<b>1 Database System Overview.....</b>	<b>1</b>
1.1 Database Logical Architecture.....	1
1.2 Query Request Handling Process.....	3
1.3 Managing Transactions.....	3
1.4 Concepts.....	6
<b>2 Database Security.....</b>	<b>8</b>
2.1 Users and Permissions.....	8
2.1.1 Default Permission Mechanism.....	8
2.1.2 Administrators.....	9
2.1.3 Separation of Duties.....	11
2.1.4 Users.....	13
2.1.5 Roles.....	14
2.1.6 Schemas.....	16
2.1.7 User Permissions.....	17
2.1.8 Row-Level Security Policy.....	18
2.2 Database Audit.....	20
<b>3 Database Quick Start.....</b>	<b>22</b>
3.1 Connecting to a Database.....	22
3.1.1 Using gsql to Connect to a Database.....	22
3.1.2 APIs.....	22
3.2 Operating a Database.....	23
3.2.1 Creating a Database Account.....	23
3.2.2 Creating and Managing Databases.....	24
3.2.3 Creating and Managing Tablespaces.....	26
3.2.4 Creating and Managing Tables.....	28
3.2.4.1 Creating a Table.....	28
3.2.4.2 Inserting Data to a Table.....	29
3.2.4.3 Updating Data in a Table.....	32
3.2.4.4 Viewing Data.....	33
3.2.4.5 Deleting Data from a Table.....	34
3.2.5 Querying System Catalogs.....	34
3.2.6 Other Operations.....	36

3.2.6.1 Creating and Managing Schemas.....	36
3.2.6.2 Creating and Managing Partitioned Tables.....	39
3.2.6.3 Creating and Managing Indexes.....	44
3.2.6.4 Creating and Managing Views.....	47
3.2.6.5 Creating and Managing Sequences.....	48
<b>4 Development and Design Proposal.....</b>	<b>50</b>
4.1 Overview.....	50
4.2 Database Object Naming Conventions.....	50
4.3 Database Object Design.....	51
4.3.1 Database and Schema Design.....	51
4.3.2 Table Design.....	52
4.3.3 Column Design.....	54
4.3.4 Constraint Design.....	54
4.3.5 View and Joined Table Design.....	55
4.4 Tool Interconnection.....	55
4.4.1 JDBC Configuration.....	55
4.5 SQL Compilation.....	57
<b>5 Application Development Guide.....</b>	<b>61</b>
5.1 Development Specifications.....	61
5.2 Obtaining the Driver Package.....	62
5.3 Development Based on JDBC.....	62
5.3.1 JDBC Package, Driver Class, and Environment Class.....	63
5.3.2 Development Process.....	65
5.3.3 Loading a Driver.....	65
5.3.4 Connecting to a Database.....	66
5.3.5 Connecting to a Database (Using SSL).....	77
5.3.6 Connecting to a Database (Using UDS).....	80
5.3.7 Running SQL Statements.....	81
5.3.8 Processing Data in a Result Set.....	86
5.3.9 Closing a Connection.....	89
5.3.10 Log Management.....	89
5.3.11 Examples: Common Operations.....	93
5.3.12 Example: Retrying SQL Queries for Applications.....	98
5.3.13 Example: Importing and Exporting Data Through Local Files.....	101
5.3.14 Example: Migrating Data from MY.....	103
5.3.15 Example: Logical Replication Code.....	104
5.3.16 Example: Parameters for Connecting to the Database in Different Scenarios.....	111
5.3.17 JDBC API Reference.....	113
5.3.17.1 java.sql.Connection.....	113
5.3.17.2 java.sql.CallableStatement.....	116
5.3.17.3 java.sql.DatabaseMetaData.....	117
5.3.17.4 java.sql.Driver.....	126

5.3.17.5 java.sql.PreparedStatement.....	127
5.3.17.6 java.sql.ResultSet.....	130
5.3.17.7 java.sql.ResultSetMetaData.....	137
5.3.17.8 java.sql.Statement.....	139
5.3.17.9 javax.sql.ConnectionPoolDataSource.....	141
5.3.17.10 javax.sql.DataSource.....	141
5.3.17.11 javax.sql.PooledConnection.....	142
5.3.17.12 javax.naming.Context.....	142
5.3.17.13 javax.naming.spi.InitialContextFactory.....	143
5.3.17.14 CopyManager.....	143
5.3.17.15 PGReplicationConnection.....	145
5.3.17.16 PGReplicationStream.....	145
5.3.17.17 ChainedStreamBuilder.....	147
5.3.17.18 ChainedCommonStreamBuilder.....	148
5.3.17.19 PGObject.....	149
5.3.18 Common JDBC Parameters.....	149
5.3.19 Troubleshooting.....	153
5.3.19.1 Incorrect batchSize Settings.....	153
5.3.20 Mapping for JDBC Data Types.....	154
5.4 Development Based on ODBC.....	155
5.4.1 ODBC Packages, Dependent Libraries, and Header Files.....	157
5.4.2 Development Process.....	157
5.4.3 Configuring a Data Source in the Linux OS.....	159
5.4.4 Configuring a Data Source in the Windows OS.....	170
5.4.5 Example: Common Functions and Batch Binding.....	174
5.4.6 Typical Application Scenarios and Configurations.....	181
5.4.7 ODBC Interface Reference.....	189
5.4.7.1 SQLAllocEnv.....	189
5.4.7.2 SQLAllocConnect.....	189
5.4.7.3 SQLAllocHandle.....	190
5.4.7.4 SQLAllocStmnt.....	191
5.4.7.5 SQLBindCol.....	191
5.4.7.6 SQLBindParameter.....	192
5.4.7.7 SQLColAttribute.....	194
5.4.7.8 SQLConnect.....	195
5.4.7.9 SQLDisconnect.....	196
5.4.7.10 SQLExecDirect.....	197
5.4.7.11 SQLExecute.....	198
5.4.7.12 SQLFetch.....	199
5.4.7.13 SQLFreeStmnt.....	200
5.4.7.14 SQLFreeConnect.....	200
5.4.7.15 SQLFreeHandle.....	200

5.4.7.16 SQLFreeEnv.....	201
5.4.7.17 SQLPrepare.....	201
5.4.7.18 SQLGetData.....	202
5.4.7.19 SQLGetDiagRec.....	203
5.4.7.20 SQLSetConnectAttr.....	206
5.4.7.21 SQLSetEnvAttr.....	207
5.4.7.22 SQLSetStmtAttr.....	208
5.5 Development Based on libpq.....	209
5.5.1 libpq Package, Dependent Library, and Header File.....	209
5.5.2 Development Process.....	209
5.5.3 Examples.....	210
5.5.4 libpq API Reference.....	216
5.5.4.1 Database Connection Control Functions.....	216
5.5.4.1.1 PQconnectdbParams.....	216
5.5.4.1.2 PQconnectdb.....	217
5.5.4.1.3 PQconninfoParse.....	217
5.5.4.1.4 PQconnectStart.....	218
5.5.4.1.5 PQerrorMessage.....	218
5.5.4.1.6 PQsetdbLogin.....	219
5.5.4.1.7 PQfinish.....	220
5.5.4.1.8 PQreset.....	220
5.5.4.1.9 PQstatus.....	221
5.5.4.2 Database Statement Execution Functions.....	222
5.5.4.2.1 PQclear.....	222
5.5.4.2.2 PQexec.....	223
5.5.4.2.3 PQexecParams.....	224
5.5.4.2.4 PQexecParamsBatch.....	224
5.5.4.2.5 PQexecPrepared.....	225
5.5.4.2.6 PQexecPreparedBatch.....	226
5.5.4.2.7 PQfname.....	227
5.5.4.2.8 PQgetvalue.....	228
5.5.4.2.9 PQnfields.....	228
5.5.4.2.10 PQntuples.....	229
5.5.4.2.11 PQprepare.....	230
5.5.4.2.12 PQresultStatus.....	231
5.5.4.3 Functions for Asynchronous Command Processing.....	232
5.5.4.3.1 PQsendQuery.....	232
5.5.4.3.2 PQsendQueryParams.....	233
5.5.4.3.3 PQsendPrepare.....	234
5.5.4.3.4 PQsendQueryPrepared.....	235
5.5.4.3.5 PQflush.....	236
5.5.4.4 Functions for Canceling Queries in Progress.....	237

5.5.4.4.1 PQgetCancel.....	237
5.5.4.4.2 PQfreeCancel.....	237
5.5.4.4.3 PQcancel.....	238
5.5.5 Connection Parameters.....	239
5.6 Psycopg-based Development.....	244
5.6.1 Development Process.....	245
5.6.2 Development Procedure.....	246
5.6.3 Examples: Common Operations.....	248
5.6.4 Psycopg API Reference.....	250
5.6.4.1 psycopg2.connect().....	250
5.6.4.2 connection.cursor().....	252
5.6.4.3 cursor.execute(query,vars_list).....	253
5.6.4.4 curosr.executemany(query,vars_list).....	253
5.6.4.5 connection.commit().....	254
5.6.4.6 connection.rollback().....	255
5.6.4.7 cursor.fetchone().....	255
5.6.4.8 cursor.fetchall().....	256
5.6.4.9 cursor.close().....	256
5.6.4.10 connection.close().....	256
5.7 Development Based on the Go Driver.....	257
5.7.1 Setting Up the Go Driver Environment.....	257
5.7.2 Development Process.....	258
5.7.3 Connecting to a Database.....	259
5.7.4 Connecting to a Database (Using SSL).....	266
5.7.5 Go APIs.....	267
5.7.5.1 sql.Open.....	267
5.7.5.2 type DB.....	268
5.7.5.3 type Stmt.....	270
5.7.5.4 type Tx.....	274
5.7.5.5 type Rows.....	276
5.7.5.6 type Row.....	276
5.7.5.7 type ColumnType.....	277
5.7.5.8 type Result.....	277
5.8 ECPG-based Development.....	278
5.8.1 Development Process.....	279
5.8.2 ecpg Components.....	280
5.8.3 ecpg Preprocessing and Compiling.....	281
5.8.4 Managing Database Connections.....	282
5.8.4.1 Connecting to a Database.....	282
5.8.4.2 Managing Connections.....	283
5.8.5 Running SQL Commands.....	284
5.8.5.1 Executing SQL Statements.....	284

5.8.5.2 Using Cursors.....	285
5.8.5.3 Managing Transactions.....	286
5.8.5.4 Prepared Statements.....	286
5.8.5.5 Embedded SQL Commands.....	287
5.8.5.5.1 ALLOCATE DESCRIPTOR.....	287
5.8.5.5.2 CONNECT.....	287
5.8.5.5.3 DEALLOCATE DESCRIPTOR.....	290
5.8.5.5.4 DECLARE.....	290
5.8.5.5.5 DESCRIBE.....	291
5.8.5.5.6 DISCONNECT.....	292
5.8.5.5.7 EXECUTE IMMEDIATE.....	293
5.8.5.5.8 GET DESCRIPTOR.....	293
5.8.5.5.9 OPEN.....	295
5.8.5.5.10 PREPARE.....	295
5.8.5.5.11 SET AUTOCOMMIT.....	296
5.8.5.5.12 SET CONNECTION.....	296
5.8.5.5.13 SET DESCRIPTOR.....	297
5.8.5.5.14 TYPE.....	298
5.8.5.5.15 VAR.....	299
5.8.5.5.16 WHENEVER.....	300
5.8.6 Querying the Result Set.....	300
5.8.7 Closing a Database Connection.....	301
5.8.8 Host Variables.....	301
5.8.8.1 Overview.....	302
5.8.8.2 DECLARE Section.....	302
5.8.8.3 Retrieving Query Results.....	302
5.8.8.4 Type Mapping.....	303
5.8.8.5 Handling Character Strings.....	304
5.8.8.6 Host Variables with Non-Primitive Types.....	305
5.8.8.7 Accessing Special Data Types.....	307
5.8.8.8 Handling Non-Primitive SQL Data Types.....	309
5.8.9 Executing Dynamic SQL Statements.....	312
5.8.9.1 Executing a Statement Without a Result Set.....	312
5.8.9.2 Executing a Statement with Input Parameters.....	312
5.8.9.3 Executing a Statement with a Result Set.....	312
5.8.10 Error Handling.....	313
5.8.10.1 Setting Callbacks.....	313
5.8.10.2 sqlca.....	314
5.8.10.3 SQLSTATE and SQLCODE.....	316
5.8.11 Preprocessor Directives.....	320
5.8.11.1 Including Files.....	320
5.8.11.2 Directives: ifdef, ifndef, else, elif, and endif.....	320

5.8.11.3 Directives: define and undef.....	320
5.8.12 Using Library Functions.....	321
5.8.13 SQL Descriptor Area.....	323
5.8.13.1 Named SQLDA.....	323
5.8.13.2 C-Structure SQLDA.....	324
5.8.14 Examples.....	328
5.8.15 ECPG API Reference.....	335
5.8.15.1 Interval Type.....	335
5.8.15.2 Numeric Type.....	336
5.8.15.3 Date Type.....	341
5.8.15.4 Timestamp Type.....	345
5.9 Debugging.....	348
<b>6 SQL Optimization.....</b>	<b>353</b>
6.1 Query Execution Process.....	353
6.2 Introduction to the SQL Execution Plan.....	356
6.2.1 Overview.....	356
6.2.2 Description.....	358
6.3 Optimization Process.....	365
6.4 Updating Statistics.....	365
6.5 Reviewing and Modifying a Table Definition.....	367
6.5.1 Overview.....	367
6.5.2 Using Partitioned Tables.....	367
6.5.3 Selecting a Data Type.....	368
6.6 Typical SQL Optimization Methods.....	368
6.6.1 Optimizing SQL Self-Diagnosis.....	368
6.6.2 Optimizing Subqueries.....	369
6.6.3 Optimizing Statistics.....	377
6.6.4 Optimizing Operators.....	379
6.7 Experience in Rewriting SQL Statements.....	381
6.8 Configuring Key Parameters for SQL Tuning.....	382
6.9 Hint-based Tuning.....	385
6.9.1 Plan Hint Optimization.....	385
6.9.2 Hint Specifying the Query Block Where the Hint Is Located.....	390
6.9.3 Hint Specifying the Query Block and Schema of a Table.....	394
6.9.4 Join Order Hints.....	395
6.9.5 Join Operation Hints.....	396
6.9.6 Rows Hints.....	397
6.9.7 Stream Operation Hints.....	398
6.9.8 Scan Operation Hints.....	399
6.9.9 Sublink Name Hints.....	401
6.9.10 Hint Errors, Conflicts, and Other Warnings.....	402
6.9.11 Optimizer GUC Parameter Hints.....	404

6.9.12 Hint for Selecting the Custom Plan or Generic Plan.....	404
6.9.13 Hints Specifying Not to Expand Subqueries.....	405
6.9.14 Hint Specifying Not to Use Global Plan Cache.....	406
6.9.15 Hint of Parameterized Paths at the Same Level.....	407
6.9.16 Hint for Setting Slow SQL Control Rules.....	409
6.9.17 Hint for Adaptive Plan Selection.....	409
6.9.18 Hint for Materializing a Sub-plan Result.....	410
6.9.19 Bitmap Scan Hints.....	411
6.9.20 Hint for Inner Table Materialization During Join.....	411
6.9.21 AGG Hint.....	412
6.10 Introduction to Plan Trace.....	413
6.11 Tuning with SQL PATCH.....	416
6.12 Optimization Cases.....	422
6.12.1 Case: Modifying the GUC Parameter rewrite_rule.....	422
6.12.2 Case: Creating an Appropriate Index.....	426
6.12.3 Case: Adding NOT NULL for the JOIN Column.....	427
6.12.4 Case: Modifying a Partitioned Table.....	428
6.12.5 Case: Rewriting SQL and Deleting Subqueries (1).....	428
6.12.6 Case: Rewriting SQL Statements and Deleting in-clause.....	429
<b>7 SQL Reference.....</b>	<b>432</b>
7.1 SQL.....	432
7.2 Keywords.....	433
7.3 Data Types.....	470
7.3.1 Numeric Types.....	470
7.3.2 Monetary Types.....	477
7.3.3 Boolean Types.....	478
7.3.4 Character Types.....	479
7.3.5 Binary Types.....	482
7.3.6 Date/Time Types.....	484
7.3.7 Geometric.....	494
7.3.8 Network Address Types.....	497
7.3.9 Bit String Types.....	499
7.3.10 UUID.....	500
7.3.11 JSON/JSONB Types.....	500
7.3.12 HLL.....	505
7.3.13 Range.....	509
7.3.14 Object Identifier Types.....	514
7.3.15 Pseudo-Types.....	516
7.3.16 XML Type.....	517
7.3.17 XMLType.....	520
7.3.18 SET Type.....	522
7.3.19 ACLItem.....	523

