does not physically store data. Instead, it serves as a mapping to data residing in external storage systems, such as HDFS or OBS. This mapping is established using metadata, which includes the table structure, the location of the data, and its file format. It enables users to directly access or operate external data using standard SQL statements. A foreign table serves as a data proxy that logically maps data in external file systems to table structures that can be identified by databases.

#### Precautions

- Only the data in text and CSV formats is supported, and the OBS connection should be configured.
- When using an OBS foreign table to access data in an OBS bucket, you need to ensure that your DWS cluster and OBS bucket are in the same region.
- Foreign tables are classified into read-only foreign tables (**READ ONLY**) and write-only foreign tables (**WRITE ONLY**). By default, foreign tables are read-only. When importing OBS data, you need to set the foreign table to **READ ONLY**. When exporting data to OBS, you need to set the foreign table to **WRITE ONLY**.
- Only the system administrator **dbadmin** or a common user who has been granted the USEFT permission can perform foreign table operations.  

```
ALTER USER user_name USEFT;
```
- The distribution mode of an OBS foreign table does not need to be explicitly specified. The default mode is **ROUNDROBIN**.

- Only constraints in **Informational Constraints** take effect for the created foreign table.
- OBS buckets cannot contain Chinese paths.

**Table 21-178** Read and write formats supported by OBS foreign tables

| Data Type  | DIST_FDW  |            |
|------------|-----------|------------|
| -          | READ ONLY | WRITE ONLY |
| ORC        | ×         | ×          |
| PARQUET    | ×         | ×          |
| CARBONDATA | ×         | ×          |
| TEXT       | √         | √          |
| CSV        | √         | √          |
| JSON       | ×         | ×          |

## Syntax

```
CREATE FOREIGN TABLE [IF NOT EXISTS] table_name
({ column_name type_name [column_constraint]
 | LIKE source_table | table_constraint [, ...]} [, ...])
SERVER server_name
OPTIONS ({ option_name ' value ' } [, ...])
[{ WRITE ONLY | READ ONLY }]
[WITH error_table_name | LOG INTO error_table_name]
[PER NODE REJECT LIMIT 'value'] ;
```

- **column\_constraint** is as follows:  
[CONSTRAINT constraint\_name]  
{PRIMARY KEY | UNIQUE}  
[NOT ENFORCED [ENABLE QUERY OPTIMIZATION | DISABLE QUERY OPTIMIZATION] | ENFORCED]
- **table\_constraint** is as follows:  
[CONSTRAINT constraint\_name]  
{PRIMARY KEY | UNIQUE} (column\_name)  
[NOT ENFORCED [ENABLE QUERY OPTIMIZATION | DISABLE QUERY OPTIMIZATION] | ENFORCED]

## Parameter Description

**Table 21-179** CREATE FOREIGN TABLE (for OBS import and export) parameters

| Parameter     | Description                                                                        | Value Range or Example |
|---------------|------------------------------------------------------------------------------------|------------------------|
| IF NOT EXISTS | Sends a notice, but does not throw an error, if a table with the same name exists. | -                      |

| Parameter          | Description                                                                                                                                                                                                    | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| table_name         | Specifies the name of the foreign table.                                                                                                                                                                       | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                                                                                                                                         |
| column_name        | Specifies the name of a column in the foreign table.                                                                                                                                                           | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                                                                                                                                         |
| type_name          | Specifies the data type of the column.                                                                                                                                                                         | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SERVER server_name | Specifies the server name of the foreign table. For OBS foreign tables used for data import and export, you can use <b>gsmpp_server</b> created by the initial database by default or use a customized server. | <ul style="list-style-type: none"><li>• If a custom server is used, the foreign data wrapper should be <b>dist_fdw</b>.</li><li>• For clusters of 8.2.0 and later versions, you can specify the following OBS access parameters in the customized <b>dist_fdw</b> server: <b>access_key</b>, <b>secret_access_key</b>, and <b>security_token</b>. If the preceding parameters are specified in the server, you do not need to specify them again in the foreign table.</li></ul> |
| OPTIONS            | Specifies parameters of foreign table data.                                                                                                                                                                    | <ul style="list-style-type: none"><li>• Data format parameters. For details, see <a href="#">Table 21-180</a>.</li><li>• Error-tolerance parameters. For details, see <a href="#">Table 21-181</a>.</li><li>• Performance parameters. For details, see <a href="#">Table 21-182</a>.</li></ul>                                                                                                                                                                                   |
| READ ONLY          | Specifies whether a foreign table is read-only. This parameter is available only for data import.                                                                                                              | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter                        | Description                                                                                                                                                                                                                                | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WRITE ONLY                       | Specifies whether a foreign table is write-only. This parameter is available only for data export.                                                                                                                                         | -                                                                                                                                                                                                                                                                                                                                                                                                                          |
| WITH<br>error_table_name         | Data format errors during import are recorded in the table specified by <b>error_table_name</b> . You can query this table after the import to obtain error details. This parameter is available only after <b>reject_limit</b> is set.    | A string, which must comply with the naming convention.<br><b>CAUTION</b><br>To be compatible with PostgreSQL open source interfaces, you are advised to replace this syntax with <b>LOG INTO</b> . When this parameter is specified, an error table is automatically created.                                                                                                                                             |
| LOG INTO<br>error_table_name     | Data format errors during import are recorded in the table specified by <b>error_table_name</b> . You can query this table after the import to obtain error details.                                                                       | A string, which must comply with the naming convention. <ul style="list-style-type: none"><li>• This parameter is available only after <b>PER NODE REJECT LIMIT</b> is set.</li><li>• When this parameter is specified, an error table is automatically created.</li></ul>                                                                                                                                                 |
| PER NODE REJECT<br>LIMIT 'value' | This parameter specifies the allowed number of data format errors on each DN during data import. If the number of errors exceeds the specified value on any DN, data import fails, an error is reported, and the system exits data import. | An <b>unlimited</b> integer. If this parameter is not specified, an error message is returned immediately.<br><b>CAUTION</b><br>This syntax specifies the error tolerance of a single node. Examples of data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. When a non-data format error occurs, the whole data import process stops. |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Value Range or Example                                                                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NOT ENFORCED | <p>Specifies that the created constraint is an informational constraint, which is not forcibly verified by the database. This option is used with <b>ENABLE QUERY OPTIMIZATION</b>.</p> <ul style="list-style-type: none"><li>• Informational rather than mandatory: You still need to specify a unique constraint for a column using <b>PRIMARY KEY</b> or <b>UNIQUE</b> to optimize the query execution plan.</li><li>• No mandatory verification: The database does not check whether the data in the external data source actually meets constraint conditions (for example, whether duplicate values exist).</li><li>• Performance optimization: The query optimizer is allowed to use an informational constraint to generate a more efficient execution plan. However, you need to ensure that the data meets constraint conditions, or the query result may be incorrect.</li><li>• <b>Risk</b>: If the actual data violates constraint conditions (for example, duplicate values exist), the query result may be incorrect (for example, the aggregation result is</li></ul> | <p>For example, the primary key is declared, but the verification is not mandatory.</p> <pre>CREATE FOREIGN TABLE hdfs_users<br/>( user_id INT PRIMARY KEY NOT<br/>ENFORCED,<br/>...</pre> |

| Parameter                     | Description                                                                                                                                                                               | Value Range or Example                                                                                                                                                                                                                                                                                                       |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | abnormal or redundant records are generated during JOIN operations).<br>For more information, see <a href="#">Informational Constraints</a> .                                             |                                                                                                                                                                                                                                                                                                                              |
| ENFORCED                      | Specifies that the created constraint is an enforced constraint that is forcibly validated by the database. This parameter is reserved. Currently, DWS does not support <b>ENFORCED</b> . | -                                                                                                                                                                                                                                                                                                                            |
| PRIMARY KEY<br>(column_name)  | Specifies the informational constraint on <b>column_name</b> .                                                                                                                            | String, which must conform to the identifier naming conventions. The column name must exist.                                                                                                                                                                                                                                 |
| ENABLE QUERY<br>OPTIMIZATION  | Enables the query optimizer to use informational constraints to generate a more efficient execution plan. This parameter is used together with <b>NOT ENFORCED</b> .                      | Create a foreign table, add a unique constraint to the <b>p_partkey int</b> column, do not enforce the constraint, and allow the optimizer to use the informational constraint to generate a better execution plan.<br>CREATE FOREIGN TABLE ft_part (<br>p_partkey int UNIQUE NOT ENFORCED ENABLE QUERY OPTIMIZATION,<br>... |
| DISABLE QUERY<br>OPTIMIZATION | Disables the query optimizer to use informational constraints to generate an efficient execution plan.                                                                                    | -                                                                                                                                                                                                                                                                                                                            |

**Table 21-180** OPTIONS parameters of the data format

| Parameter         | Description                                                                                                                                                                                                                                                                                                             | Value Range or Example |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| encrypt           | Specifies whether HTTPS is enabled for data transfer. <b>on</b> enables HTTPS and <b>off</b> disables it (in this case, HTTP is used). The default value is <b>off</b> .                                                                                                                                                | -                      |
| access_key        | Indicates the access key (AK, obtained from the user information on the console) used for the OBS access protocol. When you create a foreign table, its AK value is not encrypted and saved to the metadata table of the database. The correctness of the parameter is not verified when a foreign table is created.    | -                      |
| secret_access_key | Indicates the secret access key (SK, obtained from the user information on the console) used for the OBS access protocol. When you create a foreign table, its SK value is encrypted and saved to the metadata table of the database. The correctness of the parameter is not verified when a foreign table is created. | -                      |

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Value Range or Example                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| security_token | <p>Corresponds to the <b>SecurityToken</b> value of the temporary security credential in IAM. A temporary AK, a temporary SK, and a temporary security token form a temporary security credential. The temporary security credential is valid for no more than 24 hours. This parameter is supported by version 8.2.0 or later clusters.</p> <p><b>CAUTION</b></p> <ul style="list-style-type: none"><li>This parameter is supported by version 8.2.0 or later clusters.</li><li>When this parameter is used, <b>access_key</b> and <b>secret_access_key</b> correspond to the temporary AK and SK, respectively.</li></ul> | -                                                                                                                                                              |
| chunksize      | <p>Specifies the cache read by each OBS thread on a DN. Its value range is 8 to 512 in the unit of MB. Its default value is <b>64</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | -                                                                                                                                                              |
| location       | <p>Specifies the directory where OBS data is stored. The value can be described as a URL in the format of <b>obs://OBS bucket name/folder name</b>. Multiple URLs are separated by vertical bars ( ). Ensure that the OBS bucket and DWS cluster are in the same region. Cross-region access to OBS bucket data is not supported.</p> <p>For details about how to use this parameter, see <a href="#">Location Parameter Description</a>.</p>                                                                                                                                                                               | <p>Example:</p> <pre>OPTIONS<br/>( encoding 'utf8',      location<br/>'obs://&lt;obs_bucket_name&gt;/traffic-<br/>data/gcxx',<br/>format 'text',<br/>...</pre> |

| Parameter | Description                                                                                                                                                                                                                                                                                           | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| region    | <p>(Optional) specifies the value of <b>regionCode</b>, region information on the cloud.</p> <p>If the <b>region</b> parameter is explicitly specified, the value of <b>region</b> will be read. If the <b>region</b> parameter is not specified, the value of <b>defaultRegion</b> will be read.</p> | <p>Note the following when setting parameters for importing or exporting OBS foreign tables in TEXT or CSV format:</p> <ul style="list-style-type: none"><li>• The <b>location</b> parameter is mandatory. The prefixes <b>gsobs</b> and <b>obs</b> indicate file locations on OBS. The <b>gsobs</b> prefix should be followed by <i>obs url</i>, <i>bucket</i>, and <i>prefix</i>. The <b>obs</b> prefix should be followed by <i>bucket</i> or <i>prefix</i>.</li><li>• The data sources of multiple buckets are separated by vertical bars ( ), for example, <b>LOCATION 'obs://bucket1/folder/   obs://bucket2/'</b>. The database scans all objects in the specified folders.</li></ul> |

| Parameter | Description                                                                           | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| format    | Specifies the format of the source data file in a foreign table.                      | <p>CSV or TEXT (default value). DWS only supports CSV and TEXT formats.</p> <ul style="list-style-type: none"><li>• CSV (comma-separated format):<ul style="list-style-type: none"><li>– The CSV file can process linefeeds efficiently, but cannot process certain special characters very well.</li><li>– A CSV file is composed of records that are separated as columns by delimiters. Each record shares the same column sequence.</li></ul></li><li>• TEXT (text format):<p>Records are separated as columns by linefeed. The TEXT file can process special characters efficiently, but cannot process linefeeds well.</p></li></ul> |
| header    | Specifies whether a file contains a header with the names of each column in the file. | <p>When OBS exports data, this parameter cannot be set to <b>true</b>. Use the default value <b>false</b>, indicating that the first row of the exported data file is not the header.</p> <p>When data is imported, if <b>header</b> is <b>on</b>, the first row of the data file will be identified as title row and ignored. If <b>header</b> is <b>off</b>, the first row will be identified as a data row.</p> <p>Valid value: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>false</b> or <b>off</b>.</p>                                                                                              |

| Parameter | Description                                                                                                                                                     | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| delimiter | Specifies the column delimiter of data, and uses the default delimiter if it is not set. The default delimiter of TEXT is a tab and that of CSV is a comma (,). | <p>The value of <b>delimiter</b> can be a multi-character delimiter whose length is less than or equal to 10 bytes.</p> <ul style="list-style-type: none"><li>• The delimiter of TEXT cannot be <b>\r</b> or <b>\n</b>.</li><li>• A delimiter cannot be the same as the <b>null</b> value. The delimiter for the CSV format cannot be same as the <b>quote</b> value.</li><li>• The separator of TEXT data cannot contain letters, digits, backslashes (\), and periods (.).</li><li>• The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.</li><li>• You are advised to use a multi-character string, such as the combination of the dollar sign (\$), caret (^), and ampersand (&amp;), or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.</li></ul> |
| quote     | Specifies the quotation mark for the CSV format. The default value is a double quotation mark (").                                                              | <ul style="list-style-type: none"><li>• The <b>quote</b> value cannot be the same as the delimiter or <b>null</b> value.</li><li>• The <b>quote</b> value must be a single-byte character.</li><li>• Invisible characters are recommended as <b>quote</b> values, such as 0x07, 0x08, and 0x1b.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Parameter  | Description                                                                                    | Value Range or Example                                                                                                                                                                                                                                                                                                                                               |
|------------|------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| escape     | Specifies an escape character for a CSV file. The value must be a single-byte character.       | The default value is a double quotation mark ("). If the value is the same as the <b>quote</b> value, it will be replaced with \0.                                                                                                                                                                                                                                   |
| null       | Specifies how to represent a null value.                                                       | <ul style="list-style-type: none"><li>• The default value is \N for the TEXT format.</li><li>• The default value for the CSV format is an empty string without quotation marks.</li><li>• The <b>null</b> value cannot be \r or \n. The maximum length is 100 characters.</li><li>• The null value cannot be the same as the delimiter or quote parameter.</li></ul> |
| noescaping | Specifies whether to escape the backslash (\) and its following characters in the TEXT format. | <b>noescaping</b> is available only for the TEXT format. <b>true/on</b> or <b>false/off</b> . The default value is <b>false</b> or <b>off</b> .                                                                                                                                                                                                                      |

| Parameter | Description                                                                                                                                                                                         | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| encoding  | Specifies the encoding of a data file, that is, the encoding used to parse, check, and generate a data file. Its default value is the default <b>client_encoding</b> value of the current database. | <p>Before you import foreign tables, it is recommended that you set <b>client_encoding</b> to the file encoding format, or a format matching the character set of the file. Otherwise, unnecessary parsing and check errors may occur, leading to import errors, rollback, or even invalid data import. Before exporting foreign tables, you are also advised to specify this parameter, because the export result using the default character set may not be what you expect.</p> <p>If this parameter is not specified when you create a foreign table, a warning message will be displayed on the client.</p> <p><b>CAUTION</b></p> <ul style="list-style-type: none"><li>Currently, OBS cannot parse a file using multiple character sets during foreign table import.</li><li>Currently, OBS cannot write a file using multiple character sets during foreign table export.</li></ul> |

| Parameter            | Description                                                                                                     | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|-----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| eol                  | Specifies the newline character style of the imported or exported data file.                                    | <p>Multi-character newline characters are supported, but the newline character cannot exceed 10 bytes. Common newline characters include <code>\r</code> (0x0D), <code>\n</code> (0x0A), and <code>\r\n</code> (0x0D0A). Special newline characters include <code>\$</code> and <code>#</code>.</p> <ul style="list-style-type: none"><li>• The <b>eol</b> parameter supports only the TEXT format for data import and export.</li><li>• The value of the <b>eol</b> parameter cannot be the same as that of <b>DELIMITER</b> or <b>NULL</b>.</li><li>• The value of the <b>eol</b> parameter cannot contain digits, letters, or periods (.).</li></ul> |
| date_format          | Specifies the DATE format for data import. This syntax is available only for READ ONLY foreign tables.          | <p>Valid DATE formats. For details, see <a href="#">Date and Time Processing Functions and Operators</a>.</p> <p><b>NOTE</b><br/>If ORACLE is specified as the compatible database, the DATE format is TIMESTAMP. For details, see <b>timestamp_format</b> below.</p>                                                                                                                                                                                                                                                                                                                                                                                   |
| time_format          | Specifies the TIME format for data import. This syntax is available only for READ ONLY foreign tables.          | Valid TIME formats. Time zones are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| timestamp_format     | Specifies the TIMESTAMP format for data import. This syntax is available only for READ ONLY foreign tables.     | Valid TIMESTAMP formats. Time zones are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| smalldatetime_format | Specifies the SMALLDATETIME format for data import. This syntax is available only for READ ONLY foreign tables. | Valid SMALLDATETIME formats.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter | Description                                         | Value Range or Example                                                                                                                                                                           |
|-----------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bom       | Indicates whether a CSV file contains the utf8 BOM. | This parameter is valid only when the foreign table is read-only and uses UTF-8 code.<br><br>Value range: <b>true</b> , <b>on</b> , <b>false</b> , and <b>off</b><br>Default value: <b>false</b> |

**Table 21-181** OPTIONS fault tolerance parameters

| Parameter           | Description                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fill_missing_fields | Specifies how to handle the problem that the last column of a row in the source file is lost during data import.                                                                            | <b>true/on</b> or <b>false/off</b> . The default value is <b>false</b> or <b>off</b> . <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b> and the last column of a data row in a source data file is lost, the column will be replaced with <b>NULL</b> and no error message will be generated.</li><li>If this parameter is set to <b>false</b> or <b>off</b> and the last column of a data row in a source data file is lost, the following error information will be displayed:<br/>missing data for column "tt"</li></ul>                                                                                                                                       |
| ignore_extra_data   | Specifies whether to ignore excessive columns when the number of columns in a source data file exceeds that defined in the foreign table. This parameter is available only for data import. | <b>true/on</b> or <b>false/off</b> . The default value is <b>false</b> or <b>off</b> . <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b> and the number of source data files exceeds the number of foreign table columns, excessive columns will be ignored.</li><li>If this parameter is set to <b>false</b> or <b>off</b> and the number of source data files exceeds the number of foreign table columns, the following error information will be displayed:<br/>extra data after last expected column</li></ul> <b>CAUTION</b><br>If the linefeed at the end of a row is lost and this parameter is set to <b>true</b> , data in the next row will be ignored. |

| Parameter      | Description                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reject_limit   | Specifies the maximum number of data format errors allowed during the data import. If the number of data format errors does not reach the maximum, the data import is successful. | <p>The value is an integer or <b>unlimited</b>. If this parameter is not specified, an error message is returned immediately.</p> <p><b>CAUTION</b></p> <p>You are advised to replace this syntax with <b>PER NODE REJECT LIMIT 'value'</b>.</p> <p>Examples of data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. Once a non-data format error occurs, the whole data import process is stopped.</p> |
| force_save_err | Indicates whether to save the error information to the error table after the import exits due to an error.                                                                        | <p><b>true/on</b> or <b>false/off</b>. The default value is <b>false</b> or <b>off</b>.</p> <p>This parameter is used together with <b>reject_limit</b>. Once this parameter is enabled:</p> <ul style="list-style-type: none"><li>• If <b>reject_limit</b> is not specified, an error record will be retained in the error table.</li><li>• If <b>reject_limit</b> is set to <i>N</i>, <i>N+1</i> error records will be retained in the error table.</li></ul>                             |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| obs_null_file | <p>Imports and exports empty files between DWS and OBS.</p> <p><b>CAUTION</b></p> <ul style="list-style-type: none"><li>• This parameter is supported only in 8.2.1 or later.</li><li>• If <b>obs_null_file</b> is set to <b>true</b> or <b>on</b> and the export directory contains only the <b>_SUCCESS</b> empty file, the empty table can be exported repeatedly, while if <b>obs_null_file</b> is set to <b>false</b> or <b>off</b>, the empty table cannot be exported repeatedly.</li><li>• If <b>obs_null_file</b> is set to <b>true</b> or <b>on</b> and files are imported from multiple buckets, an error is reported for the first path that the file does not exist.</li></ul> | <p><b>true/on</b> or <b>false/off</b>. The default value is <b>false</b> or <b>off</b>.</p> <p>If <b>obs_null_file</b> is set to <b>true</b> or <b>on</b>:</p> <ul style="list-style-type: none"><li>• When an empty table is exported from DWS, an empty file named <b>_SUCCESS</b> is generated, indicating that the export is successful. When a non-empty table is exported, the original table and an empty file named <b>_SUCCESS</b> is generated.</li><li>• When a file is imported to DWS, if the file does not exist or the path is incorrect, the following error information is displayed:<br/>No such file or directory: 'XXX'</li></ul> |

| Parameter                             | Description                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compatible_illegal_chars</code> | Specifies whether to enable fault tolerance on invalid characters during data import. This syntax is available only for READ ONLY foreign tables. | <p><b>true/on</b> or <b>false/off</b>. The default value is <b>false</b> or <b>off</b>.</p> <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b>, invalid characters are tolerated and imported to the database after conversion.</li><li>If this parameter is set to <b>false</b> or <b>off</b> and an error occurs when there are invalid characters, the import will be interrupted.</li><li>The rule of error tolerance when you import invalid characters is as follows:<ol style="list-style-type: none"><li><code>\0</code> is converted to a space.</li><li>Other invalid characters are converted to question marks.</li><li>Setting <b>compatible_illegal_chars</b> to <b>true</b> or <b>on</b> enables toleration of invalid characters. If <b>NULL</b>, <b>DELIMITER</b>, <b>QUOTE</b>, and <b>ESCAPE</b> are set to spaces or question marks, errors like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to prompt the user to modify parameters that may cause confusion, preventing importing errors.</li></ol></li></ul> <p><b>CAUTION</b><br/>On a Windows platform, if OBS reads data files using the TEXT format, 0x1A will be treated as an EOF symbol and a parsing error will occur. It is the implementation constraint of the Windows platform. Since OBS on a Windows platform does not support BINARY read, the data can be read by OBS on a Linux platform.</p> |

Table 21-182 OPTIONS performance parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| file_split_threshold | This parameter is used to optimize the performance of importing data in TEXT format. It specifies the lower limit of the logical block size of a file. If this parameter is specified, large files are split based on the actual file and DN status to improve the import concurrency. The purpose is to evenly distribute tasks on each DN. Therefore, this parameter can be used in scenarios where the number of files is less than the number of DNs or the file size is unbalanced. | <b>0 to 2147483647</b> , in MB The default value is <b>0</b> , indicating that files are not split. <ul style="list-style-type: none"><li>• This parameter is supported only in 8.2.0 or later.</li><li>• This parameter supports only READ ONLY foreign tables in TEXT format.</li><li>• This parameter specifies the lower limit of the logical block size of a file. It does not specify a block size. For example, if the current file size is 1,024 MB and the number of DNs is 4, If the value of <b>file_split_threshold</b> is less than <b>256</b>, the file is evenly divided into four blocks, and a 256 MB file import task is allocated to each DN. When <b>file_split_threshold</b> is set to <b>500</b>, the file is split into 500 MB and 524 MB and allocated to two DNs because the block size cannot be less than 500 MB. This parameter is also applicable to multiple files.</li><li>• Unless there are clear requirements for block sizes, you are advised to set this parameter to a small value, for example, 10. Otherwise, the concurrency may be affected.</li></ul> |

### Location Parameter Description

- The URL of a read-only foreign table (the default permission is read-only) can end with the path prefix or the full path of the target object in the format of **obs://Bucket/Prefix**. *Prefix* indicates the prefix of an object path, for example, **obs://mybucket/tpch/nation/**.
- If the **region** parameter is explicitly specified in **obs://Bucket/Prefix**, the value of **region** will be read. If the **region** parameter is not specified, the value of **defaultRegion** will be read.

- The URL of a writable foreign table does not need to contain a file name. You can specify only one data source location for a foreign table. The directory corresponding to the location must be created before you specify the location.
- URLs specified for a read-only foreign table must be different.
- Specify **location** when inserting data to a foreign table.
- Parameter **LOCATION** supports prefixes **gsobs** and **obs**, which are identified as OBS information. **LOCATION** should be followed by **gsobs**, *OBS URL*, and *Bucket*, or by **obs** and *Bucket*.

When importing and exporting data, you are advised to use the **location** parameter as follows:

- You are advised to specify a file name for **location** during data import. If you only specify an OBS bucket or directory, all text files in it will be imported. An error message will be reported if the data format is incorrect. If you set fault tolerance, a large amount of data may be imported to the fault-tolerant table.
- Multiple files in an OBS bucket can be imported at the same time. The matched files are imported based on the file name prefix.  
For example, you can identify and import the following two files after specifying the prefix **mybucket/input\_data/product\_info** in **location**:  
mybucket/input\_data/product\_info.0  
mybucket/input\_data/product\_info.1
- If you specify a file name, for example, **1.csv**, then other files (like **1.csv1** or **1.csv22**) starting with **1.csv** in the bucket or directory where **1.csv** resides will be automatically imported. That is, **1.csv1** and **1.csv22** are automatically imported.
- To specify multiple URLs in OBS mode, separate URLs by using vertical bars (|). In gsobs mode, only one URL can be specified.
- During data export, a directory is generated for **location** by default. If you specify only a file name, the system automatically creates a directory whose name starts with the file name and then generates the file that stores the exported data. The file name is automatically generated by DWS.
- You can specify one path for **location** only during data export.

## Examples

Create a foreign table named **OBS\_ft** to import data in the .txt format from OBS to the **row\_tbl** table.

---

### CAUTION

// Hard-coded or plaintext AK and SK are risky. For security purposes, encrypt your AK and SK and store them in the configuration file or environment variables.

---

```
DROP FOREIGN TABLE IF EXISTS OBS_ft;

CREATE FOREIGN TABLE OBS_ft
(a int, b int)
SERVER gsmpp_server
OPTIONS
(location 'obs://gaussdbcheck/obs_ddl/test_case_data/txt_obs_informatonal_test001',
```

```
format 'text',
encoding 'utf8',
chunksize '32',
encrypt 'on',
ACCESS_KEY 'access_key_value_to_be_replaced',
SECRET_ACCESS_KEY 'secret_access_key_value_to_be_replaced',
delimiter E'\x08')
read only;

DROP TABLE row_tbl;

CREATE TABLE row_tbl(a int, b int);

INSERT INTO row_tbl select * from OBS_ft;
```

## Helpful Links

[ALTER FOREIGN TABLE \(for HDFS or OBS\), DROP FOREIGN TABLE](#)

## Optimization

- delimiter
  - A delimiter cannot be `\r` or `\n`, or the same as the **null** value. The delimiter of CSV cannot be same as the **quote** value.
  - The data length of a single row should be less than 1 GB. A row that has many columns using long delimiters cannot contain much valid data.
  - You are advised to use a multi-character string, such as the combination of the dollar sign (\$), caret (^), and ampersand (&), or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.
- quote
  - The value must be a single-byte character. The **quote** value cannot be the same as the delimiter or **null** value.
  - Invisible characters are recommended as **quote** values, such as 0x07, 0x08, and 0x1b.
- mode Normal
  - Supports all file types (including CSV, TEXT, and FIXED). To import data, you need to enable GDS on the data server.
- mode Shared
  - Supports the TEXT format. It does not require GDS, but all the user data has to be mounted to the same path of all the nodes through NFS.
- mode Private
  - Used in scenarios where user data has been stored under the same path as the local directory of DNs.

### 21.13.4.10 CREATE FOREIGN TABLE (for GDS Import and Export)

#### Function

**CREATE FOREIGN TABLE** creates a GDS foreign table in the current database for concurrent data import and export. The GDS foreign table can be read-only or write-only, used for concurrent data import and export, respectively. The foreign table is read-only by default.

GDS is a command line tool running on the Linux OS. It works with the foreign table mechanism to quickly import and export data. The GDS tool package needs to be installed on the server where the data source file is located. This server is called the data server or the GDS server.

## Precautions

- Only the system administrator **dbadmin** or a common user who has been granted the USEFT permission can perform foreign table operations.  
`ALTER USER user_name USEFT;`
- The distribution mode of a GDS foreign table does not need to be explicitly specified. The default is **ROUNDROBIN**.
- All constraints (including column and row constraints) are invalid to the GDS foreign table.
- GDS supports the following file formats: TEXT, CSV, and FIXED.

## Syntax

```
CREATE FOREIGN TABLE [IF NOT EXISTS] table_name
([{ column_name type_name POSITION(offset,length) | LIKE source_table } [, ...]])
SERVER gsmpp_server
OPTIONS ({ option_name 'value' } [, ...])
[{ WRITE ONLY | READ ONLY }]
[WITH error_table_name | LOG INTO error_table_name]
[REMOTE LOG 'name']
[PER NODE REJECT LIMIT 'value']
[TO { GROUP groupname | NODE (nodename [, ...]) }];
```

## Parameter Description

**Table 21-183** CREATE FOREIGN TABLE (for GDS import and export) parameters

| Parameter     | Description                                                                        | Value Range                                                                                                              |
|---------------|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| IF NOT EXISTS | Sends a notice, but does not throw an error, if a table with the same name exists. | -                                                                                                                        |
| table_name    | Specifies the name of the foreign table.                                           | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| column_name   | Specifies the name of a column in the foreign table.                               |                                                                                                                          |
| type_name     | Specifies the data type of the column.                                             | -                                                                                                                        |

| Parameter                | Description                                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POSITION(offset, length) | Defining the location of each column in the data file in fixed length mode.<br><br><b>offset</b> is the start of the column in the source file, and <b>length</b> is the length of the column. | <b>offset</b> must be greater than 0 bytes, and its unit is byte.<br><br>The length of each record must be less than or equal to 1 GB. By default, columns not in the file are replaced with null.                                                                                             |
| SERVER gsmpp_server      | Specifies the server name of the foreign table. For the GDS foreign table, its server is created by initial database, which is <b>gsmpp_server</b> .                                           | -                                                                                                                                                                                                                                                                                              |
| OPTIONS                  | Specifies parameters of foreign table data.                                                                                                                                                    | <ul style="list-style-type: none"><li>• Data format parameters. For details, see <a href="#">Table 21-184</a>.</li><li>• Error-tolerance parameters. For details, see <a href="#">Table 21-185</a>.</li><li>• Performance parameters. For details, see <a href="#">Table 21-186</a>.</li></ul> |
| READ ONLY                | Specifies whether a foreign table is read-only. This parameter is available only for data import.                                                                                              | -                                                                                                                                                                                                                                                                                              |

**Table 21-184** OPTIONS parameters of the data format

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| location  | <p>Specifies the data source location of the foreign table, which can be expressed through URLs. Separate URLs with vertical bars ( ).</p> <p>Currently, GDS can automatically create a directory defined by a foreign table during data export. If foreign table <b>location</b> specified as <b>gsfs://192.168.0.91:5000/2019/09</b> for an export task, the <b>2019/09</b> subdirectory will be automatically created in the GDS data directory if it does not already exist. Manual creation of the directory specified in the foreign table is not necessary.</p> | <ul style="list-style-type: none"><li>For a read-only foreign table imported by GDS from a remote server in parallel, its URL must end with its corresponding schema or file name. (Read-only is the default file attribute.)<br/>For example: <b>gsfs://192.168.0.90:5000/*</b> or <b>file:///data/data.txt</b> or <b>gsfs://192.168.0.90:5000/*   gsfs://192.168.0.91:5000/*</b>.</li><li>For a writable foreign table used for GDS to export data to a remote server in parallel, file names are not required in URLs. If the data source location is a remote URL, for example, <b>gsfs://192.168.0.90:5000/</b>, multiple data sources can be specified. If the number of exported data file locations is less than or equal to the number of DN, when you use the foreign table for export, data is evenly distributed to each data source location. If the number of exported data file locations is greater than the number of DN, when you export data, the data is evenly distributed to data source locations corresponding to the DN. Blank data files are created on the excess data source locations.</li><li>For a foreign table used for GDS to import data from a remote server in parallel, the number of URLs must be less than the number of DN, and URLs containing the same location cannot be used.</li><li>If the URL begins with <b>gsfs://</b>, data is imported and exported in encryption mode, and DOP cannot exceed 10.</li><li>During GDS export, the <b>2019/09</b> subdirectory in the <b>gsfs://127.0.0.1:7789/2019/09/</b> directory specified by the <b>location</b> table is automatically created.</li><li>If <b>file_type</b> is set to <b>pipe</b>, GDS determines whether the target file to be imported or exported is a pipe file or a directory based on whether the last character in the URL is a slash (/). Example:<ul style="list-style-type: none"><li>In <b>gsfs://192.168.0.90:5000/a/b</b>, GDS identifies <b>b</b> as a pipe file.</li></ul></li></ul> |

| Parameter | Description                                                      | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|           |                                                                  | <ul style="list-style-type: none"><li>– In <code>gsfs://192.168.0.90:5000/a/b/</code>, GDS identifies <b>b</b> as a directory and creates a pipe file in the directory.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| format    | Specifies the format of the data source file in a foreign table. | <p>Value range: <b>CSV</b>, <b>TEXT</b>, or <b>FIXED</b>. The default value is <b>TEXT</b>.</p> <ul style="list-style-type: none"><li>• In CSV files, escape sequences are processed as common strings. Therefore, linefeeds are processed as data.</li><li>• In TEXT files, escape sequences are processed as they are. Therefore, linefeeds are not processed as data.</li><li>• The FIXED file can process newline characters in data columns efficiently, but cannot process special characters very well.</li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• An escape sequence is a string starting with a backslash (\), including <code>\b</code> (backspace), <code>\f</code> (formfeed page break), <code>\n</code> (new line), <code>\r</code> (carriage return), <code>\t</code> (horizontal tab), <code>\v</code> (vertical tab), <code>\number</code> (octal number), and <code>\xnumber</code> (hexadecimal number). In TEXT files, strings are processed as they are. In files of other formats, strings are processed as data.</li><li>• <b>FIXED</b> is defined as follows: (<b>POSITION</b> must be specified for each column when <b>FIXED</b> is used.)<ol style="list-style-type: none"><li>1. The column length of each record is the same.</li><li>2. Spaces are used for column padding. Left padding is used for the numeric type and right padding is used for the char type.</li><li>3. No delimiters are used between columns.</li></ol></li></ul> |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| header     | <p>Specifies whether a data file contains a table header.</p> <p>header is available only for CSV and FIXED files.</p> <p>When data is imported, if <b>header</b> is <b>on</b>, the first row of the data file will be identified as title row and ignored. If header is <b>off</b>, the first row is identified as data.</p> <p>When data is exported, if <b>header</b> is <b>on</b>, <b>fileheader</b> must be specified. <b>fileheader</b> is used to specify the export header file format. If header is <b>off</b>, the exported file does not include a title row.</p> | <b>true/on</b> or <b>false/off</b> . The default value is <b>false</b> or <b>off</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| fileheader | <p>Specifies a file that defines the content in the header for exported data. The file contains one row of data description of each column.</p> <p>For example, to add a header in a file containing product information, define the file as follows:</p> <p>The information of products.\n</p>                                                                                                                                                                                                                                                                              | <ul style="list-style-type: none"><li>• This parameter is available only when <b>header</b> is <b>on</b> or <b>true</b>. The file must be prepared in advance.</li><li>• In Remote mode, the definition file must be put to the working directory of GDS (the <b>-d</b> directory specified when starting the GDS).</li><li>• The definition file can contain only one row of title information, and end with a newline character. Excess rows will be discarded. (Title information cannot contain newline character).</li><li>• The length of the definition file including the newline character cannot exceed 1 MB.</li></ul> |

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| out_filename_prefix | <p>Specifies the name prefix of the exported data file exported using GDS from a write-only foreign table.</p> <p>If <b>file_type</b> is set to <b>pipe</b>, the pipe file <b>dbName_schemaName_foreignTableName.pipe</b> is generated.</p> <p>If both <b>out_filename_prefix</b> and <b>location</b> specify a pipe name, the pipe name specified in <b>location</b> is used.</p> | <ul style="list-style-type: none"><li>• The prefix of the specified file name must be valid and compliant with the restrictions of the file system in the physical environment where the GDS is deployed. Otherwise, the file will fail to be created.<ul style="list-style-type: none"><li>– The file name prefix can contain only lowercase letters, uppercase letters, digits, and underscores (_).</li><li>– The prefix of the specified export file name cannot contain feature fields reserved for the Windows and Linux OS, including but not limited to:<br/>"con","aux","nul","prn","com0","com1","com2","com3","com4","com5","com6","com7","com8","com9","lpt0","lpt1","lpt2","lpt3","lpt4","lpt5","lpt6","lpt7","lpt8","lpt9"</li><li>– The total length of the absolute path consisting of the exported file prefix, the path specified by <b>GDS -d</b>, <b>.dat</b>, or <b>.pipe</b> should be as required by the file system where GDS is deployed.</li><li>– It is required that the prefix can be correctly parsed and identified by the receiver (including but not limited to the original database where it was exported) of the data file. Identify and modify the option that causes the file name resolution problem (if any).</li></ul></li><li>• To concurrently perform export jobs, do not use the same file name prefix for them. Otherwise, the exported files may overwrite each other or be lost in the OS or file system.</li></ul> |

| Parameter | Description                                                                                                                                                                                           | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| delimiter | Specifies the column delimiter of data, and uses the default delimiter if it is not set. The default delimiter of TEXT is a tab and that of CSV is a comma (,). No delimiter is used in FIXED format. | <p>The value of <b>delimiter</b> can be a multi-character delimiter whose length is less than or equal to 10 bytes.</p> <ul style="list-style-type: none"><li>• A delimiter cannot be <b>\r</b> or <b>\n</b>.</li><li>• A delimiter cannot be the same as the <b>null</b> value. The delimiter of CSV cannot be same as the <b>quote</b> value.</li><li>• The delimiter for the TEXT format data cannot contain any of the following characters: \.abcdefghijklmnopqrstuvwxyz0123456789.</li><li>• The data length of a single row should be less than 1 GB. If the delimiters are too long and there are too many rows, the length of valid data will be affected.</li><li>• You are advised to use a multi-character, such as the combination of the dollar sign (\$), caret (^), the ampersand (&amp;), or invisible characters, such as 0x07, 0x08, and 0x1b as the delimiter.</li><li>• For a multi-character delimiter, do not use the same characters, for example, ---.</li></ul> |
| quote     | Specifies which characters in a CSV source data file will be identified as quotation marks. The default value is a double quotation mark (").                                                         | <ul style="list-style-type: none"><li>• The quote parameter cannot be the same as the delimiter or null parameter.</li><li>• The <b>quote</b> parameter must be a single-byte character.</li><li>• Invisible characters are recommended as <b>quote</b> values, such as 0x07, 0x08, and 0x1b.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| escape    | Specifies which characters in a CSV source data file are escape characters. Escape characters can only be single-byte characters.<br><br>Default value: the same as the value of QUOTE                | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| null                     | Specifies the string that represents a null value.                                                                                                                                                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"><li>• The default value is <b>\N</b> for the TEXT format.</li><li>• The default value for the CSV format is an empty string without quotation marks.</li><li>• The null value cannot be <b>\r</b> or <b>\n</b>. The maximum length is 100 characters.</li><li>• The null value cannot be the same as the delimiter or quote parameter.</li></ul> |
| blank_number_str_to_null | Converts a variable number of spaces of the numeric type ( <b>INT1OID</b> , <b>INT2OID</b> , <b>INT4OID</b> , <b>INT8OID</b> , <b>FLOAT4OID</b> , or <b>FLOAT8OID</b> ) in a data file to <b>NULL</b> . This parameter is supported only by clusters of version 8.1.3, 8.2.1.236, 9.1.0, or later.<br><br>For example, if this option is set to <b>true</b> , <b>NULL</b> is returned when <b>null</b> , <b>null ' ' (one space)</b> , or <b>null ' ' (two spaces)</b> is defined. | The value can be <b>true</b> or <b>false</b> . The default value is <b>false</b> , which means no conversion is done.                                                                                                                                                                                                                                                              |
| noescaping               | Specifies in TEXT format, whether to escape the backslash (\) and its following characters.                                                                                                                                                                                                                                                                                                                                                                                        | <b>noescaping</b> is available only for the TEXT format. <b>true/on</b> or <b>false/off</b> . The default value is <b>false</b> or <b>off</b> .                                                                                                                                                                                                                                    |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| encoding  | <p>Specifies the encoding of a data file, that is, the encoding used to parse, check, and generate a data file. Its default value is the default <b>client_encoding</b> value of the current database.</p> <p>Before you import foreign tables, it is recommended that you set <b>client_encoding</b> to the file encoding format, or a format matching the character set of the file. Otherwise, unnecessary parsing and check errors may occur, leading to import errors, rollback, or even invalid data import. Before you import foreign tables, you are also advised to specify this parameter, because the export result using the default character set may not be what you expected.</p> <p>If this parameter is not specified when you create a foreign table, a warning message will be displayed on the client.</p> | <ul style="list-style-type: none"><li>Currently, GDS cannot parse or write in a file using multiple encoding formats during foreign table import or export.</li><li>Common encoding formats include UTF-8, GBK, and GB18030. GB18030 has two versions: GB18030 and GB18030_2022. GB18030_2022 is the latest national standard in China prepared to support Chinese characters.</li></ul> |

| Parameter    | Description                                                                                                                                                                                     | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dataencoding | Specifies the actual encoding of data in tables in the latin1 database. Converts data format during GDS data import and export. This parameter is supported by version 8.2.0 or later clusters. | <b>GBK, GB18030, GB18030_2022, and UTF8.</b><br>Typical scenarios:<br><ol style="list-style-type: none"><li>To import the GB-encoded text data to the <b>latin1</b> database and convert the data to UTF-8. Set <b>dataencoding</b> to <b>UTF8</b> and <b>encoding</b> to <b>GB</b>.</li><li>To export GB-encoded data from the <b>latin1</b> database as a UTF8 data file, set <b>dataencoding</b> to <b>GB</b> and <b>encoding</b> to <b>UTF8</b>.</li></ol> <b>CAUTION</b> <ul style="list-style-type: none"><li>This parameter can be used only in <b>latin1</b> databases.</li><li>When this parameter is used, <b>encoding</b> must be <b>GBK, GB18030, GB18030_2022, or UTF8</b>.</li></ul>                                                                                                                                                                                                                                                                                                                                            |
| mode         | Specifies the data import policy during a specific data import process. DWS supports only the <b>Normal</b> mode.                                                                               | Valid value: <ul style="list-style-type: none"><li><b>Normal</b> (default): supports all file types (CSV, TEXT, FIXED). Enabling Gauss data service to help data import.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| eol          | Specifies the newline character style of the imported or exported data file.                                                                                                                    | Value range: multi-character newline characters within 10 bytes. Common newline characters include <b>\r</b> (0x0D), <b>\n</b> (0x0A), and <b>\r\n</b> (0x0D0A). Special newline characters include <b>\$</b> and <b>#</b> . <ul style="list-style-type: none"><li>The <b>eol</b> parameter supports only the TEXT format for data import and export and does not support the CSV or FIXED format for data import. For forward compatibility, the <b>eol</b> parameter can be set to <b>0x0D</b> or <b>0x0D0A</b> for data export in the CSV and FIXED formats.</li><li>If you want to export data in FIXED format as a single row, use the <b>eol</b> parameter and set it to an empty string ". However, it is important to note that this method of exporting data cannot be directly imported into the DWS database.</li><li>The value of the <b>eol</b> parameter cannot be the same as that of <b>DELIMITER</b> or <b>NULL</b>.</li><li>The value of the <b>eol</b> parameter cannot contain digits, letters, or periods (.).</li></ul> |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conflict_delimiter | <p>This parameter is generally used with the <b>compatible_illegal_chars</b> parameter. If a data file contains a truncated Chinese character, the truncated character and a delimiter will be encoded into another Chinese character due to inconsistent encoding between the foreign table and the database. As a result, the delimiter is masked and an error will be reported, indicating that there are missing fields.</p> <p>This parameter is used to avoid encoding a truncated character and a delimiter into another character.</p> | <p>Value range: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>false</b> or <b>off</b>.</p> <ul style="list-style-type: none"><li>• If the parameter is set to <b>true</b> or <b>on</b>, encoding a truncated character and a delimiter into another character is allowed.</li><li>• If the parameter is set to <b>false</b> or <b>off</b>, encoding a truncated character and a delimiter into another character is not allowed.</li></ul> <p>This parameter is disabled by default. It is recommended that you disable this parameter, because encoding a truncated character and a delimiter into another character is rarely required. If the parameter is enabled, the scenario may be incorrectly identified and thereby causing incorrect information imported to the table.</p>                                      |
| file_type          | <p>Specifies the type of the file to be imported or exported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | <p>Value options: <b>normal</b>, <b>pipe</b>, and <b>interconn</b>. <b>normal</b> is the default value.</p> <ul style="list-style-type: none"><li>• If this parameter is set to <b>normal</b>, the file to be imported or exported is a common file.</li><li>• If this parameter is set to <b>pipe</b>, the file to be imported or exported is a named pipe.</li><li>• If the parameter is <b>interconn</b>, the current GDS foreign table is used for interconnected and compressed import and export. This parameter must be used together with the <b>gds_compress</b> parameter and is supported only by cluster 8.2.0 or later.</li></ul> <p><b>CAUTION</b></p> <p>If the value of <b>file_type</b> is set to <b>interconn</b>, GDS must be upgraded to 8.2.0 or later. Otherwise, the error message "ERROR: un-support format" will be displayed.</p> |

| Parameter        | Description                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auto_create_pipe | <p>Specifies whether the GDS process automatically creates a named pipe.</p> <p>When configuring <b>auto_create_pipe</b>, you need to set <b>file_type</b> to <b>pipe</b> or <b>interconn</b>. Otherwise, the foreign table cannot be created.</p> | <p>Value options: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>true/on</b>.</p> <ul style="list-style-type: none"><li>• If this parameter is set to <b>true</b> or <b>on</b>, the GDS process is allowed to automatically create a named pipe.</li><li>• If this parameter is set to <b>false</b> or <b>off</b>, you need to manually create a named pipe.</li><li>• If <b>auto_create_pipe</b> is set to <b>false</b> and no pipe is specified during data import and export, the <i>database name_schema name_foreign table name.pipe</i> file will be opened. If a pipe has been specified, the specified pipe in the location will be opened. If the named pipe is not written by other programs or is not opened in write mode within the period specified by the <b>pipe-timeout</b> parameter, an error message is displayed indicating that the import or export task times out. If the file is not a pipe, an error is reported when the import or export task is executed.</li><li>• If <b>auto_create_pipe</b> is set to <b>true</b> and no pipe file is specified during data import and export, the <i>database name_schema name_foreign table name.pipe</i> file will be opened. If the file is a common file, an error is reported when the file is imported or exported. If the file is a pipe, the system automatically deletes the file and re-creates the named pipe.</li><li>• You can use the <b>location</b> parameter to specify the pipe during data export, for example, <b>location'gsfs://127.0.0.1:7789/aa.pipe</b>. When <b>auto_create_pipe</b> is set to <b>true</b>, GDS automatically creates the <b>aa.pipe</b> file in the data directory.</li></ul> |

| Parameter | Description                                                                                                                                                                                                                                                               | Value Range                                                                                                                                                                                                                                                                                                                                                                                                          |

| del_pipe  | <p>Specifies whether to automatically delete the pipe file after the import or export task is complete.</p> <p>When configuring <b>del_pipe</b>, you need to set <b>file_type</b> to <b>pipe</b> or <b>interconn</b>. Otherwise, the foreign table cannot be created.</p> | <p>Value options: <b>true</b> or <b>on</b>; <b>false</b> or <b>off</b>. The default value is <b>true</b> or <b>on</b>.</p> <ul style="list-style-type: none"><li>• If this parameter is set to <b>true</b> or <b>on</b>, the GDS process will automatically delete a named pipe file.</li><li>• If this parameter is set to <b>false</b> or <b>off</b>, the GDS process will not delete a named pipe file.</li></ul> |

| Parameter                    | Description                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gds_compress</code>    | This parameter is used to reduce the network bandwidth for cluster interconnection when users use GDS pipe files. Currently, and only the Snappy algorithm is supported. This parameter is supported by version 8.2.0 or later clusters.                | <p>Value range: <b>snappy</b>. Currently, only the Snappy algorithm is supported, which means that data imported and exported through GDS pipes is compressed and decompressed using the Snappy algorithm.</p> <ul style="list-style-type: none"><li>When setting this parameter, <b>file_type</b> must be set to <b>interconn</b> and format to <b>CSV</b>. If this parameter is not set, by default, files are not compressed. Currently, this parameter can only be set to <b>snappy</b>. When using this function, ensure that the versions of the local cluster, remote cluster, and GDS are of the same version.</li><li>If the value of <b>file_type</b> is <b>interconn</b>, GDS must be upgraded to 8.2.0 or later. Otherwise, the error message "ERROR: unsupported format" is displayed.</li><li>This parameter reduces the network bandwidth between clusters and increases the cluster CPU load. You can determine whether to enable this parameter based on the site requirements.</li><li>When a GDS foreign table is used for interconnected data migration, to allow data to be compressed during migration, the GDS foreign table must support this parameter. You use interconnected foreign tables to compress and migrate data, or manually use a GDS foreign table to compress and migrate data at the network layer. Many parameters need to be set during manual procedure, you are advised to use interconnected foreign tables.</li><li>This parameter must be specified for foreign tables used for both export and import.</li></ul> |
| <code>preserve_blanks</code> | Specifies whether to retain the blank characters (including spaces, <code>\t</code> , <code>\v</code> , and <code>\f</code> ) at the end of each column during fixed-length import. This parameter is supported by version 8.2.0.100 or later clusters. | <p>Value range: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>false</b> or <b>off</b>.</p> <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b>, the trailing <code>\t</code> is retained and pruning is not performed for column data of the BYTEAOID, CHAROID, NAMEOID, TEXTOID, BPCHAROID, VARCHAROID, NVARCHAR2OID or CSTRINGOID type.</li><li>If this parameter is set to <b>false</b> or <b>off</b>, blank characters (including spaces, <code>\t</code>, <code>\v</code>, and <code>\f</code>) at the end of all data types are pruned.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fix                       | Specifies the length of fixed format data. The unit is byte. This syntax is available only for READ ONLY foreign tables.                                                                                                                                                                                                                                                                       | Value range: Less than <b>1 GB</b> , and greater than or equal to the total length specified by <b>POSITION</b> (The total length is the sum of <b>offset</b> and <b>length</b> in the last column of the table definition.)                                                                                                                                                                                                                                                                                                                                                                                                      |
| out_fix_alignme<br>nt     | Specifies how the columns of types BYTEAOID, CHAROID, NAMEOID, TEXTOID, BPCHAROID, VARCHAROID, NVARCHAR2OID, and CSTRINGOID are aligned during fixed-length export.                                                                                                                                                                                                                            | Value range: <b>align_left</b> , <b>align_right</b><br>Default value: <b>align_right</b><br><b>CAUTION</b><br>The bytea data type must be in hexadecimal format (for example, \XXXX) or octal format (for example, \XXX\XXX\XXX). The data to be imported must be left-aligned (that is, the column data starts with either of the two formats instead of spaces). Therefore, if the exported file needs to be imported using a GDS foreign table and the file data length is less than that specified by the foreign table formatter, the exported file must be left aligned. Otherwise, an error is reported during the import. |
| out_fix_num_ali<br>gnment | Specifies how the columns of numeric types TINYINT, SMALLINT, INTEGER, BINARY_INTEGER, BIGINT, NUMERIC[(p[,s])], DECIMAL[(p[,s])], NUMBER[(p[,s])], REAL, FLOAT4, DOUBLE PRECISION, FLOAT8, FLOAT[(p)], BINARY_DOUBLE, DEC[(p[,s])], INTEGER[(p[,s])], SMALLSERIAL, SERIAL and BIGSERIAL are aligned during fixed-length export. This is supported only by clusters of version 9.1.0 or later. | Value range: <b>align_left</b> , <b>align_right</b><br>Default value: <b>align_left</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter            | Description                                                                                         | Value Range                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| date_format          | Imports data of the DATE type. This syntax is available only for READ ONLY foreign tables.          | Value range: any valid DATE value. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .<br><b>CAUTION</b><br>If ORACLE is specified as the compatible database, the DATE format is TIMESTAMP. For details, see <a href="#">timestamp_format</a> below. |
| time_format          | Imports data of the TIME type. This syntax is available only for READ ONLY foreign tables.          | Value range: any valid TIME value. Time zones cannot be used. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .                                                                                                                                     |
| timestamp_format     | Imports data of the TIMESTAMP type. This syntax is available only for READ ONLY foreign tables.     | Value range: any valid TIMESTAMP value. Time zones are not supported. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .                                                                                                                             |
| smalldatetime_format | Imports data of the SMALLDATETIME type. This syntax is available only for READ ONLY foreign tables. | Value range: any valid SMALLDATETIME value. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .                                                                                                                                                       |

**Table 21-185** OPTIONS fault tolerance parameters

| Parameter           | Description                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fill_missing_fields | Specifies whether to generate an error message when the last column in a row in the source file is lost during data import. | Value range: <b>true</b> , <b>on</b> , <b>false</b> , and <b>off</b> . The default value is <b>false</b> or <b>off</b> . <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b> and the last column of a data row in a data source file is lost, the column will be replaced with <b>NULL</b> and no error message will be generated.</li><li>If this parameter is set to <b>false</b> or <b>off</b> and the last column is missing, the following error information will be displayed:<br/>missing data for column "tt"</li></ul> |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ignore_extra_data | Specifies whether to ignore excessive columns when the number of data source files exceeds the number of foreign table columns. This parameter is available during data import.                                                                                                                                                                                                                                                                                                                                                                         | <p>Value range: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>false</b> or <b>off</b>.</p> <ul style="list-style-type: none"><li>If this parameter is set to <b>true</b> or <b>on</b> and the number of data source files exceeds the number of foreign table columns, excessive columns will be ignored.</li><li>If this parameter is set to <b>false</b> or <b>off</b> and the number of data source files exceeds the number of foreign table columns, the following error information will be displayed:<br/>extra data after last expected column</li></ul> <p><b>CAUTION</b><br/>If the newline character at the end of the row is lost, setting the parameter to <b>true</b> will ignore data in the next row.</p> |
| reject_limit      | <p>Specifies the maximum number of data format errors allowed during a data import task. If the number of errors does not reach the maximum number, the data import task can still be executed.</p> <p><b>NOTE</b><br/>You are advised to replace this syntax with <b>PER NODE REJECT LIMIT 'value'</b>.</p> <p>Examples of data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. Once a non-data format error occurs, the whole data import process is stopped.</p> | <p>Value range: a positive integer or <b>unlimited</b>. Enclose positive integer values with single quotation marks ('').</p> <p>If this parameter is not specified, an error message is returned immediately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter                             | Description                                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compatible_illegal_chars</code> | <p>Specifies whether to tolerate invalid characters during data import and export. This syntax is valid for READ ONLY and WRITE ONLY foreign tables.</p> <p>Only clusters of version 8.1.3.331 or later support export fault tolerance.</p> | <p>Value range: <b>true</b>, <b>on</b>, <b>false</b>, and <b>off</b>. The default value is <b>false</b> or <b>off</b>.</p> <ul style="list-style-type: none"><li>• If the parameter is <b>true</b> or <b>on</b>, the database will accept invalid characters after converting them during import or export.</li><li>• If this parameter is set to <b>false</b> or <b>off</b>, the import process will be stopped if there are invalid characters and an error occurs.</li><li>• The rule of error tolerance when you import invalid characters is as follows:<ul style="list-style-type: none"><li>– <code>\0</code> is converted to a space.</li><li>– Other illegal characters are converted to question marks.</li><li>– If <code>compatible_illegal_chars</code> is set to <b>true</b> or <b>on</b>, the database will convert and accept the invalid characters. If <b>NULL</b>, <b>DELIMITER</b>, <b>QUOTE</b>, and <b>ESCAPE</b> are set to a spaces or question marks. Errors like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to prompt user to modify parameter values that cause confusion, preventing import errors.</li><li>– Enabling error tolerance for foreign table export will result in invalid characters being exported as question marks (?), which can lead to inconsistencies between the exported and original data when imported back into the DWS database.</li></ul></li></ul> |
| <code>replace_illegal_chars</code>    | <p>Error tolerance parameter for importing invalid characters. This parameter is used to replace <code>\0</code> with a specified string. This syntax is available only for READ ONLY foreign tables.</p>                                   | <p>The restrictions on the string used to replace <code>\0</code> are as follows:</p> <ul style="list-style-type: none"><li>• <code>compatible_illegal_chars</code> must be set to <b>true</b> or <b>on</b>.</li><li>• <code>format</code> must be set to <b>TEXT</b> or <b>CSV</b>.</li><li>• A maximum of 10 characters is allowed.</li><li>• The string cannot be the same as the delimiter, or contain the delimiter, or contain the following characters: digits, letters, backslashes (<code>\</code>), and periods (<code>.</code>).</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                      | Value Range                                             |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| WITH<br>error_table_name        | Data format errors during import are recorded in the table specified by <b>error_table_name</b> . You can query this table after the import to obtain error details. This parameter is available only after <b>reject_limit</b> is set.<br><b>NOTE</b><br>To be compatible with PostgreSQL open source interfaces, you are advised to replace this syntax with <b>LOG INTO</b> . | A string, which must comply with the naming convention. |
| LOG<br>INTO<br>error_table_name | Data format errors during import are recorded in the table specified by <b>error_table_name</b> . You can query this table after the import to obtain error details.<br><b>NOTE</b><br>This parameter is available only after <b>PER NODE REJECT LIMIT</b> is set.                                                                                                               | A string, which must comply with the naming convention. |
| REMOTE LOG<br>'name'            | The data format error information is saved as files in GDS. <b>name</b> is the prefix of the error data file.                                                                                                                                                                                                                                                                    | -                                                       |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| PER<br>NODE<br>REJECT<br>LIMIT<br>'value' | <p>This parameter specifies the allowed number of data format errors on each DN during data import. If the number of errors exceeds the specified value on any DN, data import fails, an error is reported, and the system exits data import.</p> <p><b>CAUTION</b><br/>This syntax specifies the error tolerance of a single node.<br/>Examples of data format errors include the following: a column is lost, an extra column exists, a data type is incorrect, and encoding is incorrect. When a non-data format error occurs, the whole data scanning process is stopped.</p> | An <b>unlimited</b> integer. If this parameter is not specified, an error message is returned immediately. |

**Table 21-186** OPTIONS performance parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| file_sequence | <p>Concurrently imports data in parallel through GDS foreign tables, to improve single-file import performance. This parameter is only used for data import.</p> <p>The parameter format is <b>file_sequence</b>'<i>total number of shards-current shard</i>'.<br/>Example:</p> <p><b>file_sequence '3-1'</b> indicates that the imported file is logically split into three shards and the data currently imported by the foreign table is the data on the first shard.</p> <p><b>file_sequence '3-2'</b> indicates that the imported file is logically split into three shards and the data currently imported by the foreign table is the data on the second shard.</p> <p><b>file_sequence '3-3'</b> indicates that the imported file is logically split into three shards and the data currently imported by the foreign table is the data on the third shard.</p> | <p>This parameter has the following constraints:</p> <ul style="list-style-type: none"><li>• A file can be split to a maximum of 8 shards.</li><li>• The number of currently imported shard should be less than or equal to the total number of split shards.</li><li>• Only CSV and TXT files can be imported.</li></ul> <p>When data is imported in parallel in CSV format, some shards fail to be imported in some scenarios because the CSV rules conflict with the GDS splitting logic. For details, see <a href="#">Exception Description When the file_sequence Parameter Is Used</a>.</p> |

## Examples

Create a foreign table **customer\_ft** to import data from GDS server 10.10.123.234 in TEXT format:

```
CREATE FOREIGN TABLE customer_ft
(
 c_customer_sk integer ,
 c_customer_id char(16) ,
 c_current_demo_sk integer ,
 c_current_demo_sk integer ,
 c_current_addr_sk integer ,
 c_first_ship_to_date_sk integer ,
 c_first_sales_date_sk integer ,
 c_salutation char(10) ,
 c_first_name char(20) ,
 c_last_name char(30) ,
 c_preferred_cust_flag char(1) ,
 c_birth_day integer ,
 c_birth_month integer ,
 c_birth_year integer ,
 c_birth_country varchar(20) ,
 c_login char(13) ,
 c_email_address char(50) ,
 c_last_review_date char(10)
)
 SERVER gsmpp_server
 OPTIONS
(
 location 'gsfs://10.10.123.234:5000/customer1*.dat',
 FORMAT 'TEXT' ,
 DELIMITER '|',
 encoding 'utf8',
 mode 'Normal')
READ ONLY;
```

Create a foreign table to import data from GDS servers 192.168.0.90 and 192.168.0.91 in TEXT format. Record errors that occur during data import in **foreign\_HR\_staffs\_ft**. A maximum of two data format errors are allowed during the data import.

```
CREATE FOREIGN TABLE foreign_HR_staffs_ft
(
 staff_ID NUMBER(6) ,
 FIRST_NAME VARCHAR2(20),
 LAST_NAME VARCHAR2(25),
 EMAIL VARCHAR2(25),
 PHONE_NUMBER VARCHAR2(20),
 HIRE_DATE DATE,
 employment_ID VARCHAR2(10),
 SALARY NUMBER(8,2),
 COMMISSION_PCT NUMBER(2,2),
 MANAGER_ID NUMBER(6),
 section_ID NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'gsfs://192.168.0.90:5000/* | gsfs://192.168.0.91:5000/*', format
'TEXT', delimiter 'E'\x08', null '', reject_limit '2') WITH err_HR_staffs_ft;
```

Create a foreign table to import all files in the **input\_data** directory in CSV format.

```
CREATE FOREIGN TABLE foreign_HR_staffs_ft1
(
 staff_ID NUMBER(6) ,
 FIRST_NAME VARCHAR2(20),
 LAST_NAME VARCHAR2(25),
 EMAIL VARCHAR2(25),
 PHONE_NUMBER VARCHAR2(20),
 HIRE_DATE DATE,
 employment_ID VARCHAR2(10),
```

```
SALARY NUMBER(8,2),
COMMISSION_PCT NUMBER(2,2),
MANAGER_ID NUMBER(6),
section_ID NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'file:///input_data/', format 'csv', quote E'\x08', mode 'private',
delimiter ',') WITH err_HR_staffs_ft1;
```

Create a foreign table to export data to the **output\_data** directory in CSV format.

```
CREATE FOREIGN TABLE foreign_HR_staffs_ft2
(
 staff_ID NUMBER(6) ,
 FIRST_NAME VARCHAR2(20),
 LAST_NAME VARCHAR2(25),
 EMAIL VARCHAR2(25),
 PHONE_NUMBER VARCHAR2(20),
 HIRE_DATE DATE,
 employment_ID VARCHAR2(10),
 SALARY NUMBER(8,2),
 COMMISSION_PCT NUMBER(2,2),
 MANAGER_ID NUMBER(6),
 section_ID NUMBER(4)
) SERVER gsmpp_server OPTIONS (location 'file:///output_data/', format 'csv', quote E'\x08', delimiter '|',
header 'on') WRITE ONLY;
```

## Exception Description When the file\_sequence Parameter Is Used

When data is imported in parallel in CSV format, some shards fail to be imported in the following scenario because the CSV rules conflict with the GDS splitting logic:

**Scenario:** A CSV file contains a newline character that is not escaped, the newline character is contained in the character specified by **quote**, and the data of this line is in the first row of the logical shard.

**Example:** If you import the **big.csv** file in parallel, the following information is displayed:

```
--id, username, address
10001,"customer1 name","Rose District"
10002,"customer2 name","
23 Road Rose
District NewCity"
10003,"customer3 name","NewCity"
```

After the file is split into two shards, the content of the first shard is as follows:

```
10001,"customer1 name","Rose District"
10002,"customer2 name","
23
```

The content of the second shard is as follows:

```
Road Rose
District NewCity"
10003,"customer3 name","NewCity"
```

The newline character after the first line of the second shard is contained between double quotation marks. As a result, GDS cannot determine whether the newline character is a newline character in the field or a separator in the line. Therefore, two data records on the first shard are successfully imported, but the second shard fails to be imported.

[ALTER FOREIGN TABLE \(GDS Import and Export\)](#), [DROP FOREIGN TABLE](#)

### 21.13.4.11 ALTER FOREIGN TABLE (for HDFS or OBS)

#### Function

Modifies an HDFS or OBS foreign table.

A foreign table is a virtual table within a database or big data platform that does not physically store data. Instead, it serves as a mapping to data residing in external storage systems, such as HDFS or OBS. This mapping is established using metadata, which includes the table structure, the location of the data, and its file format. It enables users to directly access or operate external data using standard SQL statements. A foreign table serves as a data proxy that logically maps data in external file systems to table structures that can be identified by databases.

Foreign tables are designed to break data silos. Foreign tables allow database users to access external system data in a familiar way through metadata mapping and export data to external systems. In this way, data can be efficiently collaborated, analyzed, and shared across systems, especially in big data scenarios, significantly reducing data movement costs and improving collaboration efficiency.

#### Precautions

None

#### Syntax

- Set the attributes of a foreign table.  

```
ALTER FOREIGN TABLE [IF EXISTS] table_name
 OPTIONS ({[ADD | SET | DROP] option ['value']} [, ...]);
```
- Set the owner of the foreign table.  

```
ALTER FOREIGN TABLE [IF EXISTS] tablename
 OWNER TO new_owner;
```
- Update a foreign table column.  

```
ALTER FOREIGN TABLE [IF EXISTS] table_name
 MODIFY ({ column_name data_type | column_name [CONSTRAINT constraint_name] NOT NULL
 [ENABLE] | column_name [CONSTRAINT constraint_name] NULL } [, ...]);
```
- Modify the columns of a foreign table.  

```
ALTER FOREIGN TABLE [IF EXISTS] tablename
 action [, ...];
```

The **action** syntax is as follows:

```
ALTER [COLUMN] column_name [SET DATA] TYPE data_type
| ALTER [COLUMN] column_name { SET | DROP } NOT NULL
| ALTER [COLUMN] column_name SET STATISTICS [PERCENT] integer
| ALTER [COLUMN] column_name OPTIONS ({[ADD | SET | DROP] option ['value']} [, ...])
| MODIFY column_name data_type
| MODIFY column_name [CONSTRAINT constraint_name] NOT NULL [ENABLE]
| MODIFY column_name [CONSTRAINT constraint_name] NULL
```

For details, see [ALTER TABLE](#).

- Add an informational constraint for a foreign table.  

```
ALTER FOREIGN TABLE [IF EXISTS] tablename
 ADD [CONSTRAINT constraint_name]
```

```
{ PRIMARY KEY | UNIQUE } (column_name)
[NOT ENFORCED [ENABLE QUERY OPTIMIZATION | DISABLE QUERY OPTIMIZATION] |
ENFORCED];
```

For details about the parameters for adding an informational constraint, see [Parameter Description](#).

- Remove a foreign table informational constraint.

```
ALTER FOREIGN TABLE [IF EXISTS] tablename
DROP CONSTRAINT constraint_name ;
```

- Set the row-level access control switch for foreign tables (supported by cluster versions 9.1.0 and later).

```
ALTER FOREIGN TABLE [IF EXISTS] tablename
ENABLE | DISABLE | FORCE | NO FORCE ROW LEVEL SECURITY
```

## Parameter Description

**Table 21-187** ALTER FOREIGN TABLE (For HDFS or OBS) parameters

| Parameter       | Description                                                                        | Value Range                               |
|-----------------|------------------------------------------------------------------------------------|-------------------------------------------|
| IF EXISTS       | Sends a message instead of an error if the specified foreign table does not exist. | -                                         |
| tablename       | Specifies the name of an existing foreign table to be modified.                    | Name of an existing foreign table.        |
| new_owner       | Specifies the new owner of the foreign table.                                      | A string that indicates a valid username. |
| data_type       | Specifies the new data type of an existing column.                                 | A string.                                 |
| constraint_name | Specifies the name of a constraint to be added or deleted.                         | A string.                                 |
| column_name     | Specifies an existing column name.                                                 | A string.                                 |

For how to modify other parameters in a foreign table, see [Parameter Description](#) in **ALTER TABLE**.

## Examples

- Create **HDFS\_Server** and set the corresponding foreign data wrapper to **HDFS\_FDW** or **DFS\_FDW**.

```
CREATE SERVER hdfs_server FOREIGN DATA WRAPPER HDFS_FDW OPTIONS (address
'10.10.0.100:25000,10.10.0.101:25000',hdfscfgpath '/opt/hadoop_client/HDFS/hadoop/etc/
hadoop',type'HDFS');
```

- Create an HDFS foreign table that does not contain partition columns.

```
DROP FOREIGN TABLE IF EXISTS ft_region;
CREATE FOREIGN TABLE ft_region
```

```
(
 R_REGIONKEY INT4,
 R_NAME TEXT,
 R_COMMENT TEXT
)
SERVER
 hdfs_server
OPTIONS
(
 FORMAT 'orc',
 encoding 'utf8',
 FOLDERNAME '/user/hive/warehouse/gauss.db/region_orc11_64stripe/'
)
DISTRIBUTE BY
 roundrobin;
```

3. Change the type of the **r\_name** column in the foreign table **ft\_region** to **text**.  
ALTER FOREIGN TABLE ft\_region ALTER r\_name TYPE TEXT;
4. Mark the **r\_name** column of the foreign table **ft\_region** as **not null**.  
ALTER FOREIGN TABLE ft\_region ALTER r\_name SET NOT NULL;

| Parameter | Description                                                                | Value Range |
|-----------|----------------------------------------------------------------------------|-------------|
| IF EXISTS | Sends a message instead of an error if the specified index does not exist. | -           |

| Parameter  | Description                                                     | Value Range                                                                           |
|------------|-----------------------------------------------------------------|---------------------------------------------------------------------------------------|
| table_name | Specifies the name of an existing foreign table to be modified. | Name of an existing foreign table.                                                    |
| option     | Specifies the name of the option to be modified.                | See <a href="#">Parameter Description</a> in <b>CREATE FOREIGN TABLE</b> for details. |
| value      | Specifies the new value of <b>option</b> .                      | -                                                                                     |
| new_owner  | Specifies the new owner of the foreign table.                   | A string that indicates a valid username.                                             |

## Examples

Create a foreign table **customer\_ft** to import data from GDS server 10.10.123.234 in TEXT format.

```
DROP FOREIGN TABLE IF EXISTS customer_ft;
CREATE FOREIGN TABLE customer_ft
(
 c_customer_sk integer ,
 c_customer_id char(16) ,
 c_current_demo_sk integer ,
 c_current_demo_sk integer ,
 c_current_addr_sk integer ,
 c_first_ship_date_sk integer ,
 c_first_sales_date_sk integer ,
 c_salutation char(10) ,
 c_first_name char(20) ,
 c_last_name char(30) ,
 c_preferred_cust_flag char(1) ,
 c_birth_day integer ,
 c_birth_month integer ,
 c_birth_year integer ,
 c_birth_country varchar(20) ,
 c_login char(13) ,
 c_email_address char(50) ,
 c_last_review_date char(10)
)
SERVER gsmpp_server
OPTIONS
(
 location 'gsfs://10.10.123.234:5000/customer1*.dat',
 FORMAT 'TEXT' ,
 DELIMITER '|',
 encoding 'utf8',
 mode 'Normal')READ ONLY;
```

Modify the **customer\_ft** attribute of the foreign table. Delete the **mode** option.

```
ALTER FOREIGN TABLE customer_ft options(drop mode);
```

[CREATE FOREIGN TABLE \(for GDS Import and Export\)](#) and [DROP FOREIGN TABLE](#)

### 21.13.4.13 DROP FOREIGN TABLE

#### Function

**DROP FOREIGN TABLE** deletes a specified foreign table.

#### Precautions

**DROP FOREIGN TABLE** forcibly deletes a specified table. After a table is deleted, any indexes that exist for the table will be deleted. The functions and stored procedures used in this table cannot be run.

#### Syntax

```
DROP FOREIGN TABLE [IF EXISTS]
table_name [, ...] [CASCADE | RESTRICT];
```

#### Parameter Description

**Table 21-189** DROP FOREIGN TABLE parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                                                                    |
|--------------------|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a message instead of an error if the specified foreign table does not exist.                  | -                                                                                                                                                                                                                                                                                              |
| table_name         | Specifies the name of the foreign table to be deleted.                                              | An existing table name.                                                                                                                                                                                                                                                                        |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically deletes all objects (such as views) that depend on the foreign table to be deleted.</li><li>• <b>RESTRICT</b>: refuses to delete the foreign table if any objects depend on it. This is the default behaviour.</li></ul> |

#### Examples

Delete the foreign table named **customer\_ft**:

```
DROP FOREIGN TABLE customer_ft;
```

## 21.13.4.14 CREATE SERVER

### Function

**CREATE SERVER** creates an external server.

An external server stores the HDFS cluster information, OBS server information, DLI connection information, or other homogeneous cluster information.

### Precautions

By default, only the system administrator can create a foreign server. Otherwise, creating a server requires USAGE permission on the foreign-data wrapper being used. The syntax is as follows:

```
GRANT USAGE ON FOREIGN DATA WRAPPER fdw_name TO username;
```

**fdw\_name** is the name of **FOREIGN DATA WRAPPER**, and **username** is the user name of creating **SERVER**.

### Syntax

```
CREATE SERVER server_name
 FOREIGN DATA WRAPPER fdw_name
 OPTIONS ({ option_name 'value' } [, ...]) ;
```

### Parameter Description

**Table 21-190** CREATE SERVER parameters

| Parameter                        | Description                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server_name                      | Name of the foreign server to be created. The server name must be unique in a database. | A string, which must contain up to 63 characters and comply with the <a href="#">identifier naming conventions</a> .                                                                                                                                                                                                                                                                                                   |
| FOREIGN DATA WRAPPER<br>fdw_name | Specifies the name of the foreign data wrapper.                                         | <b>fdw_name</b> is the data wrapper created by the system during database initialization. <ul style="list-style-type: none"><li>For an HDFS cluster, <b>fdw_name</b> can be <b>hdfs_fdw</b> or <b>dfs_fdw</b>.</li><li>For other homogeneous clusters, <b>fdw_name</b> is <b>gc_fdw</b>. For data import and export, the GDS foreign table uses <b>gsmpp_server</b>, and <b>fdw_name</b> is <b>dist_fdw</b>.</li></ul> |
| OPTIONS                          | Specifies the parameters of foreign servers.                                            | For details about the supported parameters, see <a href="#">Table 21-191</a> .                                                                                                                                                                                                                                                                                                                                         |

**Table 21-191** OPTIONS parameters

| Parameter | Description                                                           | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| address   | Specifies the IP address of the OBS service endpoint or HDFS cluster. | <p>OBS: Specifies the endpoint of the OBS service.</p> <p>HDFS: Specifies the IP address and port number of a NameNode (metadata node) in the HDFS cluster, or the IP address and port number of a CN in other homogeneous clusters.</p> <p>HDFS NameNodes are deployed in primary/secondary mode for HA. Add the addresses of the primary and secondary NameNodes to <b>ADDRESS</b>. When accessing HDFS, DWS dynamically checks for the primary NameNode.</p> <p>If the HDFS is in federation mode, you can add all router addresses to the <b>address</b> value. When DWS accesses the HDFS service, the system dynamically and randomly searches for the active router.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• The <b>address</b> option must exist. In the cross-cluster interconnection scenario, only one <b>address</b> option can be set.</li><li>• If the server type is DLI, the address is the OBS address stored on DLI.</li><li>• If the HDFS is in federation mode, that is, <b>fed 'rbf'</b>, address can be set to multiple groups of IP addresses and ports, corresponding to the address of the HDFS router.</li></ul> |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Value Range                                                                                                                                                                                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hdfscfgpath | <p>This parameter is available only when <b>type</b> is <b>HDFS</b>.</p> <p>You can set the <b>hdfscfgpath</b> parameter to specify the HDFS configuration file path. DWS accesses the HDFS cluster based on the connection configuration mode and security mode specified in the HDFS configuration file stored in that path. If the HDFS cluster is connected in non-secure mode, data transmission encryption is not supported.</p> <p>If the <b>address option</b> is not specified, the address specified by <b>hdfscfgpath</b> in the configuration file is used by default.</p> | -                                                                                                                                                                                                                                                                                                                |
| fed         | Indicates that <b>dfs_fdw</b> is connected to HDFS in federation mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <p>The value <b>rbf</b> indicates that HDFS uses the RBF mode.</p> <p><b>NOTE</b><br/>This feature is supported in 8.1.2 or later.</p>                                                                                                                                                                           |
| encrypt     | Specifies whether data is encrypted. This parameter is available only when <b>type</b> is <b>OBS</b> . The default value is <b>off</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                               | <ul style="list-style-type: none"><li>• <b>on</b> indicates that data is encrypted.</li><li>• <b>off</b> indicates that data is not encrypted.</li></ul>                                                                                                                                                         |
| access_key  | Specifies the access key (AK) (obtained by users from the OBS console) used for the OBS access protocol. When you create a foreign table, its AK value is encrypted and saved to the metadata table of the database.                                                                                                                                                                                                                                                                                                                                                                   | <ul style="list-style-type: none"><li>• If <b>FOREIGN DATA WRAPPER</b> is set to <b>dfs_fdw</b>, this parameter can be set only when type is set to OBS.</li><li>• For clusters of version 8.2.0 or later, this parameter can be specified when <b>FOREIGN DATA WRAPPER</b> is set to <b>dist_fdw</b>.</li></ul> |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                           | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| secret_access_key | Indicates the secret access key (SK) (obtained by users from the OBS page) used for the OBS access protocol. When you create a foreign table, its SK value is encrypted and saved to the metadata table of the database.                                                                                                              | <ul style="list-style-type: none"><li>• If <b>FOREIGN DATA WRAPPER</b> is set to <b>dfs_fdw</b>, this parameter can be set only when type is set to OBS.</li><li>• For clusters of 8.2.0 or later, this parameter can be specified when <b>FOREIGN DATA WRAPPER</b> is set to <b>dist_fdw</b>.</li></ul>                                                                                                                                            |
| security_token    | Corresponds to the <b>SecurityToken</b> value of the temporary security credential in IAM. A temporary AK, a temporary SK, and a temporary security token form a temporary security credential. The temporary security credential is valid for no more than 24 hours. This parameter is supported by version 8.2.0 or later clusters. | <ul style="list-style-type: none"><li>• If <b>FOREIGN DATA WRAPPER</b> is set to <b>dfs_fdw</b>, this parameter can be set only when type is set to OBS.</li><li>• For clusters of 8.2.0 or later, this parameter can be specified when <b>FOREIGN DATA WRAPPER</b> is set to <b>dist_fdw</b>.</li><li>• When this parameter is used, <b>access_key</b> and <b>secret_access_key</b> correspond to the temporary AK and SK, respectively.</li></ul> |
| type              | Specifies the <b>dfs_fdw</b> connection type.                                                                                                                                                                                                                                                                                         | <ul style="list-style-type: none"><li>• <b>OBS</b> indicates that OBS is connected.</li><li>• <b>HDFS</b> indicates that HDFS is connected.</li><li>• <b>DLI</b> indicates that DLI is connected.</li></ul>                                                                                                                                                                                                                                         |
| dli_address       | Specifies the endpoint of the DLI service. This parameter is available only when <b>type</b> is <b>DLI</b> .                                                                                                                                                                                                                          | -                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter             | Description                                                                                                                                                                                                                                                                                   | Value Range |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| dli_access_key        | Specifies the access key (AK) (obtained by users from the DLI console) used for the DLI access protocol. When you create a foreign table, its AK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>DLI</b> .        | -           |
| dli_secret_access_key | Specifies the secret access key (SK) (obtained by users from the DLI console) used for the DLI access protocol. When you create a foreign table, its SK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>DLI</b> . | -           |
| dbname                | Specifies the database name of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.                                                                                                                                         | -           |
| username              | Specifies the username of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.                                                                                                                                              | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| password  | <p>Specifies the password of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.</p> <p><b>NOTE</b></p> <p>When an on-premises cluster is migrated to the cloud, the password in the server configuration exported from the on-premises cluster is in ciphertext. The encryption and decryption keys of the on-premises cluster are different from those of the cloud cluster. Therefore, if <b>CREATE SERVER</b> is executed on the cloud cluster, the execution fails and a decryption failure error is reported. In this case, you need to manually change the password in <b>CREATE SERVER</b> to a plaintext password.</p> | -           |
| syncsrv   | <p>This parameter is used only for cross-cluster interconnection and indicates the GDS service used during data synchronization. The method for setting this parameter is the same as that for setting the <b>location</b> attribute of the GDS foreign table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 | -           |

## Examples

Create the **hdfs\_server** server, in which **hdfs\_fdw** is the built-in foreign data wrapper. (The values of **address** and **hdfscfgpath** are for reference only. Change them as required.)

```
CREATE SERVER hdfs_server FOREIGN DATA WRAPPER HDFS_FDW OPTIONS
(address '10.10.0.100:25000,10.10.0.101:25000',
 hdfscfgpath '/opt/hadoop_client/HDFS/hadoop/etc/hadoop',
 type 'HDFS'
);
```

Create the **obs\_server** server, in which **dfs\_fdw** is the foreign-data wrapper.

```
CREATE SERVER obs_server FOREIGN DATA WRAPPER DFS_FDW OPTIONS (
 address 'obs.example.com',
 access_key 'xxxxxxxx',
 secret_access_key 'yyyyyyyyyyyyyy',
 type 'obs'
);
```

Create the **dli\_server** server, in which **dfs\_fdw** is the foreign-data wrapper.

```
CREATE SERVER dli_server FOREIGN DATA WRAPPER DFS_FDW OPTIONS (
 address 'obs.example.com',
 access_key 'xxxxxxxx',
 secret_access_key 'yyyyyyyyyyyyyy',
 type 'dli',
 dli_address 'dli.example.com',
 dli_access_key 'xxxxxxxx',
 dli_secret_access_key 'yyyyyyyyyyyyyy'
);
```

Create another server in the homogeneous cluster, where **gc\_fdw** is the foreign data wrapper in the database.

```
CREATE SERVER server_remote FOREIGN DATA WRAPPER GC_FDW OPTIONS
(address '10.10.0.100:25000,10.10.0.101:25000',
 dbname 'test',
 username 'test',
 password 'xxxxxxx'
);
```

Create a server whose **FOREIGN DATA WRAPPER** is **dist\_fdw** for importing and exporting text data on OBS.

```
CREATE SERVER import_server FOREIGN DATA WRAPPER DIST_FDW OPTIONS
(
 access_key 'ak_string',
 secret_access_key 'sk_string'
);
```

## Helpful Links

[ALTER SERVER](#), [DROP SERVER](#)

### 21.13.4.15 ALTER SERVER

#### Function

Adds, modifies, and deletes the definition of a foreign server.

Existing foreign servers can be queried from the **pg\_foreign\_server** system catalog.

#### Precautions

- Only the owner of the server has the permission to run the **ALTER SERVER** command. System administrators have this permission by default.
- To change the server owner, you must own the foreign server, belong directly or indirectly to the new owner's role, and have the **USAGE** permission on the server's foreign-data wrapper.