7.3.20 Array Types.....	524
7.4 Constant and Macro.....	529
7.5 Functions and Operators.....	530
7.5.1 Logical Operators.....	531
7.5.2 Comparison Operators.....	531
7.5.3 Character Processing Functions and Operators.....	532
7.5.4 Binary String Functions and Operators.....	567
7.5.5 Bit String Functions and Operators.....	571
7.5.6 Pattern Matching Operators.....	573
7.5.7 Arithmetic Functions and Operators.....	578
7.5.8 Date and Time Processing Functions and Operators.....	595
7.5.9 Type Conversion Functions.....	626
7.5.10 Geometric Functions and Operators.....	658
7.5.11 Network Address Functions and Operators.....	669
7.5.12 Text Search Functions and Operators.....	674
7.5.13 JSON/JSONB Functions and Operators.....	680
7.5.14 HLL Functions and Operators.....	692
7.5.15 SEQUENCE Functions.....	705
7.5.16 Array Functions and Operators.....	708
7.5.17 Range Functions and Operators.....	719
7.5.18 Aggregate Functions.....	723
7.5.19 Window Functions.....	740
7.5.20 Security Functions.....	745
7.5.21 Encrypted Functions and Operators.....	753
7.5.22 Set Returning Functions.....	756
7.5.23 Conditional Expression Functions.....	758
7.5.24 System Information Functions.....	762
7.5.25 System Administration Functions.....	794
7.5.25.1 Configuration Settings Functions.....	794
7.5.25.2 Universal File Access Functions.....	794
7.5.25.3 Server Signal Functions.....	796
7.5.25.4 Backup and Restoration Control Functions.....	798
7.5.25.5 DR Control Functions for Dual-Database Instances.....	808
7.5.25.6 DR Query Functions for Dual-Database Instances.....	808
7.5.25.7 Snapshot Synchronization Functions.....	811
7.5.25.8 Database Object Functions.....	811
7.5.25.9 Advisory Lock Functions.....	817
7.5.25.10 Logical Replication Functions.....	820
7.5.25.11 Other Functions.....	846
7.5.25.12 Undo System Functions.....	876
7.5.25.13 SQL Statement Concurrency Control Function.....	897
7.5.26 Statistics Information Functions.....	903

7.5.27 Trigger Functions.....	969
7.5.28 Hash Function.....	971
7.5.29 Prompt Message Function.....	974
7.5.30 Global Temporary Table Functions.....	974
7.5.31 Fault Injection System Function.....	977
7.5.32 AI Feature Functions.....	977
7.5.33 Dynamic Data Masking Functions.....	981
7.5.34 Hierarchical Recursion Query Functions.....	982
7.5.35 Other System Functions.....	982
7.5.36 Internal Functions.....	1006
7.5.37 Global SysCache Functions.....	1014
7.5.38 Data Damage Detection and Repair Functions.....	1016
7.5.39 Functions of the XML Type.....	1030
7.5.40 Functions of the XMLType Type.....	1046
7.5.41 Global PL/SQL Cache Functions.....	1054
7.5.42 Obsolete Functions.....	1055
7.6 Expressions.....	1056
7.6.1 Simple Expressions.....	1056
7.6.2 Condition Expressions.....	1058
7.6.3 Subquery Expressions.....	1062
7.6.4 Array Expressions.....	1065
7.6.5 Row Expressions.....	1066
7.7 Pseudocolumn.....	1068
7.8 Type Conversion.....	1071
7.8.1 Overview.....	1071
7.8.2 Operators.....	1072
7.8.3 Functions.....	1074
7.8.4 Value Storage.....	1076
7.8.5 UNION, CASE, and Related Constructs.....	1077
7.9 System Operation.....	1082
7.10 Controlling Transactions.....	1083
7.11 DDL Syntax Overview.....	1083
7.12 DML Syntax Overview.....	1090
7.13 DCL Syntax Overview.....	1091
7.14 SQL Syntax.....	1092
7.14.1 SQL Syntax.....	1093
7.14.2 ABORT.....	1093
7.14.3 ALTER AGGREGATE.....	1094
7.14.4 ALTER AUDIT POLICY.....	1095
7.14.5 ALTER COLUMN ENCRYPTION KEY.....	1097
7.14.6 ALTER EVENT.....	1098
7.14.7 ALTER DATABASE.....	1099

7.14.8 ALTER DATABASE LINK.....	1102
7.14.9 ALTER DEFAULT PRIVILEGES.....	1102
7.14.10 ALTER DIRECTORY.....	1105
7.14.11 ALTER FOREIGN DATA WRAPPER.....	1105
7.14.12 ALTER FUNCTION.....	1107
7.14.13 ALTER GLOBAL CONFIGURATION.....	1110
7.14.14 ALTER GROUP.....	1111
7.14.15 ALTER INDEX.....	1112
7.14.16 ALTER LANGUAGE.....	1114
7.14.17 ALTER MASKING POLICY.....	1114
7.14.18 ALTER MATERIALIZED VIEW.....	1116
7.14.19 ALTER OPERATOR.....	1117
7.14.20 ALTER PACKAGE.....	1118
7.14.21 ALTER PROCEDURE.....	1119
7.14.22 ALTER RESOURCE LABEL.....	1123
7.14.23 ALTER RESOURCE POOL.....	1124
7.14.24 ALTER ROLE.....	1126
7.14.25 ALTER ROW LEVEL SECURITY POLICY.....	1128
7.14.26 ALTER SCHEMA.....	1130
7.14.27 ALTER SEQUENCE.....	1132

# 1 Database System Overview

---

## 1.1 Database Logical Architecture

Data nodes (DNs) in GaussDB store data on disks. This section describes the objects on each DN from the logical view and the relationship between these objects. [Figure 1-1](#) shows the database logical structure.

Figure 1-1 Database logical architecture

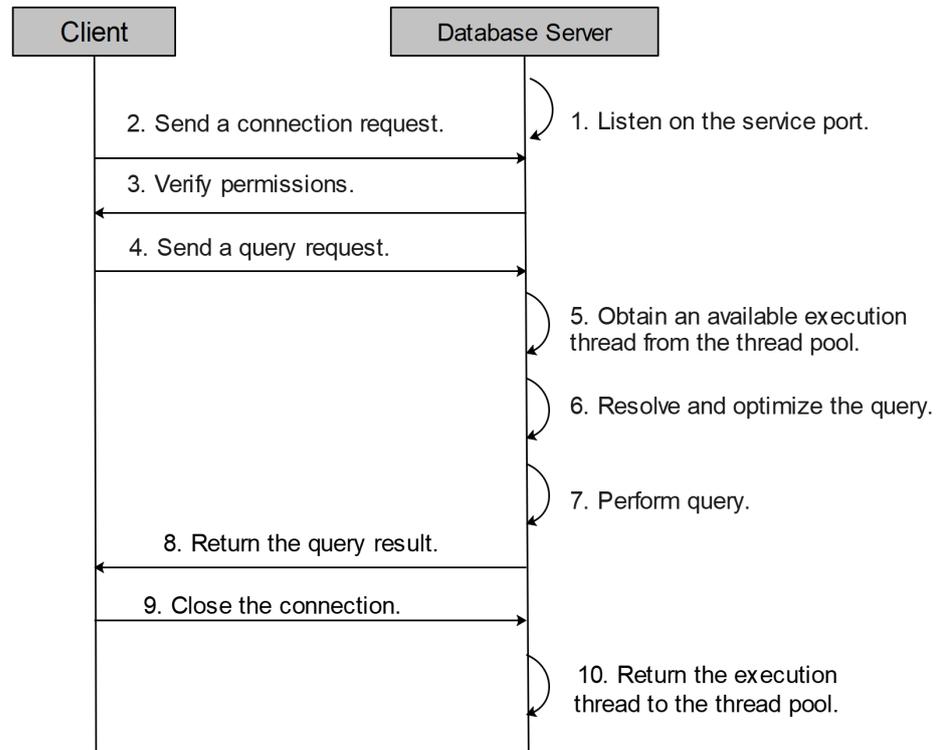

**NOTE**

- A tablespace is a directory. A database contains one or more tablespaces to store physical files of the database. Each tablespace can contain files belonging to different databases.
- A database manages various data objects and is isolated from each other. Objects managed by a database can be distributed to multiple tablespaces.
- A datafile segment stores data of only one table. A table containing more than 1 GB of data is stored in multiple datafile segments.
- One table belongs to only one database and one tablespace. The datafile segments storing the data of the same table must be in the same tablespace.
- A block is a basic unit for database management. Its default size is 8 KB.

## 1.2 Query Request Handling Process

Figure 1-2 GaussDB service response process

## 1.3 Managing Transactions

A transaction is a customized sequence of database operations, which form an integral unit of work. In GaussDB, you can start, set, commit, and roll back transactions. GaussDB supports the following transaction isolation levels: READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. READ UNCOMMITTED is not recommended. SERIALIZABLE is equivalent to REPEATABLE READ.

### Controlling Transactions

Transaction operations supported by a database are as follows:

- Starting transactions  
You can use the `START TRANSACTION` or `BEGIN` syntax to start a transaction. For details, see [START TRANSACTION](#) and [BEGIN](#).
- Setting transactions  
You can use the `SET TRANSACTION` or `SET LOCAL TRANSACTION` syntax to set transactions. For details, see [SET TRANSACTION](#).

- **Committing transactions**  
You can commit all operations of a transaction using COMMIT or END. For details, see [COMMIT | END](#).
- **Rolling back transactions**  
Rollback indicates that the system cancels all changes that a transaction has made to a database if the transaction fails to be executed due to a fault. For details, see [ROLLBACK](#).

## Transaction Isolation Levels

A transaction isolation level specifies how concurrent transactions process the same object.

### NOTE

The isolation level cannot be changed after the first data manipulation statement (SELECT, INSERT, DELETE, UPDATE, FETCH, or COPY) in a transaction is executed.

- **READ COMMITTED:** At this level, a transaction can access only committed data. This is the default level.  
The SELECT statement accesses the snapshot of the database taken when the query begins. The SELECT statement can also access the data modifications in its transaction, regardless of whether they have been committed. Note that different database snapshots may be available to two consecutive SELECT statements for the same transaction, because data may be committed for other transactions while the first SELECT statement is executed.  
At the **READ COMMITTED** level, the execution of each statement begins with a new snapshot, which contains all the transactions that have been committed by the execution time. Therefore, during a transaction, a statement can access the result of other committed transactions. Check whether a single statement always accesses absolutely consistent data in a database.  
Transaction isolation at this level meets the requirements of many applications, and is fast and easy to use. However, applications performing complicated queries and updates may require data that is more consistent than this level can provide.
- **REPEATABLE READ:** At this level, a transaction can only read data committed before it starts. Uncommitted data or data committed in other concurrent transactions cannot be read. However, a query can read earlier data modifications in its transaction, regardless of whether they have been committed. **READ COMMITTED** differs from this level in that a transaction reads the snapshot taken at the start of the transaction, not at the beginning of the current query within the transaction. Therefore, the SELECT statement within a transaction always reads the same data, and cannot read data committed by other concurrent transactions after the transaction starts. Applications at this level must be able to retry transactions, because serialization failures may occur.
- **SERIALIZABLE:** Currently, GaussDB does not support this isolation level. Setting this isolation level is equivalent to REPEATABLE READ.

 NOTE

**REPEATABLE READ is implemented based on multi-version snapshots and write skew may occur. To avoid this scenario, perform the SELECT FOR UPDATE operation on the rows involved in the transaction. An example of write skew is as follows:**

Scenario 1: Table **a** has the **id** and **value** columns of the int type. Two data records are inserted. Assume that the sum of the values of the two data records must be less than or equal to 10 in the service logic of table **a**. Two transactions are concurrently started. The values are updated and modified based on the read values. After the modification, the sum of values is less than or equal to 10 in the transactions. After the modification is committed, the sum of values is 12, which violates the assumed service logic of table **a**.

```
gaussdb=# create table a(id int, value int);
CREATE TABLE
gaussdb=# insert into a values(1,4);
INSERT 0 1
gaussdb=# insert into a values(2,4);
INSERT 0 1
session1 :
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 4
(2 rows)
gaussdb=# update a set value = 6 where id = 1;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
1 | 6
2 | 4
(2 rows)
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 4
(2 rows)
gaussdb=# update a set value = 6 where id = 2;
UPDATE 1
gaussdb=# select * from a;
id | value
----+-----
1 | 4
2 | 6
(2 rows)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# commit;
COMMIT
gaussdb=# select * from a;
id | value
----+-----
1 | 6
2 | 6
(2 rows)
```

Scenario 2: Table **a** has the **id** and **value** columns of the int type. The **id** is the primary key. When the primary key is deleted and inserted concurrently, the values of two primary keys may be read in the transaction, violating the primary key constraint.

```
gaussdb=# create table a(id int primary key, value int);
NOTICE: CREATE TABLE / PRIMARY KEY will create implicit index "a_pkey" for table "a"
CREATE TABLE
gaussdb=# insert into a values(1,10);
INSERT 0 1
session1:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# delete a where id = 1;
DELETE 1
session2:
gaussdb=# start transaction isolation level repeatable read;
START TRANSACTION
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
(1 row)
session1:
gaussdb=# commit;
COMMIT
session2:
gaussdb=# insert into a values(1, 100);
INSERT 0 1
gaussdb=# select * from a;
id | value
----+-----
 1 |   10
 1 |  100
(2 rows)
```

## 1.4 Concepts

### Databases

Databases manage various data objects and are isolated from each other. While creating a database, you can specify a tablespace. If you do not specify it, the object will be saved to the PG\_DEFAULT tablespace by default. Objects managed by a database can be distributed to multiple tablespaces.

### Tablespaces

In GaussDB, a tablespace is a directory storing physical files of the databases. Multiple tablespaces can coexist. Files are physically isolated using tablespaces and managed by a file system.

### Schemas

GaussDB schemas logically separate databases. All database objects are created under certain schemas. In GaussDB, schemas and users are loosely bound. When you create a user, a schema with the same name as the user will be created automatically. You can also create a schema or specify another schema.

### Users and Roles

GaussDB uses users and roles to control the access to databases. A role can be a database user or a group of database users, depending on role settings. Each user

can have only one role. In GaussDB, the difference between roles and users is that a role does not have the LOGIN permission by default. In GaussDB, you can put a user's role under a parent role for flexible management.

## Transactions

In GaussDB, transactions are managed by multi-version concurrency control (MVCC) and two-phase locking (2PL). It enables smooth data reads and writes. In GaussDB, an Astore storage engine saves historical version data together with the current tuple version. The GaussDB Astore engine uses a VACUUM thread instead of rollback segments to periodically delete historical version data. Generally, you do not need to pay special attention to the VACUUM thread unless you need to optimize the performance. The GaussDB Ustore engine stores historical version data to the undo rollback segments. The thread for purging undo deletes historical version data in a unified manner. In addition, GaussDB automatically commits transactions for single-statement queries (without using statements such as BEGIN to explicitly start a transaction block).

# 2 Database Security

---

## 2.1 Users and Permissions

### 2.1.1 Default Permission Mechanism

A user who creates an object is the owner of this object. By default, [separation of duties](#) is disabled after database installation. A database system administrator has the same permissions as object owners. After an object is created, only the object owner or system administrator can query, modify, and delete the object, and grant permissions for the object to other users through [GRANT](#) by default.

To enable another user to use the object, grant required permissions to the user or the role that contains the user.

GaussDB supports the following permissions: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, REFERENCES, CREATE, CONNECT, EXECUTE, USAGE, ALTER, DROP, COMMENT, INDEX, and VACUUM. Permission types are associated with object types. For permission details, see [GRANT](#).

To revoke a permission that has been granted, see [REVOKE](#). Object owners have implicit permissions (such as ALTER, DROP, COMMENT, INDEX, VACUUM, GRANT, and REVOKE) on objects. That is, once becoming the owner of an object, the owner is immediately granted the implicit permissions on the object. Object owners can remove their own common permissions (SELECT, INSERT, UPDATE, and DELETE), for example, making tables read-only to themselves or others, except the system administrator.

System catalogs and views are visible to either system administrators or all users. System catalogs and views that require system administrator permissions can be queried only by system administrators. For details, see [System Catalogs and System Views](#).

The database provides the object isolation feature. If this feature is enabled, users can view only the objects (tables, views, columns, and functions) that they have the permission to access. System administrators are not affected by this feature. For details, see [ALTER DATABASE](#).

It is not recommended to modify the permissions on system catalogs and system views.

## 2.1.2 Administrators

### Initial User

The account automatically generated during database installation is called an initial user. The initial user is also the system administrator, security administrator, audit administrator, monitor administrator, O&M administrator, and security policy administrator. It has the highest permissions in the system and can perform all operations. If the initial username is not specified during installation, the username is the same as the name of the OS user who installs the database. If the password of the initial user is not specified during the installation, the password is empty after the installation. In this case, you need to change the password of the initial user on the gsql client before performing other operations. If the initial user password is empty, you cannot perform other SQL operations, such as upgrade, capacity expansion, and node replacement, except changing the password.

An initial user bypasses all permission checks. You are advised to use an initial user as a database administrator only for database management other than service running.

### System Administrator

A system administrator is an account with the **SYSADMIN** attribute. By default, a system administrator has the same permissions as the object owner but does not have the object permissions in the `dbe_perf` schema or the permission to use Roach to perform backup and restoration.

To create a database administrator, connect to the database as the initial user or a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **SYSADMIN** option.

```
gaussdb=# CREATE USER sysadmin WITH SYSADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe SYSADMIN;
```

When ALTER USER is executed, the user must exist.

### Security Administrator

A security administrator is an account with the **CREATEROLE** attribute, which has the permission to create, modify, and delete users or roles.

If you want to create a security administrator and separation of duties is disabled, connect to the database as a system administrator or security administrator. If separation of duties is enabled, connect to the database as a security administrator and use the **CREATE USER** or **ALTER USER** statement with the **CREATEROLE** option.

```
gaussdb=# CREATE USER createrole WITH CREATEROLE password '*****';
```

Or

```
gaussdb=# ALTER USER joe CREATEROLE;
```

When ALTER USER is executed, the user must exist.