## Syntax

- Change the parameters for an external server.  

```
ALTER SERVER server_name [VERSION 'new_version']
[OPTIONS ({[ADD | SET | DROP] option ['value']} [, ...])];
```
- Change the owner of an external server.  

```
ALTER SERVER server_name
OWNER TO new_owner;
```
- Change the name of an external service.  

```
ALTER SERVER server_name
RENAME TO new_name;
```
- Refresh the HDFS configuration file.  

```
ALTER SERVER server_name REFRESH OPTIONS;
```

## Parameter Description

Table 21-192 ALTER SERVER parameters

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                               | Value Range                                                                                                            |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| server_name | Specifies the name of the external service to be modified.                                                                                                                                                                                                                                                                                                                                                | Name of an existing external server.                                                                                   |
| new_version | Specifies the new version of the external server.                                                                                                                                                                                                                                                                                                                                                         | -                                                                                                                      |
| OPTIONS     | Specifies options for the server.<br><b>ADD</b> , <b>SET</b> , and <b>DROP</b> specify the operations to be performed. If the <b>OPTIONS</b> option is not specified, the <b>ADD</b> operation is performed by default.<br><br>Currently, only <b>SET</b> is supported on an HDFS server. <b>ADD</b> and <b>DROP</b> are not supported. The syntax for SET and DROP operations is retained for later use. | <b>option</b> and <b>value</b> are corresponding operation parameters. For details, see <a href="#">Table 21-193</a> . |
| new_owner   | Specifies the new owner of the external server.                                                                                                                                                                                                                                                                                                                                                           | Valid username.                                                                                                        |
| new_name    | Specifies the new name of the external server.                                                                                                                                                                                                                                                                                                                                                            | A string compliant with the <a href="#">identifier naming rules</a> .                                                  |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                               | Value Range |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| REFRESH<br>OPTIONS | <p>Refreshes the HDFS configuration file cache information. This command is executed when the configuration file changes. If this command is not executed, an access error may occur.</p> <p>This parameter is used to update the HDFS server configuration cache and cannot be concurrently accessed by related HDFS foreign tables.</p> | -           |

**Table 21-193** Parameters for modifying **OPTIONS** supported by external servers

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Value Range |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| address     | <p>Specifies the endpoint of the OBS service.</p> <p>Specifies the IP address and port number of the primary and standby nodes of the HDFS cluster.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <b>address</b> is mandatory for HDFS servers. Therefore, <b>ADD</b> and <b>DROP</b> operations are not supported.</li><li>• <b>address</b> only supports IPv4 addresses in dot-decimal notation, and an address string cannot contain spaces. Groups of addresses are separated by commas (,). An IP address and a port number are separated by a colon (:). You are advised to configure two IP address and port pairs in an HDFS cluster. One is used as the socket address of the primary HDFS NameNode and another is used as that of the secondary HDFS NameNode.</li><li>• If the server type is DLI, the address is the OBS address stored on DLI.</li></ul> | -           |
| hdfscfgpath | <p>Specifies the HDFS cluster configuration file.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If HDFS is in security mode, <b>hdfscfgpath</b> is mandatory.</li><li>• If you set <b>hdfscfgpath</b>, you can only set one value for <b>path</b>.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | -           |

| Parameter             | Description                                                                                                                                                                                                                                                                                           | Value Range                                                                                                                                              |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| fed                   | Indicates that <b>dfs_fdw</b> is connected to HDFS in federation mode.<br><br>The value <b>rbf</b> indicates that HDFS uses the Router-based Federation (RBF) mode.<br><b>NOTE</b><br>This parameter is supported in 8.1.2 or later. In 8.0.0, this parameter is supported only in 8.0.0.10 or later. | -                                                                                                                                                        |
| encrypt               | Specifies whether data is encrypted. This parameter is available only when <b>type</b> is <b>OBS</b> . The default value is <b>off</b> .                                                                                                                                                              | <ul style="list-style-type: none"><li>• <b>on</b> indicates that data is encrypted.</li><li>• <b>off</b> indicates that data is not encrypted.</li></ul> |
| access_key            | Indicates the access key (AK) (obtained by users from the OBS page) used for the OBS access protocol. When you create a foreign table, its AK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>OBS</b> .                   | -                                                                                                                                                        |
| secret_access_key     | Indicates the secret access key (SK) (obtained by users from the OBS page) used for the OBS access protocol. When you create a foreign table, its SK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>OBS</b> .            | -                                                                                                                                                        |
| dli_address           | Specifies the endpoint of the DLI service. This parameter is available only when <b>type</b> is <b>DLI</b> .                                                                                                                                                                                          | -                                                                                                                                                        |
| dli_access_key        | Specifies the access key (AK) (obtained by users from the DLI console) used for the DLI access protocol. When you create a foreign table, its AK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>DLI</b> .                | -                                                                                                                                                        |
| dli_secret_access_key | Specifies the secret access key (SK) (obtained by users from the DLI console) used for the DLI access protocol. When you create a foreign table, its SK value is encrypted and saved to the metadata table of the database. This parameter is available only when <b>type</b> is <b>DLI</b> .         | -                                                                                                                                                        |

| Parameter | Description                                                                                                                                                                                                                                                                                                   | Value Range |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| region    | Indicates the IP address or domain name of the OBS server. This parameter is available only when <b>type</b> is <b>OBS</b> .                                                                                                                                                                                  | -           |
| dbname    | Specifies the database name of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.                                                                                                                                                         | -           |
| username  | Specifies the username of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.                                                                                                                                                              | -           |
| password  | Specifies the password of a remote cluster to be connected. This parameter is used for collaborative analysis and cross-cluster interconnection.                                                                                                                                                              | -           |
| syncsrv   | This parameter is used only for cross-cluster interconnection and indicates the GDS service used during data synchronization. The method for setting this parameter is the same as that for setting the <b>location</b> attribute of the GDS foreign table. This feature is supported only in 8.1.2 or later. | -           |

## Examples

Create the **hdfs\_server** external server, in which **hdfs\_fdw** is the built-in foreign data wrapper.

```
CREATE SERVER hdfs_server FOREIGN DATA WRAPPER HDFS_FDW OPTIONS
(address '10.10.0.100:25000,10.10.0.101:25000',
 hdfsfgpath '/opt/hadoop_client/HDFS/hadoop/etc/hadoop',
 type 'HDFS'
);
```

Modify the **address** option of the external server **hdfs\_server**.

```
ALTER SERVER hdfs_server OPTIONS (SET address '10.10.0.110:25000,10.10.0.120:25000');
```

Modify the **hdfsfgpath** option of the external server **hdfs\_server**.

```
ALTER SERVER hdfs_server OPTIONS (SET hdfsfgpath '/opt/bigdata/hadoop');
```

## Helpful Links

[CREATE SERVER](#), [DROP SERVER](#)

## 21.13.4.16 DROP SERVER

### Function

**DROP SERVER** deletes an existing data server.

### Precautions

Only the server owner can delete a server.

### Syntax

```
DROP SERVER [IF EXISTS] server_name [{CASCADE | RESTRICT}] ;
```

### Parameter Description

**Table 21-194** DROP SERVER parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a notice instead of an error if the specified server does not exist.                          | -                                                                                                                                                                                                                                     |
| server_name        | Specifies the name of the server to be deleted.                                                     | An existing server name.                                                                                                                                                                                                              |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically drops objects that depend on the server to be deleted.</li><li>• <b>RESTRICT</b> (default): refuses to delete the server if any objects depend on it.</li></ul> |

### Examples

Delete **hdfs\_server** server.

```
DROP SERVER hdfs_server;
```

## 21.13.5 Views and Materialized Views

## 21.13.5.1 CREATE VIEW

### Function

**CREATE VIEW** creates a view.

A view is a virtual table, not a base table. A database only stores the definition of a view and does not store its data. The data is still stored in the original base table. If data in the base table changes, the data in the view changes accordingly. In this sense, a view is like a window through which users can know their interested data and data changes in the database.

### Precautions

None

### Syntax

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] VIEW view_name [(column_name [, ...])]
[WITH ({view_option_name [= view_option_value]} [, ...])]
AS query;
```

#### NOTE

- You can use **WITH (security\_barriers)** to create a relatively secure view. This prevents attackers from printing hidden base table data by using the **RAISE** statement of low-cost functions.
- When the **view\_independent** GUC parameter is enabled, columns can be deleted from common views. Note that if a column-level constraint exists, the corresponding column cannot be deleted.
- Duplicate CTE names are not supported when the view decoupling function is enabled.

Example:

```
CREATE TABLE t1(a1 INT, b1 INT);
CREATE TABLE t2(a2 INT, b2 INT, c2 INT);
CREATE OR REPLACE VIEW v1 AS WITH tmp AS (SELECT * FROM t2) ,tmp1 AS (SELECT b2,c2
FROM tmp WHERE b2 = (WITH RECURSIVE tmp(aa, bb) AS (SELECT a1,b1 FROM t1) SELECT bb
FROM tmp WHERE aa = c2)) SELECT c2 FROM tmp1;
```

### Parameter Description

**Table 21-195** CREATE VIEW parameters

| Parameter        | Description                                                                    | Value Range                                                              |
|------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| OR REPLACE       | If a view with the same name already exists, redefine the view.                | -                                                                        |
| TEMP   TEMPORARY | Creates a temporary view.                                                      | -                                                                        |
| view_name        | Specifies the name of a view to be created. It is optionally schema-qualified. | A string, which must comply with the <a href="#">naming convention</a> . |

| Parameter                                                     | Description                                                                                                                                                                                                                     | Value Range                                                                                                                                    |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| column_name                                                   | Specifies an optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.                                                                                              | A string, which must comply with the <a href="#">naming convention</a> .                                                                       |
| WITH<br>( {view_option_name [= view_option_value]} [, ... ] ) | Specifies the optional parameters for a view.<br>Currently, the only parameter supported by <b>view_option_name</b> is <b>security_barrier</b> , which should be enabled when a view is intended to provide row-level security. | If security_barrier is of the boolean type, the options are as follows: <ul style="list-style-type: none"><li>• TRUE</li><li>• FALSE</li></ul> |
| query                                                         | A <b>SELECT</b> or <b>VALUES</b> statement which will provide the columns and rows of the view.                                                                                                                                 | -                                                                                                                                              |

## Examples

Create a view consisting of columns whose **spcname** is **pg\_default**:

```
CREATE VIEW myView AS
SELECT * FROM pg_tablespace WHERE spcname = 'pg_default';
```

Run the following command to redefine the existing view **myView** and create a view consisting of columns whose **spcname** is **pg\_global**:

```
CREATE OR REPLACE VIEW myView AS
SELECT * FROM pg_tablespace WHERE spcname = 'pg_global';
```

Create a view consisting of rows with **age** smaller than 12:

```
DROP TABLE IF EXISTS customer;

CREATE TABLE customer
(id int, name varchar(20) , age int)
with (orientation = column,COMPRESSION=MIDDLE)
distribute by hash(id);

INSERT INTO customer VALUES (1,'lily',10),(2, 'lucy',12),(3,'lilei',15);

CREATE VIEW customer_details_view_v1 AS
SELECT * FROM customer
WHERE age < 12;
```

## Updatable Views

After the **enable\_view\_update** parameter is enabled, the **INSERT**, **UPDATE**, **DELETE**, and **MERGE INTO** statements can be used to update simple views. Only 8.1.2 or later supports updates using the **MERGE INTO** statement.

Views that meet all the following conditions can be updated:

- The FROM clause in the view definition contains only one common table, which cannot be a system table, foreign table, DFS table, delta table, TOAST table, or error table.
- The view contains updatable columns, which are simple references to the updatable columns of the base table.
- The view definition does not contain the WITH, DISTINCT, GROUP BY, ORDER BY, FOR UPDATE, FOR SHARE, HAVING, TABLESAMPLE, LIMIT or OFFSET clause.
- The view definition does not contain the UNION, INTERSECT, or EXCEPT operation.
- The selection list of the view definition does not contain aggregate functions, window functions, or functions that return collections.
- Ensure that there is no trigger whose trigger occasion is **INSTEAD OF** in the view for **INSERT**, **UPDATE**, and **DELETE** statements. For the **MERGE INTO** statement, neither the view nor the underlying table can have triggers.
- The view definition does not contain sublinks.
- The view definition does not contain functions whose attribute is **VOLATILE**. The values of such functions can be changed during a table scan.
- The view definition does not set an alias for the column where the distribution key of the table resides, or name a common column as the distribution key column.
- When the RETURNING clause is used in the view update operation, columns in the view definition only come from the base table.

If the definition of the updatable view contains a WHERE condition, the condition restricts the UPDATE and DELETE statements from modifying rows on the base table. If the WHERE condition is not met after the UPDATE statement is executed, the updated rows cannot be queried in the view. Similarly, If the WHERE condition is not met after the INSERT statement is executed, the inserted data cannot be queried in the view. To insert, update, or delete data in a view, you must have the corresponding permission on the view and tables.

## Helpful Links

[ALTER VIEW](#), [DROP VIEW](#)

### 21.13.5.2 ALTER VIEW

#### Function

**ALTER VIEW** modifies all auxiliary attributes of a view. (To modify the query definition of a view, use **CREATE OR REPLACE VIEW**.)

#### Precautions

- Only the view owner can run **ALTER VIEW**.
- To change a view's schema, you must also have the CREATE permission on the new schema.
- To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the view's schema.

- An administrator can change the owner relationship of any view.

## Syntax

- Set the default value of the view column.  

```
ALTER VIEW [IF EXISTS] view_name
 ALTER [COLUMN] column_name SET DEFAULT expression;
```
- Remove the default value of the view column.  

```
ALTER VIEW [IF EXISTS] view_name
 ALTER [COLUMN] column_name DROP DEFAULT;
```
- Change the owner of a view.  

```
ALTER VIEW [IF EXISTS] view_name
 OWNER TO new_owner;
```
- Renames a view. The new view name can be prefixed with the schema name of the original view. The schema name cannot be changed at the same time.  

```
ALTER VIEW [IF EXISTS] view_name
 RENAME TO new_name;
ALTER VIEW [IF EXISTS] view_name
 RENAME TO schema.new_name;
```
- Set the schema of the view.  

```
ALTER VIEW [IF EXISTS] view_name
 SET SCHEMA new_schema;
```
- Set the options of the view.  

```
ALTER VIEW [IF EXISTS] view_name
 SET ({ view_option_name [= view_option_value] } [, ...]);
```
- Reset the options of the view.  

```
ALTER VIEW [IF EXISTS] view_name
 RESET (view_option_name [, ...]);
```
- Rebuild the current view and its lower-layer and upper-layer dependent views.  

```
ALTER VIEW [IF EXISTS] view_name
 REBUILD;
```
- Rebuild the current view and its lower-layer dependent views.  

```
ALTER VIEW [IF EXISTS] ONLY view_name
 REBUILD;
```

## Parameter Description

**Table 21-196** ALTER VIEW parameters

| Parameter   | Description                                                                                                                        | Value Range        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| IF EXISTS   | Sends a prompt instead of an error if the view does not exist.                                                                     | -                  |
| view_name   | Specifies the name of the view to be modified, which can include a schema.                                                         | Valid view name.   |
| column_name | Indicates an optional list of names to be used for columns of the view. If not given, the column names are deduced from the query. | Valid column name. |

| Parameter                              | Description                                                                                                                                                                                                                                                                                                         | Value Range                                                                                                                                 |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| SET/DROP<br>DEFAULT                    | Sets or deletes the default value of a column. Currently, this parameter does not take effect.                                                                                                                                                                                                                      | -                                                                                                                                           |
| new_owner                              | Specifies the new owner of the view.                                                                                                                                                                                                                                                                                | Valid username.                                                                                                                             |
| new_name                               | Specifies the new view name.                                                                                                                                                                                                                                                                                        | A string compliant with the <a href="#">identifier naming rules</a> .                                                                       |
| new_schema                             | Specifies the new schema of the view.                                                                                                                                                                                                                                                                               | Valid schema name.                                                                                                                          |
| view_option_name [= view_option_value] | This clause specifies optional parameters for a view.<br>Currently, the only parameter supported by <b>view_option_name</b> is <b>security_barrier</b> , which should be enabled when a view is intended to provide row-level security.                                                                             | <b>security_barrier</b> is of the boolean type. The options include: <ul style="list-style-type: none"><li>• TRUE</li><li>• FALSE</li></ul> |
| REBUILD                                | This clause is used for view decoupling. You can use the saved original statement to rebuild views and restore the dependencies. In 9.1.0.200 and later cluster versions, the view decoupling function does not require <b>view_independent</b> to be enabled. If a view becomes invalid, it can simply be rebuilt. | For how to use <b>REBUILD</b> , see <a href="#">REBUILD Usage Description</a> .                                                             |
| ONLY                                   | Limits view rebuilding to only the selected view and its dependencies. This function does not require <b>view_independent</b> to be enabled. If a view becomes invalid, it can simply be rebuilt.                                                                                                                   | -                                                                                                                                           |

## REBUILD Usage Description

- View rebuilding starts from the current view and updates all associated backward views. If the forward views on which the current view depends are also unavailable, automatic rebuilding is triggered.
- The temporary tables and views that have dependency relationships cannot be decoupled and dropped. However, you can perform the REBUILD operation on temporary views that do not have dependency relationships.

- View schema names and view names can be modified. The names of rebuilt view schemas or views are re-created based on the latest name, but the query operation retains the original definition.
- Only fields of the character, number, and time types in the base table can be modified. Only fields of the character, number, and time types in the base table can be modified. When a field is added to the base table, the view is not invalidated and the definition remains unchanged.
- Invalid views are exported as comments during backup. You need to manually restore the invalid views.

 **NOTE**

The upper-layer cascading views become invalid in the following scenarios:

- DROP TABLE/VIEW
- RENAME TABLE/VIEW
- ALTER TABLE DROP COLUMN
- ALTER TABLE CHANGE/ALTER COLUMN TYPE
- ALTER TABLE CHANGE/ALTER COLUMN NAME
- ALTER TABLE/VIEW NAMESPACE
- ALTER TABLE/VIEW RENAME

## Examples

Create the sample view **myview**.

```
CREATE OR REPLACE VIEW myview AS
SELECT * FROM pg_tablespace WHERE spcname = 'pg_default';
```

Change the view name.

```
ALTER VIEW myview RENAME TO product_view;
```

Change the schema of a view.

```
ALTER VIEW product_view SET schema public;
```

Rebuild a view.

```
ALTER VIEW public.product_view REBUILD;
```

Rebuild a dependent view.

```
ALTER VIEW ONLY public.product_view REBUILD;
```

## Helpful Links

[CREATE VIEW](#) and [DROP VIEW](#)

### 21.13.5.3 DROP VIEW

#### Function

**DROP VIEW** forcibly deletes an existing view in a database.

#### Precautions

Only a view owner or a system administrator can run **DROP VIEW** command.

**⚠ DANGER**

- Be cautious when using **DROP OBJECT** (e.g., **DATABASE, USER/ROLE, SCHEMA, TABLE, VIEW**) as it may cause data loss, especially with **CASCADE** deletions. Always back up data before proceeding.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

## Syntax

```
DROP VIEW [IF EXISTS] view_name [, ...] [CASCADE | RESTRICT];
```

## Parameter Description

**Table 21-197** DROP VIEW parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                          |
|--------------------|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a notice instead of an error if the specified view does not exist.                            | -                                                                                                                                                                                                                                                    |
| view_name          | Specifies the name of the view to be deleted.                                                       | An existing view.                                                                                                                                                                                                                                    |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: deletes objects (such as other views) that depend on a view to be deleted.</li><li>• <b>RESTRICT</b>: refuses to delete the view if any objects depend on it. This is the default.</li></ul> |

## Examples

Delete **myView** view.

```
DROP VIEW myView;
```

Delete **customer\_details\_view\_v2** view.

```
DROP VIEW public.customer_details_view_v2;
```

## 21.13.5.4 CREATE MATERIALIZED VIEW

### Function

CREATE MATERIALIZED VIEW creates a materialized view. This syntax is supported only by clusters of version 8.2.1.220 or later.

A materialized view is a special database object. It pre-computes complex query results and stores them in the database to accelerate queries.

When a large amount of data is frequently queried and analyzed, materialized views can be used to pre-calculate and store query results, significantly improving query performance.

### Materialized View Permissions

1. To create a materialized view, you must have the **CREATE** permission on the schema and the **SELECT** permission on the base table or column.
2. To query a materialized view, you must have the **SELECT** permission on the materialized view.
3. To refresh a materialized view, you must have the **INSERT** permission on the view and the **SELECT** permission on the base table or column.
4. Other permissions:

Materialized views support fine-grained permissions such as **ANALYZE**, **VACUUM**, **ALTER**, and **DROP**.

Materialized views support **WITH GRANT OPTION**, which means that the recipient of the permission can in turn grant it to others.

5. Security:

Materialized views do not support higher-level security control. In scenarios where the **SELECT** permission is restricted, for example, a base table has row-level access control or masking policies or its owner is a private user, materialized views cannot be created.

If a materialized view already exists and an RLS or masking policy is added to the base table or the owner of the base table is changed to a private user, the materialized view can be queried but cannot be refreshed.

### Precautions

- To use **CREATE MATERIALIZED VIEW**, ensure that **enable\_matview** is set to **on**.
- The base table of a materialized view can be a row-store table, column-store table, HStore table, hot and cold table (supported by clusters of version 9.1.0.200 or later), partitioned table, specified partition, foreign table, or another materialized view.
- Temporary tables (including global temporary tables, volatile temporary tables, and common temporary tables) are not supported. Partitions cannot be specified for partitioned tables that are automatically created.
- The CTE in the definition of a materialized view cannot contain other DML statements except the **SELECT** statement.
- The base table of a materialized view cannot have masking policies and row-level access control, or belong to a private user. Masking policies and row-

level access control may cause result set errors, while private users may cause problems such as materialized view refresh failures.

- Materialized views do not support the following storage types: foreign tables and time series tables.
- Materialized views do not allow **INSERT**, **UPDATE**, **MERGE INTO**, or **DELETE** operations.
- The result of each query to the materialized view saved to ensure that the query results are the same each time. After the **BUILD IMMEDIATE** or **REFRESH** operation, the correct result can be queried in the materialized view.
- A node group cannot be specified for a materialized view using syntax. A node group can be specified for the base table of a materialized view. The materialized view can inherit the node group information from the base table. The node groups of multiple base tables must be the same.

## Syntax

```
CREATE MATERIALIZED VIEW [IF NOT EXISTS] materialized_view_name [(column_name [, ...])]
[BUILD { DEFERRED | IMMEDIATE }]
[REFRESH [[DEFAULT] | [RESTRICT] | [CASCADE FORWARD] | [CASCADE BACKWARD] | [CASCADE
ALL]] [COMPLETE] [ON DEMAND] [[START WITH (timestampz)] | [EVERY (interval)]]]
[{ ENABLE | DISABLE } QUERY REWRITE]
[WITH ({storage_parameter = value} [, ...])]
[DISTRIBUTE BY { REPLICATION | ROUNDROBIN | { HASH (column_name [,...]) } }]
[PARTITION BY {(column_name) | date_trunc('time_unit', column_name)}]
AS query;
```

## Parameter Description

**Table 21-198** CREATE MATERIALIZED VIEW parameters

| Parameter                     | Description                                                                                                                                                                                                                | Value Range/Default Value |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| BUILD DEFERRED<br>  IMMEDIATE | <b>IMMEDIATE</b> indicates that the latest data is included when the materialized view is created.<br><br><b>DEFERRED</b> indicates that data is included only when the materialized view is refreshed for the first time. | -                         |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                  | Value Range/Default Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REFRESH   | <p>Specifies the refresh mode of a materialized view.</p> <p>After a materialized view is created, the data in the materialized view reflects only the status of the base table at the creation time. When the data in the base table changes, you need to refresh the materialized view (<b>REFRESH MATERIALIZED VIEW</b>) to update the data in the materialized view.</p> | <ul style="list-style-type: none"><li>Refresh method: The options include <b>DEFAULT</b> (default refresh) and <b>RESTRICT</b> (forcible refresh). You can only specify the refresh method for materialized views that are asynchronously refreshed in the background.</li><li>Refresh direction: When using materialized views in a cascading nested manner, the refresh direction can be specified as <b>FORWARD</b>, <b>BACKWARD</b>, or <b>ALL</b>. You can only specify the refresh direction for materialized views that are asynchronously refreshed in the background. For details, see <a href="#">REFRESH MATERIALIZED VIEW</a>.</li><li>Currently, only the <b>COMPLETE</b> refresh mode is supported, which refresh full data in the materialized view. Execute the query statement defined in the materialized view to update the materialized view.</li><li>Refresh triggering mode. <b>ON DEMAND</b>: manual refresh on demand.<br/><b>START WITH (timestamp tz)   EVERY (interval)</b>: automatic refresh at a scheduled time. <b>START WITH</b> specifies the first refresh time. <b>EVERY</b> specifies the automatic refresh interval and its value can be <b>MONTH</b>, <b>DAY</b>, <b>hour</b>, <b>MINUTE</b>, or <b>SECOND</b>.</li></ul> |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               | Value Range/Default Value                                                                                                                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENABLE   DISABLE<br>QUERY REWRITE | <p>Specifies whether to enable query rewrite.</p> <p>Query rewrite means that when a base table is queried and a materialized view is created for the base table, the database system automatically determines whether the pre-calculated result in the materialized view can be used to process the query.</p> <p>If a materialized view can be used, the pre-calculated result is directly read from the materialized view to accelerate the query.</p> | <p>Disabled by default.</p> <p>When <b>ENABLE QUERY REWRITE</b> is specified, you need to configure the GUC parameter <b>mv_rewrite_rule</b> to enable query rewrite of materialized views.</p> |
| WITH                              | Specifies the parameters for creating a materialized view.                                                                                                                                                                                                                                                                                                                                                                                                | For details, see <a href="#">Table 21-199</a> .                                                                                                                                                 |

| Parameter     | Description                                                       | Value Range/Default Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DISTRIBUTE BY | Specifies how the table is distributed or replicated between DNs. | <p>Value range: <b>REPLICATION</b>, <b>ROUNDROBIN</b>, or <b>HASH</b></p> <ul style="list-style-type: none"><li>• <b>REPLICATION</b>: Each row in the table exists on all DNs, that is, each DN has complete table data.</li><li>• <b>ROUNDROBIN</b>: Each row in the table is sent to each DN in turn. Therefore, data is evenly distributed on each DN. This value is supported only in 8.1.2 or later.</li><li>• <b>HASH</b>: Each row of the table will be placed into all the DNs based on the hash value of the specified column.</li></ul> <p>Default value: determined by the <b>default_distribution_mode</b> parameter.</p> <p><b>NOTE</b></p> <p>When the materialized view is distributed in hash mode, data skew may occur. To check for data skews in materialized views, follow the same procedures used for detecting data skews in regular tables. For details, see "Checking for Data Skew" in the <i>Data Warehouse Service (DWS) Developer Guide</i>. If data skew is identified in a materialized view, perform data skew optimization at the storage layer by referring to "Optimizing Data Skew" in the <i>Data Warehouse Service (DWS) Developer Guide</i>.</p> |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Value Range/Default Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PARTITION BY | <p>Creates a partitioned materialized view. This parameter is supported only by clusters of version 9.1.0.200 or later.</p> <p><b>CAUTION</b></p> <ul style="list-style-type: none"><li>• The partition key of a materialized view must match that of the queried table's partitioned table to ensure partition-based mapping for invalidation and refresh.</li><li>• The partition key of a materialized view must be included in the outermost SQL statement of the query to enable partition key-based updates to the materialized view.</li><li>• Materialized views support only range partitioning.</li><li>• The queried table can be a composite partition. If multiple partition tables have the same partition conditions, the mapping between the queried table and the materialized view is automatically established.</li><li>• Partition mapping of foreign tables is not supported because data changes in foreign tables cannot be detected.</li><li>• Columns that generate null values in outer joins cannot be used as partition keys.</li><li>• Merging and splitting of base table partitions are not supported.</li></ul> | <ul style="list-style-type: none"><li>• Proportional association: Specify the partition key of a partitioned table in the query as the partition key of the materialized view, creating a one-on-one mapping relationship.</li><li>• Roll-up association: Use the <b>date_trunc</b> function to roll up the partition key of a partitioned table in the query, establishing a roll-up mapping relationship. The data type should be compatible with the <b>date_trunc</b> function.</li></ul> |
| AS query     | Creates a materialized view based on the query result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 21-199 WITH parameters

| Parameter                          | Description                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORIENTATION                        | Specifies the storage mode (row-store, column-store) for table data. This parameter cannot be modified once it is set.                                                                                                                                                                                                                                            | <b>ROW</b> or <b>COLUMN</b> <ul style="list-style-type: none"><li>• <b>ROW</b> indicates that table data is stored in rows. <b>ROW</b> applies to OLTP service, which has many interactive transactions. An interaction involves many columns in the table. Using ROW can improve the efficiency.</li><li>• <b>COLUMN</b> indicates that the data is stored in columns. Column storage applies to the data warehouse service, which has a large amount of aggregation computing, and involves a few column operations.</li></ul> Default value: <b>ROW</b> |
| enable_foreign_table_query_rewrite | Specifies whether to allow query rewriting on materialized views that contain foreign tables. This parameter must be used together with <b>ENABLE QUERY REWRITE</b> .<br>The materialized view cannot detect the data changes in the foreign table. Specify this option if you want to enable query rewriting for materialized views that contain foreign tables. | <ul style="list-style-type: none"><li>• <b>on</b>: allows query rewriting on materialized views that contain foreign tables.</li><li>• <b>off</b>: does not allow query rewriting on materialized views that contain foreign tables.</li></ul> Default value: <b>off</b>                                                                                                                                                                                                                                                                                   |
| bitmap_columns                     | The bitmap index is only applicable to the <b>hstore_opt</b> table. To use it, enable the table-level parameter <b>enable_hstore_opt</b> and set <b>bitmap_columns</b> to the specified column. This is supported only by clusters of version 9.1.0.200 or later.                                                                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Parameter          | Description                                                                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| secondary_part_num | Specifies the number of level-2 partitions in a column-store table. This parameter applies only to H-Store column-store tables. This is supported only by clusters of version 9.1.0.200 or later.                              | Value range: <b>1</b> to <b>32</b><br>Default value: <b>8</b>                                                                                                                                                                                                                                                    |
| enable_hstore_opt  | When the <b>enable_hstore_opt</b> table-level parameter is enabled, the <b>enable_hstore</b> table-level parameter is also automatically enabled by default. This is supported only by clusters of version 9.1.0.200 or later. | <b>true</b> or <b>false</b><br>Default value: <b>false</b>                                                                                                                                                                                                                                                       |
| enable_turbo_store | Determines whether to create a turbo table (column-store tables). The parameter is only valid for column-store tables. This is supported only by clusters of version 9.1.0.200 or later.                                       | <b>on</b> or <b>off</b><br>Default value: <b>off</b>                                                                                                                                                                                                                                                             |
| mv_analyze_mode    | Determines the automatic analysis method for materialized views. This is supported only by clusters of version 9.1.0.200 or later.                                                                                             | <ul style="list-style-type: none"><li>• <b>none</b>: indicates that the materialized view does not automatically execute <b>ANALYZE</b> after being refreshed.</li><li>• <b>light</b>: indicates that the materialized view performs light analysis after being refreshed.</li></ul> Default value: <b>light</b> |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mv_pck_column            | Specifies a partial clustering storage for a materialized view. During the data import process to a column-store table, the data is partially sorted according to the specified column(s). This is supported only by clusters of version 9.1.0.200 or later.<br><br>Enable <b>mv_pck_column</b> and set it to a specified column. | -                                                                                                                                                                                                                                                                                                                   |
| mv_support_function_type | Enables the use of function attributes in the query statements when creating materialized views. This is supported only by clusters of version 9.1.0.200 or later.                                                                                                                                                                | <ul style="list-style-type: none"><li>• <b>stable</b>: indicates that functions of the STABLE and IMMUTABLE types can be used in query statements.</li><li>• <b>volatile</b>: indicates that functions of the VOLATILE, STABLE, and IMMUTABLE types can be used in query statements.</li></ul> Default value: empty |
| excluded_inactive_tables | Specifies that the materialized view will not be invalidated when there are data changes in the underlying base table. This is supported only by clusters of version 9.1.0.200 or later.<br><br>Set <b>excluded_inactive_tables</b> to <b>schemaName1.tableName1,schemaName2.tableName2</b> .                                     | Default value: empty                                                                                                                                                                                                                                                                                                |
| force_rewrite_timeout    | Allows query rewrite within a specified time interval after refresh, regardless of the freshness of the data in the materialized view. This is supported only by clusters of version 9.1.0.200 or later.                                                                                                                          | The unit is second. The default value is <b>0</b> .                                                                                                                                                                                                                                                                 |

| Parameter                     | Description                                                                                                                                                                                     | Value Range |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| TABLESPACE<br>tablespace_name | Specifies a tablespace for V3 storage. If <b>default_tablespace</b> is empty, the default tablespace of the database is used. This is supported only by clusters of version 9.1.0.200 or later. | -           |

## Examples

Create a base table and insert data into the base table.

```
CREATE TABLE t1 (a int, b int) DISTRIBUTE BY HASH(a);
INSERT INTO t1 SELECT x,x FROM generate_series(1,10) x;
```

Create a materialized view with the default option **BUILD IMMEDIATE**.

```
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM t1;
```

Create a materialized view in column-store mode.

```
CREATE MATERIALIZED VIEW mv2 WITH(orientation = column) AS SELECT * FROM t1;
```

Create a materialized view that is manually refreshed as required.

```
CREATE MATERIALIZED VIEW mv3 BUILD DEFERRED REFRESH ON DEMAND AS SELECT * FROM t1;
```

Create a materialized view with a scheduled refresh time.

```
CREATE MATERIALIZED VIEW mv4 BUILD DEFERRED REFRESH START WITH(trunc(sysdate)) EVERY
(interval '1 day') AS SELECT * FROM t1;
```

Create a materialized view with a bitmap index.

```
CREATE MATERIALIZED VIEW mv1
with (ORIENTATION = COLUMN, enable_hstore=true, enable_hstore_opt=on, bitmap_columns='col1') AS
SELECT * FROM base_table;
```

Create a materialized view and specify the number of level-2 partitions in a column-store table.

```
CREATE MATERIALIZED VIEW mv
WITH (ORIENTATION=COLUMN, ENABLE_HSTORE=ON, enable_hstore_opt=on, mv_pck_column='c3',
secondary_part_column = 'c2', secondary_part_num = 8) AS SELECT * FROM base_table;
```

Create a materialized view and specify the PCK column for sorting.

```
CREATE MATERIALIZED VIEW mv
WITH (ORIENTATION=COLUMN, ENABLE_HSTORE=ON, enable_hstore_opt=on, mv_pck_column='col3') AS
SELECT * FROM base_table;
```

Create a materialized view and specify the analysis method.

```
CREATE MATERIALIZED VIEW mv1 enable query rewrite
with(excluded_inactive_tables='matview_basic."T1",matview_basic."a=b"',mv_analyze_mode='none') as
SELECT * FROM base_table;
```

Create a V3 materialized view.

```
CREATE MATERIALIZED VIEW mv1
with (orientation=column, enable_hstore=true, compression=low, enable_hstore_opt=on, COLVERSION =
3.0) TABLESPACE cu_obs_tbs distribute by hash(scope_name)
AS SELECT * FROM dicttbl_low;
```

Create a materialized view that contains a foreign table for query rewriting.

```
CREATE MATERIALIZED VIEW mv1 with (enable_foreign_table_query_rewrite = true) as SELECT * FROM
base_table;
```

Create a materialized view and specify that volatile functions can be used in the query statement.

```
CREATE MATERIALIZED VIEW mv_date with(mv_support_function_type = 'volatile') as select to_date(a)
from t_date;
```

[ALTER MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

### 21.13.5.5 ALTER MATERIALIZED VIEW

#### Function

Modifies the properties of a materialized view. This syntax is supported only by clusters of version 8.2.1.220 or later.

#### Precautions

To use ALTER MATERIALIZED VIEW, ensure that **enable\_matview** is set to **on**.

#### Syntax

- Set whether to enable query rewrite for materialized views.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] { materialized_view_name }
[ENABLE | DISABLE] QUERY REWRITE;
```
- Specify how materialized views are refreshed. Currently, only **COMPLETE** is available, which rebuilds the entire materialized view from scratch, re-executing the defining query.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] { materialized_view_name }
REFRESH [[DEFAULT]] [[RESTRICT]] [[CASCADE FORWARD]] [[CASCADE BACKWARD]]
[[CASCADE ALL]] [[COMPLETE]] [[ON DEMAND]] [[START WITH (timestamp tz)]] [[EVERY
(interval)]];
```

  - REFRESH ON DEMAND** indicates that the data is manually refreshed as required.
  - START WITH** specifies the first refresh time.
  - EVERY** specifies the refresh interval. The value can be **MONTH**, **DAY**, **HOURL**, **MINUTE**, or **SECOND**.
- Change how materialized views refresh asynchronously in the background. This change applies only to materialized views that refresh this way. This syntax is supported only by clusters of version 9.1.0.200 or later. For details, see [REFRESH MATERIALIZED VIEW](#).  

```
ALTER MATERIALIZED VIEW [IF EXISTS] { materialized_view_name }
REFRESH [DEFAULT] [[RESTRICT]] [[CASCADE FORWARD]] [[CASCADE BACKWARD]]
[[CASCADE ALL]];
```

- Change the owner of the materialized view.  

```
ALTER MATERIALIZED VIEW { materialized_view_name }
OWNER TO new_owner;
```
- Allow for setting table properties of materialized views. This syntax is supported only by clusters of 9.1.0.200 and later versions.  

```
ALTER MATERIALIZED VIEW { materialized_view_name }
SET ({storage_parameter = value} [, ...])
| RESET (storage_parameter [, ...])
```
- Rename a view. Materialized views cannot be renamed across schemas. When renaming a materialized view, you can specify a schema name for **materialized\_view\_name** but cannot specify a schema name for **new\_materialized\_view\_name**.  

```
ALTER MATERIALIZED VIEW [IF EXISTS] materialized_view_name
RENAME TO new_materialized_view_name;
```

## Parameter Description

Table 21-200 ALTER MATERIALIZED VIEW parameters

| Parameter                         | Description                                                                                   | Value Range                                                                                                                                                                          |
|-----------------------------------|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS                         | If the specified materialized view does not exist, a message instead of an error is returned. | -                                                                                                                                                                                    |
| materialized_view_name            | Specifies the name of the materialized view to be modified.                                   | Name of an existing materialized view.                                                                                                                                               |
| ENABLE   DISABLE<br>QUERY REWRITE | Specifies whether to enable query rewrite.                                                    | Disabled by default.<br>When <b>ENABLE QUERY REWRITE</b> is specified, you need to configure the GUC parameter <b>mv_rewrite_rule</b> to enable query rewrite of materialized views. |

| Parameter | Description                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| storage_parameter          | Allows for setting table properties of materialized views.<br><br>Parameters such as <b>mv_pck_column</b> , <b>bitmap_columns</b> , <b>enable_foreign_table_query_rewrite</b> , <b>excluded_inactive_tables</b> , <b>force_rewrite_timeout</b> , and <b>mv_analyze_mode</b> can be set. | For details, see <a href="#">Parameter Description</a> .              |
| new_owner                  | Specifies the owner of a materialized view.                                                                                                                                                                                                                                             | Name of an existing user.                                             |
| new_materialized_view_name | Indicates the name of the new materialized view.                                                                                                                                                                                                                                        | A string compliant with the <a href="#">identifier naming rules</a> . |

## Examples

Enable query rewrite for a materialized view.

```
ALTER MATERIALIZED VIEW mv1 ENABLE QUERY REWRITE;
NOTICE: REFRESH MATERIALIZED VIEW should be executed to enable query rewrite.
ALTER MATERIALIZED VIEW
```

Modify the table properties of a materialized view.

```
ALTER MATERIALIZED VIEW mv1 SET (force_rewrite_timeout=100);
ALTER MATERIALIZED VIEW mv1 SET (mv_pck_column='col1');
ALTER MATERIALIZED VIEW mv1 SET (enable_foreign_table_query_rewrite = true);
```

Change the refresh time of the materialized view.

```
ALTER MATERIALIZED VIEW mv1 REFRESH START WITH('2025-01-01 15:15:15'::timestampz) EVERY
(interval '60 s');
```

## Helpful Links

[CREATE MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

### 21.13.5.6 REFRESH MATERIALIZED VIEW

#### Function

REFRESH MATERIALIZED VIEW refreshes materialized views. This syntax is supported only by clusters of version 8.2.1.220 or later.

The refresh mode is specified by the REFRESH parameter in the [CREATE MATERIALIZED VIEW](#) syntax. Currently, full refresh and scheduled refresh are supported.

## Precautions

The refresh operation blocks the DML operations on the base table.

## Syntax

```
REFRESH MATERIALIZED VIEW
{[schema.]materialized_view_name} [[DEFAULT] | [RESTRICT] | [CASCADE FORWARD] | [CASCADE
BACKWARD] | [CASCADE ALL]]
```

## Parameter Description

**Table 21-201** REFRESH MATERIALIZED VIEW parameters

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                               | Value Range |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| materialize<br>d_view_na<br>me | Specifies the name of the materialized view to be refreshed.                                                                                                                                                                                                                                                                                              | -           |
| DEFAULT                        | Specifies default refresh. It means that a single materialized view is not refreshed only until the base table has changed.                                                                                                                                                                                                                               | -           |
| RESTRICT                       | Specifies forced refresh. It means that a materialized view is refreshed regardless of whether the base table has changed.                                                                                                                                                                                                                                | -           |
| CASCADE<br>FORWARD             | Indicates a cascading refresh in the upward direction, starts by refreshing the current materialized view, and then refreshes the nested materialized views that depend it. The default refresh method is used.                                                                                                                                           | -           |
| CASCADE<br>BACKWARD            | Specifies cascading refresh in the downward direction. The system refreshes the lowest-level materialized view that the current materialized view relies on, then continues to refresh the nested materialized views that depend on the lowest-level one, and finally refreshes the current materialized view itself. The default refresh method is used. | -           |
| CASCADE<br>ALL                 | Specifies all cascading refreshes. First, cascading refreshes are performed downward, and then cascading refreshes are performed upward.                                                                                                                                                                                                                  | -           |

## Examples

Refresh a materialized view.

```
REFRESH MATERIALIZED VIEW mv1;
```

Perform a cascading refresh in the downward direction for materialized views.

```
CREATE TABLE t1(a int,b int);
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM t1 where a > 0;
CREATE MATERIALIZED VIEW mv2 AS SELECT * FROM mv1;
INSERT INTO t1 values(1,1),(2,2);
REFRESH MATERIALIZED VIEW mv2 cascade backward; -- After refreshing mv2, the data in mv1 was also updated.

SELECT * FROM mv1 ORDER BY 1,2;
a | b
---+---
1 | 1
2 | 2
(2 rows)

SELECT * FROM mv2 ORDER BY 1,2;
a | b
---+---
1 | 1
2 | 2
(2 rows)
```

### 21.13.5.7 DROP MATERIALIZED VIEW

#### Function

Deletes a materialized view. This syntax is supported only by clusters of version 8.2.1.220 or later.

#### Precautions

None

#### Syntax

```
DROP MATERIALIZED VIEW [IF EXISTS]
{[schema.]materialized_view_name} [, ...] [CASCADE | RESTRICT];
```

#### Parameter Description

**Table 21-202** DROP MATERIALIZED VIEW parameters

| Parameter | Description                                                                           | Value Range |
|-----------|---------------------------------------------------------------------------------------|-------------|
| IF EXISTS | Sends a notice instead of an error if the specified materialized view does not exist. | -           |

| Parameter                  | Description                                                                                         | Value Range                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| materialize<br>d_view_name | Name of the materialized view to be deleted.                                                        | Name of an existing materialized view.                                                                                                                                                                                                                      |
| CASCADE  <br>RESTRICT      | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically deletes all objects that are contained in the schema to be deleted.</li><li>• <b>RESTRICT</b>: refuses to delete the schema that contains any objects. This is the default.</li></ul> |

## Examples

Delete a materialized view.

```
DROP MATERIALIZED VIEW mv1;
```

## 21.13.6 Indexes, Sequences, and File Directories

### 21.13.6.1 CREATE INDEX

#### Function

**CREATE INDEX** creates an index in a specified table. An index in a database is a specialized data structure designed to significantly drive data retrieval operations. An index acts like a sorted directory, allowing the database system to quickly locate specific rows without needing to scan the entire table.

An index has the following functions:

1. **Accelerating queries**

In database applications, full table scans on large datasets cause slow queries. Creating indexes resolves this by allowing the database to locate data directly, bypassing the need to scan every row. For example, an index on an **id** column lets the system instantly find the record **where id=100**, dramatically improving performance.

2. **Optimizing sorting and grouping operations**

Indexes such as B-tree indexes are ordered. When a query involves **ORDER BY** or **GROUP BY**, you can directly use the order of indexes to avoid extra sorting operations and improve efficiency.

### 3. Restricting data integrity

Some indexes (such as primary key indexes and unique indexes) can enforce unique values of columns (for example, primary keys cannot be duplicate), helping maintain data integrity.

## Index Types

DWS supports the following types of indexes:

- B-tree indexes store data keys using a structure like the B+ tree, enabling fast index searches. B-tree indexes support range queries, sorting, and equality queries.
- GIN indexes are inverted index designed for complex data types that contain multiple searchable keys, such as arrays. It is ideally suited for multi-value matching, full-text search, and fuzzy queries.
- GiST indexes apply to multi-dimensional data types (such as geometry and geography) and set data types. They apply to multi-dimensional data, spatial search, and complex scopes.
- PSORT indexes are used to perform partial sort on column-store tables.

Notes:

- Row-store tables: B-tree (default), GIN, and GiST indexes
- Column-store tables: PSORT (default), B-tree, and GIN indexes

Partitioned tables have two index types: local and global.

- Local indexes (partitioned indexes) apply to individual partitions within a partitioned table. Each local index matches one partition and shares its count and range with the table. If a table partition changes, only that specific index partition requires maintenance.
- Global indexes span across all partitions, covering the entire table's data regardless of how the base table is partitioned. However, DWS currently does not support global indexes.

## Indexing Methods

**Table 21-203** Indexing methods

| Method            | Description                                                                                                                                                                                                                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unique indexes    | An index ensures the uniqueness of one or multiple attributes by acting as a constraint. When a table defines a unique constraint or primary key, DWS generates a unique index—possibly for multiple columns—on those specific columns to enforce this rule. In DWS, only B-tree supports creating unique indexes. |
| Composite indexes | A table's index can include multiple attributes. In DWS, B-tree allows multi-column indexing with up to 32 columns.                                                                                                                                                                                                |

| Method           | Description                                                                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Partial indexes  | Refers to an index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.                                                 |
| Expression index | An index can be built on a function or expression derived from one or more table columns. This type of index functions only if queries use the exact expression used during its creation. |

## Principles for Creating Indexes

Indexes are primarily used to enhance database performance (though inappropriate use can result in slower database performance). You are advised to create indexes on:

- Columns that are often queried
- Join conditions. For a query on joined columns, you are advised to create a composite index on the columns, for example, **select \* from t1 join t2 on t1.a=t2.a and t1.b=t2.b**. You can create a composite index on the **a** and **b** columns of table **t1**.
- Columns having filter criteria (especially scope criteria) of a **where** clause
- Columns that appear after **order by**, **group by**, and **distinct**.
- For point queries, create a B-tree index.

The index creation syntax on a partitioned table differs from that on an ordinary table. The partitioned table does not support concurrent index creation, partial index creation, or **NULL FIRST**.

## Precautions

- Indexes consume storage and computing resources. Creating too many indexes has negative impact on database performance (especially the performance of data import. Therefore, you are advised to import the data before creating indexes). Create indexes only when they are necessary.
- All functions and operators used in an index definition must be immutable, that is, their results must depend only on their arguments and never on any outside influence (such as the contents of another table or the current time). This restriction ensures that the behavior of the index is well-defined. When using a user-defined function on an index or in a **WHERE** statement, mark it as an immutable function.
- An index created on a partitioned table must include a partition column and all the partition keys.
- DWS can only create local indexes on partitioned tables.
- Column-store and HDFS tables support B-tree indexes. If the indexes are used, you cannot create expression and partial indexes.
- Column-store tables support creating unique indexes using B-tree indexes.
- Column-store and HDFS tables support PSORT indexes. If the PSORT indexes are used, you cannot create expression, partial, or unique indexes.

- Column-store tables support GIN indexes, rather than partial indexes and unique indexes. If GIN indexes are used, you can create expression indexes. However, an expression in this situation cannot contain empty splitters, empty columns, or multiple columns.
- Column-store indexes do not support **OR** query filter criteria and **inlist** operations.
- A primary key or unique index cannot be created for a round-robin table.
- Performing **CREATE INDEX** or **REINDEX** operations on a table triggers index rebuilding. During this process, data is dumped to a new data file, and once rebuilding is complete, the original file is deleted. For large tables, index rebuilding can consume a significant amount of disk space. Exercise caution when disk space is insufficient to prevent the cluster from becoming read-only.

**WARNING**

- For a table where a large amount of data needs to be added, deleted, or modified, it is recommended that the number of indexes be less than or equal to three. The maximum number of indexes is five.
- Do not perform the **CREATE INDEX** and **REINDEX** operations on large tables during peak hours.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

## Syntax

- Create an index on a table.  

```
CREATE [UNIQUE] INDEX [[IF NOT EXISTS] [schema_name.] index_name] ON table_name
[USING method]
 (({ column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS
{ FIRST | LAST }] }, ...)
 [NULLS [NOT] DISTINCT | NULLS IGNORE]
 [COMMENT 'text']
 [WITH ({ storage_parameter = value } [, ...])]
 [WHERE predicate];
```
- Create an index for a partitioned table.  

```
CREATE [UNIQUE] INDEX [[IF NOT EXISTS] [schema_name.] index_name] ON table_name
[USING method]
 (({ column_name | (expression) } [COLLATE collation] [opclass] [ASC | DESC] [NULLS
LAST }] }, ...)
 [NULLS [NOT] DISTINCT | NULLS IGNORE]
 [COMMENT 'text']
 LOCAL [({ PARTITION index_partition_name } [, ...])]
 [WITH ({ storage_parameter = value } [, ...])]
 ;
```

## Parameter Description

**Table 21-204** CREATE INDEX parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| UNIQUE        | Causes the system to check for duplicate values in the table when the index is created (if data exists) and each time data is added. If the inserted or updated value causes duplicate records, an error is reported.<br><br>Currently, only B-tree indexes of row-store tables and column-store tables support unique indexes.                                                                                                                   | -                                                                                   |
| IF NOT EXISTS | If <b>IF NOT EXISTS</b> is specified and no index with the same name exists, the index can be created. If an index with the same name already exists, the system will simply display a message stating that the index already exists and will not perform any additional operations during creation. When <b>IF NOT EXISTS</b> is used, the index name must be specified. This parameter is supported only by clusters of version 9.1.0 or later. | -                                                                                   |
| schema_name   | Name of the schema where the index to be created is located. The specified schema name must be the same as the schema of the table.                                                                                                                                                                                                                                                                                                               | -                                                                                   |
| index_name    | Specifies the name of the index to be created. The schema of the index is the same as that of the table.                                                                                                                                                                                                                                                                                                                                          | A string, which must comply with the <a href="#">identifier naming convention</a> . |
| table_name    | Specifies the name of the table to be indexed (optionally schema-qualified).                                                                                                                                                                                                                                                                                                                                                                      | Name of an existing table                                                           |

| Parameter    | Description                                                                                                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USING method | <p>Specifies the name of the index method to be used.</p> <ul style="list-style-type: none"><li>Row-based tables support the following index types: <b>btree</b> (default), <b>gin</b>, and <b>gist</b>.</li><li>Column-based tables support the following index types: <b>psort</b> (default), <b>btree</b>, and <b>gin</b>.</li></ul> | <p>Value range:</p> <ul style="list-style-type: none"><li><b>btree</b>: B-tree indexes store data keys using a structure like the B+ tree, enabling fast index searches. B-tree indexes support comparison and range queries.</li><li><b>gin</b>: GIN indexes work like reverse lists and handle data with many elements, such as arrays.</li><li><b>gist</b>: GiST indexes work with multidimensional data like geometry, geography, and collections.</li><li><b>psort</b>: PSORT indexes are used to perform partial sort on column-store tables.</li></ul> |
| column_name  | <p>Specifies the name of a column of the table.</p>                                                                                                                                                                                                                                                                                     | <p>Multiple columns can be specified if the index method supports multi-column indexes. A maximum of 32 columns can be specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| expression   | <p>Specifies an expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax.</p>                                                                                                                                                                  | <p>However, the parentheses can be omitted if the expression has the form of a function call.</p> <p>Expression can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on <code>upper(col)</code> would allow the clause <code>WHERE upper(col) = 'JIM'</code> to use an index.</p> <p>If an expression contains <b>IS NULL</b>, the index for this expression is invalid. In this case, you are advised to create a partial index.</p>                                                     |

| Parameter            | Description                                                                                                                               | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COLLATE<br>collation | Assigns a collation to the column (which must be of a collatable data type). If no collation is specified, the default collation is used. | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| opclass              | Specifies the name of an operator class.                                                                                                  | Specifies an operator class for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on the type <code>int4</code> would use the <b><code>int4_ops</code></b> class; this operator class includes comparison functions for values of type <code>int4</code> .<br><br>In practice, the default operator class for the column's data type is sufficient. The operator class applies to data with multiple sorts. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index. |
| ASC                  | Indicates ascending sort order (default). This option is supported only by row storage.                                                   | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DESC                 | Indicates descending sort order. This option is supported only by row storage.                                                            | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| NULLS FIRST          | Specifies that nulls sort before not-null values. This is the default when <b>DESC</b> is specified.                                      | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| NULLS LAST           | Specifies that nulls sort after not-null values. This is the default when <b>DESC</b> is not specified.                                   | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NULLS DISTINCT<br>NULLS NOT DISTINCT<br>NULLS IGNORE | Specifies how NULL values of index columns in a Unique index are processed.                                                                                                      | <p>Default value: This parameter is left empty by default. NULL values can be inserted repeatedly.</p> <p>When the inserted data is compared with the original data in the table, the NULL value can be processed in any of the following ways:</p> <ul style="list-style-type: none"><li>• <b>NULLS DISTINCT:</b> Each NULL is treated as unique, allowing repeated insertions of NULLs.</li><li>• <b>NULLS NOT DISTINCT:</b> All NULLs are seen as identical, so only one NULL is kept in the index, preventing repeated NULL insertions; only distinct non-NULL values can be added.</li><li>• <b>NULLS IGNORE:</b> NULL values are skipped during the equivalent comparison. If all indexed columns are NULL, NULLs can be inserted repeatedly; if some columns are NULL, only new non-NULL values differing from existing ones can be added.</li></ul> <p>The following table <a href="#">Table 21-206</a> lists the behaviors of the three processing modes.</p> |
| COMMENT 'text'                                       | Specifies the comment of an index.                                                                                                                                               | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| WITH<br>( {storage_parameter = value}<br>[, ... ] )  | Specifies the name of an index-method-specific storage parameter. Its value can be <b>FILLFACTOR</b> , <b>INVISIBLE</b> , <b>FASTUPDATE</b> , or <b>GIN_PENDING_LIST_LIMIT</b> . | For details about the value range and usage, see <a href="#">Table 21-205</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Value Range                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WHERE predicate                   | Creates a partial index.<br>A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet that is an often used section, you can improve performance by creating an index on just that portion. Another possible application is to use <b>WHERE</b> with <b>UNIQUE</b> to enforce uniqueness over a subset of a table. | Predicate expression can refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Presently, subquery and aggregate expressions are also forbidden in <b>WHERE</b> . |
| LOCAL                             | Local indexes (partitioned indexes) are created on each partition of a partitioned table. A local index corresponds to a partition of the partitioned table, and has the same number of partitions and the same partition range as the table. When the table partition changes, you only need to maintain the corresponding index partition.                                                                                                                                                                                                                                          | -                                                                                                                                                                                                                       |
| PARTITION<br>index_partition_name | Specifies the name of the index partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A string, which must comply with the naming convention.                                                                                                                                                                 |

**Table 21-205** WITH ( {storage\_parameter = value} [, ... ] ) parameter

| Storage Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Example                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILLFACTOR</b> | <p><b>This parameter is unavailable for GIN and PSORT indexes.</b> It indicates the fill factor of an index and its value is a percentage between 10 and 100. Index pages are packed only to the indicated percentage and the remaining space is used for subsequent INSERT and UPDATE operations, thereby reducing page splits and improving performance.</p> <p>This parameter determines the percentage of space on index pages to be packed, which affects the database performance and storage space usage. You can adjust its value to reduce page splits caused by subsequent INSERT and UPDATE operations, optimizing the storage and performance of indexes.</p> <p><b>Impact of FILLFACTOR on index performance:</b></p> <ul style="list-style-type: none"><li>● <b>Performance:</b> When an index page is fully packed and a new record needs to be inserted, the page will be split, consuming more I/O resources and time. A lower fillfactor can reduce page splits and improve the INSERT and UPDATE performance, but will increase the storage space usage. A higher fillfactor can improve the storage space usage, but may cause more page splits and degrade the INSERT and UPDATE performance.</li><li>● <b>Storage space:</b> A lower fillfactor increases the free space of each data page. A higher fillfactor stores data more compactly, reducing disk space usage.</li></ul> | <p>Create a specified B-tree index on the <b>SM_SHIP_MODE_SK</b> column in the <b>tpcds.ship_mode_t1</b> table and set <b>FILLFACTOR</b> of the index to <b>70%</b>.</p> <p>This means that each data page is only 70% full when initially packed. The remaining 30% space is reserved for future INSERT and UPDATE operations.</p> <pre>CREATE INDEX ds_ship_mode_t1_index6 ON tpcds.ship_mode_t1 USING btree(SM_SHIP_MODE_SK) WITH (FILLFACTOR = 70);</pre> |

| Storage Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Example                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>GIN_PENDING_LIST_LIMIT</b> | <p><b>This parameter is supported only by GIN indexes.</b> When fast update is enabled for GIN indexes, you can use this parameter to set the maximum size of the pending list of GIN indexes.</p> <p><b>Pending List</b> is a data structure specific to GIN indexes and is used to temporarily store index update operations. When the <b>FASTUPDATE</b> parameter is enabled for a GIN index, new index items are not directly written to the main index structure, but are stored in the pending list. When conditions are met, the index items are merged into the main index in batches.</p> <p><b>Value range:</b> 64 to <i>INT_MAX</i>. The unit is KB.</p> <p><b>Default value:</b> determined by the value of <b>gin_pending_list_limit</b> (4 MB by default).</p> |         |

**Table 21-206** Processing of NULL values in index columns in unique indexes

| Constraint         | All Index Columns Are NULL     | Some Index Columns Are NULL.                                                                               |
|--------------------|--------------------------------|------------------------------------------------------------------------------------------------------------|
| NULLS DISTINCT     | Can be inserted repeatedly.    | Can be inserted repeatedly.                                                                                |
| NULLS NOT DISTINCT | Cannot be inserted repeatedly. | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |
| NULLS IGNORE       | Can be inserted repeatedly.    | Cannot be inserted if the non-null values are equal. Can be inserted if the non-null values are not equal. |

## Example

- Create a sample table named **tpcds.ship\_mode\_t1**.

```
CREATE SCHEMA tpcds;
DROP TABLE IF EXISTS tpcds.ship_mode_t1;
CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
)
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);
```

Create a unique index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table.

```
CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

Create a unique index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table and specify how to process null values.

```
CREATE UNIQUE INDEX ds_ship_mode_t1_index5 ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK)
NULLS NOT DISTINCT;
```

Add comment to the index when creating an index on the **SM\_SHIP\_MODE\_SK** column of table **tpcds.ship\_mode\_t1**.

```
CREATE INDEX ds_ship_mode_t1_index_comment ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK)
COMMENT 'index';
```

Create a B-tree index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table.

```
CREATE INDEX ds_ship_mode_t1_index4 ON tpcds.ship_mode_t1 USING btree(SM_SHIP_MODE_SK);
```

Create a specified B-tree index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table and set **FILLFACTOR** of the index to **70%**.

```
CREATE INDEX ds_ship_mode_t1_index6 ON tpcds.ship_mode_t1 USING btree(SM_SHIP_MODE_SK)
WITH (FILLFACTOR = 70);
```

Create a specified B-tree index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table and set **INVISIBLE** to **ON** (**ON** indicates that optimizer does not generate the index scan plan. The default value is **OFF**).

```
CREATE INDEX ds_ship_mode_t1_index7 ON tpcds.ship_mode_t1 USING btree(SM_SHIP_MODE_SK)
WITH (INVISIBLE = ON);
```

Create a GIN index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table, enable fast update by configuring the **FASTUPDATE** parameter, and set the maximum pending list size of the index to 8 MB.

```
CREATE INDEX ds_ship_mode_t1_index8 ON tpcds.ship_mode_t1 USING gin(SM_SHIP_MODE_SK)
WITH (FASTUPDATE = ON, GIN_PENDING_LIST_LIMIT = 8192);
```

Create an expression index on the **SM\_CODE** column in the **tpcds.ship\_mode\_t1** table.

```
CREATE INDEX ds_ship_mode_t1_index2 ON tpcds.ship_mode_t1(SUBSTR(SM_CODE,1,4));
```

Create a partial index on the **SM\_SHIP\_MODE\_SK** column where **SM\_SHIP\_MODE\_SK** is greater than **10** in the **tpcds.ship\_mode\_t1** table.

```
CREATE UNIQUE INDEX ds_ship_mode_t1_index3 ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK)
WHERE SM_SHIP_MODE_SK>10;
```

- Create a sample table named **tpcds.customer\_address\_p1**.

```
CREATE TABLE tpcds.customer_address_p1
(
 CA_ADDRESS_SK INTEGER NOT NULL,
 CA_ADDRESS_ID CHAR(16) NOT NULL,
```

```
CA_STREET_NUMBER CHAR(10) ,
CA_STREET_NAME VARCHAR(60) ,
CA_STREET_TYPE CHAR(15) ,
CA_SUITE_NUMBER CHAR(10) ,
CA_CITY VARCHAR(60) ,
CA_COUNTY VARCHAR(30) ,
CA_STATE CHAR(2) ,
CA_ZIP CHAR(10) ,
CA_COUNTRY VARCHAR(20) ,
CA_GMT_OFFSET DECIMAL(5,2) ,
CA_LOCATION_TYPE CHAR(20)
)
DISTRIBUTE BY HASH(CA_ADDRESS_SK)
PARTITION BY RANGE(CA_ADDRESS_SK)
(
 PARTITION p1 VALUES LESS THAN (3000),
 PARTITION p2 VALUES LESS THAN (5000) ,
 PARTITION p3 VALUES LESS THAN (MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

Create the partitioned table index **ds\_customer\_address\_p1\_index1** with the name of the index partition not specified.

```
CREATE INDEX ds_customer_address_p1_index1 ON tpcds.customer_address_p1(CA_ADDRESS_SK)
LOCAL;
```

Create the partitioned table index **ds\_customer\_address\_p1\_index2** with the name of the index partition specified.

```
CREATE INDEX ds_customer_address_p1_index2 ON tpcds.customer_address_p1(CA_ADDRESS_SK)
LOCAL
(
 PARTITION CA_ADDRESS_SK_index1,
 PARTITION CA_ADDRESS_SK_index2,
 PARTITION CA_ADDRESS_SK_index3
)
;
```

Create the partitioned table index **ds\_customer\_address\_p1\_index\_comment** and add index comments.

```
CREATE INDEX ds_customer_address_p1_index_comment ON
tpcds.customer_address_p1(CA_ADDRESS_SK) COMMENT 'index' LOCAL
(
 PARTITION CA_ADDRESS_SK_index1,

## Application Differences Among NULLS DISTINCT, NULLS NOT DISTINCT, and NULLS IGNORE

Examples are provided below to illustrate the differences.

### Example

Assume that there is a **users** table that contains ID and Email (which may be NULL, indicating that no email address is provided).

#### Scenario 1: NULLS DISTINCT (NULL can be inserted repeatedly) (default)

```
--Create a table.
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT,
 email TEXT
```

```
)
DISTRIBUTE BY HASH(email);
--Create a unique index (NULLS DISTINCT by default).
CREATE UNIQUE INDEX idx_email_unique ON users (email);
--Insert data.
INSERT INTO users (id, email) VALUES (1, NULL); -- Success
INSERT INTO users (id, email) VALUES (2, NULL); -- Success (with each NULL treated as unique)
INSERT INTO users (id, email) VALUES (3, 'a@example.com'); -- Success
INSERT INTO users (id, email) VALUES (4, 'a@example.com'); -- Failure (duplicate non-NULL values)
```

```
error_code: DWS.S0010010
error_msg: Constraint Violation. STATE: 23505, message: ERROR: dn_6005_6006: duplicate key value
violates unique constraint "idx_email_unique"
Detail: Key (email)=(a@example.com) already exists.
```

### Scenario 2: NULLS NOT DISTINCT (NULL cannot be inserted repeatedly)

```
--Re-create a unique index and specify NULLS NOT DISTINCT.
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT,
 email TEXT
)
DISTRIBUTE BY HASH(email);
CREATE UNIQUE INDEX idx_email_unique ON users (email) NULLS NOT DISTINCT;
--Insert data.
INSERT INTO users (id, email) VALUES (5, NULL); -- Success (the first NULL)
INSERT INTO users (id, email) VALUES (6, NULL); -- Failure (the second NULL, violating the unique
constraint)
INSERT INTO users (id, email) VALUES (7, 'b@example.com'); -- Success
INSERT INTO users (id, email) VALUES (8, 'b@example.com'); -- Failure (duplicate non-NULL values)
```

### Scenario 3: NULLS IGNORE (NULL values are ignored.)

```
--Create an index and ignore NULL values.
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT,
 email TEXT
)
DISTRIBUTE BY HASH(email);
CREATE UNIQUE INDEX idx_email_ignore ON users (email) NULLS IGNORE;
--Insert data.
INSERT INTO users (id, email) VALUES (9, NULL); -- Success (the first NULL)
INSERT INTO users (id, email) VALUES (10, NULL); -- Success (NULL values are ignored.)
INSERT INTO users (id, email) VALUES (11, 'c@example.com'); -- Success
INSERT INTO users (id, email) VALUES (12, 'c@example.com'); -- Failure (duplicate non-NULL values)
```

## Helpful Links

- For details about how to modify and delete indexes, see [ALTER INDEX](#) and [DROP INDEX](#).
- For more index examples, see "Creating and Managing Indexes" in the *Data Warehouse Service (DWS) Developer Guide*.

## 21.13.6.2 ALTER INDEX

### Function

**ALTER INDEX** modifies the definition of an index.

## Precautions

Only the owner of an index or a system administrator can run this statement.

## Syntax

- Rename a table index. The new index name can be prefixed with the name of the schema where the original index is located, but the schema name cannot be changed at the same time.

```
ALTER INDEX [IF EXISTS] index_name
 RENAME TO new_name;
ALTER INDEX [IF EXISTS] index_name
 RENAME TO schema.new_name;
```

- Modify the storage parameter of a table index.

```
ALTER INDEX [IF EXISTS] index_name
 SET ({storage_parameter = value} [, ...]);
```

- Modify the status flag of an index.

```
ALTER INDEX [IF EXISTS] index_name
 SET ({invisible = value} [, ...]);
```

- Reset the storage parameter of a table index.

```
ALTER INDEX [IF EXISTS] index_name
 RESET (storage_parameter [, ...]);
```

- Set a table index or an index partition to be unavailable. **The syntax cannot be used for column-store tables.**

```
ALTER INDEX [IF EXISTS] index_name
 [MODIFY PARTITION index_partition_name] UNUSABLE;
```

- Rebuild a table index or index partition.

```
ALTER INDEX index_name
 REBUILD [PARTITION index_partition_name] [WITHOUT UNUSABLE];
```

- Rename an index partition. When **PG\_OBJECT** record the last modification time of an index, this syntax cannot be recorded.

```
ALTER INDEX [IF EXISTS] index_name
 RENAME PARTITION index_partition_name TO new_index_partition_name;
```

- Add and modify the index comment.

```
ALTER INDEX [IF EXISTS] index_name
 COMMENT 'text';
```

- Delete the index comment.

```
ALTER INDEX [IF EXISTS] index_name
 COMMENT '';
ALTER INDEX [IF EXISTS] index_name
 COMMENT NULL;
```

## Parameter Description

Table 21-207 ALTER INDEX parameters

| Parameter | Description                                                                      | Value Range |
|-----------|----------------------------------------------------------------------------------|-------------|
| IF EXISTS | If the specified index does not exist, a prompt instead of an error is returned. | -           |
| RENAME TO | Renames an index. It has no impact on the stored data.                           | -           |

| Parameter                                                | Description                                                                                                                                                                                                                            | Value Range                                                                     |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| SET<br>( { STORAGE_PARAMETER<br>= value } [, ...] )      | Changes one or more index-method-specific storage parameters. This command does not change the index content right away. Depending on the settings, you might need to rebuild the index with <b>REINDEX</b> to get the desired result. | For details about the value range and usage, see <a href="#">Table 21-208</a> . |
| RESET<br>( { storage_parameter }<br>[, ...] )            | Resets one or more index method-specific storage parameters of an index to default values. Similar to the <b>SET</b> statement, <b>REINDEX</b> may be used to completely update the index.                                             | -                                                                               |
| [ MODIFY PARTITION<br>index_partition_name ]<br>UNUSABLE | Sets the index on a table or index partition to be unavailable.                                                                                                                                                                        | -                                                                               |
| REBUILD [ PARTITION<br>index_partition_name ]            | Recreates the index on a table or index partition.                                                                                                                                                                                     | -                                                                               |
| WITHOUT UNUSABLE                                         | Indexes that are in an UNUSABLE state are not rebuilt when rebuilding indexes in tables or index partitions.                                                                                                                           | -                                                                               |
| RENAME PARTITION                                         | Renames an index partition.                                                                                                                                                                                                            | -                                                                               |
| COMMENT comment_text                                     | Adds, modifies, or deletes index comments.                                                                                                                                                                                             | -                                                                               |
| index_name                                               | Specifies the index name to be modified.                                                                                                                                                                                               | Name of an existing index.                                                      |
| new_name                                                 | Specifies the new name for the index.                                                                                                                                                                                                  | A string compliant with the <a href="#">identifier naming rules</a> .           |
| storage_parameter                                        | Specifies the name of an index-method-specific parameter.                                                                                                                                                                              | -                                                                               |

| Parameter                | Description                                                                                                                          | Value Range                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| invisible                | Controls whether the optimizer generates index scan plans. The default value is <b>OFF</b> .                                         | <b>ON</b> or <b>OFF</b> . <ul style="list-style-type: none"><li>• <b>ON</b> indicates that no index scan plan is generated.</li><li>• <b>OFF</b> indicates that an index scan plan is generated.</li></ul> |
| value                    | Specifies the new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter. | -                                                                                                                                                                                                          |
| new_index_partition_name | Specifies the new name of the index partition.                                                                                       | A string compliant with the <a href="#">identifier naming rules</a> .                                                                                                                                      |
| index_partition_name     | Specifies the name of the index partition.                                                                                           | A string compliant with the <a href="#">identifier naming rules</a> .                                                                                                                                      |
| comment_text             | Specifies the comment of an index.                                                                                                   | -                                                                                                                                                                                                          |

**Table 21-208** WITH ( {storage\_parameter = value} [, ... ] ) parameter description

| Storage Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Example                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| FILLFACTOR        | <p><b>This parameter is unavailable for GIN and PSORT indexes.</b> It indicates the fill factor of an index and its value is a percentage between 10 to 100. Index pages are packed only to the indicated percentage and the remaining space is used for subsequent INSERT and UPDATE operations, thereby reducing page splits and improving performance.</p> <p>This parameter determines the percentage of space on index pages to be packed, which affects the database performance and storage space usage. You can adjust its value to reduce page splits caused by subsequent INSERT and UPDATE operations, optimizing the storage and performance of indexes.</p> <p><b>Impact of FILLFACTOR on index performance:</b></p> <ul style="list-style-type: none"><li>● <b>Performance:</b> When an index page is fully packed and a new record needs to be inserted, the page will be split, consuming more I/O resources and time. A lower fillfactor can reduce page splits and improve the INSERT and UPDATE performance, but will increase the storage space usage. A higher fillfactor can improve the storage space usage, but may cause more page splits and degrade the INSERT and UPDATE performance.</li><li>● <b>Storage space:</b> A lower fillfactor increases the free space of each data page. A higher fillfactor stores data more compactly, reducing disk space usage.</li></ul> | <p>Change the fillfactor of an index to 60%.</p> <pre>ALTER INDEX<br/>tpcds.ds_ship_mode_t1_index7<br/>SET (FILLFACTOR = 60);</pre> |

| Storage Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Example                                                                                                                                                                                                                 |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p><b>How to configure FILLFACTOR:</b></p> <ul style="list-style-type: none"><li>For tables that are frequently updated, set <b>FILLFACTOR</b> to a small value, for example, <b>60</b> to <b>80</b>, to reserve space and reduce page splits.</li><li>For tables that are rarely updated, set <b>FILLFACTOR</b> to a large value, for example, <b>90</b> to <b>100</b>, to maximize storage space.</li></ul>                                                              |                                                                                                                                                                                                                         |
| <b>INVISIBLE</b>  | <p>Controls whether the optimizer generates index scan plans.</p> <p><b>Scenario:</b> If you want to disable indexes temporarily during maintenance or test the impact of indexes on performance, you can use this parameter.</p> <p><b>Value range:</b></p> <ul style="list-style-type: none"><li><b>ON</b> indicates that no index scan plan is generated.</li><li><b>OFF</b> indicates that an index scan plan is generated.</li></ul> <p><b>Default value: OFF</b></p> | <p>Not allow the optimizer to generate any index scan plan.</p> <pre>ALTER INDEX<br/>tpcds.ds_ship_mode_t1_index9<br/>SET (INVISIBLE = ON);</pre>                                                                       |
| <b>FASTUPDATE</b> | <p><b>This parameter is available only for GIN indexes.</b> It controls whether to enable fast update for GIN indexes. | Storage Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Example |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| <b>GIN_PENDING_LIST_LIMIT</b> | <p><b>This parameter is supported only by GIN indexes.</b> When fast update is enabled for GIN indexes, you can use this parameter to set the maximum size of the pending list of GIN indexes.</p> <p>The pending list is a data structure specific to GIN indexes and is used to temporarily store index update operations. When <b>FASTUPDATE</b> is enabled for a GIN index, new index items are not directly written to the main index structure, but are stored in the pending list. When conditions are met, the index items are merged into the main index in batches.</p> <p><b>Value range:</b> 64 to <i>INT_MAX</i>.<br/>The unit is KB.</p> <p><b>Default value:</b> determined by the value of <b>gin_pending_list_limit</b> (4 MB by default).</p> |         |

## Examples

Create a sample table named **tpcds.ship\_mode\_t1**.

```
DROP TABLE IF EXISTS tpcds.ship_mode_t1;
CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
)
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);
```

Create a unique index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table.

```
DROP INDEX IF EXISTS ds_ship_mode_t1_index1;
CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

Create an expression index on the **SM\_CODE** column in the **tpcds.ship\_mode\_t1** table.

```
DROP INDEX IF EXISTS ds_ship_mode_t1_index2;
CREATE INDEX ds_ship_mode_t1_index2 ON tpcds.ship_mode_t1(SUBSTR(SM_CODE,1,4));
```

Rename the **ds\_ship\_mode\_t1\_index1** index to **ds\_ship\_mode\_t1\_index5**.

```
ALTER INDEX tpcds.ds_ship_mode_t1_index1 RENAME TO ds_ship_mode_t1_index5;
```

Set the **ds\_ship\_mode\_t1\_index2** index as unusable.

```
ALTER INDEX tpcds.ds_ship_mode_t1_index2 UNUSABLE;
```

Rebuild the **ds\_ship\_mode\_t1\_index2** index.

```
ALTER INDEX tpcds.ds_ship_mode_t1_index2 REBUILD;
```

### 21.13.6.3 REINDEX

#### Function

**REINDEX** rebuilds an index using the data stored in the index's table, replacing the old copy of the index.

There are several scenarios in which **REINDEX** can be used:

- An index has become corrupted, and no longer contains valid data.
- An index has become "bloated", that is, it contains many empty or nearly-empty pages.
- You have altered a storage parameter (such as fillfactor) for an index, and wish to ensure that the change has taken full effect.

An index build with the **CONCURRENTLY** option failed, leaving an "invalid" index.

#### Precautions

Index reconstruction of the **REINDEX DATABASE** or **SYSTEM** type cannot be performed in transaction blocks.

In the storage-compute decoupling architecture, REINDEX full database indexes are not supported.

#### WARNING

- Do not perform the **CREATE INDEX** and **REINDEX** operations on large tables during peak hours.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

#### Syntax

- Recreate indexes for the entire database or system catalogs.  

```
REINDEX { DATABASE | SYSTEM } name [FORCE];
```

- Recreate an ordinary index or an index on an ordinary table.  
`REINDEX { INDEX | TABLE } name [ FORCE | WITHOUT UNUSABLE ]`
- Recreate an index partition or an index on a partition.  
`REINDEX { | TABLE } name  
PARTITION partition_name [ FORCE | WITHOUT UNUSABLE ];`

## Parameter Description

Table 21-209 REINDEX parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INDEX            | Recreates the specified index.                                                                                                                                                                                                                                                                     | -                                                                                                                                                                                                  |
| TABLE            | Recreates all indexes of the specified table. If the table has a secondary TOAST table, that is reindexed as well.                                                                                                                                                                                 | -                                                                                                                                                                                                  |
| DATABASE         | Recreates all indexes within the current database.                                                                                                                                                                                                                                                 | -                                                                                                                                                                                                  |
| SYSTEM           | Recreates all indexes on system catalogs within the current database. Indexes on user tables are not processed.                                                                                                                                                                                    | -                                                                                                                                                                                                  |
| name             | Name of the specific index, table, or database to be reindexed. Index and table names can be schema-qualified.<br><b>NOTE</b><br><b>REINDEX DATABASE</b> and <b>SYSTEM</b> can create indexes for only the current database. Therefore, <b>name</b> must be the same as the current database name. | -                                                                                                                                                                                                  |
| FORCE            | This is an obsolete option. It is ignored if specified.                                                                                                                                                                                                                                            | -                                                                                                                                                                                                  |
| WITHOUT UNUSABLE | If this parameter is specified, the <b>UNUSABLE</b> indexes or <b>UNUSABLE</b> index partitions on the object is ignored during <b>REINDEX</b> . This parameter is supported only by 9.1.0.100 and later versions.                                                                                 | -                                                                                                                                                                                                  |
| partition_name   | Specifies the name of the partition or index partition to be reindexed.                                                                                                                                                                                                                            | <ul style="list-style-type: none"><li>• If it is <b>REINDEX INDEX</b>, specify the name of an index partition.</li><li>• If it is <b>REINDEX TABLE</b>, specify the name of a partition.</li></ul> |

**NOTICE**

Index reconstruction of the **REINDEX DATABASE** or **SYSTEM** type cannot be performed in transaction blocks.

## Examples

Rebuild a single index.

```
REINDEX INDEX tpcds.tpcds_customer_index1;
```

Rebuild all indexes on the **tpcds.customer\_t1** table.

```
REINDEX TABLE tpcds.customer_t1;
```

Rebuild the partition index of partition **P1** in the partitioned table **customer\_address**.

```
DROP TABLE IF EXISTS customer_address;
CREATE TABLE customer_address
(
 ca_address_sk INTEGER NOT NULL ,
 ca_address_id CHARACTER(16) NOT NULL ,
 ca_street_number CHARACTER(10) ,
 ca_street_name CHARACTER varying(60) ,
 ca_street_type CHARACTER(15) ,
 ca_suite_number CHARACTER(10)
)
DISTRIBUTE BY HASH (ca_address_sk)
PARTITION BY RANGE(ca_address_sk)
(
 PARTITION P1 VALUES LESS THAN(2450815),
 PARTITION P2 VALUES LESS THAN(2451179),
 PARTITION P3 VALUES LESS THAN(2451544),
 PARTITION P4 VALUES LESS THAN(MAXVALUE)
);

CREATE INDEX customer_address_index on customer_address(CA_ADDRESS_SK) LOCAL;
REINDEX TABLE customer_address PARTITION P1;
```

### 21.13.6.4 DROP INDEX

#### Function

**DROP INDEX** deletes an index.

#### Precautions

Only the owner of an index or a system administrator can run **DROP INDEX** command.

#### Syntax

```
DROP INDEX [CONCURRENTLY][IF EXISTS]
index_name [, ...] [CASCADE | RESTRICT];
```

## Parameter Description

**Table 21-210** DROP INDEX parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                               |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CONCURRENTLY       | Deletes an index without locking concurrent selections, inserts, updates, and deletes on the index table. A normal <b>DROP INDEX</b> obtains an exclusive lock on the table to prevent other access until the index is deleted. With this option, the command waits until the conflicting transaction is complete.<br><b>NOTE</b><br>Note that only one index name can be specified and the <b>CASCADE</b> option is not supported. (Therefore, indexes that support <b>UNIQUE</b> or <b>PRIMARY KEY</b> constraints cannot be deleted in this way.) Regular <b>DROP INDEX</b> commands can be executed within a transaction block, but cannot be executed in <b>DROP INDEX CONCURRENTLY</b> mode. | -                                                                                                                                                                                                                                         |
| IF EXISTS          | Sends a notice instead of an error if the specified index does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | -                                                                                                                                                                                                                                         |
| index_name         | Specifies the name of the index to be deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | An existing index.                                                                                                                                                                                                                        |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically deletes all objects that depend on the index to be deleted.</li><li>• <b>RESTRICT</b> (default): refuses to delete the index if any objects depend on it.</li></ul> |

## Examples

Delete the **ds\_ship\_mode\_t1\_index2** index.

```
DROP INDEX tpcds.ds_ship_mode_t1_index2;
```

## 21.13.6.5 CREATE SEQUENCE

### Function

**CREATE SEQUENCE** adds a sequence to the current database.

A sequence is a database object that generates a series of unique, ascending, or descending values. It is mainly used to generate the primary key or unique identifier in a table.

### Precautions

- The user who creates a sequence is the owner of the sequence.
- If a schema name is specified, the sequence is created in the specified schema. Otherwise, the text search configuration is created in the current schema. The sequence name must be different from the names of other sequences, tables, indexes, views in the same schema.
- After the sequence is created, functions `nextval()` and `generate_series(1,N)` insert data to the table. Make sure that the number of times for invoking `nextval` is greater than or equal to `N+1`. Otherwise, errors will be reported because the number of times for invoking function `generate_series()` is `N+1`.
- A sequence cannot be created in the **template1** database.
- You are advised to control the number of sequences (including the SERIAL type). In distributed scenarios, sequence values are generated based on GTM. Frequent interaction with GTM severely affects performance. You are advised to reference the public sequence object or use UUIDs for unique values. To minimize the interaction with GTM, you are advised to set **CACHE** of a manually created sequence to a value greater than or equal to 10000.

### Syntax

```
CREATE SEQUENCE [IF NOT EXISTS] name [INCREMENT [BY] increment]
 [MINVALUE minvalue | NO MINVALUE | NOMINVALUE] [MAXVALUE maxvalue | NO MAXVALUE |
NOMAXVALUE]
 [START [WITH] start] [CACHE cache] [[NO] CYCLE | NOCYCLE]
 [OWNED BY { table_name.column_name | NONE }];
```

## Parameter Description

**Table 21-211** CREATE SEQUENCE parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                           | Value Range                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| IF NOT EXISTS | If <b>IF NOT EXISTS</b> is specified and a sequence with the same name does not exist, the sequence can be created successfully. If a sequence with the same name already exists during sequence creation, the system will display a message indicating that the sequence already exists and no further operations will be performed. No error will be reported.<br><br>This parameter is supported only by 9.1.0 and later versions. | -                                                                     |
| name          | Specifies the name of the sequence to be created.                                                                                                                                                                                                                                                                                                                                                                                     | A string compliant with the <a href="#">identifier naming rules</a> . |
| increment     | Specifies the step for a sequence. If the increment is a positive value, an increasing sequence is to be created. If the increment is a negative value, a decreasing sequence is to be created.<br><br>The default value is <b>1</b> .                                                                                                                                                                                                | -                                                                     |

| Parameter                                            | Description                                                                                                                                                                                                                                                                                                                            | Value Range |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| MINVALUE<br>minvalue   NO<br>MINVALUE <br>NOMINVALUE | Specifies the minimum value that can be generated by the sequence. If <b>MINVALUE</b> is not specified, or <b>NO MINVALUE</b> is specified, the default value of the ascending sequence is <b>1</b> , and that of the descending sequence is <b>-2<sup>63</sup>-1</b> .<br><br><b>NOMINVALUE</b> is equivalent to <b>NO MINVALUE</b> . | -           |
| MAXVALUE<br>maxvalue   NO<br>MAXVALUE <br>NOMAXVALUE | Specifies the maximum value that can be generated by the sequence. If <b>MAXVALUE</b> is not declared or <b>NO MAXVALUE</b> is declared, the default value of the ascending sequence is <b>2<sup>63</sup>-1</b> , and that of the descending sequence is <b>-1</b> .<br><br><b>NOMAXVALUE</b> is equivalent to <b>NO MAXVALUE</b> .    | -           |
| start                                                | Specifies the start value of the sequence.<br><br>The default value for ascending sequences is <b>minvalue</b> and for descending sequences <b>maxvalue</b> .                                                                                                                                                                          | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cache     | <p>Specifies the number of sequence numbers that are cached (pre-allocated) to the memory in a database for faster access. Within a cache period, the CN does not request a sequence number from the GTM. Instead, the CN uses the sequence number that is locally applied for in advance.</p> <p>In cluster versions 9.1.0.100 and later, the default value is specified by the GUC parameter <b>default_sequence_cache</b>.</p> <ul style="list-style-type: none"><li>• In a newly installed cluster of 9.1.0.100 or later, the default value is <b>20</b>.</li><li>• If the cluster is upgraded from an earlier version to 9.1.0.100 or later, the default value is <b>1</b>. Indicates that only one value can be generated at a time, that is, no cache.</li></ul> | <ul style="list-style-type: none"><li>• It is not recommended that you define <b>cache</b>, and <b>maxvalue</b>, and <b>minvalue</b> at the same time. The continuity of sequences cannot be ensured after <b>cache</b> is defined because unacknowledged sequences may be generated, wasting sequence number segments.</li><li>• You are advised not to set a large value for <b>cache</b> (less than 100000000). Otherwise, it takes a long time to cache the sequence number (the first <b>NEXTVAL</b> in each cache period). Set a proper value for <b>cache</b> based on services to ensure quick access without wasting sequence numbers.</li></ul> |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CYCLE   NOCYCLE | <p>Recycles sequences after the number of sequences reaches <b>maxvalue</b> or <b>minvalue</b>.</p> <p>The default value is <b>NO CYCLE</b>, indicating that no new value can be generated after the sequence reaches the maximum or minimum value. <b>NOCYCLE</b> is equivalent to <b>NO CYCLE</b>.</p> <ul style="list-style-type: none"><li>• If the sequence is defined as <b>CYCLE</b>, the sequence uniqueness cannot be ensured.</li><li>• If <b>NO CYCLE</b> is specified, any invocation of <b>nextval</b> would return an error after the sequence reaches its maximum value.</li></ul> | -                                                                                                                                                                                                                                                                                                                                                                                        |
| OWNED BY        | <p>Associates a sequence with a specified column of a specific table. If the column or the table where the column is located is deleted, the sequence is automatically deleted. The associated table and sequence must be owned by the same user and in the same schema.</p> <p>If the default value is <b>OWNED BY NONE</b>, indicating that such association does not exist.</p>                                                                                                                                                                                                                | <ul style="list-style-type: none"><li>• <b>OWNED BY</b> only establishes the association between a table column and the sequence. The sequence is not created for this column.</li><li>• You are not advised to use the sequence created using <b>OWNED BY</b> in other tables. If multiple tables need to share a sequence, the sequence must not belong to a specific table.</li></ul> |

## Examples

Create an ascending sequence named **serial**, which starts from 101:

```
CREATE SEQUENCE serial
START 101
CACHE 20;
```

Select the next number from the sequence:

```
SELECT nextval('serial');
nextval

101
```

Select the next number from the sequence:

```
SELECT nextval('serial');
nextval

102
```

Create a sequence associated with the table:

```
CREATE TABLE customer_address
(
 ca_address_sk integer not null,
 ca_address_id char(16) not null,
 ca_street_number char(10) ,
 ca_street_name varchar(60) ,
 ca_street_type char(15) ,
 ca_suite_number char(10) ,
 ca_city varchar(60) ,
 ca_county varchar(30) ,
 ca_state char(2) ,
 ca_zip char(10) ,
 ca_country varchar(20) ,
 ca_gmt_offset decimal(5,2) ,
 ca_location_type char(20)
);

CREATE SEQUENCE serial1
START 101
CACHE 20
OWNED BY customer_address.ca_address_sk;
```

Use **SERIAL** to create a serial table **serial\_table** for primary key auto-increment.

```
CREATE TABLE serial_table(a int, b serial);
INSERT INTO serial_table (a) VALUES (1),(2),(3);
SELECT * FROM serial_table ORDER BY b;
a | b
---+---
1 | 1
2 | 2
3 | 3
(3 rows)
```

## Helpful Links

[ALTER SEQUENCE, DROP SEQUENCE](#)

### 21.13.6.6 ALTER SEQUENCE

#### Function

Modifies the sequence definition.

#### Precautions

- You must be the owner of the sequence to use **ALTER SEQUENCE**.

- To change the owner, you must also be a direct or indirect member of the new role, and this role must have the **CREATE** permission on the sequence's schema.
- In the current version, you can modify only the owner, home column, and the maximum value. To modify other parameters, delete the sequence and create it again. Then, use the Setval function to restore original parameter values.
- **ALTER SEQUENCE MAXVALUE** cannot be used in transactions, functions, and stored procedures.
- After the maximum value of a sequence is changed, the cache of the sequence in all sessions is cleared.
- **ALTER SEQUENCE** blocks the invocation of **nextval**, **setval**, **curval**, and **lastval**.

## Syntax

Change the maximum value or home column of the sequence.

```
ALTER SEQUENCE [IF EXISTS] name
 [MAXVALUE maxvalue | NO MAXVALUE | NOMAXVALUE]
 [CACHE cache]
 [OWNED BY { table_name.column_name | NONE }] ;
```

Change the owner of the sequence.

```
ALTER SEQUENCE [IF EXISTS] name OWNER TO new_owner;
```

## Parameter Description

Table 21-212 ALTER SEQUENCE parameters

| Parameter                             | Description                                                                                                                                                                                                                                      | Value Range                   |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| IF EXISTS                             | Sends a message instead of an error if the sequence does not exist.                                                                                                                                                                              | -                             |
| name                                  | Specifies the name of the sequence to be modified.                                                                                                                                                                                               | Name of an existing sequence. |
| MAXVALUE<br>maxvalue   NO<br>MAXVALUE | Specifies the maximum value of a sequence. If <b>NO MAXVALUE</b> is specified, the default value of the ascending sequence is $2^{63}-1$ , and that of the descending sequence is $-1$ . <b>NOMAXVALUE</b> is equivalent to <b>NO MAXVALUE</b> . | -                             |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                      |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CACHE cache | Allocates sequence numbers in advance and stores them in memory to speed up access. This parameter is supported only by clusters of version 8.2.1.100 or later.                                                                                                                                                                                                                                                                                                                             | <ul style="list-style-type: none"><li>The minimum value of <b>cachevalue</b> is <b>1</b>. (One value can be generated at a time, that is <b>NOCACHE</b>.)</li><li>If this parameter is not specified, the old cache value is retained.</li></ul> |
| OWNED BY    | Associates a sequence with a specified field in a table. In this way, the sequence will be deleted when you delete its associated field or the table where the field belongs.<br><br>If the sequence has been associated with another table before you use this parameter, the new association will overwrite the old one. The associated table and sequence must be owned by the same user and in the same schema. If <b>OWNED BY NONE</b> is used, existing associations will be deleted. | -                                                                                                                                                                                                                                                |
| new_owner   | Specifies the username of the new owner.                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Name of an existing user.                                                                                                                                                                                                                        |

## Examples

Create the sample sequence **seq\_test** and sample table **t1**.

```
CREATE SEQUENCE seq_test START 101;
DROP TABLE IF EXISTS t1;
CREATE TABLE t1(c1 bigint default nextval('seq_test'));
```

Modify the maximum value of **serial** to **200**.

```
ALTER SEQUENCE seq_test MAXVALUE 200;
```

Change the home column of **seq\_test** to **t1.c1**.

```
ALTER SEQUENCE seq_test OWNED BY t1.c1;
```

## Helpful Links

[CREATE SEQUENCE](#) and [DROP SEQUENCE](#)

## 21.13.6.7 DROP SEQUENCE

### Function

**DROP SEQUENCE** deletes a sequence from the current database.

### Precautions

Only a sequence owner or a system administrator can delete a sequence.

### Syntax

```
DROP SEQUENCE [IF EXISTS] {[schema.]sequence_name} [, ...] [CASCADE | RESTRICT];
```

### Parameter Description

**Table 21-213** DROP SEQUENCE parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a notice instead of an error if the specified sequence does not exist.                        | -                                                                                                                                                                                                                                               |
| name               | Specifies the name of the sequence to be deleted.                                                   | Specifies an existing sequence name.                                                                                                                                                                                                            |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• CASCADE: Automatically deletes objects that depend on the sequence to be deleted.</li><li>• RESTRICT: Refuses to delete the sequence if any objects depend on it. This is the default action.</li></ul> |

### Examples

Delete sequence **serial**.

```
DROP SEQUENCE serial;
```

## 21.13.6.8 CREATE TEXT SEARCH CONFIGURATION

### Function

**CREATE TEXT SEARCH CONFIGURATION** creates a text search configuration. A text search configuration specifies a text search parser that can divide a string into

tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

## Precautions

- If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent **ALTER TEXT SEARCH CONFIGURATION** commands must be used to create mappings to make the configuration useful. If **COPY** option is specified, the parser, mapping and configuration option of text search configuration is copied automatically.
- If a schema name is specified, the text search configuration is created in the specified schema. Otherwise, the text search configuration is created in the current schema.
- The user who defines a text search configuration becomes its owner.
- **PARSER** and **COPY** options are mutually exclusive, because when an existing configuration is copied, its parser configuration is also copied.

## Syntax

```
CREATE TEXT SEARCH CONFIGURATION name
(PARSER = parser_name | COPY = source_config)
[WITH ({configuration_option = value} [, ...])];
```

## Parameter Description

**Table 21-214** CREATE TEXT SEARCH CONFIGURATION parameters

| Parameter     | Description                                                                                      | Value Range                                                              |
|---------------|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| name          | Specifies the name (optionally schema-qualified) of the text search configuration to be created. | A string, which must comply with the <a href="#">naming convention</a> . |
| parser_name   | Specifies the name of the text search parser to use for this configuration.                      | -                                                                        |
| source_config | Specifies the name of an existing text search configuration to copy.                             | -                                                                        |

| Parameter            | Description                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| configuration_option | Specifies the configuration parameter of text search configuration is mainly for the parser executed by <b>parser_name</b> or contained by <b>source_config</b> . | Currently, the default, ngram, and zhparser parsers are supported. <ul style="list-style-type: none"><li>• The parser of the default type does not have the corresponding <b>configuration_option</b>.</li><li>• For details about the <b>configuration_option</b> of the ngram and zhparser parsers, see <a href="#">Table 21-215</a>.</li></ul> |

**Table 21-215** Configuration parameters for ngram and zhparser parsers

| Parser   | Parameters for adding an account | Description                                                                                                                 | Value Range                                                                                                                                                                                                                       |

|        | multi_zall                       | Whether to display all single words individually.        | <ul style="list-style-type: none"><li>• <b>true</b>: Display all single words individually.</li><li>• <b>false</b> (default value): Do not display all single words individually.</li></ul>                 |

## Examples

Create a text search configuration named **ngram1** using the ngram parser.

```
CREATE TEXT SEARCH CONFIGURATION ngram1 (parser=ngram) WITH (gram_size = 2, grapsymbol_ignore = false);
```

Create a text search configuration named **ngram2** and copy all parameters of the existing configuration **ngram1**.

```
CREATE TEXT SEARCH CONFIGURATION ngram2 (copy=ngram1);
```

Create a text search configuration named **english\_1** and use the default text parser.

```
CREATE TEXT SEARCH CONFIGURATION english_1 (parser=default);
```

[ALTER TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

## 21.13.6.9 ALTER TEXT SEARCH CONFIGURATION

### Function

This syntax modifies the definition of a text search configuration.

Users can update the mapping from a token type to a dictionary, change the configuration's name or owner, and adjust the search configuration parameters.

### Precautions

- If a search configuration is referenced (to create an index), users are not allowed to modify it.
- To use **ALTER TEXT SEARCH CONFIGURATION**, you must be the owner of the configuration.

### Syntax

- Add a mapping from a token type to a dictionary.  

```
ALTER TEXT SEARCH CONFIGURATION name
 ADD MAPPING FOR token_type [, ...] WITH dictionary_name [, ...];
```
- Modify the text search configuration dictionary.  

```
ALTER TEXT SEARCH CONFIGURATION name
 ALTER MAPPING FOR token_type [, ...] REPLACE old_dictionary WITH new_dictionary;
```
- Modify the token type of the text search configuration.  

```
ALTER TEXT SEARCH CONFIGURATION name
 ALTER MAPPING FOR token_type [, ...] WITH dictionary_name [, ...];
```
- Change the text search configuration dictionary.  

```
ALTER TEXT SEARCH CONFIGURATION name
 ALTER MAPPING REPLACE old_dictionary WITH new_dictionary;
```
- Delete a mapping from a token type to a dictionary.  

```
ALTER TEXT SEARCH CONFIGURATION name
 DROP MAPPING [IF EXISTS] FOR token_type [, ...];
```
- Change the owner of the text search configuration.  

```
ALTER TEXT SEARCH CONFIGURATION name OWNER TO new_owner;
```
- Rename the text search configuration.  

```
ALTER TEXT SEARCH CONFIGURATION name RENAME TO new_name;
```
- Rename the text search configuration schema.  

```
ALTER TEXT SEARCH CONFIGURATION name SET SCHEMA new_schema;
```
- Modify the attributes of the text search configuration.  

```
ALTER TEXT SEARCH CONFIGURATION name SET ({ configuration_option = value } [, ...]);
```
- Reset the text search configuration attributes.  

```
ALTER TEXT SEARCH CONFIGURATION name RESET ({configuration_option} [, ...]);
```

 NOTE

- **ADD MAPPING FOR** adds a mapping for the token type to the text search configuration. If the mapping for any token type after **ADD MAPPING FOR** already exists in the text search configuration, the system reports an error.
- **ALTER MAPPING FOR** clears the existing token type mapping and then adds the specified token type mapping.
- **ALTER MAPPING REPLACE ... WITH ...** and **ALTER MAPPING FOR... REPLACE ... WITH ...** options replace **old\_dictionary** with **new\_dictionary**. Note that only when **pg\_ts\_config\_map** has tuples corresponding to **maptokentype** and **old\_dictionary**, the update will succeed. If the update fails, no messages are returned.
- **DROP MAPPING FOR** deletes the token type mapping specified in the current text search configuration. If **EXISTS** is not specified and the token type mapping specified by **DROP MAPPING FOR** does not exist in the text search configuration, the database reports an error.

## Parameter Description

**Table 21-216** ALTER TEXT SEARCH CONFIGURATION parameters

| Parameter       | Description                                                                                                                                                                   | Value Range                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| name            | Specifies the name of the text search configuration to be modified, which can include a schema.                                                                               | -                                                                     |
| token_type      | Specifies the name of the token type associated with the configured parser.                                                                                                   | For details, see <a href="#">Parsers</a> .                            |
| dictionary_name | Specifies the name of a text search dictionary to be consulted for the specified token types. If multiple dictionaries are listed, they are consulted in the specified order. | -                                                                     |
| old_dictionary  | Specifies the name of the text search dictionary to be replaced in the mapping.                                                                                               | -                                                                     |
| new_dictionary  | Specifies the name of a text search dictionary to be substituted for <b>old_dictionary</b> .                                                                                  | -                                                                     |
| new_owner       | Specifies the new owner of the text search configuration.                                                                                                                     | Valid username.                                                       |
| new_name        | Specifies the new name of the text search configuration.                                                                                                                      | A string compliant with the <a href="#">identifier naming rules</a> . |

| Parameter            | Description                                                     | Value Range                                                         |
|----------------------|-----------------------------------------------------------------|---------------------------------------------------------------------|
| new_schema           | Specifies the new schema name of the text search configuration. | Valid schema name.                                                  |
| configuration_option | Specifies the text search configuration item.                   | For details, see <a href="#">CREATE TEXT SEARCH CONFIGURATION</a> . |
| value                | Specifies the value of text search configuration option.        | -                                                                   |

## Examples

Create a text search configuration named **ngram1**.

```
DROP TEXT SEARCH CONFIGURATION IF EXISTS ngram1;
CREATE TEXT SEARCH CONFIGURATION ngram1 (parser=ngram) WITH (gram_size = 2, grapsymbol_ignore = false);
```

Add a mapping to the text search type **ngram1**.

```
ALTER TEXT SEARCH CONFIGURATION ngram1 ADD MAPPING FOR multisymbol WITH simple;
```

Change the owner of text search configuration.

```
CREATE USER joe password '{Password}';
ALTER TEXT SEARCH CONFIGURATION ngram1 OWNER TO joe;
```

Change the schema of text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION ngram1 SET SCHEMA joe;
```

Rename a text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION joe.ngram1 RENAME TO ngram_1;
```

Delete type mapping.

```
ALTER TEXT SEARCH CONFIGURATION joe.ngram_1 DROP MAPPING IF EXISTS FOR multisymbol;
```

Create a text search configuration.

```
DROP TEXT SEARCH CONFIGURATION IF EXISTS english_1;
CREATE TEXT SEARCH CONFIGURATION english_1 (parser=default);
```

Add a mapping to the text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION english_1 ADD MAPPING FOR word WITH simple,english_stem;
```

Update the text search configuration by adding mappings.

```
ALTER TEXT SEARCH CONFIGURATION english_1 ADD MAPPING FOR email WITH english_stem,
french_stem;
```

Updating the text search configuration.

```
ALTER TEXT SEARCH CONFIGURATION english_1 ALTER MAPPING REPLACE french_stem with german_stem;
```

Query text search configurations.

```
SELECT b.cfgname,a.maptokentype,a.mapseqno,a.mapdict,c.dictname FROM pg_ts_config_map
a,pg_ts_config b, pg_ts_dict c WHERE a.mapcfg=b.oid AND a.mapdict=c.oid AND b.cfgname='english_1'
ORDER BY 1,2,3,4,5;
```

| cfgname   | maptokentype | mapseqno | mapdict | dictname     |
|-----------|--------------|----------|---------|--------------|
| english_1 | 2            | 1        | 3765    | simple       |
| english_1 | 2            | 2        | 14505   | english_stem |
| english_1 | 4            | 1        | 14505   | english_stem |
| english_1 | 4            | 2        | 14511   | german_stem  |
| (4 rows)  |              |          |         |              |

[CREATE TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

21.13.6.10 DROP TEXT SEARCH CONFIGURATION

Function

**DROP TEXT SEARCH CONFIGURATION** deletes an existing text search configuration.

Precautions

To run the **DROP TEXT SEARCH CONFIGURATION** command, you must be the owner of the text search configuration.

Syntax

```
DROP TEXT SEARCH CONFIGURATION [IF EXISTS] name [CASCADE | RESTRICT];
```

Parameter Description

Table 21-217 DROP TEXT SEARCH CONFIGURATION parameters

| Parameter | Description                                                                                    | Value Range                                 |
|-----------|------------------------------------------------------------------------------------------------|---------------------------------------------|
| IF EXISTS | Sends a notice instead of an error if the specified text search configuration does not exist.  | -                                           |
| name      | Specifies the name (optionally schema-qualified) of a text search configuration to be deleted. | An existing text search configuration name. |

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• CASCADE: Automatically deletes objects that depend on the text search configuration to be deleted.</li><li>• RESTRICT: Refuses to delete the text search configuration if any objects depend on it. This is the default. This is the default.</li></ul> |

## Examples

Delete the text search configuration **ngram1**.

```
DROP TEXT SEARCH CONFIGURATION ngram1;
```

## Helpful Links

[ALTER TEXT SEARCH CONFIGURATION](#), [CREATE TEXT SEARCH CONFIGURATION](#)

### 21.13.6.11 CREATE TEXT SEARCH DICTIONARY

#### Function

**CREATE TEXT SEARCH DICTIONARY** creates a full-text retrieval dictionary. A full-text search dictionary is used to identify and process particular words during full-text retrieval.

Dictionaries are created by using predefined templates (defined in the **PG\_TS\_TEMPLATE** system catalog). Five types of dictionaries can be created, **Simple**, **Ispell**, **Synonym**, **Thesaurus**, and **Snowball**. Each type of dictionaries is used to handle different tasks.

#### Precautions

- A user with the **SYSADMIN** permission can create a dictionary. Then, the user automatically becomes the owner of the dictionary.
- A dictionary cannot be created in **pg\_temp** mode.
- After a dictionary is created or modified, any modification to the user-defined dictionary definition file will not affect the dictionary in the database. To make such modifications take effect in the dictionary in the database, run the **ALTER** statement to update the definition file of the dictionary.
- The **TEMPLATE** parameter in a dictionary cannot be modified.
- To specify a dictionary, specify both the dictionary definition file path (**FILEPATH**) and the file name (the parameter varies based on dictionary types).

- The name of a dictionary definition file can contain only lowercase letters, digits, and underscores (\_).
- The predefined dictionary file is stored in the **\$GAUSSHOME/share/postgresql/tsearch\_data** directory.

## Syntax

```
CREATE TEXT SEARCH DICTIONARY name (
 TEMPLATE = template
 [, option = value [, ...]]
);
```

## Parameter Description

**Table 21-218** CREATE TEXT SEARCH DICTIONARY parameters

| Parameter | Description                                                                                                                                                                                                                          | Value Range                                                                                                                                               |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| name      | Specifies the name (optionally schema-qualified) of the full-text search dictionary to be created.                                                                                                                                   | A string, which must comply with the <a href="#">naming convention</a> .                                                                                  |
| template  | Specifies a template name.                                                                                                                                                                                                           | Templates ( <b>Simple</b> , <b>Synonym</b> , <b>Thesaurus</b> , <b>Ispell</b> , and <b>Snowball</b> ) defined in the <b>PG_TS_TEMPLATE</b> system catalog |
| option    | Specifies the parameter name of a specific option for a full-text search dictionary. Each type of dictionaries has a template containing their custom parameters. Parameters function in a way irrelevant to their setting sequence. | For details, see <a href="#">Table 21-219</a> .                                                                                                           |
| value     | Specifies a parameter value. If the value is not an identifier or a number, enclose it with single quotation marks ("). You can also enclose identifiers and numbers with single quotation marks.                                    | -                                                                                                                                                         |

**Table 21-219** Option parameters of Simple, Ispell, Synonym, Thesaurus, and Snowball

| option                                    | Name of the option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameters for a <b>Simple</b> dictionary | STOPWORD S         | Specifies the name of a file listing stop words. The default file name extension is .stop. For example, if the value of <b>STOPWORDS</b> is <b>french</b> , the actual file name is <b>french.stop</b> . In the file, each line defines a stop word. Dictionaries will ignore blank lines and spaces in the file and convert stop-word phrases into lowercase.                                                                                                |
|                                           | ACCEPT             | Specifies whether to accept a non-stop word as recognized. The default value is <b>true</b> .<br><br>If <b>ACCEPT=true</b> is set for a <b>Simple</b> dictionary, no token will be passed to subsequent dictionaries. In this case, you are advised to place the <b>Simple</b> dictionary at the end of the dictionary list. If <b>ACCEPT=false</b> is set, you are advised to place the <b>Simple</b> dictionary before at least one dictionary in the list. |

| option | Name of the option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | FILEPATH           | <p>Specifies the directory for storing the stop word file. The stop word file can be stored locally or on the OBS server. If the file is stored locally, the directory format is '<b>file://absolute_path</b>'. If the file is stored on the OBS server, the directory format is '<b>obs://bucket/path accesskey=ak secretkey=sk region=region_name</b>'. The directory must be enclosed in single quotation marks (''). The default value is the directory where predefined dictionary files are located. Both the <b>FILEPATH</b> and <b>STOPWORDS</b> parameters need to be specified.</p> <p>To create a dictionary using the stop word file on the OBS server, perform the following steps:</p> <ol style="list-style-type: none"><li>1. Upload the stop word file to the OBS server. For example, upload the <b>french.stop</b> file to the <b>gaussdb</b> bucket on the OBS server <b>obsv3.sa-fb-1.externaldemo.com</b>. The URL is <b>https://gaussdb.obsv3.sa-fb-1.externaldemo.com/french.stop</b>. For details about how to upload the file and query the URL, see <i>Object Storage Service (OBS) User Guide</i>.</li><li>2. Add "<i>region_name</i>": "<i>obs domain</i>" to the <b>\$GAUSSHOME/etc/region_map</b> file. <i>region_name</i> can be a string consisting of uppercase letters, lowercase letters, digits, slashes (/), or underscores (_). <i>obs domain</i> indicates the domain name of the OBS server. For example, if <i>region_name</i> is set to <b>rg</b>, <b>region_map</b> is as follows: "<b>rg</b>": "<b>obsv3.sa-fb-1.externaldemo.com</b>".</li></ol> <p><b>NOTICE</b></p> <p><i>region_name</i> and <i>obs domain</i> are enclosed in double quotation marks. There is no space on the left of the colon and one space on the right of the colon.</p> <ol style="list-style-type: none"><li>3. Run the <b>CREATE TEXT SEARCH DICTIONARY</b> command to create a dictionary. The command is as follows:</li></ol> <pre>CREATE TEXT SEARCH DICTIONARY french_dict<br/>( TEMPLATE = pg_catalog.simple, STOPWORDS = french,<br/>FILEPATH = 'obs://gaussdb accesskey=xxx secretkey=yyy<br/>region=rg' );</pre> <p>The <b>french.stop</b> file is stored in the root directory of the <b>gaussdb</b> bucket. Therefore, the <i>path</i> is empty.</p> |

| option                                       | Name of the option | Description                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameters for a <b>Synonym</b> dictionary   | SYNONYM            | Specifies the name of the definition file for a <b>Synonym</b> dictionary. The default file name extension is .syn.<br><br>The file is a list of synonyms. Each line is in the format of <i>token synonym</i> , that is, token and its synonym separated by a space.                                                                                                                  |
|                                              | CASESENSITIVE      | Specifies whether tokens and their synonyms are case sensitive. The default value is <b>false</b> , indicating that tokens and synonyms in dictionary files will be converted into lowercase. If this parameter is set to <b>true</b> , they will not be converted into lowercase.                                                                                                    |
|                                              | FILEPATH           | Specifies the directory for storing <b>Synonym</b> dictionary files. The directory can be a local directory or an OBS directory. The default value is the directory where predefined dictionary files are located. The directory format and the process of creating a <b>Synonym</b> dictionary using a file on the OBS server are the same as those of the <b>Simple</b> dictionary. |
| Parameters for a <b>Thesaurus</b> dictionary | DICTFILE           | Specifies the name of a dictionary definition file. The default file name extension is .ths.<br><br>The file is a list of synonyms. Each line is in the format of <i>sample words : indexed words</i> . The colon (:) is used as a separator between a phrase and its substitute word. If multiple sample words are matched, the TZ selects the longest one.                          |

| option                                     | Name of the option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                            | DICTIONARY         | <p>Specifies the name of a subdictionary used for word normalization. This parameter is mandatory and only one subdictionary name can be specified. The specified subdictionary must exist. It is used to identify and normalize input text before phrase matching.</p> <p>If an input word cannot be recognized by the subdictionary, an error will be reported. In this case, remove the word or update the subdictionary to make the word recognizable. In addition, an asterisk (*) can be placed at the beginning of an indexed word to skip the application of a subdictionary on it, but all sample words must be recognizable by the subdictionary.</p> <p>If the sample words defined in the dictionary file contain stop words defined in the subdictionary, use question marks (?) to replace them. Assume that <b>a</b> and <b>the</b> are stop words defined in the subdictionary.</p> <p>? one ? two : swsw</p> <p><b>a one the two</b> and <b>the one a two</b> will be matched and output as <b>swsw</b>.</p> |
|                                            | FILEPATH           | <p>Specifies the directory for storing dictionary definition files. The directory can be a local directory or an OBS directory. The default value is the directory where predefined dictionary files are located. The directory format and the process of creating a <b>Synonym</b> dictionary using a file on the OBS server are the same as those of the <b>Simple</b> dictionary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Parameters for an <b>Ispell</b> dictionary | DICTFILE           | <p>Specifies the name of a dictionary definition file. The default file name extension is .dict.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                            | AFFFILE            | <p>Specifies the name of an affix file. |                                            | STOPWORDS          | <p>Specifies the name of a file listing stop words. The default file name extension is .stop. The file content format is the same as that of the file for a <b>Simple</b> dictionary.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| option                                      | Name of the option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                             | FILEPATH           | Specifies the directory for storing dictionary files. The directory can be a local directory or an OBS directory. The default value is the directory where predefined dictionary files are located. The directory format and the process of creating a <b>Synonym</b> dictionary using a file on the OBS server are the same as those of the <b>Simple</b> dictionary.                                                                                            |
| Parameters for a <b>Snowball</b> dictionary | LANGUAGE           | Specifies the name of a language whose stemming algorithm will be used. According to spelling rules in the language, the algorithm normalizes the variants of an input word into a basic word or a stem.                                                                                                                                                                                                                                                          |
|                                             | STOPWORD S         | Specifies the name of a file listing stop words. The default file name extension is .stop. The file content format is the same as that of the file for a <b>Simple</b> dictionary.                                                                                                                                                                                                                                                                                |
|                                             | FILEPATH           | Specifies the directory for storing dictionary definition files. The directory can be a local directory or an OBS directory. The default value is the directory where predefined dictionary files are located. Both the <b>FILEPATH</b> and <b>STOPWORDS</b> parameters need to be specified. The directory format and the process of creating a <b>Snowball</b> dictionary using a file on the OBS server are the same as those of the <b>Simple</b> dictionary. |

## Examples

Create an **Ispell** dictionary **english\_ispell** (the dictionary definition file is from the open source dictionary).

```
CREATE TEXT SEARCH DICTIONARY english_ispell (
 TEMPLATE = ispell,
 DictFile = english,
 AffFile = english,
 StopWords = english,
 FilePath = 'obs://bucket_name/path accesskey=ak secretkey=sk region=rg'
);
```

See examples in [Configuration Examples](#).

## 21.13.6.12 ALTER TEXT SEARCH DICTIONARY

### Function

Modifies the definition of a full-text retrieval dictionary, including its parameters, name, owner, and schema.

### Precautions

- **ALTER** is not supported by predefined dictionaries.
- Only the owner of a dictionary can do **ALTER** to the dictionary. System administrators have this permission by default.
- After a dictionary is created or modified, any modification to the user-defined dictionary definition file in the directory specified by **FilePath** will not affect the dictionary in the database. To make such modifications take effect in the dictionary in the database, run the **ALTER TEXT SEARCH DICTIONARY** statement to update the definition file of the dictionary.

### Syntax

- Modify the dictionary definition.  
`ALTER TEXT SEARCH DICTIONARY name ( option = value | option [, ...] );`
- Rename a dictionary.  
`ALTER TEXT SEARCH DICTIONARY name RENAME TO new_name;`
- Set the schema of a dictionary.  
`ALTER TEXT SEARCH DICTIONARY name SET SCHEMA new_schema;`
- Change the owner of a dictionary.  
`ALTER TEXT SEARCH DICTIONARY name OWNER TO new_owner;`

### Parameter Description

Table 21-220 ALTER TEXT SEARCH DICTIONARY parameters

| Parameter | Description                                                                                       | Value Range                                  |
|-----------|---------------------------------------------------------------------------------------------------|----------------------------------------------|
| name      | Specifies the name of the full-text search dictionary to be modified, which can include a schema. | Name of a valid full-text search dictionary. |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Value Range                                                                                         |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| option     | <p>Specifies the parameter name of the full-text search dictionary specific option to be modified. Each type of dictionaries has a template containing their custom parameters. Parameters function in a way irrelevant to their setting sequence.</p> <ul style="list-style-type: none"><li>• The <b>TEMPLATE</b> parameter in a dictionary cannot be modified.</li><li>• To specify a dictionary, specify both the dictionary definition file path (<b>FILEPATH</b>) and the file name (the parameter varies based on dictionary types).</li><li>• The name of a dictionary definition file can contain only lowercase letters, digits, and underscores (_).</li></ul> | For details about the parameters, see the <b>option</b> parameter in <a href="#">Table 21-218</a> . |
| value      | Specifies the new value of a parameter. If = and <i>value</i> are omitted, the previous settings of the parameter will be deleted and the default value will be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Corresponding <b>option</b> definition.                                                             |
| new_name   | Specifies the new name of the full-text search dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | A string compliant with the <a href="#">identifier naming rules</a> .                               |
| new_owner  | Specifies the new owner of the full-text search dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Valid username.                                                                                     |
| new_schema | Specifies the new schema of the full-text search dictionary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Valid schema name.                                                                                  |

## Examples

Create a full-text search dictionary **my\_dict**.

```
CREATE TEXT SEARCH DICTIONARY my_dict (
 TEMPLATE = snowball,
 Language = english,
 StopWords = english
);
```

Change the **Language** setting for the full-text search dictionary **my\_dict** and remove the stop word definition.

```
ALTER TEXT SEARCH DICTIONARY my_dict (Language = dutch,StopWords);
```

Update the definition of the full-text search dictionary **my\_dict** without changing any content.

```
ALTER TEXT SEARCH DICTIONARY my_dict (dummy);
```

## Helpful Links

[CREATE TEXT SEARCH DICTIONARY](#) and [DROP TEXT SEARCH DICTIONARY](#)

### 21.13.6.13 DROP TEXT SEARCH DICTIONARY

#### Function

**DROP TEXT SEARCH DICTIONARY** deletes a full-text retrieval dictionary.

#### Precautions

- **DROP** is not supported by predefined dictionaries.
- Only the owner of a dictionary can do **DROP** to the dictionary. System administrators have this permission by default.
- Execute **DROP...CASCADE** only when necessary because this operation will delete the text search configuration that uses this dictionary.

#### Syntax

```
DROP TEXT SEARCH DICTIONARY [IF EXISTS] name [CASCADE | RESTRICT]
```

#### Parameter Description

**Table 21-221** DROP TEXT TEXT SEARCH DICTIONARY parameters

| Parameter | Description                                                                                                                                               | Value Range                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| IF EXISTS | Sends a notice instead of an error if the specified full-text search dictionary does not exist.                                                           | -                               |
| name      | Specifies the name of a dictionary to be deleted. (If you do not specify a schema name, the dictionary in the current schema will be deleted by default.) | Name of an existing dictionary. |

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: Automatically deletes dependent objects of a dictionary and then deletes all dependent objects of these objects in sequence. If any text search configuration that uses the dictionary exists, <b>DROP</b> execution will fail. You can add <b>CASCADE</b> to delete all text search configurations and dictionaries that use the dictionary.</li><li>• <b>RESTRICT</b>: Rejects the deletion of a dictionary if any object depends on the dictionary. This is the default.</li></ul> |

## Examples

Delete **english** dictionary.

```
DROP TEXT SEARCH DICTIONARY english;
```

[ALTER TEXT SEARCH DICTIONARY](#), [CREATE TEXT SEARCH DICTIONARY](#)

### 21.13.6.14 CLUSTER

#### Function

This syntax clusters tables by their indexes.

- **CLUSTER** clusters the table specified by table name based on the index specified by index name. The index specified by index name must have been defined in the specified table.
- When a table is clustered, it is physically reordered based on the index information. Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order.
- When a table is clustered, DWS records which index the table was clustered by. The form **CLUSTER table\_name** reclusters the table using the same index used earlier. You can also use **SET WITHOUT CLUSTER** of **CLUSTER** or **ALTER**

**TABLE** to set indexes for subsequent clustering operations or clear any previous settings.

- **CLUSTER** without any parameters reclusters all tables that have been clustered in the database owned by the current user. If **CLUSTER** is invoked by the system administrator, it indicates all tables that have been clustered.
- When a table is being clustered, an **ACCESS EXCLUSIVE** lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the clustering is complete.

## Precautions

- **CLUSTER** cannot be executed in transactions.
- **CLUSTER** cannot be performed on HDFS tables.
- **CLUSTER** cannot be performed on global temporary tables.
- Performing a **CLUSTER** operation on a table triggers a rebuilding process where data is dumped into a new data file. Once the process is complete, the original file is deleted. Keep in mind that if the table is large, this process can consume a significant amount of disk space. When the disk space is insufficient, exercise caution when performing the **CLUSTER** operation on large tables to prevent the cluster from being read-only.
- In the storage-compute decoupled architecture, a message is displayed indicating that operations on the entire cluster database are not supported.
- Only row-store B-tree indexes support **CLUSTER**.
- In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using **CLUSTER**. If you request a range of index values from a table or if an index value matches multiple rows, **CLUSTER** helps. It does this by storing related rows on the same page. This saves disk access time and speeds up queries.
- During clustering, the system creates a temporary copy of the table in the index sequence and a temporary copy of each index in the table. The disk must have enough space for both the table and its index.
- **CLUSTER** stores clustering information. You can manually cluster tables initially, then set up a periodic maintenance script. This allows tables to be automatically clustered regularly.
- Because the optimizer records statistics about the ordering of tables, it is advisable to run **ANALYZE** on the newly clustered table. Otherwise, the optimizer might select an incorrect query plan.

## Syntax

- Cluster a table.  
`CLUSTER [ VERBOSE ] table_name [ USING index_name ];`
- Cluster a partition.  
`CLUSTER [ VERBOSE ] table_name PARTITION ( partition_name ) [ USING index_name ];`
- Cluster the table that has previously been clustered.  
`CLUSTER [ VERBOSE ];`

## Parameter Description

**Table 21-222** CLUSTER parameters

| Parameter      | Description                               | Value Range                    |
|----------------|-------------------------------------------|--------------------------------|
| VERBOSE        | Enables the display of progress messages. | -                              |
| table_name     | Specifies the name of the table.          | Name of an existing table.     |
| index_name     | Specifies the index name.                 | Name of an existing index.     |
| partition_name | Specifies the partition name.             | Name of an existing partition. |

## Examples

Create a partitioned table.

```
CREATE TABLE tpcds.inventory_p1
(
 INV_DATE_SK INTEGER NOT NULL,
 INV_ITEM_SK INTEGER NOT NULL,
 INV_WAREHOUSE_SK INTEGER NOT NULL,
 INV_QUANTITY_ON_HAND INTEGER
)
DISTRIBUTE BY HASH(INV_ITEM_SK)
PARTITION BY RANGE(INV_DATE_SK)
(
 PARTITION P1 VALUES LESS THAN(2451179),
 PARTITION P2 VALUES LESS THAN(2451544),
 PARTITION P3 VALUES LESS THAN(2451910),
 PARTITION P4 VALUES LESS THAN(2452275),
 PARTITION P5 VALUES LESS THAN(2452640),
 PARTITION P6 VALUES LESS THAN(2453005),
 PARTITION P7 VALUES LESS THAN(MAXVALUE)
);
```

Create an index named **ds\_inventory\_p1\_index1**.

```
CREATE INDEX ds_inventory_p1_index1 ON tpcds.inventory_p1 (INV_ITEM_SK) LOCAL;
```

Cluster the **tpcds.inventory\_p1** table.

```
CLUSTER tpcds.inventory_p1 USING ds_inventory_p1_index1;
```

Cluster the **p3** partition.

```
CLUSTER tpcds.inventory_p1 PARTITION (p3) USING ds_inventory_p1_index1;
```

Cluster the tables that can be clustered in the database.

```
CLUSTER;
```

## 21.13.7 Stored Procedures, Functions, Triggers, and Cursors

## 21.13.7.1 CREATE FUNCTION

### Function

A function is a reusable code block that accepts input parameters, performs specific operations, and returns a value or result set. **CREATE FUNCTION** is used to create a user-defined function (UDF) in a database, enabling other computing functions that are not supported by the built-in **system functions** of DWS and covering complex computing scenarios specific to users.

The functions have the following features:

- They support input parameters and return results depending on specific conditions.
- You must declare the return value's data type. It outputs either a single value (scalar function) or a table (table-valued function).
- By wrapping complex logic into one function, you can call it like a built-in SQL function, enhancing code reuse.

### Three DWS Function Types Based on Behaviors

SQL functions fall into three types based on their behaviors: immutable, stable, and volatile. **Table 21-223** shows their relationships.

**Table 21-223** Function types

| Function Type | Definition                                                                                                                                                                                                                                                                                                         | Typical Use Case                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| immutable     | An immutable function's output depends solely on its input parameters, ignoring external factors like database state, time, or transaction context. It consistently produces the same result when given identical inputs, regardless of when or where it is called. Additionally, it does not alter database data. | Mathematical calculations, hashing, and string operations—examples include ABS(x), POWER(a, b), and MD5(str).           |
| stable        | A stable function produces consistent results within a single query if the inputs remain unchanged. Its output depends on the database's current state, like table data or session variables, so results may vary across separate queries or transactions.                                                         | Tasks like filtering or aggregating live data, such as using MAX(col) or MIN(col), which stay constant during one scan. |

| Function Type | Definition                                                                                                                                                                                                                                                | Typical Use Case                                                                                                                                                                    |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| volatile      | Volatile functions are highly unpredictable. Their results can differ with every call or alter the database state by performing actions like writing data. Since their behavior cannot be predicted, the optimizer must recompute them on each execution. | Tasks like generating random numbers, retrieving timestamps, or executing DML operations. For instance, calling the <code>RANDOM()</code> function produces a new value every time. |

You can view the **provolatile** column in the **PG\_PROC** system catalog to check the function type. (**i** indicates immutable, **s** indicates stable, and **v** indicates volatile.)

## Pushing Functions Down to DNs (SHIPPABLE and NOT SHIPPABLE)

The **CREATE FUNCTION** syntax uses **SHIPPABLE** and **NOT SHIPPABLE** to determine if the function runs on the data node (DN).

- Functions of the **IMMUTABLE** type can always be pushed down to the DNs.
- Functions of the **STABLE** or **VOLATILE** type can be pushed down to DNs only if their attribute is **SHIPPABLE**.

Exercise caution when defining the **SHIPPABLE** attribute for a function. **SHIPPABLE** means that the entire function will be pushed down to DNs for execution. If the attribute is incorrectly set, serious problems such as result errors may occur.

The **SHIPPABLE** attribute, like **IMMUTABLE**, comes with usage limits. It requires functions to exclude elements that prevent pushdown. Once pushed down to a DN, the function's calculations must rely solely on the DN's dataset.

### Functions cannot be marked as IMMUTABLE if they:

1. Reference tables or views because their results may change when the data updates.
2. Call other **STABLE** or **VOLATILE** functions.
3. Include non-pushdown components, which clash with the **IMMUTABLE** rule. This often involves unsupported pushdown functions or syntax.
4. Perform aggregations needing **STREAM** plans (such as the `listagg` function), as these require computations on both DNs and CNs.

### Functions cannot be marked as SHIPPABLE if they:

1. Reference a hash-distributed table.
2. Include non-pushdown components, functions, or syntax. For details, see "Optimizing Statement Pushdown".
3. Involve calculations with data spread across DNs, such as aggregations.

 **CAUTION**

To optimize performance DWS, you need to define function attributes accurately. Incorrect settings can reduce query speed and produce inconsistent results.

## Precautions

- The precision values (if any) of the parameters or return values of a function are not checked.
- Always define a clear schema for table operations in your functions. For instance, use **hr.table1** to point to a table in the **hr** schema. Without this, the function might not run correctly.
- **current\_schema** and **search\_path** specified by **SET** during function creation are invalid. The values of **search\_path** and **current\_schema** after function execution are the same as those before function execution.
- If a function has output parameters, the **SELECT** statement uses the default values of the output parameters when calling the function. When the **CALL** statement calls the function, it requires that the output parameter values are adapted to Oracle. When the **CALL** statement calls an overloaded PACKAGE function, it can use the default values of the output parameters. For details, see examples in [CALL](#).
- Only the functions compatible with PostgreSQL or those with the **PACKAGE** attribute can be overloaded. After **REPLACE** is specified, a new function is created instead of replacing a function if the number of parameters, parameter type, or return value is different.
- You can use the **SELECT** statement to specify different parameters using identical functions, but cannot use the **CALL** statement to call identical functions without the **PACKAGE** attribute because **CALL** aligns with Oracle syntax.
- When you create a function, you cannot insert other agg functions out of the avg function or other functions.
- In non-logical cluster mode, return values, parameters, and variables cannot be set to the tables of the Node Groups that are not installed in the system by default. The internal statements of SQL functions cannot be executed on such tables.
- In logical cluster mode, if return values and parameters of the function are user tables, all the tables must be in the same logical cluster. If the function body involves operations on multiple logical cluster tables, the function cannot be set to **IMMUTABLE** or **SHIPPABLE**, preventing the function from being pushed down to a DN.
- In logical cluster mode, the parameters and return values of the function cannot use the **%type** to reference a table column type. Otherwise, the function will fail to be created.
- By default, the permissions to execute new functions are granted to **PUBLIC**. For details, see [GRANT](#). You can revoke the default execution permissions from **PUBLIC** and grant them to other users as needed. To avoid the time window during which new functions can be accessed by all users, create functions in transactions and set function execution permissions.

- In a cluster with multiple CNs, the input or output parameters of a function cannot be set to the temporary table type. This is because the correct temporary schema cannot be obtained based on the table name when the function is created on a non-current CN. As a result, the accurate table type cannot be obtained.

## Syntax

- Syntax (compatible with PostgreSQL) for creating a user-defined function:

```
CREATE [OR REPLACE] FUNCTION function_name
([{ argname [argmode] argtype [{ DEFAULT | := | = } expression] } [, ...]])
[RETURNS rettype [DETERMINISTIC] | RETURNS TABLE ({ column_name column_type }
[, ...])]
LANGUAGE lang_name
[
 { IMMUTABLE | STABLE | VOLATILE }
 | { SHIPPABLE | NOT SHIPPABLE }
 | WINDOW
 | [NOT] LEAKPROOF
 | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER | AUTHID DEFINER |
AUTHID CURRENT_USER }
 | { FENCED | NOT FENCED }
 | { PACKAGE }

 | COST execution_cost
 | ROWS result_rows
 | SET configuration_parameter { { TO | = } value | FROM CURRENT } }
][...]
{
 AS 'definition'
 | AS 'obj_file', 'link_symbol'
}
```

- Oracle syntax of creating a customized function:

```
CREATE [OR REPLACE] FUNCTION function_name
([{ argname [argmode] argtype [{ DEFAULT | := | = } expression] } [, ...]])
RETURN rettype [DETERMINISTIC]
[
 { IMMUTABLE | STABLE | VOLATILE }
 | { SHIPPABLE | NOT SHIPPABLE }
 | { PACKAGE }
 | { FENCED | NOT FENCED }
 | [NOT] LEAKPROOF
 | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER |
AUTHID DEFINER | AUTHID CURRENT_USER }
]
[
 | COST execution_cost
 | ROWS result_rows
 | SET configuration_parameter { { TO | = } value | FROM CURRENT }
]
][...]
{
 IS | AS
} plsql_body
/
```

## Parameter Description

**Table 21-224** CREATE FUNCTION parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                            | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| function_name | Specifies the name of the function to be created.<br><b>CAUTION</b><br>If the name of the function to be created is the same as that of a system function, you are advised to specify a schema. When invoking a user-defined function, you need to specify a schema. Otherwise, the system preferentially invokes the system function. | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                                                                                                                                                                            |
| argname       | Specifies the name of a function parameter.                                                                                                                                                                                                                                                                                            | A string, which must comply with the naming convention.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| argmode       | Specifies the mode of a function parameter.                                                                                                                                                                                                                                                                                            | <b>IN, OUT, INOUT, or VARIADIC.</b> <ul style="list-style-type: none"><li>• <b>IN</b>: input parameter. The default value is <b>IN</b>.</li><li>• <b>OUT</b>: output parameter. Only this type can include <b>VARIADIC</b>.</li><li>• <b>INOUT</b>: both input and output parameters.</li><li>• <b>OUT VARIADIC</b>: output parameter, which is defined as an array type.</li></ul> <b>CAUTION</b><br>The parameters of <b>OUT</b> and <b>INOUT</b> cannot be used in function definition of <b>RETURNS TABLE</b> . |
| argtype       | Data types of function parameters.                                                                                                                                                                                                                                                                                                     | For details about common data types, see <a href="#">Data Types</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| expression    | Indicates the default expression of a parameter.                                                                                                                                                                                                                                                                                       | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter          | Description                                                                                                                                                                                                                                                                                          | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| rettype            | Indicates the return data type.                                                                                                                                                                                                                                                                      | When there is <b>OUT</b> or <b>IN OUT</b> parameter, the <b>RETURNS</b> clause can be omitted. If the clause exists, the result type of the clause must be the same as that of the output parameter. If there are multiple output parameters, the result type of the clause is <b>RECORD</b> . Otherwise, the result type of the clause is the same as that of a single output parameter.<br><br>The <b>SETOF</b> modifier indicates that the function will return a set of items, rather than a single item. |
| DETERMINISTIC      | Adapted to Oracle SQL syntax. You are not advised to use it.                                                                                                                                                                                                                                         | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| column_name        | Specifies the column name.                                                                                                                                                                                                                                                                           | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| column_type        | Specifies the column type.                                                                                                                                                                                                                                                                           | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| definition         | Specifies a string constant defining the function; the meaning depends on the language. It can be an internal function name, a path pointing to a target file, a SQL query, or text in a procedural language.                                                                                        | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| LANGUAGE lang_name | Indicates the name of the language that is used to implement the function. It can be <b>SQL</b> , <b>internal</b> , or the name of user-defined process language. To ensure downward compatibility, the name can use single quotation marks. Contents in single quotation marks must be capitalized. | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Parameter | Description                                                                                                                                                                                                                                                                                                                       | Value Range |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| WINDOW    | <p>Indicates that the function is a window function. The WINDOW attribute cannot be changed when the function definition is replaced.</p> <p><b>CAUTION</b><br/>For a user-defined window function, the value of <b>LANGUAGE</b> can only be <b>internal</b>, and the referenced internal function must be a window function.</p> | -           |

| Parameter | Description                                                                                      | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IMMUTABLE | Indicates that the function always returns the same result if the parameter values are the same. | <p>If the input argument of the function is a constant, the function value is calculated at the optimizer stage. The advantage is that the expression value can be obtained as early as possible, so the cost estimation is more accurate and the execution plan generated is better.</p> <p>A user-defined <b>IMMUTABLE</b> function is automatically pushed down to DN for execution, which may cause potential risks. If a function is defined as <b>IMMUTABLE</b> but the function execution process is in fact not <b>IMMUTABLE</b>, serious problems such as result errors may occur. Therefore, exercise caution when defining the <b>IMMUTABLE</b> attribute for a function.</p> <p>Examples:</p> <ol style="list-style-type: none"><li>1. If a user-defined function references objects such as tables and views, the function cannot be defined as <b>IMMUTABLE</b>, because the function may return different results when the data in a referenced table changes.</li><li>2. Call other <b>STABLE</b> or <b>VOLATILE</b> functions.</li><li>3. Include non-pushdown components, which clash with the <b>IMMUTABLE</b> rule. Typical scenarios include functions and syntax that cannot be pushed down.</li><li>4. If a user-defined function contains an aggregation operation that will generate <b>STREAM</b> plans to complete the operation (meaning that DN and CN are involved for results calculation, such as the <b>LISTAGG</b> function), the function cannot be defined as <b>IMMUTABLE</b>.</li></ol> |

| Parameter | Description                                                                                                                                                                                                          | Value Range                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |                                                                                                                                                                                                                      | To prevent possible problems, you can set <b>behavior_compat_options</b> to <b>check_function_conflicts</b> in the database to check definition conflicts. This method can identify the <b>1</b> and <b>2</b> scenarios described above. |
| STABLE    | Indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter values, but that its result varies by SQL statements. | -                                                                                                                                                                                                                                        |
| VOLATILE  | Indicates that the function value can change even within a single table scan, so no optimizations can be made.                                                                                                       | -                                                                                                                                                                                                                                        |

| Parameter                  | Description                                                             | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SHIPPABLE<br>NOT SHIPPABLE | Indicates whether the function can be pushed down to DNs for execution. | <ul style="list-style-type: none"><li>Functions of the IMMUTABLE type can always be pushed down to the DNs.</li><li>Functions of the STABLE or VOLATILE type can be pushed down to DNs only if their attribute is <b>SHIPPABLE</b>. Exercise caution when defining the <b>SHIPPABLE</b> attribute for a function. <b>SHIPPABLE</b> means that the entire function will be pushed down to DNs for execution. If the attribute is incorrectly set, serious problems such as result errors may occur.</li></ul> <p>Similar to the <b>IMMUTABLE</b> attribute, the <b>SHIPPABLE</b> attribute has use restrictions. The function cannot contain factors that do not allow the function to be pushed down for execution. If a function is pushed down to a single DN for execution, the function's calculation logic will depend only on the data set of the DN.</p> <p>Examples:</p> <ol style="list-style-type: none"><li>If a function references a hash table, you cannot define the function as <b>SHIPPABLE</b>.</li><li>If a function contains factors, functions, or syntax that cannot be pushed down, the function cannot be defined as SHIPPABLE. For details, see Optimizing Statement Pushdown.</li><li>If a function's calculation process involves data across DNs, the function cannot be defined as <b>SHIPPABLE</b>. For example, some aggregation operations involve data across DNs.</li></ol> |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                      | Value Range                                                                                                                                                                                                                                                            |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PACKAGE                              | Indicates whether the function can be overloaded. PostgreSQL-style functions can be overloaded, and this parameter is designed for Oracle-style functions.                                                                                                                                                                                                       | <ul style="list-style-type: none"><li>• All PACKAGE and non-PACKAGE functions cannot be overloaded or replaced.</li><li>• PACKAGE functions do not support parameters of the VARIADIC type.</li><li>• The PACKAGE attribute of functions cannot be modified.</li></ul> |
| LEAKPROOF                            | Indicates that the function has no side effects. <b>LEAKPROOF</b> can be set only by the system administrator.                                                                                                                                                                                                                                                   | -                                                                                                                                                                                                                                                                      |
| CALLED ON NULL INPUT                 | Declares that some parameters of the function can be invoked in normal mode if the parameter values are <b>NULL</b> . This parameter can be omitted.                                                                                                                                                                                                             | -                                                                                                                                                                                                                                                                      |
| RETURNS NULL ON NULL INPUT<br>STRICT | Indicates that the function always returns <b>NULL</b> whenever any of its parameters are <b>NULL</b> . If this parameter is specified, the function is not executed when there are <b>NULL</b> parameters; instead a <b>NULL</b> result is returned automatically.<br><br>The usage of <b>RETURNS NULL ON NULL INPUT</b> is the same as that of <b>STRICT</b> . | -                                                                                                                                                                                                                                                                      |
| EXTERNAL                             | The keyword EXTERNAL is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not only external ones.                                                                                                                                                                                                      | -                                                                                                                                                                                                                                                                      |

| Parameter                               | Description                                                                                                                                                                                                                                                         | Value Range                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SECURITY INVOKER<br>AUTHID CURRENT_USER | Indicates that the function is to be executed with the permissions of the user that calls it. This parameter can be omitted.<br><br><b>SECURITY INVOKER</b> and <b>AUTHID CURRENT_USER</b> have the same functions.                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                |
| SECURITY DEFINER<br>AUTHID DEFINER      | Specifies that the function is to be executed with the permissions of the user that created it.<br><br>The usage of <b>AUTHID DEFINER</b> is the same as that of <b>SECURITY DEFINER</b> .                                                                          | -                                                                                                                                                                                                                                                                                                                                                                                                                |
| FENCED<br>NOT FENCED                    | (Effective only for C functions) Specifies whether functions are executed in fenced mode. In NOT FENCED mode, a function is executed in a CN or DN process. In FENCED mode, a function is executed in a new fork process, which does not affect CN or DN processes. | Application scenarios: <ul style="list-style-type: none"><li>• Develop or debug a function in FENCED mode and execute it in NOT FENCED mode. This reduces the cost of the fork process and communication.</li><li>• Perform complex OS operations, such as open a file, process signals and threads, in FENCED mode so that DWS running is not affected.</li><li>• The default value is <b>FENCED</b>.</li></ul> |
| COST<br>execution_cost                  | A positive number giving the estimated execution cost for the function. The unit of <b>execution_cost</b> is <b>cpu_operator_cost</b> .                                                                                                                             | Positive                                                                                                                                                                                                                                                                                                                                                                                                         |
| ROWS<br>result_rows                     | Estimates the number of rows returned by the function. This is only allowed when the function is declared to return a set.                                                                                                                                          | Its value is a positive number. The default value is <b>1000</b> .                                                                                                                                                                                                                                                                                                                                               |

| Parameter               | Description                                                                                                                                                      | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| configuration_parameter | Specifies the parameter value configured for the function.                                                                                                       | <ul style="list-style-type: none"><li>• <b>value</b><br/>Sets a specified database session parameter to a specified value. If the value is <b>DEFAULT</b> or <b>RESET</b>, the default setting is used in the new session. <b>OFF</b> closes the setting.<br/>Value range: a string<ul style="list-style-type: none"><li>– DEFAULT</li><li>– OFF</li><li>– RESET</li></ul>Specifies the default value.</li><li>• <b>from current</b><br/>Uses the value of <b>configuration_parameter</b> of the current session.</li></ul> |
| plsql_body              | Indicates the PL/SQL stored procedure body.<br><br>When the function is creating users, the log will record unencrypted passwords. You are not advised to do it. | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Example: Calculate the Sum of Two Integers Using an SQL Function

Syntax:

```
CREATE OR REPLACE FUNCTION func_add_sql(
integer, --The first integer parameter is not named and is referenced by the location parameter
$1.
integer --The second integer parameter is not named and is referenced by the location
parameter $2.
)
RETURNS integer --The return type of the function is integer.
AS 'select $1 + $2;' --The function body adds the location parameters $1 and $2.
LANGUAGE SQL --The SQL language is used to implement this function.
IMMUTABLE --The function type is IMMUTABLE, which indicates that the same result is
returned for the same input.
RETURNS NULL ON NULL INPUT; --It is same as STRICT. If any parameter is NULL, the function
returns NULL.
```

Return the sum of the two input parameters.

```
SELECT func_add_sql(8,3);
```

func\_add\_sql

11

Return null because the input parameter is null.

```
SELECT func_add_sql(Null,3);
```

`func_add_sql`

*(Null)*

## Example: Increment an Integer, in PL/pgSQL

Syntax:

```
CREATE OR REPLACE FUNCTION func_increment_plsql(
i integer --The input parameter is of the integer type.
) RETURNS integer --The return value of the function is of the integer type.
AS $$
 BEGIN --The function body begins.
 RETURN i + 1; --The return result is the sum of 1 and the input parameter.
 END;
$$ LANGUAGE plpgsql; --The function is written in PL/pgSQL.
```

Return the integer auto-increment result.

```
SELECT func_increment_plsql(5);
```

`func_increment_plsql`

6

The input parameter is specified by the first column of the **numbers** table. After the function is used for calculation, the calculation result is returned to the second column.

```
DROP TABLE IF EXISTS numbers;
CREATE TABLE numbers (value integer);
INSERT INTO numbers VALUES (1), (2), (3), (4), (5);
SELECT value, func_increment_plsql(value) AS incremented_value FROM numbers ORDER BY 1;
```

| value | incremented_value |
|-------|-------------------|
| 1     | 2                 |
| 2     | 3                 |
| 3     | 4                 |
| 4     | 5                 |
| 5     | 6                 |

## Example: Return a Record in PL/pgSQL

```
CREATE OR REPLACE FUNCTION compute(
i int, ---The input parameter is of the integer type.
out result_1 bigint, --The output result is 1 and the data type is large integer.
out result_2 bigint --The output result is 2 and the data type is large integer.
)
RETURNS SETOF RECORD --A record containing more than one output parameter is returned.
AS $$
BEGIN
 result_1 = i + 1; -- It is used to calculate the first result value. The input value is increased by 1.
 result_2 = i * 10; -- It is used to calculate the second result value. The input value is multiplied
by 10.
 RETURN next; --It returns the current calculation result and then continue to execution
(multiple rows can be returned).
END;
$$LANGUAGE plpgsql; --The function is written in PL/pgSQL.
```

Return the following information when the function is called once.

```
SELECT * FROM compute(5);
```

| result_1 | result_2 |
|----------|----------|
| 6        | 50       |

Generate a sequence of 1, 2, and 3, and call the compute function for each value in the sequence.

```
SELECT i, (compute(i)).* --Call the compute function first, and then expand all columns returned by the
function.
FROM generate_series(1, 3) --Generate a temporary sequence containing 1, 2, and 3 to assign values to
i.
AS t(i); --Assign the result to temporary table t, in which i is the column name.
```

| i | result_1 | result_2 |
|---|----------|----------|
| 1 | 2        | 10       |
| 2 | 3        | 20       |
| 3 | 4        | 30       |

The data in table **test\_data** is used. The **value** column in the table is used as the input parameter of the compute function. The calculation result is as follows:

```
DROP TABLE IF EXISTS test_data;
CREATE TABLE test_data (id serial, value int);
INSERT INTO test_data (value) VALUES (2), (4), (6);
```

```
SELECT id, value, (compute(value)).*
FROM test_data ORDER BY 1;
```

| id | value | result_1 | result_2 |
|----|-------|----------|----------|
| 1  | 2     | 3        | 20       |
| 2  | 4     | 5        | 40       |
| 3  | 6     | 7        | 60       |

## Example: Create an SQL Function that Returns Multiple Output Parameters

Syntax:

```
CREATE OR REPLACE FUNCTION func_dup_sql(
in int, --The input parameter is of the integer type.
out f1 int, --The first output parameter is of the integer type.
out f2 text) --The second output parameter is of the text type.
AS $$
SELECT $1, CAST($1 AS text) || 's text' -- Function body. The query returns two columns. The first column is
the input parameter $1, and the second column is the parameter converted to text and concatenated with
is text.
$$ LANGUAGE SQL;
```

Execute the function.

```
SELECT * FROM func_dup_sql(42);
```

| f1 | f2         |
|----|------------|
| 42 | 42 is text |

## Example: Create an Overloaded Function with the PACKAGE Attribute

Define two overloaded functions named **package\_func\_overload** in **package**. The two functions have different meanings depending on the parameter type.

```
CREATE OR REPLACE FUNCTION package_func_overload(
col int, --The first input parameter is of the integer type.
col2 int --The second input parameter is of the integer type.
)
RETURN integer PACKAGE
AS
DECLARE
 col_type text; -- Declare a local variable.
BEGIN
 col := 122; --Set the first parameter to 122.
 dbms_output.put_line('two int parameters ' || col2);
 RETURN 0; --Return the integer 0.
END;
/

CREATE OR REPLACE FUNCTION package_func_overload(
col int,
col2 smallint
)
RETURN integer PACKAGE
AS
DECLARE
 col_type text;
BEGIN
 col := 122;
 dbms_output.put_line('two smallint parameters ' || col2);
 RETURN 0;
END;
/
```

## Function Pushdown Logic and Example

Pushdown logic for functions has two main aspects:

1. The system checks if the entire function can be pushed down based on its **SHIPPABLE** attribute.
2. If the full function is not pushed down, the optimizer automatically determines which individual SQL statements within the function can be executed separately.

## Function-invoking Statements Without User Tables

When a function is called without referencing the user table, the statement runs on the CN, and the function body is not pushed down. Here is how it works:

1. First, execute the function. Since the statement does not include the user table, it always runs on the CN.
2. Next, execute the statements inside the function body. These can be pushed down if nothing prevents it (using FQS or STREAM plan frameworks).

**CAUTION**

- Calling a function alone (without user tables) with SQL join queries still produces accurate results.
- Pushdown only matters if the function call includes user tables directly.
- Execution plans within the function are not visible by default. Setting **enable\_track\_record\_subsql** to **on** to log them.

**Example: The function body is NOT SHIPPABLE, and the calling statement lacks the user table.**

```
CREATE TABLE student (
 id integer,
 name character varying(50),
 age integer
)
WITH (orientation=row, compression=no)
DISTRIBUTE BY HASH(id);

CREATE TABLE stuscore(
 id integer,
 score integer
)
WITH (orientation=row, compression=no)
DISTRIBUTE BY HASH(id);

INSERT INTO student VALUES (1,'bob',17),(3,'peter',18),(4,'david',15),(8,'alice',17);
INSERT INTO stuscore VALUES (1,88),(3,68),(8,100),(4,90);

--Create a NOT SHIPPABLE function.
CREATE OR REPLACE FUNCTION get_student_id(name character varying)
 RETURNS TABLE(id integer)
 LANGUAGE plpgsql
 VOLATILE NOT FENCED NOT SHIPPABLE
AS $function$
DECLARE
BEGIN
 RETURN QUERY (SELECT id FROM mytest.student WHERE name=$1);
END $function$;
```

Check the execution plan for this function call.

```
EXPLAIN VERBOSE SELECT * FROM get_student_id('alice');
```

Since the user table is missing, the results do not indicate if the function was pushed down, as pushdown only matters when the user table is present.

| QUERY PLAN                                                |                                           |        |            |         |         |
|-----------------------------------------------------------|-------------------------------------------|--------|------------|---------|---------|

| Output: id                                                |                                           |        |            |         |         |

## Function-invoking Statements with User Tables

When a function-calling statement includes a user table, its pushdown capability depends on the function's SHIPPABLE attribute.

**Example: The function attribute is NOT SHIPPABLE and the calling statement contains a user table.**

Check the execution plan to confirm that the function cannot be pushed down.

```
EXPLAIN VERBOSE SELECT get_student_id('alice') FROM stuscore;
```

| QUERY PLAN                                           |                                                   |                                         |  |   |        |
|------------------------------------------------------|---------------------------------------------------|-----------------------------------------|--|---|--------|
| id                                                   | operation                                         | E-rows   E-distinct   E-width   E-costs |  |   |        |
| -----+-----+-----+-----+-----                        |                                                   |                                         |  |   |        |
| 1   ->                                               | Data Node Scan on stuscore "_REMOTE_TABLE_QUERY_" | 30000                                   |  | 0 | 157.35 |
|                                                      |                                                   |                                         |  |   |        |
| SQL Diagnostic Information                           |                                                   |                                         |  |   |        |
| -----                                                |                                                   |                                         |  |   |        |
| SQL is not plan-shipping                             |                                                   |                                         |  |   |        |
| reason: Function get_student_id() can not be shipped |                                                   |                                         |  |   |        |

**Example: The function attribute is SHIPPABLE and the calling statement contains a user table.**

```
--Change the function attribute to SHIPPABLE.
CREATE OR REPLACE FUNCTION get_student_id(name character varying)
 RETURNS TABLE(id integer)
 LANGUAGE plpgsql
 VOLATILE NOT FENCED SHIPPABLE
AS $function$
DECLARE
BEGIN
 RETURN QUERY (SELECT id FROM mytest.student WHERE name=$1);
END $function$;
```

Check the execution plan to confirm that the function can be pushed down.

```
EXPLAIN VERBOSE SELECT get_student_id('alice') FROM stuscore;
```

## Helpful Links

[ALTER FUNCTION](#), [DROP FUNCTION](#)

### 21.13.7.2 ALTER FUNCTION

#### Function

**ALTER FUNCTION** modifies the attributes of a customized function.

#### Precautions

- Only the function owner or a user granted the ALTER permission can run **ALTER FUNCTION**. System administrators have this permission by default.
- To change the function owner, you must be a direct or indirect member of the new owning role.
- To change the function owner, you must have CREATE permission on the function's schemas.
- To change a function's schema, you must also have the CREATE permission on the new schema.
- If a function involves operations on temporary tables, **ALTER FUNCTION** cannot be used.

#### Syntax

- Modify the additional parameter of the custom function.  
**ALTER FUNCTION** function\_name ( ( [ { [ argmode ] [ argname ] argtype } [ , ... ] ] )  
action [ ... ] [ RESTRICT ] ;

The syntax of the **action** clause is as follows:

```
{ CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
| { IMMUTABLE | STABLE | VOLATILE }
```

```
| {SHIPPABLE | NOT SHIPPABLE}
| {NOT FENCED | FENCED}
| {MASKED | NOT MASKED}
| [NOT] LEAKPROOF
| { [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
| AUTHID { DEFINER | CURRENT_USER }
| COST execution_cost
| ROWS result_rows
| SET configuration_parameter { { TO | = } { value | DEFAULT } } FROM CURRENT}
| RESET {configuration_parameter | ALL}
```

- Rename a custom function. You can add the schema name before the new function name. However, you cannot change the schema name at the same time.

```
ALTER FUNCTION funname ([{ [argmode] [argname] argtype } [, ...]])
 RENAME TO new_name;
ALTER FUNCTION funname ([{ [argmode] [argname] argtype } [, ...]])
 RENAME TO schema.new_name;
```

- Modify the owner of the custom function.

```
ALTER FUNCTION funname ([{ [argmode] [argname] argtype } [, ...]])
 OWNER TO new_owner;
```

- Modify the schema of the custom function.

```
ALTER FUNCTION funname ([{ [argmode] [argname] argtype } [, ...]])
 SET SCHEMA new_schema;
```

## Parameter Description

Table 21-225 ALTER FUNCTION parameters

| Parameter     | Description                                                                                                         | Value Range                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| function_name | Specifies the function name to be modified.                                                                         | Name of an existing function.                                                   |
| argmode       | Specifies the mode of an argument. It indicates whether a parameter is an input, output, or input/output parameter. | <b>IN</b> , <b>OUT</b> , or <b>IN OUT</b> .<br>The default value is <b>IN</b> . |
| argname       | Specifies the parameter name.                                                                                       | A string compliant with the <a href="#">identifier naming rules</a> .           |
| argtype       | Specifies the parameter type of a function.                                                                         | Valid types are listed in <a href="#">Data Types</a> .                          |
| new_name      | Specifies the new name of a function.                                                                               | A string compliant with the <a href="#">identifier naming rules</a> .           |
| new_owner     | Specifies the new owner of a function.                                                                              | Valid username or role name.                                                    |
| new_schema    | Specifies the new schema of a function.                                                                             | Existing schema.                                                                |

| Parameter                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Value Range                                                                                                          |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| CALLED ON NULL INPUT   RETURNS NULL ON NULL INPUT   STRICT | <ul style="list-style-type: none"><li>• <b>CALLED ON NULL INPUT</b> declares that some parameters of a function can be invoked in normal mode if the parameter values are <b>NULL</b>. By default, the usage is the same as specifying the parameters.</li><li>• <b>STRICT</b> indicates that the function always returns <b>NULL</b> whenever any of its parameters are <b>NULL</b>. If this parameter is specified, the function is not called when there are <b>NULL</b> parameters; instead a <b>NULL</b> result is returned automatically.</li><li>• The usage of <b>RETURNS NULL ON NULL INPUT</b> is the same as that of <b>STRICT</b>.</li></ul> | -                                                                                                                    |
| IMMUTABLE   STABLE   VOLATILE                              | <ul style="list-style-type: none"><li>• <b>IMMUTABLE</b> indicates that the function always returns the same result if the parameter values are the same.</li><li>• <b>STABLE</b> indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same parameter values, but that its result varies by SQL statements.</li><li>• <b>VOLATILE</b> indicates that the function value can change in one table scanning and no optimization is performed.</li></ul>                                                                                                          | For details about IMMUTABLE, STABLE, and VOLATILE, see <a href="#">Three DWS Function Types Based on Behaviors</a> . |
| SHIPPABLE   NOT SHIPPABLE                                  | <p>Indicates whether the function can be pushed down to DN for execution.</p> <ul style="list-style-type: none"><li>• Functions of the IMMUTABLE type can always be pushed down to the DN.</li><li>• Functions of the STABLE or VOLATILE type can be pushed down to DN only if their attribute is <b>SHIPPABLE</b>.</li></ul>                                                                                                                                                                                                                                                                                                                            | -                                                                                                                    |

| Parameter                            | Description                                                                                                                                                                                                                                             | Value Range                                              |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| MASKED   NOT MASKED                  | Specifies whether the function performs masking when the GUC parameter <b>enable_redactcol_computable</b> is enabled. <b>MASKED</b> supports system function modification and cannot be used together with actions in other <b>ALTER</b> functions.     | -                                                        |
| LEAKPROOF                            | Indicates that the function has no side effect and specifies that the parameter includes only the returned value. <b>LEAKPROOF</b> can be set only by the system administrator.                                                                         | -                                                        |
| EXTERNAL (optional)                  | Used d for SQL compatibility. This function applies to all functions, including external ones.                                                                                                                                                          | -                                                        |
| SECURITY INVOKER/AUTHID CURRENT_USER | Declares that the function will be executed according to the permission of the user that invokes it. By default, the usage is the same as specifying the parameters.<br><b>SECURITY INVOKER</b> and <b>AUTHID CURRENT_USER</b> have the same functions. | -                                                        |
| SECURITY DEFINER/AUTHID DEFINER      | Specifies that the function is to be executed with the permissions of the user that created it. By default, the usage is the same as specifying the parameters.<br>The usage of <b>AUTHID DEFINER</b> is the same as that of <b>SECURITY DEFINER</b> .  | -                                                        |
| COST<br>execution_cost               | A positive number giving the estimated execution cost for the function.<br>The unit of <b>execution_cost</b> is <b>cpu_operator_cost</b> .                                                                                                              | Positive                                                 |
| ROWS result_rows                     | Estimates the number of rows returned by the function. This is only allowed when the function is declared to return a set.                                                                                                                              | A positive number.<br>The default value is <b>1000</b> . |

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Value Range |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| configuration_parameter | <ul style="list-style-type: none"><li>value<br/>Sets a specified database session parameter to a specified value.<ul style="list-style-type: none"><li><b>DEFAULT</b> or <b>RESET</b> indicates that the default settings of the system are used in a new session.</li><li><b>OFF</b> indicates that the setting is disabled.</li></ul></li><li>Specifies the default value.</li><li>from current<br/>Uses the value of <b>configuration_parameter</b> of the current session.</li></ul> | A string    |

## Examples

Create the **func\_add\_sql2** function for calculating the sum of two integers and get the results. If the input is **null**, **null** will be returned.

```
DROP FUNCTION IF EXISTS func_add_sql2;
CREATE FUNCTION func_add_sql2(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
END;
/
;
```

Alter the execution rule of the **func\_add\_sql2** function to **IMMUTABLE**. That is, the same result is returned if the parameter is not changed.

```
ALTER FUNCTION func_add_sql2(INTEGER, INTEGER) IMMUTABLE;
```

Change the name of the **func\_add\_sql2** function to **add\_two\_number**.

```
ALTER FUNCTION func_add_sql2(INTEGER, INTEGER) RENAME TO add_two_number;
```

Change the owner of the **add\_two\_number** function to dbadmin.

```
ALTER FUNCTION add_two_number(INTEGER, INTEGER) OWNER TO dbadmin;
```

## Helpful Links

[CREATE FUNCTION](#) and [DROP FUNCTION](#)

### 21.13.7.3 DROP FUNCTION

#### Function

**DROP FUNCTION** deletes an existing function.

## Precautions

- To delete an overloaded function, you must specify the function's parameter (argument) type. For non-overloaded functions, you can delete them by just specifying the function name.
- If a function involves operations on temporary tables, the function cannot be deleted by running **DROP FUNCTION**.

## Syntax

```
DROP FUNCTION [IF EXISTS] function_name
[([{ argmode } [argname] argtype } [, ...]]) [CASCADE | RESTRICT] ;
```

## Parameter Description

**Table 21-226** DROP FUNCTION parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                                                    |
|--------------------|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a notice instead of an error if the specified table does not exist.                           | -                                                                                                                                                                                                                                                                              |
| function_name      | Specifies the name of the function to be deleted.                                                   | Use an existing function name.                                                                                                                                                                                                                                                 |
| argmode            | Specifies the mode of a function parameter.                                                         | -                                                                                                                                                                                                                                                                              |
| argname            | Specifies the name of a function parameter.                                                         | -                                                                                                                                                                                                                                                                              |
| argtype            | Specifies the data type of a function parameter.                                                    | -                                                                                                                                                                                                                                                                              |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically deletes all objects that depend on the function to be deleted (such as operators).</li><li>• <b>RESTRICT</b>: refuses to delete the function if any objects depend on it. This is the default.</li></ul> |

## Examples

Delete the function **add\_two\_number**.

```
DROP FUNCTION add_two_number;
```

## Helpful Links

[ALTER FUNCTION](#), [CREATE FUNCTION](#)

## 21.13.7.4 CREATE PROCEDURE

### Function

**CREATE PROCEDURE** creates a stored procedure.

Stored procedures are sets of precompiled SQL statements that are stored in a database and repeatedly executed.

### Precautions

- When creating a stored procedure, you need to explicitly specify the schema (for example, **schema.table**) that the table object belongs to, or there may be an execution exception.
- **current\_schema** and **search\_path** specified by **SET** during the stored procedure creation are invalid. **search\_path** and **current\_schema** before and after function execution should be the same.
- When creating a stored procedure, it is not allowed to nest other aggregate functions or system functions outside the avg function.
- The precision values of the parameters or return values of a stored procedure are not checked.
- In a cluster with multiple CNs, the input or output parameters of a stored procedure cannot be set to the temporary table type. When a stored procedure is created on a CN that is not currently connected, the correct temporary schema cannot be obtained based on the table name, resulting in an incorrect table type.
- A stored procedure can have multiple return values or no return value. After a stored procedure without a return value is invoked, the command output is empty.
- If a stored procedure has output parameters, the **SELECT** statement uses the default values of the output parameters when calling the procedure. When the **CALL** statement calls the stored procedure, it requires that the output parameter values are adapted to Oracle. When the **CALL** statement calls a non-overloaded function, output parameters must be specified. When the **CALL** statement calls an overloaded PACKAGE function, it can use the default values of the output parameters. For details, see the examples in [CALL](#).
- A stored procedure with the PACKAGE attribute can use overloaded functions.
- Stored procedures cannot be submitted by segment.
- The content in CREATE FUNCTION also applies to CREATE PROCEDURE. For details, see [CREATE FUNCTION](#). After a stored procedure is created, the definition of **CREATE FUNCTION** is returned when the definition is queried.

### Syntax

```
CREATE [OR REPLACE] PROCEDURE procedure_name
[(([argmode] [argname] argtype [{ DEFAULT | := | = } expression]) [, ...])]
[
 { IMMUTABLE | STABLE | VOLATILE }
 | { SHIPPABLE | NOT SHIPPABLE }
 | { PACKAGE }
 | [NOT] LEAKPROOF
 | { CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
 | [{ EXTERNAL } SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER | AUTHID DEFINER | AUTHID
```

```
CURRENT_USER}
| COST execution_cost
| ROWS result_rows
| SET configuration_parameter { [TO | =] value | FROM CURRENT }
][...]
{ IS | AS }
plsql_body
/
```

## Parameter Description

**Table 21-227** CREATE PROCEDURE parameters

| Parameter      | Description                                                                                                                                                                                                            | Value Range                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OR REPLACE     | Replaces the original definition when two stored procedures are with the same name.                                                                                                                                    | -                                                                                                                                                                                                                                                                                                                                                                                            |
| procedure_name | Specifies the name of the stored procedure that is created (optionally with schema names).                                                                                                                             | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                                                     |
| argmode        | Specifies the mode of the parameter.<br><b>OUT</b> and <b>INOUT</b> cannot be used in procedure definition of <b>RETURNS TABLE</b> .                                                                                   | <b>IN</b> , <b>OUT</b> , <b>INOUT</b> , or <b>VARIADIC</b> . <ul style="list-style-type: none"><li>• <b>IN</b> (default value): input parameter.</li><li>• <b>OUT</b>: output parameter. Only this type can include <b>VARIADIC</b>.</li><li>• <b>INOUT</b>: both input and output parameters.</li><li>• <b>OUT VARIADIC</b>: output parameter, which is defined as an array type.</li></ul> |
| argname        | Specifies the name of the parameter.<br>There is no strict requirement on the sequence of <b>argname</b> and <b>argmode</b> . You are advised to use <b>argname</b> , <b>argmode</b> , and <b>argtype</b> in sequence. | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                                                     |
| argtype        | Specifies the type of the parameter.                                                                                                                                                                                   | A valid data type.                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                           | Description                                                                                                                                                 | Value Range |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| IMMUTABLE  <br>STABLE  <br>VOLATILE | Specifies a constraint.<br>Parameters here are<br>similar to those of<br><b>CREATE FUNCTION</b> . For<br>details, see <a href="#">CREATE<br/>FUNCTION</a> . | -           |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Value Range |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| SHIPPABLE   NOT SHIPPABLE | <p>Specifies whether a stored procedure can be pushed down to DNs for execution.</p> <ul style="list-style-type: none"><li>• IMMUTABLE stored procedures can always be pushed down to DNs for execution.</li><li>• STABLE and VOLATILE stored procedures can be pushed down to DNs for execution only when the SHIPPABLE attribute is used.</li></ul> <p>SHIPPABLE indicates that the entire stored procedure will be pushed down to DNs for execution. If SHIPPABLE is incorrectly set, serious problems such as incorrect results may occur.</p> <p>SHIPPABLE, like IMMUTABLE, comes with usage limits. It requires stored procedures to exclude elements that prevent pushdown. Once pushed down to a DN, the stored procedures must rely solely on the DN's dataset in the internal computing.</p> <p>Examples:</p> <ol style="list-style-type: none"><li>1. If a stored procedure references a hash table, you cannot define the procedure as <b>SHIPPABLE</b>.</li><li>2. If factors such as stored procedures and syntax cannot</li></ol> | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Value Range |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
|           | <p>be pushed down, the stored procedure cannot be defined as <b>SHIPPABLE</b>. For details, see Optimizing Statement Pushdown.</p> <p>3. If a stored procedure's calculation process involves data across DNs, the procedure cannot be defined as <b>SHIPPABLE</b>. For example, some aggregation operations involve data across DNs.</p>                                                                                                                                                                                     |             |
| PACKAGE   | <p>Specifies whether the stored procedure can be overloaded. PostgreSQL-style stored procedures can be overloaded, and this parameter is designed for Oracle-style stored procedures.</p> <ul style="list-style-type: none"><li>• All PACKAGE and non-PACKAGE stored procedures cannot be overloaded or replaced.</li><li>• Stored procedures with the PACKAGE attribute functions do not support parameters in the <b>VARIADIC</b> mode.</li><li>• The PACKAGE attribute of a stored procedure cannot be modified.</li></ul> | -           |

| Parameter                              | Description                                                                                                                                                                                                                                                                                                                                                                    | Value Range |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| LEAKPROOF                              | Specifies that the parameters of the stored procedure include only return values.<br><b>LEAKPROOF</b> can be set only by the system administrator.                                                                                                                                                                                                                             | -           |
| CALLED ON NULL INPUT                   | Declares that some parameters of the stored procedure can be called in normal mode if the parameter values are <b>NULL</b> . It can be omitted.                                                                                                                                                                                                                                | -           |
| RETURNS NULL ON NULL INPUT   STRICT    | <b>STRICT</b> specifies that the stored procedure always returns <b>NULL</b> whenever any of its parameters are <b>NULL</b> . If it is specified, the stored procedure is not executed when there are <b>NULL</b> parameters; instead a <b>NULL</b> result is returned automatically.<br>The usage of <b>RETURNS NULL ON NULL INPUT</b> is the same as that of <b>STRICT</b> . | -           |
| EXTERNAL                               | The keyword <b>EXTERNAL</b> is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all stored procedures not only external ones.                                                                                                                                                                                                     | -           |
| SECURITY INVOKER   AUTHID CURRENT_USER | Specifies that the stored procedure is to be executed with the permissions of the user that calls it. It can be omitted.<br><b>SECURITY INVOKER</b> and <b>AUTHID CURRENT_USER</b> have the same functions.                                                                                                                                                                    | -           |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                        |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| SECURITY DEFINER   AUTHID DEFINER | Specifies that the stored procedure will be executed with the permissions of the user who created it.<br><b>AUTHID DEFINER</b> and <b>SECURITY DEFINER</b> have the same functions.                                                                                                                                                                                                                                                                                                                                                                                                               | -                                                                  |
| COST<br>execution_cost            | Estimates the execution cost of the stored procedure. The unit of <b>execution_cost</b> is <b>cpu_operator_cost</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Positive                                                           |
| ROWS result_rows                  | Estimates the number of rows returned by the stored procedure. This is only allowed when the stored procedure is declared to return a set.                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Its value is a positive number. The default value is <b>1000</b> . |
| configuration_parameter           | Specifies parameter values configured in the stored procedure. <ul style="list-style-type: none"><li>• <b>value</b><br/>Sets a specified database session parameter to a specified value. Value range: a string<br/>Specifies the default value.<ul style="list-style-type: none"><li>– <b>DEFAULT</b>: The setting will be used in new sessions.</li><li>– <b>OFF</b>: The setting is disabled.</li><li>– <b>RESET</b>: The setting will be used in new sessions.</li></ul></li><li>• <b>from current</b><br/>Uses the value of <b>configuration_parameter</b> of the current session.</li></ul> | -                                                                  |

| Parameter  | Description                                                                                                                                                                                                                                                                                      | Value Range |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| plsql_body | Specifies the PL/SQL stored procedure body.<br>When you create a user, or perform other operations requiring password input in a stored procedure, the system catalog and csv log records the unencrypted password. You are advised not to perform such operations in the stored procedure body. | -           |

## Examples

- Create the stored procedure **prc\_add**, where **param1** is an input parameter and **param2** is an input and output parameter. The procedure calculates the sum of **param1** and **param2**, assigns the result to **param2**, and outputs the result.

```
CREATE OR REPLACE PROCEDURE prc_add
(
 param1 IN INTEGER,
 param2 IN OUT INTEGER
)
AS
BEGIN
 param2:= param1 + param2;
 dbms_output.put_line('result is: '||to_char(param2));
END;
/
```

Call the stored procedure **prc\_add**.

```
CALL prc_add(2,3);
```

- Create the stored procedure **pro\_variadic**. The parameter mode of **param1** is **VARIADIC**. The integer array is converted to a TEXT format and then output via **param2**.

```
CREATE OR REPLACE PROCEDURE pro_variadic (param1 VARIADIC int4[],param2 OUT TEXT)
AS
BEGIN
 param2:= param1::text;
END;
/
```

Execute the stored procedure **pro\_variadic**.

```
SELECT pro_variadic(VARIADIC param1=> array[1,2,3,4]);
```

- Create the stored procedure **package\_func\_overload** with the PACKAGE attribute.

```
CREATE OR REPLACE PROCEDURE package_func_overload(col int, col2 out varchar)
PACKAGE
AS
DECLARE
 col_type text;
BEGIN
 col2 := '122';
```

```
dbms_output.put_line('two varchar parameters ' || col2);
END;
/
```

For details about how to delete a stored procedure, see [DROP PROCEDURE](#). For details about how to call a stored procedure, see [CALL](#).