## Audit Administrator

An audit administrator is an account with the **AUDITADMIN** attribute, which has the permission to view and delete audit logs.

If you want to create an audit administrator and separation of duties is disabled, connect to the database only as a system administrator or security administrator. If separation of duties is enabled, connect to the database only as the initial user and use the **CREATE USER** or **ALTER USER** statement with the **AUDITADMIN** option.

```
gaussdb=# CREATE USER auditadmin WITH AUDITADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe AUDITADMIN;
```

When ALTER USER is executed, the user must exist.

## Monitor Administrator

A monitor administrator is an account with the **MONADMIN** attribute and has the permission to view views and functions in the db\_perf schema. The monitor administrator can also grant or revoke object permissions in the db\_perf schema.

To create a monitor administrator, connect to the database as a system administrator and use the **CREATE USER** or **ALTER USER** statement with the **MONADMIN** option.

```
gaussdb=# CREATE USER monadmin WITH MONADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe MONADMIN;
```

When ALTER USER is executed, the user must exist.

## O&M Administrator

An O&M administrator is an account with the **OPRADMIN** attribute and has the permission to use Roach to perform backup and restoration.

To create an O&M administrator, connect to the database as an initial user and use the **CREATE USER** or **ALTER USER** statement with the **OPRADMIN** option.

```
gaussdb=# CREATE USER opradmin WITH OPRADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe OPRADMIN;
```

When ALTER USER is executed, the user must exist.

## Security Policy Administrator

A security policy administrator is an account with the **POLADMIN** attribute and has the permission to create resource tags, masking policies, and unified audit policies.

To create a security policy administrator, connect to the database as an administrator and use the **CREATE USER** or **ALTER USER** statement with the **POLADMIN** option.

```
gaussdb=# CREATE USER poladmin WITH POLADMIN password '*****';
```

Or

```
gaussdb=# ALTER USER joe POLADMIN;
```

When ALTER USER is executed, the user must exist.

## 2.1.3 Separation of Duties

Descriptions in **Default Permission Mechanism** and **Administrators** are about the initial situation after the database system is created. By default, the system administrator with the **SYSADMIN** attribute has the highest permission in the system.

To avoid risks caused by centralized permissions, you can enable separation of duties to assign the system administrator's user creation permission to security administrators and audit management permission to audit administrators.

After separation of duties, the system administrator does not have the **CREATEROLE** attribute (security administrator) or the **AUDITADMIN** attribute (audit administrator). That is, the system administrator can neither create roles or users, nor view or maintain database audit logs. For details about the **CREATEROLE** and **AUDITADMIN** attributes, see **CREATE ROLE**.

Separation of duties does not take effect for an initial user. Therefore, you are advised to use an initial user as a database administrator only for database management other than service running.

To enable separation of duties, set the GUC parameter **enableSeparationOfDuty** to **on**.

If you need to use the separation of duties model, specify it during database initialization. You are advised not to switch the permission management model back and forth. In particular, if you want to switch from a non-separation-of-duties permission management model to the separation-of-duties permission management model, you need to review the permission set of existing users. If a user has the system administrator permission and audit administrator permission, the permissions need to be tailored.

---

After separation of duties, the system administrator does not have permissions for non-system schemas of other users. Therefore, the system administrator cannot access the objects in other users' schemas before being granted the permissions. For details about permission changes before and after enabling separation of duties, see **Table 2-1** and **Table 2-2**.

**Table 2-1** Default user permissions

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	Has all permissions.	Can create, modify, delete, access, or grant permissions for tablespaces.	Cannot create, modify, delete, or grant permissions for tablespaces and can access tablespaces if the access permission is granted.		
Schemas		Has all permissions for all schemas except dbperf.	Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.		
User-defined functions		Has all permissions for all user-defined functions.	Has all permissions for their own functions, and has only the call permission for other users' functions.		
User-defined tables or views		Has all permissions for all user-defined tables or views.	Has all permissions for their own tables or views, but does not have permissions for other users' tables or views.		

**Table 2-2** Changes in permissions after separation of duties

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
Tablespaces	No change. Has all permissions.	No change.	No change.		
Schemas		Permissions reduced Has all permissions for their own schemas, but does not have permissions for non-system schemas of other users.	No change.		
User-defined functions		Cannot access functions in non-system schemas of other users before being granted the permissions.	No change.		

Object Name	Initial User (ID: 10)	System Administrator	Security Administrator	Audit Administrator	Common User
User-defined tables or views		Cannot access tables or views in non-system schemas of other users before being granted the permissions.	No change.		

#### NOTICE

PG\_STATISTIC and PG\_STATISTIC\_EXT store sensitive information about statistical objects, such as high-frequency MCVs. After separation of duties is enabled, the system administrator can still access the two system catalogs to obtain sensitive information in the statistics.

## 2.1.4 Users

You can use CREATE USER and ALTER USER to create and manage database users, respectively. A database system contains one or more databases. Users and roles are shared within the entire database system, but their data is not shared. That is, a user can connect to any database, but after the connection is successful, any user can access only the database declared in the connection request.

In modes other than **Separation of Duties**, GaussDB user accounts can be created and deleted only by a system administrator or a security administrator with the **CREATEROLE** attribute. In separation-of-duties mode, a user account can be created only by an initial user or a security administrator.

When a user logs in, GaussDB authenticates the user. A user can own databases and database objects (such as tables), and grant permissions of these objects to other users and roles. In addition to system administrators, users with the **CREATEDB** attribute can create databases and grant permissions on these databases.

### Adding, Modifying, and Deleting Users

- To create a user, use the SQL statement **CREATE USER**.  
For example, create user **joe** and set the **CREATEDB** attribute for the user.  
gaussdb=# CREATE USER joe WITH CREATEDB PASSWORD "\*\*\*\*\*";  
CREATE ROLE
- To create a system administrator, use the **CREATE USER** statement with the **SYSADMIN** option.
- To delete an existing user, use **DROP USER**.
- To change a user account (for example, rename the user or change the password), use **ALTER USER**.

- To view a user list, query the **PG\_USER** view.  
`gaussdb=# SELECT * FROM pg_user;`
- To view user attributes, query the **PG\_AUTHID** system catalog.  
`gaussdb=# SELECT * FROM pg_authid;`

## Permanent User

GaussDB provides a permanent user solution. You can create a permanent user with the **PERSISTENCE** attribute, which can use the `service_reserved_connections` channel to connect to the database.

### NOTE

`service_reserved_connections` indicates the minimum number of connections reserved with the **PERSISTENCE** attribute. You are advised not to set this parameter to a large value.

```
gaussdb=# CREATE USER user_persistence WITH PERSISTENCE IDENTIFIED BY "*****";
```

Only the initial user is allowed to create, modify, and delete permanent users with the **PERSISTENCE** attribute.

## 2.1.5 Roles

After a role is granted to a user through **GRANT**, the user will have all the permissions of the role. It is recommended that roles be used to efficiently grant permissions. For example, you can create different roles of design, development, and maintenance personnel, grant the roles to users, and then grant specific data permissions required by different users. When permissions are granted or revoked at the role level, these changes take effect on all members of the role.

GaussDB provides an implicitly defined group **PUBLIC** that contains all roles. By default, all new users and roles have the permissions of **PUBLIC**. For details about the default permissions of **PUBLIC**, see **GRANT**. To revoke permissions of **PUBLIC** from a user or role, or re-grant these permissions to them, add the **PUBLIC** keyword in the **REVOKE** or **GRANT** statement.

To view all roles, query the system catalog **PG\_ROLES**.

```
SELECT * FROM PG_ROLES;
```

## Adding, Modifying, and Deleting Roles

In scenarios other than separation of duties, a role can be created, modified, and deleted only by a system administrator or a user with the **CREATEROLE** attribute. In **separation-of-duties** scenarios, a role can be created, modified, and deleted only by an initial user or a user with the **CREATEROLE** attribute.

- To create a role, use **CREATE ROLE**.
- To add or delete users in an existing role, use **ALTER ROLE**.
- To delete a role, use **DROP ROLE**. **DROP ROLE** deletes only a role, rather than member users in the role.

## Built-in Roles

GaussDB provides a group of default roles whose names start with **gs\_role\_**. These roles are provided to access to specific, typically high-privileged operations. You

can grant these roles to other users or roles within the database so that they can use specific functions. These roles should be given with great care to ensure that they are used where they are needed. [Table 2-3](#) describes the permissions of built-in roles.

**Table 2-3** Built-in roles and their permissions

Roles	Permission
gs_role_signal_backend	Permission to call the <code>pg_cancel_backend</code> , <code>pg_terminate_backend</code> , and <code>pg_terminate_session</code> functions to cancel or terminate other sessions, or to call the <code>pg_terminate_active_session_socket</code> function to close active sessions and the socket connection of the client. However, this role cannot perform operations on sessions of the initial user or <b>PERSISTENCE</b> user.
gs_role_tablespace	Permission to create a tablespace.
gs_role_replication	Permission to call logical replication functions, such as <code>kill_snapshot</code> , <code>pg_create_logical_replication_slot</code> , <code>pg_create_physical_replication_slot</code> , <code>pg_drop_replication_slot</code> , <code>pg_replication_slot_advance</code> , <code>pg_create_physical_replication_slot_exten</code> , <code>pg_logical_slot_get_changes</code> , <code>pg_logical_slot_peek_changes</code> , <code>pg_logical_slot_get_binary_changes</code> , and <code>pg_logical_slot_peek_binary_changes</code> .
gs_role_account_lock	Permission to lock and unlock users. However, this role cannot lock or unlock the initial user or users with the <b>PERSISTENCE</b> attribute.
gs_role_pldebugger	Permission to debug functions in <code>dbe_pldebugger</code> .
gs_role_public_dblink_drop	Permission to delete public database links.
gs_role_public_dblink_alter	Permission to modify public database links.

The restrictions on built-in roles are as follows:

- The role names starting with **gs\_role\_** are reserved for built-in roles in the database. Do not create users, roles, or schemas starting with **gs\_role\_** or rename existing users, roles, or schemas to names starting with **gs\_role\_**.
- Do not perform ALTER or DROP operations on built-in roles.
- By default, built-in roles do not have the LOGIN permission and do not have preset passwords.
- The `gsql` meta-commands `\du` and `\dg` do not display information about built-in roles. However, if `pattern` is set to a specific built-in role, the information is displayed.

- When separation of duties is disabled, the initial user, users with the SYSADMIN permission, and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. When separation-of-duties is enabled, the initial user and users with the ADMIN OPTION built-in role permission have the permission to perform GRANT and REVOKE operations on built-in roles. Example:  

```
GRANT gs_role_signal_backend TO user1;  
REVOKE gs_role_signal_backend FROM user1;
```

## 2.1.6 Schemas

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to manage, and third-party applications can be added to corresponding schemas without causing conflicts.

Each database has one or more schemas. Each schema contains tables and other types of objects. When a database is created, a public schema named **public** is created by default, and all users have the USAGE permission on this schema. In addition, each database has a pg\_catalog schema, which contains system catalogs and all built-in data types, functions, and operators. Only system administrators and initial users can create common functions, aggregate functions, stored procedures, and synonym objects in public and pg\_catalog schemas. Only initial users can create operators in public and pg\_catalog schemas. Other users cannot create the preceding five types of objects even if they are granted the CREATE permission on the public and pg\_catalog schemas. You can group database objects by schema. A schema is similar to an OS directory but cannot be nested. By default, only the initial user can create objects in pg\_catalog.

The same database object name can be used in different schemas of the same database without causing conflicts. For example, both a\_schema and b\_schema can contain a table named **mytable**. Users with required permissions can access objects across multiple schemas of the same database.

When you run the **CREATE USER** command to create a user, the system creates a schema with the same name as the user in the database where the command is executed.

Database objects are generally created in the first schema in a database search path. For details about the first schema and how to change the schema order, see [Search Path](#).

### Creating, Modifying, and Deleting Schemas

- To create a schema, use **CREATE SCHEMA**. By default, the initial user and system administrator can create schemas. Other users can create schemas in the database only when they have the CREATE permission on the database. For details about how to grant the permission, see the syntax in **GRANT**.
- To change the name or owner of a schema, use **ALTER SCHEMA**. The schema owner can change a schema.
- To delete a schema and its objects, use **DROP SCHEMA**. The schema owner can delete a schema.
- To create a table in a schema, use the *schema\_name.table\_name* format to specify the table. If *schema\_name* is not specified, the table will be created in the first schema in [search path](#).

- To view the owner of a schema, perform the join query on the system catalogs PG\_NAMESPACE and PG\_USER. Replace *schema\_name* in the statement with the name of the schema to be queried.  

```
gaussdb=# SELECT s.nspname,u.username AS nspowner FROM pg_namespace s, pg_user u WHERE nspname='schema_name' AND s.nspowner = u.usesysid;
```
- To view a list of all schemas, query the system catalog PG\_NAMESPACE.  

```
gaussdb=# SELECT * FROM pg_namespace;
```
- To view a list of tables in a schema, query the system catalog PG\_TABLES. For example, the following query will return a table list from PG\_CATALOG in the schema:  

```
gaussdb=# SELECT distinct(tablename),schemaname from pg_tables where schemaname = 'pg_catalog';
```

## Search Path

A search path is defined in the **search\_path** parameter. The parameter value is a list of schema names separated by commas (.). If no target schema is specified during object creation, the object will be added to the first schema listed in the search path. If there are objects with the same name across different schemas and no schema is specified for an object query, the object will be returned from the first schema containing the object in the search path.

- To view the current search path, use **SHOW**.

```
gaussdb=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```

The default value of **search\_path** is "*\$user*",**public**. *\$user* indicates the name of the schema with the same name as the current session user. If the schema does not exist, *\$user* will be ignored. By default, after a user connects to a database that has schemas with the same name, objects will be added to all the schemas. If there are no such schemas, objects will be added only to the public schema.

- To change the default schema of the current session, run the SET statement.

Set the search path to **myschema, public** (**myschema** will be searched first).  

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```

## 2.1.7 User Permissions

- To grant permissions for an object to a user, use **GRANT**.

When permissions for a table or view in a schema are granted to a user or role, the USAGE permission of the schema must be granted together. Otherwise, the user or role can only see these objects but cannot access them.

In the following example, permissions for the schema **tpcds** are first granted to user **joe**, and then the SELECT permission for the **tpcds.web\_returns** table is also granted:

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO joe;
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns to joe;
```

- Grant a role to a user to allow the user to inherit the object permissions of the role.
  - a. Create a role.  
Create a role **lily** and grant the system permission **CREATEDB** to the role.

```
gaussdb=# CREATE ROLE lily WITH CREATEDB PASSWORD '*****';
```

- b. To grant object permissions to a role, use **GRANT**.

For example, first grant permissions for the schema `tpcds` to the role `lily`, and then grant the `SELECT` permission of the `tpcds.web_returns` table to `lily`.

```
gaussdb=# GRANT USAGE ON SCHEMA tpcds TO lily;
gaussdb=# GRANT SELECT ON TABLE tpcds.web_returns TO lily;
```

- c. Grant the role permissions to a user.

```
gaussdb=# GRANT lily TO joe;
```

#### NOTE

When the permissions of a role are granted to a user, the attributes of the role are not transferred together.

- To revoke user permissions, use **REVOKE**.

## 2.1.8 Row-Level Security Policy

The row-level security feature enables database access control to be accurate to each row of data tables. In this way, the same SQL query may return different results for different users.

You can create a row-level security policy for a data table. The policy defines an expression that takes effect only for specific database users and SQL operations. When a database user accesses the data table, if an SQL statement meets the specified row-level security policies of the data table, the expressions that meet the specified condition will be combined by using `AND` or `OR` based on the attribute type (`PERMISSIVE` | `RESTRICTIVE`) and applied to the execution plan in the query optimization phase.

Row-level security policy is used to control the visibility of row-level data in tables. By predefining filters for data tables, the expressions that meet the specified condition can be applied to execution plans in the query optimization phase, which will affect the final execution result. Currently, the SQL statements that can be affected include `SELECT`, `UPDATE`, and `DELETE`.