### 21.13.7.5 DROP PROCEDURE

#### Function

**DROP PROCEDURE** deletes an existing stored procedure.

#### Precautions

None.

#### Syntax

```
DROP PROCEDURE [IF EXISTS] procedure_name ;
```

#### Parameter Description

**Table 21-228** DROP PROCEDURE parameters

| Parameter      | Description                                                                | Value Range                             |
|----------------|----------------------------------------------------------------------------|-----------------------------------------|
| IF EXISTS      | Sends a notice instead of an error if the stored procedure does not exist. | -                                       |
| procedure_name | Specifies the name of the stored procedure to be deleted.                  | An existing name of a stored procedure. |

#### Examples

Delete a stored procedure.

```
DROP PROCEDURE prc_add;
```

[CREATE PROCEDURE](#)

### 21.13.7.6 CREATE TRIGGER

#### Function

Creates a trigger. The trigger will be associated with a specified table or view, and will execute a specified function when certain events occur.

## Precautions

- Currently, triggers can be created only on ordinary row-store tables, instead of on column-store tables, temporary tables, or unlogged tables.
- If multiple triggers of the same kind are defined for the same event, they will be fired in alphabetical order by name.
- A trigger works only on one table. There is no limit on the number of triggers that can be created. However, more triggers on a table consume more performance.
- Triggers are usually used for data association and synchronization between multiple tables. SQL execution performance is greatly affected. Therefore, you are advised not to use this statement when a large amount of data needs to be synchronized and performance requirements are high.
- When a trigger meets the following conditions, the trigger statement and trigger itself can be pushed together down to a DN for execution, improving the trigger execution performance:
  - **enable\_trigger\_shipping** and **enable\_fast\_query\_shipping** are both enabled. (This is the default configuration.)
  - The trigger function used by the source table is a PL/pgSQL function (recommended).
  - The source and target tables have the same type and number of distribution keys, are both row-store tables, and belong to the same Node Group.
  - The **INSERT**, **UPDATE**, or **DELETE** statement on the source table contains an expression about equality comparison between all the distribution keys and the *NEW* or *OLD* variable.
  - The **INSERT**, **UPDATE**, or **DELETE** statement on the source table can be pushed down without a trigger.
  - There are only six types of triggers, specified by **INSERT/UPDATE/DELETE**, **AFTER/BEFORE**, and **FOR EACH ROW**, on the source table, and all the triggers can be pushed down.
- The following details trigger types:
  - **INSTEAD OF** triggers must be marked as **FOR EACH ROW** and can be defined only on views.
  - **BEFORE** and **AFTER** triggers on a view must be marked as **FOR EACH STATEMENT**.
  - **TRUNCATE** triggers must be marked as **FOR EACH STATEMENT**.

## Syntax

```
CREATE [CONSTRAINT] TRIGGER trigger_name { BEFORE | AFTER | INSTEAD OF } { event [OR ...] }
ON table_name
[FROM referenced_table_name]
{ NOT DEFERRABLE | [DEFERRABLE] } { INITIALLY IMMEDIATE | INITIALLY DEFERRED } }
[FOR [EACH] { ROW | STATEMENT }]
[WHEN (condition)]
EXECUTE PROCEDURE function_name (arguments);
```

Events include:

```
INSERT
UPDATE [OF column_name [, ...]]
```

DELETE  
TRUNCATE

## Parameter Description

**Table 21-229** CREATE TRIGGER parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                      | Value Range                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| CONSTRAINT   | Creates a constraint trigger, that is, a trigger is used as a constraint. Such a trigger is similar to a regular trigger except that the timing of the trigger firing can be adjusted using <b>SET CONSTRAINTS</b> . Constraint triggers must be <b>AFTER ROW</b> triggers.                                                                      | -                                                                        |
| trigger_name | Specifies the name of the trigger to be created.<br><br>The name cannot be schema-qualified because the trigger inherits the schema of its table. In addition, triggers on the same table cannot be named the same. For a constraint trigger, this is also the name to use when you modify the trigger's behavior using <b>SET CONSTRAINTS</b> . | A string, which must comply with the <a href="#">naming convention</a> . |
| BEFORE       | Specifies that a trigger function is called before the trigger event.                                                                                                                                                                                                                                                                            | -                                                                        |
| AFTER        | Specifies that a trigger function is called after the trigger event. A constraint trigger can only be specified as <b>AFTER</b> .                                                                                                                                                                                                                | -                                                                        |
| INSTEAD OF   | Specifies that a trigger function directly replaces the trigger event.                                                                                                                                                                                                                                                                           | -                                                                        |

| Parameter                                | Description                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| event                                    | Event for starting a trigger.                                                                                                                                                                                     | <p>Values are <b>INSERT</b>, <b>UPDATE</b>, <b>DELETE</b>, and <b>TRUNCATE</b>. You can also specify multiple trigger events through <b>OR</b>.</p> <p>For <b>UPDATE</b> events, use the following syntax to specify a list of columns:<br/>UPDATE OF column_name1<br/>[, column_name2 ... ]</p> <p>The trigger will only fire if at least one of the listed columns is mentioned as a target of the <b>UPDATE</b> statement. <b>INSTEAD OF UPDATE</b> events do not support lists of columns.</p> |
| table_name                               | Specifies the name of the table where a trigger needs to be created.                                                                                                                                              | Name of an existing table in the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| referenced_table_name                    | Specifies the name of another table referenced by a constraint. This parameter can be specified only for constraint triggers. It does not support foreign key constraints and is not recommended for general use. | Name of an existing table in the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DEFERRABLE   NOT DEFERRABLE              | Specifies the start time of the trigger. It can only be specified for constraint triggers. Controls whether the constraint can be deferred.<br>For details, see <a href="#">CREATE TABLE</a> .                    | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| INITIALLY IMMEDIATE   INITIALLY DEFERRED | If a constraint is deferrable, the two clauses specify the default time to check the constraint, and can be specified only for constraint triggers.<br>For details, see <a href="#">CREATE TABLE</a> .            | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Value Range |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| FOR EACH ROW   FOR EACH STATEMENT | <p>Specifies the frequency of firing a trigger.</p> <ul style="list-style-type: none"><li>• <b>FOR EACH ROW</b> indicates that the trigger should be fired once for every row affected by the trigger event.</li><li>• <b>FOR EACH STATEMENT</b> indicates that the trigger should be fired just once per SQL statement.</li></ul> <p>If this parameter is not specified, the default value <b>FOR EACH STATEMENT</b> will be used. Constraint triggers can only be specified as <b>FOR EACH ROW</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | -           |
| condition                         | <p>Specifies a Boolean expression that determines whether a trigger function will actually be executed. If <b>WHEN</b> is specified, the function will be called only when <b>condition</b> returns <b>true</b>.</p> <ul style="list-style-type: none"><li>• In <b>FOR EACH ROW</b> triggers, the <b>WHEN</b> condition can reference the columns of old or new row values by writing <b>OLD.column_name</b> or <b>NEW.column_name</b>, respectively. Note that <b>INSERT</b> triggers cannot reference <b>OLD</b> and <b>DELETE</b> triggers cannot reference <b>NEW</b>.</li><li>• <b>INSTEAD OF</b> triggers do not support <b>WHEN</b> conditions.</li><li>• <b>WHEN</b> expressions cannot contain subqueries.</li><li>• For constraint triggers, evaluation of the <b>WHEN</b> condition is not deferred, but occurs immediately after the update operation is performed. If the condition does not return <b>true</b>, the trigger will not be queued for deferred execution.</li></ul> | -           |
| function_name                     | <p>Specifies a user-defined function, which must be declared as taking no parameters and returning data of the trigger type. This function is executed when a trigger fires.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                | Value Range |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| arguments | Specifies an optional, comma-separated list of parameters to be provided to a function when a trigger is executed. Parameters are literal string constants. Simple names and numeric constants can also be included, but they will all be converted to strings. Check descriptions of the implementation language of a trigger function to find out how these parameters are accessed within the function. | -           |

**Table 21-230** Types of triggers supported on tables and views

| Trigger Timing | Trigger Event        | Row-level     | Statement-level  |
|----------------|----------------------|---------------|------------------|
| BEFORE         | INSERT/UPDATE/DELETE | Tables        | Tables and views |
|                | TRUNCATE             | Not supported | Tables           |
| AFTER          | INSERT/UPDATE/DELETE | Tables        | Tables and views |
|                | TRUNCATE             | Not supported | Tables           |
| INSTEAD OF     | INSERT/UPDATE/DELETE | Views         | Not supported    |
|                | TRUNCATE             | Not supported | Not supported    |

**Table 21-231** Special variables in the functions PL/pgSQL triggers

| Variable | Description                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------|
| NEW      | New tuple for <b>INSERT/UPDATE</b> operations. This variable is <b>NULL</b> for <b>DELETE</b> operations. |
| OLD      | Old tuple for <b>UPDATE/DELETE</b> operations. This variable is <b>NULL</b> for <b>INSERT</b> operations. |
| TG_NAME  | Trigger name                                                                                              |
| TG_WHEN  | Trigger timing ( <b>BEFORE/AFTER/INSTEAD OF</b> )                                                         |

| Variable        | Description                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------|
| TG_LEVEL        | Trigger frequency ( <b>ROW/STATEMENT</b> )                                                                               |
| TG_OP           | Trigger event ( <b>INSERT/UPDATE/DELETE/TRUNCATE</b> )                                                                   |
| TG_RELID        | OID of the table where a trigger is located                                                                              |
| TG_RELNAME      | Name of the table where a trigger is located. (This variable is now discarded and is replaced by <b>TG_TABLE_NAME</b> .) |
| TG_TABLE_NAME   | Name of the table where a trigger is located.                                                                            |
| TG_TABLE_SCHEMA | Schema information of the table where a trigger is located                                                               |
| TG_NARGS        | Number of parameters for a trigger function                                                                              |
| TG_ARGV[]       | List of parameters for a trigger function                                                                                |

## Examples

Create a source table and a trigger table:

```
CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

Create the trigger function **tri\_insert\_func()**:

```
CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
 INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
 RETURN NEW;
END
$$ LANGUAGE PLPGSQL;
```

Create the trigger function **tri\_update\_func()**:

```
CREATE OR REPLACE FUNCTION tri_update_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
 UPDATE test_trigger_des_tbl SET id3 = NEW.id3 WHERE id1=OLD.id1;
 RETURN OLD;
END
$$ LANGUAGE PLPGSQL;
```

Create the trigger function **tri\_delete\_func()**:

```
CREATE OR REPLACE FUNCTION tri_delete_func() RETURNS TRIGGER AS
$$
DECLARE
BEGIN
```

```
DELETE FROM test_trigger_des_tbl WHERE id1=OLD.id1;
RETURN OLD;
END
$$ LANGUAGE PLPGSQL;
```

Create an **INSERT** trigger:

```
CREATE TRIGGER insert_trigger
BEFORE INSERT ON test_trigger_src_tbl
FOR EACH ROW
EXECUTE PROCEDURE tri_insert_func();
```

Create an **UPDATE** trigger:

```
CREATE TRIGGER update_trigger
AFTER UPDATE ON test_trigger_src_tbl
FOR EACH ROW
EXECUTE PROCEDURE tri_update_func();
```

Create a **DELETE** trigger:

```
CREATE TRIGGER delete_trigger
BEFORE DELETE ON test_trigger_src_tbl
FOR EACH ROW
EXECUTE PROCEDURE tri_delete_func();
```

[ALTER TRIGGER](#), [DROP TRIGGER](#), [ALTER TABLE](#)

### 21.13.7.7 ALTER TRIGGER

#### Function

**ALTER TRIGGER** modifies the definition of a trigger.

#### Precautions

Only the owner of a table where a trigger is created and system administrators can run the **ALTER TRIGGER** statement.

#### Syntax

```
ALTER TRIGGER trigger_name ON table_name RENAME TO new_name;
```

#### Parameter Description

**Table 21-232** ALTER TRIGGER parameters

| Parameter    | Description                                                                  | Value Range                                           |
|--------------|------------------------------------------------------------------------------|-------------------------------------------------------|
| trigger_name | Specifies the name of the trigger to be modified.                            | Valid trigger name.                                   |
| table_name   | Specifies the name of the table where the trigger to be modified is located. | Name of the valid table where the trigger is located. |

| Parameter | Description                     | Value Range                                                           |
|-----------|---------------------------------|-----------------------------------------------------------------------|
| new_name  | Specifies the new trigger name. | A string compliant with the <a href="#">identifier naming rules</a> . |

## Examples

Create sample tables **test\_trigger\_src\_tbl** and **test\_trigger\_des\_tbl**.

```
DROP TABLE IF EXISTS test_trigger_src_tbl;
DROP TABLE IF EXISTS test_trigger_des_tbl;

CREATE TABLE test_trigger_src_tbl(id1 INT, id2 INT, id3 INT);
CREATE TABLE test_trigger_des_tbl(id1 INT, id2 INT, id3 INT);
```

Create the **tri\_insert\_func()** trigger function.

```
DROP FUNCTION IF EXISTS tri_insert_func;
CREATE OR REPLACE FUNCTION tri_insert_func() RETURNS TRIGGER AS
$$
 DECLARE
 BEGIN
 INSERT INTO test_trigger_des_tbl VALUES(NEW.id1, NEW.id2, NEW.id3);
 RETURN NEW;
 END
$$ LANGUAGE PLPGSQL;
```

Create the **insert\_trigger** trigger.

```
CREATE TRIGGER insert_trigger
 BEFORE INSERT ON test_trigger_src_tbl
 FOR EACH ROW
 EXECUTE PROCEDURE tri_insert_func();
```

Modify the **insert\_trigger** trigger.

```
ALTER TRIGGER insert_trigger ON test_trigger_src_tbl RENAME TO delete_trigger_renamed;
```

Disable the **delete\_trigger\_renamed** trigger.

```
ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER delete_trigger_renamed;
```

Disable all triggers on the **test\_trigger\_src\_tbl** table.

```
ALTER TABLE test_trigger_src_tbl DISABLE TRIGGER ALL;
```

### 21.13.7.8 DROP TRIGGER

#### Function

**DROP TRIGGER** deletes a trigger.

## Precautions

Only the owner of a trigger and system administrators can run the **DROP TRIGGER** statement.

## Syntax

```
DROP TRIGGER [IF EXISTS] trigger_name ON table_name [CASCADE | RESTRICT];
```

## Parameter Description

**Table 21-233** DROP TRIGGER parameters

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                              |
|--------------------|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF EXISTS          | Sends a notice instead of an error if the specified trigger does not exist.                         | -                                                                                                                                                                                                                        |
| trigger_name       | Specifies the name of the trigger to be deleted.                                                    | An existing trigger.                                                                                                                                                                                                     |
| table_name         | Specifies the name of the table where the trigger to be deleted is located.                         | An existing table having a trigger                                                                                                                                                                                       |
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: Deletes objects that depend on the trigger.</li><li>• <b>RESTRICT</b>: Refuses to delete the trigger if any objects depend on it. This is the default.</li></ul> |

## Examples

Delete trigger **insert\_trigger**.

```
DROP TRIGGER insert_trigger ON test_trigger_src_tbl;
```

## Helpful Links

[CREATE TRIGGER](#), [ALTER TRIGGER](#), [ALTER TABLE](#)

### 21.13.7.9 FETCH

## Function

**FETCH** retrieves data using a previously-created cursor.

A cursor has an associated position, which is used by **FETCH**. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result.

- When created, a cursor is positioned before the first row.
- After fetching some rows, the cursor is positioned on the row most recently retrieved.
- If **FETCH** runs off the end of the available rows then the cursor is left positioned after the last row, or before the first row if fetching backward.
- **FETCH ALL** or **FETCH BACKWARD ALL** will always leave the cursor positioned after the last row or before the first row.

## Precautions

- If **NO SCROLL** is defined for the cursor, a backward fetch like **FETCH BACKWARD** is not allowed.
- The forms **NEXT**, **PRIOR**, **FIRST**, **LAST**, **ABSOLUTE**, and **RELATIVE** appropriately fetch a record after moving the cursor. If the cursor is already after the last row before being moved, an empty result is returned, and the cursor is left positioned before the first row (backward fetch) or after the last row (forward fetch) as appropriate.
- The forms using **FORWARD** and **BACKWARD** retrieve the indicated number of rows moving in the forward or backward direction, leaving the cursor positioned on the last-returned row (or after (backward fetch)/before (forward fetch) all rows, if the count exceeds the number of rows available).
- **RELATIVE 0**, **FORWARD 0**, and **BACKWARD 0** all request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case, no row is returned.
- If the cursor of **FETCH** involves a column-store table, backward fetches like **BACKWARD**, **PRIOR**, and **FIRST** are not supported.

## Syntax

```
FETCH [direction { FROM | IN }] cursor_name;
```

The **direction** clause specifies optional parameters.

```
NEXT
| PRIOR
| FIRST
| LAST
| ABSOLUTE count
| RELATIVE count
| count
| ALL
| FORWARD
| FORWARD count
| FORWARD ALL
| BACKWARD
| BACKWARD count
| BACKWARD ALL
```

## Parameter Description

**Table 21-234** FETCH parameters

| Parameter                    | Description                                                            | Value Range                                     |
|------------------------------|------------------------------------------------------------------------|-------------------------------------------------|
| direction_clause             | Defines the fetch direction.                                           | For details, see <a href="#">Table 21-235</a> . |
| { FROM   IN }<br>cursor_name | Specifies the cursor name using the keyword <b>FROM</b> or <b>IN</b> . | Name of the cursor                              |

**Table 21-235** Value range of direction\_clause

| Value Range                    | Description                                                                                                                                                                                                                            | Remarks                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NEXT</b><br>(default value) | Fetches the next row.                                                                                                                                                                                                                  | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>PRIOR</b>                   | Fetches the prior row.                                                                                                                                                                                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>FIRST</b>                   | Fetches the first row of the query (same as <b>ABSOLUTE 1</b> ).                                                                                                                                                                       | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>LAST</b>                    | Fetches the last row of the query (same as <b>ABSOLUTE -1</b> ).                                                                                                                                                                       | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ABSOLUTE</b><br>count       | Fetches the ( <b>count</b> )'th row of the query.<br><b>ABSOLUTE</b> fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway. | <b>count</b> is a possibly-signed integer constant: <ul style="list-style-type: none"><li>• If <b>count</b> is a positive integer, fetches the (<b>count</b>)'th row of the query, starting from the first row. If <b>count</b> is less than the current cursor position, a <b>rewind</b> operation is required, which is currently not supported.</li><li>• If <b>count</b> is a negative value or 0, a backward scanning is required, which is currently not supported.</li></ul> |

| Value Range    | Description                                                                                 | Remarks                                                                                                                                                                                                                                                                                                                                                    |
|----------------|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RELATIVE count | Fetches the (count)'th succeeding row, or the abs(count)'th prior row if count is negative. | <b>count</b> is a possibly-signed integer constant: <ul style="list-style-type: none"><li>• If <b>count</b> is a positive integer, fetches the (count)'th succeeding row.</li><li>• If <b>count</b> is a negative value, a backward scanning is required, which is currently not supported.</li><li>• <b>RELATIVE 0</b> fetches the current row.</li></ul> |
| count          | Fetches the next <b>count</b> rows (same as <b>FORWARD count</b> ).                         | -                                                                                                                                                                                                                                                                                                                                                          |
| ALL            | Fetches all remaining rows (same as <b>FORWARD ALL</b> ).                                   | -                                                                                                                                                                                                                                                                                                                                                          |
| FORWARD        | Fetches the next row (same as <b>NEXT</b> ).                                                | -                                                                                                                                                                                                                                                                                                                                                          |
| FORWARD count  | Fetches the next or prior <b>count</b> rows (same as <b>RELATIVE count</b> ).               | -                                                                                                                                                                                                                                                                                                                                                          |
| FORWARD ALL    | Fetches all remaining rows.                                                                 | -                                                                                                                                                                                                                                                                                                                                                          |
| BACKWARD       | Fetches the prior row (same as <b>PRIOR</b> ).                                              | -                                                                                                                                                                                                                                                                                                                                                          |
| BACKWARD count | Fetches the prior <b>count</b> rows (scanning backwards).                                   | <b>count</b> is a possibly-signed integer constant: <ul style="list-style-type: none"><li>• If <b>count</b> is a positive integer, fetches the (count)'th prior row.</li><li>• If <b>count</b> is a negative integer, fetches the abs(count)'th succeeding row.</li><li>• <b>BACKWARD 0</b> re-fetches the current row.</li></ul>                          |
| BACKWARD ALL   | Fetches all prior rows (scanning backwards).                                                | -                                                                                                                                                                                                                                                                                                                                                          |

## Examples

Example 1: Run the **SELECT** statement to read a table using a cursor.

Set up the **cursor1** cursor.

```
CURSOR cursor1 FOR SELECT * FROM tpods.customer_address ORDER BY 1;
```

Fetch the first three rows from **cursor1**.

```
FETCH FORWARD 3 FROM cursor1;
```

Example 2: Use a cursor to read the content in the **VALUES** clause.

Set up the cursor **cursor2**.

```
CURSOR cursor2 FOR VALUES(1,2),(0,3) ORDER BY 1;
```

Fetch the first two rows from **cursor2**.

```
FETCH FORWARD 2 FROM cursor2;
```

[CLOSE](#), [MOVE](#)

### 21.13.7.10 MOVE

## Function

**MOVE** repositions a cursor without retrieving any data. **MOVE** works exactly like the **FETCH** command, except it only repositions the cursor and does not return rows.

## Precautions

None

## Syntax

```
MOVE [direction [FROM | IN]] cursor_name;
```

The **direction** clause specifies optional parameters.

```
NEXT
| PRIOR
| FIRST
| LAST
| ABSOLUTE count
| RELATIVE count
| count
| ALL
| FORWARD
| FORWARD count
| FORWARD ALL
| BACKWARD
| BACKWARD count
| BACKWARD ALL
```

## Parameter Description

**MOVE** command parameters are the same as **FETCH** command parameters. For details, see [Parameter Description](#) in **FETCH**.

 **NOTE**

On successful completion, a **MOVE** command returns a command tag of the form **MOVE count**. The **count** is the number of rows that a **FETCH** command with the same parameters would have returned (possibly zero).

## Examples

Create table **reason** and insert data into it.

```
DROP TABLE IF EXISTS reason;
CREATE TABLE reason
(
 a int primary key,
 b int,
 c int
);

INSERT INTO reason VALUES (1, 2, 3);
```

Start a transaction.

```
START TRANSACTION;
```

Define **cursor1** cursor.

```
CURSOR cursor1 FOR SELECT * FROM tpceds.reason;
```

Skip the first three rows of **cursor1**.

```
MOVE FORWARD 3 FROM cursor1;
```

Fetch the first four rows from **cursor1**.

```
FETCH 4 FROM cursor1;
```

Close a cursor.

```
CLOSE cursor1;
```

End the transaction.

```
END;
```

### 21.13.7.11 CURSOR

#### Function

This statement is used to create a cursor and retrieve specified rows of data from a query.

To process SQL statements, the stored procedure process assigns a memory segment to store context association. Cursors are handles or pointers to context regions. With cursors, stored procedures can control alterations in context regions.

#### Precautions

- **CURSOR** is used only in transaction blocks.

- Generally, **CURSOR** and **SELECT** both have text returns. Since data is stored in binary format in the system, the system needs to convert the data from the binary format to the text format. If data is returned in text format, the client-end application needs to convert the data back to a binary format for processing. **FETCH** implements conversion between binary data and text data.
- Use a binary cursor unless necessary, since a text cursor occupies larger storage space than a binary cursor. A binary cursor returns internal binary data, which is easier to operate. To return data in text format, it is advisable to retrieve data in text format, therefore reducing workload at the client end. For example, the value 1 in an integer column of a query is returned as a character string 1 if a default cursor is used, but is returned as a 4-byte binary value (big-endian) if a binary cursor is used.

## Syntax

```
CURSOR cursor_name
[BINARY] [NO SCROLL] [{ WITH | WITHOUT } HOLD]
FOR query ;
```

## Parameter Description

Table 21-236 CURSOR parameters

| Parameter                | Description                                                                                                                                                                                                                                                                                                                             | Value Range                                                              |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| cursor_name              | Specifies the name of the cursor to be created.                                                                                                                                                                                                                                                                                         | A string, which must comply with the <a href="#">naming convention</a> . |
| BINARY                   | Specifies that data retrieved by the cursor will be returned in binary format, not in text format.                                                                                                                                                                                                                                      | -                                                                        |
| NO SCROLL                | Specifies the mode of data retrieval by the cursor. <ul style="list-style-type: none"><li>• <b>NO SCROLL</b>: If <b>NO SCROLL</b> is specified, backward fetches will be rejected.</li><li>• Not stated: The system automatically determines whether the cursor can be used for backward fetches based on the execution plan.</li></ul> | -                                                                        |
| WITH HOLD   WITHOUT HOLD | Specifies whether the cursor can still be used after the cursor creation event. <ul style="list-style-type: none"><li>• <b>WITH HOLD</b> indicates that the cursor can still be used.</li><li>• <b>WITHOUT HOLD</b> indicates that the cursor cannot be used. (default setting)</li></ul>                                               | -                                                                        |

| Parameter | Description                                                                             | Value Range                                    |
|-----------|-----------------------------------------------------------------------------------------|------------------------------------------------|
| query     | The <b>SELECT</b> or <b>VALUES</b> clause specifies the row to return the cursor value. | Use the <b>SELECT</b> or <b>VALUES</b> clause. |

## Examples

Start a transaction.

```
START TRANSACTION;
```

Create a cursor named **cursor1**:

```
CURSOR cursor1 FOR SELECT * FROM tpods.customer_address ORDER BY 1;
```

create a cursor named **cursor2**:

```
CURSOR cursor2 FOR VALUES(1,2),(0,3) ORDER BY 1;
```

Usage of the **WITH HOLD** cursor:

1. Set up the **WITH HOLD** cursor.  

```
DECLARE cursor3 CURSOR WITH HOLD FOR SELECT * FROM tpods.customer_address ORDER BY 1;
```
2. Fetch the first two rows from cursor3.  

```
FETCH FORWARD 2 FROM cursor3;
```
3. End the transaction.  

```
END;
```
4. Fetch the next row from cursor3.  

```
FETCH FORWARD 1 FROM cursor3;
```
5. Close the cursor.  

```
CLOSE cursor3;
```

[FETCH](#)

### 21.13.7.12 CLOSE

#### Function

**CLOSE** frees the resources associated with a cursor.

#### Precautions

- After a cursor is closed, no subsequent operations are allowed on it.
- Cursors that are no longer used should be closed.
- Each non-held open cursor should be implicitly closed after the transaction that created the cursor is terminated with **COMMIT** or **ROLLBACK**.
- A holdable cursor is implicitly closed when the transaction that creates the cursor exits through **ROLLBACK**.
- If the transaction that creates a cursor is committed, the cursor remains open until an explicit **CLOSE** operation is performed or the client is disconnected.

- DWS does not have an explicit **OPEN** cursor statement. A cursor opens when you define it with the **CURSOR** command. You can see all available cursors by querying the **pg\_cursors** system view.

## Syntax

```
CLOSE { cursor_name | ALL };
```

## Parameter Description

Table 21-237 CLOSE parameters

| Parameter   | Description                                    | Value Range                 |
|-------------|------------------------------------------------|-----------------------------|
| cursor_name | Specifies the name of the cursor to be closed. | Name of an existing cursor. |
| ALL         | Closes all open cursors.                       | -                           |

## Examples

Close a cursor.

```
CLOSE cursor1;
```

## 21.13.8 Data Masking and Security

### 21.13.8.1 CREATE ROW LEVEL SECURITY POLICY

#### Function

**CREATE ROW LEVEL SECURITY POLICY** creates a row-level access control policy for a table.

The policy takes effect only after row-level access control is enabled (by running **ALTER TABLE... ENABLE ROW LEVEL SECURITY** | **ALTER FOREIGN TABLE ... ENABLE ROW LEVEL SECURITY**).

Currently, row-level access control affects the read (**SELECT**, **UPDATE**, **DELETE**) of data tables and does not affect the write (**INSERT** and **MERGE INTO**) of data tables. The table owner or system administrators can create an expression in the **USING** clause. When the client reads the data table, the database server combines the expressions that meet the condition and applies it to the execution plan in the statement rewriting phase of a query. For each tuple in a data table, if the expression returns **TRUE**, the tuple is visible to the current user; if the expression returns **FALSE** or **NULL**, the tuple is invisible to the current user.

A row-level access control policy name is specific to a table. A data table cannot have row-level access control policies with the same name. Different data tables can have the same row-level access control policy.

Row-level access control policies can be applied to specified operations (**SELECT**, **UPDATE**, **DELETE**, and **ALL**). **ALL** indicates that **SELECT**, **UPDATE**, and **DELETE** will be affected. For a new row-level access control policy, the default value **ALL** will be used if you do not specify the operations that will be affected.

Row-level access control policies can be applied to a specified user (role) or to all users (**PUBLIC**). For a new row-level access control policy, the default value **PUBLIC** will be used if you do not specify the user that will be affected.

## Precautions

- Row-level access control policies can be defined for row-store tables, row-store partitioned tables, column-store tables, column-store partitioned tables, replication tables, unlogged tables, hash tables, and non-EXTERNAL SCHEMA foreign tables.
- Row-level access control policies cannot be defined for HDFS tables, EXTERNAL SCHEMA foreign tables, and temporary tables.
- Row-level access control policies cannot be defined for views.
- A maximum of 100 row-level access control policies cannot be defined for a table.
- Users with administrator permissions, initial O&M users (Ruby), table owners, and members of the table owner role are not affected by row-level access control and can view full data of the table.
- Tables queried by using SQL statements, views, functions, and stored procedures are affected by row-level access control policies.
- The type of a column on which a row-level access control policy depends cannot be changed. For example, the following modifications are not supported:

```
ALTER TABLE public.all_data ALTER COLUMN role TYPE text;
```

## Syntax

```
CREATE [ROW LEVEL SECURITY] POLICY policy_name ON table_name
[AS { PERMISSIVE | RESTRICTIVE }]
[FOR { ALL | SELECT | UPDATE | DELETE }]
[TO { role_name | PUBLIC } [, ...]]
USING (using_expression)
```

## Parameter Description

**Table 21-238** CREATE ROW LEVEL SECURITY POLICY parameters

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| policy_name | Specifies the name of a row-level access control policy to be created. The names of row-level access control policies for a table must be unique.                                                                                                                                                                                                                                                                                                                                                                 | -           |
| table_name  | Specifies the name of a table to which a row-level access control policy is applied.                                                                                                                                                                                                                                                                                                                                                                                                                              | -           |
| PERMISSIVE  | Specifies that the row-level access control policy is to be created as a permissive policy. For a given query, all applicable permissive policies are combined using the OR operator. Row-level access control policies are permissive by default.                                                                                                                                                                                                                                                                | -           |
| RESTRICTIVE | Specifies that the row-level access control policy is to be created as a restrictive policy. For a given query, all applicable restrictive policies are combined using the AND operator.<br><br>At least one permissive policy is required to grant access to data records. If only restrictive policies are used, no records will be accessible. When both permissive and restrictive policies are used, a record is accessible only when it passes at least one permissive policy and all restrictive policies. | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| command   | Specifies the SQL operations affected by a row-level access control policy, including <b>ALL</b> , <b>SELECT</b> , <b>UPDATE</b> , and <b>DELETE</b> . If this parameter is not specified, the default value <b>ALL</b> will be used, covering <b>SELECT</b> , <b>UPDATE</b> , and <b>DELETE</b> . | <p>If <i>command</i> is set to <b>SELECT</b>, only tuple data that meets the condition (the return value of <i>using_expression</i> is <b>TRUE</b>) can be queried. The operations that are affected include <b>SELECT</b>, <b>UPDATE.... RETURNING</b>, and <b>DELETE... RETURNING</b>.</p> <p>If <i>command</i> is set to <b>UPDATE</b>, only tuple data that meets the condition (the return value of <i>using_expression</i> is <b>TRUE</b>) can be updated. The operations that are affected include <b>UPDATE</b>, <b>UPDATE ... RETURNING</b>, and <b>SELECT ... FOR UPDATE/SHARE</b>.</p> <p>If <i>command</i> is set to <b>DELETE</b>, only tuple data that meets the condition (the return value of <i>using_expression</i> is <b>TRUE</b>) can be deleted. The operations that are affected include <b>DELETE</b> and <b>DELETE ... RETURNING</b>.</p> <p>The following table <a href="#">Table 21-239</a> describes the relationship between row-level access control policies and SQL statements.</p> |
| role_name | Specifies database users affected by a row-level access control policy.<br><b>NOTICE</b><br>System administrators are not affected by row access control.                                                                                                                                          | If this parameter is not specified, the default value <b>PUBLIC</b> will be used, indicating that all database users will be affected. You can specify multiple affected database users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter        | Description                                                                                   | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| using_expression | Specifies an expression defined for a row-level access control policy (return type: boolean). | The expression cannot contain aggregate functions and window functions. In the statement rewriting phase of a query, if row-level access control for a data table is enabled, the expressions that meet the specified conditions will be added to the plan tree. The expression is calculated for each tuple in the data table. For <b>SELECT</b> , <b>UPDATE</b> , and <b>DELETE</b> , row data is visible to the current user only when the return value of the expression is <b>TRUE</b> . If the expression returns <b>FALSE</b> , the tuple is invisible to the current user. In this case, the user cannot view the tuple through the <b>SELECT</b> statement, update the tuple through the <b>UPDATE</b> statement, or delete the tuple through the <b>DELETE</b> statement. |

**Table 21-239** Relationship between row-level security policies and SQL statements

| Command                 | SELECT/ALL Policy | UPDATE/ALL Policy | DELETE/ALL Policy |
|-------------------------|-------------------|-------------------|-------------------|
| SELECT                  | Existing row      | No                | No                |
| SELECT FOR UPDATE/SHARE | Existing row      | Existing row      | No                |
| UPDATE                  | No                | Existing row      | No                |
| UPDATE RETURNING        | Existing row      | Existing row      | No                |
| DELETE                  | No                | No                | Existing row      |
| DELETE RETURNING        | Existing row      | No                | Existing row      |

## Example 1: Create a Row-level Access Control Policy That the Current User Can Only View Its Own Data.

1. Create users **alice** and **bob**.  

```
CREATE ROLE alice PASSWORD '{password}';
CREATE ROLE bob PASSWORD '{password}';
```
2. Create the data table **public.all\_data**.  

```
CREATE TABLE public.all_data(id int, role varchar(100), data varchar(100));
```
3. Insert data into the table.  

```
INSERT INTO all_data VALUES(1, 'alice', 'alice data');
INSERT INTO all_data VALUES(2, 'bob', 'bob data');
INSERT INTO all_data VALUES(3, 'peter', 'peter data');
```
4. Grant the read permission for the **all\_data** table to users **alice** and **bob**.  

```
GRANT SELECT ON all_data TO alice, bob;
```
5. Enable row-level access control.  

```
ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;
```
6. Create a row-level access control policy to specify that the current user can view only its own data.  

```
CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);
```
7. View information about the **all\_data** table.

```
\d+ all_data
```

```
Table "public.all_data"
Column | Type | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id | integer | | plain | |
role | character varying(100) | | extended | |
data | character varying(100) | | extended | |
```

```
Row Level Security Policies:
```

```
 POLICY "all_data_rls"
 USING (((role)::name = "current_user"()))
```

```
Has OIDs: no
```

```
Distribute By: HASH(id)
```

```
Location Nodes: ALL DATANODES
```

```
Options: orientation=row, compression=no, enable_rowsecurity=true
```

8. Run **SELECT**.  

```
SELECT * FROM all_data;
id | role | data
---+---+---
1 | alice | alice data
2 | bob | bob data
3 | peter | peter data
(3 rows)
EXPLAIN(COSTS OFF) SELECT * FROM all_data;
QUERY PLAN

Streaming (type: GATHER)
Node/s: All datanodes
-> Seq Scan on all_data
(3 rows)
```

9. Switch to the **alice** user.

```
set role alice password '{password}';
```

10. Perform the **SELECT** operation.  

```
SELECT * FROM all_data;
id | role | data
---+---+---
1 | alice | alice data
(1 row)
EXPLAIN(COSTS OFF) SELECT * FROM all_data;
QUERY PLAN

Streaming (type: GATHER)
```

```
Node/s: All datanodes
-> Seq Scan on all_data
 Filter: ((role)::name = 'alice'::name)
Notice: This query is influenced by row level security feature
(5 rows)
```

## Example 2: Partition Permission Management Through Row-Level Control

1. Create user **alice**.  

```
CREATE ROLE alice PASSWORD '{password1}';
```
2. Create the range partitioned table **web\_returns\_p1** and insert data into the table.  

```
CREATE TABLE web_returns_p1
(
 wr_returned_date_sk integer,
 wr_returned_time_sk integer,
 wr_item_sk integer NOT NULL,
 wr_refunded_customer_sk integer
)
WITH (orientation = column)
DISTRIBUTE BY HASH (wr_item_sk)
PARTITION BY RANGE(wr_returned_date_sk)
(
 PARTITION p2016 START(800) END(830) EVERY(1)
);

INSERT INTO web_returns_p1 values (801,17,11,102);
INSERT INTO web_returns_p1 values (802,18,12,103);
```
3. Grant the read permission on the **web\_returns\_p1** table to user **alice**.  

```
GRANT SELECT ON web_returns_p1 TO alice;
```
4. Enable row-level access control.  

```
ALTER TABLE web_returns_p1 ENABLE ROW LEVEL SECURITY;
```
5. Create row-level access control policy **web\_returns\_rsl**. In the command, **wr\_returned\_date\_sk** is a partition name of the **web\_returns\_p1** partition table, and **801** is the partition value.  

```
CREATE ROW LEVEL SECURITY POLICY web_returns_rsl ON web_returns_p1
USING('wr_returned_date_sk' = '801');
```
6. Impose the row-level access control policy **web\_returns\_rsl** on user **alice**.  

```
ALTER ROW LEVEL SECURITY POLICY web_returns_rsl ON web_returns_p1 TO alice;
```
7. Switch to the **alice** user.  

```
set role alice password '{password1}';
```
8. Query the **web\_returns\_p1** table.  

```
select * from web_returns_p1;
```

### 21.13.8.2 ALTER ROW LEVEL SECURITY POLICY

#### Function

**ALTER ROW LEVEL SECURITY POLICY** modifies an existing row-level access control policy, including the policy name and the users and expressions affected by the policy.

## Precautions

Only the table owner or administrators can perform this operation.

## Syntax

```
ALTER [ROW LEVEL SECURITY] POLICY [IF EXISTS] policy_name ON table_name RENAME TO
new_policy_name
```

```
ALTER [ROW LEVEL SECURITY] POLICY policy_name ON table_name
[TO { role_name | PUBLIC } [, ...]]
[USING (using_expression)]
```

## Parameter Description

**Table 21-240** ALTER ROW LEVEL SECURITY POLICY parameters

| Parameter        | Description                                                                                                                                                                     | Value Range                                          |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| policy_name      | Specifies the name of a row-level access control policy to be modified.                                                                                                         | A string compliant with the identifier naming rules. |
| table_name       | Specifies the name of a table to which a row-level access control policy is applied.                                                                                            | Name of an existing table.                           |
| new_policy_name  | Specifies the new name of a row-level access control policy.                                                                                                                    | -                                                    |
| role_name        | Specifies names of users affected by a row-level access control policy will be applied. <b>PUBLIC</b> indicates that the row-level access control policy will affect all users. | Name of an existing role.                            |
| using_expression | Specifies an expression defined for a row-level access control policy. The return value is of the boolean type.                                                                 | -                                                    |

## Examples

Enable row-level access control.

```
ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;
```

Change the name of the **all\_data\_rls** policy.

```
ALTER ROW LEVEL SECURITY POLICY all_data_rls ON all_data RENAME TO all_data_new_rls;
```

Change the users affected by the row-level access control policy.

```
ALTER ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data TO alice, bob;
```

Modify the expression defined for the access control policy.

```
ALTER ROW LEVEL SECURITY POLICY all_data_new_rls ON all_data USING (id > 100 AND role =
current_user);
```

## Helpful Links

[CREATE ROW LEVEL SECURITY POLICY](#) and [DROP ROW LEVEL SECURITY POLICY](#)

### 21.13.8.3 DROP ROW LEVEL SECURITY POLICY

#### Function

Deletes a row-level access control policy from a table.

#### Precautions

Only the table owner or administrators can delete a row-level access control policy from the table.

#### Syntax

```
DROP [ROW LEVEL SECURITY] POLICY [IF EXISTS] policy_name ON table_name [CASCADE | RESTRICT]
```

#### Parameter Description

**Table 21-241** DROP ROW LEVEL SECURITY POLICY parameters

| Parameter            | Description                                                                                                                                                           | Value Range                                                                            |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| IF EXISTS            | Reports a notice instead of an error if the specified row-level access control policy does not exist.                                                                 | -                                                                                      |
| policy_name          | Specifies the name of a row-level access control policy to be deleted.                                                                                                | An existing name of a row-level access control policy.                                 |
| table_name           | Specifies the name of a table to which a row-level access control policy to be deleted belongs.                                                                       | An existing name of the data table to which a row-level access control policy belongs. |
| CASCADE/<br>RESTRICT | The two parameters are used only for syntax compatibility. No objects depend on access control policies and thereby <b>CASCADE</b> is equivalent to <b>RESTRICT</b> . | -                                                                                      |

#### Examples

Delete the row-level access control policy **all\_data\_rls** from table **all\_data**.

```
DROP ROW LEVEL SECURITY POLICY all_data_rls ON all_data;
```

## Helpful Links

[ALTER ROW LEVEL SECURITY POLICY](#), [CREATE ROW LEVEL SECURITY POLICY](#)

### 21.13.8.4 CREATE REDACTION POLICY

#### Function

**CREATE REDACTION POLICY** creates a data redaction policy for a table.

#### Precautions

- The data masking feature is controlled by **feature\_support\_options**. If error information "REDACTION POLICY is not yet supported, please add enable\_data\_redaction into feature\_support\_options." or "Cannot use the feature of data redaction, please drop existed redaction policy or add enable\_data\_redaction into feature\_support\_options." is displayed, the data masking feature is not enabled. In this case, you need to contact technical support to set **feature\_support\_options**.
- Only the table object owner and users who have been granted the **gs\_redaction\_policy** preset role are authorized to create data masking policies.
- Data masking policies can be created for regular tables and non-EXTERNAL-SCHEMA foreign tables (such as OBS, HDFS, GDS, and foreign tables for coordinated analysis), but not for system catalogs, EXTERNAL SCHEMA foreign tables, temporary tables, UNLOGGED tables, views, or functions.
- Synonyms cannot be used to create redaction policies for ordinary table objects.
- Table objects and redaction policies have a one-to-one mapping relationship. A redaction policy is a collection of data redaction functions that can be applied to multiple columns in a table. You can set different redaction functions for different columns.
- A redaction policy is enabled by default upon its creation, that is, the **enable** parameter of the policy is **true** by default.
- Redaction policies do not take effect on users with the **sysadmin** permission. Data in the redacted columns is always visible to such users.
- Data redaction policies can be matched with specified roles.

#### Syntax

```
CREATE REDACTION POLICY [IF NOT EXISTS] policy_name ON table_name [{ BEFORE | AFTER }
old_policy_name]
[WHEN (when_expression)]
[ADD COLUMN column_name WITH redaction_function_name ([argument [, ...]])] [, ...];
```

## Parameter Description

**Table 21-242** CREATE REDACTION POLICY parameters

| Parameter      | Description                                                                                                                                                                                                                                                                          | Value Range |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| policy_name    | Specifies the name of a redaction policy.                                                                                                                                                                                                                                            | -           |
| table_name     | Specifies the name of the table to which the redaction policy is applied.                                                                                                                                                                                                            | -           |
| BEFORE   AFTER | Specifies the relative location where the current policy is created. Generally, one masking policy is used for one table. The default value indicates that the current policy is created after the last candidate policy of the target table recorded in the current system catalog. | -           |

| Parameter                   | Description                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WHEN<br>( when_expression ) | Specifies the expression used for the redaction policy to take effect. The redaction policy takes effect only when this expression is true. | <p>When a query statement is querying a table where a redaction policy is enabled, the redacted data is invisible in the query only if the WHEN expression for the redaction policy is true. Generally, the WHEN clause is used to specify the users for which the redaction policy takes effect.</p> <p>The WHEN clause must comply with the following rules:</p> <ol style="list-style-type: none"><li>1. The expression can be a combination of multiple subexpressions connected by AND and/or OR.</li><li>2. Each subexpression supports only the =, &lt;&gt;, !=, &gt;=, &gt;, &lt;=, and &lt; operators. The left and right operand values can only be constant values or one of the following system constant values:<br/><b>SESSION_USER</b>,<br/><b>CURRENT_USER</b>, <b>USER</b>,<br/><b>CURRENT_ROLE</b>, and<br/><b>CURRENT_SCHEMA</b> system constants or the <b>SYS_CONTEXT</b> system function.</li><li>3. Each subexpression can be an IN or NOT IN expression. The value for the left operand can be any of the system constant values listed in rule 2, and each element in the array of the right operand must be a constant value.</li><li>4. Each subexpression can be a <b>pg_has_role(user, role, privilege)</b> system function.</li><li>5. If you want a redaction policy to be valid in all conditions, that is, you want it to take effect on all users (including the table owner), you are advised to use the</li></ol> |

| Parameter               | Description                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                                                                                                                                                               |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                                                                                                                                                                                                                                                                                                                    | (1=1) expression to create this policy.<br><br>6. If the WHEN clause is not specified, the redaction policy is disabled by default. You need to manually specify a WHEN expression for the policy to take effect.                                                                                                                         |
| column_name             | Specifies the name of the table column to which the redaction policy is applied.                                                                                                                                                                                                                                   | -                                                                                                                                                                                                                                                                                                                                         |
| redaction_function_name | Specifies the redaction function applied to the specified table column.                                                                                                                                                                                                                                            | -                                                                                                                                                                                                                                                                                                                                         |
| arguments               | Specifies the list of arguments of the redaction function.<br><br>You can use the built-in masking functions <b>MASK_NONE</b> , <b>MASK_FULL</b> , and <b>MASK_PARTIAL</b> , or create your own masking functions by using the C language or PL/pgSQL. For details, see <a href="#">Data Redaction Functions</a> . | <ul style="list-style-type: none"><li>• <b>MASK_NONE</b>: indicates that no masking is performed.</li><li>• <b>MASK_FULL</b>: indicates that all data is masked to a fixed value.</li><li>• <b>MASK_PARTIAL</b>: indicates that partial masking is performed based on the specified character type, numeric type, or time type.</li></ul> |

## Examples

### Create redaction policy for a specified user.

1. Create users **alice** and **matu**.  

```
CREATE ROLE alice PASSWORD '{password}';
CREATE ROLE matu PASSWORD '{password}';
```
2. Create the table object **emp** as user **alice**, and insert data into the table.  

```
CREATE TABLE emp(id int, name varchar(20), salary NUMERIC(10,2));
INSERT INTO emp VALUES(1, 'July', 1230.10), (2, 'David', 999.99);
```
3. Create the redaction policy **mask\_emp** for the **emp** table as user **alice** and make the **salary** column invisible to user **matu**.  

```
CREATE REDACTION POLICY mask_emp ON emp WHEN(current_user = 'matu') ADD COLUMN salary
WITH mask_full(salary);
```
4. Grant the **SELECT** permission on the **emp** table to user **matu** as user **alice**.  

```
GRANT SELECT ON emp TO matu;
```
5. Switch to user **matu**.  

```
SET ROLE matu PASSWORD '{password}';
```

6. Query the **emp** table. Data in the **salary** column has been redacted.  

```
SELECT * FROM emp;
```

#### Create redaction policy for the role.

1. Create the role **redact\_role**.  

```
CREATE ROLE redact_role PASSWORD '{password}';
```
2. Add users **matu** and **alice** to the role **redact\_role**.  

```
GRANT redact_role to matu,alice;
```
3. Create a table object **emp1** as the administrator and insert data.  

```
CREATE TABLE emp1(id int, name varchar(20), salary NUMERIC(10,2));
INSERT INTO emp1 VALUES(3, 'Rose', 2230.20), (4, 'Jack', 899.88);
```
4. Create a redaction policy **mask\_emp1** for the table object **emp1** as the administrator to make the **salary** column invisible to role **redact\_role**.  

```
CREATE REDACTION POLICY mask_emp1 ON emp1 WHEN (pg_has_role(current_user, 'redact_role',
'member')) ADD COLUMN salary WITH mask_full(salary);
```

If no user is specified, the current user (**current\_user**) is used by default.

```
CREATE REDACTION POLICY mask_emp1 ON emp1 WHEN (pg_has_role('redact_role', 'member'))
ADD COLUMN salary WITH mask_full(salary);
```
5. Grant the **SELECT** permission on the **emp1** table to user **matu** as the administrator.  

```
GRANT SELECT ON emp1 TO matu;
```
6. Switch to user **matu**.  

```
SET ROLE matu PASSWORD '{password}';
```
7. Query the **emp** table. Data in the **salary** column has been redacted.  

```
SELECT * FROM emp1;
```

## Helpful Links

[ALTER REDACTION POLICY](#), [DROP REDACTION POLICY](#)

### 21.13.8.5 ALTER REDACTION POLICY

#### Function

**ALTER REDACTION POLICY** modifies a data redaction policy applied to a specified table.

#### Precautions

Only the table object owner and users with the **gs\_redaction\_policy** preset role can modify the masking policy.

#### Syntax

- Modify the expression used for a redaction policy to take effect.  

```
ALTER REDACTION POLICY policy_name ON table_name WHEN (when_expression);
```
- Enable or disable a redaction policy.  

```
ALTER REDACTION POLICY policy_name ON table_name ENABLE | DISABLE;
```
- Rename a redaction policy.  

```
ALTER REDACTION POLICY policy_name ON table_name RENAME TO new_policy_name;
```
- Add, modify, or delete a column on which the redaction policy is used.  

```
ALTER REDACTION POLICY policy_name ON table_name
action;
```

There are several clauses of **action**:

```
[INHERIT] ADD COLUMN column_name WITH redaction_function_name ([argument [, ...]])
| [INHERIT] MODIFY COLUMN column_name WITH redaction_function_name ([argument [, ...]])
| DROP COLUMN column_name
```

## Parameter Description

**Table 21-243** ALTER REDACTION POLICY parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                   | Value Range                                                                               |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| policy_name             | Specifies the name of the redaction policy to be modified.                                                                                                                                                                                                                                                                                                    | Name of an existing masking policy.                                                       |
| table_name              | Specifies the name of the table to which the redaction policy is applied.                                                                                                                                                                                                                                                                                     | Name of an existing table.                                                                |
| when_expression         | Specifies the new expression used for the redaction policy to take effect.                                                                                                                                                                                                                                                                                    | -                                                                                         |
| ENABLE   DISABLE        | Specifies whether to enable or disable the current redaction policy. <ul style="list-style-type: none"><li>• <b>ENABLE</b>: makes the data masking policy of the table take effect again.</li><li>• <b>DISABLE</b>: disables the masking policy applied to the table.</li></ul>                                                                               | -                                                                                         |
| new_policy_name         | Specifies the new name of the redaction policy.                                                                                                                                                                                                                                                                                                               | A string compliant with the <a href="#">identifier naming rules</a> .                     |
| column_name             | Specifies the name of the table column to which the redaction policy is applied. <ul style="list-style-type: none"><li>• To add a column, use a column name that has not been bound to any redaction functions.</li><li>• To modify a column, use the name of an existing column.</li><li>• To delete a column, use the name of an existing column.</li></ul> | -                                                                                         |
| redaction_function_name | Specifies the name of a redaction function.                                                                                                                                                                                                                                                                                                                   | For details about the supported functions, see <a href="#">Data Redaction Functions</a> . |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                     | Value Range                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| arguments | <p>Specifies the list of arguments of the masking function.</p> <ul style="list-style-type: none"><li>• <b>MASK_NONE</b>: indicates that no masking is performed.</li><li>• <b>MASK_FULL</b>: indicates that all data is masked to a fixed value.</li><li>• <b>MASK_PARTIAL</b>: indicates that data of the specified character type, numeric type, or time type is partially masked.</li></ul> | <p>For details about the supported functions, see <a href="#">Data Redaction Functions</a>.</p> |

## Examples

Create a user named **test\_role** and an example table named **emp**, and insert data into the table.

```
CREATE ROLE test_role PASSWORD '{Password}';
```

```
DROP TABLE IF EXISTS emp;
CREATE TABLE emp(id int, name varchar(20), salary NUMERIC(10,2));
INSERT INTO emp VALUES(1, 'July', 1230.10), (2, 'David', 999.99);
```

Define a masking policy **mask\_emp** on the **emp** table that hides the **salary** column from the user **test\_role**.

```
CREATE REDACTION POLICY mask_emp ON emp WHEN(current_user = 'test_role') ADD COLUMN salary
WITH mask_full(salary);
```

Modify the expression for the data masking policy to take effect for the specified role. (If no user is specified, the policy takes effect for the current user by default.)

```
ALTER REDACTION POLICY mask_emp ON emp WHEN (pg_has_role(current_user, 'redact_role', 'member'));
ALTER REDACTION POLICY mask_emp ON emp WHEN (pg_has_role('redact_role', 'member'));
```

Modify the expression for the masking policy to take effect for all users.

```
ALTER REDACTION POLICY mask_emp ON emp WHEN (1=1);
```

Disable the masking policy.

```
ALTER REDACTION POLICY mask_emp ON emp DISABLE;
```

Enable the masking policy again.

```
ALTER REDACTION POLICY mask_emp ON emp ENABLE;
```

Change the masking policy name to **mask\_emp\_new**.

```
ALTER REDACTION POLICY mask_emp ON emp RENAME TO mask_emp_new;
```

Add a column with the masking policy used.

```
ALTER REDACTION POLICY mask_emp_new ON emp ADD COLUMN name WITH mask_partial(name, '*', 1,
length(name));
```

Modify the masking policy for the **name** column. Use the **MASK\_FULL** function to redact all data in the **name** column.

```
ALTER REDACTION POLICY mask_emp_new ON emp MODIFY COLUMN name WITH mask_full(name);
```

Delete an existing column where the masking policy is used.

```
ALTER REDACTION POLICY mask_emp_new ON emp DROP COLUMN name;
```

### 21.13.8.6 DROP REDACTION POLICY

#### Function

**DROP REDACTION POLICY** deletes a data masking policy applied to a specified table.

#### Precautions

Only the table owner and users granted the **gs\_redaction\_policy** preset role have the permission to delete data masking policies.

#### Syntax

```
DROP REDACTION POLICY [IF EXISTS] policy_name ON table_name;
```

#### Parameter Description

**Table 21-244** DROP REDACTION POLICY parameters

| Parameter   | Description                                                                                       | Value Range                                                                |
|-------------|---------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| IF EXISTS   | Sends a notice instead of throwing an error if the redaction policy to be deleted does not exist. | -                                                                          |
| policy_name | Specifies the name of the masking policy to be deleted.                                           | An existing name of the masking policy.                                    |
| table_name  | Specifies the name of the table with the masking policy to be deleted.                            | An existing name of the table to which the data masking policy is applied. |

#### Examples

Delete the masking policy **mask\_emp** from table **emp**.

```
DROP REDACTION POLICY mask_emp ON emp;
```

### 21.13.9 Resource Pools and Filtering Rules

## 21.13.9.1 CREATE RESOURCE POOL

### Function

**CREATE RESOURCE POOL** creates a resource pool and specifies the Cgroup for the resource pool. The system resources (CPU, memory, I/O, and storage resources) of a database are limited. When multiple types of services (such as data loading, batch analysis, and real-time query) are running at the same time, they may compete for resources and hinder operations. As a result, the throughput decreases and the overall performance deteriorates. Allocating system resources correctly prevents efficiency loss due to poor resource use. DWS offers a resource management feature that lets you create separate resource pools for different needs. These pools keep resources independent from one another.

This syntax is for reference only. You are advised to create a resource pool on the console. For details about resource pools, see "DWS Resource Load Management" in the *User Guide*.

### Precautions

As long as the current user has **CREATE** permission, it can create a resource pool.

### Syntax

```
CREATE RESOURCE POOL pool_name
[WITH ({MEM_PERCENT=pct | CONTROL_GROUP="group_name" | ACTIVE_STATEMENTS=stmt |
MAX_DOP = dop | MEMORY_LIMIT='memory_size' | io_limits=io_limits | io_priority='priority' |
nodegroup='nodegroup_name' | is_foreign = boolean | except_rule='except_rule' | weight=bandwidth_weight
| enable_concurrency_scaling=boolean}[, ...]]);
```

### Parameter Description

**Table 21-245** CREATE RESOURCE POOL parameters

| Parameter | Description                                                                                                                    | Value Range or Example                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| pool_name | Specifies the name of a resource pool.<br><br>The name of a resource pool cannot be same as that of an existing resource pool. | A string, which must comply with the <a href="#">identifier naming convention</a> . |

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Value Range or Example                                                                                                                                                                                                                                                                                                                                                              |

| CONTROL_GROUP | <p>Specifies the name of a Cgroup.</p> <p>Control groups (Cgroups) are a mechanism provided by the Linux kernel to restrict, record, and isolate physical resources (such as CPU, memory, and I/O resources) used by process groups. Cgroups have strict restrictions on Linux system resources. If a process is added to a Cgroup, it can use only restricted resources. For details about Cgroup principles, see the product manual corresponding to your OS.</p> <p>The <b>DefaultClass Cgroup</b> is preset in the environment, and the Timeshare Cgroup under the <b>DefaultClass</b> is divided into the following four levels: <b>Rush</b>, <b>High</b>, <b>Medium</b>, and <b>Low</b>.</p> <ul style="list-style-type: none"><li>• You can use either double quotation marks ("" ) or single quotation mark (') in the syntax when setting the name of a Cgroup.</li><li>• The value of <b>group_name</b> is case-sensitive.</li><li>• If <b>group_name</b> is not specified, the string "Medium" will be used by default in the syntax, indicating the <b>Medium</b> Timeshare Cgroup under <b>DefaultClass</b>.</li></ul> | <p>Create a default resource pool, and associate it with the <b>Medium</b> Timeshare Workload Cgroup under <b>DefaultClass</b>.<br/><code>CREATE RESOURCE POOL pool1;</code></p> <p>Create a resource pool, and associate it with the <b>High</b> Timeshare Workload Cgroup under <b>DefaultClass</b>.<br/><code>CREATE RESOURCE POOL pool2 WITH (CONTROL_GROUP="High");</code></p> |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                      | Value Range or Example                                                                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACTIVE_STATEMENTS | Specifies the maximum number of complex statements that can be concurrently executed in a resource pool. The value is a number ranging from <b>-1</b> to <i>INT_MAX</i> . If this parameter is not specified, the default value <b>10</b> is used.                                                                                               | Create <b>pool3</b> and set the maximum number of complex statements that can be concurrently executed to 5, the memory usage to 50%, and the network weight to 5.<br><pre>CREATE RESOURCE POOL pool3 WITH (ACTIVE_STATEMENTS=5, MEM_PERCENT=50, weight=5);</pre> |
| MAX_DOP           | Specifies the maximum number of simple SQL statements that can be concurrently executed in a resource pool. The value is a number ranging from <b>-1</b> to <i>INT_MAX</i> . The value <b>-1</b> or <b>0</b> indicates that the maximum number of statements is not limited. If the value is not specified, the default value <b>-1</b> is used. | Create <b>pool4</b> and set the maximum number of concurrent simple SQL statements to 10.<br><pre>CREATE RESOURCE POOL pool4 WITH (MAX_DOP=10);</pre>                                                                                                             |
| MEMORY_LIMIT      | Specifies the estimated maximum memory for a resource pool.<br>A string. <ul style="list-style-type: none"><li>• <b>default</b>: The memory limit is half of the resource pool memory.</li><li>• <b>unlimited</b>: no limit.</li><li>• The value is from 1 KB to 2047 GB.</li></ul> If this parameter is not specified, <b>default</b> is used.  | -                                                                                                                                                                                                                                                                 |
| MEM_PERCENT       | Specifies the proportion of available resource pool memory to the total memory or group user memory. <ul style="list-style-type: none"><li>• The value ranges from <b>0</b> to <b>100</b>. The default value is <b>0</b>.</li></ul>                                                                                                              | -                                                                                                                                                                                                                                                                 |

| Parameter   | Description                                                                                                                                                                         | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| io_limits   | This parameter has been discarded in 8.1.2 and is reserved for compatibility with earlier versions.                                                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| io_priority | This parameter has been discarded in 8.1.2 and is reserved for compatibility with earlier versions.                                                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| nodegroup   | Specifies the name of a logical cluster where the resource pool is. The logical cluster must already exist.                                                                         | If the logical cluster name contains uppercase letters or special characters or begins with a digit, enclose the name with double quotation marks in SQL statements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| is_foreign  | In logical cluster mode, the current resource pool is used to control the resources of common users who are not associated with the logical cluster specified by <b>nodegroup</b> . | <ul style="list-style-type: none"><li>• <b>nodegroup</b> must specify an existing logical cluster, and cannot be <b>elastic_group</b> or the default Node Group (<b>group_version1</b>), which is generated during cluster installation.</li><li>• If <b>is_foreign</b> is set to <b>true</b>, the resource pool cannot be associated with users. That is, <b>CREATE USER... RESOURCE POOL</b> cannot be used to configure resource pools for users. The resource pool automatically checks whether the users are associated with its logical cluster. If they are not, they will be controlled by the resource pool when performing operations on DNs in the logical cluster.</li></ul> |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                      | Value Range or Example                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| except_rule                | Name of an exception rule set.<br><br>An exception rule set is a set of rule thresholds that define the job execution time, job queuing time, CPU usage, and maximum disk flushing. It is used together with a resource pool. When an exception rule is triggered during job execution, the job is terminated or degraded.<br><br>For more information, see <a href="#">CREATE EXCEPT RULE</a> . | <a href="#">Example: Create an exception rule to terminate a job when the job runs for more than 10 seconds.</a>                                                                                                                                                                                                              |
| weight                     | Specifies the network bandwidth weight of the resource pool. The value is an integer ranging from <b>-1</b> to <b>2147483647</b> . The default value is <b>-1</b> , indicating that no weight is set.                                                                                                                                                                                            | -                                                                                                                                                                                                                                                                                                                             |
| enable_concurrency_scaling | Specifies whether to enable the elastic concurrency expansion function. This function is supported only by clusters of version 9.1.0.100 or later.                                                                                                                                                                                                                                               | <ul style="list-style-type: none"><li>• <b>true</b> indicates that the elastic concurrent expansion function of jobs in the resource pool is enabled.</li><li>• <b>false</b> indicates that the elastic concurrent expansion function of jobs in the resource pool is disabled.</li></ul> The default value is <b>false</b> . |

## Examples

This example assumes that Cgroups have been created by users in advance.

Create a default resource pool, and associate it with the **Medium** Timeshare Workload Cgroup under **DefaultClass**.

```
CREATE RESOURCE POOL pool1;
```

Create a resource pool, and associate it with the **High** Timeshare Workload Cgroup under **DefaultClass**.

```
CREATE RESOURCE POOL pool2 WITH (CONTROL_GROUP="High");
```

Create **pool\_p** and set the maximum number of complex statements that can be concurrently executed to 5, the memory usage to 50%, and the network weight to 5.

```
CREATE RESOURCE POOL pool_p WITH (ACTIVE_STATEMENTS=5, MEM_PERCENT=50, weight=5);
```

Query the configuration parameters of the resource pool in the PG\_RESOURCE\_POOL system catalog.

```
SELECT * FROM PG_RESOURCE_POOL WHERE respool_name = 'pool_p';
```

```
gaussdb-> SELECT * FROM PG_RESOURCE_POOL WHERE respool_name = 'pool_p';
respool_name | mem_percent | cpu_affinity | control_group | active_statements | max_dop | memory_limit | parentid | io_li
mits | io_priority | nodegroup | is_foreign | short_acc | except_rule | weight | enable_concurrency_scaling

pool_p | 50 | -1 | DefaultClass:Medium | 5 | -1 | default | | 0
(1 row)
```

Create an exception rule set **except\_rule4**, set **elapsedtime** to **10** (unit: seconds), and create a resource pool and bind the exception rule to the resource pool.

```
CREATE EXCEPT RULE except_rule4 WITH (elapsedtime=10);
CREATE resource pool resource_pool_a4 WITH (except_rule='except_rule4');
```

Create a resource pool and enable the elastic concurrent expansion function of the resource pool.

```
CREATE RESOURCE POOL pool6 WITH (enable_concurrency_scaling=true);
```

## Example: Create an exception rule to terminate a job when the job runs for more than 10 seconds.

In DWS resource load management, exception rules take effect only after being bound to a resource pool, and then the user who executes a job is bound to a specified resource pool. If an exception rule is triggered when a user executes a job, the job will be terminated. Perform the following operations to simulate the termination process.

### Step 1 Create a test table and import data to the table.

1. Connect to the database as the system administrator and run the following SQL statements to create temporary table **src** to provide data sources for subsequent INSERT operations:
 

```
CREATE SCHEMA test;
CREATE TABLE test.src AS SELECT 1;
```
2. Run the following SQL statements to create table **test.test**:
 

```
DROP TABLE IF EXISTS test.test;
CREATE TABLE test.test(a int, b numeric(15,2)) WITH(orientation=column);
```
3. Run the SQL statements to insert 20 million rows of data into the two tables. It takes about half a minute. Please wait.
 

```
INSERT INTO test.test SELECT generate_series(1,20000000) % 1000,generate_series(1,20000000)
FROM test.src;
```

### Step 2 Create exception rule set **except\_rule4** and set **elapsedtime** to 10 seconds.

```
CREATE EXCEPT RULE except_rule4 WITH (elapsedtime=10);
```

### Step 3 Create resource pool **resource\_pool\_a4** and bind the exception rule to it.

```
CREATE resource pool resource_pool_a4 WITH (except_rule='except_rule4');
```

### Step 4 Create a job user and bind the user to **resource\_pool\_a4**. The password is configured as required.

```
CREATE USER user4 RESOURCE POOL 'resource_pool_a4' PASSWORD 'password';
```

**Step 5** Grant the permission to access table **test.test** to **user4**.

```
GRANT USAGE ON SCHEMA test TO user4;
GRANT SELECT ON TABLE test.test TO user4;
```

**Step 6** Connect to the database as **user4** and run the following SQL statement. Once the statement is executed for more than 10 seconds, it is terminated.

```
SELECT * FROM test.test;
```

```
gaussdb=> SELECT * FROM test.test;
ERROR: canceling statement due to workload manager exception.
DETAIL: except rule [except_rule4] is meet condition:rule [elapsedtime] is over limit, current value is:11.
gaussdb=>
```

**Step 7** Check exception rule definitions in the **PG\_EXCEPT\_RULE** system catalog.

```
SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule4';
```

```
gaussdb=> SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule4';
 name | rule | value
-----+-----+-----
except_rule4 | action | abort
except_rule4 | elapsedtime | 10
(2 rows)
```

----End

[ALTER RESOURCE POOL](#), [DROP RESOURCE POOL](#), [CREATE EXCEPT RULE](#)

### 21.13.9.2 ALTER RESOURCE POOL

#### Function

**ALTER RESOURCE POOL** changes the Cgroup of a resource pool.

#### Precautions

Users having the ALTER permission can modify resource pools.

#### Syntax

```
ALTER RESOURCE POOL pool_name
 WITH ({MEM_PERCENT=pct | CONTROL_GROUP='group_name' | ACTIVE_STATEMENTS=stmt | MAX_DOP
= dop | MEMORY_LIMIT='memory_size' | io_limits=io_limits | io_priority='priority' |
nodegroup='nodegroup_name' | except_rule='except_rule' | weight=bandwidth_weight |
enable_concurrency_scaling=boolean}[, ...]);
```

## Parameter Description

**Table 21-246** ALTER RESOURCE POOL parameters

| Parameter   | Description                                                                                                             | Value Range                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pool_name   | Specifies the name of the resource pool to be modified.                                                                 | Name of an existing resource pool                                                                                                                                                                                           |
| group_name  | Specifies the name of a Cgroup.                                                                                         | Name of an existing Cgroup                                                                                                                                                                                                  |
| stmt        | Specifies the maximum number of statements that can be concurrently executed in a resource pool.                        | Numeral type. The value ranges from -1 to INT_MAX.                                                                                                                                                                          |
| dop         | Specifies the maximum number of simple SQL statements that can be concurrently executed in a resource pool.             | Numeral type. The value ranges from -1 to INT_MAX.                                                                                                                                                                          |
| memory_size | Specifies the estimated maximum memory for a resource pool.                                                             | Value range: a string <ul style="list-style-type: none"><li>● <b>default</b>: The memory limit is half of the resource pool memory.</li><li>● <b>unlimited</b>: no limit.</li><li>● Value range: 1 KB to 2047 GB.</li></ul> |
| mem_percent | Specifies the proportion of available resource pool memory to the total memory or group user memory.                    | The value of <b>mem_percent</b> for a common user is an integer ranging from 0 to 100. The default value is <b>0</b> .                                                                                                      |
| io_limits   | This parameter has been discarded in the 8.1.2 cluster version and is reserved for compatibility with earlier versions. | -                                                                                                                                                                                                                           |
| io_priority | This parameter has been discarded in the 8.1.2 cluster version and is reserved for compatibility with earlier versions. | -                                                                                                                                                                                                                           |
| except_rule | Specifies the exception rule set.                                                                                       | -                                                                                                                                                                                                                           |
| weight      | Specifies the network bandwidth weight of a resource pool.                                                              | -                                                                                                                                                                                                                           |

| Parameter                  | Description                                                                                                                                                                            | Value Range                                                                                                                                                                                                                                                                                                           |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable_concurrency_scaling | Specifies whether to enable the elastic concurrency expansion function. This function is supported only by clusters of version 9.1.0.100 or later. The default value is <b>false</b> . | <b>true</b> or <b>false</b> <ul style="list-style-type: none"><li>• <b>true</b> indicates that the elastic concurrent expansion function of jobs in the resource pool is enabled.</li><li>• <b>false</b> indicates that the elastic concurrent expansion function of jobs in the resource pool is disabled.</li></ul> |

 **NOTE**

- You can use double quotation marks (") or single quotation marks (') to set the Cgroup name **group\_name**.
- The value of **group\_name** is case-sensitive.
- When **group\_name** is not specified, the default value "Medium" is used. It is the "Medium" Timeshare Cgroup of the DefaultClass Cgroup.
- If a database user specifies the Timeshare string (**Rush**, **High**, **Medium**, or **Low**) in the syntax, for example, if **control\_group** is set to **High**, the resource pool will be associated with the **High** Timeshare Cgroup under **DefaultClass**.

## Examples

Create an example resource pool **pool\_test**, whose Cgroup is **Medium Timeshare Workload** under **DefaultClass**.

```
DROP RESOURCE POOL IF EXISTS pool_test;
CREATE RESOURCE POOL pool_test;
```

Specify **High Timeshare Workload** under **DefaultClass** as the Cgroup for the resource pool **pool\_test**.

```
ALTER RESOURCE POOL pool_test WITH (CONTROL_GROUP="High");
```

Disable the elastic concurrent expansion function for jobs in a specified resource pool.

```
ALTER RESOURCE POOL pool_test WITH (enable_concurrency_scaling=false);
```

### 21.13.9.3 DROP RESOURCE POOL

#### Function

**DROP RESOURCE POOL** deletes a resource pool.

 **NOTE**

If a role has been associated with a resource pool, the resource pool cannot be deleted.

## Precautions

The user must have the DROP permission in order to delete a resource pool.

## Syntax

```
DROP RESOURCE POOL [IF EXISTS] pool_name;
```

## Parameter Description

**Table 21-247** DROP RESOURCE POOL parameters

| Parameter | Description                                                                       | Value Range                                             |
|-----------|-----------------------------------------------------------------------------------|---------------------------------------------------------|
| IF EXISTS | Sends a notice instead of an error if the specified resource pool does not exist. | -                                                       |
| pool_name | Specifies the name of a created resource pool.                                    | A string, which must comply with the naming convention. |

## Example

Delete resource pool **pool**.

```
DROP RESOURCE POOL pool;
```

[ALTER RESOURCE POOL](#), [CREATE RESOURCE POOL](#)

### 21.13.9.4 CREATE EXCEPT RULE

## Function

**CREATE EXCEPT RULE** creates an exception rule set. You can specify specific rule thresholds and the operations (**abort** or **penalty**) to be performed after an exception rule is triggered.

In a distributed database, query tasks are executed by multiple nodes in parallel. Each node independently processes part of the data and summarizes the results. However, if any node encounters a performance bottleneck, the entire query will be slowed down even if other nodes complete the query quickly. In some extreme cases, a query statement may occupy a large number of resources, causing high node resource usage. As a result, compute or storage resources are insufficient, affecting services and even causing performance deterioration or even unavailability of the entire cluster.

When configuring exception rules in DWS, you can set resource restrictions (such as execution time, memory, and disk) for queries. When an exception rule is triggered during SQL statement execution, the execution is automatically terminated. This prevents abnormal queries from breaking down the cluster, ensuring stability and reducing the O&M workload of the database administrator. For example, if the execution time, disk space, or memory usage exceeds the threshold, the query is automatically terminated.

In DWS resource load management, exception rules take effect only after being bound to a resource pool, and then the user who executes a job is bound to a specified resource pool. If an exception rule is triggered when a user executes a job, the job will be terminated.

You can also set resource pools and exception rules on the management console. For details, see "DWS Resource Management Overview" in the *User Guide*.

## Precautions

Exception rules within the same group work together using an AND condition. For example, if the execution time is set to 1,000 seconds (setting **elapsetime** to **1000**) and the memory limit is set to 500 MB (setting **memsize** to **500**), the system terminates a job only when both conditions are met. Reaching just one threshold does not stop the job.

## Syntax

```
CREATE EXCEPT RULE except_rule_name
WITH (
 | BLOCKTIME = VALUE,
 | CPUTIME = VALUE,
 | ELAPSETIME = VALUE,
 | CPUSKEWPERCENT = VALUE,
 | SPILLSIZE = VALUE,
 | BROADCASTSIZE = VALUE,
 | MEMSIZE = VALUE,
 | CPUAVGPERCENT = VALUE,
 | BANDWIDTH = VALUE,
 | ACTION = ['abort' | 'penalty']
);
```

## Parameter Description

Table 21-248 CREATE EXCEPT RULE parameters

| Parameter        | Description                                         | Value Range                                                                                                                                                        |
|------------------|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| except_rule_name | Name of an exception rule set.                      | A string, which must comply with <a href="#">Identifier Naming Conventions</a> .                                                                                   |
| blocktime        | Maximum duration of job queue blocking, in seconds. | Numeric type. The value can be <b>-1</b> or ranges from <b>1</b> to <b>INT64_MAX</b> . Set the value to <b>-1</b> , which indicates that the value is not limited. |

| Parameter              | Description                                                                 | Value Range                                                              |
|------------------------|-----------------------------------------------------------------------------|--------------------------------------------------------------------------|
| elapsedtime            | Maximum job execution duration, in seconds.                                 | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |
| allcputime             | Maximum CPU time used during job running. The unit is second.               | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |
| cpuske<br>wpercen<br>t | Average CPU usage during job execution. The unit is percentage.             | Numeric type. The value can be -1 or ranges from 1 to 100.               |
| cpuavgp<br>ercent      | CPU usage skew during job execution. The unit is percentage.                | Numeric type. The value can be -1 or ranges from 1 to 100.               |
| spillsize              | Maximum size of data spilled to disks during job execution. The unit is MB. | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |
| broadca<br>stsize      | Maximum broadcast size of a job. The unit is MB.                            | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |
| memsiz<br>e            | Maximum memory size used for job execution. Unit: MB.                       | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |
| bandwi<br>dth          | Maximum bandwidth that can be used for job execution. Unit: MB.             | Numeric type. The value can be -1 or ranges from 1 to <b>INT64_MAX</b> . |

## Basic Example

Create an exception rule set (**except\_rule1**) and set the **blocktime** to 3000 seconds and **spillsize** to 4000 MB. If a statement is blocked for more than 3000 seconds and the spill size exceeds 4000 MB, the statement will be terminated.

```
CREATE EXCEPT RULE except_rule1 WITH (blocktime=3000, spillsize=4000, action=abort);
```

Create an exception rule set (**except\_rule2**) and set the **memsize** threshold to 5000 MB. The default operation following an exception is **abort**.

```
CREATE EXCEPT RULE except_rule2 WITH (memsize=3000);
```

Create a resource pool and bind it to exception rule set **except\_rule3**.

```
CREATE resource pool resource_pool_a1 WITH (except_rule='except_rule3');
```

## Example: Create an exception rule to terminate a job when the job runs for more than 10 seconds.

In DWS resource load management, exception rules take effect only after being bound to a resource pool, and then the user who executes a job is bound to a specified resource pool. If an exception rule is triggered when a user executes a job, the job will be terminated. Perform the following operations to simulate the termination process.

### Step 1 Create a test table and import data to the table.

1. Connect to the database as the system administrator and run the following SQL statements to create temporary table **src** to provide data sources for subsequent INSERT operations:  

```
CREATE SCHEMA test;
CREATE TABLE test.src AS SELECT 1;
```
2. Run the following SQL statements to create table **test.test**:  

```
DROP TABLE IF EXISTS test.test;
CREATE TABLE test.test(a int, b numeric(15,2)) WITH(orientation=column);
```
3. Run the SQL statements to insert 20 million rows of data into the two tables. It takes about half a minute. Please wait.  

```
INSERT INTO test.test SELECT generate_series(1,20000000) % 1000,generate_series(1,20000000)
FROM test.src;
```

### Step 2 Create exception rule set **except\_rule4** and set **elapsedtime** to 10 seconds.

```
CREATE EXCEPT RULE except_rule4 WITH (elapsedtime=10);
```

### Step 3 Create resource pool **resource\_pool\_a4** and bind the exception rule to it.

```
CREATE resource pool resource_pool_a4 WITH (except_rule='except_rule4');
```

### Step 4 Create a job user and bind the user to **resource\_pool\_a4**. The password is configured as required.

```
CREATE USER user4 RESOURCE POOL 'resource_pool_a4' PASSWORD 'password';
```

### Step 5 Grant the permission to access table **test.test** to **user4**.

```
GRANT USAGE ON SCHEMA test TO user4;
GRANT SELECT ON TABLE test.test TO user4;
```

### Step 6 Connect to the database as **user4** and run the following SQL statement. Once the statement is executed for more than 10 seconds, it is terminated.

```
SELECT * FROM test.test;
```

```
gaussdb=> SELECT * FROM test.test;
ERROR: canceling statement due to workload manager exception.
DETAIL: except rule [except_rule4] is meet condition:rule [elapsedtime] is over limit, current value is:11.
gaussdb=>
```

### Step 7 Check exception rule definitions in the **PG\_EXCEPT\_RULE** system catalog.

```
SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule4';
```

```
gaussdb=> SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule4';
 name | rule | value
-----+-----+-----
except_rule4 | action | abort
except_rule4 | elapsedtime | 10
(2 rows)
```

----End

[ALTER EXCEPT RULE](#), [DROP EXCEPT RULE](#), [CREATE RESOURCE POOL](#)

21.13.9.5 ALTER EXCEPT RULE

Function

This syntax modifies an exception rule set. You can modify one or more specific rule thresholds in a rule set.

Precautions

When **ALTER** is used to add a new rule threshold, the original rules in the **WITH** parameter are retained and are not cleared. For example, if a rule set contains only one rule, that is, the maximum duration of job queue blocking (**blocktime**) is 100 seconds, and you want to add another rule, that is, the maximum job execution time (**elapsedtime**) is 1000 seconds, the rule set will contain two rules. For details, see the following example.

Syntax

```
ALTER EXCEPT RULE except_rule_name
 WITH (
 | BLOCKTIME = VALUE,
 | CPUTIME = VALUE,
 | ELAPSEDTIME = VALUE,
 | CPUSKEWPERCENT = VALUE,
 | SPILLSIZE = VALUE,
 | BROADCASTSIZE = VALUE,
 | MEMSIZE = VALUE,
 | CPUAVGPERCENT = VALUE,
 | BANDWIDTH = VALUE,
 | ACTION = ['abort' | 'penalty']
);
```

Parameter Description

Table 21-249 ALTER EXCEPT RULE parameters

| Parameter | Description                                         | Value Range                                                                            |
|-----------|-----------------------------------------------------|----------------------------------------------------------------------------------------|
| rule_name | Name of an exception rule set.                      | A string compliant with the <a href="#">identifier naming rules</a> .                  |
| blocktime | Maximum duration of job queue blocking, in seconds. | Numeric type. The value can be <b>-1</b> or ranges from <b>1</b> to <b>INT64_MAX</b> . |

| Parameter      | Description                                                          | Value Range                                                      |
|----------------|----------------------------------------------------------------------|------------------------------------------------------------------|
| elapsedtime    | Maximum job execution duration, in seconds.                          | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |
| allcputime     | Maximum CPU time used during job running, in seconds.                | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |
| cpuskewpercent | CPU usage skew during job execution, in percentage.                  | Numeric type. The value can be -1 or ranges from 1 to 100.       |
| cpuavgpercent  | Average CPU usage during job execution, in percentage.               | Numeric type. The value can be -1 or ranges from 1 to 100.       |
| spillsize      | Maximum size of data spilled to disks during job execution, in MB.   | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |
| broadcastsize  | Maximum broadcast size of a job, in MB.                              | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |
| memsize        | Maximum memory size used for job execution, in MB.                   | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |
| bandwidth      | Maximum network bandwidth that can be used for job execution, in MB. | Numeric type. The value can be -1 or ranges from 1 to INT64_MAX. |

## Examples

Create an exception rule **except\_rule1**.

```
CREATE EXCEPT RULE except_rule_1 WITH (blocktime=2000, spillsize=3000, action=abort);
```

Change the blocktime threshold of exception rule set **except\_rule1** to **3000s** and the space for spilled data to **4000 MB**.

```
ALTER EXCEPT RULE except_rule_1 WITH (blocktime=3000, spillsize=4000);
```

Check whether the exception rule is modified successfully by querying the **PG\_EXCEPT\_RULE** system catalog.

```
SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule_1';
```

```
gaussdb=> SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule_1';
 name | rule | value
-----+-----+-----
except_rule_1 | action | abort
except_rule_1 | blocktime | 3000
except_rule_1 | spillsize | 4000
(3 rows)
```

Add a new rule, that is, the maximum job execution time (**elapsedtime**) is 2000 seconds.

```
ALTER EXCEPT RULE except_rule_1 WITH (elapsedtime=2000);
```

Check the exception rule again. The rule is modified successfully. **Note that the original rule is retained instead of being cleared.**

```
SELECT * FROM PG_EXCEPT_RULE WHERE name = 'except_rule_1';
```

Create a resource pool and bind it to exception rule set **except\_rule\_1**.

```
CREATE resource pool resource_pool_a1 WITH (except_rule='except_rule_1');
```

Unbind the exception rule set from the resource pool **resource\_pool\_a1**.

```
ALTER resource pool resource_pool_a1 WITH (except_rule='None');
```

Helpful Links

[CREATE EXCEPT RULE](#) and [DROP EXCEPT RULE](#)

21.13.9.6 DROP EXCEPT RULE

Function

This syntax deletes a specified exception rule set.

Precautions

Only the system administrator can perform the **DROP EXCEPT RULE** operation.

Syntax

```
DROP EXCEPT RULE [IF EXISTS]
rule_name ;
```

Parameter Description

Table 21-250 DROP EXCEPT RULE parameters

| Parameter | Description                                                                         | Value Range |
|-----------|-------------------------------------------------------------------------------------|-------------|
| IF EXISTS | Sends a message instead of an error if the specified exception rule does not exist. | -           |

| Parameter | Description                                   | Value Range                             |
|-----------|-----------------------------------------------|-----------------------------------------|
| rule_name | Indicates the name of the exception rule set. | Name of an existing exception rule set. |

## Examples

Create exception rule set **except\_rule\_1**.

```
CREATE EXCEPT RULE except_rule_1 WITH (blocktime=2000, spillsize=3000, action=abort);
```

Delete rule set **except\_rule\_1**.

```
DROP EXCEPT RULE except_rule_1;
```

Delete rule set **except\_rule\_2** if it exists.

```
DROP EXCEPT RULE IF EXISTS except_rule_2;
```

[CREATE EXCEPT RULE, ALTER EXCEPT RULE](#)

### 21.13.9.7 CREATE BLOCK RULE

## Function

**CREATE BLOCK RULE** creates a query filtering rule, including the query filtering rule name, bound client name, client IP address, user, and matching mode. During routine database operations, executing abnormal SQL statements may use too many resources, affecting database performance and stability. You can create query filtering rules to intercept such SQL statements.

Currently, you can specify the regular expression of an SQL statement for interception. For example, intercepting the SELECT statement of a table of a user. You can also specify the value of **unique\_sql\_id** or **sql\_hash** of an SQL statement for interception.

This document provides basic SQL syntax. You can also configure the query filtering rules on the console. For details, see "Using DWS Query Filters to Intercept Slow SQL Statements" in the *User Guide*.

## Precautions

- This syntax is supported only by clusters of version 9.1.0.100 or later.
- Only a user with the database owner permission or the **gs\_role\_block** role permission can run **CREATE BLOCK RULE**. A system administrator has this permission by default.
- Common users cannot run **CREATE BLOCK RULE**. To run it, they must be authorized by the system administrator. The authorization syntax is as follows:  

```
GRANT gs_role_block TO user;
```

You are advised to narrow down the application scope when creating a query filtering rule to improve performance.

## Syntax

```
CREATE BLOCK RULE [IF NOT EXISTS] block_name
[[TO user_name@'host'] | [TO user_name] | [TO 'host']] |
[FOR UPDATE | SELECT | INSERT | DELETE | MERGE] |
FILTER BY
{ SQL ('text') | TEMPLATE (template_parameter = value) }
[WITH ({ with_parameter = value }, [, ...])];
```

## Parameter Description

Table 21-251 CREATE BLOCK RULE parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| block_name | Specifies the name of the filtering rule to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | A string compliant with the <a href="#">identifier naming rules</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TO         | <p>Specifies the object or client IP address that determines whether the filtering rule takes effect. The options are as follows:</p> <ul style="list-style-type: none"><li>• <b>TO user_name@'host'</b>: The filtering rule takes effect only when both the username and client IP address are met.</li><li>• <b>TO user_name</b>: The query filtering rule takes effect only when the username is met, regardless of the client IP address.</li><li>• <b>TO 'host'</b>: The query filtering rule takes effect only when the client IP address is met, regardless of the username.</li></ul> | <p>The query filtering rule takes effect only when the client IP address is <b>192.168.0.59</b> and the login username is <b>user1</b>.<br/>CREATE BLOCK RULE query_block TO user1@'192.168.0.59' FOR SELECT FILTER BY SQL('test.test');</p> <p>The query filtering rule takes effect only when the login username is <b>user1</b>, regardless of the client IP address.<br/>CREATE BLOCK RULE query_block TO user1 FOR SELECT FILTER BY SQL('test.test');</p> <p>The query filtering rule takes effect only when the client IP address is <b>192.168.0.59</b>, regardless of the login user.<br/>CREATE BLOCK RULE query_block TO '192.168.0.59' FOR SELECT FILTER BY SQL('test.test');</p> |
| FOR        | Specifies the statement type. Its value can be UPDATE, SELECT, INSERT, DELETE, or MERGE INTO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| with_parameter | Indicates the parameters for querying filter rule details. | <p>The following parameters can be set together. The query that meets any of the parameters will be filtered.</p> <ul style="list-style-type: none"><li>• <b>application_name</b>: client name.</li><li>• <b>query_band</b>: load identifier.</li><li>• <b>table_num</b>: number of base tables scanned by the statement.</li><li>• <b>partition_num</b>: maximum number of partitions to be scanned by the operator.</li><li>• <b>estimate_row</b>: estimated maximum number of table rows scanned by the operator.</li><li>• <b>resource_pool</b>: name of the resource pool to be switched to.</li><li>• <b>max_active_num</b>: maximum number of concurrent statements corresponding to the rule.</li><li>• <b>is_warning</b>: whether an alarm or error is reported when a statement is intercepted. <b>on</b> indicates that an alarm is reported, and <b>off</b> (default value) indicates that an error is reported.</li></ul> |

## Example: Intercept SQL Statements Based on Keywords

Connect to the database as the system administrator and run the following SQL statements to create a temporary table (**src**) to provide data sources for subsequent INSERT operations:

```
CREATE SCHEMA test;
CREATE TABLE test.src AS SELECT 1;
```

Run the following SQL statements to create table **test.test**:

```
DROP TABLE IF EXISTS test.test;
CREATE TABLE test.test(a int, b numeric(15,2)) WITH(orientation=column);
```

Run the SQL statements to insert 20 million rows of data into the two tables. It takes about half a minute. Please wait.

```
INSERT INTO test.test SELECT generate_series(1,20000000) % 1000,generate_series(1,20000000) FROM test.src;
```

Create **user1** and grant the user the permission to access table **test.test**.

```
CREATE USER user1 PASSWORD "password";
GRANT USAGE ON SCHEMA test TO user1;
GRANT SELECT ON TABLE test.test TO user1;
```

Connect to the database as **user1** and query table data. The query result shows that **user1** can query data in table **test.test** without creating a filtering rule

```
SELECT sum(b) FROM test.test GROUP BY a;
```

```
gaussdb=> SELECT sum(b) FROM test.test GROUP BY a;
 sum

199990060000.00
199990120000.00
199990180000.00
199990240000.00
199990300000.00
199990360000.00
199990420000.00
199990480000.00
199990540000.00
199990600000.00
199990660000.00
199990720000.00
199990780000.00
```

Connect to the database as a system administrator and create a query filtering rule (query\_block) to intercept the SQL statements queried by **user1**. The filtering method is **SQL**. If an SQL statement contains the keyword **test** (table name), the SQL statement is filtered.

```
CREATE BLOCK RULE query_block
TO user1@'192.168.0.59' --The rule applies to user1 and the client IP address is 192.168.0.59.
FOR SELECT --Filter SELECT-related operations.
FILTER BY
SQL('test.test') --The filtering mode is SQL. Any statements that contain keyword test (table
name) are intercepted.
WITH --The statements that meet the following conditions are intercepted.
(
 application_name='gsq', --The client name is gsq.
 table_num='1', --The number of base table scans is 1.
 estimate_row='10', --The number of rows in the base table to be scanned is 10.
 is_warning='off' --An error is reported.
)
;
```

Query the created filtering rule by using the **pg\_get\_blockruledef** view. The command output indicates that the rule has taken effect.

```
SELECT * FROM pg_get_blockruledef('query_block');
```

```
gaussdb=> SELECT * FROM pg_get_blockruledef('query_block');
pg_get_blockruledef

CREATE BLOCK RULE query_block TO user1@'192.168.0.59' FOR SELECT FILTER BY SQL('test.test') WITH(application_name='gsq',table_num='1',estimate_row='10',is_warning='false');
(1 row)
```

Switch back to the user, connect to the database, and query the following SQL statement again. If information similar to "the statement is intercepted: ERROR: hit block rule query\_block xxx" is displayed, the statement is intercepted.

```
SELECT sum(b) FROM test.test GROUP BY a;
```

```
gaussdb=> SELECT sum(b) FROM test.test GROUP BY a;
ERROR: hit block rule query_block(user_name: user1, client_addr: 192.168.8.59, application_name: gsql, block_type: SELECT, regexp_sql: test.test, is_warning: false, table_num: 1(1), estimate_row: 10(2000000))
```

## Example: Intercept SQL Statements Based on the `unique_sql_id` or `sql_hash`

Continue with the preceding example. Switch back to the system administrator, connect to the database, and run the following command to query `unique_sql_id` and `sql_hash`:

```
EXPLAIN VERBOSE SELECT sum(b) FROM test.test GROUP BY a;
```

Record `unique_sql_id` and `sql_hash` in the command output.

```
===== Query Summary =====

System available mem: 1269760KB
Query Max mem: 1269760KB
Query estimated mem: 1919KB
Turbo Engine: true
Parser runtime: 0.071 ms
Planner runtime: 0.337 ms
Unique SQL Id: 3324222175
Unique SQL Hash: sql_170d0c75c472043b0cd35e05903c382f
(34 rows)
```

Delete the original filtering rule and create one based on `unique_sql_id`.

```
DROP BLOCK RULE query_block;
CREATE BLOCK RULE query_block FILTER BY TEMPLATE(unique_sql_id='3324222175');
```

Switch to `user1` again. An error is reported and the statement is intercepted.

```
SELECT sum(b) FROM test.test GROUP BY a;
```

```
gaussdb=> SELECT sum(b) FROM test.test GROUP BY a;
ERROR: hit block rule query_block(unique_sql_id: 3324222175)
```

Similarly, execute the statement as the system administrator. The statement is intercepted. It can be concluded that the `unique_sql_id` is used to filter and intercept SQL statements regardless of users. The SQL statement executed by all users is intercepted, and the interception effect is better.

```
SELECT sum(b) FROM test.test GROUP BY a;
```

```
gaussdb=> SELECT sum(b) FROM test.test GROUP BY a;
ERROR: hit block rule query_block(unique_sql_id: 3324222175)
```

Delete the filtering rule and create one based on `sql_hash`.

```
DROP BLOCK RULE query_block;
CREATE BLOCK RULE query_block FILTER BY
TEMPLATE(sql_hash='sql_170d0c75c472043b0cd35e05903c382f');
```

Switch to `user1` again. An error is reported and the statement is intercepted.

```
gaussdb=> SELECT sum(b) FROM test.test GROUP BY a;
ERROR: hit block rule query_block(sql_hash: sql_170d0c75c472043b0cd35e05903c382f)
```

## Helpful Links

### ALTER BLOCK RULE, DROP BLOCK RULE

This document provides basic SQL syntax. You can also configure the query filtering rules on the console. For details, see "Using DWS Query Filters to Intercept Slow SQL Statements" in the *User Guide*.

## FAQ: Why Does the Statement Fail to Be Intercepted After a Query Filtering Rule Is Created?

Some fields may not be intercepted as expected in different plans. For example:

```
CREATE BLOCK RULE test filter BY SQL('test')with(estimate_row='3');
SELECT * FROM test;
```

```
c1 | c2
---+---
 1 | 2
 1 | 2
 1 | 2
 1 | 2
 1 | 2
(5 rows)
```

In this case, the statement keyword is matched, and the number of rows queried exceeds the upper limit of three rows, but the statement is not intercepted.

```
postgres=# explain verbose select * from test;
 QUERY PLAN

id | operation | E-rows | E-distinct | E-width | E-costs
---+-----
 1 | -> Data Node Scan on "__REMOTE_FQS_QUERY__" | 0 | | 0 | 0.00

Targetlist Information (identified by plan id)

 1 --Data Node Scan on "__REMOTE_FQS_QUERY__"
 Output: test.c1, test.c2
 Node/s: All datanodes (node_group, bucket:16384)
 Remote query: SELECT c1, c2 FROM public.test
```

The **FQS (fast\_query\_shipping)** plan is used, that is, the **enable\_fast\_query\_shipping** parameter is set to **on**. As a result, no estimation information is available. The interception fails. CN lightweight plan will cause the same result. If the statement is forced to use the stream plan, the interception is successful.

```
SET enable_stream_operator=on;
SET enable_fast_query_shipping=off;
```

```
postgres=# set enable_stream_operator=on;
SET
postgres=# set enable_fast_query_shipping=off;
SET
postgres=# select * from test;
ERROR: hit block rule test(regex_sql: test, estimate_row: 3(5))
postgres=# explain verbose select * from test;
 QUERY PLAN

id | operation | E-rows | E-distinct | E-width | E-costs
---+-----+-----+-----+-----+
 1 | -> Row Adapter | 5 | | 8 | 69.00
 2 | -> Vector Streaming (type: GATHER) | 5 | | 8 | 69.00
 3 | -> CStore Scan on public.test | 5 | | 8 | 59.01

Targetlist Information (identified by plan id)

 1 --Row Adapter
 Output: c1, c2
 2 --Vector Streaming (type: GATHER)
 Output: c1, c2
 Node/s: All datanodes (node_group, bucket:16384)
 3 --CStore Scan on public.test
 Output: c1, c2
 Distribute Key: c1
```

In conclusion, if the estimation information is inaccurate, false interception or missing interception may occur. Plan information is obtained through estimation, so this error cannot be avoided.

## FAQ: How Do I Check Interception Records?

After a query filtering rule is created, many slow SQL statements are intercepted. You can view the intercepted statements in the system catalog **GS\_WLM\_SESSION\_INFO**. The **abort\_info** column records the interception information, that is, the error information of the query.

Connect to the **postgres** database and run the following command:

```
SELECT abort_info,query FROM GS_WLM_SESSION_INFO WHERE abort_info like '%hit block rule%'; --
Querying all interception records
SELECT abort_info,query FROM GS_WLM_SESSION_INFO WHERE abort_info like '%hit block rule
query_block_new%' -- Querying only the interception records whose rule name is query_block_new.
```

| query                                                                                                                                                                                                          | abort_info |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| postgres-> SELECT abort_info,query FROM OS_WLP_SESSION_TEMP WHERE abort_info like '%hit block rule%';                                                                                                          |            |
| -----                                                                                                                                                                                                          |            |
| hit block rule query_block(unique_sql_id: 3891488456)                                                                                                                                                          | select     |
| * from test.test;                                                                                                                                                                                              |            |

### 21.13.9.8 ALTER BLOCK RULE

## Function

This function modifies the attributes of a filtering rule, including the filtering rule name, bound client name, client IP address, user, and matching mode.

During routine database operations, executing abnormal SQL statements may use too many resources, affecting database performance and stability. You can create query filtering rules to intercept such SQL statements.

## Precautions

- This syntax is supported only by clusters of version 9.1.0.100 or later.
- Only a user with the database owner permission or the **gs\_role\_block** role permission can run the **ALTER BLOCK RULE** statement. A system administrator has this permission by default.
- Common users cannot run **CREATE BLOCK RULE**. To run it, they must be authorized by the system administrator. The authorization syntax is as follows:  
GRANT gs\_role\_block TO user;

You are advised to narrow down the application scope when creating a query filtering rule to improve performance.

- The **DEFAULT** syntax is used to reset an attribute, but it applies only to optional options.

## Syntax

```
ALTER BLOCK RULE block_name
 [[TO user_name@'host'] | [TO user_name] | [TO 'host'] | [TO DEFAULT]] |
 [FOR UPDATE | SELECT | INSERT | DELETE | MERGE | DEFAULT] |
 FILTER BY
 { SQL ('text') | TEMPLATE (template_parameter = value) }
 [WITH ({ with_parameter = value }, [...])];
ALTER BLOCK RULE block_name RENAME to new_block_name;
```

## Parameter Description

Table 21-252 ALTER BLOCK RULE parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| block_name | Name of the query filtering rule whose attributes need to be modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | A string, which must comply with the <a href="#">naming convention</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| TO         | <p>Specifies the object or client IP address that determines whether the filtering rule takes effect. The options are as follows:</p> <ul style="list-style-type: none"><li>• <b>TO user_name@'host'</b>: The filtering rule takes effect only when both the username and client IP address are met.</li><li>• <b>TO user_name</b>: The query filtering rule takes effect only when the username is met, regardless of the client IP address.</li><li>• <b>TO 'host'</b>: The query filtering rule takes effect only when the client IP address is met, regardless of the username.</li></ul> | <p>The query filtering rule takes effect only when the client IP address is <b>192.168.0.59</b> and the login username is <b>user1</b>.</p> <pre>ALTER BLOCK RULE query_block TO user1@'192.168.0.59' FOR SELECT FILTER BY SQL('test.test');</pre> <p>The query filtering rule takes effect only when the login username is <b>user1</b>, regardless of the client IP address.</p> <pre>ALTER BLOCK RULE query_block TO user1 FOR SELECT FILTER BY SQL('test.test');</pre> <p>The query filtering rule takes effect only when the client IP address is <b>192.168.0.59</b>, regardless of the login user.</p> <pre>ALTER BLOCK RULE query_block TO '192.168.0.59' FOR SELECT FILTER BY SQL('test.test');</pre> |

| Parameter | Description                                                                                   | Value Range |
|-----------|-----------------------------------------------------------------------------------------------|-------------|
| FOR       | Specifies the statement type. Its value can be UPDATE, SELECT, INSERT, DELETE, or MERGE INTO. | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| FILTER BY | <p>Specifies the filtering method.<br/>Value:</p> <ul style="list-style-type: none"><li>• <b>SQL:</b> SQL statements are filtered based on its content. Regular expression matching is performed on statements based on keywords. For example, the length of a table name cannot exceed 1024 characters. It is recommended that the keywords be as simple as possible.</li><li>• <b>TEMPLATE:</b> SQL statements are filtered based on templates. This method intercepts specific statements executed by all users, which is more efficient. | with_parameter | Parameters for querying filter rule details.                                                                                                                                     | <ul style="list-style-type: none"><li>• <b>application_name</b>: client name.</li><li>• <b>query_band</b>: load identifier.</li><li>• <b>table_num</b>: number of base tables scanned by the statement.</li><li>• <b>partition_num</b>: maximum number of partitions to be scanned by the operator.</li><li>• <b>estimate_row</b>: estimated maximum number of table rows scanned by the operator.</li><li>• <b>resource_pool</b>: name of the resource pool to be switched to.</li><li>• <b>max_active_num</b>: maximum number of concurrent statements corresponding to the rule.</li><li>• <b>is_warning</b>: whether an alarm or error is reported when a statement is intercepted. <b>on</b> indicates that an alarm is reported, and <b>off</b> (default value) indicates that an error is reported.</li></ul> |

## Examples

Create a query rule **query\_block**.

```
CREATE BLOCK RULE query_block FILTER BY SQL('update table_table set a=1');
```

Modify the attributes of the query rule **query\_block**.

```
ALTER BLOCK RULE query_block
TO user1@'192.168.0.59'
FOR SELECT
FILTER BY
SQL('select * from table_name')
```

```
WITH (application_name='gsq!',
query_band='test1',
table_num='2',
partition_num='3',
estimate_row='1000',
resource_pool='rsp1',
max_active_num='3',
is_warning='off'
);
```

Query the modified filter rule through the **pg\_get\_blockruledef** view.

```
SELECT * FROM pg_get_blockruledef('query_block');
```

```
gaussdb> SELECT * FROM pg_get_blockruledef('query_block');
pg_get_blockruledef

CREATE BLOCK RULE query_block TO user1@'192.168.0.59' FOR SELECT FILTER BY SQL('select * from table_name') WITH(application_name='gsq!',query_band='test1',partition_num='3',table_num='2',estimate_row='1000',resource_pool='rsp1',max_active_num='3',is_warning='true');
(1 row)
```

Rename the query rule **query\_block**.

```
ALTER BLOCK RULE query_block RENAME TO query_block_new;
```

Note that if only some parameters are reset when the rule is modified, the original values of other parameters are retained. In other words, only the specified parameters are modified, and all parameters are not overwritten or cleared.

```
ALTER BLOCK RULE query_block_new
TO user1@'192.168.0.59'
FOR SELECT
FILTER BY
SQL('select * from table_name')
WITH (
query_band='test2',
table_num='3');
SELECT * FROM pg_get_blockruledef('query_block_new');
```

The command output shows that only the values of **query\_band** and **table\_num** are changed, and the values of other parameters are retained.

```
gaussdb> SELECT * FROM pg_get_blockruledef('query_block_new');
pg_get_blockruledef

CREATE BLOCK RULE query_block_new TO user1@'192.168.0.59' FOR SELECT FILTER BY SQL('select * from table_name') WITH(application_name='gsq!',query_band='test2',partition_num='3',table_num='3',estimate_row='1000',resource_pool='rsp1',max_active_num='3',is_warning='true');
(1 row)
```

Similarly, new filter criteria will not clear the previous filter criteria. For example:

```
CREATE BLOCK RULE query_block_1 FILTER BY SQL('update table_table set a=1')
WITH (application_name='gsq!',
query_band='test1');

ALTER BLOCK RULE query_block_1 FILTER BY SQL('update table_table set a=1')
WITH (
table_num='2',
partition_num='3',
estimate_row='1000',
resource_pool='rsp1',
max_active_num='3',
is_warning='off'
);
SELECT * FROM pg_get_blockruledef('query_block');
```

The command output shows that the original **application\_name** and **query\_band** parameters are retained.

```
gusssdb-> SELECT * FROM pg_get_blockruledef('query_block');
pg_get_blockruledef

CREATE BLOCK RULE query_block TO user3@192.168.0.59 FOR SELECT FILTER BY SQL('select * from table_name') WITH(application_name='gsol',query_bands='test1',table_num='2',estimate_row='1000',resource_pool='rsp1',as
x_active_num='3',is_warning='true');
(1 row)
```

[CREATE BLOCK RULE, DROP BLOCK RULE](#)

21.13.9.9 DROP BLOCK RULE

Function

DROP BLOCK RULE deletes a query filtering rule. A query filtering rule includes the filtering rule name, bound client name, client IP address, user, and matching mode. During routine database operations, executing abnormal SQL statements may use too many resources, affecting database performance and stability. You can create query filtering rules to intercept such SQL statements.

Precautions

- This syntax is supported only by clusters of 9.1.0.100 and later versions.
- Only a user with the database owner permission or the **gs\_role\_block** role permission can run the **DROP BLOCK RULE** command. The system administrator has this permission by default.
- Common users cannot run **CREATE BLOCK RULE**. To run it, they must be authorized by the system administrator. The authorization syntax is as follows:  
GRANT gs\_role\_block TO user;  
You are advised to narrow down the application scope when querying filtering rules to improve performance.

Syntax

```
DROP BLOCK RULE [IF EXISTS] block_name;
```

Parameter Description

Table 21-253 DROP BLOCK RULE parameters

| Parameter  | Description                                                                               | Value Range                                     |
|------------|-------------------------------------------------------------------------------------------|-------------------------------------------------|
| IF EXISTS  | Sends a message instead of an error if the specified query filtering rule does not exist. | -                                               |
| block_name | Name of the query filtering rule to be deleted.                                           | The value must be an existing filter rule name. |

Examples

Create a query filtering rule named **query\_block**.

```
CREATE BLOCK RULE query_block FILTER BY SQL('update table_table set a=1');
```

Delete a query filtering rule named **query\_block**.

```
DROP BLOCK RULE query_block;
DROP BLOCK RULE IF EXISTS query_block;
```

## 21.13.10 Performance and Execution Plans

### 21.13.10.1 CREATE STATISTICS

#### Function

Creates an extended statistics object for a table in the current database. The object is owned by the user who executes the command. This syntax is supported only by clusters of version 8.2.1.200 or later (not supported by clusters of version 8.3.0).

#### Precautions

- Currently, this command can only be used to create expression statistics.
- Expression statistics cannot be created for temporary tables.
- Expression statistics cannot be created on partitions of a table.
- Statistics cannot be created for expressions that contain aggregate functions, subqueries, window functions, and return sets.

#### Syntax

```
CREATE STATISTICS [IF NOT EXISTS] statistics_name
ON (expression) [, ...]
FROM table_name
```

#### Parameter Description

**Table 21-254** CREATE STATISTICS parameters

| Parameter       | Description                                                                                                                                          | Value Range                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| statistics_name | Indicates the name of the new statistics object.                                                                                                     | A string, which must comply with the <a href="#">identifier naming conventions</a> . |
| expression      | Indicates the expression on which statistics are collected. One or more expressions are supported. Multiple expressions are separated by commas (,). | -                                                                                    |

| Parameter  | Description                                                           | Value Range |
|------------|-----------------------------------------------------------------------|-------------|
| table_name | Indicates the name of the table whose statistics are to be collected. | -           |

## Examples

Creates a sample table and insert data into it.

```
CREATE TABLE t1_row(id int, dt timestamp) WITH (orientation = row) DISTRIBUTE BY HASH (id);
INSERT INTO t1_row values (generate_series(1, 721), generate_series('2023-01-01'::timestamp,
'2023-01-31'::timestamp, '1 hour'::interval));
```

Create an expression statistics object for the table and run the ANALYZE command to collect statistics.

```
CREATE STATISTICS s1_t1_row ON EXTRACT(HOUR FROM dt), EXTRACT(DAY FROM dt) FROM t1_row;
ANALYZE t1_row;
```

View the query plan of the statement.

```
SET enable_fast_query_shipping = OFF;
EXPLAIN VERBOSE SELECT * FROM t1_row WHERE EXTRACT(HOUR FROM dt) BETWEEN 0 AND 12;
```

[DROP STATISTICS](#)

### 21.13.10.2 DROP STATISTICS

#### Function

Deletes an extended statistics object. This syntax is supported only by clusters of version 8.2.1.200 or later (not supported by clusters of version 8.3.0).

#### Precautions

None

#### Syntax

```
DROP STATISTICS [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

#### Parameter Description

**Table 21-255** DROP STATISTICS parameters

| Parameter | Description                                                                                                     | Value Range |
|-----------|-----------------------------------------------------------------------------------------------------------------|-------------|
| IF EXISTS | Sends a notification rather than reporting an error if the specified extended statistics object does not exist. | -           |

| Parameter          | Description                                                                            | Value Range                                  |
|--------------------|----------------------------------------------------------------------------------------|----------------------------------------------|
| name               | Indicates the name of the extended statistics object to be deleted.                    | An existing extended statistics object name. |
| CASCADE   RESTRICT | This parameter does not take effect. No objects depend on extended statistics objects. | -                                            |

## Examples

Deletes an extended statistics object.  
`DROP STATISTICS s1_t1_row;`

## 21.13.11 Connections, Sessions, and Resource Clearing

### 21.13.11.1 CLEAN CONNECTION

#### Function

**CLEAN CONNECTION** clears database connections when a database is abnormal. You may use this statement to delete a specific user's connections to a specified database.

#### Precautions

You must specify either **dbname** or **username**.

#### Syntax

```
CLEAN CONNECTION
TO { COORDINATOR (nodename [, ...]) | NODE (nodename [, ...]) } ALL [CHECK] [FORCE] }
[FOR DATABASE dbname]
[TO USER username];
```

## Parameter Description

**Table 21-256** CLEAN CONNECTION parameters

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                          | Value Range                               |
|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| CHECK                                                                         | This parameter can be specified only when the node list is specified as <b>TO ALL</b> . Setting this parameter will check whether a database is accessed by other sessions before its connections are cleared. If any sessions are detected before <b>DROP DATABASE</b> is executed, an error will be reported and the database will not be deleted. | -                                         |
| FORCE                                                                         | This parameter can be specified only when the node list is specified as <b>TO ALL</b> . Setting this parameter will send SIGTERM signals to all the threads related to the specified <b>dbname</b> and <b>username</b> and forcibly shut them down.                                                                                                  | -                                         |
| COORDINATOR<br>( nodename [, ... ] )  <br>NODE ( nodename<br>[, ... ] )   ALL | Deletes connections on a specified node. There are three scenarios: <ul style="list-style-type: none"><li>• Deletes connections to a specified CN.</li><li>• Deletes connections to a specified DN.</li><li>• Deletes connections to all CNs and DNs.</li></ul>                                                                                      | <b>nodename</b> is an existing node name. |
| dbname                                                                        | Deletes connections to a specific database. If this parameter is not specified, connections to all databases will be deleted.                                                                                                                                                                                                                        | Valid database name.                      |
| username                                                                      | Deletes connections of a specific user. If this parameter is not specified, connections of all users will be deleted.                                                                                                                                                                                                                                | Valid username.                           |

### Examples

Clean connections to nodes dn1 and dn2 for the **template1** database.

```
CLEAN CONNECTION TO NODE (dn1,dn2) FOR DATABASE template1;
```

Clean user **jack**'s connections to dn1.

```
CLEAN CONNECTION TO NODE (dn1) TO USER jack;
```

Delete all connections to the gaussdb database.

```
CLEAN CONNECTION TO ALL FORCE FOR DATABASE gaussdb;
```

### 21.13.11.2 ALTER SYSTEM KILL SESSION

#### Function

**ALTER SYSTEM KILL SESSION** ends a session.

#### Precautions

None

#### Syntax

```
ALTER SYSTEM KILL SESSION 'session_sid, serial' [IMMEDIATE];
```

#### Parameter Description

**Table 21-257** ALTER SYSTEM KILL SESSION parameters

| Parameter           | Description                                                                     | Value Range                                                                                                        |
|---------------------|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| session_sid, serial | Specifies the SID and SERIAL of a session.                                      | The <b>SIDs</b> and <b>SERIALs</b> of all sessions that can be queried from the system catalog <b>V\$SESSION</b> . |
| IMMEDIATE           | Indicates that a session will be ended instantly after the command is executed. | -                                                                                                                  |

### Examples

Query session information.

```
SELECT sid,serial#,username FROM V$SESSION;
```

| sid             | serial# | username |
|-----------------|---------|----------|
| 140131075880720 | 0       |          |
| 140131025549072 | 0       |          |
| 140131073779472 | 0       |          |
| 140131071678224 | 0       |          |
| 140131125774096 | 0       |          |

```
140131127875344 | 0 |
140131113629456 | 0 |
140131094742800 | 0 |
(8 rows)
```

End the session whose SID is 140131075880720.

```
ALTER SYSTEM KILL SESSION '140131075880720,0' IMMEDIATE;
```

### 21.13.11.3 ALTER SESSION

#### Function

**ALTER SESSION** defines or modifies the conditions or parameters that affect the current session. Modified session parameters are kept until the current session is disconnected.

#### Precautions

- If the **START TRANSACTION** command is not executed before the **SET TRANSACTION** command, the transaction is ended instantly and the command does not take effect.
- You can use the transaction\_mode(s) method declared in the **START TRANSACTION** command to avoid using the **SET TRANSACTION** command.

#### Syntax

- Set transaction parameters of a session.  

```
ALTER SESSION SET [SESSION CHARACTERISTICS AS] TRANSACTION
 { ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED } | { READ ONLY | READ
 WRITE } } [, ...] ;
```
- Set other running parameters of a session.  

```
ALTER SESSION SET
 {{config_parameter { { TO | = } { value | DEFAULT }
 | FROM CURRENT }} | CURRENT_SCHEMA [TO | =] { schema | DEFAULT }
 | TIME_ZONE time_zone
 | SCHEMA schema
 | NAMES encoding_name
 | ROLE role_name PASSWORD 'password'
 | SESSION AUTHORIZATION { role_name PASSWORD 'password' | DEFAULT }
 | XML OPTION { DOCUMENT | CONTENT }
 } ;
```

## Parameter Description

**Table 21-258** ALTER SESSION parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                           |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SESSION               | Indicates that the specified parameters take effect for the current session. This is the default value if neither <b>SESSION</b> nor <b>LOCAL</b> appears.<br><br>If <b>SET</b> or <b>SET SESSION</b> is executed within a transaction that is later aborted, the effects of the <b>SET</b> command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another <b>SET</b> . | -                                                                                                                                                                                                     |
| config_parameter      | Indicates the configurable run-time parameters. You can use <b>SHOW ALL</b> to view available run-time parameters.<br><br><b>NOTE</b><br>Some parameters that viewed by <b>SHOW ALL</b> cannot be set by <b>SET</b> . For example, <b>max_datanodes</b> .                                                                                                                                                                                                                                          | -                                                                                                                                                                                                     |
| value                 | Indicates the new value of the <b>config_parameter</b> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                  | This parameter can be specified as string constants, identifiers, numbers, or comma-separated lists of these. <b>DEFAULT</b> can be written to indicate resetting the parameter to its default value. |
| TIME_ZONE<br>timezone | Indicates the local time zone for the current session.                                                                                                                                                                                                                                                                                                                                                                                                                                             | A valid local time zone. The corresponding run-time parameter is <b>TimeZone</b> . The default value is <b>PRC</b> .                                                                                  |
| CURRENT_SCHEMA<br>A   | Indicates the current schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Name of an existing schema.                                                                                                                                                                           |
| SCHEMA schema         | Indicates the current schema. Here the schema is a string.<br><br>Example: set schema 'public';                                                                                                                                                                                                                                                                                                                                                                                                    | -                                                                                                                                                                                                     |

| Parameter              | Description                                                                                                               | Value Range                                                                                                                                            |
|------------------------|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAMES<br>encoding_name | Indicates the client character encoding name. This command is equivalent to <b>set client_encoding to encoding_name</b> . | A valid character encoding name. The run-time parameter corresponding to this option is <b>client_encoding</b> . The default encoding is <b>UTF8</b> . |
| XML OPTION<br>option   | Indicates the XML resolution mode.                                                                                        | <ul style="list-style-type: none"><li>• CONTENT (default)</li><li>• DOCUMENT</li></ul>                                                                 |

## Examples

Create the **ds** schema.

```
CREATE SCHEMA ds;
```

Set the search path of the schema.

```
SET SEARCH_PATH TO ds, public;
```

Set the time/date type to the traditional postgres format (date before month).

```
SET DATESTYLE TO postgres, dmy;
```

Set the character code of the current session to UTF8.

```
ALTER SESSION SET NAMES 'UTF8';
```

Set the time zone to Berkeley of California.

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone to Italy.

```
SET TIME ZONE 'Europe/Rome';
```

Set the current schema.

```
ALTER SESSION SET CURRENT_SCHEMA TO tpceds;
```

Set **XML OPTION** to **DOCUMENT**.

```
ALTER SESSION SET XML OPTION DOCUMENT;
```

Create the role **joe**, and set the session role to **joe**.

```
CREATE ROLE joe WITH PASSWORD '{password}';
ALTER SESSION SET SESSION AUTHORIZATION joe PASSWORD '{password}';
```

Switch to the default user.

```
ALTER SESSION SET SESSION AUTHORIZATION default;
```

[SET](#)

## 21.13.11.4 DISCARD

### Function

Releases internal resources related to database sessions.

The **DISCARD** command is used to reset the status of some or all sessions. Different **DISCARD** clauses release different types of resources. The **DISCARD ALL** command releases all temporary resources related to the current session and resets them to the initial state.

### Precautions

- After the **DISCARD VOLATILE { TEMPORARY | TEMP }** statement is executed, all volatile temporary table resources in the current session will be cleared. However, the statement cannot clear a single volatile temporary table resource.
- If a global temporary table occupies resources in a session, you need to run the **DISCARD** command to clear the resources of all sessions before performing DDL operations.
- After **DISCARD ALL** is executed successfully, schemas starting with **pg\_temp** and **pg\_toast\_temp** are also deleted.
- **DISCARD ALL** cannot be executed in a transaction.

### Syntax

```
DISCARD {{ GLOBAL { TEMPORARY | TEMP } [TABLE table_name] } |
 { VOLATILE { TEMPORARY | TEMP } } |
 { ALL | TEMP | TEMPORARY | PLANS | SEQUENCES }}
```

### Parameter Description

Table 21-259 DISCARD parameters

| Parameter                                        | Description                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VOLATILE { TEMPORARY   TEMP }                    | Releases resources related to the VOLATILE temporary table in the current session.                                                                                                                                                                                                                                     |
| GLOBAL { TEMPORARY   TEMP } [ TABLE table_name ] | <ul style="list-style-type: none"><li>• Run the <b>DISCARD GLOBAL TEMP</b> command to release resources related to the global temporary table in the current session.</li><li>• <b>DISCARD GLOBAL TEMP TABLE table_name</b> releases resources of a specified global temporary table in the current session.</li></ul> |
| TEMP   TEMPORARY                                 | Releases resources related to all temporary tables in the current session, including volatile and global temporary tables.                                                                                                                                                                                             |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLANS     | Releases all cached query plans in the current session and forces them to be replanned when related <b>PREPARE</b> statements are used next time.                                                                                                                                                                                                                                    |
| SEQUENCES | Discards all cached sequence-related states, including <b>curval()/lastval()</b> information and any pre-allocated sequence values that have not been returned through <b>nextval()</b> .                                                                                                                                                                                            |
| ALL       | Releases all temporary resources related to the current session and resets them to their initial state. This has almost the same effect as executing the following statement sequence:<br>SET SESSION AUTHORIZATION DEFAULT;<br>RESET ALL;<br>DEALLOCATE ALL;<br>CLOSE ALL;<br>UNLISTEN *;<br>SELECT pg_advisory_unlock_all();<br>DISCARD PLANS; DISCARD SEQUENCES;<br>DISCARD TEMP; |

## Examples

### DISCARD global temporary tables

```
CREATE GLOBAL TEMP TABLE t_global_temp(a int,b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using round-robin as the distribution mode by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE

INSERT INTO t_global_temp VALUES(1,1),(2,2);
INSERT 0 2

DROP TABLE t_global_temp;
ERROR: can not DROP TABLE when global temp table "t_global_temp" is in use

DISCARD GLOBAL TEMP TABLE t_global_temp;

DROP TABLE t_global_temp;
DROP TABLE
```

The **DISCARD VOLATILE** command clears all resources related to volatile temporary tables in the current session.

```
CREATE VOLATILE TEMP TABLE TX1(A INT) DISTRIBUTE BY HASH(A);
CREATE TABLE
CREATE VOLATILE TEMP TABLE TX2(A INT) DISTRIBUTE BY HASH(A);
CREATE TABLE

SELECT * FROM TX1;
a

(0 rows)
SELECT * FROM TX2;
a

(0 rows)

DISCARD VOLATILE TEMP;
```

```
SELECT * FROM TX1;
ERROR: relation "tx1" does not exist
LINE 1: SELECT * FROM TX1;
 ^
SELECT * FROM TX2;
ERROR: relation "tx2" does not exist
LINE 1: SELECT * FROM TX2;
```

After **DISCARD TEMP** is run, all temporary table resources in the current session are cleared.

```
CREATE GLOBAL TEMP TABLE t_global_temp(a int,b int);
NOTICE: The 'DISTRIBUTE BY' clause is not specified. Using round-robin as the distribution mode by default.
HINT: Please use 'DISTRIBUTE BY' clause to specify suitable data distribution column.
CREATE TABLE
INSERT INTO t_global_temp VALUES(1,1),(2,2);
INSERT 0 2

CREATE VOLATILE TEMP TABLE t_volatile_temp(a int,b int);
CREATE TEMP TABLE t_temp(a int,b int);

DISCARD TEMP;

SELECT * FROM t_global_temp;
a | b
---+---
(0 rows)

SELECT * FROM t_volatile_temp;
ERROR: relation "t_volatile_temp" does not exist
LINE 1: select * from t_volatile_temp;

SELECT * FROM t_temp;
ERROR: relation "t_temp" does not exist
LINE 1: select * from t_temp;
```

## 21.13.11.5 TRUNCATE

### Function

**TRUNCATE** quickly removes all rows from a database table.

It has the same effect as an unqualified DELETE, but since it does not actually scan the table, it is faster. This is most effective on large tables.

## Differences Among TRUNCATE TABLE, DELETE TABLE, and DROP TABLE

**Table 21-260** Differences among TRUNCATE TABLE, DELETE TABLE, and DROP TABLE

| Dimension       | TRUNCATE TABLE                                                         | DELETE TABLE                                                   | DROP TABLE                          |
|-----------------|------------------------------------------------------------------------|----------------------------------------------------------------|-------------------------------------|
| Syntax          | DDL                                                                    | DML                                                            | DDL                                 |
| Deleted content | All data in the table is deleted, but the table schema is not deleted. | Only the content is deleted and the definition is not deleted. | Content and definition are deleted. |
| Space release   | The space is released.                                                 | The space is not released.                                     | The space is released.              |

| Dimension       | TRUNCATE TABLE                                                                                                                                                                              | DELETE TABLE                                                                                           | DROP TABLE                                                                |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Execution Speed | Fast<br>Data is deleted by releasing the data pages used to store table data. Only the page release is recorded in the transaction log. Less system and transaction log resources are used. | Slow<br>Each time a row is deleted, a record is generated for each deleted row in the transaction log. | Fastest                                                                   |
| Scenario        | You need to quickly delete data from a table while retaining the table schema, and the data volume is large.                                                                                | You need to delete data based on specific conditions and the data volume is under control.             | You need to delete the entire table, including the table schema and data. |

## Precautions

- Exercise caution when running the **TRUNCATE TABLE** statement. Before running this statement, ensure that the table data can be deleted or has been backed up. After you run the **TRUNCATE TABLE** statement to delete table data, the data cannot be restored.
- The **TRUNCATE** operation on global temporary tables only truncates data of the current session. Data of other sessions is not affected.
- In the storage-compute decoupling architecture, it is not possible to perform the **TRUNCATE** operation on common tables and temporary tables simultaneously.

### WARNING

- Avoid performing **ALTER TABLE**, **ALTER TABLE PARTITION**, **DROP PARTITION**, and **TRUNCATE** operations during peak hours to prevent long SQL statements from blocking these operations or SQL services.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

## Syntax

**TRUNCATE** empties a table or set of tables.

```
TRUNCATE [TABLE] [ONLY] { [[database_name.]schema_name.]table_name [*] } [, ...]
[CONTINUE IDENTITY] [CASCADE | RESTRICT] ;
```

## Parameter Description

**Table 21-261** TRUNCATE parameters

| Parameter          | Description                                                                                                                                                   | Value Range                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ONLY               | Specifies the range of tables to be cleared.<br><br>This parameter is reserved only for compatibility with PostgreSQL. DWS does not support inherited tables. | <ul style="list-style-type: none"><li>If <b>ONLY</b> is specified, only the specified table is cleared.</li><li>If <b>ONLY</b> is not specified, the specified table and all its inherited tables (if any) are cleared.</li></ul>                                                                                                                                                                       |
| database_name      | Specifies the name of the database where the table to be cleared is located.                                                                                  | An existing database name.                                                                                                                                                                                                                                                                                                                                                                              |
| schema_name        | Specifies the schema name of the table to be cleared.                                                                                                         | An existing schema name.                                                                                                                                                                                                                                                                                                                                                                                |
| table_name         | Specifies the name of the table to be cleared (which can be schema-qualified).                                                                                | An existing table name.                                                                                                                                                                                                                                                                                                                                                                                 |
| CONTINUE IDENTITY  | Does not change the values of sequences.                                                                                                                      | This parameter is set to the default value.                                                                                                                                                                                                                                                                                                                                                             |
| CASCADE   RESTRICT | (Optional) Specifies the method of clearing tables that have foreign key references.                                                                          | <ul style="list-style-type: none"><li><b>CASCADE</b>: automatically truncates all tables that have foreign-key references to any of the named tables, or to any tables added to the group due to <b>CASCADE</b>.</li><li><b>RESTRICT</b>: refuses to truncate if any of the tables have foreign-key references from tables that are not listed in the command.</li></ul> The default value is RESTRICT. |

## Examples

1. Creates the sample table **test\_t** and insert data into it.

```
CREATE TABLE test_t
(
 col_id INT PRIMARY KEY,
 col_number INT NOT NULL,
 col_date DATE NOT NULL,
 col_price NUMERIC (10,2),
 col_status TEXT
)
```

```
WITH (ORIENTATION = COLUMN)
DISTRIBUTE BY HASH (col_id);

INSERT INTO test_t VALUES
(01,300,'2025-03-01',99.20,'sold'),
(02,400,'2025-04-01',95.50,'sold'),
(03,450,'2025-05-01',420.50,'sold'),
(04,100,'2025-06-01',100.85,'restock');
```

2. View data in the **test\_t** table.

```
SELECT * FROM test_t;
```

| col_id | col_number | col_date            | col_price | col_status |
|--------|------------|---------------------|-----------|------------|
| 1      | 300        | 2025-03-01 00:00:00 | 99.20     | sold       |
| 2      | 400        | 2025-04-01 00:00:00 | 95.50     | sold       |
| 3      | 450        | 2025-05-01 00:00:00 | 420.50    | sold       |
| 4      | 100        | 2025-06-01 00:00:00 | 100.85    | restock    |

(4 rows)

3. Clear the **test\_t** table.

```
TRUNCATE test_t;
```

If the following information is displayed, the table is cleared successfully.

```
TRUNCATE TABLE
```

4. View the table definition. The TRUNCATE TABLE operation clears the table but retains the table definition.

```
SELECT * FROM pg_get_tabledef('public.test_t');
pg_get_tabledef

SET search_path = public;
CREATE TABLE test_t (
 col_id integer NOT NULL,
 col_number integer NOT NULL,
 col_date timestamp(0) without time zone NOT NULL,
 col_price numeric(10,2),
 col_status text
)
WITH (orientation=column, compression=middle, colversion=2.0, enable_delta=false)+
DISTRIBUTE BY HASH(col_id)
;
(1 row)
```

## 21.13.11.6 VACUUM

### Function

**VACUUM** reclaims storage space occupied by tables or B-tree indexes. In normal database operation, rows that have been deleted are not physically removed from their table; they remain present until a **VACUUM** is done. Therefore, it is necessary to execute **VACUUM** periodically, especially on frequently-updated tables.

### Differences between VACUUM and VACUUM FULL

The **VACUUM** command comes in two types: **VACUUM** and **VACUUM FULL**. **VACUUM** performs a simpler process known as **LAZY VACUUM** compared to **VACUUM FULL**. The table below highlights the key differences between **LAZY VACUUM** and **VACUUM FULL**.

**Table 21-262** Differences between VACUUM and VACUUM FULL

| Item                 | VACUUM                                                                                                                                                                       | VACUUM FULL                                                                                                                                                                     |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Space cleanup        | When you delete a record at the end of the table, its space is freed and given back to the operating system. For records elsewhere, their space becomes available for reuse. | Regardless of location, all deleted data eventually frees up physical space for the OS. New data insertion requires allocating fresh disk pages.                                |
| Lock type            | A Level-4 lock (ShareUpdateExclusive-Lock) allows concurrent operations.                                                                                                     | A Level-8 lock (AccessExclusiveLock) locks the table entirely, pausing all other actions during its execution.                                                                  |
| Physical space       | Not released.                                                                                                                                                                | Released.                                                                                                                                                                       |
| Transaction ID       | Not reclaimed.                                                                                                                                                               | Reclaimed.                                                                                                                                                                      |
| Resource consumption | The execution requires little resources and can be performed periodically.                                                                                                   | The execution requires significant resources. Make sure the database's disk usage nears its limit before starting. Also, carry out this task when there is less data to handle. |
| Effect               | Table performance will be slightly improved.                                                                                                                                 | Table performance is greatly improved.                                                                                                                                          |

## Auto Cleanup (AUTOVACUUM)

The **VACUUM** operation frees up space, enhancing query performance. DWS offers automatic cleanup, which you can activate under specific conditions as needed. You can configure this on the console by referring to "Managing O&M Plans" in the *Data Warehouse Service (DWS) User Guide*.

## Precautions

- With no table specified, **VACUUM** processes all the tables that the current user has permission to vacuum in the current database. With a table specified, **VACUUM** processes only that table.
- To perform **VACUUM** on a table, you must be the owner of the table, granted with the **VACUUM** permission on the table, or granted with the **gs\_role\_vacuum\_any** role. By default, a system administrator has this permission. However, database owners are allowed to **VACUUM** all tables in their databases, except shared catalogs. (The restriction for shared catalogs means that a true database-wide **VACUUM** can only be executed by the system administrator). **VACUUM** skips over any tables that the calling user does not have the permission to vacuum.

- **VACUUM** cannot be executed inside a transaction block.
- It is recommended that active production databases be vacuumed frequently (at least nightly), in order to remove dead rows. **VACUUM ANALYZE** executes a **VACUUM** operation and then an **ANALYZE** operation for each selected table. After adding or deleting a large number of rows, it might be a good idea to execute the **VACUUM ANALYZE** command for the affected table. This will update the system catalogs with the results of all recent changes, and allow the optimizer to make better choices in planning queries.
- **VACUUM** causes a substantial increase in I/O traffic, which might cause poor performance for other active sessions. Therefore, it is sometimes advisable to use the cost-based **VACUUM** delay feature.
- When **VERBOSE** is specified, **VACUUM** prints progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.
- When the option list is surrounded by parentheses, the options can be written in any order. If there are no brackets, the options must be given in the order displayed in the syntax.
- During **VACUUM** on column-store tables, four internal operations occur: **VACUUM** on the primary table, **VACUUM** on the Desc table of the primary table, **VACUUM** on the delta table of the primary table, and migration of data from the delta table to the primary table. **VACUUM** does not reclaim the storage space of the delta table. To reclaim it, do **VACUUM DELTAMERGE** to the column-store table. By default, the **VACUUM** primary table operation is enabled. You can disable this function by setting the **colvacuum\_threshold\_scale\_factor** parameter.
- The **VACUUM** operation on column-store primary tables does not support temporary tables, multi-temperature tables, and time series tables.
- This operation does not immediately free up space. To reclaim space right away, execute the `vac_fileclear_relation` function after running **VACUUM**; this will place an exclusive lock on the chosen table.
- Plain **VACUUM** (without **FULL**) recycles space and makes it available for reuse. This form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. **VACUUM FULL** executes wider processing, including moving rows across blocks to compress tables so they occupy minimum number of disk blocks. This form is much slower and requires an exclusive lock on each table while it is being processed.
- **FULL** is recommended only in special scenarios. For example, you wish to physically narrow the table to decrease the occupied disk space after deleting most rows of a table. **VACUUM FULL** usually shrinks more table size than **VACUUM**. If the physical space usage does not decrease after you run the command, check whether there are other active transactions (that have started before you delete data transactions and not ended before you run **VACUUM FULL**). If there are such transactions, run this command again when the transactions quit.
- **VACUUM** and **VACUUM FULL** clear deleted tuples after the delay specified by **vacuum\_defer\_cleanup\_age**.
- Running **VACUUM FULL** on system catalogs can only be done when the database is offline. Otherwise, table locks, exceptions, and errors may occur.

- Running **VACUUM FULL** on a column-store partitioned table locks the table and its partitions.
- A distributed deadlock may occur when **VACUUM FULL** and DML statements run concurrently in the following scenarios:
  - **VACUUM FULL** on subpartitions and **INSERT/UPDATE/DELETE** on the primary table
  - **VACUUM FULL** on a full table and **SELECT** on a full table or **SELECT** on subpartitions
- In the storage-compute decoupled architecture, a message is displayed indicating that the full database **VACUUM**, **VACUUM FULL**, **VACUUM ANALYZE**, or **VACUUM DELTAMERGE** is not supported.
- When you run the **VACUUM** command on a column-store 3.0 table during redistribution in the architecture with decoupled storage and compute, the system keeps the data intact and shows the message below instead of clearing it.

When you run **VACUUM**, the **VACUUM** operation is skipped.

```
VACUUM tpcds.web_returns_p1;
```

```
NOTICE: skip vacuum relation "web_returns_p1" since it is in redistribution state
```

When you run **VACUUM ANALYZE**, the **VACUUM** operation is skipped, but statistics are collected.

```
VACUUM ANALYZE tpcds.web_returns_p1;
```

```
NOTICE: skip vacuum relation "web_returns_p1" since it is in redistribution state
```

#### WARNING

- When the **VACUUM FULL** operation is performed on a table, the table and index on the table are rebuilt. During the rebuilding, data is written to a new data file. After the rebuilding is complete, the original file is deleted. If the table is large, rebuilding consumes a large amount of disk space. When the disk space is insufficient, exercise caution when performing the **VACUUM FULL** operation on large tables to prevent the cluster from being read-only.
- Execute **VACUUM FULL** on tables with a high dirty page rate and small CU ratio exceeding 25% at regular intervals. Perform **VACUUM FULL** on common tables during low-traffic hours and on system tables when they are offline.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.

## Syntax

- Reclaim space and update statistics. The keyword sequence must be given in the order in which the syntax is displayed.

```
VACUUM [({ FULL | FREEZE | VERBOSE | {ANALYZE | ANALYSE } } [...])]
[table_name [(column_name [, ...])]] [PARTITION (partition_name)];
```

- Reclaim space, without updating statistics information.

```
VACUUM [FULL [COMPACT]] [FREEZE] [VERBOSE] [table_name] [PARTITION
(partition_name)];
```

- Reclaim space and update statistics information, with a specific order of keywords required.

```
VACUUM [FULL] [FREEZE] [VERBOSE] { ANALYZE | ANALYSE } [VERBOSE]
[table_name [(column_name [, ...])]] [PARTITION (partition_name)];
```

- For HDFS and column-store tables, migrate data from the delta table to the primary table. The **partition\_name** parameter is supported only by 8.2.1.200 and later cluster versions.

```
VACUUM DELTAMERGE [table_name][partition_name];
```

- For HDFS tables, delete the empty value partition directory of HDFS table in HDFS storage.

```
VACUUM HDFSDIRECTORY [table_name];
```

## Parameter Description

Table 21-263 VACUUM parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Value Range |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| FULL      | <p>Selects the parameter, which can reclaim more space, but takes much longer and exclusively locks the table.</p> <p><b>FULL</b> options can also contain the <b>COMPACT</b> parameter, which is only used for the HDFS table. Specifying the <b>COMPACT</b> parameter improves <b>VACUUM FULL</b> operation performance.</p> <p><b>NOTICE</b></p> <ul style="list-style-type: none"><li><b>COMPACT</b> and <b>PARTITION</b> cannot be used at the same time.</li><li>Using <b>FULL</b> will cause statistics missing. To collect statistics, add the keyword <b>ANALYZE</b> to <b>VACUUM FULL</b>.</li></ul> | -           |

| Parameter               | Description                                                                                                                                                                                                                                                                            | Value Range                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| FREEZE                  | Resolves the transaction ID wraparound issue by default. Using FREEZE sets <b>vacuum_freeze_min_age</b> to 0 during VACUUM.<br><b>NOTICE</b><br>Since DWS employs 64-bit XIDs, the wraparound problem does not occur theoretically. Avoid using <b>VACUUM FREEZE</b> unless necessary. | -                                                |
| VERBOSE                 | Prints a detailed vacuum activity report for each table.                                                                                                                                                                                                                               | -                                                |
| ANALYZE<br> <br>ANALYSE | Updates statistics used by the optimizer to determine the most efficient way to execute a query.                                                                                                                                                                                       | -                                                |
| table_name              | Indicates the name (optionally schema-qualified) of a specific table to vacuum.                                                                                                                                                                                                        | Defaults are all tables in the current database. |
| column_name             | Indicates the name of a specific field to analyze.                                                                                                                                                                                                                                     | Defaults are all columns.                        |

| Parameter      | Description                                                                                                                                                                                                                                                                                                                    | Value Range                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| PARTITION      | <p>Specifies that the table to be cleared is a partitioned table. HDFS tables do not support the PARTITION parameter.</p> <p><b>NOTE</b><br/>If the <b>PARTITION</b> and <b>COMPACT</b> parameters are used at the same time, the following error message is displayed:<br/><b>COMPACT can not be used with PARTITION.</b></p> | -                            |
| partition_name | Indicates the partition name of a specific table to vacuum.                                                                                                                                                                                                                                                                    | Defaults are all partitions. |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 | Value Range |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| DELTA MERGE | For HDFS tables and column-store tables, migrate data in the delta table of HDFS tables or column-store tables to the primary table. If the data volume of the delta table is less than 60,000 rows, the data will not be migrated. Otherwise, the data will be migrated to HDFS, and the delta table will be cleared by <b>TRUNCATE</b> . For a column-store table, this operation always transfers all data in the delta table to the CU. | -           |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Value Range |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
|           | <p><b>NOTE</b></p> <p>The following DFX functions are provided to return the data storage in the delta table of a column-store table (for an HDFS table, it can be returned by <b>EXPLAIN ANALYZE</b>):</p> <ul style="list-style-type: none"><li>pgxc_get_delta_info(TEXT): The input parameter is a column-store table name. The delta table information on each node is collected and displayed, including the number of active tuples, table size, and maximum block ID.</li><li>get_delta_info(TEXT): The input parameter is a column-store table name. The system summarizes the results returned from pgxc_get_delta_info and returns the total number of active tuples, total table size, and maximum block ID in the delta table. When querying delta information about a temporary table, you need to specify the schema of the temporary table. Otherwise, an error is reported, indicating that the table cannot be found.</li></ul> |             |

| Parameter      | Description                                                                               | Value Range |
|----------------|-------------------------------------------------------------------------------------------|-------------|
| HDFS DIRECTORY | Deletes the empty value partition directory of HDFS table in HDFS storage for HDFS table. | -           |

## Examples

Delete all tables in the current database.

```
VACUUM;
```

Reclaim the space of partition **P2** of the **tpcds.web\_returns\_p1** table without updating statistics.

```
VACUUM FULL tpcds.web_returns_p1 PARTITION(P2);
```

Reclaim the space of the **tpcds.web\_returns\_p1** table and update statistics.

```
VACUUM FULL ANALYZE tpcds.web_returns_p1;
```

Delete all tables in the current database and collect statistics about the query optimizer.

```
VACUUM ANALYZE;
```

Delete only the **reason** table.

```
VACUUM (VERBOSE, ANALYZE) tpcds.reason;
```

Perform the **DELTAMERGE** operation on the column-store table **table\_delta**.

```
VACUUM DELTAMERGE tpcds.table_delta;
```

Perform the **DELTAMERGE** operation only on partition **p1** of the column-store table **table\_delta**.

```
VACUUM DELTAMERGE tpcds.table_delta partition(p1);
```

## 21.13.12 Settings and Comments

### 21.13.12.1 SHOW

#### Function

**SHOW** shows the current value of a run-time parameter. You can use the **SET** statement to set these parameters.

#### Precautions

Some parameters that can be viewed by **SHOW** are read-only. You can view but cannot modify their values.

## Syntax

```
SHOW
{
 configuration_parameter |
 CURRENT_SCHEMA |
 TIME_ZONE |
 TRANSACTION ISOLATION LEVEL |
 SESSION AUTHORIZATION |
 ALL
};
```

## Parameter Description

See [Parameter Description](#) in **RESET**.

## Examples

Show the value of **timezone**.

```
SHOW timezone;
```

Show the current setting of the **DateStyle** parameter.

```
SHOW DateStyle;
```

Show the current setting of all parameters.

```
SHOW ALL;
```

## Helpful Links

[SET](#), [RESET](#)

### 21.13.12.2 SET

## Function

**SET** modifies a run-time parameter.

## Precautions

Most run-time parameters can be modified by executing **SET**. Some parameters cannot be modified after a server or session starts.

## Syntax

- Set the system time zone.  

```
SET [SESSION | LOCAL] TIME_ZONE { timezone | LOCAL | DEFAULT };
```
- Set the schema of the table.  

```
SET [SESSION | LOCAL]
{CURRENT_SCHEMA { TO | = } { schema | DEFAULT }
| SCHEMA 'schema'};
```
- Set client encoding.  

```
SET [SESSION | LOCAL] NAMES encoding_name;
```
- Set XML parsing mode.  

```
SET [SESSION | LOCAL] XML OPTION { DOCUMENT | CONTENT };
```
- Set other running parameters.

```
SET [LOCAL | SESSION]
 { {config_parameter { { TO | = } { value | DEFAULT }
 | FROM CURRENT }}};
```

## Parameter Description

**Table 21-264** SET parameters

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Value Range                                                                                                          |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| SESSION                  | <p>Indicates that the specified parameters take effect for the current session. This is the default value if neither <b>SESSION</b> nor <b>LOCAL</b> appears.</p> <p>If <b>SET</b> or <b>SET SESSION</b> is executed within a transaction that is later aborted, the effects of the <b>SET</b> command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another <b>SET</b>.</p>                                                   | -                                                                                                                    |
| LOCAL                    | <p>Indicates that the specified parameters take effect for the current transaction. After <b>COMMIT</b> or <b>ROLLBACK</b>, the session-level setting takes effect again.</p> <p>The effects of <b>SET LOCAL</b> last only till the end of the current transaction, whether committed or not. A special case is <b>SET</b> followed by <b>SET LOCAL</b> within a single transaction: the <b>SET LOCAL</b> value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the <b>SET</b> value will take effect.</p> | -                                                                                                                    |
| TIME_ZONE<br>timezone    | Indicates the local time zone for the current session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | A valid local time zone. The corresponding run-time parameter is <b>TimeZone</b> . The default value is <b>PRC</b> . |
| CURRENT_SCHEMA<br>schema | Indicates the current schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Specifies an existing schema name.                                                                                   |
| SCHEMA<br>schema         | <p>Indicates the current schema. Here the schema is a string.</p> <p>Example: set schema 'public';</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     | -                                                                                                                    |

| Parameter               | Description                                                                                                                                                                                                                                                             | Value Range                                                                                                                                            |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAMES<br>encoding_name  | Indicates the client character encoding name. This command is equivalent to <b>set client_encoding to encoding_name</b> .                                                                                                                                               | A valid character encoding name. The run-time parameter corresponding to this option is <b>client_encoding</b> . The default encoding is <b>UTF8</b> . |
| XML<br>OPTION<br>option | Indicates the XML resolution mode.                                                                                                                                                                                                                                      | CONTENT (default) and DOCUMENT                                                                                                                         |
| config_parameter        | Indicates the configurable run-time parameters. You can use <b>SHOW ALL</b> to view available run-time parameters.<br><b>NOTE</b><br>Some parameters that viewed by <b>SHOW ALL</b> cannot be set by <b>SET</b> . For example, <b>max_datanodes</b> .                   | -                                                                                                                                                      |
| value                   | Indicates the new value of the <b>config_parameter</b> parameter. This parameter can be specified as string constants, identifiers, numbers, or comma-separated lists of these. <b>DEFAULT</b> can be written to indicate resetting the parameter to its default value. | -                                                                                                                                                      |

## Examples

Configure the search path of the **tpcds** schema.

```
SET search_path TO tpcds, public;
```

Set the date style to the traditional POSTGRES style (date placed before month).

```
SET datestyle TO postgres;
```

### 21.13.12.3 RESET

#### Function

**RESET** restores run-time parameters to their default values. The default values are parameter default values compiled in the **postgresql.conf** configuration file.

**RESET** is an alternative spelling for:

**SET configuration\_parameter TO DEFAULT**

## Precautions

**RESET** and **SET** have the same transaction behavior. Their impact will be rolled back.

## Syntax

```
RESET {configuration_parameter | CURRENT_SCHEMA | TIME_ZONE | TRANSACTION_ISOLATION_LEVEL |
SESSION_AUTHORIZATION | ALL};
```

## Parameter Description

**Table 21-265** RESET parameters

| Parameter                   | Description                                          | Value Range                                                                                                                                                                                                 |
|-----------------------------|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| configuration_parameter     | Specifies the name of a settable run-time parameter. | You can view run-time parameters by running the <b>SHOW ALL</b> command.<br><b>NOTE</b><br>Some parameters that viewed by <b>SHOW ALL</b> cannot be set by <b>SET</b> . For example, <b>max_datanodes</b> . |
| CURRENT_SCHEMA              | Specifies the current schema.                        | -                                                                                                                                                                                                           |
| TIME_ZONE                   | Specifies the time zone.                             | -                                                                                                                                                                                                           |
| TRANSACTION_ISOLATION_LEVEL | Specifies the transaction isolation level.           | -                                                                                                                                                                                                           |
| SESSION_AUTHORIZATION       | Specifies the session authorization.                 | -                                                                                                                                                                                                           |
| ALL                         | Specifies all runtime parameters.                    | -                                                                                                                                                                                                           |

## Examples

Reset **timezone** to the default value.

```
RESET timezone;
```

Set all parameters to their default values.

```
RESET ALL;
```

## 21.13.12.4 SET CONSTRAINTS

### Function

**SET CONSTRAINTS** sets the behavior of constraint checking within the current transaction.

**IMMEDIATE** constraints are checked at the end of each statement. **DEFERRED** constraints are not checked until transaction commit. Each constraint has its own **IMMEDIATE** or **DEFERRED** mode.

Upon creation, a constraint is given one of three characteristics **DEFERRABLE INITIALLY DEFERRED**, **DEFERRABLE INITIALLY IMMEDIATE**, or **NOT DEFERRABLE**. The third class is always **IMMEDIATE** and is not affected by the **SET CONSTRAINTS** command. The first two classes start every transaction in specified modes, but its behaviors can be changed within a transaction by **SET CONSTRAINTS**.

**SET CONSTRAINTS** with a list of constraint names changes the mode of just those constraints (which must all be deferrable). If multiple constraints match a name, the name is affected by all of these constraints. **SET CONSTRAINTS ALL** changes the modes of all deferrable constraints.

When **SET CONSTRAINTS** changes the mode of a constraint from **DEFERRED** to **IMMEDIATE**, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the **SET CONSTRAINTS** command. If any such constraint is violated, the **SET CONSTRAINTS** fails (and does not change the constraint mode). Therefore, **SET CONSTRAINTS** can be used to force checking of constraints to occur at a specific point in a transaction.

Only foreign key constraints are affected by this setting. Check and unique constraints are always checked immediately when a row is inserted or modified.

### Precautions

**SET CONSTRAINTS** sets the behavior of constraint checking only within the current transaction. Therefore, if you execute this command outside of a transaction block (**START TRANSACTION/COMMIT** pair), it will not appear to have any effect.

### Syntax

```
SET CONSTRAINTS { ALL | { name } [, ...] } { DEFERRED | IMMEDIATE };
```

### Parameter Description

Table 21-266 SET CONSTRAINTS parameters

| Parameter | Description                    | Value Range                                                                                  |
|-----------|--------------------------------|----------------------------------------------------------------------------------------------|
| name      | Specifies the constraint name. | An existing constraint name. which can be found in the system catalog <b>pg_constraint</b> . |

| Parameter | Description                                                          | Value Range |
|-----------|----------------------------------------------------------------------|-------------|
| ALL       | Indicates all constraints.                                           | -           |
| DEFERRED  | Indicates that constraints are not checked until transaction commit. | -           |
| IMMEDIATE | Indicates that constraints are checked at the end of each statement. | -           |

## Examples

Set that constraints are checked when a transaction is committed.

```
SET CONSTRAINTS ALL DEFERRED;
```

### 21.13.12.5 SET SESSION AUTHORIZATION

## Function

**SET SESSION AUTHORIZATION** sets the session user identifier and the current user identifier of the current SQL session to a specified user.

## Precautions

The session identifier can be changed only when the initial session user has the system administrator rights. Otherwise, the system supports the command only when the authenticated user name is specified.

## Syntax

- SET SESSION AUTHORIZATION** sets the session user identifier and the current user identifier of the current session.

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION role_name PASSWORD '{password}';
```

- Reset the identifiers of the session and current users to the initially authenticated user names.

```
{SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT
| RESET SESSION AUTHORIZATION};
```

## Parameter Description

**Table 21-267** SET SESSION AUTHORIZATION parameters

| Parameter | Description                                                                  | Value Range |
|-----------|------------------------------------------------------------------------------|-------------|
| SESSION   | Indicates that the specified parameters take effect for the current session. | -           |

| Parameter | Description                                                                                       | Value Range           |
|-----------|---------------------------------------------------------------------------------------------------|-----------------------|
| LOCALE    | Indicates that the specified command takes effect only for the current transaction.               | -                     |
| role_name | Specifies the role name.                                                                          | An existing role name |
| password  | Specifies the password of a role. It must comply with the password convention.                    | -                     |
| DEFAULT   | Reset the identifiers of the session and current users to the initially authenticated user names. | -                     |

## Examples

Set the current user to **paul**.

```
SET SESSION AUTHORIZATION paul password '{password};
```

View the current session user and the current user.

```
SELECT SESSION_USER, CURRENT_USER;
```

Reset the current user.

```
RESET SESSION AUTHORIZATION;
```

[SET ROLE](#)

### 21.13.12.6 COMMENT

#### Function

**COMMENT** defines or changes the comment of an object.

#### Precautions

- Only one comment string is stored for each object. To modify a comment, issue a new **COMMENT** command for the same object. To remove a comment, write **NULL** at the location of the text string. Comments are automatically deleted when their objects are deleted.
- There is no security for viewing comments. Any user with database access can see all object comments. Comments on shared items like databases, roles, and tablespaces are visible to any user connected to any database in the cluster. Avoid adding sensitive security information to comments.
- For most objects, only the owner of the object can set comments. A role has no owner. So, only a system admin can use the **COMMENT ON ROLE** command for system admin roles. Roles with the **CREATE ROLE** permission

can add comments to non-admin roles. Administrators can comment on anything.

Syntax

```
COMMENT ON
{
 AGGREGATE agg_name (agg_type [, ...]) |
 CAST (source_type AS target_type) |
 COLLATION object_name |
 COLUMN { table_name.column_name | view_name.column_name } |
 CONSTRAINT constraint_name ON table_name |
 CONVERSION object_name |
 DATABASE object_name |
 DOMAIN object_name |
 EXTENSION object_name |
 FOREIGN DATA WRAPPER object_name |
 FOREIGN TABLE object_name |
 FUNCTION function_name ([{[argmode] [argname] argtype} [, ...]]) |
 INDEX object_name |
 LARGE OBJECT large_object_oid |
 OPERATOR operator_name (left_type, right_type) |
 OPERATOR CLASS object_name USING index_method |
 OPERATOR FAMILY object_name USING index_method |
 [PROCEDURAL] LANGUAGE object_name |
 ROLE object_name |
 RULE rule_name ON table_name |
 SCHEMA object_name |
 SERVER object_name |
 TABLE object_name |
 TABLESPACE object_name |
 TEXT SEARCH CONFIGURATION object_name |
 TEXT SEARCH DICTIONARY object_name |
 TEXT SEARCH PARSER object_name |
 TEXT SEARCH TEMPLATE object_name |
 TYPE object_name |
 VIEW object_name
}
IS 'text';
```

Parameter Description

Table 21-268 COMMENT parameters

| Parameter   | Description                                                       | Value Range |
|-------------|-------------------------------------------------------------------|-------------|
| agg_name    | Specifies the name of the aggregate function to be commented out. | -           |
| agg_type    | Specifies the data types of the aggregation function parameters.  | -           |
| source_type | Specifies the name of the source data type of the cast.           | -           |
| target_type | Specifies the name of the target data type of the cast.           | -           |

| Parameter                                        | Description                                                                                                                                                   | Value Range                           |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| object_name                                      | Specifies the name of an object.                                                                                                                              | -                                     |
| table_name.column_name<br>/view_name.column_name | Specifies the column whose comment is defined or modified. You can add the table name or view name as the prefix.                                             | -                                     |
| constraint_name                                  | Specifies the table constraints whose comment is defined or modified.                                                                                         | Name of an existing table constraint. |
| table_name                                       | Specifies the table name.                                                                                                                                     | Name of an existing table.            |
| function_name                                    | Specifies the function whose comment is defined or modified.                                                                                                  | Use an existing function name.        |
| argmode/argname/<br>argtype                      | Specifies the schema, name, and type of the function parameters.                                                                                              | -                                     |
| large_object_oid                                 | Specifies the OID of the large object whose comment is defined or modified.                                                                                   | -                                     |
| operator_name                                    | Specifies the name of the operator.                                                                                                                           | -                                     |
| left_type/right_type                             | Specifies the data type of the operation parameter, which can be specified by a pattern. Write NONE for the missing argument of a prefix or postfix operator. | -                                     |
| text                                             | Specifies the new comment.                                                                                                                                    | A string.                             |

## Examples

Create a sample table **CUSTOMER** and add comments to the **customer.c\_customer\_sk** column of the table.

```
CREATE TABLE IF NOT EXISTS CUSTOMER
(
 C_CUSTKEY BIGINT NOT NULL CONSTRAINT C_CUSTKEY_pk PRIMARY KEY ,
 C_NAME VARCHAR(25) ,
 C_ADDRESS VARCHAR(40) ,
 C_NATIONKEY INT ,
```

```
C_PHONE CHAR(15) ,
C_ACCTBAL DECIMAL(15,2)
)
DISTRIBUTE BY HASH(C_CUSTKEY);

COMMENT ON COLUMN customer.c_customer_sk IS 'Primary key of customer demographics table.';
```

Create the **customer\_details\_view** view and add comments to the view.

```
CREATE OR REPLACE VIEW customer_details_view AS SELECT * FROM CUSTOMER;
COMMENT ON VIEW customer_details_view_v2 IS 'View of customer detail';
```

Add comments to the **customer** table.

```
COMMENT ON TABLE customer IS 'This is my table';
```

## 21.13.13 Publications and Subscriptions

### 21.13.13.1 CREATE PUBLICATION

#### Function

**CREATE PUBLICATION** adds a new publication to the current database. The publication name must be different from the name of any existing publication in the current database. A publication is essentially the replication of data changes in a set of tables achieved by logical replication.

#### Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- If neither **FOR TABLE** nor **FOR ALL TABLES** is specified, a publication starts with a set of empty tables. Tables can be added later.
- Creating a publication does not start replication. It defines only one group and filtering logic for future subscribers. To create a publication, the caller must have CREATE permission on the current database.
- To add a table to a publication, the caller must have ownership of the table. To use FOR ALL TABLES and FOR ALL TABLES IN SCHEMA clauses, the caller must have system administrator permissions.
- Do not add a table to the same publication by using FOR TABLE and FOR ALL TABLES IN SCHEMA.

#### Syntax

```
CREATE PUBLICATION name
[FOR ALL TABLES
 | FOR publication_object [, ...]]
[WITH (publication_parameter [=value] [, ...])];
```

The syntax of using **publication\_object** is as follows:

```
TABLE table_name [, ...]
| ALL TABLES IN SCHEMA schema_name [, ...]
```

## Parameter Description

**Table 21-269** CREATE PUBLICATION parameters

| Parameter                                              | Description                                                                                                                               | Value Range                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name                                                   | Specifies the name of a new publication.                                                                                                  | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                      |
| FOR ALL TABLES                                         | Marks a publication as replications of all fine-grained DR primary table changes in the database, including tables to be created.         | -                                                                                                                                                                                                                                                                                                                                                             |
| FOR TABLE                                              | Specifies the list of tables to be added to a publication. Only the fine-grained DR primary table can be a part of the publication.       | -                                                                                                                                                                                                                                                                                                                                                             |
| table_name                                             | Name of the table to be added to the publication, which can include the schema name.                                                      | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                      |
| FOR ALL TABLES IN SCHEMA                               | Marks a publication as replications of all fine-grained DR primary table changes a specified schema list, including tables to be created. | -                                                                                                                                                                                                                                                                                                                                                             |
| schema_name                                            | The name of the schema to be added to the publication.                                                                                    | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                                                                                                                                      |
| WITH<br>( publication_parameter [=value]<br>[, ... ] ) | Specifies optional parameters for a publication. Parameters in the right column are supported.                                            | publish: Specifies the DML operations that will be published to the subscriber.<br>Value range: A string. Separate the operations by commas (,). The available operations are insert, update, delete, and truncate.<br><br>By default, all actions are released. Therefore, the default value of this option is <b>insert, update, delete, and truncate</b> . |

## Examples

- Create sample table **tpcds.ship\_mode\_t1**.

```
CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
) WITH (ORIENTATION = COLUMN,enable_disaster_cstore='on')
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);
```

Create sample table **tpcds.customer\_address\_p1**.

```
CREATE TABLE tpcds.customer_address_p1
(
 CA_ADDRESS_SK INTEGER NOT NULL,
 CA_ADDRESS_ID CHAR(16) NOT NULL,
 CA_STREET_NUMBER CHAR(10) ,
 CA_STREET_NAME VARCHAR(60) ,
 CA_STREET_TYPE CHAR(15) ,
 CA_SUITE_NUMBER CHAR(10) ,
 CA_CITY VARCHAR(60) ,
 CA_COUNTY VARCHAR(30) ,
 CA_STATE CHAR(2) ,
 CA_ZIP CHAR(10) ,
 CA_COUNTRY VARCHAR(20) ,
 CA_GMT_OFFSET DECIMAL(5,2) ,
 CA_LOCATION_TYPE CHAR(20)
) WITH (ORIENTATION = COLUMN,enable_disaster_cstore='on')
DISTRIBUTE BY HASH(CA_ADDRESS_SK);
```

Create sample schema **myschema1**.

```
CREATE SCHEMA myschema1;
```

Create sample schema **myschema2**.

```
CREATE SCHEMA myschema2;
```

- Create a publication for all changes of two tables and two schemas.  

```
CREATE PUBLICATION mypublication FOR TABLE users, departments, ALL TABLES IN SCHEMA myschema1, myschema2;
```
- Create a publication for all changes in all tables.  

```
CREATE PUBLICATION alltables FOR ALL TABLES;
```

### 21.13.13.2 ALTER PUBLICATION

#### Function

**ALTER PUBLICATION** modifies the publication attributes.

#### Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- This statement can be used by the owner of a publication and the system administrator only.

- To alter the publication owner, you must also be a direct or indirect member of the new owning role, and that role must have CREATE privilege on the database.
- In a publication with **FOR ALL TABLES**, the new publication owner must be the system administrator.
- An administrator can change the owner relationship of any publication.

## Syntax

- Add objects to a publication.  
`ALTER PUBLICATION name ADD publication_object [, ...]`
- Delete objects from a publication.  
`ALTER PUBLICATION name DROP publication_object [, ...]`
- Replace the current object with a specified object.  
`ALTER PUBLICATION name SET publication_object [, ...]`
- Set publication parameters. Retain the original values of the parameters that are not mentioned.  
`ALTER PUBLICATION name SET ( publication_parameter [= value] [, ... ] )`
- Change the publication owner.  
`ALTER PUBLICATION name OWNER TO new_owner`
- Rename the publication.  
`ALTER PUBLICATION name RENAME TO new_name`

The syntax of using **publication\_object** is as follows:

```
TABLE table_name [, ...]
| ALL TABLES IN SCHEMA schema_name [, ...]
```

## Parameter Description

**Table 21-270** ALTER PUBLICATION parameters

| Parameter                                               | Description                                                                      | Value Range                                                                                                    |
|---------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| name                                                    | Specifies the publication name to be modified.                                   | -                                                                                                              |
| table_name                                              | Specifies the table name.                                                        | Name of an existing table.                                                                                     |
| schema_name                                             | Specifies the schema name.                                                       | Name of an existing schema.                                                                                    |
| SET<br>( publication_<br>parameter [= value] [, ... ] ) | Modifies the publication parameters initially set by <b>CREATE PUBLICATION</b> . | For details about the parameters, see the <a href="#">Parameter Description</a> in <b>CREATE PUBLICATION</b> . |
| new_owner                                               | Specifies the new owner of the publication.                                      | Name of an existing user.                                                                                      |
| new_name                                                | Specifies the new name of the publication.                                       | A string compliant with the <a href="#">identifier naming rules</a> .                                          |

## Examples

- Add a table to a publication.  
`ALTER PUBLICATION mypublication ADD TABLE mydata2;`
- Deletes a schema from a publication.  
`ALTER PUBLICATION mypublication DROP ALL TABLES IN SCHEMA myschema1;`
- Reset a publication object.  
`ALTER PUBLICATION mypublication SET TABLE mydata2, ALL TABLES IN SCHEMA myschema2;`
- Change the publication owner.  
`ALTER PUBLICATION mypublication OWNER TO user1;`
- Change the publication name.  
`ALTER PUBLICATION mypublication RENAME TO mypublication1;`

### 21.13.13.3 DROP PUBLICATION

#### Function

**DROP PUBLICATION** deletes a publication.

#### Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- This statement can be used by the publication owner and system administrators only.

#### Syntax

```
DROP PUBLICATION [IF EXISTS] name [, ...] [CASCADE | RESTRICT]
```

#### Parameter Description

Table 21-271 DROP PUBLICATION parameters

| Parameter          | Description                                                                                                                                          | Value Range              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| IF EXISTS          | If the specified publication does not exist, no error is thrown. Instead, a notification is reported indicating that the publication does not exist. | -                        |
| name               | Specifies the name of the publication you want to delete.                                                                                            | An existing publication. |
| CASCADE   RESTRICT | Currently, these keywords do not work because there is no dependency on publications.                                                                | -                        |

## Examples

Delete a publication.  
`DROP PUBLICATION mypublication;`

### 21.13.13.4 CREATE SUBSCRIPTION

## Function

**CREATE SUBSCRIPTION** adds a new subscription to the current database. The subscription name must be different from a name of any existing subscription in the database. A subscription represents a replication for connecting to the publication side.

## Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- A subscription can be created only by the system administrator.

## Syntax

```
CREATE SUBSCRIPTION name
 CONNECTION 'conninfo'
 PUBLICATION publication_name [, ...]
 [WITH (subscription_parameter [= value] [, ...])]
```

## Parameter Description

**Table 21-272** CREATE SUBSCRIPTION parameters

| Parameter | Description                           | Value Range                                                                          |
|-----------|---------------------------------------|--------------------------------------------------------------------------------------|
| name      | Specifies the name of a subscription. | A string, which must comply with the <a href="#">identifier naming conventions</a> . |

| Parameter | Description                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| conninfo  | <p>Specifies the string for connecting to the publication side.</p> <p>Example: <b>host=1.1.1.1,2.2.2.2</b><br/><b>port=10000,20000</b><br/><b>dbname=postgres</b><br/><b>user=repusr1</b><br/><b>password=password</b></p> | <ul style="list-style-type: none"><li>• <b>host</b><br/>IP address of the publication side. You can specify the IP addresses of both the primary and standby nodes of the publication side. Separate the IP addresses with commas (,).</li><li>• <b>port</b><br/>The publication port cannot be the primary port. Instead, it must be the primary port number plus 1. Otherwise, the port number conflicts with the thread pool. You can specify the ports of both the primary and standby nodes of the publication side. Separate the ports with commas (,).</li></ul> <p><b>CAUTION</b><br/>The number of hosts must be the same as that of ports.</p> <ul style="list-style-type: none"><li>• <b>dbname</b><br/>Specifies the database where a publication is deployed.</li><li>• <b>user and password</b><br/>Specifies the username and password used to connect to the publication side. The user has the system administrator permission (<b>SYSADMIN</b>) or O&amp;M administrator permission (<b>OPRADMIN</b>).</li></ul> |

| Parameter        | Description                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| publication_name | Specifies the name of the publication you want to subscribe to on the publication side. A subscription corresponds to multiple publications. | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| WITH             | Specifies the optional parameters for a subscription. The right column lists the supported parameters.                                       | <ul style="list-style-type: none"><li>• <b>enabled</b><br/>Specifies whether a subscription should be actively replicated, or whether it should be just set but not started.<br/>The value can be <b>true</b> or <b>false</b>.<br/>The default value is <b>true</b>.</li><li>• <b>create_slot</b><br/>Specifies whether a replication slot is created on the publisher.<br/>The value can be <b>true</b> or <b>false</b>.<br/>The default value is <b>true</b>.</li><li>• <b>slot_name</b><br/>Specifies the name of the replication slot.<br/>Value range: a string<br/>Default value: the subscription name</li></ul> |

## Examples

Create a subscription to tables of the publication **mypublication** on a remote server.