Scenario 1: A table summarizes the data of different users. Users can view only their own data.

```
-- Create users alice, bob, and peter.
gaussdb=# CREATE USER alice PASSWORD '*****';
gaussdb=# CREATE USER bob PASSWORD '*****';
gaussdb=# CREATE USER peter PASSWORD '*****';

-- Create the all_data table that contains user information.
gaussdb=# CREATE TABLE all_data(id int, role varchar(100), data varchar(100));

-- Insert data into the data table.
gaussdb=# INSERT INTO all_data VALUES(1, 'alice', 'alice data');
gaussdb=# INSERT INTO all_data VALUES(2, 'bob', 'bob data');
gaussdb=# INSERT INTO all_data VALUES(3, 'peter', 'peter data');

-- Grant the read permission for the all_data table to users alice, bob, and peter.
gaussdb=# GRANT SELECT ON all_data TO alice, bob, peter;

-- Enable row-level security policy.
gaussdb=# ALTER TABLE all_data ENABLE ROW LEVEL SECURITY;

-- Create a row-level security policy to specify that the current user can view only their own data.
gaussdb=# CREATE ROW LEVEL SECURITY POLICY all_data_rls ON all_data USING(role = CURRENT_USER);
```

```
-- View table details.
gaussdb=# \d+ all_data
          Table "public.all_data"
Column |          Type          | Modifiers | Storage | Stats target | Description
-----+-----+-----+-----+-----+-----
id     | integer                |           | plain   |              |
role   | character varying(100) |           | extended|              |
data   | character varying(100) |           | extended|              |
Row Level Security Policies:
  POLICY "all_data_rls" FOR ALL
  TO public
  USING (((role)::name = "current_user"()))
Has OIDs: no
Location Nodes: ALL DATANODES
Options: orientation=row, compression=no, enable_rowsecurity=true

-- Switch to user alice and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
id | role | data
---+---+---
 1 | alice | alice data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> Seq Scan on all_data
      Filter: ((role)::name = 'alice'::name)
Notice: This query is influenced by row level security feature
(5 rows)

-- Switch to user peter and run SELECT * FROM public.all_data.
gaussdb=# SELECT * FROM public.all_data;
id | role | data
---+---+---
 3 | peter | peter data
(1 row)

gaussdb=# EXPLAIN(COSTS OFF) SELECT * FROM public.all_data;
          QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> Seq Scan on all_data
      Filter: ((role)::name = 'peter'::name)
Notice: This query is influenced by row level security feature
(5 rows)
```

### NOTICE

PG\_STATISTIC and PG\_STATISTIC\_EXT store sensitive information about statistical objects, such as high-frequency MCVs. If the permission to query the two system catalogs is granted to a common user after the row-level security policy is created, the common user can still access the two system catalogs to obtain sensitive information in the statistical objects.

## 2.2 Database Audit

### Context

Database audit is critical to the security of the database system. Database audit administrators can use the audit logs to reproduce a series of events that cause faults in the database and identify unauthorized users, unauthorized operations, and the time when these operations are performed.

You need to understand the following information about the audit function:

- The overall audit switch **audit\_enabled** supports dynamic loading. After you change the switch status when the database is running, the change takes effect immediately and you do not need to restart the database. Its default value is **on**, indicating that the audit function is enabled.
- In addition to the overall audit switch, each audit item has an independent switch. An audit item is available only after its own switch is turned on.
- The switch of each audit supports dynamic loading. After changing the audit switch status when the database is running, the modification takes effect immediately without restarting the database.

**Table 2-4** describes the audit items supported by GaussDB. If you need to modify a specific audit configuration item, contact the administrator. For details about parameter types and value ranges, see "Configuring Running Parameters > GUC Parameters > Auditing" in *Administrator Guide*.

**Table 2-4** Audit items

Configuration Item	Description
User login and logout audit	Parameter: <b>audit_login_logout</b> Its default value is <b>7</b> , which indicates that the function of user login and logout audit is enabled. <b>0</b> indicates that the function of user login and logout audit is disabled. Other values are not recommended.
Database startup, stop, recovery, and switchover audit	Parameter: <b>audit_database_process</b> Its default value is <b>1</b> , which indicates that the audit of database startup, stop, recovery, and switchover is enabled.
User locking and unlocking audit	Parameter: <b>audit_user_locked</b> Its default value is <b>1</b> , which indicates that the audit of user locking and unlocking is enabled.
Unauthorized access audit	Parameter: <b>audit_user_violation</b> Its default value is <b>0</b> , which indicates that the audit of unauthorized access disabled.

Configuration Item	Description
Permission granting and revoking audit	Parameter: <b>audit_grant_revoke</b> Its default value is <b>1</b> , which indicates that the audit of permission granting and revoking is enabled.
Full audit of user operations	Parameter: <b>full_audit_users</b> Its default value is an empty string, indicating that the default configuration is used and no full audit of user operations is configured.
Names and IP addresses of clients that do not need to be audited	Parameter: <b>no_audit_client</b> Its default value is an empty string, indicating that the default configuration is used and no clients and IP addresses are added to the audit blacklist.
Audit of CREATE, ALTER, and DROP operations on database objects	Parameter: <b>audit_system_object</b> Its default value is <b>67121159</b> , which indicates that the CREATE, ALTER, and DROP operations only on databases, schemas, users, and SQL patches are audited.
Audit of INSERT, UPDATE, and DELETE operations on a specific table	Parameter: <b>audit_dml_state</b> Its default value is <b>0</b> , which indicates that the audit of DML operations (except SELECT) on a specific table is disabled.
SELECT operation audit	Parameter: <b>audit_dml_state_select</b> Its default value is <b>0</b> , which indicates that the audit of the SELECT operation is disabled.
COPY operation audit	Parameter: <b>audit_copy_exec</b> Its default value is <b>1</b> , which indicates that the audit of COPY operations is enabled.
Audit of execution of stored procedures and customized functions	Parameter: <b>audit_function_exec</b> Its default value is <b>0</b> , which indicates that no execution audit logs of stored procedures and customized functions are recorded.
Audit of system functions in the whitelist	Parameter: <b>audit_system_function_exec</b> Its default value is <b>0</b> , which indicates that audit logs of system function execution are not recorded.
SET operation audit	Parameter: <b>audit_set_parameter</b> Its default value is <b>0</b> , which indicates that the audit of the SET operation is disabled.
Transaction ID record	Parameter: <b>audit_xid_info</b> Its default value is <b>0</b> , which indicates that the function of recording transaction IDs in audit logs is disabled.

# 3 Database Quick Start

---

## 3.1 Connecting to a Database

### 3.1.1 Using gsql to Connect to a Database

gsql is a client tool provided by GaussDB. You can use gsql to connect to a database and then enter, edit, and execute SQL statements in an interactive manner. For details about the connection mode, see [Connecting to a DB Instance](#).

---

#### NOTICE

For primary/standby instances, you can use a client tool to connect to a database through a primary DN. Before connection, you must obtain the IP address and port number of the server where the primary DN is deployed. You are not advised to connect a database through a standby DN when services are running properly.

---

### 3.1.2 APIs

You can use standard database APIs, such as ODBC and JDBC, to develop GaussDB-based applications.

#### Supported APIs

Each application is an independent GaussDB development project. APIs alleviate applications from directly operating in databases, and enhance the database portability, extensibility, and maintainability. [Table 3-1](#) lists the APIs supported by GaussDB and the download addresses.

**Table 3-1** Database APIs

API	How to Obtain
ODBC	<ul style="list-style-type: none"><li>Linux: Driver: <code>GaussDB-Kernel_Database version number_OS version number_64bit_Odbc.tar.gz</code> unixODBC source code package: <a href="https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gz">https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gz</a></li><li>Windows: Driver: <code>GaussDB-Kernel_Database version number_Windows_Odbc.tar.gz</code></li></ul>
JDBC	<ul style="list-style-type: none"><li>Driver: <code>GaussDB-Kernel_Database version number_OS version number_64bit_Jdbc.tar.gz</code></li><li>Driver: <code>org.postgresql.Driver</code></li></ul>

The JDBC and ODBC APIs are used to connect to the database remotely. Therefore, you need to configure a remote connection in GaussDB. Contact the administrator for related operations.

For details about more APIs, see [Application Development Guide](#).

## 3.2 Operating a Database

This section explains how to use databases, including creating database accounts, databases, and tables, inserting data to tables, and querying data in tables.

### 3.2.1 Creating a Database Account

Only administrators that are created during database installation can access the initial database by default. You can also create other database accounts.

```
gaussdb=# CREATE USER joe WITH PASSWORD "*****";
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

In this case, you have created a user account named **joe**, and the user password is **\*\*\*\*\***.

Set user **joe** as a system administrator.

```
gaussdb=# GRANT ALL PRIVILEGES TO joe;
```

Run the **GRANT** command to set related permissions. For details, see [GRANT](#).

#### NOTE

For more information about database users, see [Users and Permissions](#).

## 3.2.2 Creating and Managing Databases

### Prerequisites

Only the database system administrator or users granted with database creation permissions can create a database. For details about how to grant database creation permissions to a user, see [Users and Permissions](#).

### Context

- GaussDB has two default template databases **template0** and **template1** and a default user database **postgres**. The default compatible database type of Postgres is O (that is, **DBCOMPATIBILITY** is set to **A**). In this compatible type, empty strings are processed as null values.
- **CREATE DATABASE** creates a database by copying a template database (**template0** by default). Do not use a client or other methods to connect to or operate the two template databases.

#### NOTE

- The template database does not contain any user table. You can view the attributes of the template database in the PG\_DATABASE system catalog.
- The **template0** template does not allow user connections. Only the initial user of the database and the system administrator can connect to **template1**.
- A database system consists of multiple databases. A client can connect to only one database at a time. Users cannot query data across databases. If GaussDB contains multiple databases, set the **-d** parameter to specify the database instance to be connected.

### Precautions

Assume that the database encoding is SQL\_ASCII. (You can run the **show server\_encoding;** command to query the encoding used for storing data in the current database.) If the database object name contains multi-byte characters (such as Chinese) or if the object name length exceeds the allowed maximum (63 bytes), the database truncates the last byte (not the last character) of the object name. In this case, half characters may appear.

To resolve this problem, you need to:

- Ensure that the name of the data object does not exceed the maximum length.
- Change the default database storage code set (**server\_encoding**) to UTF-8.
- Exclude multi-byte characters from object names.
- If you fail to delete an object whose name is truncated mistakenly, specify its original name to delete it, or manually delete it from the corresponding system catalog on each node.

### Procedure

#### Step 1 Create a database named **db\_tpcc**.

```
gaussdb=# CREATE DATABASE db_tpcc;  
CREATE DATABASE
```

 NOTE

- Database names must comply with the general naming convention rules of SQL identifiers. The current role automatically becomes the owner of this new database.
- If a database system is used to support independent users and projects, store them in different databases.
- If the projects or users are associated with each other and share resources, store them in one database. However, you can divide them into different schemas. A schema is a logical structure, and the access permission for a schema is controlled by the permission system module.
- A database name contains a maximum of 63 bytes and the excessive bytes at the end of the name will be truncated by the server. You are advised to specify a database name no longer than 63 bytes when you create a database.

- New databases are created in the `pg_default` tablespace by default. Specify another tablespace.

```
gaussdb=# CREATE DATABASE db_tpcc WITH TABLESPACE = hr_local;  
CREATE DATABASE
```

*hr\_local* indicates the tablespace name. For details about how to create a tablespace, see [Creating and Managing Tablespaces](#).

- After creating the `db_tpcc` database, you can perform other operations in the default `postgres` database. Alternatively, you can perform the following operations to exit the `postgres` database, connect to the `db_tpcc` database as a new user, and perform operations such as creating tables:

```
gaussdb=# \q  
gsq -d db_tpcc -p 8000 -U joe  
Password for user joe:  
gsq ((GaussDB Kernel 503.1.XXX build f521c606) compiled at 2021-09-16 14:55:22 commit 2935  
last mr 6385 release)  
Non-SSL connection (SSL connection is recommended when requiring high-security)  
Type "help" for help.  
db_tpcc=>
```

**Step 2** View databases.

- Run the `\l` meta-command to view the database list of the database system.  
gaussdb=# \l
- Query the database list in the `pg_database` system catalog.  
gaussdb=# **SELECT datname FROM pg\_database;**

**Step 3** Modify the database.

You can modify database configuration such as the database owner, name, and default settings.

- Set the default search path for the database.  
gaussdb=# **ALTER DATABASE db\_tpcc SET search\_path TO pa\_catalog,public;**  
ALTER DATABASE
- Rename the database.  
gaussdb=# **ALTER DATABASE db\_tpcc RENAME TO human\_tpcds;**  
ALTER DATABASE

**Step 4** Delete the database.

You can run the **DROP DATABASE** command to delete a database. This command deletes the system catalog of the database and the database directory on the disk. Only the database owner or system administrator can delete a database. A database accessed by users cannot be deleted. You need to connect to another database before deleting this database.

Delete the database.

```
gaussdb=# DROP DATABASE human_tpcds;  
DROP DATABASE
```

----End

## 3.2.3 Creating and Managing Tablespaces

### Context

The administrator can use tablespaces to control the layout of disks where a database is installed. The advantages are as follows:

- If the disk partition or tablespace initially allocated to the database is full and the space cannot be logically extended, you can create and use tablespaces in other partitions until the system space is reconfigured.
- Tablespaces allow the administrator to distribute data based on the schema of database objects, improving system performance.
  - A frequently used index can be stored in a disk having stable performance and high computing speed, such as a solid-state device.
  - A table that stores archived data and is rarely used or has low performance requirements can be placed in a disk with a slow computing speed.
- You can use tablespaces to limit the disk space of databases. If a tablespace shares a partition with other tablespaces, the tablespace will never occupy the space allocated to other tablespaces.
- You can use tablespaces to manage the disk space used to store database data. The database will switch to the read-only mode when the disk usage of the tablespace reaches 90%. Once the disk usage drops below 90%, the database will be restored to the read-write mode.

You are advised to use the background monitoring program or Database Manager to monitor the disk space usage when using the database to prevent the database from switching to the read-only mode.

- Each tablespace corresponds to a file system directory. If *database node data directory* /**pg\_location/mount1/path1** is an empty directory for which users have read and write permissions, an absolute path tablespace can be created in this directory.

If the tablespace quota management is used, the performance may deteriorate by about 30%. **MAXSIZE** specifies the maximum quota for each database node. The deviation must be within 500 MB. Determine whether to set a tablespace to its maximum size as required.

GaussDB provides two tablespaces: `pg_default` and `pg_global`.

- Default tablespace `pg_default`: stores non-shared system catalogs, user tables, user table indexes, temporary tables, temporary table indexes, and internal temporary tables. The corresponding storage directory is the base directory in the instance data directory.
- Shared tablespace `pg_global`: stores shared system catalogs. The corresponding storage directory is the base directory in the global data directory.

## Precautions

You are advised not to use user-defined tablespaces in scenarios such as Huawei Cloud. This is because user-defined tablespaces are usually used with storage media other than the main storage (storage device where the default tablespace is located, such as a disk) to isolate I/O resources that can be used by different services. Storage devices use standard configurations and do not have other available storage media in scenarios such as Huawei Cloud. If the user-defined tablespace is not properly used, the system cannot run stably for a long time and the overall performance is affected. Therefore, you are advised to use the default tablespace.

## Procedure

- Create a tablespace.

- a. Create user **jack**.

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*****';
```

If the following information is displayed, the creation is successful:

```
CREATE ROLE
```

- b. Create a tablespace.

```
gaussdb=# CREATE TABLESPACE fastspace RELATIVE LOCATION 'tablespace/tablespace_1';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

**fastspace** is the new tablespace, and *Database node data directory/pg\_location/tablespace/tablespace\_1* is an empty directory for which users have read and write permissions.

- c. Grant the permission of accessing the **fastspace** tablespace to user **jack** as a database system administrator.

```
gaussdb=# GRANT CREATE ON TABLESPACE fastspace TO jack;
```

If the following information is displayed, the grant operation is successful:

```
GRANT
```

- Create an object in a tablespace.

If you have the CREATE permission on the tablespace, you can create database objects in the tablespace, such as tables and indexes.

Take creating a table as an example:

- Method 1: Create a table in a specified tablespace.

```
gaussdb=# CREATE TABLE foo(i int) TABLESPACE fastspace;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Method 2: Run **SET default\_tablespace** to set the default tablespace and then create a table.

```
gaussdb=# SET default_tablespace = 'fastspace';
```

```
SET
```

```
gaussdb=# CREATE TABLE foo2(i int);
```

```
CREATE TABLE
```

In this example, **fastspace** is the default tablespace, and **foo2** is the created table.

- Query a tablespace.

- Method 1: Check the pg\_tablespace system catalog. View all the tablespaces defined by the system and users.

```
gaussdb=# SELECT spcname FROM pg_tablespace;
```

- Method 2: Run the meta-command of the gsql program to query the tablespaces.

```
gaussdb=# \db
```

- Query the tablespace usage.
  - a. Query the current usage of the tablespace.

```
gaussdb=# SELECT PG_TABLESPACE_SIZE('example');
```

Information similar to the following is displayed:

```
pg_tablespace_size
-----
                2146304
(1 row)
```

**2146304** is the size of the tablespace, and its unit is byte.

- b. Calculate the tablespace usage.

Tablespace usage = Value of **PG\_TABLESPACE\_SIZE**/Size of the disk where the tablespace resides

- Modify a tablespace.

Rename tablespace **fastspace** to **fspace**.

```
gaussdb=# ALTER TABLESPACE fastspace RENAME TO fspace;
ALTER TABLESPACE
```

- Delete a tablespace and related data.

- Delete user **jack**.

```
gaussdb=# DROP USER jack CASCADE;
DROP ROLE
```

- Delete tables **foo** and **foo2**.

```
gaussdb=# DROP TABLE foo;
gaussdb=# DROP TABLE foo2;
```

If the following information is displayed, the operation is successful:

```
DROP TABLE
```

- Delete tablespace **fspace**.

```
gaussdb=# DROP TABLESPACE fspace;
DROP TABLESPACE
```

#### NOTE

Only the tablespace owner or system administrator can drop a tablespace.

## 3.2.4 Creating and Managing Tables

### 3.2.4.1 Creating a Table

#### Context

A table is created in a database and can be saved in different databases. Tables under different schemas in a database can have the same name.