```
CREATE SUBSCRIPTION mysub
 CONNECTION 'host=192.168.1.50 port=5432 user=foo dbname=foodb password=*****'
 PUBLICATION mypublication;
```

## 21.13.13.5 ALTER SUBSCRIPTION

### Function

This syntax modifies the attributes of a subscription.

### Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- Only the owner of a subscription can execute **ALTER SUBSCRIPTION**, and the new owner must be a system administrator.

### Syntax

- Update the connection information of a subscription.  
`ALTER SUBSCRIPTION name CONNECTION 'conninfo';`
- Update the name of the publication on the publisher side.  
`ALTER SUBSCRIPTION name SET PUBLICATION publication_name [ , ... ];`
- Enable a subscription.  
`ALTER SUBSCRIPTION name ENABLE;`
- Disable a subscription.  
`ALTER SUBSCRIPTION name DISABLE;`
- Set subscription parameters.  
`ALTER SUBSCRIPTION name SET ( subscription_parameter [= value] [ , ... ] );`
- Change the subscription owner.  
`ALTER SUBSCRIPTION name OWNER TO new_owner;`
- Rename the subscription.  
`ALTER SUBSCRIPTION name RENAME TO new_name;`

### Parameter Description

Table 21-273 ALTER SUBSCRIPTION parameters

| Parameter             | Description                                                                                            | Value Range                                                                                                 |
|-----------------------|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| name                  | Specifies the name of the subscription to be modified.                                                 | Name of an existing subscription.                                                                           |
| CONNECTION 'conninfo' | Alters the connection attributes initially set by <b>CREATE SUBSCRIPTION</b> .                         | For details about the parameters, see <a href="#">Parameter Description</a> in <b>CREATE SUBSCRIPTION</b> . |
| publication_name      | Specifies the name of a new publication.                                                               | A string compliant with the <a href="#">identifier naming rules</a> .                                       |
| ENABLE                | Enables a previously disabled subscription and starts logical replication at the end of a transaction. | -                                                                                                           |

| Parameter                                              | Description                                                                                | Value Range                                                                                                          |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| DISABLE                                                | Disables a running subscription and stops logical replication at the end of a transaction. | -                                                                                                                    |
| SET<br>( publication_parameter [= value]<br>[, ... ] ) | Modifies the publication parameters initially set by <b>CREATE PUBLICATION</b> .           | For details about the parameters, see the <a href="#">Parameter Description</a> part in <b>CREATE SUBSCRIPTION</b> . |
| new_owner                                              | Specifies the name new subscription owner.                                                 | Name of an existing user.                                                                                            |
| new_name                                               | Specifies the new name of the subscription.                                                | A string compliant with the <a href="#">identifier naming rules</a> .                                                |

## Examples

Modify subscription connection information.

```
ALTER SUBSCRIPTION mysub CONNECTION 'host=192.168.1.51 port=5432 user=foo dbname=foodb
password=xxxx';
```

## Helpful Links

[CREATE SUBSCRIPTION](#) and [DROP SUBSCRIPTION](#)

### 21.13.13.6 DROP SUBSCRIPTION

#### Function

**DROP SUBSCRIPTION** deletes a subscription.

#### Precautions

- This statement is supported by version 8.2.0.100 or later clusters.
- A subscription can be deleted by the system administrator only.

#### Syntax

```
DROP SUBSCRIPTION [IF EXISTS] name
```

## Parameter Description

Table 21-274 DROP SUBSCRIPTION parameters

| Parameter | Description                                                                                                                                            | Value Range               |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| IF EXISTS | If the specified subscription does not exist, no error is thrown. Instead, a notification is reported indicating that the subscription does not exist. | -                         |
| name      | Specifies the name of the subscription you want to delete.                                                                                             | An existing subscription. |

## Examples

```
Delete a subscription.
DROP SUBSCRIPTION mysub;
```

## 21.13.14 Other

### 21.13.14.1 CREATE SYNONYM

#### Function

**CREATE SYNONYM** is used to create a synonym object. A synonym is an alias of a database object and is used to record the mapping between database object names. You can use synonyms to access associated database objects.

#### Precautions

- The user of a synonym should be its owner.
- If the schema name is specified, create a synonym in the specified schema. Otherwise create a synonym in the current schema.
- Database objects that can be accessed using synonyms include tables, views, functions, and stored procedures.
- To use synonyms, you must have the required permissions on associated objects.
- The following DML statements support synonyms: **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **EXPLAIN**, and **CALL**.
- The **CREATE SYNONYM** statement of an associated function or stored procedure cannot be used in a stored procedure. You are advised to use synonyms existing in the **pg\_synonym** system catalog in the stored procedure.

## Syntax

```
CREATE [OR REPLACE] SYNONYM synonym_name
FOR object_name;
```

## Parameter Description

**Table 21-275** CREATE SYNONYM parameters

| Parameter   | Description                                                                                                                                                | Value Range                                                                                 |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| synonym     | Name of a synonym which is created (optionally with schema names)                                                                                          | A string that must comply with the rules in <a href="#">Identifier Naming Conventions</a> . |
| object_name | Name of an object that is associated (optionally with schema names)<br><b>NOTE</b><br><b>object_name</b> can be the name of an object that does not exist. | A string that must comply with the rules in <a href="#">Identifier Naming Conventions</a> . |

## Examples

Create schema **ot**.

```
CREATE SCHEMA ot;
```

Create table **ot.t1** and its synonym **t1**.

```
CREATE TABLE ot.t1(id int, name varchar2(10)) DISTRIBUTE BY hash(id);
CREATE OR REPLACE SYNONYM t1 FOR ot.t1;
```

Use synonym **t1**.

```
SELECT * FROM t1;
INSERT INTO t1 VALUES (1, 'ada'), (2, 'bob');
UPDATE t1 SET t1.name = 'cici' WHERE t1.id = 2;
```

Create synonym **v1** and its associated view **ot.v\_t1**.

```
CREATE SYNONYM v1 FOR ot.v_t1;
CREATE VIEW ot.v_t1 AS SELECT * FROM ot.t1;
```

Use synonym **v1**.

```
SELECT * FROM v1;
```

Create overloaded function **ot.add** and its synonym **add**.

```
CREATE OR REPLACE FUNCTION ot.add(a integer, b integer) RETURNS integer AS
$$
SELECT $1 + $2
$$
LANGUAGE sql;

CREATE OR REPLACE FUNCTION ot.add(a decimal(5,2), b decimal(5,2)) RETURNS decimal(5,2) AS
$$
SELECT $1 + $2
$$
```

```
LANGUAGE sql;
CREATE OR REPLACE SYNONYM add FOR ot.add;
```

Use synonym **add**.

```
SELECT add(1,2);
SELECT add(1,2,2.3);
```

Create stored procedure **ot.register** and its synonym **register**.

```
CREATE PROCEDURE ot.register(n_id integer, n_name varchar2(10))
SECURITY INVOKER
AS
BEGIN
 INSERT INTO ot.t1 VALUES(n_id, n_name);
END;
/

CREATE OR REPLACE SYNONYM register FOR ot.register;
```

Use synonym **register** to invoke the stored procedure.

```
CALL register(3,'mia');
```

## Helpful Links

[ALTER SYNONYM](#), [DROP SYNONYM](#)

### 21.13.14.2 ALTER SYNONYM

#### Function

**ALTER SYNONYM** is used to modify the attribute of a synonym.

#### Precautions

- Only the owner of the **SYNONYM** object can be changed.
- Only the system administrator and the owner of the **SYNONYM** object can change its owner information.
- The modifier must be a direct or indirect member of the new owner, and the new owner must have the **CREATE** permission on the schema to which the synonym belongs.

#### Syntax

```
ALTER SYNONYM synonym_name
OWNER TO new_owner;
```

#### Parameter Description

**Table 21-276** ALTER SYNONYM parameters

| Parameter    | Description                                                            | Value Range                  |
|--------------|------------------------------------------------------------------------|------------------------------|
| synonym_name | Name of the synonym to be modified, which can include the schema name. | Name of an existing synonym. |

| Parameter | Description                                   | Value Range     |
|-----------|-----------------------------------------------|-----------------|
| OWNER TO  | Clause used to modify the owner of a synonym. | -               |
| new_owner | New owner of a synonym.                       | Valid username. |

## Examples

Create synonym **t1**.

```
CREATE OR REPLACE SYNONYM t1 FOR ot.t1;
```

Create user **u1**.

```
CREATE USER u1 PASSWORD '{password}';
```

Change the owner of the synonym **t1** to **u1**.

```
ALTER SYNONYM t1 OWNER TO u1;
```

## Helpful Links

[CREATE SYNONYM](#) and [DROP SYNONYM](#)

### 21.13.14.3 DROP SYNONYM

## Function

**DROP SYNONYM** is used to delete a synonym object.

## Precautions

Only a synonym owner or a system administrator can run the **DROP SYNONYM** command.

## Syntax

```
DROP SYNONYM [IF EXISTS] synonym_name [CASCADE | RESTRICT];
```

## Parameter Description

**Table 21-277** DROP SYNONYM parameters

| Parameter    | Description                                                                           | Value Range               |
|--------------|---------------------------------------------------------------------------------------|---------------------------|
| IF EXISTS    | Sends a notice instead of reporting an error if the specified synonym does not exist. | -                         |
| synonym_name | Name of a synonym which is deleted (optionally with schema names)                     | An existing synonym name. |

| Parameter          | Description                                                                                         | Value Range                                                                                                                                                                                                                                                          |
|--------------------|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CASCADE   RESTRICT | Specifies how to process related data in the dependent object when a delete operation is performed. | <ul style="list-style-type: none"><li>• <b>CASCADE</b>: automatically deletes objects (such as views) that depend on the synonym to be deleted.</li><li>• <b>RESTRICT</b>: refuses to delete the synonym if any objects depend on it. This is the default.</li></ul> |

## Examples

Delete a synonym.

```
DROP SYNONYM t1;
```

## Helpful Links

[ALTER SYNONYM](#) and [CREATE SYNONYM](#)

### 21.13.14.4 ALTER LARGE OBJECT

## Function

This syntax modifies the definition of a large object. The only function of ALTER LARGE OBJECT is to assign a new owner.

## Precautions

Only the owner of a large object can run this command. System administrators have this permission by default.

## Syntax

```
ALTER LARGE OBJECT large_object_oid
OWNER TO new_owner;
```

## Parameter Description

**Table 21-278** ALTER LARGE OBJECT parameters

| Parameter        | Description                                       | Value Range                       |
|------------------|---------------------------------------------------|-----------------------------------|
| large_object_oid | OID of the large object to be modified            | Name of an existing large object. |
| OWNER TO         | Clause used to modify the owner of a large object | -                                 |

| Parameter | Description             | Value Range                       |
|-----------|-------------------------|-----------------------------------|
| new_owner | Owner of a large object | Name of an existing user or role. |

## Examples

None.

### 21.13.14.5 CREATE BARRIER

#### Function

Creates a barrier for cluster nodes. The barrier can be used for data restoration.

#### Precautions

Before creating a barrier, ensure that **gtm\_backup\_barrier** and **enable\_cbm\_tracking** are set to **on** for CNs and DN nodes in the cluster.

#### Syntax

```
CREATE BARRIER [barrier_name] ;
```

#### Parameter Description

**barrier\_name**

(Optional) Indicates the name of a barrier.

A string compliant with the [identifier naming rules](#).

## Examples

Create a barrier without specifying its name.

```
CREATE BARRIER;
```

Create a barrier named **barrier1**.

```
CREATE BARRIER 'barrier1';
```

## 21.14 DML Syntax

### 21.14.1 DML Syntax Overview

Data Manipulation Language (DML) is used to perform operations on data in database tables, such as inserting, updating, querying, or deleting data.

#### Insert Data

Inserting data refers to adding one or multiple records to a database table. For details, see [INSERT](#).

## Updating Data

Modifying data refers to modifying one or multiple records in a database table. For details, see [UPDATE](#).

## Querying Data

The database query statement **SELECT** is used to search required information in a database. For details, see [SELECT](#).

## Deleting Data

For details about how to delete data that meets specified conditions from a table, see [DELETE](#).

## Copying Data

DWS provides a statement for copying data between tables and files. For details, see [COPY](#).

## Locking a Table

DWS provides multiple lock modes to control concurrent accesses to table data. For details, see [LOCK](#).

## Run the following statement to invoke the function:

DWS provides three statements for invoking functions. These statements are the same in the syntax structure. For details, see [CALL](#).

## 21.14.2 CALL

### Function

**CALL** calls defined functions or stored procedures.

### Precautions

If the name of a user-defined function is the same as that of a system function, you need to specify a schema when invoking the user-defined function. Otherwise, the system preferentially invokes the system function.

### Syntax

```
CALL [schema.] {func_name| procedure_name} (param_expr);
```

## Parameter Description

**Table 21-279** CALL parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Value Range                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| schema     | Specifies the name of the schema to which a function or stored procedure belongs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| func_name  | Specifies the name of the function or stored procedure to be called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Use an existing function name.                                                                                           |
| param_expr | <p>Specifies a list of parameters in the function. You can use ":" or "&gt;" to separate a parameter name from its value. By doing so, parameters can be arranged in any order. If the parameter list contains only parameter values, the sequence of the parameter values must be the same as that defined in the function or stored procedure.</p> <p><b>NOTE</b></p> <p>The parameters include input parameters (whose name and type are separated by <b>IN</b>) and output parameters (whose name and type are separated by <b>OUT</b>). When you run the <b>CALL</b> statement to call a function or stored procedure, the parameter list must contain an output parameter for non-overloaded functions. You can set the output parameter to a variable or any constant. For details, see <a href="#">Examples</a>. For an overloaded package function, the parameter list can have no output parameter, but the function may not be found. If an output parameter is contained, it must be a constant.</p> | Names of existing function parameters or stored procedure parameters.                                                    |

## Examples

Create the **func\_add\_sql** function to compute the sum of two integers and return the result:

```
CREATE FUNCTION func_add_sql(num1 integer, num2 integer) RETURN integer
AS
BEGIN
RETURN num1 + num2;
END;
/
```

Transfer based on parameter values:

```
CALL func_add_sql(1, 3);
```

Transfer based on the naming flags:

```
CALL func_add_sql(num1 => 1,num2 => 3);
CALL func_add_sql(num2 := 2, num1 := 3);
```

Delete a function:

```
DROP FUNCTION func_add_sql;
```

Create a function with output parameters:

```
CREATE FUNCTION func_increment_sql(num1 IN integer, num2 IN integer, res OUT integer)
RETURN integer
AS
BEGIN
res := num1 + num2;
END;
/
```

Set output parameters to constants:

```
CALL func_increment_sql(1,2,1);
```

Set output parameters to variables:

```
DECLARE
res int;
BEGIN
func_increment_sql(1, 2, res);
dbms_output.put_line(res);
END;
/
```

Create overloaded functions:

```
create or replace procedure package_func_overload(col int, col2 out int) package
as
declare
col_type text;
begin
col := 122;
dbms_output.put_line('two out parameters ' || col2);
end;
/
create or replace procedure package_func_overload(col int, col2 out varchar)
package
as
declare
col_type text;
begin
col2 := '122';
dbms_output.put_line('two varchar parameters ' || col2);
end;
/
```

Call a function:

```
call package_func_overload(1, 'test');
call package_func_overload(1, 1);
```

Delete a function:

```
DROP FUNCTION func_increment_sql;
```

## 21.14.3 COPY

### Function

**COPY** copies data between tables and files. **COPY FROM** copies data from a file to a table. **COPY TO** copies data from a table to a file.

Use **COPY FROM** and **COPY TO** for limited local data transfers with low concurrency.

---

#### NOTICE

- Since DWS is a fully managed cloud service, direct access to backend nodes is not available, making the **COPY** syntax unusable in this environment. Instead, employ the **\COPY** command via the gsql client; note that other tools like SQL editors do not support it.
  - For better results, save your data files on OBS and use OBS foreign tables for importing into the database.
- 

### Precautions

- **COPY** applies to only tables and does not apply to views.
- To insert data to a table, you must have the permission to insert data.
- If a list of columns is specified, **COPY** will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, **COPY FROM** will insert the default values for those columns.
- If a source data file is specified, the file must be accessible from the server. If **STDIN** is specified, data is transmitted between the client and server. Separate columns by pressing **Tab**. Enter **\.** in a new line to indicate the end of input.
- If the number of columns in a row of the data file is smaller or larger than the expected number, **COPY FROM** displays an error message.
- A backslash and a period (**\.**) indicate the end of data. The end identifier is not required for reading data from a file and is required for copying data between client applications.
- In **COPY FROM**, **"\N"** indicates an empty character string, and **"\\N"** indicates the actual data **"\N"**.
- **COPY FROM** does not support pre-processing of data during data import, for example, expression calculation and default value filling. If you need to perform pre-processing during data import, you need to import the data to a temporary table, and then run SQL statements to insert data to the table using expression or function operations. However, this method may cause I/O expansion, deteriorating data import performance.
- Transactions will be rolled back when data format errors occur during **COPY FROM** execution. In this case, error information is insufficient so you cannot easily locate the incorrect data from a large amount of raw data.
- You can use **COPY TO** to export data in TEXT or CSV format to OBS, but cannot use **COPY FROM** to import data from OBS. For CSV files that are

exported to OBS and contain utf8 BOM, you are advised to use OBS to import them. Otherwise, the BOM field may fail to be identified.

## Syntax

- Copy the data from a file to a table:

```
COPY table_name [(column_name [, ...])]
 FROM { 'filename' | STDIN }
 [[USING] DELIMITERS 'delimiters']
 [WITHOUT ESCAPING]
 [LOG ERRORS]
 [LOG ERRORS data]
 [REJECT LIMIT 'limit']
 [[WITH] (option [, ...])]
 | copy_option
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

### NOTE

In the SQL syntax, **FIXED, FORMATTER ( { column\_name( offset, length ) } [, ...] )**, and **[ ( option [, ...] ) | copy\_option [ ...] ]** can be in any sequence.

- Copy the data from a table to a file:

```
COPY table_name [(column_name [, ...])]
 TO { 'filename' | STDOUT }
 [[USING] DELIMITERS 'delimiters']
 [WITHOUT ESCAPING]
 [[WITH] (option [, ...])]
 | copy_option
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

```
COPY query
 TO { 'filename' | STDOUT }
 [WITHOUT ESCAPING]
 [[WITH] (option [, ...])]
 | copy_option
 | FIXED FORMATTER ({ column_name(offset, length) } [, ...]) [(option [, ...]) | copy_option
 [...]]];
```

### NOTE

- The syntax constraints of **COPY TO** are as follows:  
(**query**) is incompatible with **[USING] DELIMITER**. If the data of **COPY TO** comes from a query result, **COPY TO** cannot specify **[USING] DELIMITERS**.
- Use spaces to separate **copy\_option** following **FIXED FORMATTER**.
- **copy\_option** is the native parameter, while **option** is the parameter imported by a compatible foreign table.
- In the SQL syntax, **FIXED, FORMATTER ( { column\_name( offset, length ) } [, ...] )**, and **[ ( option [, ...] ) | copy\_option [ ...] ]** can be in any sequence.

## Parameter Description

**Table 21-280** COPY parameters

| Parameter   | Description                                                                                                                                                                                                                                                                                                                 | Value Range                                                                                                                                                                                                                                                                                                          |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| query       | Copies the query result.                                                                                                                                                                                                                                                                                                    | A <b>SELECT</b> or <b>VALUES</b> command in parentheses.                                                                                                                                                                                                                                                             |
| table_name  | Specifies the name (optionally schema-qualified) of an existing table.                                                                                                                                                                                                                                                      | An existing table name.                                                                                                                                                                                                                                                                                              |
| column_name | Specifies the list of optional fields to be copied.                                                                                                                                                                                                                                                                         | If the column list is not specified, all columns in the table will be copied.                                                                                                                                                                                                                                        |
| STDIN       | Indicates that the input comes from the client application.                                                                                                                                                                                                                                                                 | -                                                                                                                                                                                                                                                                                                                    |
| STDOUT      | Specifies that output goes to the client application.                                                                                                                                                                                                                                                                       | -                                                                                                                                                                                                                                                                                                                    |
| FIXED       | Fixes column length. <ul style="list-style-type: none"><li>• When the column length is fixed, <b>DELIMITER</b>, <b>NULL</b>, and <b>CSV</b> cannot be specified.</li><li>• When <b>FIXED</b> is specified, <b>BINARY</b>, <b>CSV</b>, and <b>TEXT</b> cannot be specified by <b>option</b> or <b>copy_option</b>.</li></ul> | The definition of fixed length: <ul style="list-style-type: none"><li>• The column length of each record is the same.</li><li>• Spaces are added to short columns. Digit type columns must be left-aligned, and character columns must be right-aligned.</li><li>• No delimiters are used between columns.</li></ul> |

| Parameter                            | Description                                                                                                  | Value Range                                                                                                                                                                               |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [USING]<br>DELIMITER<br>'delimiters' | The string that separates columns within each row (line) of the file, and it cannot be larger than 10 bytes. | The delimiter cannot include any of the following characters:<br>\\abcdefghijklmnopqrstuvwxyz0123456789<br>The default value is a tab character in text format and a comma in CSV format. |
| WITHOUT<br>ESCAPING                  | Specifies that the backslash (\) and its following characters are not escaped in text format.                | Only the text format is supported.                                                                                                                                                        |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                 |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| LOG ERRORS | <p>If this parameter is specified, the error tolerance mechanism for data type errors in the <b>COPY FROM</b> statement is enabled. Row errors are recorded in the <b>public.pgxc_copy_error_log</b> table in the database for future reference.</p> <p><b>NOTICE</b></p> <p>The restrictions of this error tolerance parameter are as follows:</p> <ul style="list-style-type: none"><li>• This error tolerance mechanism captures only the data type errors (DATA_EXCEPTION) that occur during data parsing of <b>COPY FROM</b> on a CN. Other errors, such as network errors between CNs and DN or expression conversion errors on DNs, are not captured.</li><li>• Before enabling error tolerance for <b>COPY FROM</b> for the first time in a database, check whether the <b>public.pgxc_copy_error_log</b> table exists. If it does not, call the <code>copy_error_log_create()</code> function to create it. If it does, copy its data elsewhere and call the <code>copy_error_log_create()</code> function to create the table. For details about columns in the <b>public.pgxc_copy_error_log</b> table, see <a href="#">Table 21-60</a>.</li><li>• While a <b>COPY FROM</b> statement with specified <b>LOG ERRORS</b> is being executed, if <b>public.pgxc_copy_error_log</b> does not exist or does not have the table definitions compliant with the predefined in <code>copy_error_log_create()</code>, an error will be reported. Ensure that the error table is created using the <code>copy_error_log_create()</code> function. Otherwise, <b>COPY FROM</b> statements with error tolerance may fail to be run.</li><li>• If existing error tolerance parameters (for example, <b>IGNORE_EXTRA_DATA</b>) of the <b>COPY</b> statement are enabled, the error of the corresponding type will be processed as specified by the parameters and no error will be reported. Therefore, the error table does not contain such error data.</li><li>• The coverage scope of this error tolerance mechanism is the same as that of a GDS foreign table. You are advised to filter query results based on table names or the timestamp of marking the start of <b>COPY FROM</b> statement execution. For how to process error data, see the section about handling error tables.</li></ul> | A value set while data is imported using <b>COPY FROM</b> . |

| Parameter                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOG ERRORS DATA                 | The differences between <b>LOG ERRORS DATA</b> and <b>LOG ERRORS</b> are as follows: <ul style="list-style-type: none"><li>• <b>LOG ERRORS DATA</b> records error row data (<b>rawrecord</b>).</li><li>• When this parameter is used, if the error content is too complex, the error may fail to be written into the fault tolerance table. As a result, the task fails.</li></ul>                                                                                                                                                                                                           | -                                                                                                                                                                                                                                                                                                                                   |
| REJECT LIMIT 'limit'            | Used with the <b>LOG ERROR</b> parameter to set the upper limit of the tolerated errors in the <b>COPY FROM</b> statement. If the number of errors exceeds the limit, later errors will be reported based on the original mechanism.<br><b>NOTE</b><br>Different from the GDS error tolerance mechanism, in the error tolerance mechanism described in the description of <b>LOG ERRORS</b> , the count of <b>REJECT LIMIT</b> is calculated based on the number of data parsing errors on the CN where the <b>COPY FROM</b> statement is run, not based on the number of errors on each DN. | A positive integer (1 to INTMAX) or <b>unlimited</b><br>Default value: <ul style="list-style-type: none"><li>• If <b>LOG ERRORS</b> is not specified, an error is reported.</li><li>• If <b>LOG ERRORS</b> is specified, the default value is <b>0</b>.</li></ul>                                                                   |
| FORMATTER                       | Defines the position of each column in the data file in the <b>column(offset,length)</b> format when the fixed length mode is used (that is, the <b>FIXED</b> parameter is specified).                                                                                                                                                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"><li>• The value of <b>offset</b> must be larger than 0. The unit is byte.</li><li>• The value of <b>length</b> must be larger than 0. The unit is byte.</li><li>• The total length of all columns must be less than 1 GB.</li><li>• Replace columns that are not in the file with NULL.</li></ul> |
| OPTION { option_name 'value ' } | Specifies all types of parameters of a compatible foreign table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | For details, see <a href="#">Table 21-281</a> .                                                                                                                                                                                                                                                                                     |

| Parameter                                   | Description                                               | Value Range                                     |
|---------------------------------------------|-----------------------------------------------------------|-------------------------------------------------|
| COPY_OPTION<br>{ option_name<br>' value ' } | Specifies all types of native parameters of <b>COPY</b> . | For details, see <a href="#">Table 21-282</a> . |

**Table 21-281** OPTION parameters

| Parameter | Description                                                                                                                                                                    | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORMAT    | Specifies the format of the source data file in the foreign table.                                                                                                             | <p>CSV, text, fixed, and binary files are supported.</p> <ul style="list-style-type: none"><li>• The CSV file can process newline characters efficiently, but cannot process certain special characters well.</li><li>• The TEXT file can process special characters efficiently, but cannot process newline character well.</li><li>• The FIXED file can process newline characters in data columns efficiently, but cannot process special characters well.</li><li>• All data in the BINARY file is stored/read as binary format rather than as text. It is faster than the text and CSV formats, but a binary-format file is less portable.</li></ul> <p>Default value: <b>TEXT</b></p> |
| OIDS      | <p>Copies the OID for each row.</p> <p><b>NOTE</b></p> <p>An error is raised if OIDs are specified for a table that does not have OIDs, or in the case of copying a query.</p> | <ul style="list-style-type: none"><li>• true/on</li><li>• false/off</li></ul> <p>Default value: <b>false</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Value Range                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DELIMITER | <p>Specifies the character that separates columns within each row (line) of the file.</p> <ul style="list-style-type: none"><li>• A delimiter cannot be \r or \n.</li><li>• A delimiter cannot be the same as null. The delimiter for CSV cannot be same as quote.</li><li>• The delimiter for the TEXT format data cannot contain lowercase letters, digits, or dot (.).</li><li>• The data length of a single row should be less than 1 GB. If the delimiters are too long and there are too many rows, the length of valid data will be affected.</li><li>• You are advised to use multi-characters and invisible characters for delimiters. For example, you can use multi-characters (such as \$^&amp;) and invisible characters (such as 0x07, 0x08, and 0x1b).</li><li>• For a multi-character delimiter, do not use the same characters, for example, ---.</li></ul> <p><b>NOTE</b></p> | <p>The value of <b>delimiter</b> can be a multi-character delimiter whose length is less than or equal to 10 bytes.</p> <p>Default value:</p> <ul style="list-style-type: none"><li>• A tab character in TEXT format</li><li>• A comma (,) in CSV format</li><li>• No delimiter in FIXED format</li></ul>                                                             |
| NULL      | <p>Specifies how to represent a null value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"><li>• The null value cannot be \r or \n. The maximum length is 100 characters.</li><li>• The null value cannot be the same as the delimiter or quote parameter.</li></ul> <p>Default value:</p> <ul style="list-style-type: none"><li>• An empty string without quotation marks in CSV format</li><li>• \N in TEXT format</li></ul> |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Value Range                                                                                                                                                                                                                                                                                                                                            |

| TIMESTAMP_FORMAT            | Imports data of the <b>TIMESTAMP</b> type. This parameter is valid only for <b>COPY FROM</b> import.<br><br>The <b>BINARY</b> format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur.     | Valid <b>TIMESTAMP</b> formats. Time zones are not supported. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .                                                                                                                                                                                                                                                                                                                                                                      |
| SMALLDATE_TIME_FORMAT<br>AT | Imports data of the <b>SMALLDATETIME</b> type. This parameter is valid only for <b>COPY FROM</b> import.<br><br>The <b>BINARY</b> format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. | Valid <b>SMALLDATETIME</b> formats. For details, see <a href="#">Date and Time Processing Functions and Operators</a> .                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SERVER          | Specifies the OBS server, which takes effect only when <b>COPY TO</b> is used. <b>filename</b> is a path on OBS, indicating that data is exported to OBS.                                                                                                                                                                                                                                    | Name of the created OBS server.                                                                                                                                                                                                                                                                                                                                                                                 |
| BOM             | Specifies whether to add the UTF-8 BOM field to the exported CSV file. This parameter is valid only when <b>COPY TO</b> is executed and the <b>SERVER</b> parameter is set to a valid value. The exported file must be encoded in UTF-8 format.                                                                                                                                              | <ul style="list-style-type: none"><li>• true/on</li><li>• false/off</li></ul> Default value: <b>false</b>                                                                                                                                                                                                                                                                                                       |
| MAXROW          | Specifies the maximum number of lines in an exported file. A new file is generated if the number of lines exceeds the maximum. This parameter is valid only when <b>COPY TO</b> is executed and the <b>SERVER</b> parameter is set to a valid value. When <b>HEADER</b> is set to <b>true</b> , <b>MAXROW</b> must be greater than 1. It must be specified together with <b>FILEPREFIX</b> . | 1-2147483647                                                                                                                                                                                                                                                                                                                                                                                                    |
| FILEPREFIX      | Specifies the prefix of an export file name. This parameter is valid only when <b>COPY TO</b> is executed and the <b>SERVER</b> parameter is set to a valid value. It must be specified together with <b>MAXROW</b> .                                                                                                                                                                        | A valid string that does not start or end with a slash (/).                                                                                                                                                                                                                                                                                                                                                     |
| PRESERVE_BLANKS | Specifies whether to retain the blank characters (including spaces, \t, \v, and \f) at the end of each column during fixed-length import. This parameter is supported only by clusters of 8.2.0.100 or later.                                                                                                                                                                                | <ul style="list-style-type: none"><li>• <b>true/on</b>: indicates that the trailing \t is retained and the column data of the BYTEAOID, CHAROID, NAMEOID, TEXTOID, BPCHAROID, VARCHAROID, NVARCHAR2OID and CSTRINGOID types is not pruned.</li><li>• <b>false/off</b>: prunes trailing white space characters (including spaces, \t, \v, and \f) of all data types.</li></ul> Default value: <b>false/off</b> . |

**Table 21-282** COPY\_OPTION parameters

| Parameter           | Description                                                                                                                                                                                                                                                               | Value Range                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OIDS                | Copies the OID for each row.<br>An error is raised if OIDs are specified for a table that does not have OIDs, or in the case of copying a query.                                                                                                                          | -                                                                                                                                                                                                                                                                                                                                                                                                                        |
| NULL<br>null_string | Specifies the string that represents a null value.<br><b>NOTICE</b><br>When using <b>COPY FROM</b> , any data item that matches this string will be stored as a <b>NULL</b> value, so you should make sure that you use the same string as you used with <b>COPY TO</b> . | <ul style="list-style-type: none"><li>• The null value cannot be \r or \n. The maximum length is 100 characters.</li><li>• The null value cannot be the same as the delimiter or quote parameter.</li></ul> Default value: <ul style="list-style-type: none"><li>• \N in TEXT format</li><li>• An empty string without quotation marks in CSV format</li></ul>                                                           |
| HEADER              | Specifies whether a file contains a header with the names of each column in the file. header is available only for CSV and FIXED files.                                                                                                                                   | <ul style="list-style-type: none"><li>• When data is imported, if <b>header</b> is <b>on</b>, the first row of the data file will be identified as title row and ignored. If header is <b>off</b>, the first row is identified as data.</li><li>• When data is exported, if header is <b>on</b>, <b>fileheader</b> must be specified. If header is <b>off</b>, the exported file does not include a title row.</li></ul> |

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Value Range      |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| FILEHEADER                                 | <p>Specifies a file that defines the content in the header for exported data. The file contains data description of each column.</p> <p><b>NOTICE</b></p> <ul style="list-style-type: none"><li>• This parameter is available only when <b>header</b> is <b>on</b> or <b>true</b>.</li><li>• <b>fileheader</b> specifies an absolute path.</li><li>• The file can contain only one row of header information, and ends with a linefeed. Excess rows will be discarded. (Header information cannot contain linefeeds.)</li><li>• The length of the file including the linefeed cannot exceed 1 MB.</li></ul>                                                                                                                                                   | -                |
| FREEZE                                     | <p>Sets the <b>COPY</b> loaded data row as <b>frozen</b>, like these data have executed <b>VACUUM FREEZE</b>.</p> <p>This is a performance option of initial data loading. The data will be frozen only when the following three requirements are met:</p> <ul style="list-style-type: none"><li>• The table being loaded has been created or truncated in the current subtransaction before copying.</li><li>• There are no cursors open in the current transaction.</li><li>• There are no original snapshots in the current transaction.</li></ul> <p><b>NOTICE</b></p> <p>When <b>COPY</b> is completed, all other sessions will immediately recognize the data. This violates the general principle of MVCC visibility and leads to potential risks.</p> | -                |
| FORCE NOT NULL<br>column_name [, ...]      | Assigns a value to a specified column in <b>CSV COPY FROM</b> mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Existing fields. |
| FORCE QUOTE<br>{ column_name [, ...]   * } | Forces quotation marks to be used for all non-null values in each specified column in <b>CSV COPY TO</b> mode. NULL values are not enclosed in quotation marks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Existing fields. |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                               | Value Range                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| BINARY                         | The binary format option causes all data to be stored/read as binary format rather than as text. In binary mode, you cannot declare <b>DELIMITER</b> , <b>NULL</b> , or <b>CSV</b> . After the binary type is specified, you cannot use <b>option</b> or <b>copy_option</b> to specify the CSV, fixed, and text types.                                    | -                                                                                                                               |
| CSV                            | Enables the CSV mode. After the CSV type is specified, you cannot use <b>option</b> or <b>copy_option</b> to specify the binary, fixed, or text type.                                                                                                                                                                                                     | -                                                                                                                               |
| QUOTE [AS] 'quote_character'   | Specifies the quote character for a CSV file. <ul style="list-style-type: none"><li>• The quote parameter cannot be the same as the delimiter or null parameter.</li><li>• The <b>quote</b> parameter must be a single one-byte character.</li><li>• Invisible characters are recommended as <b>quote</b> values, such as 0x07, 0x08, and 0x1b.</li></ul> | Default value: double quotation mark (")                                                                                        |
| ESCAPE [AS] 'escape_character' | Specifies an escape character for a CSV file. The value must be a single-byte character.                                                                                                                                                                                                                                                                  | The default value is a double quotation mark ("). If it is the same as the value of <b>quote</b> , it will be replaced with \0. |

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                               | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EOL<br>'newline_character'  | Specifies the newline character style of the imported or exported data file.                                                                                                                                                                                                                                                                                                                                              | <p>Multi-character newline characters are supported, but the newline character cannot exceed 10 bytes.</p> <p>Common newline characters include <code>\r</code> (0x0D), <code>\n</code> (0x0A), and <code>\r\n</code> (0x0D0A). Special newline characters include <code>\$</code> and <code>#</code>.</p> <ul style="list-style-type: none"><li>• The <b>EOL</b> parameter supports only the TEXT format for data import and export. For forward compatibility, the <b>EOL</b> parameter can be set to <b>0x0D</b> or <b>0x0D0A</b> for data export in the CSV and FIXED formats.</li><li>• The value of the <b>EOL</b> parameter cannot be the same as that of <b>DELIMITER</b> or <b>NULL</b>.</li><li>• The <b>EOL</b> parameter value cannot contain lowercase letters, digits, or dot (.).</li></ul> |
| ENCODING<br>'encoding_name' | Specifies the name of a file encoding format.                                                                                                                                                                                                                                                                                                                                                                             | Valid encoding formats.<br>Default value: current encoding format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IGNORE_EXTRA_DATA           | <p>When the number of data source files exceeds the number of foreign table columns, excess columns at the end of the row are ignored. This parameter is available only during data importing.</p> <p>If you do not use this parameter, and the number of data source files exceeds the number of foreign table columns, the following error information will be displayed:<br/>extra data after last expected column</p> | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Value Range                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| COMPATIBLE_ILLEGAL_CHARS | <p>Specifies error tolerance for invalid characters during importing. Invalid characters are converted before importing. No error is reported and the import is not interrupted. The binary format is not supported. When data of such format is imported, error "cannot specify bulkload compatibility options in BINARY mode" will occur. It is valid only for <b>COPY FROM</b> import.</p> <p>If this parameter is not used, an error is reported when an invalid character is encountered during the import, and the import is interrupted.</p> <p>The rule of error tolerance when you import invalid characters is as follows:</p> <ul style="list-style-type: none"><li>• \0 is converted to a space.</li><li>• Other invalid characters are converted to question marks.</li><li>• Setting <b>compatible_illegal_chars</b> to <b>true/on</b> enables toleration of invalid characters. If <b>NULL</b>, <b>DELIMITER</b>, <b>QUOTE</b>, and <b>ESCAPE</b> are set to spaces or question marks, errors like "illegal chars conversion may confuse COPY escape 0x20" will be displayed to prompt the user to modify parameters that may cause confusion, preventing importing errors.</li></ul> | -                                                                                                                              |
| FILL_MISSING_FIELDS      | <p>Specifies whether to generate an error message when the last column in a row in the source file is lost during data loading.</p> <p><b>NOTICE</b><br/>Do not specify this option. If this option is enabled, the parser will ignore the data problem during CN data parsing (that is, the fault tolerance range of the COPY error table) and report an error again on the DN. As a result, the COPY error table (with <b>LOG ERRORS REJECT LIMIT</b> enabled) cannot capture such data exceptions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <ul style="list-style-type: none"><li>• true/on</li><li>• false/off</li></ul> <p>Default value: <b>false</b> or <b>off</b></p> |

| Parameter       | Description                                                                                                                                                                                                      | Value Range                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRESERVE_BLANKS | Specifies whether to retain the blank characters (including spaces, \t, \v, and \f) at the end of each column during fixed-length import. This parameter is supported by clusters of version 8.2.0.100 or later. | <ul style="list-style-type: none"><li>• <b>true/on</b>: indicates that the trailing \t is retained and the column data of the BYTEAOID, CHAROID, NAMEOID, TEXTOID, BPCHAROID, VARCHAROID, NVARCHAR2OID and CSTRINGOID types is not pruned.</li><li>• <b>false/off</b>: prunes trailing white space characters (including spaces, \t, \v, and \f) of all data types.</li></ul> Default value: <b>false/off</b> . |

The following special backslash sequences are recognized by **COPY FROM**:

**Table 21-283** Special backslash sequences

| Backslash Sequence | Description                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| \b                 | Backslash (ASCII 8)                                                                                                |
| \f                 | Form feed (ASCII 12)                                                                                               |
| \n                 | Newline character (ASCII 10)                                                                                       |
| \r                 | Carriage return character (ASCII 13)                                                                               |
| \t                 | Tab (ASCII 9)                                                                                                      |
| \v                 | Vertical tab (ASCII 11)                                                                                            |
| \digits            | Backslash followed by one to three octal digits specifies the ASCII value is the character with that numeric code. |
| \xdigits           | Backslash followed by an x and one or two hex digits specifies the character with that numeric code.               |

### Example (supported only by the gsql client)

Copy data from the **tpcds.ship\_mode** file to the **/home/omm/ds\_ship\_mode.dat** file:

```
\COPY tpcds.ship_mode TO '/home/omm/ds_ship_mode.dat';
```

Copy the query result from the **tpcds.ship\_mode** file to the **/home/omm/ds\_ship\_mode.dat** file.

```
\COPY (SELECT * FROM tpcds.ship_mode WHERE a <> null) TO '/home/omm/ds_ship_mode.dat';
```

Write **tpcds.ship\_mode** as output to **stdout**:

```
\COPY tpcds.ship_mode TO stdout;
```

Create the **tpcds.ship\_mode\_t1** table:

```
CREATE TABLE tpcds.ship_mode_t1
(
 SM_SHIP_MODE_SK INTEGER NOT NULL,
 SM_SHIP_MODE_ID CHAR(16) NOT NULL,
 SM_TYPE CHAR(30) ,
 SM_CODE CHAR(10) ,
 SM_CARRIER CHAR(20) ,
 SM_CONTRACT CHAR(20)
)
WITH (ORIENTATION = COLUMN, COMPRESSION=MIDDLE)
DISTRIBUTE BY HASH(SM_SHIP_MODE_SK);
```

Copy data from **stdin** to the **tpcds.ship\_mode\_t1** table:

```
\COPY tpcds.ship_mode_t1 FROM stdin;
```

Copy data from the **/home/omm/ds\_ship\_mode.dat** file to the **tpcds.ship\_mode\_t1** table:

```
\COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat';
```

Copy data from the **/home/omm/ds\_ship\_mode.dat** file to the **tpcds.ship\_mode\_t1** table, with the import format set to TEXT (**format 'text'**), the delimiter set to **\t** (delimiter **E'\t'**), excessive columns ignored (**ignore\_extra\_data 'true'**), and characters not escaped (**noescaping 'true'**).

```
\COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' WITH(format 'text', delimiter E'\t',
ignore_extra_data 'true', noescaping 'true');
```

Copy data from the **/home/omm/ds\_ship\_mode.dat** file to the **tpcds.ship\_mode\_t1** table, with the import format set to FIXED, fixed-length format specified (**FORMATTER(SM\_SHIP\_MODE\_SK(0, 2), SM\_SHIP\_MODE\_ID(2,16), SM\_TYPE(18,30), SM\_CODE(50,10), SM\_CARRIER(61,20), SM\_CONTRACT(82,20))**), excessive columns ignored (**ignore\_extra\_data**), and headers included (**header**).

```
\COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' FIXED
FORMATTER(SM_SHIP_MODE_SK(0, 2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10),
SM_CARRIER(61,20), SM_CONTRACT(82,20)) header ignore_extra_data;
```

Copy data from the **/home/omm/ds\_ship\_mode.dat** file to the **tpcds.ship\_mode\_t1** table, with the import format set to FIXED, fixed-length format specified (**FORMATTER(SM\_SHIP\_MODE\_SK(0, 2), SM\_SHIP\_MODE\_ID(2,16), SM\_TYPE(18,30), SM\_CODE(50,10), SM\_CARRIER(61,20), SM\_CONTRACT(82,20))**), excessive columns ignored (**ignore\_extra\_data**), headers included (**header**), and trailing **\t** retained.

```
\COPY tpcds.ship_mode_t1 FROM '/home/omm/ds_ship_mode.dat' (FORMAT 'fixed', FORMATTER
```

```
(SM_SHIP_MODE_SK(0,2), SM_SHIP_MODE_ID(2,16), SM_TYPE(18,30), SM_CODE(50,10),
SM_CARRIER(61,20), SM_CONTRACT(82,20)), PRESERVE_BLANKS>true', HEADER 'true',
IGNORE_EXTRA_DATA 'true');
```

Export **tpcds.ship\_mode\_t1** as a text file **ds\_ship\_mode.dat** in the OBS directory /**bucket/path/**. You need to specify the server options that contain OBS access information:

```
COPY tpcds.ship_mode_t1 TO '/bucket/path/ds_ship_mode.dat' WITH (format 'text', encoding 'utf8', server
'obs_server');
```

Export **tpcds.ship\_mode\_t1** as a CSV file in the OBS directory /**bucket/path/**. You need to specify the server options that contain OBS access information. The file contains the title line and BOM header. A single file can contain a maximum of 1000 lines. If the number of lines exceeds 1000, a new file is generated. The user-defined file name prefix is **justprefix**:

```
COPY (select * from tpcds.ship_mode_t1 where SM_SHIP_MODE_SK=1060) TO '/bucket/path/' WITH (format
'csv', header 'on', encoding 'utf8', server 'obs_server', bom 'on', maxrow '1000', fileprefix 'justprefix');
```

Delete the **tpcds.ship\_mode\_t1** table:

```
DROP TABLE tpcds.ship_mode_t1;
```

## 21.14.4 DELETE

### Function

Deletes rows that satisfy the **WHERE** clause from the specified table. If the **WHERE** clause does not exist, all rows in the table will be deleted. The result is a valid, but an empty table.

### Precautions

- You must have the **DELETE** permission on the table to delete from it, as well as the **SELECT** permission for any table in the **USING** clause or whose values are read in the **condition**.
- For replication tables, **DELETE** can be performed only in the following two scenarios:
  - Scenarios with primary key constraints.
  - Scenario where the execution plan can be pushed down.
- For column-store tables, the **RETURNING** clause is currently not supported.

---

#### WARNING

- Avoid using **UPDATE** or **DELETE** to modify or delete a large volume of data and use **TRUNCATE PARTITION** or **DROP PARTITION** instead.
  - For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Data Warehouse Service (DWS) Developer Guide*.
- 

### Syntax

```
[WITH [RECURSIVE] with_query [...]]
DELETE [/*+ plan_hint */] FROM [ONLY] table_name [*] [[AS] alias]
```

```
[PARTITION (partition_name) | PARTITION FOR (partition_key_value [, ...])]
[USING using_list]
[WHERE condition | WHERE CURRENT OF cursor_name]
[RETURNING { * | { output_expr [[AS] output_name] } [, ...] }];
```

## Parameter Description

Table 21-284 DELETE parameters

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range             |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| WITH<br>[ RECURSIVE ]<br>with_query<br>[, ...] | <p>The <b>WITH</b> clause allows you to specify one or more subqueries that can be referenced by name in the primary query, equal to temporary table.</p> <p>If <b>RECURSIVE</b> is specified, it allows a <b>SELECT</b> subquery to reference itself by name.</p> <p>The format of <b>with_query</b> is as follows:<br/>with_query_name [ ( column_name [, ...] ) ] AS<br/>( {select   values   insert   update   delete} )</p> <p>-- <b>with_query_name</b> specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of</p> <p><b>column_name</b> specifies the column name displayed in the subquery result set.</p> <p>Each subquery can be a <b>SELECT</b>, <b>VALUES</b>, <b>INSERT</b>, <b>UPDATE</b> or <b>DELETE</b> statement.</p> | -                       |
| plan_hint<br>clause                            | Following the keyword in the <b>/*+ */</b> format, hints are used to optimize the plan generated by a specified statement block. For details, see "DWS Performance Tuning" > "SQL Tuning" > "Hint-based Tuning" in <i>Data Warehouse Service (DWS) Developer Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | -                       |
| ONLY                                           | <p>If <b>ONLY</b> is specified, only the specified table is deleted. If <b>ONLY</b> is not specified, the specified table and all its inherited tables are deleted.</p> <p>This parameter is reserved only for compatibility with PostgreSQL. DWS does not support inherited tables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | -                       |
| table_name                                     | Specifies the name (optionally schema-qualified) of a target table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | An existing table name. |

| Parameter                    | Description                                                                                                                                                                                      | Value Range                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| alias                        | Specifies the alias for the target table.                                                                                                                                                        | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| partition_name               | Specifies the name of a partition. Only clusters of version 8.2.1 or later support this option.                                                                                                  | An existing partition name.                                                                                              |
| partition_key_value          | Specifies the key value of a partition.<br>The value specified by <b>PARTITION FOR ( partition_key_value [, ...] )</b> can uniquely identify a partition.                                        | Value range of the partition key for the partition to be renamed.                                                        |
| using_list                   | Specifies the <b>USING</b> clause.                                                                                                                                                               | -                                                                                                                        |
| condition                    | Specifies an expression that returns a value of type boolean. Only rows for which this expression returns <b>true</b> will be deleted.                                                           | -                                                                                                                        |
| WHERE CURRENT OF cursor_name | Not supported currently. Only syntax interface is provided.                                                                                                                                      | -                                                                                                                        |
| output_expr                  | Specifies an expression to be computed and returned by the <b>DELETE</b> command after each row is deleted. The expression can use any column names of the table. Write * to return all columns. | -                                                                                                                        |
| output_name                  | Specifies a name to use for a returned column.                                                                                                                                                   | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |

## Examples

Create the **tpcds.customer\_address\_bak** table:

```
CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;
```

Delete employees whose **ca\_address\_sk** is less than **14888** in the **tpcds.customer\_address\_bak** table:

```
DELETE FROM tpcds.customer_address_bak WHERE ca_address_sk < 14888;
```

Delete the employees whose **ca\_address\_sk** is **14891**, **14893**, and **14895** from **tpcds.customer\_address\_bak**:

```
DELETE FROM tpcds.customer_address_bak WHERE ca_address_sk in (14891,14893,14895);
```

Delete all data in the **tpcds.customer\_address\_bak** table:

```
DELETE FROM tpcds.customer_address_bak;
```

Use a subquery (to delete the row-store table **tpcds.warehouse\_t30**) to obtain a temporary table **temp\_t**, and then query all data in the temporary table **temp\_t**:

```
WITH temp_t AS (DELETE FROM tpcds.warehouse_t30 RETURNING *) SELECT * FROM temp_t ORDER BY 1;
```

Delete partition **p1** from the partitioned table **test\_range\_row**:

```
CREATE TABLE test_range_row(a int, d int)
DISTRIBUTE BY hash(a) PARTITION BY RANGE(d)
(
 PARTITION p1 values LESS THAN (60),
 PARTITION p2 values LESS THAN (75),
 PARTITION p3 values LESS THAN (90),
 PARTITION p4 VALUES LESS THAN (maxvalue)
);
INSERT OVERWRITE INTO test_range_row PARTITION(p1) VALUES(55,51);
INSERT OVERWRITE INTO test_range_row PARTITION(p3) VALUES(85,80);

DELETE FROM test_range_row PARTITION(p1);
```

## 21.14.5 EXPLAIN

### Function

**EXPLAIN** outputs the execution plan of SQL statements. You can analyze the execution plan to locate slow SQL statements and optimize SQL statements.

The execution plan shows how the tables referenced by the SQL statement will be scanned, for example, by plain sequential scan or index scan. If multiple tables are referenced, the execution plan also shows what join algorithms will be used to bring together the required rows from each input table. The most critical part of the display is the estimated statement execution cost, which is the planner's guess at how long it will take to run the statement.

The **ANALYZE** option (**EXPLAIN ANALYZE**) causes the statement to be actually executed, not only planned. The actual execution time of each step is displayed. This helps you verify the accuracy of the execution plan and evaluate the actual performance.

### Syntax

- Display the execution plan of an SQL statement, which supports multiple options and has no requirements for the order of options.

```
EXPLAIN [(option [, ...])] statement;
```

The syntax of the **option** clause is as follows:

```
ANALYZE [boolean] |
ANALYSE [boolean] |
VERBOSE [boolean] |
COSTS [boolean] |
CPU [boolean] |
DETAIL [boolean] |
NODES [boolean] |
NUM_NODES [boolean] |
```

```
BUFFERS [boolean] |
TIMING [boolean] |
PLAN [boolean] |
FORMAT { TEXT | XML | JSON | YAML } |
BLOCKNAME [boolean] |
OUTLINE [boolean] |
WARMUP |
WARMUP HOT
```

- Display the execution plan of an SQL statement, where options are in order.  
`EXPLAIN { [ { ANALYZE | ANALYSE } ] [ VERBOSE ] | PERFORMANCE } statement;`
- Display information required for reproducing the execution plan of an SQL statement. The information is usually used for fault locating. The **STATS** option must be used independently.  
`EXPLAIN ( STATS [ boolean ] ) statement;`
- Display the detailed time consumption of the DDL statement execution. This syntax is supported only by clusters of version 9.1.0 or later.  
`EXPLAIN PERFORMANCE statement;`  
DDL statement such as CREATE, CREATE INDEX, DROP, VACUUM FULL, ANALYZE, and COPY are supported.
- Perform pre-query and cache the pre-queried data to the local disk for higher query speed. This syntax is supported only by clusters of 9.1.0.200 and later versions.  
`EXPLAIN WARMUP statement;`  
`EXPLAIN WARMUP HOT statement;`

## Parameter Description

Table 21-285 EXPLAIN parameters

| Parameter                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range                                                                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| statement                                  | Specifies the SQL statement to be analyzed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | -                                                                                                                                                                                 |
| ANALYZE<br>boolean  <br>ANALYSE<br>boolean | <p>The <b>ANALYZE</b> option causes the statement to be executed, not only planned. Then actual runtime statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.</p> <p>To use <b>EXPLAIN ANALYZE</b> on an <b>INSERT</b>, <b>UPDATE</b>, <b>DELETE</b>, <b>CREATE TABLE AS</b>, or <b>EXECUTE</b> statement without letting the command affect your data, you can place it in a transaction and roll back it after the analysis is complete.</p> <pre>START TRANSACTION;<br/>EXPLAIN ANALYZE ...;<br/>ROLLBACK;</pre> | <ul style="list-style-type: none"><li>• <b>TRUE</b>: displays the actual run times and other statistics.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b> |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                | Value Range                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VERBOSE<br>boolean   | Displays additional information about the query plan.<br>Additional information includes the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. | <ul style="list-style-type: none"><li>• <b>TRUE</b>: The information is displayed.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>            |
| COSTS boolean        | Displays the estimated total cost of each plan node, as well as the estimated number of rows and the estimated width of each row.                                                                                                                                                                                                          | <ul style="list-style-type: none"><li>• <b>TRUE</b>: The information is displayed.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>            |
| CPU boolean          | Displays CPU usage.                                                                                                                                                                                                                                                                                                                        | <ul style="list-style-type: none"><li>• <b>TRUE</b>: The CPU usage is displayed.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>              |
| DETAIL<br>boolean    | Displays DN information.<br><b>NOTE</b><br>For clusters of 8.2.1 or later, when <b>Detail</b> is enabled in <b>EXPLAIN</b> , the time required for comparing skew values is displayed in the execution plan.                                                                                                                               | <ul style="list-style-type: none"><li>• <b>TRUE</b>: prints DN information.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>                   |
| NODES<br>boolean     | Prints information about the nodes executed by query.                                                                                                                                                                                                                                                                                      | <ul style="list-style-type: none"><li>• <b>TRUE</b>: prints information about executed nodes.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b> |
| NUM_NODES<br>boolean | Prints the quantity of executing nodes.                                                                                                                                                                                                                                                                                                    | <ul style="list-style-type: none"><li>• <b>TRUE</b>: prints the number of DNs.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>                |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range                                                                                                                                                                                                                                                                                                                                      |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BUFFERS<br>boolean   | Displays information about the buffer usage.<br><br>The buffer information includes the number of shared blocks hit, read, and updated, the number of local blocks hit, read, and updated, the number of temp blocks hit, read, and updated. Shared blocks contain data from regular tables and indexes, local blocks contain data from temporary tables and indexes, and temporary blocks contain short-term working data used in sorts, hashes. | <ul style="list-style-type: none"><li>• <b>TRUE</b>: displays information on buffer usage.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>FALSE</b>                                                                                                                                                                             |
| TIMING<br>boolean    | Displays the actual startup time and time spent in each node in the output.                                                                                                                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"><li>• <b>TRUE</b>: displays the information.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b>                                                                                                                                                                                          |
| PLAN boolean         | Specifies whether to store the execution plan in the <b>plan_table</b> table. When this option is enabled, the execution plan is stored in <b>PLAN_TABLE</b> and is not displayed on the current screen. Therefore, this option cannot be used together with other options when it is enabled.                                                                                                                                                    | <ul style="list-style-type: none"><li>• <b>ON</b>: The execution plan is stored in <b>plan_table</b> and is not displayed on the current screen. If the plan is stored successfully, <b>EXPLAIN SUCCESS</b> is returned.</li><li>• <b>OFF</b>: The execution plan is not stored but is printed on the screen.</li></ul> Default value: <b>ON</b> |
| FORMAT               | Specifies the output format.<br><br>The output content of each format is the same. XML, JSON, and YAML are easier for programs to parse SQL statements.                                                                                                                                                                                                                                                                                           | Text, XML, JSON, and YAML formats are supported.<br><br>Default value: <b>TEXT</b>                                                                                                                                                                                                                                                               |
| BLOCKNAME<br>boolean | Displays the blockname information of an operator.<br><br>The blockname information is printed only when <b>explain_perf_mode</b> is set to <b>pretty</b> .                                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"><li>• <b>TRUE</b>: displays blockname information.</li><li>• <b>FALSE</b>: displays no blockname information.</li></ul> Default value: <b>TRUE</b>                                                                                                                                                             |

| Parameter          | Description                                                                                                                                                                                                                              | Value Range                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OUTLINE<br>boolean | Displays outline information extracted from the plan.<br>The outline is printed only when <b>explain_perf_mode</b> is set to <b>pretty</b> .                                                                                             | <ul style="list-style-type: none"><li>• <b>TRUE</b>: displays outline information.</li><li>• <b>FALSE</b>: displays no outline information.</li></ul> Default value: <b>TRUE</b>                                   |
| PERFORMANCE        | This option prints all relevant information in execution.                                                                                                                                                                                | -                                                                                                                                                                                                                  |
| STATS boolean      | Specifies whether to display information required for reproducing the execution plan of an SQL statement, including the object definition, statistics, and configuration parameters. The information is usually used for fault locating. | <ul style="list-style-type: none"><li>• <b>TRUE</b>: display information required for reproducing the execution plan of an SQL statement.</li><li>• <b>FALSE</b>: No display.</li></ul> Default value: <b>TRUE</b> |
| WARMUP             | Processes the queried data in the sequence of A1in > A1out > Am. This is supported only by clusters of version 9.1.0.200 or later.                                                                                                       | -                                                                                                                                                                                                                  |
| WARMUP HOT         | Directly adds the queried data to the Am column. This is supported only by clusters of version 9.1.0.200 or later.                                                                                                                       | -                                                                                                                                                                                                                  |

## Examples

Create the **tpcds.customer\_address\_p1** table.

```
CREATE TABLE tpcds.customer_address_p1 AS TABLE tpcds.customer_address;
```

Change the value of **explain\_perf\_mode** to **normal**.

```
SET explain_perf_mode=normal;
```

Display an execution plan for simple queries in the table.

```
EXPLAIN SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

Data Node Scan on "__REMOTE_FQS_QUERY__" (cost=0.00..0.00 rows=0 width=0)
Node/s: All datanodes
(2 rows)
```

Generate an execution plan in JSON format (assume **explain\_perf\_mode** is set to **normal**).

```
EXPLAIN(FORMAT JSON) SELECT * FROM tpcds.customer_address_p1;
QUERY PLAN

[
 {
 "Plan": {
 +
 +
 +
```

```

 "Node Type": "Data Node Scan", +
 "RemoteQuery name": "__REMOTE_FQS_QUERY__",+
 "Alias": "__REMOTE_FQS_QUERY__", +
 "Startup Cost": 0.00, +
 "Total Cost": 0.00, +
 "Plan Rows": 0, +
 "Plan Width": 0, +
 "Nodes": "All datanodes" +
 } +
 } +
]
(1 row)

```

If there is an index and we use a query with an indexable **WHERE** condition, **EXPLAIN** might show a different plan.

```

EXPLAIN SELECT * FROM tpcds.customer_address_p1 WHERE ca_address_sk=10000;
QUERY PLAN

Data Node Scan on "__REMOTE_LIGHT_QUERY__" (cost=0.00..0.00 rows=0 width=0)
Node/s: datanode2
(2 rows)

```

Generate an execution plan in YAML format (assume **explain\_perf\_mode** is set to **normal**).

```

EXPLAIN(FORMAT YAML) SELECT * FROM tpcds.customer_address_p1 WHERE ca_address_sk=10000;
QUERY PLAN

- Plan:
 Node Type: "Data Node Scan"
 RemoteQuery name: "__REMOTE_LIGHT_QUERY__"
 Alias: "__REMOTE_LIGHT_QUERY__"
 Startup Cost: 0.00
 Total Cost: 0.00
 Plan Rows: 0
 Plan Width: 0
 Nodes: "datanode2"
(1 row)

```

Here is an example of an execution plan with cost estimates suppressed.

```

EXPLAIN(COSTS FALSE)SELECT * FROM tpcds.customer_address_p1 WHERE ca_address_sk=10000;
QUERY PLAN

Data Node Scan on "__REMOTE_LIGHT_QUERY__"
Node/s: datanode2
(2 rows)

```

Here is an example of an execution plan for a query that uses an aggregate function.

```

EXPLAIN SELECT SUM(ca_address_sk) FROM tpcds.customer_address_p1 WHERE ca_address_sk<10000;
QUERY PLAN

Aggregate (cost=18.19..14.32 rows=1 width=4)
-> Streaming (type: GATHER) (cost=18.19..14.32 rows=3 width=4)
 Node/s: All datanodes
 -> Aggregate (cost=14.19..14.20 rows=3 width=4)
 -> Seq Scan on customer_address_p1 (cost=0.00..14.18 rows=10 width=4)
 Filter: (ca_address_sk < 10000)
(6 rows)

```

-- Delete the **tpcds.customer\_address\_p1** table.

```
DROP TABLE tpcds.customer_address_p1;
```

Run the **EXPLAIN PERFORMANCE** command for the **ANALYZE** statement.

```
EXPLAIN PERFORMANCE ANALYZE t2_dist_row;
QUERY EXEC INFO

## 21.14.6 EXPLAIN PLAN

### Function

You can run the **EXPLAIN PLAN** statement to save the information about an execution plan to the **PLAN\_TABLE** table. Different from the **EXPLAIN** statement, **EXPLAIN PLAN** only stores plan information and does not print it on the screen.

### Syntax

```
EXPLAIN PLAN
[SET STATEMENT_ID = string]
FOR statement ;
```

## Parameter Description

**Table 21-286** EXPLAIN PLAN parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLAN         | Stores plan information in <b>PLAN_TABLE</b> . If the storing is successful, <b>EXPLAIN SUCCESS</b> is returned.                                                                                                                                                                                                                            |
| STATEMENT_ID | Tags a query. The tag information will be stored in <b>PLAN_TABLE</b> .<br><b>NOTE</b><br>If the <b>EXPLAIN PLAN</b> statement does not contain <b>SET STATEMENT_ID</b> , the value of <b>STATEMENT_ID</b> is empty by default. In addition, the value of <b>STATEMENT_ID</b> cannot exceed 30 bytes. Otherwise, an error will be reported. |

## Precautions

- **EXPLAIN PLAN** cannot be executed on DNs.
- Plan information cannot be collected for SQL statements that failed to be executed.
- Data in **PLAN\_TABLE** is in a session-level life cycle. Sessions are isolated from users and thereby users can view data of only the current session and current user.
- **PLAN\_TABLE** cannot be joined with GDS foreign tables.
- For a query that cannot be pushed down, object information cannot be collected and only such information as **REMOTE\_QUERY** and **CTE** can be collected. For details, see [Example 2](#).

## Example 1

You can perform the following steps to collect execution plans of SQL statements by running **EXPLAIN PLAN**:

**Step 1** Import TPC-H sample data.

**Step 2** Run the **EXPLAIN PLAN** statement.

### NOTE

After the **EXPLAIN PLAN** statement is executed, plan information is automatically stored in **PLAN\_TABLE**. **INSERT**, **UPDATE**, and **ANALYZE** cannot be performed on **PLAN\_TABLE**.

For details about **PLAN\_TABLE**, see the **PLAN\_TABLE** system view.

```
explain plan set statement_id='TPCH-Q4' for
select
o_orderpriority,
count(*) as order_count
from
orders
where
o_orderdate >= '1993-07-01'::date
and o_orderdate < '1993-07-01'::date + interval '3 month'
and exists (
select
```

```

*
from
lineitem
where
l_orderkey = o_orderkey
and l_commitdate < l_receiptdate
)
group by
o_orderpriority
order by
o_orderpriority;

```

**Step 3 Query PLAN\_TABLE.**

```
SELECT * FROM PLAN_TABLE;
```

| statement_id | plan_id  | id | operation           | options     | object_name | object_type | object_owner | projection                                    |
|--------------|----------|----|---------------------|-------------|-------------|-------------|--------------|-----------------------------------------------|
| TPCH-Q4      | 16781167 | 1  | ROW ADAPTER         |             |             |             |              | ORDERS.O_ORDERPRIORITY, (PG_CATALOG.COUNT(*)) |
| TPCH-Q4      | 16781167 | 2  | VECTOR SORT         |             |             |             |              | ORDERS.O_ORDERPRIORITY, (PG_CATALOG.COUNT(*)) |
| TPCH-Q4      | 16781167 | 3  | VECTOR AGGREGATE    | HASHED      |             |             |              | ORDERS.O_ORDERPRIORITY, PG_CATALOG.COUNT(*)   |
| TPCH-Q4      | 16781167 | 4  | VECTOR STREAMING    | GATHER      |             |             |              | ORDERS.O_ORDERPRIORITY, (COUNT(*))            |
| TPCH-Q4      | 16781167 | 5  | VECTOR AGGREGATE    | HASHED      |             |             |              | ORDERS.O_ORDERPRIORITY, COUNT(*)              |
| TPCH-Q4      | 16781167 | 6  | VECTOR NESTED LOOPS | SEMI        |             |             |              | ORDERS.O_ORDERPRIORITY                        |
| TPCH-Q4      | 16781167 | 7  | TABLE ACCESS        | CSTORE SCAN | ORDERS      | TABLE       | TPCH         | ORDERS.O_ORDERPRIORITY, ORDERS.O_ORDERKEY     |
| TPCH-Q4      | 16781167 | 8  | VECTOR MATERIALIZE  |             |             |             |              | LINEITEM.L_ORDERKEY                           |
| TPCH-Q4      | 16781167 | 9  | TABLE ACCESS        | CSTORE SCAN | LINEITEM    | TABLE       | TPCH         | LINEITEM.L_ORDERKEY                           |

**Step 4 Delete data from PLAN\_TABLE.**

```
DELETE FROM PLAN_TABLE WHERE xxx;
```

----End

**Example 2**

For a query that cannot be pushed down, only such information as **REMOTE\_QUERY** and **CTE** can be collected from **PLAN\_TABLE** after **EXPLAIN PLAN** is executed.

The optimizer generates a plan for pushing down statements. In this case, only **REMOTE\_QUERY** can be collected.

```

explain plan set statement_id = 'test remote query' for
select
current_user
from
customer;

```

**Query PLAN\_TABLE.**

```
SELECT * FROM PLAN_TABLE;
```

| statement_id      | plan_id  | id | operation      | options   | object_name      | object_type  | object_owner | projection    |
|-------------------|----------|----|----------------|-----------|------------------|--------------|--------------|---------------|
| test remote query | 29360133 | 1  | NESTED LOOPS   | CARTESIAN |                  |              |              | 'apple'::name |
| test remote query | 29360133 | 2  | DATA NODE SCAN |           | customer         | REMOTE_QUERY |              |               |
| test remote query | 29360133 | 3  | DATA NODE SCAN |           | customer_address | REMOTE_QUERY |              |               |

(3 rows)

**21.14.7 LOCK****Function**

**LOCK TABLE** obtains a table-level lock.

When the lock for commands referencing a table is automatically acquired, DWS always uses the lock mode with minimum constraints. Use **LOCK** if users need a more strict lock mode. For example, suppose an application runs a transaction at the **Read Committed** isolation level and needs to ensure that data in a table remains stable in the duration of the transaction. To achieve this, you could obtain **SHARE** lock mode over the table before the query. This will prevent concurrent

data changes and ensure subsequent reads of the table see a stable view of committed data. It is because the **SHARE** lock mode conflicts with the **ROW EXCLUSIVE** lock acquired by writers, and your **LOCK TABLE name IN SHARE MODE** statement will wait until any concurrent holders of **ROW EXCLUSIVE** mode locks commit or roll back. Therefore, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

## Precautions

- **LOCK TABLE** is useless outside a transaction block: the lock would remain held only to the completion of the statement. If **LOCK TABLE** is out of any transaction block, an error is reported.
- If no lock mode is specified, then **ACCESS EXCLUSIVE**, the most restrictive mode, is used.
- **LOCK TABLE ... IN ACCESS SHARE MODE** requires the **SELECT** permission on the target table. All other forms of **LOCK** require table-level **UPDATE** and/or the **DELETE** permission.
- There is no **UNLOCK TABLE** command. Locks are always released at transaction end.
- **LOCK TABLE** only deals with table-level locks, and so the mode names involving **ROW** are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, **ROW EXCLUSIVE** mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as **LOCK TABLE** is concerned, differing only in the rules about which modes conflict with which. For details about the rules, see [Lock Levels and Conflicts](#).

## Syntax

```
LOCK [TABLE] {[ONLY] name [, ...] {name [*]} [, ...]}
 [IN {ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE | SHARE | SHARE
ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE | UPDATE EXCLUSIVE} MODE]
 [NOWAIT] [LOCAL COORDINATOR ONLY];
```

## Lock Levels and Conflicts

DWS uses lock modes to control how concurrent transactions access resources, ensuring data consistency and preventing loss.

[Table 21-287](#) shows the eight main lock modes and their potential conflicts.

**Table 21-287** Conflicts between lock modes

| Lock Mode       | Lock Level | Lock Usage                                                  | Conflict |
|-----------------|------------|-------------------------------------------------------------|----------|
| AccessShareLock | 1          | SELECT statement, allowing other transactions to read data. | 8        |

| Lock Mode                | Lock Level | Lock Usage                                                                                                                                                                                           | Conflict        |
|--------------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| RowShareLock             | 2          | SELECT FOR UPDATE or FOR SHARE, allowing other transactions to read but preventing writes.                                                                                                           | 7 8             |
| RowExclusiveLock         | 3          | INSERT, UPDATE, and DELETE                                                                                                                                                                           | 5 6 7 8         |
| ShareUpdateExclusiveLock | 4          | VACUUM (non-FULL), ANALYZE, CREATE INDEX CONCURRENTLY, and COMMENT ON statements allows other transactions to read data but blocks writes.                                                           | 4 5 6 7 8       |
| ShareLock                | 5          | CREATE INDEX (non-CONCURRENTLY) allows other transactions to read data, but they cannot write data.                                                                                                  | 3 4 6 7 8       |
| ShareRowExclusiveLock    | 6          | Similar to RowExclusiveLock, this lock lets you read data safely by using <b>ROW SELECT...FOR UPDATE</b> . But it permits RowShareLock, allowing others to read the row but not update or delete it. | 3 4 5 6 7 8     |
| ExclusiveLock            | 7          | This lock prevents <b>RowShareLock</b> or <b>SELECT... FOR UPDATE</b> operations.                                                                                                                    | 2 3 4 5 6 7 8   |
| AccessExclusive-Lock     | 8          | The lock stops other transactions from reading and writing data during <b>ALTER TABLE</b> , <b>DROP TABLE</b> , or <b>VACUUM FULL</b> operations.                                                    | 1 2 3 4 5 6 7 8 |

## Parameter Description

Table 21-288 LOCK parameters

| Parameter | Description                                                                                                                                                           | Value Range             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| name      | The name (optionally schema-qualified) of an existing table to lock.<br><br>The tables are locked one-by-one in the order specified in the <b>LOCK TABLE</b> command. | An existing table name. |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                   | Value Range |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| ONLY                   | If <b>ONLY</b> is specified, only the specified table is deleted. If <b>ONLY</b> is not specified, the specified table and all its inherited tables are deleted.<br><br>This parameter is reserved only for compatibility with PostgreSQL. DWS does not support inherited tables.                                                                                                             | -           |
| ACCESS SHARE           | <b>ACCESS SHARE</b> allows only read operations on a table. In general, any SQL statements that only read a table and do not modify it will acquire this lock mode. The <b>SELECT</b> command acquires a lock of this mode on referenced tables.                                                                                                                                              | -           |
| ROW SHARE              | <b>ROW SHARE</b> allows concurrent read of a table but does not allow any other operations on the table.<br><b>SELECT FOR UPDATE</b> and <b>SELECT FOR SHARE</b> automatically acquire the <b>ROW SHARE</b> lock on the target table and add the <b>ACCESS SHARE</b> lock to other referenced tables except <b>FOR SHARE</b> and <b>FOR UPDATE</b> .                                          | -           |
| ROW EXCLUSIVE          | Like <b>ROW SHARE</b> , <b>ROW EXCLUSIVE</b> allows concurrent read of a table and modification of data in the table. <b>UPDATE</b> , <b>DELETE</b> , and <b>INSERT</b> automatically acquire this lock on the target table and add the <b>ACCESS SHARE</b> lock to other referenced tables. Generally, all commands that modify table data acquire the <b>ROW EXCLUSIVE</b> lock for tables. | -           |
| SHARE UPDATE EXCLUSIVE | This mode protects a table against concurrent schema changes and <b>VACUUM</b> runs.<br><br>Acquired by <b>VACUUM</b> (without <b>FULL</b> ), <b>ANALYZE</b> and <b>CREATE INDEX CONCURRENTLY</b> statements.                                                                                                                                                                                 | -           |

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   | Value Range                                                                                                |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| SHARE               | <b>SHARE</b> allows concurrent queries of a table but does not allow modification of the table.<br><br>Acquired by CREATE INDEX (without CONCURRENTLY).                                                                                                                                                                                                                                                                                       | -                                                                                                          |
| SHARE ROW EXCLUSIVE | <b>SHARE ROW EXCLUSIVE</b> protects a table against concurrent data changes, and is self-exclusive so that only one session can hold it at a time.<br><br>No SQL statements automatically acquire this lock mode.                                                                                                                                                                                                                             | -                                                                                                          |
| EXCLUSIVE           | <b>EXCLUSIVE</b> allows concurrent queries of the target table but does not allow any other operations.<br><br>This mode allows only concurrent <b>ACCESS SHARE</b> locks; that is, only reads from the table can proceed in parallel with a transaction holding this lock mode.<br><br>No SQL statements automatically acquire this lock mode on user tables. However, it will be acquired on some system tables in case of some operations. | -                                                                                                          |
| ACCESS EXCLUSIVE    | This mode guarantees that the holder is the only transaction accessing the table in any way.<br><br>Acquired by the <b>ALTER TABLE</b> , <b>DROP TABLE</b> , <b>TRUNCATE</b> , <b>REINDEX</b> , <b>CLUSTER</b> , and <b>VACUUM FULL</b> commands.                                                                                                                                                                                             | This is also the default lock mode for <b>LOCK TABLE</b> statements that do not specify a mode explicitly. |
| UPDATE EXCLUSIVE    | The <b>UPDATE EXCLUSIVE</b> lock allows concurrent <b>(AUTO) VACUUM</b> and <b>(AUTO) ANALYZE</b> , but does not allow concurrent <b>(AUTO) VACUUM</b> .<br><b>NOTE</b> <ul style="list-style-type: none"><li>This parameter is supported only by clusters of version 8.2.1.200 or later.</li><li>The <b>UPDATE EXCLUSIVE</b> lock is used only in the <b>VACUUM</b> syntax.</li></ul>                                                        | -                                                                                                          |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| NOWAIT                 | Specifies that <b>LOCK TABLE</b> should not wait for any conflicting locks to be released: if the specified locks cannot be acquired immediately without waiting, the transaction is aborted.<br><br>If <b>NOWAIT</b> is not specified, <b>LOCK TABLE</b> obtains a table-level lock, waiting if necessary for any conflicting locks to be released.                                                                                                                                              | -           |
| LOCAL COORDINATOR ONLY | Specifies that <b>LOCK TABLE</b> is executed only on the CN that receives the current session request and is not delivered to other CNs or all DN. This is used only for metadata operations to improve efficiency.<br><br><b>NOTICE</b> <ul style="list-style-type: none"><li>• This parameter is supported by version 8.2.0.100 or later clusters.</li><li>• Currently, only the <b>ACCESS SHARE</b> lock mode is supported. If other lock modes are used, an error will be reported.</li></ul> | -           |

## Examples

Obtain a **SHARE** lock on a primary key table when going to perform inserts into a foreign key table.

```
START TRANSACTION;

LOCK TABLE tpceds.reason IN SHARE MODE;

SELECT r_reason_desc FROM tpceds.reason WHERE r_reason_sk=5;
r_reason_desc

Parts missing
(1 row)

COMMIT;
```

Obtain a **SHARE ROW EXCLUSIVE** lock on a primary key table when performing a delete operation.

```
CREATE TABLE tpceds.reason_t1 AS TABLE tpceds.reason;

START TRANSACTION;

LOCK TABLE tpceds.reason_t1 IN SHARE ROW EXCLUSIVE MODE;

DELETE FROM tpceds.reason_t1 WHERE r_reason_desc IN(SELECT r_reason_desc FROM tpceds.reason_t1
WHERE r_reason_sk < 6);
```

```
DELETE FROM tpcds.reason_t1 WHERE r_reason_sk = 7;
COMMIT;
```

Delete the **tpcds.reason\_t1** table.

```
DROP TABLE tpcds.reason_t1;
```

Add the ACCESS SHARE lock to the table and set the lock scope to the current CN.

```
BEGIN;
LOCK TABLE lock_test IN ACCESS SHARE MODE LOCAL COORDINATOR ONLY;
SELECT pg_get_tabledef('lock_test');
END;
```

## 21.14.8 MERGE INTO

### Function

**MERGE INTO** matches data in a source table with that in a target table based on a join condition. If data matches, **UPDATE** will be executed on the target table. Otherwise, **INSERT** will be executed. **MERGE INTO** handles both UPDATE and INSERT operations within a single statement, potentially improving performance.

### Precautions

- To run **MERGE INTO**, you must have the UPDATE and INSERT permissions for the target table, as well as the SELECT permission for the source table.
- **PREPARE** is not supported.
- **MERGE INTO** cannot be executed during redistribution.
- **MERGE INTO** cannot be executed for target tables that contain triggers.
- When executing **MERGE INTO** for the round-robin table, you are advised to disable the GUC parameter **allow\_concurrent\_tuple\_update**, or some **MERGE INTO** statements are not supported.

### Syntax

```
MERGE [/*+ plan_hint */] INTO table_name [partition_clause] [[AS] alias]
USING { { table_name | view_name } | subquery } [partition_clause] [[AS] alias]
ON (condition)
[
 WHEN MATCHED THEN
 UPDATE SET { column_name = { expression | DEFAULT } |
 (column_name [, ...]) = ({ expression | DEFAULT } [, ...]) } [, ...]
 [WHERE condition]
]
[
 WHEN NOT MATCHED THEN
 INSERT { DEFAULT VALUES |
 [(column_name [, ...])] VALUES ({ expression | DEFAULT } [, ...]) [, ...] [WHERE condition] }
];
```

where partition\_clause can be:

```
PARTITION (partition_name) | PARTITION FOR (partition_key_value [, ...])
```

## Parameter Description

Table 21-289 MERGE INTO parameters

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Value Range       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| <b>plan_hint</b><br>clause | Following the keyword in the <i>/*+ */</i> format, hints are used to optimize the plan generated by a specified statement block. For details, see "DWS Performance Tuning" > "SQL Tuning" > "Hint-based Tuning" in <i>Data Warehouse Service (DWS) Developer Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                  | -                 |
| <b>INTO</b> clause         | <p>Specifies the target table that is being updated or has data being inserted.</p> <ul style="list-style-type: none"><li>• <b>table_name</b><br/>Specifies the name of the target table.</li><li>• <b>partition_clause</b><br/>Specifies a partition in the target table. This parameter is supported only by clusters of version 9.1.0 or later.<br/><br/>Partitions can be specified only if the target table is a partitioned one. The specified partition name must already exist in the target table or the partition specified by the partition key already exists.</li><li>• <b>alias</b><br/>Specifies the alias for the target table.</li></ul> | Valid table name. |

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range              |

| <b>WHEN NOT MATCHED</b> clause | <p>Specifies that the <b>INSERT</b> operation is performed if data in the source table does not match that in the target table based on the condition.</p> <ul style="list-style-type: none"><li>An <b>INSERT</b> clause cannot contain multiple <b>VALUES</b>.</li><li>The order of <b>WHEN MATCHED</b> and <b>WHEN NOT MATCHED</b> clauses can be reversed. One of them can be used by default, but they cannot be both used at one time. Two <b>WHEN MATCHED</b> or <b>WHEN NOT MATCHED</b> clauses cannot be specified at the same time.</li><li>If a partition in the target table is specified and more data beyond the scope of the partition is inserted, the error message "The inserted partition key is not mapped to the specified 'partition_name' partition" will be displayed.</li></ul> | -                                                                               |
| DEFAULT                        | Sets the column to its default value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | The value is <b>NULL</b> if no specified default value has been assigned to it. |
| WHERE condition                | <p>Specifies the conditions for the <b>UPDATE</b> and <b>INSERT</b> clauses. The two clauses will be executed only when the conditions are met. This parameter can be left empty.</p> <p>System columns cannot be referenced in <b>WHERE condition</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | -                                                                               |

## Examples

Create the target table **products** and source table **newproducts**, and insert data to them.

```
CREATE TABLE products
(
 product_id INTEGER,
 product_name VARCHAR2(60),
 category VARCHAR2(60)
);

INSERT INTO products VALUES (1501, 'vivitar 35mm', 'electronics');
INSERT INTO products VALUES (1502, 'olympus is50', 'electronics');
INSERT INTO products VALUES (1600, 'play gym', 'toys');
INSERT INTO products VALUES (1601, 'lamaze', 'toys');
```

```
INSERT INTO products VALUES (1666, 'harry potter', 'dvd');

CREATE TABLE newproducts
(
 product_id INTEGER,
 product_name VARCHAR2(60),
 category VARCHAR2(60)
);

INSERT INTO newproducts VALUES (1502, 'olympus camera', 'electronics');
INSERT INTO newproducts VALUES (1601, 'lamaze', 'toys');
INSERT INTO newproducts VALUES (1666, 'harry potter', 'toys');
INSERT INTO newproducts VALUES (1700, 'wait interface', 'books');
```

Run **MERGE INTO**. If the **product\_id** field is matched and the **product\_name** field in the target table is not **play gym**, UPDATE is executed. If the **product\_id** field is not matched and the **category** field in the source table is **books**, INSERT is executed.

```
MERGE INTO products p
USING newproducts np
ON (p.product_id = np.product_id)
WHEN MATCHED THEN
 UPDATE SET p.product_name = np.product_name, p.category = np.category WHERE p.product_name !=
'play gym'
WHEN NOT MATCHED THEN
 INSERT VALUES (np.product_id, np.product_name, np.category) WHERE np.category = 'books';
```

View the query result. The data in **product\_id** of rows 1502 and 1666 in the **products** table was updated, and the data in row 1700 was newly inserted.

```
SELECT * FROM products ORDER BY product_id;
product_id | product_name | category
-----+-----+-----
1501 | vivitar 35mm | electronics
1502 | olympus camera | electronics
1600 | play gym | toys
1601 | lamaze | toys
1666 | harry potter | toys
1700 | wait interface | books
(6 rows)
```

## 21.14.9 INSERT and UPSERT

### 21.14.9.1 INSERT

#### Function

**INSERT** inserts new rows into a table.

#### Precautions

- For details about how to use INSERT, see the "INSERT Operation" in *Data Warehouse Service (DWS) Developer Guide*.
- You must have the **INSERT** permission on a table in order to insert into it.
- Use of the **RETURNING** clause requires the **SELECT** permission on all columns mentioned in **RETURNING**.
- If you use the **query** clause to insert rows from a query, you of course need to have the **SELECT** permission on any table or column used in the query.

- Using the **OVERWRITE** clause requires both **SELECT** and **TRUNCATE** permissions on the table since it deletes existing data before inserting new records.
- When you connect to a database compatible to Teradata and **td\_compatible\_truncation** is **on**, a long character string will be automatically truncated. If later **INSERT** statements (not involving foreign tables) insert long strings to columns of char- and varchar-typed columns in the target table, the system will truncate the long strings to ensure no strings exceed the maximum length defined in the target table.

#### NOTICE

If inserting multi-byte character data (such as Chinese characters) to database with the character set byte encoding (SQL\_ASCII, LATIN1), and the character data crosses the truncation position, the string is truncated based on its bytes instead of characters. Unexpected result will occur in tail after the truncation. If you want correct truncation result, you are advised to adopt encoding set such as UTF-8, which has no character data crossing the truncation position.

## Syntax

```
[WITH [RECURSIVE] with_query [, ...]]
INSERT [/*+ plan_hint */] [IGNORE | OVERWRITE] INTO table_name [partition_clause] [AS alias]
[(column_name [, ...])]
 { DEFAULT VALUES
 | VALUES { ({ expression | DEFAULT } [, ...]) } [, ...]
 | query }
 [ON DUPLICATE KEY duplicate_action | ON CONFLICT [conflict_target] conflict_action]
 [RETURNING { * | { output_expression [[AS] output_name] }, ... }] ;
```

where partition\_clause can be:

```
PARTITION (partition_name)
| PARTITION FOR (partition_key_value [, ...])
```

and duplicate\_action can be:

```
UPDATE { column_name = { expression | DEFAULT } |
 (column_name [, ...]) = ({ expression | DEFAULT } [, ...])
 } [, ...]
```

and conflict\_target can be one of:

```
({ index_column_name | (index_expression) } [COLLATE collation] [opclass] [, ...]) [WHERE
index_predicate]
ON CONSTRAINT constraint_name
```

and conflict\_action is one of:

```
DO NOTHING
DO UPDATE SET { column_name = { expression | DEFAULT } |
 (column_name [, ...]) = ({ expression | DEFAULT } [, ...])
 } [, ...]
[WHERE condition]
```

## Parameter Description

**Table 21-290** INSERT parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Value Range or Example                                                                      |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| WITH<br>[ RECURSIVE ]<br>with_query [, ...] | <p>The <b>WITH</b> clause allows you to specify one or more subqueries that can be referenced by name in the primary query, equal to temporary table.</p> <p>If <b>RECURSIVE</b> is specified, it allows a <b>SELECT</b> subquery to reference itself by name.</p> <p>The format of <b>with_query</b> is as follows:<br/>with_query_name [ ( column_name [, ...] ) ] AS<br/>( {select   values   insert   update   delete} )</p> <p><b>with_query_name</b> specifies the name of the result set generated by a subquery. Such names can be used to access the result sets of subqueries in a query.</p> <p><b>column_name</b> specifies the column name displayed in the subquery result set.</p> <p>Each subquery can be a <b>SELECT</b>, <b>VALUES</b>, <b>INSERT</b>, <b>UPDATE</b> or <b>DELETE</b> statement.</p> | <a href="#">Generating Temporary Tables with WITH and Inserting Data into Another Table</a> |
| <b>plan_hint</b><br>clause                  | Following the keyword in the <b>/*+ */</b> format, hints are used to optimize the plan generated by a specified statement block. For details, see "DWS Performance Tuning" > "SQL Tuning" > "Hint-based Tuning" in <i>Data Warehouse Service (DWS) Developer Guide</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | -                                                                                           |
| IGNORE                                      | <p>Specifies that the data that duplicates an existing primary key or unique key value will be ignored.</p> <p>For details, see <a href="#">UPSERT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <a href="#">Using IGNORE to Ignore Primary Key Conflicts</a>                                |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Value Range or Example |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| OVERWRITE | <p>Specifies the overwrite mode. After this mode is used, the original data is cleared and only the newly inserted data exists. This parameter is available only for clusters of version 8.1.1 or later.</p> <p>You can specify the columns on which <b>OVERWRITE</b> takes effect, and the other columns will keep their original data. If a column has no original data, its value is <b>NULL</b>.</p> <p><b>INSERT OVERWRITE</b> constraint:</p> <ul style="list-style-type: none"><li>• Do not perform <b>OVERWRITE</b> and <b>INSERT INTO</b> operations at the same time. Otherwise, data written in real time may be unexpectedly cleared.</li><li>• <b>INSERT OVERWRITE</b> is unavailable for replication tables. <b>OVERWRITE</b> applies to the scenario where a large amount of data is imported. You are not advised to use <b>OVERWRITE</b> to insert a small amount of data.</li><li>• Do not concurrently perform insert overwrite operations on the same table. Otherwise, an error similar to "tuple concurrently updated." will be reported.</li><li>• If the cluster is being scaled out and data redistribution is required for the table where <b>INSERT OVERWRITE</b> is performed, <b>INSERT OVERWRITE</b> clears the current data and automatically distributes the inserted data to the new nodes after scale-out. If <b>INSERT OVERWRITE</b> and the data redistribution of the table are performed at the same time, <b>INSERT OVERWRITE</b> will interrupt the data redistribution of the table.</li><li>• <b>OVERWRITE</b> allows you to insert data into an OBS foreign table in overwrite mode, where the data in the original directory will be overwritten.</li><li>• The foreign table supports <b>OVERWRITE</b> single-partition and multi-level Value partitioning. This function is supported only in 9.1.0.100 and later versions.</li></ul> | -                      |

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range or Example         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
|                | <p>Example: INSERT OVERWRITE into table_name partition for (p1_value, p2_value...) ...</p> <ul style="list-style-type: none"><li>When <b>INSERT OVERWRITE</b> and <b>ALTER TABLE...ADD PARTITION</b> are both executed on a given table, the number of partitions on different nodes may be inconsistent. As a result, an error is reported during the execution of <b>INSERT OVERWRITE</b>. You are advised to run <b>INSERT OVERWRITE</b> again.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                |
| table_name     | Specifies the name of the target table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | An existing table name.        |
| AS             | Specifies an alias for the target table <i>table_name</i> . <i>alias</i> indicates the alias name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | -                              |
| column_name    | <p>Specifies the name of a column in a table.</p> <ul style="list-style-type: none"><li>The column name can be qualified with a subfield name or array subscript, if needed.</li><li>Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or <b>NULL</b> if there is none. (Inserting into only some fields of a composite column leaves the other fields null.)</li><li>The target column names <b>column_name</b> can be listed in any order. If no list of column names is given at all, the default is all the columns of the table in their declared order.</li><li>The target columns are the first N column names, if there are only N columns supplied by the value clause or query.</li><li>The values supplied by the <b>value</b> clause or <b>query</b> are associated with the explicit or implicit column list left-to-right.</li></ul> | An existing column name.       |
| partition_name | Specifies the name of a partition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Name of an existing partition. |

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         | Value Range or Example                                                                                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| partition_key_value | Specifies the key value of a partition.<br>The value specified by <b>PARTITION FOR ( partition_key_value [, ...] )</b> can uniquely identify a partition. Multiple partition key values can be specified. Use commas (,) to separate multiple partition key values.                                                                                                                                                                                 | Value range of the partition key of the partition to be renamed.                                                                                                         |
| expression          | Specifies an expression or a value to assign to the corresponding column. <ul style="list-style-type: none"><li>• If single-quotation marks are inserted in a column, the single-quotation marks need to be used for escape.</li><li>• If the expression for any column is not of the correct data type, automatic type conversion will be attempted. If the attempt fails, data insertion fails and the system returns an error message.</li></ul> | <a href="#">Inserting an Expression or Value into a Column</a>                                                                                                           |
| DEFAULT             | Specifies the default value of the corresponding field name.                                                                                                                                                                                                                                                                                                                                                                                        | The value is <b>NULL</b> if no specified default value has been assigned to it. For details, see <a href="#">Using the Default Value of a Column When Writing Data</a> . |
| query               | Specifies a query statement ( <b>SELECT</b> statement) that uses the query result as the inserted data.                                                                                                                                                                                                                                                                                                                                             | <a href="#">Inserting Query Results into a Table</a>                                                                                                                     |
| ON DUPLICATE KEY    | Specifies that the data that duplicates an existing primary key or unique key value will be updated.<br><i>duplicate_action</i> specifies the columns and data to be updated.<br>For details, see <a href="#">UPSERT</a> .                                                                                                                                                                                                                          | <a href="#">Inserting Data with ON DUPLICATE KEY for Handling Primary Key/Unique Conflicts</a>                                                                           |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Value Range or Example                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| ON CONFLICT       | <p>Specifies that the data that duplicates an existing primary key or unique key value will be ignored or updated.</p> <p><i>conflict_target</i> specifies the column name <i>index_column_name</i>, expression <i>index_expression</i> that contains multiple column names, or constraint name <i>constraint_name</i>. It is used to infer whether there is a unique index from the column name, the expression that contains multiple column names, or the constraint name. <i>index_column_name</i> and <i>index_expression</i> must comply with the index column format of <b>CREATE INDEX</b>.</p> <p><i>conflict_action</i> specifies the policy to be executed upon a primary key or unique constraint conflict. There are two available actions:</p> <ul style="list-style-type: none"><li>• <b>DO NOTHING</b>: Ignore the conflict.</li><li>• <b>DO UPDATE SET</b>: Update data upon a conflict. The columns and data to be updated must be specified.</li></ul> <p>For details, see <a href="#">UPSERT</a>.</p> | <a href="#">Examples</a>                                                                                                 |
| RETURNING         | Returns the inserted rows. The syntax of the <b>RETURNING</b> list is identical to that of the output list of <b>SELECT</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <a href="#">Using RETURNING to Return Insertion Results</a>                                                              |
| output_expression | An expression used to calculate the output of the <b>INSERT</b> command after each row is inserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | The expression can use any column names of the table. Write * to return all columns of the inserted row(s).              |
| output_name       | Specifies a name to use for a returned column.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |

## Inserting One or More Data Records

Create the **reason\_t1** table.

```
DROP TABLE IF EXISTS reason_t1;
CREATE TABLE reason_t1
(
 TABLE_SK INTEGER ,
 TABLE_ID VARCHAR(20) ,
 TABLE_NA VARCHAR(20)
);
```

Insert one data record to the table.

```
INSERT INTO reason_t1(TABLE_SK, TABLE_ID, TABLE_NA) VALUES (1, 'S01', 'StudentA');
```

Insert one data record into the table. This command is equivalent to the last one.

```
INSERT INTO reason_t1 VALUES (1, 'S01', 'StudentA');
```

Insert records whose **TABLE\_SK** is less than **1** into the table.

```
INSERT INTO reason_t1 SELECT * FROM reason_t1 WHERE TABLE_SK < 1;
```

Insert records into the table.

```
INSERT INTO reason_t1 VALUES (1, 'S01', 'StudentA'),(2, 'T01', 'TeacherA'),(3, 'T02', 'TeacherB');
SELECT * FROM reason_t1 ORDER BY 1;
```

| table_sk | table_id | table_na |
|----------|----------|----------|
| 1        | S01      | StudentA |
| 1        | S01      | StudentA |
| 1        | S01      | StudentA |
| 2        | T01      | TeacherA |
| 3        | T02      | TeacherB |

## Inserting Query Results into a Table

Insert data back into the **reason\_t1** table.

```
INSERT INTO reason_t1 SELECT * FROM reason_t1;
```

## Using RETURNING to Return Insertion Results

Insert table data and return the values of **table\_id** and **table\_na** corresponding to the inserted data.

```
INSERT INTO reason_t1 SELECT * FROM reason_t1 RETURNING table_id, table_na;
```

| table_id | table_na |
|----------|----------|
| T01      | TeacherA |
| T02      | TeacherB |
| S01      | StudentA |
| T02      | TeacherB |
| T01      | TeacherA |

Insert data and return all column values of the inserted data.

```
INSERT INTO reason_t1 SELECT * FROM reason_t1 RETURNING *;
```

| table_sk | table_id | table_na |
|----------|----------|----------|
| 2        | T01      | TeacherA |
| 3        | T02      | TeacherB |
| 2        | T01      | TeacherA |
| 3        | T02      | TeacherB |
| 1        | S01      | StudentA |

Insert data and return the value of the renamed column **my\_id**.

```
INSERT INTO reason_t1 VALUES (1, 'S01', 'StudentA') RETURNING table_id AS my_id;
```

| my_id |
|-------|
| S01   |

## Using INSERT OVERWRITE to Insert Data in Overwriting Mode

Use INSERT OVERWRITE to update data in a table, that is, insert data in overwriting mode (clear the data in the target table first).

```
INSERT OVERWRITE INTO reason_t1 values (5, 'S02', 'StudentB');
SELECT * FROM reason_t1 ORDER BY 1;
```

| table_sk | table_id | table_na |
|----------|----------|----------|
| 5        | S02      | StudentB |

## Using the Default Value of a Column When Writing Data

```
DROP TABLE IF EXISTS products;
CREATE TABLE products (
```

```
id INT PRIMARY KEY,
name VARCHAR(50),
price DECIMAL(10, 2) DEFAULT 0.00
);
```

Insert a data record. If the value of the **price** column is not defined, **0.00** is used by default.

```
INSERT INTO products (id, name)VALUES (201, 'phone'); -- The price column uses the default value 0.00.
```

Insert a data record and explicitly use the default value.

```
INSERT INTO products (id, name, price)VALUES (202, 'pad', DEFAULT); -- Explicitly use the default value.
SELECT * FROM product;
```

| id  | name  | price |
|-----|-------|-------|
| 201 | phone | 0.00  |
| 202 | pad   | 0.00  |

## Generating Temporary Tables with WITH and Inserting Data into Another Table

Insert some data in a table to another table: Use the **WITH** subquery to obtain a temporary table **temp\_t**, and then insert all data in **temp\_t** to another table **reason\_t1**.

```
WITH temp_t AS (SELECT * FROM reason_t1) INSERT INTO reason_t1 SELECT * FROM temp_t ORDER BY 1;
```

## Using IGNORE to Ignore Primary Key Conflicts

```
DROP TABLE IF EXISTS users;
CREATE TABLE users (
id INT PRIMARY KEY,
username VARCHAR(50)
)
DISTRIBUTE BY HASH (id);
```

Insert two records whose primary keys are both **1**. A conflict occurs and the operation cannot be performed.

```
INSERT INTO users (id, username)
VALUES (1, 'john_doe'),
(2, 'jane_smith'),
(1, 'duplicate_user'); --Primary key conflict. Insertion failed.
```

```
error_code: DWS.S0010010
error_msg: Constraint Violation. STATE: 23505, message: ERROR: dn_6005_6006: duplicate key value violates
unique constraint "users_pkey"
Detail: Key (id)=(1) already exists.
```

Use **IGNORE** to ignore the conflict. The conflicting data is ignored and skipped.

```
INSERT IGNORE INTO users (id, username)
VALUES (1, 'john_doe'),
(2, 'jane_smith'),
(1, 'duplicate_user'); -- Conflicting data will be ignored.
SELECT * FROM users;
```

| id | username   |
|----|------------|
| 1  | john_doe   |
| 2  | jane_smith |

## Inserting Data with ON DUPLICATE KEY for Handling Primary Key/Unique Conflicts

```
DROP TABLE IF EXISTS user_logins;
CREATE TABLE user_logins
(user_id int primary key,
login_count int)
DISTRIBUTE BY HASH (user_id);
```

Insert two records. The primary key of the second record conflicts with that of the first record. The insertion fails.

```
INSERT INTO user_logins VALUES (1, 1);
INSERT INTO user_logins VALUES (1, 1); --Primary key conflict. Insertion failed.
SELECT * FROM user_logins;
```

| user_id | login_count |
|---------|-------------|
| 1       | 1           |

If a duplicate key exists, increment the **login\_count** field by 1 using the **ON DUPLICATE KEY** clause.

```
INSERT INTO user_logins VALUES (1, 1) ON DUPLICATE KEY UPDATE login_count = login_count + 1;
SELECT * FROM user_logins;
```

| user_id | login_count |
|---------|-------------|
| 1       | 2           |

## Inserting an Expression or Value into a Column

```
CREATE TABLE tt01 (id int,content varchar(50));
```

```
INSERT INTO tt01 values (1,'Jack say "hello"'); --Insert "Jack say'hello'" and add single quotation marks to escape.
```

```
INSERT INTO tt01 values (2,'Rose do 50%');
```

```
INSERT INTO tt01 values (3,'Lilei say "world"'); --Insert "Lilei say'world'" and add single quotation marks to escape.
```

```
INSERT INTO tt01 values (4,'Hanmei do 100%');
```

```
SELECT * FROM tt01;
```

| id | content           |
|----|-------------------|
| 3  | Lilei say 'world' |
| 2  | Rose do 50%       |
| 1  | Jack say 'hello'  |
| 4  | Hanmei do 100%    |

## Inserting Data into a Specified Partition of a Partitioned Table

Insert data into a specified partition of a partitioned table.

```
CREATE TABLE test_range_row(a int, d int)
DISTRIBUTE BY hash(a) PARTITION BY RANGE(d)
(
 PARTITION p1 values LESS THAN (60),
 PARTITION p2 values LESS THAN (75),
 PARTITION p3 values LESS THAN (90),
 PARTITION p4 VALUES LESS THAN (maxvalue)
);
INSERT OVERWRITE INTO test_range_row PARTITION(p1) VALUES(55,51);
INSERT OVERWRITE INTO test_range_row PARTITION(p3) VALUES(85,80);

DELETE FROM test_range_row PARTITION(p1);
```

Insert data into a partition of a partitioned table.

```
CREATE FOREIGN TABLE test_ft(c1 text, c2 text, c3 text, c4 text)
PARTITION BY (c1,c2,c3) AUTOMAPPED;
```

Insert data into the level-1 (p1\_1) partition.

```
INSERT OVERWRITE INTO test_ft PARTITION FOR(p1_1) VALUES(p1_1,2,3,4);
```

Insert data into the level-2 (p1\_2, p2\_2) partition.

```
INSERT OVERWRITE INTO test_ft PARTITION FOR(p1_2,p2_2) VALUES(p1_2,p2_2,3,4);
```

Insert data into the level-3 (p1\_3,p2\_3,p3\_3) partition.

```
INSERT OVERWRITE INTO test_ft PARTITION FOR(p1_3,p2_3,p3_3) VALUES(p1_3,p2_3,p3_3,4);
```

## Setting hive\_compat\_options to Avoid Interpreting Empty Strings as 0 in MySQL Compatibility Mode

In MySQL compatibility mode, DWS treats an empty string as 0 during data operations by default.

For example, importing data from Hive to DWS in finance can cause issues if an empty string is treated as 0. Since these values mean different things in finance, this mistake alters the data, reducing its accuracy and trustworthiness.

To ensure data integrity and consistency during data import, you can set the GUC parameter `hive_compat_options` to **empty\_str\_to\_null** for conversion logic. When an empty string is inserted, the system converts the empty string to NULL.

Create a MySQL-compatible database.

```
CREATE DATABASE mysqlpdb DBCOMPATIBILITY 'MYSQL';
```

Reconnect to the new database **mysqlpdb**, run the following statements, and insert an empty string.

```
CREATE TABLE test1 (a int, b int);
INSERT INTO test1 VALUES (1, "");
```

Query the data. The empty string is set to 0.

```
SELECT * FROM test1;
```

```
mysqlpdb=> SELECT * FROM test1;
a | b
---+---
1 | 0
(1 row)
```

Set the GUC parameter **hive\_compat\_options** to **empty\_str\_to\_null**.

```
ALTER DATABASE mysqlpdb SET hive_compat_options TO empty_str_to_null;
```

Insert data again.

```
INSERT INTO test1 VALUES (2, "");
```

Query the data. The empty string is automatically converted to NULL.

```
SELECT * FROM test1;
```

```
mysqlpdb=> SELECT * FROM test1;
a | b
---+---
1 | 0
2 |
(2 rows)
```

## Optimization

- VALUES

When you insert data in batches using the **INSERT** statement, you are advised to combine multiple records into one statement to insert data, improving data loading performance. Example: **INSERT INTO sections VALUES (30, 'Administration', 31, 1900), (40, 'Development', 35, 2000), (50, 'Development', 60, 2001);**

### 21.14.9.2 UPSERT

## Function

**UPSERT** inserts rows into a table. When a primary key or unique constraint conflict occurs, it can choose to update the conflicting data or ignore the conflict.

---

#### NOTICE

The **UPSERT** syntax is supported only in 8.1.1 and later.

---

## Precautions

---

#### WARNING

- Do not concurrently update the same column-store table using the **UPDATE** and **UPSERT** statements.
  - For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Developer Guide*.
- 
- Permission requirements: Only users with the **INSERT** or **UPDATE** permission on a table can run the **UPSERT** statement to insert data to or update data in the table.

- Index requirements: The **UPSERT** statement of updating data upon conflict can be executed only when the target table contains a primary key or unique index. The **UPSERT** statement of updating data upon conflict cannot be executed if no unique indexes are available. You can execute the statement only after the indexes are rebuilt.
- Other requirements:
  - The **WITH** clause cannot be used at the same time.
  - **INSERT OVERWRITE** cannot be used at the same time.
  - The **UPDATE** clause and its **WHERE** clause do not support subqueries.
  - **VALUES(colname)** in the **UPDATE** clause does not support outer nested functions. That is, the usage similar to **sqrt(VALUES(colname))** is not supported. To support this function, use the **EXCLUDED.colname** syntax.
  - **INSERT INTO ON CONFLICT(...) DO UPDATE** must contain **conflict\_target**. That is, a column or constraint name must be specified.
  - The distribution column cannot be updated. (Exception: Update is allowed if the distribution key is the same as the updated value.)

```
CREATE TABLE t1(dist_key int PRIMARY KEY, a int, b int);
INSERT INTO t1 VALUES(1,2,3) ON CONFLICT(dist_key) DO UPDATE SET dist_key =
EXCLUDED.dist_key, a = EXCLUDED.a + 1;
INSERT INTO t1 VALUES(1,2,3) ON CONFLICT(dist_key) DO UPDATE SET dist_key = dist_key, a =
EXCLUDED.a + 1;
```
  - The **UPSERT** statement cannot be executed on the target table that contains a trigger (with the **INSERT** or **UPDATE** trigger event).
  - The **UPSERT** statement is not supported for updatable views.
  - The **UPDATE** clause, the **WHERE** clause of **UPDATE**, and the index condition expression should not contain **functions that cannot be pushed down**.
  - Unique indexes cannot be deferred.
  - When performing the update operation of **UPSERT** using **INSERT INTO SELECT**, pay attention to the query result sequence of **SELECT**. In a distributed environment, if the **ORDER BY** statement is not used, the sequence of returned results may be different each time the same **SELECT** statement is executed. As a result, the execution result of the **UPSERT** statement does not meet the expectation.
  - Multiple updates are not supported. When conflicting data groups exist, you will see an error like "INSERT ON CONFLICT DO UPDATE command cannot affect row a second time." This does not happen if the query uses a PGXC plan. For details, see [FAQs](#).
- Impact on performance:
  - When **UPSERT** is executed on column-store tables, enable DELTA tables to avoid small CUs from being generated. A large number of small CUs may cause tables to bloat or lead to poor query performance.
  - **UPSERT**, **UPDATE**, and **DELETE** operations cannot be concurrently performed because they need to wait for the CU lock. This problem cannot be solved even if the DELTA table is enabled. To execute **UPSERT**, **UPDATE**, and **DELETE** operations concurrently on column-store tables, use HStore tables.
- Deadlock: A distributed deadlock may occur, resulting in query hanging. When many **UPSERT** commands run together in a transaction or batch via JDBC

with **setAutoCommit(false)**, deadlocks can happen if several tasks try to update the same row simultaneously. This occurs because different threads on various nodes might update rows in varying orders. To solve this issue, you can:

- a. Decrease the value of the GUC parameter **lockwait\_timeout** (default value: 20 minutes). A distributed deadlock error will be reported after waiting for *the value of lockwait\_timeout*. You can decrease the value of this parameter to reduce the service waiting time caused by a deadlock.
- b. Only import data with the same primary key through one database connection. You can run **UPSERT** statements at the same time.
- c. Ensure that only one UPSERT statement is executed in each transaction. In this way, **UPSERT** statements can be executed concurrently.
- d. Run all **UPSERT** operations one at a time in a single thread; avoid running them simultaneously.

Method 1 reduces waiting time but does not fix deadlocks. When using the **UPSERT** statement in services, lower this parameter's value. Methods 2, 3, and 4 resolve deadlocks, with method 2 being preferred due to its superior performance.

## Syntax

For details, see [Syntax](#) of **INSERT**. The following table describes the syntax of **UPSERT**.

The first syntax does not specify an index. The system checks for conflicts on all primary keys or unique indexes. If a conflict exists, the system ignores or updates the corresponding data.

The second syntax is to specify an index. The primary key or unique index is inferred from the column name, the expression that contains column names, or the constraint name specified in the **ON CONFLICT** clause.

- Scenario 1: If inserting data causes a conflict, the system updates the current data with the new information.
  - Conflict update without specifying an index:  
`INSERT INTO ON DUPLICATE KEY UPDATE`
  - Conflict update with an index specified:  
`INSERT INTO ON CONFLICT(...) DO UPDATE SET`  
`INSERT INTO ON CONFLICT ON CONSTRAINT con_name DO UPDATE SET`
- Scenario 2: If a data insertion causes a conflict, the system skips the operation.
  - Conflict ignorance without specifying an index:  
`INSERT IGNORE`  
`INSERT INTO ON CONFLICT DO NOTHING`
  - Conflict ignorance with an index specified:  
`INSERT INTO ON CONFLICT(...) DO NOTHING`  
`INSERT INTO ON CONFLICT ON CONSTRAINT con_name DO NOTHING`

Table 21-291 UPSERT parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range or Example |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| ON CONFLICT (...) | <p>The system determines the primary key or unique index by analyzing the given column or constraint names for a specific index's syntax. You can specify a single column name or multiple column names by using an expression, for example, <b>(column1, column2, column3)</b>.</p> <p><b>collation</b> and <b>opclass</b> can be specified when you create an index. Therefore, you can also specify them after the column name for index inference.</p> <p><b>COLLATE collation</b> specifies the collation of a column, and <b>opclass</b> specifies the name of the operator class. For details, see <a href="#">CREATE INDEX</a>.</p> <p>When inferring the unique index from an expression that includes multiple column names, the system checks whether there is a unique index that exactly contains all the column names specified by <b>conflict_target</b>.</p> <ul style="list-style-type: none"><li>• If <b>collation</b> and <b>opclass</b> are not specified, a match is considered found as long as a column has the same name as the specified single column or multiple columns have the same names as those specified by the column expression (regardless of the values of <b>collation</b> and <b>opclass</b> specified for the index column).</li><li>• If <b>collation</b> and <b>opclass</b> are specified, their values must also match the <b>collation</b> and <b>opclass</b> of the index.</li></ul> | -                      |
| UPDATE clause     | <p>The <b>UPDATE</b> clause can use <b>VALUES(colname)</b> or <b>EXCLUDED.colname</b> to reference inserted data. <b>EXCLUDED</b> indicates the data row that should be excluded due to conflict. For details about the syntax example, see <a href="#">Examples</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | -                      |

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                        | Value Range or Example |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>WHERE</b> clause | <ul style="list-style-type: none"><li>The <b>WHERE</b> clause is used to determine whether a specified condition is met when data conflict occurs. If yes, update the conflicting data. Otherwise, ignore the conflict.</li><li>Only syntax 2 of <b>Update Data Upon Conflict</b> can specify the <b>WHERE</b> clause, that is, <b>INSERT INTO ON CONFLICT(...) DO UPDATE SET WHERE</b>.</li></ul> | -                      |

## Examples

Create table **reason\_t2** and insert data into it.

```
DROP TABLE IF EXISTS reason_t2;
CREATE TABLE reason_t2
(
 a int primary key,
 b int,
 c int
);

INSERT INTO reason_t2 VALUES (1, 2, 3);
SELECT * FROM reason_t2 ORDER BY 1;
a | b | c
---+---+---
1 | 2 | 3
(1 rows)
```

Insert two data records into the table **reason\_t2**. One data record conflicts and the other does not. Conflicting data is ignored, and non-conflicting data is inserted.

```
INSERT INTO reason_t2 VALUES (1, 4, 5),(2, 6, 7) ON CONFLICT(a) DO NOTHING;
SELECT * FROM reason_t2 ORDER BY 1;
a | b | c
---+---+---
1 | 2 | 3
2 | 6 | 7
(2 rows)
```

Insert two data records into the table **reason\_t2**. One data record conflicts and the other does not. Update conflicting information and add new data where there is no conflict. **EXCLUDED.b** and **EXCLUDED.c** refer to columns **b** and **c** for the inserted values, which are 4 and 5 in this case.

```
INSERT INTO reason_t2 VALUES (1, 4, 5),(3, 8, 9) ON CONFLICT(a) DO UPDATE SET b = EXCLUDED.b, c = EXCLUDED.c;
SELECT * FROM reason_t2 ORDER BY 1;
a | b | c
---+---+---
1 | 4 | 5
2 | 6 | 7
3 | 8 | 9
(3 rows)
```

Filter the updated rows.

```
INSERT INTO reason_t2 VALUES (2, 7, 8) ON CONFLICT (a) DO UPDATE SET b = excluded.b, c = excluded.c
WHERE reason_t2.c = 7;
SELECT * FROM reason_t2 ORDER BY 1;
a | b | c
---+---+---
1 | 4 | 5
2 | 7 | 8
3 | 8 | 9
(3 rows)
```

Insert data into the table **reason\_t**. Update the conflicting data and adjust the mapping. That is, update column c to column b and column b to column c.

```
INSERT INTO reason_t2 VALUES (1, 2, 3) ON CONFLICT (a) DO UPDATE SET b = excluded.c, c = excluded.b;
SELECT * FROM reason_t2 ORDER BY 1;
a | b | c
---+---+---
1 | 3 | 2
2 | 7 | 8
3 | 8 | 9
(3 rows)
```

## FAQs

Multiple updates are not supported. When conflicting data groups exist, you will see an error like "INSERT ON CONFLICT DO UPDATE command cannot affect row a second time." This does not happen if the query uses a PGXC plan. Below is an example.

```
CREATE TABLE t1(id int PRIMARY KEY, a int, b int);
SET explain_perf_mode=pretty;
-- Use the stream query plan:
EXPLAIN (COSTS OFF) INSERT INTO t1 VALUES(1,2,3),(1,5,6) ON CONFLICT(id) DO UPDATE SET a =
EXCLUDED.a + 1;
 QUERY PLAN

id | operation
---+-----
1 | -> Streaming (type: GATHER)
2 | -> Insert on t1
3 | -> Streaming(type: REDISTRIBUTE)
4 | -> Values Scan on "VALUES*"
Predicate Information (identified by plan id)

2 --Insert on t1
 Conflict Resolution: UPDATE
 Conflict Arbiter Indexes: t1_pkey
===== Query Summary =====

System available mem: 819200KB
Query Max mem: 819200KB
Query estimated mem: 3104KB
(18 rows)
INSERT INTO t1 VALUES(1,2,3),(1,5,6) ON CONFLICT(id) DO UPDATE SET a = EXCLUDED.a + 1;
ERROR: dn_xxxx: INSERT ON CONFLICT DO UPDATE command cannot affect row a second time
HINT: Ensure that no rows proposed for insertion within the same command have duplicate constrained
values.
-- Disable the stream plan and generate a PGXC plan:
set enable_stream_operator = off;
EXPLAIN (COSTS OFF) INSERT INTO t1 VALUES(1,2,3),(1,5,6) ON CONFLICT(id) DO UPDATE SET a =
EXCLUDED.a + 1;
 QUERY PLAN

id | operation
---+-----
1 | -> Insert on t1
2 | -> Values Scan on "VALUES*"
Predicate Information (identified by plan id)
```

```

1 --Insert on t1
 Conflict Resolution: UPDATE
 Conflict Arbiter Indexes: t1_pkey
 Node expr: id
(11 rows)
INSERT INTO t1 VALUES(1,2,3),(1,5,6) ON CONFLICT(id) DO UPDATE SET a = EXCLUDED.a + 1;
INSERT 0 2
```

## 21.14.10 UPDATE

### Function

**UPDATE** updates data in a table. **UPDATE** changes the values of the specified columns in all rows that satisfy the condition. The **WHERE** clause clarifies conditions. The columns to be modified need be mentioned in the **SET** clause; columns not explicitly modified retain their previous values.

### Precautions

- For details about the UPDATE operation, see "UPDATE and DELETE Operations" in the *Data Warehouse Service (DWS) Developer Guide*.
- Permission requirements: To modify a table, you must have the UPDATE permission on the table and the SELECT permission on any table involved in the expression or condition.
- The distribution column of a table cannot be modified.
- You are not advised to create a table that needs to be frequently updated as a replication table.
- Constraints on column-store tables:
  - Column-store tables do not support the **RETURNING** clause.
  - Column-store tables do not support non-deterministic update. If you update data in one row with multiple rows of data in a column-store table, an error is reported.
  - Memory space that records update operations in column-store tables is not reclaimed. You need to clean it by executing **VACUUM FULL table\_name**.
  - Column-store tables support lightweight **UPDATE** operations, which only rewrite the updated columns to reduce space usage. To enable column-store lightweight **UPDATE**, configure **enable\_light\_colupdate**. It is disabled by default.
  - Column-store lightweight **UPDATE** is unavailable and automatically changes to the regular **UPDATE** operation in the following scenarios: updating an index column, updating a primary key column, updating a partition column, updating a PCK column, and online scaling.
  - There is a low probability that an error is reported when column-store lightweight **UPDATE** and backend column-store **AUTOVACUUM** coexist. To avoid such an issue, you can run **ALTER TABLE** to set the table-level parameter **enable\_column\_autovacuum\_garbage** to **off** (**off** means that the backend column-store **AUTOVACUUM** of tables is disabled).

### Syntax

```
UPDATE [/*+ plan_hint */] [ONLY] table_name [*] [[AS] alias]
[PARTITION (partition_name) | PARTITION FOR (partition_key_value [, ...])]
```

```
SET {column_name = { expression | DEFAULT }
| (column_name [, ...]) = { ({ expression | DEFAULT } [, ...]) |sub_query } }[, ...]
[FROM from_list] [WHERE condition]
[RETURNING {*
| {output_expression [[AS] output_name]} [, ...] }];
```

where sub\_query can be:

```
SELECT [ALL | DISTINCT [ON (expression [, ...])]]
{ * | {expression [[AS] output_name]} [, ...] }
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY grouping_element [, ...]]
[HAVING condition [, ...]]
```

## Parameter Description

Table 21-292 UPDATE parameters

| Parameter                  | Description                                                                                                                                                                                                                                                                                         | Example                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>plan_hint</b><br>clause | Following the keyword in the <b>/#+ */</b> format, hints are used to optimize the plan generated by a specified statement block. For details, see "DWS Performance Tuning" > "SQL Tuning" > "Hint-based Tuning" in <i>Data Warehouse Service (DWS) Developer Guide</i> .                            | -                                                                                                                                                             |
| table_name                 | Specifies the name (optionally schema-qualified) of the table to be updated.                                                                                                                                                                                                                        | <b>test.table1</b><br>( <b>test</b> is the schema name).                                                                                                      |
| [AS] alias                 | Specifies a short alias for the table for easy reference. Its value is a string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                     | Update the <b>employees</b> table with alias <b>e</b> :<br>UPDATE employees<br>AS e SET e.salary =<br>e.salary * 1.1 WHERE<br>e.department =<br>'technology'; |
| partition_name             | Specifies the partition name. If this parameter is specified, the data corresponding to the partition name will be updated. It is available for range partitioned tables, list partitioned tables, and other named partitioned tables. Only clusters of version 8.2.1 or later support this option. | Update data in the partition <b>p1</b> :<br>UPDATE<br>test_range_row<br>PARTITION(p1) SET<br>d = 41;                                                          |
| partition_key_value        | Specifies the partition key value. If this parameter is specified, the data corresponding to the partition key value will be updated<br><br>The value specified by <b>PARTITION FOR (partition_key_value [, ...])</b> can uniquely identify a partition.                                            | Update the value of <b>b</b> to <b>20</b> for the partition with key 41:<br>UPDATE<br>test_range_row<br>PARTITION FOR (41)<br>SET b = 20;                     |

| Parameter   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Example                                                                                                                                                                                 |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| column_name | <p>Renames a column.</p> <p>You can refer to this column by specifying the table name and column name of the target table. Example:<br/><code>UPDATE foo SET foo.col_name = 'GaussDB';</code></p> <p>You can refer to this column by specifying the target table alias and the column name. Example:<br/><code>UPDATE foo AS f SET f.col_name = 'GaussDB';</code></p>                                                                                                | -                                                                                                                                                                                       |
| expression  | An expression or value to assign to the column.                                                                                                                                                                                                                                                                                                                                                                                                                      | <p>Discount the product price by 20%:</p> <pre>UPDATE products SET price = price * 0.8 WHERE product_id = 101;</pre>                                                                    |
| DEFAULT     | Sets the column to its default value. The value is <b>NULL</b> if no specified default value has been assigned to it.                                                                                                                                                                                                                                                                                                                                                | <p>Reset the status and login times of inactive users:</p> <pre>UPDATE users SET status = DEFAULT, login_count = DEFAULT WHERE last_login &lt; CURRENT_DATE - INTERVAL '30 days';</pre> |
| sub_query   | <p>Specifies the subquery, which is used to update the target table based on the query results of other tables in the same database.</p> <p>For details about clauses in the <b>SELECT</b> statement, see <a href="#">SELECT</a>.</p>                                                                                                                                                                                                                                | <p>Update the average salary of a department using a subquery.</p> <pre>UPDATE departments d SET avg_salary = ( SELECT AVG(salary) FROM employees e WHERE e.dept_id = d.dept_id);</pre> |
| from_list   | <p>Specifies a table expression, that allows the columns from other tables to appear in the WHERE condition and update the target table. This is similar to the list of tables that can be specified in the <b>FROM</b> clause of a <b>SELECT</b> statement.</p> <p><b>NOTICE</b></p> <p>Note that the target table must not appear in the <b>from_list</b>, unless you intend a self-join (in which case it must appear with an alias in the <b>from_list</b>).</p> | <p><b>Example: Use the FROM from_list Clause to Preferentially Process Orders of Customers with High VIP Levels</b></p>                                                                 |

| Parameter         | Description                                                                                                                                                                                                                           | Example                                                                                                                                                                                                                                                                                  |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| condition         | Specifies an expression that follows WHERE and returns a result of the boolean type. Only rows for which this expression returns <b>true</b> are updated.                                                                             | Update the values of the students whose math scores are lower than 80:<br>UPDATE<br>student_scores SET<br>math_score =<br>math_score + 5,<br>update_time =<br>NOW() WHERE<br>math_score < 80;                                                                                            |
| output_expression | Specifies an expression to be computed and returned by the <b>UPDATE</b> command after each row is updated.<br><br>Value range: any table and table columns listed in FROM. The asterisk (*) indicates that all columns are returned. | Update and return the stock information before and after the update:<br>UPDATE inventory<br>SET stock = stock -<br>10 WHERE category<br>= 'Electronics'<br>RETURNING<br>item_id AS "Product<br>ID", name AS<br>"Product name",<br>stock AS "New<br>stock", stock + 10<br>AS "Old stock"; |
| output_name       | Specifies the name of the column returned by RETURNING to optimize the output. Its value is a string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                  | -                                                                                                                                                                                                                                                                                        |

## Examples: Common UPDATE Scenarios

Create a sample table and insert data into it.

```
DROP TABLE IF EXISTS products;
CREATE TABLE products (
 product_id INT PRIMARY KEY, --Product ID
 name VARCHAR(100), --Product name
 price DECIMAL(10,2), --Product price
 stock INT, --Product stock
 last_updated TIMESTAMP -Data update time
);

INSERT INTO products VALUES
(101, 'Phone', 2999.00, 50, NULL),
(102, 'PC', 5999.00, 30, NULL),
(103, 'PAD', 1999.00, 20, NULL);
```

Increase the price of all products by 20% (using a statement without **WHERE** to update the values of all records).

```
UPDATE products SET price = price * 1.2 , last_updated = NOW();
SELECT * FROM products ORDER BY 1;
```

| product_id | name  | price   | stock | last_updated               |
|------------|-------|---------|-------|----------------------------|
| 101        | Phone | 3598.80 | 50    | 2025-05-27 21:44:13.759399 |
| 102        | PC    | 7198.80 | 30    | 2025-05-27 21:44:13.759399 |
| 103        | PAD   | 2398.80 | 20    | 2025-05-27 21:44:13.759399 |

Increase the price of the PAD by 500 (using a statement with **WHERE** to update the specified data).

```
UPDATE products SET price = price + 500 , last_updated = NOW()
WHERE name = 'PAD';
SELECT * FROM products ORDER BY 1;
```

| product_id | name  | price   | stock | last_updated               |
|------------|-------|---------|-------|----------------------------|
| 101        | Phone | 3598.80 | 50    | 2025-05-27 21:44:13.759399 |
| 102        | PC    | 7198.80 | 30    | 2025-05-27 21:44:13.759399 |
| 103        | PAD   | 2898.80 | 20    | 2025-05-27 21:47:20.690807 |

Discount the price of products whose stock is greater than 40 by 20% (using a statement with **WHERE** to update data in a specified range).

```
UPDATE products SET price = price * 0.8 , last_updated = NOW()
WHERE stock > 40;
SELECT * FROM products ORDER BY 1;
```

| product_id | name  | price   | stock | last_updated               |
|------------|-------|---------|-------|----------------------------|
| 101        | Phone | 2879.04 | 50    | 2025-05-27 21:53:31.996656 |
| 102        | PC    | 7198.80 | 30    | 2025-05-27 21:44:13.759399 |
| 103        | PAD   | 2898.80 | 20    | 2025-05-27 21:47:20.690807 |

Adjust the price and stock of the PC (Specifying multiple values in **SET**)

```
UPDATE products SET price = price - 1000 , stock = stock - 10, last_updated = NOW()
WHERE name = 'PC';
SELECT * FROM products ORDER BY 1;
```

| product_id | name  | price   | stock | last_updated               |
|------------|-------|---------|-------|----------------------------|
| 101        | Phone | 2879.04 | 50    | 2025-05-27 21:53:31.996656 |
| 102        | PC    | 6198.80 | 20    | 2025-05-27 22:00:07.851013 |
| 103        | PAD   | 2898.80 | 20    | 2025-05-27 21:47:20.690807 |

## Example: Update a Specified Partition of a Partitioned Table

Create a sample table and import data into it.

```
DROP TABLE IF EXISTS test_range_row;
CREATE TABLE test_range_row(a int, b int,d int)
DISTRIBUTE BY hash(a) PARTITION BY RANGE(d)
(
 PARTITION p1 values LESS THAN (60),
 PARTITION p2 values LESS THAN (75),
 PARTITION p3 values LESS THAN (90),
 PARTITION p4 VALUES LESS THAN (maxvalue)
);

INSERT INTO test_range_row PARTITION(p1) VALUES(55,20,51);
INSERT INTO test_range_row PARTITION(p1) VALUES(54,18,59);
INSERT INTO test_range_row PARTITION(p2) VALUES(15,18,63);
INSERT INTO test_range_row PARTITION(p3) VALUES(12,21,80);
INSERT INTO test_range_row PARTITION(p3) VALUES(83,21,85);
INSERT INTO test_range_row PARTITION(p4) VALUES(36,21,97);

SELECT * FROM test_range_row ORDER BY d;
```

| a  | b  | d  |
|----|----|----|
| 55 | 20 | 51 |
| 54 | 18 | 59 |
| 15 | 18 | 63 |
| 12 | 21 | 80 |
| 83 | 21 | 85 |
| 36 | 21 | 97 |

Total Records: 6

Change the values of column **d** to **41** in partition **p1**.

```
UPDATE test_range_row PARTITION(p1) SET d = 41;
SELECT * FROM test_range_row ORDER BY d;
```

| a  | b  | d  |
|----|----|----|
| 54 | 18 | 41 |
| 55 | 20 | 41 |
| 15 | 18 | 63 |
| 12 | 21 | 80 |
| 83 | 21 | 85 |
| 36 | 21 | 97 |

Total Records: 6

According to the preceding result, the partition is **p1**, where the values of column **d** are less than **60**. The values of column **d** in partition **p1** are changed to **41**.

Update the values of column **b** to **20** in the partition where the partition key value is 41.

```
UPDATE test_range_row PARTITION FOR (41) SET b = 20;
SELECT * FROM test_range_row ORDER BY d;
```

| a  | b  | d  |
|----|----|----|
| 54 | 20 | 41 |
| 55 | 20 | 41 |
| 15 | 18 | 63 |
| 12 | 21 | 80 |
| 83 | 21 | 85 |
| 36 | 21 | 97 |

Total Records: 6

## Example: Use the FROM from\_list Clause to Preferentially Process Orders of Customers with High VIP Levels

The target table needs to be updated. The orders table needs to be updated, but the **FROM** clause needs to be used to associate the **customer ID** field in the **customers** table to obtain customer VIP levels.

Create the customer information table and order table, which contain the following fields:

```
DROP TABLE IF EXISTS customers;
CREATE TABLE customers (--Customer information table to be created
 customer_id INT PRIMARY KEY, -- Customer ID
 name VARCHAR(100), --Customer name
 vip_level INT --VIP level
);
DROP TABLE IF EXISTS orders;
CREATE TABLE orders (--Order table to be created
 order_id INT PRIMARY KEY, --Order ID
 customer_id INT, --Customer ID
 amount DECIMAL(10,2), --Consumption amount
 status VARCHAR(20) --Order status
);
```

Insert test data and ensure the order status of customers is pending (It means that the orders of the three customers are not processed.)

```
INSERT INTO customers VALUES
(1,'Tom', 1)
(2,'Jack', 3),
(3,'Tony', 2);
INSERT INTO orders VALUES
(1001, 1, 500.00, 'pending'),
(1002, 2, 1200.00, 'pending'),
(1003, 3, 800.00, 'pending');
SELECT * FROM orders;
```

| order_id | customer_id | amount  | status  |
|----------|-------------|---------|---------|
| 1002     | 2           | 1200.00 | pending |
| 1001     | 1           | 500.00  | pending |
| 1003     | 3           | 800.00  | pending |

Total Records: 3

Orders of customers with high VIP levels need be prioritized when there are too many orders. **FROM from\_list** is used to associate the customer ID in the customer table to obtain the customer VIP level. In this example, orders of customers with VIP level 3 or higher need to be processed first.

```
UPDATE orders o
SET status = 'priority' --Set the order status to priority.
FROM customers c
WHERE o.customer_id = c.customer_id AND c.vip_level >= 3; --Obtain the customers whose VIP levels are
 higher than 3 from the customer table.
SELECT * FROM orders;
```

| order_id | customer_id | amount  | status   |
|----------|-------------|---------|----------|
| 1002     | 2           | 1200.00 | priority |
| 1001     | 1           | 500.00  | pending  |
| 1003     | 3           | 800.00  | pending  |

Total Records: 3

## Example: Use DEFAULT to Reset the Status of an Inactive User

Create a user table (with DEFAULT) and insert data.

```
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 user_id INT PRIMARY KEY, --User ID
 username VARCHAR(50), --Username
 login_count INT DEFAULT 0, -- Number of login times. The default value is 0.
 last_login TIMESTAMP, --Last login time
 status VARCHAR(20) DEFAULT 'active'; --User status. The default value is active.
)

INSERT INTO users (user_id, username, login_count, last_login) VALUES
(1, 'user1', 5, '2023-06-01 10:00:00'),
(2, 'user2', 3, '2023-06-15 14:30:00');
SELECT * FROM users;
```

| user_id | username | login_count | last_login          | status |
|---------|----------|-------------|---------------------|--------|
| 2       | user2    | 3           | 2023-06-15 14:30:00 | active |
| 1       | user1    | 5           | 2023-06-01 10:00:00 | active |

Total Records: 2

Reset the status and login times of inactive users:

```
UPDATE users SET
status = DEFAULT, -- Reset the status to active
login_count = DEFAULT -- Reset the login times to 0
WHERE last_login < CURRENT_DATE - INTERVAL '30 days';
SELECT * FROM users;
```

| user_id | username | login_count | last_login          | status |
|---------|----------|-------------|---------------------|--------|
| 1       | user1    | 0           | 2023-06-01 10:00:00 | active |
| 2       | user2    | 0           | 2023-06-15 14:30:00 | active |

## 21.14.11 VALUES

### Function

**VALUES** computes a row or a set of rows based on given values. It is most commonly used to generate a constant table within a large command.

### Precautions

- **VALUES** lists with large numbers of rows should be avoided, as you might encounter out-of-memory failures or poor performance. **VALUES** appearing within **INSERT** is a special case, because the desired column types are known from the **INSERT**'s target table, and need not be inferred by scanning the **VALUES** list. In this case, **VALUE** can handle larger lists than are practical in other contexts.
- If more than one row is specified, all the rows must have the same number of elements.

### Syntax

```
VALUES {(expression [, ...])} [, ...]
[ORDER BY { sort_expression [ASC | DESC | USING operator] } [, ...]]
[{ [LIMIT { count | ALL }] [OFFSET start [ROW | ROWS]] } | { LIMIT start, { count | ALL } }]
[FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY];
```

### Parameter Description

Table 21-293 VALUES parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                    | Value Range |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| expression      | Specifies a constant or expression to compute and insert at the indicated place in the resulting table or set of rows.<br><br>In a <b>VALUES</b> list appearing at the top level of an <b>INSERT</b> , an expression can be replaced by <b>DEFAULT</b> to indicate that the destination column's default value should be inserted. <b>DEFAULT</b> cannot be used when <b>VALUES</b> appears in other contexts. | -           |
| sort_expression | Specifies an expression or integer constant indicating how to sort the result rows.                                                                                                                                                                                                                                                                                                                            | -           |
| ASC             | Indicates ascending sort order.                                                                                                                                                                                                                                                                                                                                                                                | -           |
| DESC            | Indicates descending sort order.                                                                                                                                                                                                                                                                                                                                                                               | -           |
| operator        | Specifies a sorting operator.                                                                                                                                                                                                                                                                                                                                                                                  | -           |

| Parameter                                               | Description                                                                                                        | Value Range                     |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|---------------------------------|
| count                                                   | Specifies the maximum number of rows to return.                                                                    | -                               |
| start                                                   | Specifies the number of rows to skip before starting to return rows.                                               | -                               |
| FETCH { FIRST   NEXT } [ count ]<br>{ ROW   ROWS } ONLY | The <b>FETCH</b> clause restricts the total number of rows starting from the first row of the return query result. | The default value is <b>1</b> . |

## Inserting One or More Data Records

Create the **reason\_t1** table.

```
DROP TABLE IF EXISTS reason_t1;
CREATE TABLE reason_t1
(
 TABLE_SK INTEGER ,
 TABLE_ID VARCHAR(20),
 TABLE_NA VARCHAR(20)
);
```

Insert one data record to the table.

```
INSERT INTO reason_t1(TABLE_SK, TABLE_ID, TABLE_NA) VALUES (1, 'S01', 'StudentA');
```

Insert one data record into the table. This command is equivalent to the last one.

```
INSERT INTO reason_t1 VALUES (1, 'S01', 'StudentA');
```

Insert records whose **TABLE\_SK** is less than **1** into the table.

```
INSERT INTO reason_t1 SELECT * FROM reason_t1 WHERE TABLE_SK < 1;
```

Insert records into the table.

```
INSERT INTO reason_t1 VALUES (1, 'S01', 'StudentA'),(2, 'T01', 'TeacherA'),(3, 'T02', 'TeacherB');
SELECT * FROM reason_t1 ORDER BY 1;
```

| table_sk | table_id | table_na |
|----------|----------|----------|
| 1        | S01      | StudentA |
| 1        | S01      | StudentA |
| 1        | S01      | StudentA |
| 2        | T01      | TeacherA |
| 3        | T02      | TeacherB |

## 21.15 DCL Syntax

### 21.15.1 DCL Syntax Overview

Data control language (DCL) is used to set or modify database users or role rights.

#### Authorization

DWS provides a statement for granting rights to data objects and roles. For details, see [GRANT](#).

#### Revoking Rights

DWS provides a statement for revoking rights. For details, see [REVOKE](#).

#### Setting Default Rights

DWS allows users to set rights for objects that will be created. For details, see [ALTER DEFAULT PRIVILEGES](#).

### 21.15.2 ALTER DEFAULT PRIVILEGES

#### Function

**ALTER DEFAULT PRIVILEGES** allows you to set the permissions that will be used for objects to be created. It does not affect permissions assigned to existing objects.

A user can modify only the default permissions of objects created by the user or the role to which the user belongs. These permissions can be set globally (all objects created in the database) or for objects in a specified schema.

To view information about the default permissions of database users, query the system catalog **PG\_DEFAULT\_ACL**.

#### Precautions

- Only the permissions for tables (including views), sequences, functions, and types (including domains) can be altered.
- The VACUUM, DROP, and ALTER permissions on foreign tables cannot be granted to users.

#### Syntax

```
ALTER DEFAULT PRIVILEGES
[FOR { ROLE | USER } target_role [, ...]]
[IN SCHEMA schema_name [, ...]]
abbreviated_grant_or_revoke;
```

The **abbreviated\_grant\_or\_revoke** clause is used to specify the objects for which permissions are granted or revoked. The options include:

- `grant_on_tables_clause`
- `grant_on_functions_clause`
- `grant_on_types_clause`
- `grant_on_sequences_clause`
- `revoke_on_tables_clause`
- `revoke_on_functions_clause`
- `revoke_on_types_clause`
- `revoke_on_sequences_clause`

**grant\_on\_tables\_clause** grants permissions on tables.

```
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ANALYZE | ANALYSE
| VACUUM | ALTER | DROP }
[, ...] | ALL [PRIVILEGES] }
ON TABLES
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

**grant\_on\_functions\_clause** grants permissions on functions.

```
GRANT { { EXECUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON FUNCTIONS
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

**grant\_on\_types\_clause** grants permissions on types.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON TYPES
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

**grant\_on\_sequences\_clause** grants permissions on sequences.

```
GRANT { { USAGE | SELECT | UPDATE }
[, ...] | ALL [PRIVILEGES] }
ON SEQUENCES
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION]
```

**revoke\_on\_tables\_clause** revokes permissions on tables.

```
REVOKE [GRANT OPTION FOR]
{ { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ANALYZE | ANALYSE |
VACUUM | ALTER | DROP }
[, ...] | ALL [PRIVILEGES] }
ON TABLES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

**revoke\_on\_functions\_clause** revokes permissions on functions.

```
REVOKE [GRANT OPTION FOR]
{ { EXECUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON FUNCTIONS
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

**revoke\_on\_types\_clause** revokes permissions on types.

```
REVOKE [GRANT OPTION FOR]
{ USAGE | ALL [PRIVILEGES] }
ON TYPES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

**revoke\_on\_sequences\_clause** revokes permissions on sequences.

```
REVOKE [GRANT OPTION FOR]
{ { USAGE | SELECT | UPDATE }
[, ...] | ALL [PRIVILEGES] }
```

```
ON SEQUENCES
FROM { [GROUP] role_name | PUBLIC } [, ...]
[CASCADE | RESTRICT | CASCADE CONSTRAINTS]
```

## Parameter Description

Table 21-294 ALTER DEFAULT PRIVILEGES parameters

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FOR { ROLE   USER }<br>target_role<br>[, ...] | <p><b>target_role</b> following <b>FOR ROLE/USER</b> can be a role or user name that will create objects in the future. That is, the role or user name corresponding to the owner of the objects to be created in the future. If <b>FOR ROLE/USER</b> is omitted, the current role or user is assumed.</p> <p><b>target_role</b> must have the <b>CREATE</b> permissions for <b>schema_name</b>. You can use the <b>has_schema_privilege</b> function to check whether a role or user has the <b>CREATE</b> permission on a schema.</p> <pre>SELECT a.rolname, n.nspname FROM pg_authid<br/>as a, pg_namespace as n WHERE<br/>has_schema_privilege(a.oid, n.oid, 'CREATE');</pre> | <p>Name of an existing role or user.</p> <p>For example, grant the permission to user <b>jim</b> to access objects created by user <b>lily</b> in the future.</p> <pre>ALTER DEFAULT PRIVILEGES<br/>FOR ROLE lily IN SCHEMA<br/>lily GRANT SELECT ON<br/>tables TO jim;</pre> <p>or</p> <pre>ALTER DEFAULT PRIVILEGES<br/>FOR USER lily IN SCHEMA<br/>lily GRANT SELECT ON<br/>tables TO jim;</pre> |
| schema_name                                   | <p>Name of an existing schema.</p> <p>If a schema name is specified, the default permissions of all objects created in this schema will be modified. If <b>IN SCHEMA</b> is omitted, global permissions are modified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <p>Name of an existing schema.</p>                                                                                                                                                                                                                                                                                                                                                                  |
| role_name                                     | <p>Name of an existing role whose permissions are to be granted or revoked.</p> <p><b>NOTE</b></p> <p>If you want to delete a role that is granted with default permissions, you must revoke the default permissions or use <b>DROP OWNED BY</b> to delete the default permission records of the role.</p>                                                                                                                                                                                                                                                                                                                                                                        | <p>Name of an existing role.</p>                                                                                                                                                                                                                                                                                                                                                                    |

## Examples

- Grant the **SELECT** permission on all the tables (and views) in **tpcds** to every user.  

```
ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT SELECT ON TABLES TO PUBLIC;
```
- Grant the **INSERT** permission on all the tables in **tpcds** to user **jack**.  

```
ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds GRANT INSERT ON TABLES TO jack;
```

- Revoke the preceding permissions.  

```
ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE SELECT ON TABLES FROM PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA tpcds REVOKE INSERT ON TABLES FROM jack;
```
- Assume that there are two users **test1** and **test2**. If you require that user **test2** can query tables created by user **test1**, execute the following statements:
  - a. Grant the schema permission of user **test1** to **test2**.  

```
GRANT usage, create ON SCHEMA test1 TO test2;
```
  - b. Grant user **test2** the permission to query tables of user **test1**. **Note:** FOR USER can also be changed to FOR ROLE, but the effect is the same.  

```
ALTER DEFAULT PRIVILEGES FOR USER test1 IN SCHEMA test1 GRANT SELECT ON tables TO test2;
```
  - c. Create a table as user **test1**.  

```
SET ROLE test1 password '{password}';
CREATE TABLE test3(a int, b int);
```
  - d. Enable the **test2** user to perform the query.  

```
SET ROLE test2 password '{password}';
SELECT * FROM test1.test3;
a | b
---+---
(0 rows)
```

## 21.15.3 ANALYZE | ANALYSE

### Function

This syntax gathers statistics on table content within a database. These statistics include both table-level and column-level details. Table-level data is kept in **PG\_CLASS**, while column-level details are stored in **PG\_STATISTIC**. The query planner relies on this information to choose the best execution strategy.

Its key purposes are:

- Optimizing query performance: supplies data distribution insights to the query optimizer for generating efficient plans.
- Enhancing plan accuracy: helps the optimizer better estimate the cost of various query paths.
- Selecting indexes: assists the optimizer in deciding if and which indexes to use.

### Scenarios Requiring the ANALYZE Operation

- **Significant data changes**  
Significant data changes, such as importing, updating, or deleting large amounts of data, alter row counts and data characteristics, requiring updated table statistics.
- **Newly added data querying**  
Daily updates to a service table with fresh data may lead to inaccurate queries if statistics are not refreshed promptly. The following tables have the characteristics of this scenario:

- Service tables that grow over time.
- Service tables that have daily data updates.
- Tables with fresh data that needs to be processed and analyzed.

Typically, after importing data, users process and analyze it using filters on partitioned tables.

```
passtime > '2020-01-19 00:00:00' AND pastime < '2020-01-20 00:00:00'
```

Without running **ANALYZE** after importing new data, the optimizer finds that the **passtime** filter range exceeds the recorded statistical limits. This leads to an incorrect row estimate, showing only one tuple matches the condition where **passtime** falls between 2020-01-19 00:00:00 and 2020-01-20 00:00:00.

## Precautions

- If no parameters are specified, **ANALYZE** analyzes each table and partitioned table in the database. You can also specify **table\_name**, **column**, and **partition\_name** to limit the analysis to a specified table, column, or partitioned table.
- Users who can execute **ANALYZE** on a specific table include the owner of the table, owner of the database where the table is, users with the **ANALYZE** permission on the table, users who are granted the **gs\_role\_analyze\_any** role, and users with the **SYSADMIN** attribute.
- To collect statistics using percentage sampling, you must have the **ANALYZE** and **SELECT** permissions.
- If the **enable\_analyze\_partition** parameter is enabled and the table-level **incremental\_analyze** parameter is set for a partitioned table, the **ANALYZE** statement is executed on partitions lacking statistics or with data changes. The statistics of the partition main table are then generated by combining the partition statistics.
- Only cluster versions 8.1.1 and later support using anonymous blocks, transaction blocks, functions, or stored procedures to perform the **ANALYZE** operation on an unsharded table.
- However, for analyzing an entire database, the **ANALYZE** operation of each table is in different transactions. Therefore, the current version does not support the **ANALYZE** execution for the entire database in anonymous blocks, transaction blocks, functions, or stored procedures.
- Statistics updates of PG\_CLASS related columns cannot be rolled back.
- The **ANALYZE** statistics of global temporary tables in each session are independent. Each session has its own statistics.
- **ANALYZE** and **ANALYZE VERIFY** are used to check whether data files of common tables (row-store and column-store tables) in a database are damaged. Currently, this function does not support HDFS tables.
- Most **ANALYZE VERIFY** operations are used for abnormal scenario detection, and require a release version. Remote read is not triggered in the **ANALYZE VERIFY** scenario. Therefore, the remote read parameter does not take effect. If the system detects that the page is damaged due to an error in the key system table, the system reports an error and stops the detection.

**WARNING**

- If more than 10% of a table's records are added or modified at once, explicitly execute the **ANALYZE** operation.
- For more information about development and design specifications, see "DWS Development and Design Proposal" in the *Developer Guide*.

## Syntax

- Collect statistics information about a table.  

```
{ ANALYZE | ANALYZE } [{ VERBOSE | LIGHT | FORCE | PREDICATE }]
[table_name [(column_name [, ...])]] ;
```
- Collect statistics about a partition.  

```
{ ANALYZE | ANALYZE } [{ VERBOSE | LIGHT | FORCE }]
[table_name [(column_name [, ...])]]
PARTITION (partition_name) ;
```

  - Ordinary partitioned tables support the syntax for collecting statistics on a specific partition, but not the actual function of it. **ANALYZE** on a specified partition will cause a warning message.
  - Temporary sampling tables cannot be used to collect partition statistics.
  - Multi-column statistics and expression statistics on partitions are not supported.
- Collect statistics about a foreign table.  

```
{ ANALYZE | ANALYZE } [VERBOSE]
{ foreign_table_name | FOREIGN TABLES } ;
```
- Collect statistics about multiple columns.  

```
{ANALYZE | ANALYZE} [VERBOSE]
table_name ((column_1_name, column_2_name [, ...]));
```

  - To sample data in percentage, set **default\_statistics\_target** to a negative number.
  - The statistics about a maximum of 32 columns can be collected at a time.
  - You are not allowed to collect statistics about multiple columns in system catalogs, global temporary tables, or HDFS foreign tables.
- Check the data files in the current database.  

```
{ANALYZE | ANALYZE} VERIFY {FAST|COMPLETE};
```

  - All operations on the database are supported. Because many tables are involved, you are advised to save the result in redirection mode: **gsql -d database -p port -f "verify.sql"> verify\_warning.txt 2>&1**.
  - HDFS tables (internal and foreign tables), temporary tables, and unlog tables are not supported.
  - Only the NOTICE message is displayed for external tables. The detection of internal tables is included in the external tables that depend on them, but it is not shown externally.
  - This command can be used to process tolerant errors. The assert operation in a debug version may cause the core to fail to execute commands. Therefore, you are advised to perform this operation in a release version.
  - If a key system table is damaged during a full database operation, an error is reported and the operation stops.

- Check data files of tables and indexes.  
`{ANALYZE | ANALYSE} VERIFY {FAST|COMPLETE} table_name[index_name] [CASCADE];`
  - You can perform operations on common tables and index tables, but cannot perform **CASCADE** operations on index tables. The reason is that **CASCADE** is used to process all index tables of the primary table. When the index table is checked separately, **CASCADE** is not required.
  - HDFS tables (internal and foreign tables), temporary tables, and unlog tables are not supported.
  - When the primary table is checked, the internal tables of the primary table, such as the **toast** table and **cudesc** table, are also checked.
  - When the system displays a message indicating that the index table is damaged, you are advised to run the **reindex** command to recreate the index.
- Check the data files of the table partition.  
`{ANALYZE | ANALYSE} VERIFY {FAST|COMPLETE} table_name PARTITION {(partition_name)} [CASCADE];`
  - You can detect a single partition of a table, but cannot perform the **CASCADE** operation on index tables.
  - HDFS tables (internal and foreign tables), temporary tables, and unlog tables are not supported.

## Parameter Description

Table 21-295 ANALYZE | ANALYSE parameters

| Parameter | Description                                                                                                                                                                                                                                           | Value Range |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| VERBOSE   | After <b>VERBOSE</b> is enabled, <b>ANALYZE</b> sends progress information, indicating the table being processed. Statistics about the table are also printed.                                                                                        | -           |
| LIGHT     | In <b>LIGHT</b> mode, the system stores table statistics in memory instead of writing them to the system catalog. Executing this command locks the table at a certain level. Specify this option within parentheses, like <b>ANALYZE (LIGHT) t1</b> . | -           |
| FORCE     | In <b>FORCE</b> mode, you can override locks on table statistics and run <b>ANALYZE</b> . Add this option in parentheses like this: <b>ANALYZE (FORCE) t1</b> .                                                                                       | -           |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PREDICATE          | <p><b>PREDICATE</b> indicates that only the statistics of the currently identified predicate column are calculated. This parameter is supported only by clusters of version 9.1.0.100 or later. You can set the <b>analyze_predicate_column_threshold</b> parameter to determine whether the <b>ANALYZE</b> operation on predicate columns is supported. A value of <b>0</b> indicates that the <b>ANALYZE</b> operation is disabled. A value greater than <b>0</b> indicates that the <b>ANALYZE</b> operation is enabled only for tables whose number of columns is greater than or equal to this value.</p> <p>Use this option in parentheses, for example, <b>ANALYZE (PREDICATE) xxx</b>.</p> <p>Predicate information is collected in the query parsing phase. Dynamic sampling also supports predicate column sampling.</p> | -                                                                                                                                                                                          |
| table_name         | <p>Specifies the name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.</p> <p>Currently, you can use <b>ANALYZE</b> to collect statistics from row-store tables, column-store tables, HDFS tables, ORC- and CARBONDATA-formatted OBS foreign tables, and foreign tables for collaborative analysis.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   | The table name can contain a maximum of 63 characters, including letters, digits, underscores (_), dollar signs (\$), and number signs (#). It must start with a letter or underscore (_). |
| column_name        | Specifies the name of a specific column to analyze. All columns are analyzed by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Existing column name (format: <b>column_1_name, column_2_name, column_3_name....</b> )                                                                                                     |
| partition_name     | Analyzes the statistics of the partitioned table. Currently the partitioned table supports the syntax of analyzing a partitioned table, but does not execute this syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | A string, which must comply with the naming convention of the partition name.                                                                                                              |
| foreign_table_name | Specifies the name (possibly schema-qualified) of a specific table to analyze. The data of the table is stored in HDFS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | A string, which must comply with the naming convention of foreign tables.                                                                                                                  |

| Parameter      | Description                                                                     | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FOREIGN TABLES | Analyzes HDFS foreign tables stored in HDFS and accessible to the current user. | A string, which must comply with the naming rules of HDFS foreign tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| index_name     | Name of the index table to be analyzed, which may contain the schema name.      | A string, which must comply with the naming rules of index tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FAST COMPLETE  | Verifies row-store tables and column-store tables in different modes.           | <ul style="list-style-type: none"><li>• Row-store tables<ul style="list-style-type: none"><li>– In FAST mode, the CRC and page header of the row-store table are verified. If the verification fails, an alarm is generated.</li><li>– In COMPLETE mode, the pointer and tuple of the row-store table are parsed and verified.</li></ul></li><li>• Column-store tables<ul style="list-style-type: none"><li>– In FAST mode, the CRC and magic of the column-store table are verified. If the verification fails, an alarm is generated.</li><li>– In COMPLETE mode, CUs of column-store tables are parsed and verified.</li></ul></li></ul> |
| CASCADE        | In <b>CASCADE</b> mode, all indexes of the current table are checked.           | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Examples

- Do **ANALYZE** to update statistics in the **customer\_info** table:  
`ANALYZE customer_info;`
- Do **ANALYZE VERBOSE** to update statistics and display table information in the **customer\_info** table:  
`ANALYZE VERBOSE customer_info;`  
INFO: analyzing "cstore.pg\_delta\_3394584009"(cn\_5002 pid=53078)  
INFO: analyzing "public.customer\_info"(cn\_5002 pid=53078)  
INFO: analyzing "public.customer\_info" inheritance tree(cn\_5002 pid=53078)  
`ANALYZE`
- Update the statistics of the **name** and **email** columns in the **customer\_info** table.  
`ANALYZE customer_info (name, email);`
- Update the statistics of the **customer\_info** table in lightweight mode.  
`ANALYZE (LIGHT) customer_info;`
- Update the statistics of the **customer\_info** table in forcible mode, even if the table is locked.  
`ANALYZE (FORCE) customer_info;`
- Update only the statistics of predicate columns. Only the predicate columns collected so far are sampled. The statistics are used after the query service is stable.  
`ANALYZE (PREDICATE) customer_info;`  

You can use the `pg_stat_get_predicate_columns` function to query the predicate columns of a table. The table name in the following example is **customer\_info**. Replace it with the actual table name.

```
SELECT pr.attnum,pa.attname FROM
pg_catalog.pg_stat_get_predicate_columns('customer_info'::regclass) pr LEFT JOIN pg_attribute pa ON
pa.attrelid='customer_info'::regclass AND pa.attnum = pr.attnum;
```

## 21.15.4 DEALLOCATE

### Function

Deallocates a previously prepared statement. If a prepared statement is not explicitly deleted, it is deleted at the end of the session.

For details about prepared statements, see [PREPARE](#).

### Precautions

None

### Syntax

```
DEALLOCATE [PREPARE] { name | ALL };
```

## Parameter Description

Table 21-296 DEALLOCATE parameters

| Parameter | Description                                                                            | Value Range                                                               |
|-----------|----------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| PREPARE   | Creates a prepared statement. This keyword is optional and does not affect operations. | -                                                                         |
| name      | Specifies the name of the prepared statement to be deleted.                            | A string, which must comply with the naming rules of prepared statements. |
| ALL       | Deallocates all prepared statements.                                                   | A string, which must comply with the prepared statement format.           |

## Examples

None

## 21.15.5 DO

### Function

**DO** executes an anonymous code block.

A code block is a function body without parameters. Its return type is **void**. It is analyzed and executed at the same time.

### Precautions

- Before using a programming language, install it in the current database using **CREATE LANGUAGE**. If no language is specified, **plpgsql** is installed by default.
- To use an untrusted language, you must be a system administrator or have the USAGE permission for programming languages.

### Syntax

```
DO [LANGUAGE lang_name] code;
```

## Parameter Description

Table 21-297 DO parameters

| Parameter | Description                                          | Value Range                                                                               |
|-----------|------------------------------------------------------|-------------------------------------------------------------------------------------------|
| lang_name | Name of the programming language used to parse code. | Program language that complies with the specifications. The default language is PL/pgSQL. |
| code      | Programming language code that can be executed.      | A string.                                                                                 |

## Examples

Grant user **webuser** all the operation permissions on views in the **tpcds** schema:

```
DO $$DECLARE r record;
BEGIN
 FOR r IN SELECT c.relname,n.nspname FROM pg_class c,pg_namespace n
 WHERE c.relnamespace = n.oid AND n.nspname = 'tpcds' AND relkind IN ('r','v')
 LOOP
 EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident(r.table_name) || ' TO
webuser';
 END LOOP;
END$$;
```

## 21.15.6 EXECUTE

### Function

**EXECUTE** executes a prepared statement. Because a prepared statement exists only in the lifetime of a session, the prepared statement must be created by an earlier **PREPARE** statement in the current session.

### Precautions

If the **PREPARE** statement creating the prepared statement declares certain parameters, the parameter set transferred to the **EXECUTE** statement must be compatible. Otherwise, an error occurs.

### Syntax

```
EXECUTE name [(parameter [, ...])] ;
```

## Parameter Description

Table 21-298 EXECUTE parameters

| Parameter | Description                                                                                                                                                                      | Value Range                                                                                                   |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| name      | Specifies the name of the statement to be executed.                                                                                                                              | A string, which must comply with the naming rules of prepared statements.                                     |
| parameter | Specifies a parameter of the prepared statement. It must be an expression that generates a value compatible with the data type specified when the prepared statement is created. | A string, which is an expression of a value that is compatible with the data type of the specified parameter. |

## Examples

Create and run a prepared statement for the **INSERT** statement:

```
PREPARE insert_reason(integer,character(16),character(100)) AS INSERT INTO tpcds.reason_t1
VALUES($1,$2,$3);
EXECUTE insert_reason(52, 'AAAAAAADDDAAAAA', 'reason 52');
```

## 21.15.7 EXECUTE DIRECT

### Function

**EXECUTE DIRECT** executes an SQL statement on a specified node. Generally, the cluster automatically allocates an SQL statement to proper nodes. **EXECUTE DIRECT** is mainly used for database maintenance and testing.

### Precautions

- Only a system administrator can run the **EXECUTE DIRECT** statement.
- To ensure data consistency across nodes, only the **SELECT** statement can be used. Transaction statements, DDL, and DML cannot be used.
- When the AVG aggregation calculation is performed on the specified DN using such statements, the result set is returned in array, for example, {4,2}. The result of sum is 4, and that of count is 2.
- Do not run the **SELECT** statement on nodes where CNs reside because user table data is not stored there.
- **EXECUTE DIRECT** cannot be nested. If the inner SQL statement to be executed is also **EXECUTE DIRECT**, run only the bottom-layer **EXECUTE DIRECT** statement.

## Syntax

```
EXECUTE DIRECT ON (nodename [, ...]) query ;
```

## Parameter Description

**Table 21-299** EXECUTE DIRECT parameters

| Parameter | Description              | Value Range                                                   |
|-----------|--------------------------|---------------------------------------------------------------|
| nodename  | Node name                | A string that indicates the name of an existing node.         |
| query     | Statement to be executed | A string that indicates a SQL statement that can be executed. |

## Examples

Query records in table **tpcds.customer\_address** on the dn\_6001\_6002 node:

```
EXECUTE DIRECT ON(dn_6001_6002) 'select count(*) from tpcds.customer_address';
count

16922
(1 row)
```

## 21.15.8 GRANT

### Functions and Precautions

**GRANT** grants permissions to roles and users.

**GRANT** is used in the following scenarios:

### Granting System Permissions (SYSADMIN, CREATEDB, CREATEROLE, AUDITADMIN, and LOGIN) to Roles or Users

System permissions are also called user attributes, including **SYSADMIN**, **CREATEDB**, **CREATEROLE**, **AUDITADMIN**, and **LOGIN**.

**Table 21-300** System permissions

| System Permission | Description                                 | Can Be Granted or Revoked |
|-------------------|---------------------------------------------|---------------------------|
| <b>SYSADMIN</b>   | Allows you to view special system catalogs. | Yes                       |
| <b>CREATEDB</b>   | Allows you to creates databases.            | No                        |
| <b>CREATEROLE</b> | Allow you to create users and roles.        |                           |

| System Permission | Description                         | Can Be Granted or Revoked |
|-------------------|-------------------------------------|---------------------------|
| <b>AUDITADMIN</b> | Allows you to view audit logs.      |                           |
| <b>LOGIN</b>      | Allows you to connect to databases. |                           |

System permissions are generally specified using **CREATE ROLE** or **ALTER ROLE** syntax.

The **SYSADMIN** permission can be granted and revoked using **GRANT ALL PRIVILEGE** and **REVOKE ALL PRIVILEGE**, respectively.

System permissions cannot be inherited by a user from a role, and cannot be granted using **PUBLIC**.

## Granting Database Objects (Tables, Views, Specified Columns, Databases, Functions, and Schemas) to Roles or Users

### Precautions

- Do not perform **GRANT** on a table partition. Otherwise, an alarm will be generated.
- To rename an existing object, you must own the object and have the **CREATE** permission on the schema of the object.
- When you grant table or view rights to other users, you also need to grant the **USAGE** permission for the schema that the tables and views belong to. Without this permission, the users granted with the table or view rights can only see the object names, but cannot access them.
- **GRANT** grants specified database object permissions to one or more roles. These permissions are appended to those already granted, if any.
- The key word **PUBLIC** indicates that the permissions are to be granted to all roles, including those that might be created later. **PUBLIC** can be regarded as an implicitly defined group including all roles. Any particular role will have the sum of permissions granted directly to it using **GRANT**, permissions granted to any role it is presently a member of, and permissions granted to **PUBLIC**.
- If **WITH GRANT OPTION** is specified, the recipient of a permission can in turn grant it to others. This option cannot be granted to **PUBLIC**. Only DWS supports this operation.
- DWS grants the permissions for objects of certain types to **PUBLIC**. By default, permissions for tables, table columns, sequences, external data sources, external servers, schemas, and tablespace are not granted to **PUBLIC**. However, permissions for the following objects are granted to **PUBLIC**: **CONNECT** and **CREATE TEMP TABLE** permissions for databases, **EXECUTE** permission for functions, and **USAGE** permission for languages and data types (including domains). An object owner can revoke the default permissions granted to **PUBLIC** and grant permissions to other users as needed. For security purposes, you are advised to create an object and set permissions for

it in the same transaction so that other users do not have time windows to use the object. In addition, you can run the **ALTER DEFAULT PRIVILEGES** statement to modify the initial default permissions.

## Granting the Permissions of a Role or r User to Others

Grant a role's or user's permissions to one or more roles or users. In this case, every role or user can be regarded as a set of one or more database permissions.

- If **WITH ADMIN OPTION** is specified, the member can in turn grant permissions in the role to others, and revoke permissions in the role as well.
- If a role or user granted with certain permissions is changed or revoked, the permissions inherited from the role or user also change.
- A database administrator can grant permissions to and revoke them from any role or user.
- Roles having **CREATEROLE** permission can grant or revoke membership in any role that is not an administrator.

## Permissions

**Table 21-301** GRANT permissions

| Parameter         | Description                                                                                                                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SELECT            | Allows <b>SELECT</b> from any column, or the specific columns listed, of the specified table, view, or sequence.                                                                                                                                    |
| INSERT            | Allows <b>INSERT</b> of a new row into the specified table.                                                                                                                                                                                         |
| UPDATE            | Allows <b>UPDATE</b> of any column, or the specific columns listed, of the specified table. <b>SELECT ... FOR UPDATE</b> and <b>SELECT ... FOR SHARE</b> also require this permission on at least one column, in addition to the SELECT permission. |
| DELETE            | Allows <b>DELETE</b> of a row from the specified table.                                                                                                                                                                                             |
| TRUNCATE          | Allows <b>TRUNCATE</b> on the specified table.                                                                                                                                                                                                      |
| REFERENCES        | To create a foreign key constraint, it is necessary to have this permission on both the referencing and referenced columns.                                                                                                                         |
| TRIGGER           | To create a trigger, you must have the TRIGGER permission on the table or view.                                                                                                                                                                     |
| ANALYZE   ANALYSE | To perform the ANALYZE   ANALYSE operation on a table to collect statistics data, you must have the ANALYZE   ANALYSE permission on the table.                                                                                                      |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE           | <ul style="list-style-type: none"><li>For databases, allows new schemas to be created within the database.</li><li>For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have the <b>CREATE</b> permission on the schema of the object.</li><li>For sub-clusters, allows tables to be created.</li></ul>                                                                                                                                                      |
| CONNECT          | Allows the user to connect to the specified database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| TEMPORARY   TEMP | Allows temporary tables to be created when the specified database is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| EXECUTE          | Allows the use of the specified function and the use of any operators that are implemented on top of the function.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| USAGE            | <ul style="list-style-type: none"><li>Procedural languages: It allows the use of the specified language for the creation of functions in that language.</li><li>Schemas: It allows access to objects contained in the specified schema. Without this permission, it is still possible to see the object names.</li><li>Sequences: It allows the use of the nextval function.</li><li>Sub-clusters: It allows users who can access objects contained in the specified schema to access tables in a specified sub-cluster.</li></ul> |
| COMPUTE          | Allows users to perform elastic computing in a computing sub-cluster that they have the compute permission on.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ALTER            | Allows you to modify tables, schemas, or functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DROP             | Allows you to delete tables, schemas, or functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| VACUUM           | Allows <b>VACUUM</b> to be executed on tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ALL PRIVILEGES   | Grants all of the available permissions at once. Only system administrators have permission to run <b>GRANT ALL PRIVILEGES</b> .                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WITH GRANT OPTION | If <b>WITH GRANT OPTION</b> is specified, the recipient of a permission can in turn grant it to others. This option cannot be granted to <b>PUBLIC</b> . <ul style="list-style-type: none"><li>• <b>WITH GRANT OPTION</b> cannot be used with <b>NODE GROUP</b>.</li><li>• When using <b>WITH GRANT OPTION</b>, ensure that <b>grant_with_grant_option</b> is set for <b>security_enable_options</b>.</li></ul> |
| WITH ADMIN OPTION | Specifies whether permission transfer is allowed. If <b>WITH ADMIN OPTION</b> is specified, members of a role can grant membership of the role to others.                                                                                                                                                                                                                                                       |

## Syntax

- Grant the table or view access permission to a specified role or user. Do not perform **GRANT** on a table partition. Otherwise, an alarm will be generated.  
GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ANALYZE | ANALYSE | VACUUM | ALTER | DROP } [, ...]  
| ALL [ PRIVILEGES ] }  
ON { [ TABLE ] table\_name [, ...]  
| ALL TABLES IN SCHEMA schema\_name [, ...] }  
TO { [ GROUP ] role\_name | PUBLIC } [, ...]  
[ WITH GRANT OPTION ];

### CAUTION

Do not perform concurrent GRANT or REVOKE operations (including **ON TABLE** and **ON ALL TABLES IN SCHEMA**) on a given table or view, or do not perform both GRANT or REVOKE and DDL operations on a given table or view. Otherwise, an error similar to "tuple concurrently updated." is reported.

- Grant the column access permission to a specified role or user.  
GRANT { { SELECT | INSERT | UPDATE | REFERENCES } ( column\_name [, ...] ) } [, ...]  
| ALL [ PRIVILEGES ] ( column\_name [, ...] ) }  
ON [ TABLE ] table\_name [, ...]  
TO { [ GROUP ] role\_name | PUBLIC } [, ...]  
[ WITH GRANT OPTION ];
- Grant the schema access permission to a specified role or user.  
GRANT { { CREATE | USAGE | ALTER | DROP } [, ...] | ALL [ PRIVILEGES ] }  
ON SCHEMA schema\_name [, ...]  
TO { [ GROUP ] role\_name | PUBLIC } [, ...]  
[ WITH GRANT OPTION ];

### CAUTION

When you grant table or view rights to other users, you also need to grant the USAGE permission for the schema that the tables and views belong to. Without this permission, the users granted with the table or view rights can only see the object names, but cannot access them.

- Grant the database access permission to a specified role or user.

```
GRANT { { CREATE | CONNECT | TEMPORARY | TEMP } [, ...]
 | ALL [PRIVILEGES] }
ON DATABASE database_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant a role's permissions to other users or roles.

```
GRANT role_name [, ...]
TO role_name [, ...]
[WITH ADMIN OPTION];
```

- Grant all permissions to a specified role.

```
GRANT ALL { PRIVILEGES | PRIVILEGE }
TO role_name;
```

- Grant the domain access permission to a specified role or user.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON DOMAIN domain_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

#### NOTE

The current version does not support granting the domain access permission.

- Grant the external data source access permission to a specified role or user.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON FOREIGN DATA WRAPPER fdw_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the external server access permission to a specified role or user.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON FOREIGN SERVER server_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the function access permission to a specified role or user.

```
GRANT { { EXECUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
ON { FUNCTION {function_name ([{[argmode] [arg_name] arg_type } [, ...]) } [, ...]
 | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the procedural language access permission to a specified role or user.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON LANGUAGE lang_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

#### NOTE

The current version does not support granting the procedural language access permission.

- Grant the large object access permission to a specified role or user.

```
GRANT { { SELECT | UPDATE } [, ...] | ALL [PRIVILEGES] }
ON LARGE OBJECT loid [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

#### NOTE

The current version does not support granting the large object access permission.

- Grant the sequence access permission to a specified role or user.

```
GRANT { { SELECT | UPDATE | USAGE } [, ...] | ALL [PRIVILEGES] }
ON { SEQUENCE sequence_name [, ...]
 | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the sub-cluster access permission to a specified role or user. Common users cannot perform **GRANT** or **REVOKE** operations on node groups.

```
GRANT { CREATE | USAGE | COMPUTE | ALL [PRIVILEGES] }
ON NODE GROUP group_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

- Grant the type access permission to a specified role or user.

```
GRANT { USAGE | ALL [PRIVILEGES] }
ON TYPE type_name [, ...]
TO { [GROUP] role_name | PUBLIC } [, ...]
[WITH GRANT OPTION];
```

 **NOTE**

The current version does not support granting the type access permission.