#### Creating a Table

Create a table.

```
gaussdb=# CREATE TABLE customer_t1
(
  c_customer_sk          integer,
```

```
c_customer_id    char(5),
c_first_name    char(6),
c_last_name     char(8)
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

**c\_customer\_sk**, **c\_customer\_id**, **c\_first\_name**, and **c\_last\_name** are the column names of the table. **integer**, **char(5)**, **char(6)**, and **char(8)** are column name types.

 **NOTE**

- By default, new database objects are created in the \$user schema. For more details about schemas, see [Creating and Managing Schemas](#).
- In addition to the created tables, a database contains many system catalogs. These system catalogs contain database installation information and information about various queries and processes in GaussDB. You can collect information about the database by querying system catalogs. For details, see [Querying System Catalogs](#).
- For more details about how to create a table, see [CREATE TABLE](#).

### 3.2.4.2 Inserting Data to a Table

A new table contains no data. You need to insert data to the table before using it. This section describes how to insert a row or multiple rows of data using the **INSERT** command and to insert data from a specified table. Contact the administrator if a large amount of data needs to be imported.

## Context

The length of a character on the server and client may vary by the character sets they use. A string entered on the client will be processed based on the server's character set, so the result may differ from expected.

**Table 3-2** Comparison of character set output between the client and server

Procedure	Server and Client Use Same Encoding	Server and Client Use Different Encoding
No operations are performed on the string while it is saved and read.	Your expected result is returned.	If the encoding for input and output on the client is the same, your expected result is returned.
Operations (such as executing string functions) are performed to the string while it is saved and read.	Your expected result is returned.	The result may not be as expected, depending on the operations performed on the string.

Procedure	Server and Client Use Same Encoding	Server and Client Use Different Encoding
A long string is truncated while it is saved.	Your expected result is returned.	If the character sets used on the client and server have different character length, the result may not be as expected.

More than one of the preceding operations can be performed to a string. For example, if the character sets of the client and server are different, a string may be processed and then truncated. In this case, the result will also be unexpected. For details, see [Table 3-3](#).

 NOTE

Long strings are truncated only if **DBCOMPATIBILITY** is set to **TD** and the GUC parameter **td\_compatible\_truncation** is set to **on**.

Create **table1** and **table2** to be used in the example.

```
gaussdb=# CREATE TABLE table1(id int, a char(6), b varchar(6),c varchar(6));
gaussdb=# CREATE TABLE table2(id int, a char(20), b varchar(20),c varchar(20));
```

**Table 3-3** Examples

No.	Server Character Set	Client Character Set	Automatic Truncation Enabled	Example	Result	Description
1	SQL_ASCII	UTF8	Yes	gaussdb=# INSERT INTO table1 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78'));	id  a b c ----+----- +-----+----- 1   87  87  87	A string is reversed on the server and then truncated. Because character sets used by the server and client are different, character A is displayed in multiple bytes on the server and the result is incorrect.

No.	Server Character Set	Client Character Set	Automatic Truncation Enabled	Example	Result	Description
2	SQL_ASCII	UTF8	Yes	<pre>gaussdb=# INSERT INTO table1 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));</pre>	<pre>id  a b c ----+-----  2   873  873  873</pre>	A string is reversed and then automatically truncated. Therefore, the result is unexpected.
3	SQL_ASCII	UTF8	Yes	<pre>gaussdb=# INSERT INTO table1 VALUES(3,'87A123','87A123','87A123');</pre>	<pre>id   a   b   c ----+-----  3   87A1   87A1   87A1</pre>	The column length in the string type is an integer multiple of the length in client character encoding. Therefore, the result is correct after truncation.
4	SQL_ASCII	UTF8	No	<pre>gaussdb=# INSERT INTO table2 VALUES(1,reverse('123AA78'),reverse('123AA78'),reverse('123AA78')); gaussdb=# INSERT INTO table2 VALUES(2,reverse('123A78'),reverse('123A78'),reverse('123A78'));</pre>	<pre>id  a b c ----+-----  1   87 321  87 321   87 321  2   87321  87321  87321</pre>	Similar to the first example, multi-byte characters no longer indicate the original characters after being reversed.

## Procedure

You need to create a table before inserting data to it. For details about how to create a table, see [Creating and Managing Tables](#).

- Insert a row to table **customer\_t1**.

Data values are arranged in the same order as the columns in the table and are separated by commas (.). Generally, column values are text values (constants). But column values can also be scalar expressions.

```
gaussdb=# INSERT INTO customer_t1(c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', 'Grace');
```

If you know the sequence of the columns in the table, you can obtain the same result without listing these columns. For example, the following command generates the same result as the preceding command:

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello', 'Grace');
```

If you do not know some of the column values, you can omit them. If no value is specified for a column, the column is set to the default value.

Example:

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_first_name) VALUES (3769, 'Grace');
```

```
gaussdb=# INSERT INTO customer_t1 VALUES (3769, 'hello');
```

You can also specify the default value of a column or row:

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (3769, 'hello', DEFAULT);
```

```
gaussdb=# INSERT INTO customer_t1 DEFAULT VALUES;
```

- Insert multiple rows to a table.

```
gaussdb=# INSERT INTO customer_t1 (c_customer_sk, c_customer_id, c_first_name) VALUES (6885, 'maps', 'Joes'), (4321, 'tpcds', 'Lily'), (9527, 'world', 'James');
```

You can also insert multiple rows by running the command for inserting one row for multiple times. However, you are advised to run this command to improve efficiency.

- Assume that you have created a backup table **customer\_t2** for table **customer\_t1**. To insert data from **customer\_t1** to **customer\_t2**, run the following commands:

```
gaussdb=# CREATE TABLE customer_t2 (
  c_customer_sk      integer,
  c_customer_id      char(5),
  c_first_name       char(6),
  c_last_name        char(8)
);
```

```
gaussdb=# INSERT INTO customer_t2 SELECT * FROM customer_t1;
```

#### NOTE

If implicit conversion is not implemented between the column data types of the specified table and those of the current table, the two tables must have the same column data types when data is inserted from the specified table to the current table.

- Delete a backup table.

```
gaussdb=# DROP TABLE customer_t2 CASCADE;
```

#### NOTE

If the table to be deleted is in dependent relationship with other tables, you need to delete its dependent tables first.

### 3.2.4.3 Updating Data in a Table

Existing data in a database can be updated. You can update one row, all rows, or specified rows of data, or update data in a single column without affecting the data in the other columns.

The following information is required when the UPDATE statement is used to update rows:

- Table name and column name of the data to be updated

- New column value
- Rows to be updated

Generally, the SQL language does not provide a unique ID for a row of data. Therefore, it is impossible to directly specify the rows of the data to be updated. However, you can specify the rows by declaring the conditions that must be met by the updated row. If a table contains primary keys, you can specify a row using the primary keys.

For details about how to create a table and insert data to it, see [Creating a Table](#) and [Inserting Data to a Table](#).

**c\_customer\_sk** in the table **customer\_t1** must be changed from **9527** to **9876**:

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = 9876 WHERE c_customer_sk = 9527;
```

You can use a schema to modify the table name. If no such modifier is specified, the table is located based on the default schema path. SET is followed by the column and the new column value. The new value can be a constant or an expression.

For example, increase all the values in the **c\_customer\_sk** column by 100.

```
gaussdb=# UPDATE customer_t1 SET c_customer_sk = c_customer_sk + 100;
```

This statement does not contain the WHERE clause, so all rows are updated. If the statement contains the WHERE clause, only the rows matching the clause are updated.

In the SET clause, the equal sign (=) indicates value setting. In the WHERE clause, the equal sign indicates comparison. A WHERE condition does not have to be an equality comparison, but can be another operator.

You can run an UPDATE statement to update multiple columns by specifying multiple values in the SET clause. Example:

```
gaussdb=# UPDATE customer_t1 SET c_customer_id = 'Admin', c_first_name = 'Local' WHERE c_customer_sk = 4421;
```

After data has been updated or deleted in batches, a large number of deletion markers are generated in the data file. During query, data with these deletion markers needs to be scanned as well. In this case, a large amount of data with deletion marks can greatly affect the query performance after batch updates or deletions. If data needs to be updated or deleted in batches frequently, you are advised to periodically execute the VACUUM FULL statement to maintain the query performance.

### 3.2.4.4 Viewing Data

- Run the following command to query information about all tables in a database in the system catalog **pg\_tables**:  

```
gaussdb=# SELECT * FROM pg_tables;
```
- Run the **\d+** command of the **gsq**l tool to query table attributes:  

```
gaussdb=# \d+ customer_t1;
```
- Run the following command to query the data volume of table **customer\_t1**:  

```
gaussdb=# SELECT count(*) FROM customer_t1;
```
- Run the following command to query all data in the table **customer\_t1**:  

```
gaussdb=# SELECT * FROM customer_t1;
```

- Run the following command to query only the data in the column **c\_customer\_sk**:  
gaussdb=# `SELECT c_customer_sk FROM customer_t1;`
- Run the following command to filter repeated data in the column **c\_customer\_sk**:  
gaussdb=# `SELECT DISTINCT( c_customer_sk ) FROM customer_t1;`
- Run the following command to query all data whose column **c\_customer\_sk** is **3869**:  
gaussdb=# `SELECT * FROM customer_t1 WHERE c_customer_sk = 3869;`
- Run the following command to collate data based on the column **c\_customer\_sk**:  
gaussdb=# `SELECT * FROM customer_t1 ORDER BY c_customer_sk;`

### 3.2.4.5 Deleting Data from a Table

Outdated data may need to be deleted when tables are used. Data can be deleted from tables only by row.

SQL statements can only access and delete an independent row by declaring conditions that match the row. If a table has a primary key, you can use it to specify a row. You can delete several rows that match the specified condition or delete all the rows from a table.

For example, delete all the rows whose **c\_customer\_sk** column is **3869** from the table **customer\_t1**.

```
gaussdb=# DELETE FROM customer_t1 WHERE c_customer_sk = 3869;
```

To delete all rows from the table, run either of the following commands:

```
gaussdb=# DELETE FROM customer_t1;
```

Or

```
gaussdb=# TRUNCATE TABLE customer_t1;
```

#### NOTE

If you need to delete an entire table, you are advised to use the TRUNCATE statement rather than DELETE.

Delete the created table.

```
gaussdb=# DROP TABLE customer_t1;
```

## 3.2.5 Querying System Catalogs

In addition to the created tables, a database contains many system catalogs. These system catalogs contain database installation information and information about various queries and processes in GaussDB. You can obtain information about the database by querying system catalogs.

In [System Catalogs and System Views](#), the description about each table specifies whether the table is visible to all users or only the initial user. To query tables that are visible only to the initial user, log in as the initial user.

GaussDB provides the following types of system catalogs and views:

- PostgreSQL-compatible system catalogs and views

**Step 2** View the running query statements. View the database names, users performing queries, query status, and the corresponding PID which are connected to the running query statements.

```
SELECT datname, username, state,pid FROM pg_stat_activity;
 datname | username | state | pid
-----+-----+-----+-----
 testdb  | Ruby    | active | 140298793514752
 testdb  | Ruby    | active | 140298718004992
 testdb  | Ruby    | idle   | 140298650908416
 testdb  | Ruby    | idle   | 140298625742592
 testdb  | omm     | active | 140298575406848
(5 rows)
```

If the **state** column is **idle**, the connection is idle and requires a user to enter a command.

Identify only active query statements.

```
SELECT datname, username, state, pid FROM pg_stat_activity WHERE state != 'idle';
```

**Step 3** To cancel queries that have been running for a long time, use the `PG_TERMINATE_BACKEND` function to end sessions based on the thread ID.

```
SELECT PG_TERMINATE_BACKEND(140298793514752);
```

If the following information is displayed, the session is successfully terminated:

```
PG_TERMINATE_BACKEND
-----
 t
(1 row)
```

If the following information is displayed, a user has terminated the current session:

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
```

#### NOTE

1. When an initial user uses the `PG_TERMINATE_BACKEND` function to terminate the backend threads of active sessions, the `gsql` client is reconnected automatically rather than be logged out. The message "The connection to the server was lost. Attempting reset: Succeeded." is returned. If non-initial users do this operation, the message "The connection to the server was lost. Attempting reset: Failed." is returned. This is because only initial users can log in to the system in password-free mode.
2. If the `PG_TERMINATE_BACKEND` function is used to end inactive backend threads, and the thread pool is enabled, idle sessions do not have thread IDs and cannot be terminated. In non-thread pool mode, terminated sessions are not automatically reconnected.

```
FATAL: terminating connection due to administrator command
FATAL: terminating connection due to administrator command
The connection to the server was lost. Attempting reset: Succeeded.
```

----End

## 3.2.6 Other Operations

### 3.2.6.1 Creating and Managing Schemas

#### Context

Schemas allow multiple users to use the same database without interference. In this way, database objects can be organized into logical groups that are easy to

manage, and third-party applications can be added to corresponding schemas without causing conflicts. Schema management involves creating a schema, using a schema, deleting a schema, setting a search path for a schema, and setting schema permissions.

## Precautions

- GaussDB contains one or more named databases. Users and user groups are shared within the database, but their data is not shared. Any user who has connected to a server can access only the database specified in the connection request.
- A database can have one or more schemas, and a schema can contain tables and other data objects, such as data types, functions, and operators. One object name can be used in different schemas. For example, both schema1 and schema2 can have a table named **mytable**.
- Different from databases, schemas are not isolated. You can access the objects in a schema of the connected database if you have schema permissions. To manage schema permissions, you need to have knowledge about database permissions.
- A schema named with the **PG\_** prefix cannot be created because this type of schema is reserved for the database system.
- Each time a new user is created, the system creates a schema with the same name for the new user in the current database. In other databases, such a schema needs to be manually created.
- To reference a table that is not modified with a schema name, the system uses **search\_path** to find the schema that the table belongs to. `pg_temp` and `pg_catalog` are always the first two schemas to be searched no matter whether or how they are specified in **search\_path**. **search\_path** is a schema name list, and the first table detected in it is the target table. If no target table is found, an error will be reported. (If a table exists but the schema it belongs to is not listed in **search\_path**, the search fails as well.) The first schema in **search\_path** is called "current schema". This schema is the first one to be searched. If no schema name is declared, newly created database objects are saved in this schema by default.
- Each database has a `pg_catalog` schema, which contains system catalogs and all built-in data types, functions, and operators. `pg_catalog` is a part of the search path and has the second highest search priority. It is searched after the schema of temporary tables and before other schemas specified in **search\_path**. This search order ensures that database built-in objects can be found. To use a custom object that has the same name as a built-in object, you can specify the schema of the custom object.

## Procedure

- Manage users and their permissions.

- Create a schema.

```
gaussdb=# CREATE SCHEMA myschema;
```

If the following information is displayed, the schema named **myschema** is successfully created:

```
CREATE SCHEMA
```

To create or access an object in the schema, specify the complete object name, which consists of the schema name and the object names separated by periods (.). Example: **myschema.table**.

- Create a schema and specify the owner.

```
gaussdb=# CREATE SCHEMA myschema AUTHORIZATION omm;
```

If the following information is displayed, the myschema schema that belongs to the **omm** user is created successfully:

```
CREATE SCHEMA
```

- Use a schema.

If you want to create or access an object in a specified schema, the object name must contain the schema name. To be specific, the name consists of a schema name and an object name, which are separated by a dot (.).

- Create the **mytable** table in myschema.

```
gaussdb=# CREATE TABLE myschema.mytable(id int, name varchar(20));
CREATE TABLE
```

To specify the location of an object, the object name must contain the schema name.

- Query all data of the **mytable** table in myschema.

```
gaussdb=# SELECT * FROM myschema.mytable;
id | name
----+-----
(0 rows)
```

- View the search path of a schema.

You can set **search\_path** to specify the sequence of schemas in which objects are searched. The first schema listed in the search path will become the default schema. If no schema is specified during object creation, the object will be created in the default schema.

- View the search path.

```
gaussdb=# SHOW SEARCH_PATH;
search_path
-----
"$user",public
(1 row)
```

- Set the search path to **myschema, public** (**myschema** will be searched first).

```
gaussdb=# SET SEARCH_PATH TO myschema, public;
SET
```

- Set permissions for a schema.

By default, a user can only access database objects in their own schema. Only after a user is granted with the usage permission for a schema by the schema owner, the user can access the objects in the schema.

By granting the CREATE permission for a schema to a user, the user can create objects in this schema. By default, all roles have the USAGE permission in the public schema, but common users do not have the CREATE permission in the public schema. It is insecure for a common user to connect to a specified database and create objects in its public schema. If the common user has the CREATE permission on the public schema, it is advised to:

- Revoke **PUBLIC**'s permission to create objects in the public schema.

**public** indicates the schema and **PUBLIC** indicates all roles.

```
gaussdb=# REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

- View the current schema.  

```
gaussdb=# SELECT current_schema();
current_schema
-----
myschema
(1 row)
```
- Create user **jack** and grant the usage permission for **myschema** to the user.  

```
gaussdb=# CREATE USER jack IDENTIFIED BY '*****';
CREATE ROLE
gaussdb=# GRANT USAGE ON schema myschema TO jack;
GRANT
```
- Revoke the usage permission for **myschema** from **jack**.  

```
gaussdb=# REVOKE USAGE ON schema myschema FROM jack;
REVOKE
```
- Delete a schema.
  - If a schema is empty, that is, it contains no database objects, you can run the **DROP SCHEMA** command. For example, delete an empty schema named **nullschema**.  