## Parameter Description

Table 21-302 GRANT parameters

| Parameter     | Description                                                                                                                 | Value Range                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| role_name     | Specifies an existing user name. To obtain the value, see PG_USER.                                                          | A string, which must comply with the naming convention. Enter a maximum of 63 characters.                                                                                                                     |
| table_name    | Specifies an existing table name. To obtain the value, see PG_TABLES.                                                       | A string of no more than 63 characters, starting with a letter or underscore (_). The value can contain letters, digits, underscores (_), dollar signs (\$), and number signs (#).                            |
| column_name   | Specifies an existing column name. To obtain the value, run:<br><pre>SELECT * FROM<br/>PG_GET_TABLEDEF('table name');</pre> | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                      |
| schema_name   | Specifies an existing schema name. To obtain the value, see PG_NAMESPACE.                                                   | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                      |
| database_name | Specifies an existing database name. To obtain the value, PG_DATABASE.                                                      | A string that complies with the naming convention, which includes uppercase and lowercase letters, digits, underscores (_), and dollar signs (\$). However, it cannot begin with a digit or dollar sign (\$). |

| Parameter     | Description                                                                                                                      | Value Range                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| function_name | Specifies an existing function name. To obtain the value, PG_PROC.                                                               | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| sequence_name | Specifies a sequence schema name. To obtain the value, view PG_SEQUENCES (supported only by clusters of version 9.1.0 or later). | A string that contains only letters (both uppercase and lowercase), special characters #, \$, and digits.                |
| domain_name   | Specifies an existing domain type.                                                                                               | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| fdw_name      | Specifies an existing foreign data wrapper name.                                                                                 | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| lang_name     | Specifies an existing language name.                                                                                             | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| type_name     | Specifies an existing type name.                                                                                                 | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| group_name    | Specifies an existing sub-cluster name.                                                                                          | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| argmode       | Specifies the parameter mode of a function.                                                                                      | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| arg_name      | Specifies the parameter name of a function.                                                                                      | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |
| arg_type      | Specifies the parameter type of a function.                                                                                      | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |

| Parameter | Description                                                           | Value Range                                                                                                              |
|-----------|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| loid      | Specifies the identifier of the large object that contains this page. | A string, which must comply with the naming convention. For details, see <a href="#">Identifier Naming Conventions</a> . |

## Examples

- **Grant system permissions to a user or role.**
  - Grant all available permissions of user **sysadmin** to user **joe**:  

```
GRANT ALL PRIVILEGES TO joe;
```

Afterward, user **joe** has the sysadmin permissions.
- **Grant object permissions to a user or role.**
  - Grant the SELECT permission on the **tpcds.reason** table to user **joe**:  

```
GRANT SELECT ON TABLE tpcds.reason TO joe;
```
  - Grant all permissions of the **tpcds.reason** table to user **kim**.  

```
GRANT ALL PRIVILEGES ON tpcds.reason TO kim;
```

After the granting succeeds, user **kim** has all the permissions of the **tpcds.reason** table, including the add, delete, modify, and query permissions.
  - Grant the permission to use the **tpcds** schema to user **joe**.  

```
GRANT USAGE ON SCHEMA tpcds TO joe;
```

After the authorization is successful, user **joe** has the **USAGE** permission of the schema and can access the objects contained in the schema.
  - Grant the query permission for the **r\_reason\_sk**, **r\_reason\_id**, and **r\_reason\_desc** columns and the update permission for the **r\_reason\_desc** column in the **tpcds.reason** table to user **joe**:  

```
GRANT select (r_reason_sk,r_reason_id,r_reason_desc),update (r_reason_desc) ON tpcds.reason TO joe;
```

After the granting succeeds, user **joe** immediately has the query permission of the **r\_reason\_sk** and **r\_reason\_id** columns in the **tpcds.reason** table.

```
GRANT select (r_reason_sk, r_reason_id) ON tpcds.reason TO joe ;
```
  - Grant the **EXECUTE** permission of the **func\_add\_sql** function to user **joe**.  

```
CREATE FUNCTION func_add_sql(f1 integer,f2 integer) RETURNS integer
AS 'select $1 + $2;'
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;
GRANT EXECUTE ON FUNCTION func_add_sql(integer, integer) TO joe;
```
  - Grant the **UPDATE** permission of the sequence **serial** to user **joe**.  

```
GRANT UPDATE ON SEQUENCE serial TO joe;
```
  - Grant user **joe** the database connection permission of gaussdb and the permission to create schemas in gaussdb.  

```
GRANT create,connect on database gaussdb TO joe ;
```
  - Grant the **tpcds** schema access permission and object creation permission to this role, but do not enable it to grant these permissions to others:  

```
GRANT USAGE,CREATE ON SCHEMA tpcds TO tpcds_manager;
```
- **Grant the permissions of a user or role to other users or roles.**

- Grant the permissions of user **joe** to user **manager**, and allow **manager** to grant these permissions to others:  
`GRANT joe TO manager WITH ADMIN OPTION;`
- Grant the permissions of user **manager** to user **senior\_manager**:  
`GRANT manager TO senior_manager;`

## 21.15.9 PREPARE

### Function

**PREPARE** creates a prepared statement.

A prepared statement is a performance optimizing object on the server. When the **PREPARE** statement is executed, the specified query is parsed, analyzed, and rewritten. When the **EXECUTE** is executed, the prepared statement is planned and executed. This avoids repetitive parsing and analysis. After the **PREPARE** statement is created, it exists throughout the database session. Once it is created (even if in a transaction block), it will not be deleted when a transaction is rolled back. It can only be deleted by explicitly invoking [DEALLOCATE](#) or automatically deleted when the session ends.

### Precautions

None

### Syntax

```
PREPARE name [(data_type [, ...])] AS statement;
```

### Parameter Description

Table 21-303 PREPARE parameters

| Parameter | Description                                                     | Value Range                                                            |
|-----------|-----------------------------------------------------------------|------------------------------------------------------------------------|
| name      | Name of a prepared statement. It must be unique in the session. | A string                                                               |
| data_type | Data type of the parameter.                                     | -                                                                      |
| statement | SQL statement that can be executed.                             | Any <b>SELECT INSERT, UPDATE, DELETE</b> , or <b>VALUES</b> statement. |

### Examples

Create and run a prepared statement for the **INSERT** statement:

```
PREPARE insert_reason(integer,character(16),character(100)) AS INSERT INTO tpcds.reason_t1
VALUES($1,$2,$3);
EXECUTE insert_reason(52, 'AAAAAAAADDAAAAAA', 'reason 52');
```

## Helpful Links

[DEALLOCATE](#)

## 21.15.10 REASSIGN OWNED

### Function

**REASSIGN OWNED** changes the owner of a database.

**REASSIGN OWNED** requires that the system change owners of all the database objects owned by **old\_role** to **new\_role**.

### Precautions

- **REASSIGN OWNED** is often executed before deleting a rule. Because objects in other databases are not affected, you usually need to run this command in each database that contains the objects owned by the role to be deleted.
- You must have the permissions on the original and target roles to execute it.
- The resource management module does not monitor the data switch of the syntax. You need to call **select gs\_wlm\_readjust\_user\_space(0)** to manually calibrate the monitoring data.

### Syntax

```
REASSIGN OWNED BY old_role [, ...] TO new_role;
```

### Parameter Description

**Table 21-304** REASSIGN OWNED parameters

| Parameter | Description                                             | Value Range                                                                                                                                                             |
|-----------|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| old_role  | Role name of the old owner.                             | A string of no more than 63 characters. Enter a string starting with a letter or underscore (_) and containing letters, digits, underscores (_), and dollar signs (\$). |
| new_role  | Name of the new role that will become the object owner. | A string of no more than 63 characters. Enter a string starting with a letter or underscore (_) and containing letters, digits, underscores (_), and dollar signs (\$). |

### Examples

Reassign all database objects owned by the **joe** and **jack** roles to **admin**:

```
REASSIGN OWNED BY joe, jack TO admin;
```

## 21.15.11 REVOKE

### Function

**REVOKE** revokes rights from one or more roles.

### Precautions

If a non-owner user of an object attempts to **REVOKE** rights on the object, the command is executed based on the following rules:

- If the user has no right whatsoever on the object, the command will fail outright.
- If some permissions are available, the command proceeds, but it revokes only those rights for which the user has grant options.
- The **REVOKE ALL PRIVILEGES** forms will issue an error message if no grant options are held, while the other forms will issue a warning if grant options for any of the rights named in the command are not held.
- Do not perform **REVOKE** to a table partition. Performing **REVOKE** to a partitioned table incurs an alarm.

### Syntax

- Revoke the permission of specified table and view.

```
REVOKE [GRANT OPTION FOR]
 { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER | ANALYZE |
 ANALYZE | VACUUM | ALTER | DROP }[, ...]
 | ALL [PRIVILEGES] }
 ON { [TABLE] table_name [, ...]
 | ALL TABLES IN SCHEMA schema_name [, ...] }
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

#### CAUTION

Do not perform concurrent GRANT or REVOKE operations (including **ON TABLE** and **ON ALL TABLES IN SCHEMA**) on a given table or view, or do not perform both GRANT or REVOKE and DDL operations on a given table or view. Otherwise, an error similar to "tuple concurrently updated." is reported.

- Revoke the permission of specified fields on the table.

```
REVOKE [GRANT OPTION FOR]
 { { SELECT | INSERT | UPDATE | REFERENCES } (column_name [, ...])[, ...]
 | ALL [PRIVILEGES] (column_name [, ...]) }
 ON [TABLE] table_name [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of a specified database.

```
REVOKE [GRANT OPTION FOR]
 { { CREATE | CONNECT | TEMPORARY | TEMP } [, ...]
 | ALL [PRIVILEGES] }
 ON DATABASE database_name [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of a specified function.

```
REVOKE [GRANT OPTION FOR]
 { { EXECUTE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
 ON { FUNCTION {function_name ([{[argmode] [arg_name] arg_type} [, ...]) } } [, ...]
 | ALL FUNCTIONS IN SCHEMA schema_name [, ...] }
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of a specified large object.

```
REVOKE [GRANT OPTION FOR]
 { { SELECT | UPDATE } [, ...] | ALL [PRIVILEGES] }
 ON LARGE OBJECT loid [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission on a specified sequence.

```
REVOKE [GRANT OPTION FOR]
 { { SELECT | UPDATE | USAGE } [, ...] | ALL [PRIVILEGES] }
 ON SEQUENCE sequence_name [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of a specified schema.

```
REVOKE [GRANT OPTION FOR]
 { { CREATE | USAGE | ALTER | DROP } [, ...] | ALL [PRIVILEGES] }
 ON SCHEMA schema_name [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of a specified sub-cluster.

```
REVOKE [GRANT OPTION FOR]
 { CREATE | USAGE | COMPUTE | ALL [PRIVILEGES] }
 ON NODE GROUP group_name [, ...]
 FROM { [GROUP] role_name | PUBLIC } [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the permission of roles based on roles.

```
REVOKE [ADMIN OPTION FOR]
 role_name [, ...] FROM role_name [, ...]
 [CASCADE | RESTRICT];
```

- Revoke the sysadmin permission of a specified role.

```
REVOKE ALL { PRIVILEGES | PRIVILEGE } FROM role_name;
```

## Parameter Description

The keyword **PUBLIC** indicates an implicitly defined group that has all roles. For details about the **REVOKE** permission and related parameters, see [Parameter Description](#) in "GRANT".

 **NOTE**

- Permissions of a role include the permissions directly granted to the role, permissions inherited from the parent role, and permissions granted to **PUBLIC**. Therefore, revoking the **SELECT** permission for an object from **PUBLIC** does not necessarily mean that the **SELECT** permission for the object has been revoked from all roles, because the **SELECT** permission directly granted to roles and inherited from parent roles still remains. Similarly, if the **SELECT** permission is revoked from a user and the **PUBLIC** user still has the **SELECT** permission, the user can still use the **SELECT** permission.
- If user A holds the **UPDATE** rights on a table and the **WITH GRANT OPTION** and has granted them to user B, the rights that user B holds are called dependent rights. If the rights or the grant option held by user A is revoked, the dependent rights still exist. Those dependent rights are also revoked if **CASCADE** is specified.
- A user can only revoke rights that were granted directly by that user. If, for example, user A has granted a right with grant option (**WITH ADMIN OPTION**) to user B, and user B has in turn granted it to user C, then user A cannot revoke the right directly from C. However, user A can revoke the grant option held by user B and use **CASCADE**. In this manner, the rights held by user C are automatically revoked. For another example, if both user A and user B have granted the same right to C, A can revoke his own grant but not B's grant, so C will still effectively have the right.
- If the role executing **REVOKE** holds rights indirectly via more than one role membership path, it is unspecified which containing role will be used to execute the command. In such cases, it is best practice to use **SET ROLE** to become the specific role you want to do the **REVOKE** as, and then execute **REVOKE**. Failure to do so may lead to deleting rights not intended to delete, or not deleting any rights at all.

## Examples

Revoke the sysadmin permission of user **joe**:

```
REVOKE ALL PRIVILEGES FROM joe;
```

Revoke the permissions granted in a specified schema.

```
REVOKE USAGE,CREATE ON SCHEMA tpcds FROM tpcds_manager;
```

Revoke the **CONNECT** privilege from user **joe**.

```
REVOKE CONNECT ON DATABASE mydatabase FROM joe;
```

Revoke the membership of role **admins** from user **joe**.

```
REVOKE admins FROM joe;
```

Revoke all the privileges of user **joe** for the **myView** view.

```
REVOKE ALL PRIVILEGES ON myView FROM joe;
```

Revoke the insert permission for the **customer\_t1** table from **public**.

```
REVOKE INSERT ON customer_t1 FROM PUBLIC;
```

Revoke user **joe**'s permission for the **tpcds** schema.

```
REVOKE USAGE ON SCHEMA tpcds FROM joe;
```

Revoke the query permissions for **r\_reason\_sk** and **r\_reason\_id** in the **tpcds.reason** table from user **joe**.

```
REVOKE select (r_reason_sk, r_reason_id) ON tpcds.reason FROM joe;
```

Revoke user **joe**'s execute permission on function **func\_add\_sql**.

```
REVOKE execute ON FUNCTION func_add_sql(integer, integer) FROM joe CASCADE;
```

[GRANT](#)

## 21.16 DQL Syntax

### 21.16.1 DQL Syntax Overview

Data Query Language (DQL) can obtain data from tables or views.

#### Query

DWS provides statements for obtaining data from tables or views. For details, see [SELECT](#).

#### Defining a New Table Based on Query Results

DWS provides a statement for creating a table based on query results and inserting the queried data into the table. For details, see [SELECT INTO](#).

### 21.16.2 SELECT

#### Function

Retrieves data from a table or view.

Serving as an overlaid filter for a database table, **SELECT** using SQL keywords retrieves required data from data tables.

#### Precautions

- For details about how to use SELECT, see "SELECT Operation" in *Data Warehouse Service (DWS) Developer Guide*.
- Using **SELECT** can join HDFS and ordinary tables, but cannot join ordinary and GDS foreign tables. That is, a **SELECT** statement cannot contain both ordinary and GDS foreign tables.
- You must have the SELECT permission on each column used in the **SELECT** command. If **FOR UPDATE** or **FOR SHARE** is used, the UPDATE permission is also required.

#### Syntax

The syntax format of the main clause is shown below. The syntax formats of the FROM and GROUP BY clauses are defined separately. For details about the FROM and GROUP BY clauses, see [FROM Clause Parameters](#) and [GROUP BY Parameters](#).

##### NOTE

SELECT supports the simplified query syntax, which is equivalent to **select \* from table\_name**.

```
TABLE { ONLY {(table_name)| table_name} | table_name [*]};
```

```
[WITH [RECURSIVE] with_query [, ...]]
SELECT [/*+ plan_hint */] [ALL | DISTINCT [ON (expression [, ...])]]
{ * | {expression [[AS] output_name]} [, ...] }
[FROM from_item [, ...]]
[WHERE condition]
[GROUP BY grouping_element [, ...]]
[HAVING condition [, ...]]
[WINDOW {window_name AS (window_definition)} [, ...]]
[{ UNION | INTERSECT | EXCEPT | MINUS } [ALL | DISTINCT] select]
[ORDER BY {expression [[ASC | DESC | USING operator] | nlssort_expression_clause } [NULLS { FIRST |
LAST }]} [, ...]]
[{ [LIMIT { count | ALL }] [OFFSET start [ROW | ROWS]] } | { LIMIT start, { count | ALL } }]
[FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY]
[{FOR { UPDATE | SHARE } [OF table_name [, ...]] [NOWAIT]} [...]];
```

---

#### NOTICE

In **condition** and **expression**, you can use the aliases of expressions in the output column in compliance with the following rules:

- Only aliases at the same level can be referenced.
  - Only aliases in the output column can be referenced.
  - A prior expression is referenced only in a subsequent expression.
  - The **volatile** function cannot be used.
  - The **Window** function cannot be used.
  - Do not reference an alias in the **join on** condition.
  - An error is reported if the output column contains multiple referenced aliases.
-

## SELECT Main Clause Parameters

Table 21-305 SELECT parameters

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WITH<br>[ RECURSIVE ]<br>with_query<br>[, ...] | <p>Specifies one or more subqueries (CTE) that can be referenced by name in the primary query. The subqueries act as temporary tables. If a given subquery result needs to be referenced multiple times, use WITH to simplify the code logic and improve the coding efficiency.</p> <p>If <b>RECURSIVE</b> is specified, it allows a <b>SELECT</b> subquery to reference itself by name.</p> <p>The format of <b>with_query</b>:</p> <pre>with_query_name [ ( column_name [, ...] ) ] AS<br/>[ [ NOT ] MATERIALIZED ] ( {select   values   insert  <br/>update   delete} )</pre> | <ul style="list-style-type: none"><li>• <b>with_query_name</b> specifies the name of the result set generated by the subquery. You can use this name to access the result set of the subquery.</li><li>• <b>[ NOT ] MATERIALIZED</b> specifies this parameter to change the default behavior.<ul style="list-style-type: none"><li>– If <b>MATERIALIZED</b> is specified, the subquery is executed once, and the result set is materialized for the primary query to query the result set for multiple times.</li><li>– If <b>NOT MATERIALIZED</b> is specified, <b>with_query</b> is referenced only once by the primary query and is not executed separately. Instead,</li></ul></li></ul> |

| Parameter | Description | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |             | <p><b>with_query</b> is substituted with its reference in the primary query and executed alongside it.</p> <ul style="list-style-type: none"><li>- <b>NOT MATERIALIZED</b> is ignored in the following cases:<ul style="list-style-type: none"><li>- The subquery contains volatile functions.</li><li>- The subquery is a <b>SELECT</b> or <b>VALUES</b> statement containing <b>FOR UPDATE</b> or <b>FOR SHARE</b>.</li><li>- The subquery is an <b>INSERT</b>, <b>UPDATE</b>, or <b>DELETE</b> statement.</li><li>- <b>RECURSIVE</b> is specified for <b>with_query</b>.</li><li>- If <b>with_query2</b> is</li></ul></li></ul> |

| Parameter | Description | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |             | <div>referenced more than once and it references <b>with_query1</b>, which referenced itself in the outer layer, <b>with_query2</b> cannot take the place where it can be referenced.</div> <div>For example, in the following example, <b>tmp2</b> is referenced twice. Because <b>tmp2</b> references <b>tmp1</b> which referenced itself in the outer layer, <b>tmp2</b> will be materialized even if <b>NOT MATERIALIZED</b> is specified.</div> <div>with recursive<br/>tmp1(b) as<br/>(values(1)<br/>union all</div> |

| Parameter                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Value Range or Example                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <pre>(with tmp2<br/>as not<br/>materialized<br/>(select *<br/>from tmp1)<br/>select tt1.b<br/>+ tt2.b from<br/>tmp2 tt1,<br/>tmp2 tt2))<br/>select * from<br/>tmp1;</pre> <ul style="list-style-type: none"><li>• <b>column_name</b> specifies a column name displayed in the subquery result set.</li><li>• Each subquery can be a <b>SELECT</b>, <b>VALUES</b>, <b>INSERT</b>, <b>UPDATE</b> or <b>DELETE</b> statement.</li></ul> |
| <b>plan_hint</b> clause                | This clause, in the format <b>/*+ */</b> , comes after the <b>SELECT</b> keyword. It is used to enhance the plan of a <b>SELECT</b> statement block.<br><br>For details, see "DWS Performance Tuning" > "SQL Tuning" > "Hint-based Tuning" in the <i>Data Warehouse Service (DWS) Developer Guide</i> .                                                                                                                                                                               | -                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ALL                                    | Specifies that all rows that meet the conditions are returned. This is the default behavior and can be omitted.                                                                                                                                                                                                                                                                                                                                                                       | -                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DISTINCT [ ON ( expression [, ...] ) ] | Removes all duplicate rows from the <b>SELECT</b> result to ensure that each row is unique.<br><br><b>ON ( expression [, ...] )</b> is only reserved for the first row among all the rows with the same result calculated using given expressions.<br><br><b>NOTICE</b><br><b>DISTINCT ON</b> expression is explained with the same rule of <b>ORDER BY</b> . Unless you use <b>ORDER BY</b> to guarantee that the required row appears first, you cannot know what the first row is. | -                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter              | Description                                                                                                                                                                                                                                                                                                                  | Value Range or Example                                                                                                                                                                                                                                                                                                                   |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SELECT</b> list     | Indicates columns to be queried. Some or all columns (using wildcard character *) can be queried.<br><br>You may use the <b>AS output_name</b> clause to give an alias for an output column. The alias is used for the displaying of the output column.                                                                      | Column names may be either of: <ul style="list-style-type: none"><li>Manually input column names which are spaced using commas (,).</li><li>Fields computed in the <b>FROM</b> clause.</li><li>Generally, the keyword <b>AS</b> can be omitted. For example, <b>select 2a</b> is implicitly converted to <b>select 2 as a</b>.</li></ul> |
| <b>FROM</b> clause     | Indicates one or more source tables for <b>SELECT</b> . For details, see <a href="#">Table 21-306</a> .                                                                                                                                                                                                                      | -                                                                                                                                                                                                                                                                                                                                        |
| <b>WHERE</b> clause    | The <b>WHERE</b> clause forms an expression for row selection to narrow down the query range of <b>SELECT</b> .                                                                                                                                                                                                              | <ul style="list-style-type: none"><li><b>LIKE</b> operator</li><li>The <b>(+)</b> operator is not recommended.</li></ul> For details, see <a href="#">Restrictions on the WHERE Clause</a> .                                                                                                                                             |
| <b>GROUP BY</b> clause | Condenses query results into a single row or selected rows that share the same values for the grouped expressions.                                                                                                                                                                                                           | For details, see <a href="#">Table 21-308</a> .                                                                                                                                                                                                                                                                                          |
| <b>HAVING</b> clause   | Filters group rows created by <b>GROUP BY</b> . It is similar to <b>WHERE</b> , but is usually used with <b>GROUP BY</b> to filter out special groups. The <b>HAVING</b> clause compares some attributes of groups with a constant. Only groups that match the logical expression in the <b>HAVING</b> clause are extracted. | -                                                                                                                                                                                                                                                                                                                                        |

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Value Range or Example |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>WINDOW</b><br>clause | <p>Defines a window function. The format is <b>WINDOW</b> <i>window_name</i> <b>AS</b> ( <i>window_definition</i> ) [, ...]. <i>window_name</i> indicates a name that can be referenced from subsequent window definitions. <i>window_definition</i> indicates the window rule, which can be expressed in the following format:</p> <pre>[ existing_window_name ]<br/>[ PARTITION BY expression [, ...] ]<br/>[ ORDER BY expression [ ASC   DESC   USING<br/>operator ] [ NULLS { FIRST   LAST } ] [, ...] ]<br/>[ frame_clause ]</pre> <p><b>frame_clause</b> defines a <b>window frame</b> for the window function. The window function (not all window functions) depends on <b>window frame</b> and <b>window frame</b> is a set of relevant rows of the current query row. <b>frame_clause</b> can be expressed in the following forms:</p> <pre>[ RANGE   ROWS ] frame_start<br/>[ RANGE   ROWS ] BETWEEN frame_start AND<br/>frame_end</pre> <p><b>frame_start</b> and <b>frame_end</b> can be expressed in the following forms:</p> <pre>UNBOUNDED PRECEDING<br/>value PRECEDING (not supported for <b>RANGE</b>)<br/>CURRENT ROW<br/>value FOLLOWING (not supported for <b>RANGE</b>)<br/>UNBOUNDED FOLLOWING</pre> <p><b>NOTICE</b><br/>For the query of column storage table, only <b>row_number</b> window function is supported, <b>frame_clause</b> is not supported.</p> | -                      |

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Value Range or Example |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>UNION</b> clause     | <p>Computes the set union of the rows returned by the involved <b>SELECT</b> statements.</p> <p>The <b>UNION</b> clause has the following constraints:</p> <ul style="list-style-type: none"><li>• By default, the result of <b>UNION</b> does not contain any duplicate rows unless the <b>ALL</b> option is specified.</li><li>• Multiple <b>UNION</b> operators in the same <b>SELECT</b> statement are evaluated left to right, unless otherwise specified by parentheses.</li><li>• <b>FOR UPDATE</b> cannot be specified either for a <b>UNION</b> result or for any input of a <b>UNION</b>.</li></ul> <p>General expression:</p> <pre>select_statement UNION [ALL] select_statement</pre> <ul style="list-style-type: none"><li>• <b>select_statement</b> can be any <b>SELECT</b> statement without an <b>ORDER BY</b>, <b>LIMIT</b>, or <b>FOR UPDATE</b> clause.</li><li>• <b>ORDER BY</b> and <b>LIMIT</b> in parentheses can be attached in a sub-expression.</li></ul> | -                      |
| <b>INTERSECT</b> clause | <p>Computes the set intersection of rows returned by the involved <b>SELECT</b> statements. The result of <b>INTERSECT</b> does not contain any duplicate rows.</p> <p>The <b>INTERSECT</b> clause has the following constraints:</p> <ul style="list-style-type: none"><li>• Multiple <b>INTERSECT</b> operators in the same <b>SELECT</b> statement are evaluated left to right, unless otherwise specified by parentheses.</li><li>• Processing <b>INTERSECT</b> preferentially when <b>UNION</b> and <b>INTERSECT</b> operations are executed for results of multiple <b>SELECT</b> statements.</li></ul> <p>General format:</p> <pre>select_statement INTERSECT select_statement</pre> <p><b>select_statement</b> can be any <b>SELECT</b> statement without a <b>FOR UPDATE</b> clause.</p>                                                                                                                                                                                    | -                      |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Value Range or Example |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| <b>EXCEPT</b> clause | <p>The <b>EXCEPT</b> operator computes the set of rows that are in the result of the left <b>SELECT</b> statement but not in the result of the right one.</p> <p><b>EXCEPT</b> clause has the following common form:</p> <pre>select_statement EXCEPT [ ALL ] select_statement</pre> <ul style="list-style-type: none"><li>• <b>select_statement</b> can be any <b>SELECT</b> statement without a <b>FOR UPDATE</b> clause.</li><li>• The result of <b>EXCEPT</b> does not contain any duplicate rows unless the <b>ALL</b> option is specified. To execute <b>ALL</b>, a row that has <math>m</math> duplicates in the left table and <math>n</math> duplicates in the right table will appear <math>\text{MAX}(m-n, 0)</math> times in the result set.</li><li>• Multiple <b>EXCEPT</b> operators in the same <b>SELECT</b> statement are evaluated left to right, unless parentheses dictate otherwise. <b>EXCEPT</b> binds at the same level as <b>UNION</b>.</li><li>• Currently, <b>FOR UPDATE</b> cannot be specified either for an <b>EXCEPT</b> result or for any input of an <b>EXCEPT</b>.</li></ul> | -                      |
| <b>MINUS</b> clause  | Has the same function and syntax as <b>EXCEPT</b> clause.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | -                      |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Value Range or Example                                                                                                                |

| <b>ORDER BY</b> clause    | <p>Sorts data retrieved by <b>SELECT</b> in descending or ascending order. If the <b>ORDER BY</b> expression contains multiple columns:</p> <ul style="list-style-type: none"><li>• If two columns are equal according to the leftmost expression, they are compared according to the next expression and so on.</li><li>• If they are equal according to all specified expressions, they are returned in an implementation-dependent order.</li><li>• Columns sorted by <b>ORDER BY</b> must be contained in the result retrieved by <b>SELECT</b>.</li></ul> <p><b>NOTICE</b></p> <ul style="list-style-type: none"><li>• If <b>ORDER BY</b> is not specified, the query results are returned following the generation sequence in the database system.</li><li>• You can add the keyword <b>ASC</b> (in ascending order) or <b>DESC</b> (in descending order) next to any expression in the <b>ORDER BY</b> clause. If the keyword is not specified, <b>ASC</b> is used by default.</li><li>• To sort query results by case-insensitive Chinese pinyin, set the encoding mode to <b>UTF-8</b> or <b>GBK</b> during database creation.</li></ul> | -                                                                                                                                     |
| nlssort_expression_clause | <p>Sets the sorting mode. The format is as follows:</p> <pre>NLSSORT ( column_name, ' NLS_SORT = { SCHINESE_PINYIN_M   generic_m_ci } ' )</pre> <p><b>NLS_SORT</b>: indicates a field to be ordered in a special mode. Currently, only the Chinese Pinyin order and case insensitive order are supported. Values:</p> <ul style="list-style-type: none"><li>• <b>SCHINESE_PINYIN_M</b>: Chinese characters are sorted by pinyin. Currently, only level-1 Chinese characters in the GBK character set can be sorted. To use this sort method, specify <b>GBK</b> as the encoding format when you create the database. If you do not do so, this value is invalid.</li><li>• <b>generic_m_ci</b>, case-insensitive order.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                  | <ul style="list-style-type: none"><li>• <a href="#">Example: Use NLSSORT to Sort Query Results Without Case Sensitivity</a></li></ul> |

| Parameter                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Value Range or Example                                                |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| [ { [ LIMIT<br>{ count  <br>ALL } ]<br>[ OFFSET start<br>[ ROW  <br>ROWS ] ] }  <br>{ LIMIT start,<br>{ count  <br>ALL } } ] | <p>The <b>LIMIT</b> clause consists of two independent <b>LIMIT</b> clauses, an <b>OFFSET</b> clause, and a <b>LIMIT</b> clause with multiple parameters.</p> <p>LIMIT { count   ALL }<br/>OFFSET start [ ROW   ROWS ]<br/>LIMIT start, { count   ALL }</p> <p><b>count</b> in the clauses specifies the maximum number of rows to return, while <b>start</b> specifies the number of rows to skip before starting to return rows. When both are specified, <b>start</b> rows are skipped before starting to count the <b>count</b> rows to be returned. A multi-parameter <b>LIMIT</b> clause cannot be used together with a single-parameter <b>LIMIT</b> or <b>OFFSET</b> clause.</p> <p>Example:<br/>LIMIT 10 OFFSET 20; -- Skip the first 20 rows and return the next 10 rows, that is, return rows 21 to 30.<br/>LIMIT 5, 10; -- Skip the first five lines and returns the last 10 rows, that is, returns the rows 6 to 16.</p> | -                                                                     |
| FETCH { FIRST  <br>NEXT }<br>[ count ]<br>{ ROW  <br>ROWS } ONLY                                                             | The <b>FETCH</b> clause restricts the total number of rows starting from the first row of the return query result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | If <b>count</b> is not specified, the default value <b>1</b> is used. |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Value Range or Example |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| FOR UPDATE   SHARE clause | <p>The <b>FOR UPDATE</b> clause locks the selected rows in a <b>SELECT</b> query to prevent other transactions from modifying or deleting them until the current transaction is completed. This means that any transactions attempting to execute <b>UPDATE</b>, <b>DELETE</b>, or <b>SELECT FOR UPDATE</b> on these rows will be blocked until the current transaction is finished.</p> <p><b>NOWAIT</b> option: prevents an operation from waiting for other transactions to commit. If the selected row cannot be locked immediately, an error is reported when <b>SELECT FOR UPDATE NOWAIT</b> is executed.</p> <ul style="list-style-type: none"><li>• If specified tables are named in <b>FOR UPDATE/SHARE</b>, then only rows coming from those tables are locked; any other tables used in <b>SELECT</b> are simply read as usual. Otherwise, locking all tables in the command.</li><li>• If <b>FOR UPDATE</b> or <b>FOR SHARE</b> is applied to a view or sub-query, it affects all tables used in the view or sub-query.</li><li>• Multiple <b>FOR UPDATE</b> and <b>FOR SHARE</b> clauses can be written if it is necessary to specify different locking behaviors for different tables.</li><li>• If the same table is mentioned (or implicitly affected) by both <b>FOR UPDATE</b> and <b>FOR SHARE</b> clauses, it is processed as <b>FOR UPDATE</b>. Similarly, a table is processed as <b>NOWAIT</b> if that is specified in any of the clauses affecting it.</li><li>• <b>FOR SHARE</b> or <b>FOR UPDATE</b>: requires a shared lock instead of an exclusive lock for each retrieved row. A share lock blocks other transaction from performing <b>UPDATE</b>, <b>DELETE</b>, or <b>SELECT FOR UPDATE</b> on these rows, but it does not prevent them from performing <b>SELECT FOR SHARE</b>.</li></ul> | -                      |

| Parameter | Description                                                                                                                                                                                                                                                                                                                             | Value Range or Example |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
|           | <b>NOTICE</b> <ul style="list-style-type: none"><li>For SQL statements containing <b>FOR UPDATE</b> or <b>FOR SHARE</b>, their execution plans will be pushed down to DN. If the pushdown fails, an error will be reported.</li><li>The query of column storage table does not support <b>FOR UPDATE</b> or <b>FOR SHARE</b>.</li></ul> |                        |

## FROM Clause Parameters

FROM from\_item clause format:

```
{[ONLY] table_name [*] [partition_clause] [[AS] alias [(column_alias [, ...])]]
[(select) [AS] alias [(column_alias [, ...])]]
[with_query_name [[AS] alias [(column_alias [, ...])]]]
[function_name ([argument [, ...]]) [AS] alias [(column_alias [, ...] | column_definition [, ...])]]
[function_name ([argument [, ...]]) AS (column_definition [, ...])]
[from_item [NATURAL] join_type from_item [ON join_condition | USING (join_column [, ...])]] }
```

**Table 21-306** FROM clause parameters

| Parameter    | Description                                                                                                                                                                                                                                             | Value Range or Example                                                                                                          |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| table_name   | Indicates the name (optionally schema-qualified) of an existing table or view, for example, <b>schema_name.table_name</b> .                                                                                                                             | A string, which must comply with the naming convention.<br><br>For details, see <a href="#">Identifier Naming Conventions</a> . |
| alias        | Gives a temporary alias to a table to facilitate the quotation by other queries.<br><br>An alias is used for brevity or to eliminate ambiguity for self-joins. When an alias is provided, it completely hides the actual name of the table or function. | A string, which must comply with the naming convention.<br><br>For details, see <a href="#">Identifier Naming Conventions</a> . |
| column_alias | Specifies the column alias.                                                                                                                                                                                                                             | A string, which must comply with the naming convention.<br><br>For details, see <a href="#">Identifier Naming Conventions</a> . |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Value Range or Example                                                                                                                                                                                                                                                                                                                                      |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| partition_clause | <p>Queries data in the specified partition of a partitioned table. The format is as follows:</p> <pre>PARTITION { ( partition_name )  <br/>FOR ( partition_value [, ...] ) }</pre> <ul style="list-style-type: none"><li>• <b>partition_name</b>: indicates the partition name.</li><li>• <b>partition_value</b>: indicates the partition key value. If there are many partition keys, use the <b>PARTITION FOR</b> clause to specify the value of the only partition key you want to use.</li></ul> <p><b>NOTICE</b><br/>Partitions can be specified only for ordinary tables.</p> | <p>Examples:</p> <pre>SELECT * FROM<br/>tpcds.reason_p<br/>PARTITION<br/>(P_05_BEFORE);</pre>                                                                                                                                                                                                                                                               |
| subquery         | <p>Performs a subquery in the <b>FROM</b> clause. A temporary table is created to save subquery results.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>For example, assign an alias <b>e</b> to a subquery result and use it as a <b>FROM</b> data source.</p> <pre>SELECT<br/>d.department_name,<br/>e.avg_salary FROM<br/><br/>( SELECT department_id,<br/>AVG(salary) AS<br/>avg_salary FROM<br/>employees GROUP<br/>BY department_id) AS e<br/><br/>JOIN departments d ON<br/>e.department_id = d.id;</pre> |
| with_query_name  | <p><b>WITH</b> clause can also be the source of <b>FROM</b> clause and can be referenced with the name queried by executing <b>WITH</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>A string, which must comply with the naming convention.</p> <p>For details, see <a href="#">Identifier Naming Conventions</a>.</p> <p>For example, use <b>WITH cte</b> and reference <b>cte</b> in a <b>FROM</b> clause.</p> <pre>WITH cte AS (SELECT id,<br/>name FROM users)<br/>SELECT * FROM cte AS<br/>user_info;</pre>                             |

| Parameter                 | Description                                                                                                                       | Value Range or Example                                                                                                                                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| function_name             | Specifies the function name. Function calls can appear in the <b>FROM</b> clause.                                                 | A string, which must comply with the naming convention.<br>For details, see <a href="#">Identifier Naming Conventions</a> .                                                                                                                            |
| join_type                 | Specifies the JOIN type.                                                                                                          | Supported JOIN types: <ul style="list-style-type: none"><li>• [ INNER ] JOIN</li><li>• LEFT [ OUTER ] JOIN</li><li>• RIGHT [ OUTER ] JOIN</li><li>• FULL [ OUTER ] JOIN</li><li>• CROSS JOIN</li></ul> For details, see <a href="#">Table 21-307</a> . |
| ON join_condition         | A join condition to define which rows have matches in joins. Example: ON left_table.a = right_table.a                             | -                                                                                                                                                                                                                                                      |
| USING(join_column[, ...]) | ON left_table.a = right_table.a AND left_table.b = right_table.b ... abbreviation. Corresponding columns must have the same name. | -                                                                                                                                                                                                                                                      |
| NATURAL                   | <b>NATURAL</b> is a shorthand for a <b>USING</b> list that mentions all columns in the two tables that have the same names.       | -                                                                                                                                                                                                                                                      |
| from item                 | Specifies the name of the query source object connected.                                                                          | -                                                                                                                                                                                                                                                      |

**Table 21-307** Five types of join\_type

| Parameter      | Description                                                                                                                                                                                                                                                                       |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ INNER ] JOIN | A <b>JOIN</b> clause consists of two <b>FROM</b> items. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, <b>JOIN</b> nests left-to-right. In any case, <b>JOIN</b> binds more tightly than the commas separating <b>FROM</b> items. |

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LEFT [ OUTER ] JOIN  | Returns all rows in the qualified Cartesian product (all combined rows that pass its join condition), and pluses one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting <b>NULL</b> values for the right-hand columns.<br><br>Note that only the <b>JOIN</b> clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.                                                                                                                                                                                                                         |
| RIGHT [ OUTER ] JOIN | Returns all the joined rows, plus one row for each unmatched right-hand row (extended with <b>NULL</b> on the left). This is just a notational convenience, since you could convert it to a <b>LEFT OUTER JOIN</b> by switching the left and right inputs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FULL [ OUTER ] JOIN  | Returns all the joined rows, pluses one row for each unmatched left-hand row (extended with <b>NULL</b> on the right), and pluses one row for each unmatched right-hand row (extended with <b>NULL</b> on the left).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CROSS JOIN           | <b>CROSS JOIN</b> is equivalent to <b>INNER JOIN ON (TRUE)</b> , which means no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain <b>FROM</b> and <b>WHERE</b> .<br><b>NOTE</b> <ul style="list-style-type: none"><li>For the <b>INNER</b> and <b>OUTER</b> join types, a join condition must be specified, namely exactly one of <b>NATURAL ON</b>, <b>join_condition</b>, or <b>USING (join_column [, ...])</b>. For <b>CROSS JOIN</b>, none of these clauses can appear.</li><li><b>CROSS JOIN</b> and <b>INNER JOIN</b> produce a simple Cartesian product, the same result as you get from listing the two items at the top level of <b>FROM</b>.</li></ul> |

## GROUP BY Parameters

The **group** clause is as follows:

```
(
| expression
| (expression [, ...])
| ROLLUP ({ expression | (expression [, ...]) } [, ...])
| CUBE ({ expression | (expression [, ...]) } [, ...])
| GROUPING SETS (grouping_element [, ...])
```

**Table 21-308** GROUP By parameters

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Examples |
|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| ROLLUP<br>( { expression  <br>( expression<br>[, ...] ) }<br>[, ...] ) | <p>ROLLUP calculates the standard aggregation value specified by an ordered grouping column in GROUP BY, creates a high-level partial sum from right to left, and finally creates a cumulative sum. A group can be regarded as a series of grouping sets. Example:<br/>GROUP BY ROLLUP (a,b,c)</p> <p>The preceding condition expression is equivalent to:<br/>GROUP BY GROUPING SETS((a,b,c), (a,b), (a), ( ))</p> <p>The elements in the <b>ROLLUP</b> clause can be independent fields or expressions, or a list contained in parentheses. If it is a list in parentheses, they must be a whole when the grouping set is generated. Example:<br/>GROUP BY ROLLUP ((a,b), (c,d))</p> <p>The preceding condition expression is equivalent to:<br/>GROUPING SETS ((a,b,c,d), (a,b), (c,d), ( ))</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Examples |
| CUBE<br>( { expression  <br>( expression<br>[, ...] ) }<br>[, ...] )   | <p>A CUBE grouping is an extension to the GROUP BY clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). CUBE can be understood as all dimensions, that is, all combinations of columns in the aggregation key.</p> <p>In terms of multidimensional analysis, CUBE generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example, given three expressions (<math>n=3</math>) in the CUBE clause, the operation results in <math>2^n = 2^3 = 8</math> groupings. Rows grouped on the values of <math>n</math> expressions are called regular rows, and the rest are called superaggregate rows. Example:<br/>GROUP BY CUBE (a,b,c)</p> <p>The preceding condition expression is equivalent to:<br/>GROUP BY GROUPING SETS((a,b,c), (a,b), (a,c), (b,c), (a), (b), (c), ( ))</p> <p>The elements in the <b>CUBE</b> clause can be independent fields or expressions, or a list contained in parentheses. If it is a list in parentheses, they must be a whole when the grouping set is generated. Example:<br/>GROUP BY CUBE (a, (b, c), d)</p> <p>The preceding condition expression is equivalent to:<br/>GROUP BY GROUPING SETS ((a,b,c,d), (a,b,c), (a), ( ))</p> | Examples |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Examples                 |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| GROUPING SETS<br>( grouping_element [, ...] ) | <p><b>GROUPING SETS</b> is another extension to the <b>GROUP BY</b> clause. It allows users to specify multiple <b>GROUP BY</b> clauses. The option is used to define a grouping set. Each grouping set needs to be included in a separate parenthesis. A blank parenthesis (()) indicates that all data is processed as a group. This improves efficiency by trimming away unnecessary data. You can specify the required data group for query.</p> <p><b>NOTICE</b><br/>If the <b>SELECT</b> list expression quotes some ungrouped fields and no aggregate function is used, an error is displayed. This is because multiple values may be returned for ungrouped fields.</p> | <a href="#">Examples</a> |

## Restrictions on the WHERE Clause

1. For the **WHERE** clause, if a special character %, \_, or \ is queried in the **LIKE** operator, use the backslash (\) for escape.

```
CREATE TABLE tt01 (id int,content varchar(50));

INSERT INTO tt01 values (1,'Jack say "hello"');
INSERT INTO tt01 values (2,'Rose do 50%');
INSERT INTO tt01 values (3,'Lilei say "world"');
INSERT INTO tt01 values (4,'Hanmei do 100%');

SELECT * FROM tt01;
id | content
---+-----
3 | Lilei say 'world'
4 | Hanmei do 100%
1 | Jack say 'hello'
2 | Rose do 50%
(4 rows)

SELECT * FROM tt01 WHERE content like '%"he%';
id | content
---+-----
1 | Jack say 'hello'
(1 row)

SELECT * FROM tt01 WHERE content like '%50\%';
id | content
---+-----
2 | Rose do 50%
(1 row)
```

2. In the **WHERE** clause, you can use the operator (+) to convert a table join to an outer join. However, this method is not recommended because it is not the standard SQL syntax and may raise syntax compatibility issues during platform migration. The restrictions on using the plus sign (+) are as follows:
  - a. It can appear only in the **WHERE** clause.
  - b. If a table join has been specified in the **FROM** clause, the operator (+) cannot be used in the **WHERE** clause.
  - c. The operator (+) can work only on columns of tables or views, instead of on expressions.

- d. If table A and table B have multiple join conditions, the operator (+) must be specified in all the conditions. Otherwise, the operator (+) will not take effect, and the table join will be converted into an inner join without any prompt information.
- e. Tables specified in a join condition where the operator (+) works cannot cross queries or subqueries. If tables where the operator (+) works are not in the **FROM** clause of the current query or subquery, an error will be reported. If a peer table for the operator (+) does not exist, no error will be reported and the table join will be converted into an inner join.
- f. Expressions where the operator (+) is used cannot be directly connected through **OR**.
- g. If a column where the operator (+) works is compared with a constant, the expression becomes a part of the join condition.
- h. A table cannot have multiple foreign tables.
- i. The operator (+) can appear only in the following expressions: comparison, **NOT**, **ANY**, **ALL**, **IN**, **NULLIF**, **IS DISTINCT FROM**, and **IS OF** expressions. It is not allowed in other types of expressions. In addition, **AND** and **OR** are not allowed in these expressions.
- j. The operator (+) can be used to convert a table join only to a left or right outer join, instead of a full join. That is, the operator (+) cannot be specified on both tables of an expression.

### Example: Use WITH to Implement Subqueries

Obtain the **temp\_t** temporary table by a subquery and query all records in this table.

```
WITH temp_t(name,isdba) AS (SELECT username,usesuper FROM pg_user) SELECT * FROM temp_t;
```

Explicitly specify **MATERIALIZED** for the **with\_query** named **temp\_t**, and then query all data in the **temp\_t** table.

```
WITH temp_t(name,isdba) AS MATERIALIZED (SELECT username,usesuper FROM pg_user) SELECT * FROM temp_t;
```

Explicitly specify **NOT MATERIALIZED** for the **with\_query** named **temp\_t**, and then query all data in the **temp\_t** table.

```
WITH temp_t(name,isdba) AS NOT MATERIALIZED (SELECT username,usesuper FROM pg_user)
SELECT * FROM temp_t t1 WHERE name LIKE 'A%'
UNION ALL
SELECT * FROM temp_t t2 WHERE name LIKE 'B%';
```

### Example: Other Common SELECT Scenarios

Query all the **r\_reason\_sk** records in the **tpcds.reason** table and de-duplicate them.

```
SELECT DISTINCT(r_reason_sk) FROM tpcds.reason;
```

Example of a **LIMIT** clause: Obtain a record from the table.

```
SELECT * FROM tpcds.reason LIMIT 1;
```

Example of a **LIMIT** clause: Obtain the third record from the table.

```
SELECT * FROM tpcds.reason LIMIT 1 OFFSET 2;
```

Example of a **LIMIT** clause: Obtain the first two records from a table.

```
SELECT * FROM tpcds.reason LIMIT 2;
```

Query all records and sort them in alphabetic order.

```
SELECT r_reason_desc FROM tpcds.reason ORDER BY r_reason_desc;
```

Use table aliases to obtain data from the **pg\_user** and **pg\_user\_status** tables.

```
SELECT a.username,b.locktime FROM pg_user a,pg_user_status b WHERE a.usesysid=b.roloid;
```

Example of the **FULL JOIN** clause: Join data in the **pg\_user** and **pg\_user\_status** tables.

```
SELECT a.username,b.locktime,a.usesuper FROM pg_user a FULL JOIN pg_user_status b on a.usesysid=b.roloid;
```

Example of the **GROUP BY** clause: Filter data based on query conditions, and group the results.

```
SELECT r_reason_id, AVG(r_reason_sk) FROM tpcds.reason GROUP BY r_reason_id HAVING AVG(r_reason_sk) > 25;
```

Example of the **GROUP BY** clause: Group the results by alias.

```
SELECT r_reason_id AS id FROM tpcds.reason GROUP BY id;
```

Example of the **UNION** clause: Merge the names started with W and N in the **r\_reason\_desc** column in the **tpcds.reason** table.

```
SELECT r_reason_sk, tpcds.reason.r_reason_desc
FROM tpcds.reason
WHERE tpcds.reason.r_reason_desc LIKE 'W%'
UNION
SELECT r_reason_sk, tpcds.reason.r_reason_desc
FROM tpcds.reason
WHERE tpcds.reason.r_reason_desc LIKE 'N%';
```

## Example: Use WITH RECURSIVE to Query the Hierarchical Relationship of a Three-Level Department in a Company

Take the recursion of three levels of departments in a company as an example. In a table that contains level-1, level-2, and level-3 departments, use the keyword **RECURSIVE** to query all level-2 and level-3 departments of a department (for example, the technology department).

Prepare data:

```
DROP TABLE IF EXISTS departments;
CREATE TABLE departments
(id varchar(10),
pid varchar(10),
dept_name varchar(50));
INSERT INTO departments VALUES('0',null,'Head office');
INSERT INTO departments VALUES('1','0','Technology'); -- Level-1 department
INSERT INTO departments VALUES('2','0','Marketing');
INSERT INTO departments VALUES('3','0','HR');
INSERT INTO departments VALUES('4','0','Business');
INSERT INTO departments VALUES('5','0','Maintenance');
INSERT INTO departments VALUES('1-1','1','R&D Center'); -- Level-2 department
INSERT INTO departments VALUES('1-2','1','Pre-Research');
INSERT INTO departments VALUES('1-3','1','Network');
INSERT INTO departments VALUES('1-4','1','Test');
INSERT INTO departments VALUES('1-5','1','Architecture');
```

```
INSERT INTO departments VALUES('1-1-1','1-1','Frontend'); -- Level-3 department
INSERT INTO departments VALUES('1-1-2','1-1','Backend');
INSERT INTO departments VALUES('1-1-3','1-1','Design');
INSERT INTO departments VALUES('2-1','2','Branding');
INSERT INTO departments VALUES('2-2','2','Pricing');
INSERT INTO departments VALUES('2-3','2','Training');
```

Query the original data of the table. In the command output, it is difficult to determine the relationship of the three levels of departments.

```
SELECT * FROM departments;
```

| id    | pid    | dept_name    |
|-------|--------|--------------|
| 1     | 0      | Technology   |
| 4     | 0      | Business     |
| 1-2   | 1      | Pre-Research |
| 1-5   | 1      | Architecture |
| 1-1-3 | 1-1    | Design       |
| 2-3   | 2      | Training     |
| 0     | (Null) | Head office  |
| 3     | 0      | HR           |

In this case, use the keyword **WITH RECURSIVE** to query all level-2 and level-3 departments under the technology department.

```
WITH RECURSIVE t1 AS (-- Define a common expression named t1.
SELECT id,pid,dept_name FROM departments WHERE id='1' -- Initialize the recursive root node: Query the
record whose ID is 1, that is, the technology department.
UNION ALL --Recursively combine results (duplicate items are retained).
SELECT --Recursive part: query data layer by layer.
t2.id, --Subnode ID, that is, the name of each level-1 department.
t2.pid, --Parent node ID, that is, the head office.
t2.dept_name --Subnode name.
FROM departments t2
INNER JOIN t1 ON t2.pid = t1.id --Connect the recursive result through the parent node ID.
)
SELECT id,dept_name FROM t1 ORDER BY id; --(Final query) All level-2 and level-3 departments are
displayed by ID.
```

| id    | dept_name    |
|-------|--------------|
| 1     | Technology   |
| 1-1   | R&D Center   |
| 1-1-1 | Frontend     |
| 1-1-2 | Backend      |
| 1-1-3 | Design       |
| 1-2   | Pre-Research |
| 1-3   | Network      |
| 1-4   | Test         |
| 1-5   | Architecture |

View that the preceding query results are not intuitive. To display the department of each level, run the following command:

```
WITH RECURSIVE t1 AS (
 SELECT --Initialize the root node of recursion: Query the record whose ID is 1, that is, the technology
 department, and convert data type from record to text.
 id,
 pid,
 dept_name::text -- Explicitly convert the data type to text (prepared for subsequent path concatenation).
 FROM departments
 WHERE id='1'

 UNION ALL

 SELECT --Recursive part: concatenate the level path.
 t2.id,
 t2.pid,
 (t1.dept_name||'-'>||t2.dept_name)::text AS dept_name --Concatenate the parent path and the current
 node name, for example, Technology -> R&D Center.
 FROM departments t2
 INNER JOIN t1 ON t2.pid = t1.id)

SELECT id,dept_name FROM t1 ORDER BY id; --(Final query) Display the result with the level path
```

| id    | dept_name                        |
|-------|----------------------------------|
| 1     | Technology                       |
| 1-1   | Technology->R&D Center           |
| 1-1-1 | Technology->R&D Center->Frontend |
| 1-1-2 | Technology->R&D Center->Backend  |
| 1-1-3 | Technology->R&D Center->Design   |
| 1-2   | Technology->Pre-Research         |
| 1-3   | Technology->Network              |
| 1-4   | Technology->Test                 |
| 1-5   | Technology->Architecture         |

## Example: Use NLSSORT to Sort Query Results Without Case Sensitivity

Case-insensitive order:

```
CREATE TABLE stu_icode_info (id bigint, name text) DISTRIBUTE BY REPLICATION;
INSERT INTO stu_icode_info VALUES (1, 'aaaa'), (2, 'AAAA');
SELECT * FROM stu_icode_info ORDER BY NLSSORT (name, 'NLS_SORT = generic_m_ci');
id | name
----+-----
1 | aaaa
2 | AAAA
(2 rows)
```

## Example: Query Data in a Partitioned Table

Create the partitioned table **tpcds.reason\_p**, insert data, and obtain data from the **P\_05\_BEFORE** partition of the table.

```
CREATE TABLE tpcds.reason_p
(
 r_reason_sk integer,
 r_reason_id character(16),
 r_reason_desc character(100)
)
PARTITION BY RANGE (r_reason_sk)
(
 partition P_05_BEFORE values less than (05),
 partition P_15 values less than (15),
 partition P_25 values less than (25),
 partition P_35 values less than (35),
 partition P_45_AFTER values less than (MAXVALUE)
);

INSERT INTO tpcds.reason_p values(3,'AAAAAAAAABAAAAAAAA','reason 1'),
(10,'AAAAAAAAABAAAAAAAA','reason 2'),(4,'AAAAAAAAABAAAAAAAA','reason 3'),
(10,'AAAAAAAAABAAAAAAAA','reason 4'),(10,'AAAAAAAAABAAAAAAAA','reason 5'),
```

```
(20,'AAAAAAAACAAAAAA','reason 6'),(30,'AAAAAAAACAAAAAA','reason 7');
```

```
SELECT * FROM tpcds.reason_p PARTITION (P_05_BEFORE);
r_reason_sk | r_reason_id | r_reason_desc
```

```
-----+-----+-----
 4 | AAAAAAABAAAAAA | reason 3
 3 | AAAAAAABAAAAAA | reason 1
```

```
(2 rows)
```

—Query the number of rows in partition **P\_15**:

```
SELECT count(*) FROM tpcds.reason_p PARTITION (P_15);
count
```

```

 3
(1 row)
```

Example of the **GROUP BY** clause: Group records in the **tpcds.reason\_p** table by **r\_reason\_id**, and count the number of records in each group.

```
SELECT COUNT(*),r_reason_id FROM tpcds.reason_p GROUP BY r_reason_id;
count | r_reason_id
```

```
-----+-----
 2 | AAAAAAABAAAAAA
 5 | AAAAAAABAAAAAA
```

```
(2 rows)
```

Example of the **HAVING** clause: Group records in the **tpcds.reason\_p** table by **r\_reason\_id**, count the number of records in each group, and display only values whose number of **r\_reason\_id** is greater than 2.

```
SELECT COUNT(*) c,r_reason_id FROM tpcds.reason_p GROUP BY r_reason_id HAVING c>2;
c | r_reason_id
```

```
-----+-----
 5 | AAAAAAABAAAAAA
```

```
(1 row)
```

Example of the **IN** clause: Group records in the **tpcds.reason\_p** table by **r\_reason\_id**, count the number of records in each group, and display only the numbers of records whose **r\_reason\_id** is **AAAAAAAABAAAAAA** or **AAAAAAAADAAAAAA**.

```
SELECT COUNT(*),r_reason_id FROM tpcds.reason_p GROUP BY r_reason_id HAVING r_reason_id
IN('AAAAAAAABAAAAAA','AAAAAAAADAAAAAA');
count | r_reason_id
```

```
-----+-----
 5 | AAAAAAABAAAAAA
```

```
(1 row)
```

Example of the **INTERSECT** clause: Query records whose **r\_reason\_id** is **AAAAAAAABAAAAAA** and whose **r\_reason\_sk** is smaller than 5.

```
SELECT * FROM tpcds.reason_p WHERE r_reason_id='AAAAAAAABAAAAAA' INTERSECT SELECT * FROM
tpcds.reason_p WHERE r_reason_sk<5;
```

```
r_reason_sk | r_reason_id | r_reason_desc
```

```
-----+-----+-----
 4 | AAAAAAABAAAAAA | reason 3
 3 | AAAAAAABAAAAAA | reason 1
```

```
(2 rows)
```

Example of the **EXCEPT** clause: Query records whose **r\_reason\_id** is **AAAAAAAABAAAAAA** and whose **r\_reason\_sk** is greater than or equal to 4.

```
SELECT * FROM tpcds.reason_p WHERE r_reason_id='AAAAAAAABAAAAAA' EXCEPT SELECT * FROM
tpcds.reason_p WHERE r_reason_sk<4;
```

```
r_reason_sk | r_reason_id | r_reason_desc
```

```
-----+-----+-----
 10 | AAAAAAABAAAAAA | reason 2
 10 | AAAAAAABAAAAAA | reason 5
 10 | AAAAAAABAAAAAA | reason 4
```

```
4 | AAAAAAAAAAAAAAAAAA | reason 3
(4 rows)
```

Specify the operator (+) in the **WHERE** clause to indicate a left join.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where t1.sr_customer_sk =
t2.c_customer_sk(+)
order by 1 desc limit 1;
sr_item_sk | c_customer_id
-----+-----
18000 |
(1 row)
```

Specify the operator (+) in the **WHERE** clause to indicate a right join.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where t1.sr_customer_sk(+) =
t2.c_customer_sk
order by 1 desc limit 1;
sr_item_sk | c_customer_id
-----+-----
| AAAAAAAJINGEBAAA
(1 row)
```

Specify the operator (+) in the **WHERE** clause to indicate a left join and add a join condition.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where t1.sr_customer_sk =
t2.c_customer_sk(+) and t2.c_customer_sk(+) < 1 order by 1 limit 1;
sr_item_sk | c_customer_id
-----+-----
1 |
(1 row)
```

If the operator (+) is specified in the **WHERE** clause, do not use expressions connected through **AND/OR**.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where not(t1.sr_customer_sk =
t2.c_customer_sk(+) and t2.c_customer_sk(+) < 1);
ERROR: Operator "+" can not be used in nesting expression.
LINE 1: ...tomer_id from store_returns t1, customer t2 where
not(t1.sr_...
```

If the operator (+) is specified in the **WHERE** clause which does not support expression macros, an error will be reported.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where (t1.sr_customer_sk =
t2.c_customer_sk(+))::bool;
ERROR: Operator "+" can only be used in common expression.
```

If the operator (+) is specified on both sides of an expression in the **WHERE** clause, an error will be reported.

```
select t1.sr_item_sk,t2.c_customer_id from store_returns t1, customer t2 where t1.sr_customer_sk(+) =
t2.c_customer_sk(+);
ERROR: Operator "+" can't be specified on more than one relation in one join condition
HINT: "t1", "t2"...are specified Operator "+" in one condition.
```

## Example: Use GROUP BY for a Query (ROLLUP, CUBE, and GROUPING SETS as Part of GROUP BY)

In some report scenarios, data is often grouped using GROUP BY. In the following example, obtain the number of employees in level-2 departments under a level-1 department.

```
DROP TABLE IF EXISTS emp;
CREATE TABLE emp(
```

```
id int primary key, --Employee ID
name text, --Employee name
dep_1 text, --Level-1 department
dep_2 text --Level-2 department
);
```

```
INSERT INTO emp VALUES
(01, 'liwei', 'Product', 'SRE'),
(02, 'liming', 'Product', 'U1'),
(03, 'hanlei', 'Product', 'U1'),
(04, 'hanmeimei', 'Product', 'SRE'),
(05, 'dingjun', 'Product', 'SRE'),
(06, 'huxue', 'Product', 'E1'),
(07, 'liuyi', 'Product', 'E1'),
(08, 'luhua', 'Product', 'E1'),
(09, 'yangjing', 'Product', 'U1'),
(10, 'binbin', 'Product', 'U1'),
(11, 'jim', 'Product', 'SRE'),
(12, 'leo', 'Product', 'SER');
```

```
SELECT COUNT(*), dep_2 FROM emp GROUP BY dep_2; --Count the number of employees in level-2
departments.
```

| count | dep_2 |
|-------|-------|
| 1     | SER   |
| 3     | E1    |
| 4     | SRE   |
| 4     | U1    |

In common statistical report services, the total number of employees in a level-1 department (that is, the sum of employees in level-2 departments) needs to be calculated. In this case, **ROLLUP** can be used to ensure that there is an additional row of total data in the result, as shown in the following command output. In the following figure, **count** is **12** and **dep\_2** is **Null**, which indicate that the total number of employees in the level-1 department is 12.

```
SELECT COUNT(*), dep_2 FROM emp GROUP BY ROLLUP(dep_2) ORDER BY 1;
```

| count | dep_2  |
|-------|--------|
| 1     | SER    |
| 3     | E1     |
| 4     | U1     |
| 4     | SRE    |
| 12    | (Null) |

The following describes how to use ROLLUP, CUBE, and GROUPING SETS.

- **ROLLUP:**

Create **customer** table.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer
(
 c_id char(16) not null, --Customer ID
 c_name char(20), --Customer name
 c_age integer, --Age
 c_country varchar(20), --Country
 c_class char(10), --Customer level
 c_gender text, --Gender
 c_balance numeric); --Balance

INSERT INTO customer VALUES(1, 'tom', '20', 'Region A', '1', 'male', 300);
INSERT INTO customer VALUES(2, 'jack', '30', 'Region B', '1', 'male', 100);
INSERT INTO customer VALUES(3, 'rose', '40', 'Region C', '1', 'female', 200);
INSERT INTO customer VALUES(4, 'Frank', '60', 'Region D', '1', 'male', 100);
INSERT INTO customer VALUES(5, 'Leon', '20', 'Region A', '2', 'male', 200);
INSERT INTO customer VALUES(6, 'Lucy', '20', 'Region A', '1', 'female', 500);
```

**ROLLUP** generates subtotals and grand totals across multiple levels of aggregation within a single query. It starts from the most detailed level of aggregation and progressively rolls up to less detailed levels, ultimately producing a grand total.

```
-- Group by c_country and c_class, then group by c_country, and finally group by the entire table.
SELECT c_country, c_class, sum(c_balance) FROM customer GROUP BY ROLLUP(c_country, c_class)
ORDER BY 1,2,3;
```

| c_country | c_class | sum  |
|-----------|---------|------|
| Region A  | 1       | 800  |
| Region A  | 2       | 200  |
| Region A  | (Null)  | 1000 |
| Region B  | 1       | 100  |
| Region B  | (Null)  | 100  |
| Region C  | 1       | 200  |
| Region C  | (Null)  | 200  |
| Region D  | 1       | 100  |
| Region D  | (Null)  | 100  |
| (Null)    | (Null)  | 1400 |

Total Records: 10

The preceding statement is equivalent to:

```
SELECT c_country, c_class, SUM(c_balance) FROM customer GROUP BY c_country, c_class UNION ALL
SELECT c_country, null, SUM(c_balance) FROM customer GROUP BY c_country
UNION ALL
SELECT null, null, SUM(c_balance) FROM customer ORDER BY 1,2,3;
```

- **CUBE:**

CUBE can be understood as all dimensions, that is, all combinations of columns in the aggregation key.

```
-- Perform GROUP BY on (c_country,c_class), (c_country), and (c_class) in sequence, and on the entire table.
SELECT c_country, c_class, SUM(c_balance) FROM customer GROUP BY CUBE(c_country, c_class)
ORDER BY 1,2,3;
```

| c_country | c_class | sum  |
|-----------|---------|------|
| Region A  | 1       | 800  |
| Region A  | 2       | 200  |
| Region A  | (Null)  | 1000 |
| Region B  | 1       | 100  |
| Region B  | (Null)  | 100  |
| Region C  | 1       | 200  |
| Region C  | (Null)  | 200  |
| Region D  | 1       | 100  |
| Region D  | (Null)  | 100  |
| (Null)    | 1       | 1200 |
| (Null)    | 2       | 200  |
| (Null)    | (Null)  | 1400 |

Total Records: 12

The preceding statement is equivalent to:

```
SELECT c_country, c_class, SUM(c_balance) FROM customer GROUP BY c_country, c_class
union all
SELECT c_country, null, SUM(c_balance) FROM customer GROUP BY c_country
union all
SELECT null, null, SUM(c_balance) FROM customer
union all
SELECT NULL, c_class, SUM(c_balance) FROM customer GROUP BY c_class order by 1,2,3;
```

- **GROUPING SETS:**

**GROUPING SETS** is different from **ROLLUP** and **CUBE**. It extracts some records from the results of **ROLLUP** and **CUBE**.

```
-- Perform GROUP BY on (c_class) and (c_country) separately.
SELECT c_country, c_class, SUM(c_balance) FROM customer GROUP BY GROUPING SETS(c_country,
c_class) ORDER BY 1,2,3;
```

| c_country | c_class | sum  |
|-----------|---------|------|
| Region A  | (Null)  | 1000 |
| Region B  | (Null)  | 100  |
| Region C  | (Null)  | 200  |
| Region D  | (Null)  | 100  |
| (Null)    | 1       | 1200 |
| (Null)    | 2       | 200  |

Total Records: 6

The preceding statement is equivalent to:

```
SELECT c_country, null, SUM(c_balance) FROM customer GROUP BY c_country
UNION ALL
SELECT null, c_class, sum(c_balance) FROM customer GROUP BY c_class ORDER BY 1,2,3;
```

## 21.16.3 SELECT INTO

### Function

**SELECT INTO** defines a new table based on a query result and insert data obtained by query to the new table.

Different from **SELECT**, data found by **SELECT INTO** is not returned to the client. The table columns have the same names and data types as the output columns of the **SELECT**.

### Precautions

**CREATE TABLE AS** provides functions similar to **SELECT INTO** in functions and provides a superset of functions provided by **SELECT INTO**. You are advised to replace **SELECT INTO** with **CREATE TABLE AS** because **SELECT INTO** cannot be used in stored procedures and **SELECT INTO (column)** cannot receive blank rows.

### Syntax

```
[WITH [RECURSIVE] with_query [, ...]]
SELECT [ALL | DISTINCT [ON (expression [, ...])]]
 { * | {expression [[AS] output_name] [, ...] }
 INTO [[GLOBAL | LOCAL | VOLATILE] { TEMPORARY | TEMP } | UNLOGGED] [TABLE] new_table
 [FROM from_item [, ...]]
 [WHERE condition]
 [GROUP BY expression [, ...]]
 [HAVING condition [, ...]]
 [WINDOW {window_name AS (window_definition)} [, ...]]
 [{ UNION | INTERSECT | EXCEPT | MINUS } [ALL | DISTINCT] select]
 [ORDER BY {expression [[ASC | DESC | USING operator] | nlssort_expression_clause } [NULLS { FIRST |
LAST }]} [, ...]]
 [{ [LIMIT { count | ALL }] [OFFSET start [ROW | ROWS]] | { LIMIT start, { count | ALL } }]
```

```
[FETCH { FIRST | NEXT } [count] { ROW | ROWS } ONLY]
[{FOR { UPDATE | SHARE } [OF table_name [, ...]] [NOWAIT]} [...]];
```

## Parameter Description

**INTO** [ [ **GLOBAL** | **LOCAL** | **VOLATILE** ] { **TEMPORARY** | **TEMP** } | **UNLOGGED** ]  
[ **TABLE** ] **new\_table**

[ **GLOBAL** | **LOCAL** | **VOLATILE** ] { **TEMPORARY** | **TEMP** } specifies the type of a temporary table. For details, see the description of **GLOBAL** | **LOCAL** | **VOLATILE** in [Parameter Description](#).

**UNLOGGED** indicates that the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead log, which makes them considerably faster than ordinary tables. However, they are not crash-safe: an unlogged table is automatically truncated after a crash or unclean shutdown. The contents of an unlogged table are also not replicated to standby servers. Any indexes created on an unlogged table are automatically unlogged as well.

**new\_table** specifies the name of the new table.

### NOTE

For details about other **SELECT INTO** parameters, see [SELECT Main Clause Parameters](#) in **SELECT**.

## Examples

Add values whose **TABLE\_SK** is less than 3 in the **reason\_t** table to the new table.

```
CREATE TABLE reason_t
(
 TABLE_SK INTEGER ,
 TABLE_ID VARCHAR(20) ,
 TABLE_NA VARCHAR(20)
);
INSERT INTO reason_t VALUES (1, 'S01', 'StudentA'), (2, 'T01', 'TeacherA'), (3, 'T02', 'TeacherB'), (3, 'S02', 'StudentB');

SELECT * INTO reason_t_bck FROM reason_t WHERE TABLE_SK < 3;
INSERT 0 2
```

# 21.17 TCL Syntax

## 21.17.1 TCL Syntax Overview

Transaction Control Language (TCL) controls the time and effect of database transactions and monitors the database.

### Commit

DWS uses the **COMMIT** or **END** statement to commit transactions. For details, see [COMMIT](#) | [END](#).

## Setting a Savepoint

DWS creates a new savepoint in the current transaction. For details, see [SAVEPOINT](#).

## Rollback

DWS rolls back the current transaction to the last committed state. For details, see [ROLLBACK](#).

## 21.17.2 ABORT

### Function

**ABORT** rolls back the current transaction and cancels the changes in the transaction.

This command is equivalent to [ROLLBACK](#), and is present only for historical reasons. Now **ROLLBACK** is recommended.

### Precautions

**ABORT** has no impact outside a transaction, but will provoke a warning.

### Syntax

```
ABORT [WORK | TRANSACTION] ;
```

### Parameter Description

**WORK | TRANSACTION**

This keyword is optional and does not affect the **ABORT** operation.

### Examples

Abort a transaction. Performed update operations will be undone.

```
ABORT;
```

### Helpful Links

[SET TRANSACTION](#), [COMMIT | END](#), [ROLLBACK](#)

## 21.17.3 BEGIN

### Function

**BEGIN** may be used to initiate an anonymous block or a single transaction. This section describes the syntax of **BEGIN** used to initiate an anonymous block. For details about the **BEGIN** syntax that initiates transactions, see [START TRANSACTION](#).

An anonymous block is a structure that can dynamically create and execute stored procedure code instead of permanently storing code as a database object in the database.

## Precautions

None

## Syntax

- Enable an anonymous block:  

```
[DECLARE [declare_statements]]
BEGIN
execution_statements
END;
/
```
- -- Start a transaction:  

```
BEGIN [WORK | TRANSACTION]
[
 {
 ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE
 READ }
 | { READ WRITE | READ ONLY }
 } [, ...]
];
```

## Parameter Description

Table 21-309 BEGIN parameters

| Parameter            | Description                                                                           | Value Range                    |
|----------------------|---------------------------------------------------------------------------------------|--------------------------------|
| declare_statements   | Declares a variable, including its name and type, for example, <b>sales_cnt int</b> . | -                              |
| execution_statements | Specifies the statement to be executed in an anonymous block.                         | Use an existing function name. |

## Examples

- Start a transaction block.  

```
BEGIN;
```
- Start a transaction block at the REPEATABLE READ isolation level.  

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```
- Generate a string using an anonymous block.  

```
BEGIN
dbms_output.put_line('Hello');
END;
/
```

## Helpful Links

[START TRANSACTION](#)

## 21.17.4 CHECKPOINT

### Function

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to a disk.

**CHECKPOINT** forces a transaction log checkpoint. By default, WALs periodically specify checkpoints in a transaction log. You may use **gs\_guc** to specify run-time parameters **checkpoint\_segments** and **checkpoint\_timeout** to adjust the atomized checkpoint intervals.

### Precautions

- Only a system administrator has the permission to call **CHECKPOINT**.
- CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system.

### Syntax

```
CHECKPOINT;
```

### Parameter Description

None

### Examples

Set a checkpoint:

```
CHECKPOINT;
```

## 21.17.5 COMMIT | END

### Function

**COMMIT** or **END** commits all operations of a transaction.

### Precautions

Only the transaction creators or system administrators can run the **COMMIT** command. The creation and commit operations must be in different sessions.

### Syntax

```
{ COMMIT | END } [WORK | TRANSACTION] ;
```

## Parameter Description

**Table 21-310** COMMIT | END parameters

| Parameter          | Description                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------|
| COMMIT   END       | Commits the current transaction and make all changes made by the transaction become visible to others. |
| WORK   TRANSACTION | The keyword is optional and only improves readability, with no effect on transaction commitment.       |

## Examples

Commit the transaction to make all changes permanent:

```
COMMIT;
```

## Helpful Links

[ROLLBACK](#)

## 21.17.6 COMMIT PREPARED

### Function

**COMMIT PREPARED** commits a prepared two-phase transaction.

### Precautions

- The function is only available in maintenance mode (when GUC parameter **xc\_maintenance\_mode** is **on**). Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.
- Only the transaction creators or system administrators can run the **COMMIT** command. The creation and commit operations must be in different sessions.
- The transaction function is maintained automatically by the database, and should be not visible to users.

### Syntax

```
COMMIT PREPARED transaction_id ;
COMMIT PREPARED transaction_id WITH CSN;
```

## Parameter Description

**Table 21-311** COMMIT PREPARED parameters

| Parameter                   | Description                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| transaction_id              | Identifier of the transaction to be committed. The identifier cannot be the same as any identifier used by the current prepared transaction. |
| CSN(commit sequence number) | Sequence number of the transaction to be committed. The value is a 64-bit ascending unsigned number.                                         |

## Helpful Links

[PREPARE TRANSACTION](#), [ROLLBACK PREPARED](#)

## 21.17.7 PREPARE TRANSACTION

### Function

**PREPARE TRANSACTION** prepares the current transaction for two-phase commit.

After this command, the transaction is no longer associated with the current session; instead, its state is fully stored on disk, and there is a high probability that it can be committed successfully, even if a database crash occurs before the commit is requested.

Once prepared, a transaction can later be committed or rolled back with **COMMIT PREPARED** or **ROLLBACK PREPARED**, respectively. Those commands can be issued from any session, not only the one that executed the original transaction.

From the point of view of the issuing session, **PREPARE TRANSACTION** is not unlike a **ROLLBACK** command: after executing it, there is no active current transaction, and the effects of the prepared transaction are no longer visible. (The effects will become visible again if the transaction is committed.)

If the **PREPARE TRANSACTION** command fails for any reason, it becomes a **ROLLBACK** and the current transaction is canceled.

### Precautions

- The transaction function is maintained automatically by the database, and should be not visible to users.
- When running the **PREPARE TRANSACTION** command, increasing the value of **max\_prepared\_transactions** in configuration file **postgresql.conf**. You are advised to set **max\_prepared\_transactions** to a value not less than that of **max\_connections** so that one pending prepared transaction is available for each session.

## Syntax

```
PREPARE TRANSACTION transaction_id;
```

## Parameter Description

### transaction\_id

An arbitrary identifier that later identifies this transaction for **COMMIT PREPARED** or **ROLLBACK PREPARED**. The identifier must be different from those for current prepared transactions.

Value range: The identifier must be written as a string literal, and must be less than 200 bytes long.

## Helpful Links

[COMMIT PREPARED](#), [ROLLBACK PREPARED](#)

## 21.17.8 SAVEPOINT

### Function

**SAVEPOINT** establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that rolls back all commands that are executed after the savepoint was established, restoring the transaction state to what it was at the time of the savepoint.

### Precautions

- Use **ROLLBACK TO SAVEPOINT** to roll back to a savepoint. Use **RELEASE SAVEPOINT** to destroy a savepoint but keep the effects of the commands executed after the savepoint was established.
- Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.
- **SAVEPOINT** cannot be used for functions, anonymous blocks, or stored procedures.
- In the case of an unexpected termination of a distributed thread or process caused by a node or connection failure, or of an error caused by the inconsistency between source and destination table structures in a COPY FROM operation, the transaction cannot be rolled back to the established savepoint. Instead, the entire transaction will be rolled back.
- According to the SQL standard, a savepoint is destroyed automatically when another savepoint with the same name is established. In DWS, old savepoints are kept, though only the most recent one will be used for rollback or release. Releasing the newer savepoint with **RELEASE SAVEPOINT** will cause the older one to again become accessible to **ROLLBACK TO SAVEPOINT** and **RELEASE SAVEPOINT**. Except for this, **SAVEPOINT** is fully SQL conforming.

## Syntax

```
SAVEPOINT savepoint_name;
```

## Parameter Description

### **savepoint\_name**

Specifies the name of a new savepoint.

## Examples

- Create a savepoint and undo all commands executed after the savepoint is created:

```
START TRANSACTION;
INSERT INTO table1 VALUES (1);
SAVEPOINT my_savepoint;
INSERT INTO table1 VALUES (2);
ROLLBACK TO SAVEPOINT my_savepoint;
INSERT INTO table1 VALUES (3);
COMMIT;
```

Query the table content, which should contain 1 and 3 but not 2, because 2 has been rolled back.

- Create and then destroy a savepoint.

```
START TRANSACTION;
INSERT INTO table1 VALUES (3);
SAVEPOINT my_savepoint;
INSERT INTO table1 VALUES (4);
RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

Query the table content, which should contain both 3 and 4.

## 21.17.9 SET TRANSACTION

### Function

**SET TRANSACTION** sets the characteristics of the current transaction. It has no effect on any subsequent transactions. Available transaction characteristics include the transaction separation level and transaction access mode (read/write or read only).

### Precautions

None

### Syntax

Set the isolation level and access mode of the transaction.

```
{ SET [LOCAL] TRANSACTION|SET SESSION CHARACTERISTICS AS TRANSACTION }
{ ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
| { READ WRITE | READ ONLY } } [, ...]
```

## Parameter Description

**Table 21-312** SET TRANSACTION parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCAL                  | Indicates that the specified command takes effect only for the current transaction.                                                                                                                                                                                                                                                                                          | -                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| SESSION                | Indicates that the specified command takes effect only for the current session.                                                                                                                                                                                                                                                                                              | A string, which must comply with the naming convention.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ISOLATION LEVEL        | <p>Specifies the transaction isolation level that determines the data that a transaction can view if other concurrent transactions exist.</p> <p><b>NOTE</b><br/>The isolation level of a transaction cannot be reset after the first clause (<b>INSERT</b>, <b>DELETE</b>, <b>UPDATE</b>, <b>FETCH</b>, <b>COPY</b>) for modifying data is executed in the transaction.</p> | <ul style="list-style-type: none"><li>• <b>READ COMMITTED</b>: Only committed data is read. The default value is <b>READ COMMITTED</b>.</li><li>• <b>READ UNCOMMITTED</b>: DWS does not support <b>READ UNCOMMITTED</b>. If <b>READ UNCOMMITTED</b> is set, <b>READ COMMITTED</b> is executed instead.</li><li>• <b>REPEATABLE READ</b>: Only the data committed before transaction start is read. Uncommitted data or data committed in other concurrent transactions cannot be read.</li><li>• <b>SERIALIZABLE</b>: DWS does not support <b>SERIALIZABLE</b>. If <b>SERIALIZABLE</b> is set, <b>REPEATABLE READ</b> is executed instead.</li></ul> |
| READ WRITE   READ ONLY | Specifies the transaction access mode.                                                                                                                                                                                                                                                                                                                                       | Read-write mode or read-only mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Examples

Set the isolation level of the current transaction to **READ COMMITTED** and the access mode to **READ ONLY**:

```
START TRANSACTION;
SET LOCAL TRANSACTION ISOLATION LEVEL READ COMMITTED READ ONLY;
COMMIT;
```

# 21.17.10 START TRANSACTION

## Function

**START TRANSACTION** starts a transaction. If the isolation level, read/write mode, or deferrable mode is specified, a new transaction will have those characteristics. You can also specify them using [SET TRANSACTION](#).

## Precautions

None

## Syntax

Format 1: START TRANSACTION

```
START TRANSACTION
[
{
ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
| { READ WRITE | READ ONLY }
} [, ...]
];
```

Format 2: BEGIN

```
BEGIN [WORK | TRANSACTION]
[
{
ISOLATION LEVEL { READ COMMITTED | READ UNCOMMITTED | SERIALIZABLE | REPEATABLE READ }
| { READ WRITE | READ ONLY }
} [, ...]
];
```

## Parameter Description

Table 21-313 START TRANSACTION parameters

| Parameter          | Description                                                                       | Value Range |
|--------------------|-----------------------------------------------------------------------------------|-------------|
| WORK   TRANSACTION | Optional keyword in the <b>BEGIN</b> format, which does not affect the operation. | -           |

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                  | Value Range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| READ WRITE<br>  READ ONLY | Transaction access mode.                                                                                                                                                                                                                                                                                                                                                     | Read-write mode or read-only mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Examples

- Start a transaction in default mode.  

```
START TRANSACTION;
SELECT * FROM tpceds.reason;
END;
```
- Start a transaction with the isolation level being **READ COMMITTED** and the access mode being **READ WRITE**:  

```
START TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
SELECT * FROM tpceds.reason;
COMMIT;
```

## Helpful Links

[COMMIT | END, ROLLBACK, SET TRANSACTION](#)

## 21.17.11 ROLLBACK

### Function

Rolls back the current transaction and backs out all updates in the transaction.

**ROLLBACK** backs out of all changes that a transaction makes to a database if the transaction fails to be executed due to a fault.

### Precautions

If a **ROLLBACK** statement is executed out of a transaction, no error occurs, but a warning information is displayed.

## Syntax

```
ROLLBACK [WORK | TRANSACTION];
```

## Parameter Description

### WORK | TRANSACTION

This keyword is optional and only improves readability, with no effect on the **ROLLBACK** operation.

## Examples

Undo all changes in the current transaction:

```
ROLLBACK;
```

## Helpful Links

[COMMIT | END](#)

## 21.17.12 RELEASE SAVEPOINT

### Function

**RELEASE SAVEPOINT** destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands executed after the savepoint was established. To do that, use **ROLLBACK TO SAVEPOINT**. Destroying a savepoint when it is no longer needed allows the system to reclaim some resources earlier than transaction end.

**RELEASE SAVEPOINT** also destroys all savepoints that were established after the named savepoint was established.

### Precautions

- Specifying a savepoint name that was not previously defined causes an error.
- It is not possible to release a savepoint when the transaction is in an aborted state.
- If multiple savepoints have the same name, only the one that was most recently defined is released.

## Syntax

```
RELEASE [SAVEPOINT] savepoint_name;
```

## Parameter Description

### *savepoint\_name*

Specifies the name of the savepoint you want to destroy.

## Examples

Create and then destroy a savepoint:

```
BEGIN;
 INSERT INTO tpcds.table1 VALUES (3);
 SAVEPOINT my_savepoint;
 INSERT INTO tpcds.table1 VALUES (4);
 RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

## 21.17.13 ROLLBACK PREPARED

### Function

**ROLLBACK PREPARED** cancels a transaction ready for two-phase committing.

### Precautions

- The function is only available in maintenance mode (when GUC parameter **xc\_maintenance\_mode** is **on**). Exercise caution when enabling the mode. It is used by maintenance engineers for troubleshooting. Common users should not use the mode.
- Only the user that initiates a transaction or the system administrator can roll back the transaction.
- The transaction function is maintained automatically by the database, and should be not visible to users.

### Syntax

```
ROLLBACK PREPARED transaction_id ;
```

### Parameter Description

**transaction\_id**

Specifies the identifier of the transaction to be submitted. The identifier must be different from those for current prepared transactions.

## 21.17.14 ROLLBACK TO SAVEPOINT

### Function

**ROLLBACK TO SAVEPOINT** rolls back to a savepoint. It implicitly destroys all savepoints that were established after the named savepoint.

Rolls back all commands that were executed after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

## Precautions

- Specifying a savepoint name that has not been established is an error.
- Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a **FETCH** or **MOVE** command inside a savepoint that is later rolled back, the cursor remains at the position that **FETCH** left it pointing to (that is, the cursor motion caused by **FETCH** is not rolled back). Closing a cursor is not undone by rolling back, either. A cursor whose execution causes a transaction to abort is put in a cannot-execute state, so while the transaction can be restored using **ROLLBACK TO SAVEPOINT**, the cursor can no longer be used.
- Use **ROLLBACK TO SAVEPOINT** to roll back to a savepoint. Use **RELEASE SAVEPOINT** to destroy a savepoint but keep the effects of the commands executed after the savepoint was established.

## Syntax

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] savepoint_name;
```

## Parameter Description

### **savepoint\_name**

Rolls back the name of the specified savepoint.

## Examples

Undo the effects of the commands executed after my\_savepoint was established.

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by savepoint rollback:

```
BEGIN;
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
SAVEPOINT foo;
FETCH 1 FROM foo;
?column?

1
ROLLBACK TO SAVEPOINT foo;
FETCH 1 FROM foo;
?column?

2
COMMIT;
```