```
gaussdb=# DROP SCHEMA IF EXISTS nullschema;
DROP SCHEMA
```
  - To delete a schema that is not null, use the keyword **CASCADE** to delete it and all its objects. For example, delete **myschema** and all its objects in it.  

```
gaussdb=# DROP SCHEMA myschema CASCADE;
DROP SCHEMA
```
  - Delete user **jack**.  

```
gaussdb=# DROP USER jack;
DROP ROLE
```

### 3.2.6.2 Creating and Managing Partitioned Tables

#### Context

GaussDB supports range partitioned tables, interval partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data within a certain range is mapped to each partition. The range is determined by the partition key specified when the partitioned table is created. This partitioning mode is most commonly used. The partition key is usually a date. For example, sales data is partitioned by month.
- Interval partitioned table: A special type of range partitioned tables. Compared with range partitioned tables, interval value definition is added. When no matching partition can be found for an inserted record, a partition can be automatically created based on the interval value.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.

A partitioned table has the following advantages over an ordinary table:

- High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
- High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
- Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

To convert an ordinary table to a partitioned table, you need to create a partitioned table and import data to it from the ordinary table. When you design tables, plan whether to use partitioned tables based on service requirements.

## Procedure

Example 1: Use the default tablespace.

- Create a partitioned table (assuming that the **tpcds** schema has been created).

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN(10000),
  PARTITION P3 VALUES LESS THAN(15000),
  PARTITION P4 VALUES LESS THAN(20000),
  PARTITION P5 VALUES LESS THAN(25000),
  PARTITION P6 VALUES LESS THAN(30000),
  PARTITION P7 VALUES LESS THAN(40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer\_address** table to the **tpcds.web\_returns\_p2** table.

Suppose that the backup table **tpcds.web\_returns\_p2** of the **tpcds.customer\_address** table has been created in the database. You can insert the data of the **tpcds.customer\_address** table into the backup table **tpcds.web\_returns\_p2**.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
```

```

ca_street_type character(15) ,
ca_suite_number character(10) ,
ca_city character varying(60) ,
ca_county character varying(30) ,
ca_state character(2) ,
ca_zip character(10) ,
ca_country character varying(20) ,
ca_gmt_offset numeric(5,2) ,
ca_location_type character(20)
)
PARTITION BY RANGE (ca_address_sk)
(
PARTITION P1 VALUES LESS THAN(5000),
PARTITION P2 VALUES LESS THAN(10000),
PARTITION P3 VALUES LESS THAN(15000),
PARTITION P4 VALUES LESS THAN(20000),
PARTITION P5 VALUES LESS THAN(25000),
PARTITION P6 VALUES LESS THAN(30000),
PARTITION P7 VALUES LESS THAN(40000),
PARTITION P8 VALUES LESS THAN(MAXVALUE)
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpods.web_returns_p2 SELECT * FROM tpods.customer_address;
INSERT 0 0

```

- Modify the row movement attributes of the partitioned table.

```

gaussdb=# ALTER TABLE tpods.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE

```

- Delete a partition.

Delete partition **P8**.

```

gaussdb=# ALTER TABLE tpods.web_returns_p2 DROP PARTITION P8;
ALTER TABLE

```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE).

```

gaussdb=# ALTER TABLE tpods.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE

```

- Rename partitions.

– Rename partition **P8** to **P\_9**.

```

gaussdb=# ALTER TABLE tpods.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE

```

– Rename partition **P\_9** to **P8**.

```

gaussdb=# ALTER TABLE tpods.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE

```

- Query a partition.

Query partition **P6**.

```

gaussdb=# SELECT * FROM tpods.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpods.web_returns_p2 PARTITION FOR (35888);

```

- Delete a partitioned table and its tablespaces.

```

gaussdb=# DROP TABLE tpods.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpods.web_returns_p2;
DROP TABLE

```

Example 2: Use a user-defined tablespace (assuming that the **tpods** schema has been created).

Perform the following operations on a range partitioned table:

- Create tablespaces.

```
gaussdb=# CREATE TABLESPACE example1 RELATIVE LOCATION 'tablespace1/tablespace_1';
gaussdb=# CREATE TABLESPACE example2 RELATIVE LOCATION 'tablespace2/tablespace_2';
gaussdb=# CREATE TABLESPACE example3 RELATIVE LOCATION 'tablespace3/tablespace_3';
gaussdb=# CREATE TABLESPACE example4 RELATIVE LOCATION 'tablespace4/tablespace_4';
```

If the following information is displayed, the creation is successful:

```
CREATE TABLESPACE
```

- Create a partitioned table.

```
gaussdb=# CREATE TABLE tpcds.customer_address
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
TABLESPACE example1
PARTITION BY RANGE (ca_address_sk)
(
  PARTITION P1 VALUES LESS THAN(5000),
  PARTITION P2 VALUES LESS THAN( 10000),
  PARTITION P3 VALUES LESS THAN( 15000),
  PARTITION P4 VALUES LESS THAN( 20000),
  PARTITION P5 VALUES LESS THAN( 25000),
  PARTITION P6 VALUES LESS THAN( 30000),
  PARTITION P7 VALUES LESS THAN( 40000),
  PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

- Insert data.

Insert data from the **tpcds.customer\_address** table to the **tpcds.web\_returns\_p2** table.

Suppose that the backup table **tpcds.web\_returns\_p2** of the **tpcds.customer\_address** table has been created in the database. You can insert the data of the **tpcds.customer\_address** table into the backup table **tpcds.web\_returns\_p2**.

```
gaussdb=# CREATE TABLE tpcds.web_returns_p2
(
  ca_address_sk integer NOT NULL ,
  ca_address_id character(16) NOT NULL ,
  ca_street_number character(10) ,
  ca_street_name character varying(60) ,
  ca_street_type character(15) ,
  ca_suite_number character(10) ,
  ca_city character varying(60) ,
  ca_county character varying(30) ,
  ca_state character(2) ,
  ca_zip character(10) ,
  ca_country character varying(20) ,
  ca_gmt_offset numeric(5,2) ,
  ca_location_type character(20)
)
TABLESPACE example1
PARTITION BY RANGE (ca_address_sk)
```

```
(
    PARTITION P1 VALUES LESS THAN(5000),
    PARTITION P2 VALUES LESS THAN( 10000),
    PARTITION P3 VALUES LESS THAN( 15000),
    PARTITION P4 VALUES LESS THAN(20000),
    PARTITION P5 VALUES LESS THAN(25000),
    PARTITION P6 VALUES LESS THAN(30000),
    PARTITION P7 VALUES LESS THAN(40000),
    PARTITION P8 VALUES LESS THAN(MAXVALUE) TABLESPACE example2
)
ENABLE ROW MOVEMENT;
CREATE TABLE
gaussdb=# INSERT INTO tpceds.web_returns_p2 SELECT * FROM tpceds.customer_address;
INSERT 0 0
```

- Modify the row movement attributes of the partitioned table.

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 DISABLE ROW MOVEMENT;
ALTER TABLE
```

- Delete a partition.

Delete partition **P8**.

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 DROP PARTITION P8;
ALTER TABLE
```

- Add a partition.

Add partition **P8** and set its range to [40000,MAXVALUE).

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 ADD PARTITION P8 VALUES LESS THAN
(MAXVALUE);
ALTER TABLE
```

- Rename partitions.

- Rename partition **P8** to **P\_9**.

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 RENAME PARTITION P8 TO P_9;
ALTER TABLE
```

- Rename partition **P\_9** to **P8**.

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 RENAME PARTITION FOR (40000) TO P8;
ALTER TABLE
```

- Change the tablespace of a partition.

- Change the tablespace of partition **P6** to **example3**.

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 MOVE PARTITION P6 TABLESPACE example3;
ALTER TABLE
```

- Change the tablespace of partition **P4** to **example4**:

```
gaussdb=# ALTER TABLE tpceds.web_returns_p2 MOVE PARTITION P4 TABLESPACE example4;
ALTER TABLE
```

- Query a partition.

Query partition **P6**.

```
gaussdb=# SELECT * FROM tpceds.web_returns_p2 PARTITION (P6);
gaussdb=# SELECT * FROM tpceds.web_returns_p2 PARTITION FOR (35888);
```

- Delete a partitioned table and its tablespaces.

```
gaussdb=# DROP TABLE tpceds.customer_address;
DROP TABLE
gaussdb=# DROP TABLE tpceds.web_returns_p2;
DROP TABLE
gaussdb=# DROP TABLESPACE example1;
gaussdb=# DROP TABLESPACE example2;
gaussdb=# DROP TABLESPACE example3;
gaussdb=# DROP TABLESPACE example4;
DROP TABLESPACE
```

### 3.2.6.3 Creating and Managing Indexes

#### Context

Indexes accelerate data access but increase the processing time of insertion, update, and deletion operations. Therefore, before creating an index, consider whether it is necessary and select the columns where indexes are to be created. You can determine whether to create an index for a table by analyzing the service processing and data use of applications, as well as columns that are frequently used as search criteria or need to be collated.

Indexes are created based on columns in database tables. Therefore, you must correctly identify which columns require indexes. You are advised to create indexes for any of the following columns:

- Columns that are often searched and queried. This speeds up searches.
- Columns that function as primary keys. This enforces the uniqueness of the columns and the data collation structures in organized tables.
- Columns that are often joined. This increases the join efficiency.
- Columns that are often searched by range. The index helps collate data, and therefore the specified ranges are contiguous.
- Columns that often need to be collated. The index helps collate data, reducing the time for a collation query.
- Columns where the WHERE clause is executed frequently. This speeds up condition judgment.
- Columns that often appear after the keywords ORDER BY, GROUP BY, and DISTINCT.

#### NOTE

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.
- Partitioned table indexes are classified into local indexes and global indexes. A local index corresponds to a specific partition, and a global index corresponds to the entire partitioned table.
- When logical replication is enabled, if you need to create a primary key index that contains system columns, you must set the **REPLICA IDENTITY** attribute of the table to **FULL** or use **USING INDEX** to specify a unique, non-local, non-deferrable index that does not contain system columns and contains only columns marked **NOT NULL**.

#### Procedure

To create a partitioned table, see [Creating and Managing Partitioned Tables](#).

- Create an index.
  - Create the local index **tpcds\_web\_returns\_p2\_index1** without specifying the partition name.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index1 ON tpcds.web_returns_p2
(ca_address_id) LOCAL;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```

- Create the local index **tpcds\_web\_returns\_p2\_index2** with the partition name specified.

```
gaussdb=# CREATE INDEX tpcds_web_returns_p2_index2 ON tpcds.web_returns_p2
(ca_address_sk) LOCAL
```

```
(
PARTITION web_returns_p2_P1_index,
PARTITION web_returns_p2_P2_index TABLESPACE example3,
PARTITION web_returns_p2_P3_index TABLESPACE example4,
PARTITION web_returns_p2_P4_index,
PARTITION web_returns_p2_P5_index,
PARTITION web_returns_p2_P6_index,
PARTITION web_returns_p2_P7_index,
PARTITION web_returns_p2_P8_index
) TABLESPACE example2;
```

If the following information is displayed, the creation is successful:

```
CREATE INDEX
```

- Create the global index **tpcds\_web\_returns\_p2\_global\_index** for a partitioned table.

```
CREATE INDEX tpcds_web_returns_p2_global_index ON tpcds.web_returns_p2
(ca_street_number) GLOBAL;
```

- Change the tablespace of an index partition.

- Change the tablespace of index partition **web\_returns\_p2\_P2\_index** to **example1**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION
web_returns_p2_P2_index TABLESPACE example1;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Change the tablespace of index partition **web\_returns\_p2\_P3\_index** to **example2**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 MOVE PARTITION
web_returns_p2_P3_index TABLESPACE example2;
```

If the following information is displayed, the modification is successful:

```
ALTER INDEX
```

- Rename an index partition.

Rename the index partition **web\_returns\_p2\_P8\_index** to **web\_returns\_p2\_P8\_index\_new**.

```
gaussdb=# ALTER INDEX tpcds.tpcds_web_returns_p2_index2 RENAME PARTITION
web_returns_p2_P8_index TO web_returns_p2_P8_index_new;
```

If the following information is displayed, the rename operation is successful:

```
ALTER INDEX
```

- Query indexes.

- Query all indexes defined by the system and users.

```
gaussdb=# SELECT RELNAME FROM PG_CLASS WHERE RELKIND='i' or RELKIND='I';
```

- Query information about a specified index.

```
gaussdb=# \di+ tpcds.tpcds_web_returns_p2_index2
```

- Delete indexes.

```
gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index1;
gaussdb=# DROP INDEX tpcds.tpcds_web_returns_p2_index2;
```

If the following information is displayed, the deletion is successful:

```
DROP INDEX
```

GaussDB supports four methods for creating indexes. For details, see [Table 3-4](#).

 **NOTE**

- After an index is created, the system automatically determines when to reference it. If the system determines that indexing is faster than sequential scan, the index will be used.
- After an index is successfully created, it must be synchronized with the associated table to ensure new data can be accurately located, which increases the data operation load. Therefore, delete unnecessary indexes periodically.

**Table 3-4** Indexing methods

Indexing Method	Description
Unique index	An index that requires the uniqueness of an index attribute or an attribute group. If a table declares unique constraints or primary keys, GaussDB automatically creates unique indexes (or composite indexes) for columns that form the primary keys or unique constraints. Currently, unique indexes can be created only for the B-tree and UB-tree in GaussDB.
Composite index	An index that can be defined for multiple attributes of a table. Currently, the B-tree in GaussDB supports composite indexes.
Partial index	An index that can be created for subsets of a table. This indexing method contains only tuples that meet condition expressions.
Expression index	An index that is built on a function or expression calculated based on one or more attributes of a table. An expression index works only when the queried expression is the same as the created expression.

- Create an ordinary table.  
gaussdb=# `CREATE TABLE tpcds.customer_address_bak AS TABLE tpcds.customer_address;`  
INSERT 0 0

- Create an ordinary index.

For the **tpcds.customer\_address\_bak** table, you need to perform the following operations frequently:

gaussdb=# `SELECT ca_address_sk FROM tpcds.customer_address_bak WHERE ca_address_sk=14888;`

Generally, the database system needs to scan the **tpcds.customer\_address\_bak** table row by row to query all matched tuples. If the size of the **tpcds.customer\_address\_bak** table is large but only a few (possibly zero or one) of the **WHERE** conditions are met, the performance of this sequential scan is poor. If the database system uses an index to maintain the **ca\_address\_sk** attribute, the database system only needs to search a few tree layers for the matched tuples. This greatly improves data query performance. Furthermore, indexes can improve the update and deletion operation performance in the database.

Create an index.

```
gaussdb=# CREATE INDEX index_wr_returned_date_sk ON tpcds.customer_address_bak  
(ca_address_sk);  
CREATE INDEX
```

- Create a unique index.

Create a unique index on the **SM\_SHIP\_MODE\_SK** column in the **tpcds.ship\_mode\_t1** table.

```
gaussdb=# CREATE UNIQUE INDEX ds_ship_mode_t1_index1 ON  
tpcds.ship_mode_t1(SM_SHIP_MODE_SK);
```

- Create a composite index.

To frequently query records with **ca\_address\_sk** being **5050** and **ca\_street\_number** smaller than **1000** in the **tpcds.customer\_address\_bak** table, run the following command:

```
gaussdb=# SELECT ca_address_sk,ca_address_id FROM tpcds.customer_address_bak WHERE  
ca_address_sk = 5050 AND ca_street_number < 1000;
```

Define a composite index on **ca\_address\_sk** and **ca\_street\_number** columns.

```
gaussdb=# CREATE INDEX more_column_index ON  
tpcds.customer_address_bak(ca_address_sk ,ca_street_number );  
CREATE INDEX
```

- Create a partial index.

If you only want to find records with **ca\_address\_sk** being **5050**, you can create a partial index to facilitate your query.

```
gaussdb=# CREATE INDEX part_index ON tpcds.customer_address_bak(ca_address_sk) WHERE  
ca_address_sk = 5050;  
CREATE INDEX
```

- Create an expression index.

Frequently query records with **ca\_street\_number** smaller than **1000**.

```
gaussdb=# SELECT * FROM tpcds.customer_address_bak WHERE trunc(ca_street_number) < 1000;
```

The following expression index can be created for this query task:

```
gaussdb=# CREATE INDEX para_index ON tpcds.customer_address_bak (trunc(ca_street_number));  
CREATE INDEX
```

- Delete the **tpcds.customer\_address\_bak** table.

```
gaussdb=# DROP TABLE tpcds.customer_address_bak;  
DROP TABLE
```

### 3.2.6.4 Creating and Managing Views

#### Context

If some columns in one or more tables in a database are frequently searched for, an administrator can define a view for these columns, and then users can directly access these columns in the view without entering search criteria.

Different from a base table, a view is a virtual table. Only view definition is stored in the database and view data is not. The data is stored in a base table. If data in the base table changes, the data in the view changes accordingly. A view is like a window through which users can know their interested data and data changes in the database. A view is triggered every time it is referenced.

#### Managing Views

- Create a view.

Create the **MyView** view. In the command, **tpcds.web\_returns** indicates the created user table that contains the **wr\_refunded\_cash** integer column.

```
gaussdb=# CREATE OR REPLACE VIEW MyView AS SELECT * FROM tpcds.web_returns WHERE
trunc(wr_refunded_cash) > 10000;
CREATE VIEW
```

#### NOTE

The **OR REPLACE** parameter in this command is optional. It indicates that if the view exists, the new view will replace the existing view.

- Query a view.

Query **MyView**.

```
gaussdb=# SELECT * FROM MyView;
```

- Query views of the current user.

```
gaussdb=# SELECT * FROM my_views;
```

- Query all views.

```
gaussdb=# SELECT * FROM adm_views;
```

- Query details about a specified view.

View details about **MyView**.

```
gaussdb=# \d+ MyView
```

```
View "PG_CATALOG.MyView"
Column | Type | Modifiers | Storage | Description
-----+-----+-----+-----+-----
USERNAME | CHARACTER VARYING(64) | | extended |
View definition:
SELECT PG_AUTHID.ROLNAME::CHARACTER VARYING(64) AS USERNAME
FROM PG_AUTHID;
```

- Delete a view.

Delete **MyView**.

```
gaussdb=# DROP VIEW MyView;
DROP VIEW
```

## 3.2.6.5 Creating and Managing Sequences

### Context

A sequence is a database object that generates unique integers. Sequence numbers are generated according to a certain rule. Sequences are unique because they increase automatically. This is why they are often used as primary keys.

You can create a sequence for a column in either of the following methods:

- Set the data type of a column to **sequence integer**. A sequence will be automatically created by the database for this column.
- Use the **CREATE SEQUENCE** statement to create a sequence. Set the initial value of the `nextval('sequence_name')` function to the default value of a column.

### Procedure

Method 1: Set the data type of a column to a sequence integer. Example:

```
gaussdb=# CREATE TABLE T1
(
  id serial,
  name text
);
```

If the following information is displayed, the creation is successful:

```
CREATE TABLE
```

Method 2: Create a sequence and set the initial value of the **nextval('sequence\_name')** function to the default value of a column.

1. Create a sequence.

```
gaussdb=# CREATE SEQUENCE seq1 cache 100;
```

If the following information is displayed, the creation is successful:

```
CREATE SEQUENCE
```

2. Set the default value of a column so that the column has a unique identification attribute.

```
gaussdb=# CREATE TABLE T2  
(  
  id int not null default nextval('seq1'),  
  name text  
);
```

If the following information is displayed, the default value has been specified:

```
CREATE TABLE
```

3. Associate a sequence with a column.

Associate a sequence with a specified column included in a table. In this way, the sequence will be deleted when you delete its associated column or the table where the column belongs to.

```
gaussdb=# ALTER SEQUENCE seq1 OWNED BY T2.id;
```

If the following information is displayed, the operation is successful:

```
ALTER SEQUENCE
```

#### NOTE

The preceding methods are similar, except that the second method specifies cache for the sequence. A sequence having cache defined has inconsecutive values (such as 1, 4, and 5) and cannot maintain the order of its values. After the dependent column of a sequence has been specified, once the sequence is deleted, the sequence of the dependent will be deleted. A sequence shared by multiple columns is not forbidden in a database, but you are advised not to do that.

In the current version, you can specify the auto-increment column or set the default value of a column to **nextval('seqname')** when defining a table. You cannot add an auto-increment column or a column whose default value is **nextval('seqname')** to an existing table.

# 4 Development and Design Proposal

---

## 4.1 Overview

This section describes the design specifications for database modeling and application development. Modeling based on these specifications can better fit the processing architecture of GaussDB and output more efficient service SQL code.

The meaning of "Proposal" and "Notice" in this section is as follows:

- **Proposal:** Design rules. Services complying with the rules can run efficiently, and those violating the rules may have low performance or logic errors.
- **Notice:** Details requiring attention during service development. This term identifies SQL behavior that complies with SQL standards but users may have misconceptions about, and default behavior that users may be unaware of in a program.

## 4.2 Database Object Naming Conventions

Database object names must meet the following requirements:

- The name length of a table or an identifier cannot exceed 63 bytes.
- An identifier starts with a letter or underscore (\_) and can contain letters, digits, underscores (\_), dollar signs (\$), and number signs (#).
- If an identifier is enclosed in double quotation marks (""), any combination of valid characters can be used, for example, "123gs\_column".
- Identifiers are case insensitive unless they are enclosed in double quotation marks.
- Do not use reserved or non-reserved keywords to name database objects.

### NOTE

To query the GaussDB keywords, run `select * from pg_get_keywords()` or refer to [Keywords](#).

- Do not use a string enclosed in double quotation marks ("") to define the database object name, unless you need to specify its capitalization. Case sensitivity of database object names makes problem location difficult.

- Use the same naming format for database objects.
  - In a system undergoing incremental development or service migration, you are advised to comply with its historical naming conventions.
  - You are advised to use multiple words separated with underscores (\_).
  - You are advised to use intelligible names and common acronyms or abbreviations for database objects. Acronyms or abbreviations that are generally understood are recommended. For example, you can use English words or Chinese pinyin indicating actual business terms. The naming format should be consistent within a database instance.
  - A variable name must be descriptive and meaningful. It must have a prefix indicating its type.
- The name of a table object should indicate its main characteristics, for example, whether it is an ordinary, temporary, or unlogged table.
  - An ordinary table name should indicate the business relevant to a dataset.
  - Temporary tables are named in the format of **tmp\_Suffix**.
  - Unlogged tables are named in the format of **ul\_Suffix**.
  - Foreign tables are named in the format of **f\_Suffix**.
  - Do not create database objects whose names start with **redis\_**.
  - Do not create database objects whose names start with **mlog\_** or **matviewmap\_**.
  - Do not create database objects whose names start with **gs\_role\_**.
- The name of a table object shall not exceed 63 bytes. If the length of a table name exceeds this value, the kernel truncates the table name. As a result, the table name is inconsistent with the configured value. In addition, characters may be truncated in different character sets and unexpected characters may appear.

## 4.3 Database Object Design

### 4.3.1 Database and Schema Design

In GaussDB, services can be isolated by databases and schemas. Databases share little resources and cannot directly access each other. Connections to and permissions on them are also isolated. Schemas share more resources than databases do. User permissions on schemas and subordinate objects can be controlled using the GRANT and REVOKE syntax.

- You are advised to use schemas to isolate services for convenience and resource sharing.
- It is recommended that system administrators create schemas and databases and then assign required permissions to users.

### Database Design

- Create databases as required by your service. Do not use the default **postgres** database of a database instance.

- In a database instance, it is recommended that the number of user-defined databases be 3 and no more than 10. If there are too many user-defined databases, O&M operations, such as upgrade and backup, will be inefficient.
- To make your database compatible with most characters, you are advised to use the UTF-8 encoding when creating a database.
- When you create a database, exercise caution when you set **ENCODING** and **DBCOMPATIBILITY** configuration items. GaussDB supports the A, B, C, and PG compatibility modes, which are compatible with the Oracle syntax, MySQL syntax, Teradata syntax, and Postgres syntax, respectively. The syntax behavior varies according to the compatibility mode. By default, the A compatibility mode is used.
- By default, a database owner has all permissions for all objects in the database, including the deletion permission. Exercise caution when deleting a permission.

## Schema Design

- It is recommended that the number of schemas in the actual user environment be no more than 100. If there are too many schemas in a database, operations that depend on the number of schemas, such as `gs_dump`, becomes slow.
- To let a user access an object in a schema, assign the usage permission and the permissions for the object to the user, unless the user has the `sysadmin` permission or is the schema owner.
- To let a user create an object in the schema, grant the `CREATE` permission for the schema to the user.
- By default, a schema owner has all permissions for all objects in the schema, including the deletion permission. Exercise caution when deleting a permission.

### 4.3.2 Table Design

Generally, well-designed table must comply with the following rules:

- Reduce the amount of data to be scanned. You can use the pruning mechanism of a partitioned table.
- Minimize random I/Os. Through clustering, you can sequentially store hot data, converting random I/O to sequential I/O to reduce the cost of I/O scanning.

### Selecting a Partitioning Mode

Comply with the following rules to partition a table containing a large amount of data:

- Create partitions on columns that indicate certain ranges, such as dates and regions.
- A partition name should show the data characteristics of a partition. For example, its format can be *Keyword+Range* characteristics.
- Set the upper limit of a partition to **MAXVALUE** to prevent data overflow.

**Table 4-1** Table partitioning modes and scenarios

Partitioning Mode	Description
Range	Table data is partitioned by range.
Interval	Table data is partitioned by range. If the data exceeds the range, a new partition is automatically created based on the interval.
List	Table data is partitioned by a specified column based on a specific value.
Hash	Table data is partitioned by hash.

The example of defining a partitioned table is as follows:

```
-- Create a range partitioned table.
CREATE TABLE staffS_p1
(
  staff_ID    NUMBER(6) not null,
  FIRST_NAME  VARCHAR2(20),
  LAST_NAME   VARCHAR2(25),
  EMAIL       VARCHAR2(25),
  PHONE_NUMBER VARCHAR2(20),
  HIRE_DATE   DATE,
  employment_ID VARCHAR2(10),
  SALARY      NUMBER(8,2),
  COMMISSION_PCT NUMBER(4,2),
  MANAGER_ID  NUMBER(6),
  section_ID  NUMBER(4)
)
PARTITION BY RANGE (HIRE_DATE)
(
  PARTITION HIRE_19950501 VALUES LESS THAN ('1995-05-01 00:00:00'),
  PARTITION HIRE_19950502 VALUES LESS THAN ('1995-05-02 00:00:00'),
  PARTITION HIRE_maxvalue VALUES LESS THAN (MAXVALUE)
);

-- Create an interval partitioned table. The table has two initial partitions. When data that is not in
the partition range is inserted, another partition is automatically added.
CREATE TABLE sales
(prod_id NUMBER(6),
cust_id NUMBER,
time_id DATE,
channel_id CHAR(1),
promo_id NUMBER(6),
quantity_sold NUMBER(3),
amount_sold NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
INTERVAL('1 day')
( PARTITION p1 VALUES LESS THAN ('2019-02-01 00:00:00'),
  PARTITION p2 VALUES LESS THAN ('2019-02-02 00:00:00')
);

-- Create a list partitioned table.
CREATE TABLE test_list (col1 int, col2 int)
partition by list(col1)
(
  partition p1 values (2000),
  partition p2 values (3000),
  partition p3 values (4000),
  partition p4 values (5000)
);
```

```
-- Create a hash partitioned table.  
CREATE TABLE test_hash (col1 int, col2 int)  
partition by hash(col1)  
(  
partition p1,  
partition p2  
);
```

For details about the table partition syntax, see [CREATE TABLE PARTITION](#).

### 4.3.3 Column Design

#### Selecting a Data Type

To improve query efficiency, comply with the following rules when designing columns:

- Use the most efficient data types allowed.  
If all of the following number types provide the required service precision, they are recommended in descending order of priority: integer, floating point, and numeric.
- In tables that are logically related, columns having the same meaning should use the same data type.
- For string data, you are advised to use variable-length strings and specify the maximum length. Ensure that the specified maximum length is greater than the maximum number of characters to be stored. Otherwise, an error is reported, causing service interruption. You are advised not to use CHAR(n), BPCHAR(n), NCHAR(n), or CHARACTER(n), unless you know that the string length is fixed.

For details about string types, see [Common String Types](#).

#### Common String Types

Every column requires a data type suitable for its data characteristics. [Character Types](#) lists common string types in GaussDB.

### 4.3.4 Constraint Design

#### DEFAULT and NULL Constraints

- If all the column values can be obtained from services, you are advised not to use the DEFAULT constraint. Otherwise, unexpected results will be generated during data loading.
- Add NOT NULL constraints to columns that never have NULL values. The optimizer automatically optimizes the columns in certain scenarios.
- Explicitly name all constraints excluding NOT NULL and DEFAULT.

#### Unique Constraints

- The constraint name should indicate that it is a unique constraint, for example, *UNIIncluded columns*.

## Primary Key Constraints

- The constraint name should indicate that it is a primary key constraint, for example, *PKIncluded columns*.

## Check Constraints

- The constraint name should indicate that it is a check constraint, for example, *CKIncluded columns*.

## 4.3.5 View and Joined Table Design

### View Design

- Do not nest views unless they have strong dependency on each other.
- Try to avoid collation operations in a view definition.

### Joined Table Design

- Minimize joined columns across tables.
- Use the same data type for joined columns.
- The names of joined columns should indicate their relationship. For example, they can use the same name.

## 4.4 Tool Interconnection

### 4.4.1 JDBC Configuration

Currently, third-party tools are connected to GaussDB through JDBC. This section describes the precautions for configuring the tool.

#### Connection Parameters

- When a third-party tool connects to GaussDB through JDBC, JDBC sends a connection request to GaussDB. By default, the following configuration parameters are added. For details, see the implementation of the `ConnectionFactoryImpl` class in the JDBC code.

```
params = {  
    { "user", user },  
    { "database", database },  
    { "client_encoding", "UTF8" },  
    { "DateStyle", "ISO" },  
    { "extra_float_digits", "3" },  
    { "TimeZone", createPostgresTimeZone() },  
};
```

These parameters may cause the JDBC and `gsqL` clients to display inconsistent data, for example, date data display mode, floating point precision representation, and timezone.

If the result is not as expected, you are advised to explicitly set these parameters in the Java connection setting.

When the database is connected through JDBC, **extra\_float\_digits** is set to **3**. When the database is connected using `gsqL`, **extra\_float\_digits** is set to **0**. As

a result, the precision of the same data displayed in JDBC clients may be different from that displayed in gsql clients.

- In precision-sensitive scenarios, the numeric type is recommended.
- When JDBC connects to the database, ensure that the following three time zones are the same:
  - Time zone of the host where the JDBC client is located
  - Time zone of the host where the GaussDB database instance is located.
  - Time zone used during GaussDB database instance configuration.

#### NOTE

For details about how to set the time zone, contact the administrator.

## fetchsize

To use **fetchsize** in applications, disable **autocommit**. Enabling the **autocommit** switch makes the **fetchsize** configuration invalid.

## autocommit

You are advised to enable **autocommit** in the code for connecting to GaussDB by the JDBC. If **autocommit** needs to be disabled to improve performance or for other purposes, applications need to ensure that transactions are committed. For example, explicitly commit transactions after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

## Connection Releasing

- You are advised to use connection pools to limit the number of connections from applications. Do not connect to a database every time you run an SQL statement.
- After an application completes its jobs, disconnect it from GaussDB to release occupied resources. You are advised to set the session timeout interval in the jobs.
- Reset the session environment before releasing connections to the JDBC connection pool. Otherwise, historical session information may cause object conflicts.
  - If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
  - If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

## CopyManager

In the scenario where the ETL tool is not used and real-time data import is required, it is recommended that you use the CopyManager API driven by the GaussDB JDBC to import data in batches during application development.

## 4.5 SQL Compilation

### DDL

- In GaussDB, you are advised to perform DDL operations (such as table creation and COMMENT) in a unified manner. Prevent DDL operations in batch processing jobs so that performance is not affected.
- Perform the TRUNCATE operation immediately after the unlogged table is used because GaussDB cannot ensure the security of unlogged tables in abnormal scenarios.
- Suggestions on the storage mode of temporary and unlogged tables are the same as those on base tables.
- The total length of an index column cannot exceed 50 bytes. Otherwise, the index size will increase greatly, resulting in large storage cost and low index performance.
- Do not delete objects using DROP...CASCADE, unless the dependency between objects is specified. Otherwise, the objects may be deleted by mistake.

### Data Loading and Unloading

- Explicitly set the inserted column list in the INSERT statement. Example:  

```
INSERT INTO task(name,id,comment) VALUES ('task1','100','100th task');
```
- After data is imported to the database in batches or the data increment reaches the threshold, you are advised to analyze tables to prevent the execution plan from being degraded due to inaccurate statistics.
- To clear all data in a table, you are advised to use TRUNCATE TABLE instead of DELETE TABLE. DELETE TABLE is not efficient and cannot release disk space occupied by the deleted data.

### Type Conversion

- Convert data types explicitly. If you perform implicit conversion, the result may differ from expected.
- During data query, explicitly specify the data type for constants, and do not attempt to perform any implicit data type conversion.
- If **sql\_compatibility** is set to **A**, null strings will be automatically converted to **NULL** during data import. If null strings need to be reserved, set **sql\_compatibility** to **C**.

### Query Operation

- Do not return a large number of result sets to a client except the ETL program. If a large result set is returned, consider modifying your service design.
- Perform DDL and DML operations encapsulated in transactions. For example, operations such as TRUNCATE TABLE, UPDATE TABLE, DELETE TABLE, and DROP TABLE cannot be restored once they are committed. You are advised to encapsulate such operations in transactions so that you can roll back the operations if necessary.

- During query compilation, you are advised to list all columns to be queried and avoid using `SELECT *`. Doing so reduces output lines, improves query performance, and avoids the impact of adding or deleting columns on front-end service compatibility.
- During table object access, add the schema prefix to the table object to avoid accessing an unexpected table due to schema switchover.
- The cost of joining more than three tables or views, especially full joins, is difficult to be estimated. You are advised to use the `WITH TABLE AS` statement to create interim tables to improve the readability of SQL statements.
- Avoid using Cartesian products or full joins. Cartesian products and full joins will result in a sharp expansion of result sets and poor performance.
- Only `IS NULL` and `IS NOT NULL` can be used to determine NULL value comparison results. If any other method is used, NULL is returned. For example, NULL instead of expected Boolean values is returned for `NULL<>NULL`, `NULL=NULL`, and `NULL<>1`.
- Do not use `count(col)` instead of `count(*)` to count the total number of records in a table. `count(*)` counts the NULL value (actual rows) while `count(col)` does not.
- While executing `count(col)`, the number of NULL record rows is counted as 0. While executing `sum(col)`, NULL is returned if all records are NULL. If not all the records are NULL, the number of NULL record rows is counted as 0.
- To count multiple columns using `count()`, column names must be enclosed in parentheses, for example, `count( col1, col2, col3 )`. Note: When multiple columns are used to count the number of NULL record rows, a row is counted even if all the selected columns are NULL. The result is the same as that when `count(*)` is executed.
- NULL records are not counted when `count(distinct col)` is used to calculate the number of non-NULL columns that are not repeated.
- If all statistical columns are NULL when `count(distinct (col1,col2,...))` is used to count the number of unique values in multiple columns, Null records are also counted, and the records are considered the same.
- Use the connection operator `||` to replace the concat function for string connection, because the concat function needs to query type tables and function tables, which slows down the basic performance. In addition, because the concat output is related to the data type, the execution plan generated by the concat function cannot calculate results in advance. As a result, the query performance severely deteriorates.
- Use the time-related macros listed in [Table 1](#) to replace the now function and obtain the current time, because the execution plan generated by the now function cannot be pushed down to disks. As a result, the query performance severely deteriorates.

**Table 4-2** Time-related macros

Macro Name	Description	Example
CURRENT_DATE	Obtains the current date, excluding the hour, minute, and second details.	gaussdb=# SELECT CURRENT_DATE; date ----- 2018-02-02 (1 row)
CURRENT_TIME	Obtains the current time, excluding the year, month, and day.	gaussdb=# SELECT CURRENT_TIME; timetz ----- 00:39:34.633938+08 (1 row)
CURRENT_TIMESTAMP( n)	Obtains the current date and time, including year, month, day, hour, minute, and second.  <b>NOTE</b> <i>n</i> indicates the number of digits after the decimal point in the time string.	gaussdb=# SELECT CURRENT_TIMESTAMP(6); timestampz ----- 2018-02-02 00:39:55.231689+08 (1 row)

- Do not use scalar subquery statements. A scalar subquery is a subquery in the output list of the SELECT statement. In the following example, "SELECT COUNT(\*) FROM films f WHERE f.did = s.id" is a scalar subquery statement:  
SELECT id, (SELECT COUNT(\*) FROM films f WHERE f.did = s.id) FROM staffs\_p1 s;

Scalar subqueries often result in query performance deterioration. During application development, scalar subqueries need to be converted into equivalent table associations based on the service logic.

- In WHERE clauses, the filter conditions should be collated. The condition that few records are selected for reading (the number of filtered records is small) is listed at the beginning.
- Filter conditions in WHERE clauses should comply with unilateral rules, that is, to place the column name on one side of a comparison operator. In this way, the optimizer automatically performs pruning optimization in some scenarios. The format is *col op expression*, where *col* indicates a table column, *op* indicates a comparison operator, such as = and >, and *expression* indicates an expression that does not contain a column name. Example:  
SELECT id, from\_image\_id, from\_person\_id, from\_video\_id FROM face\_data WHERE current\_timestamp(6) - time < '1 days'::interval;

The modification is as follows:

```
SELECT id, from_image_id, from_person_id, from_video_id FROM face_data where time > current_timestamp(6) - '1 days'::interval;
```

- Do not perform unnecessary collation operations. Collation requires a large amount of memory and CPU. If service logic permits, ORDER BY and LIMIT can be combined to reduce resource overhead. By default, GaussDB performs collation by ASC & NULL LAST.
- When the ORDER BY clause is used for collation, specify collation modes (**ASC** or **DESC**), and use NULL FIRST or NULL LAST for NULL record sorting.

- Do not rely on only the LIMIT clause to return the result set displayed in a specific sequence. Combine ORDER BY and LIMIT clauses if some specific result sets are returned, and use OFFSET to skip specific results if necessary.
- If the service logic is accurate, you are advised to use UNION ALL instead of UNION.
- If a filter condition contains only an OR expression, convert the OR expression to UNION ALL to improve performance. SQL statements that use OR expressions cannot be optimized, resulting in slow execution. For example, the conversion of the following statements:

```
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 300 AND inline=301) OR (cdp= 301 AND inline=302) OR (cdp= 302 AND inline=301);
```

Convert the statement to the following:

```
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 300 AND inline=301)  
union all  
SELECT * FROM scdc.pub_menu  
WHERE (cdp= 301 AND inline=302)  
union all  
SELECT * FROM tablename  
WHERE (cdp= 302 AND inline=301)
```

- If an IN(val1, val2, val3...) expression contains a large number of columns, you are advised to replace it with the IN (VALUES (val1), (val2),(val3)...) statement. The optimizer will automatically convert the IN constraint into a non-correlated subquery to improve the query performance.
- Use (NOT) EXIST instead of (NOT) IN when associated columns do not contain null values. For example, in a query statement, if the **T1.C1** column does not contain any **NULL** value, add the **NOT NULL** constraint to the **T1.C1** column, and then rewrite the statements.

```
SELECT * FROM T1 WHERE T1.C1 NOT IN (SELECT T2.C2 FROM T2);
```

Rewrite the statement as follows:

```
SELECT * FROM T1 WHERE NOT EXISTS (SELECT * FROM T2 WHERE T1.C1=T2.C2);
```

#### NOTE

- If the value of the **T1.C1** column is not **NOT NULL**, the preceding rewriting cannot be performed.
- If the **T1.C1** column is the output of a subquery, check whether the output is **NOT NULL** based on the service logic.
- Use cursors instead of the LIMIT OFFSET syntax to perform pagination queries to avoid resource overheads caused by multiple executions. A cursor must be used in a transaction, and you must disable the cursor and commit the transaction once the query is finished.

# 5 Application Development Guide

## 5.1 Development Specifications

If the connection pool mechanism is used during application development, comply with the following specifications:

- If GUC parameters are set in the connection, run **SET SESSION AUTHORIZATION DEFAULT;RESET ALL;** to clear the connection status before you return the connection to the connection pool.
- If a temporary table is used, delete the temporary table before you return the connection to the connection pool.

If you do not do so, the connection state in the connection pool will remain, which affects subsequent operations using the connection pool.

[Table 5-1](#) describes the compatibility of application development drivers.

**Table 5-1** Compatibility Description

Driver	Compatibility Description
JDBC and Go	The new drivers are forward compatible with the database. To use the new features added to the driver and database, you must upgrade the database.
ODBC, libpq, Psycopg, and ecpg	The driver version must match the database version.

**NOTICE**

- Setting **behavior\_compat\_options** to 'proc\_outparam\_override' is applicable only in A-compatible mode.
- In principle, you need to set the compatibility parameter after the database creation, instead of switching the parameters when using the database.
- The JDBC driver must be upgraded to that maps to GaussDB Kernel 503.1 or later if the following features are used:
  - The **s2** compatibility parameter is enabled and the validity check of **sessiontimezone** is set.

If the driver is used in a multi-thread environment:

The JDBC driver is non-thread-safe and does not guarantee that the connection methods are synchronized. The caller synchronizes the calls to the driver.

## 5.2 Obtaining the Driver Package

### Obtaining the Driver Package

Download the required packages listed in [Table 5-2](#).

**Table 5-2** Driver package download list

Version	Download Address
3.x	<a href="#">Driver package</a> <a href="#">Verification package for the driver package</a>

To prevent a software package from being tampered with during transmission or storage, download the corresponding verification package and perform the following steps to verify the software package:

1. Upload the software package and verification package to the same directory on a Linux VM.
2. Run the following command to verify the integrity of the software package:

```
cat GaussDB_driver.zip.sha256 | sha256sum --check
```

If **OK** is displayed in the command output, the verification is successful.

```
GaussDB_driver.zip: OK
```

## 5.3 Development Based on JDBC

Java Database Connectivity (JDBC) is a Java API for running SQL statements. It provides unified access APIs for different relational databases, based on which applications process data. The GaussDB library supports JDBC 4.2 and requires JDK 1.8 for code compiling. It does not support JDBC-ODBC bridge.

## 5.3.1 JDBC Package, Driver Class, and Environment Class

### JDBC Package

Obtain the package from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Jdbc.tar.gz**. After the decompression, you will obtain the following JDBC packages in .jar format:

- **gsjdbc4.jar**: The main class name is **org.postgresql.Driver**, and the URL prefix of the database connection is **jdbc:postgresql**. This driver package applies to the scenario where services are migrated from PostgreSQL. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
- **gscejdbc.jar**: The main class name is **com.huawei.gaussdb.jdbc.Driver**. The URL prefix of database connections is **jdbc:gaussdb**. This driver package contains the dependent libraries related to encryption and decryption that need to be loaded to the encrypted database. This driver package is recommended in encrypted scenarios. Currently, only EulerOS is supported. Before using the **gscejdbc.jar** driver package, set the environment variable **LD\_LIBRARY\_PATH**. For details, see "Setting Encrypted Equality Queries > Using JDBC to Operate an Encrypted Database" in *Feature Guide*.
- **opengaussjdbc.jar**: The main class name is **com.huawei.opengauss.jdbc.Driver**. The URL prefix of the database connection is **jdbc:opengauss**. This driver package is recommended. This driver package is used when both PostgreSQL and GaussDB are accessed in a JVM process.

---

#### NOTICE

- The loading paths and URL prefixes of driver classes vary in different driver packages, but the API functions are the same.
  - **gsjdbc200.jar**: The main class name is **com.huawei.gauss200.jdbc.Driver**, and the URL prefix of the database connection is **jdbc:gaussdb**. This driver package applies to the scenario where services are migrated from GaussDB 200. The driver class and loading path are the same as those before the migration, but the supported APIs are different. The APIs that are not supported need to be adjusted on the service side.
  - The **gsjdbc4** driver package cannot be used to operate the PostgreSQL database. Although the connection can be successfully established in some versions, some API behaviors are different from those of PostgreSQL JDBC, which may cause unknown errors.
  - The PostgreSQL driver package cannot be used to operate GaussDB. Although the connection can be successfully established in some versions, some API behaviors are different from those of GaussDB JDBC, which may cause unknown errors.
-

## Driver Class

Before establishing a database connection, load the **org.postgresql.Driver** database driver class.

### NOTE

1. GaussDB is compatible with PostgreSQL in the use of JDBC. Therefore, when two JDBC drivers are used in the same process, class names may conflict.
2. Compared with the PostgreSQL driver, the GaussDB JDBC driver has the following enhanced features:
  1. The SHA256 encryption mode is supported for login.
  2. The third-party log framework that implements the sf4j API can be connected.
  3. DR failover is supported.

## Environment Class

JDK 1.8 must be configured on the client. The configuration method is as follows:

**Step 1** Enter **java -version** in the MS-DOS window (command prompt in Windows) to check the JDK version. Ensure that the JDK version is JDK1.8. If JDK is not installed, download the installation package from the official website and install it.

**Step 2** Configure system environment variables.

1. Right-click **My computer** and choose **Properties**.
2. In the navigation pane, choose **Advanced system settings**.
3. In the **System Properties** dialog box, click **Environment Variables** on the **Advanced** tab page.
4. In the **System variables** area of the **Environment Variables** dialog box, click **New** or **Edit** to configure system variables. For details, see [Table 5-3](#).

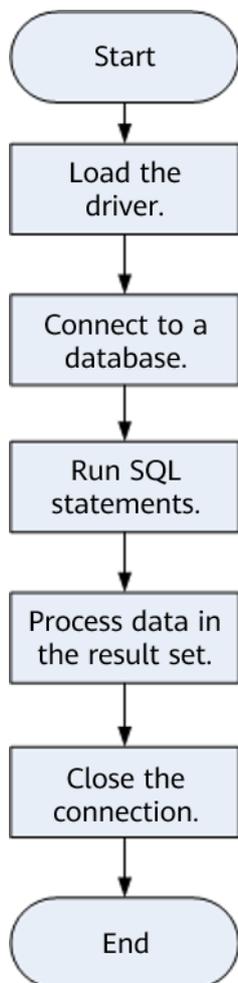

**Table 5-3** Variables

Variable	Operation	Variable Value
JAVA_HOME	<ul style="list-style-type: none"><li>- If the variable exists, click <b>Edit</b>.</li><li>- If the variable does not exist, click <b>New</b>.</li></ul>	Specifies the Java installation directory. Example: <b>C:\Program Files\Java\jdk1.8.0_131</b> .
Path	Click <b>Edit</b> .	<ul style="list-style-type: none"><li>- If <i>JAVA_HOME</i> is configured, add <i>%JAVA_HOME%\bin</i> before the variable value.</li><li>- If <i>JAVA_HOME</i> is not configured, add the full Java installation path before the variable value: <b>C:\Program Files\Java\jdk1.8.0_131\bin</b></li></ul>
CLASSPATH	Click <b>New</b> .	<b>%JAVA_HOME%\lib;%JAVA_HOME%\lib\tools.jar</b>

----End

## 5.3.2 Development Process

Figure 5-1 JDBC-based application development process

## 5.3.3 Loading a Driver

Load the database driver before creating a database connection.

You can load the driver in the following ways:

- Implicitly load the driver at any position before a connection is created in the code: `Class.forName("org.postgresql.Driver")`. For details about the code for creating a connection, see [Examples](#).
- Specify the driver name when a JVM is started. This parameter is used to execute Java code in the DOS window or on Linux. Example: `java -Djdbc.drivers=org.postgresql.Driver jdbctest`.

### NOTE

`jdbctest` is the name of a test application.

## 5.3.4 Connecting to a Database

After a database is connected, it can be used to run SQL statements to operate data.

### Function Prototype

JDBC provides three database connection methods.

- `DriverManager.getConnection(String url)`
- `DriverManager.getConnection(String url, Properties info)`
- `DriverManager.getConnection(String url, String user, String password)`

## Parameters

**Table 5-4** Database connection parameters

Parameter	Description
url	<p><b>postgresql.jar</b> database connection descriptor. The format is as follows:</p> <ul style="list-style-type: none"> <li>• jdbc:postgresql:database</li> <li>• jdbc:postgresql://host/database</li> <li>• jdbc:postgresql://host:port/database</li> <li>• jdbc:postgresql://host:port/database?param1=value1&amp;param2=value2</li> <li>• jdbc:postgresql://host1:port1,host2:port2/database?param1=value1&amp;param2=value2</li> </ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• <b>database</b> indicates the name of the database to connect.</li> <li>• <b>host</b> indicates the name or IP address of the database server. For security purposes, the primary database node forbids access from other nodes in the database without authentication. To access the primary database node from inside the database, deploy the JDBC program on the host where the primary database node is located and set <b>host</b> to <b>127.0.0.1</b>. Otherwise, the error message "FATAL: Forbid remote connection with trust method!" may be displayed.</li> </ul> <p>It is recommended that the service system be deployed outside the database. Otherwise, the database performance may be affected.</p> <p>By default, the local host is used to connect to the server.</p> <ul style="list-style-type: none"> <li>• <b>port</b> indicates the port number of the database server. By default, the database on port 5431 of the local host is connected.</li> <li>• <b>param</b> indicates a database connection attribute. The parameter can be configured in the URL. The URL starts with a question mark (?), uses an equal sign (=) to assign a value to the parameter, and uses an ampersand (&amp;) to separate parameters. You can also use the attributes of the info object for configuration. For details, see <a href="#">Examples</a>.</li> <li>• <b>value</b> indicates the database connection attribute values.</li> <li>• The <b>connectTimeout</b> and <b>socketTimeout</b> parameters must be set for connection. If they are not set, the default value <b>0</b> is used, indicating that the connection will not time out. When the network between the DN and client is faulty, the client does not receive the ACK packet from the DN. In this case, the client starts the timeout retransmission mechanism to continuously retransmit packets. A timeout error is reported only when the timeout interval reaches the default value <b>600s</b>. As a result, the RTO is high.</li> </ul>

Parameter	Description
info	<p>Database connection attributes (all attributes are case sensitive). Common attributes are described as follows:</p> <ul style="list-style-type: none"> <li>● <b>PGDBNAME</b>: string type. It specifies the database name. You do not need to set this parameter in the URL because the database name is automatically parsed from the URL.</li> <li>● <b>PGHOST</b>: string type. This parameter specifies the host IP address. For details, see <a href="#">Examples</a>.</li> <li>● <b>PGPORT</b>: integer type. It specifies the host port number. For details, see <a href="#">Examples</a>.</li> <li>● <b>user</b>: string type. It specifies the database user who creates the connection.</li> <li>● <b>password</b>: string type. It specifies the password of the database user.</li> <li>● <b>enable_ce</b>: string type. <b>enable_ce=1</b> indicates that JDBC supports the basic capability of encrypted equality query.</li> <li>● <b>refreshClientEncryption</b>: string type. If <b>refreshClientEncryption</b> is set to <b>1</b> (default value), the encrypted database supports cache update on the client.</li> <li>● <b>loggerLevel</b>: string type. The following log levels are supported: <b>OFF</b>, <b>DEBUG</b>, and <b>TRACE</b>. The value <b>OFF</b> indicates that the log function is disabled. <b>DEBUG</b> and <b>TRACE</b> logs record information of different levels.</li> <li>● <b>loggerFile</b>: string type. It specifies the name of a log file. You can specify a directory for storing logs. If no directory is specified, logs are stored in the directory where the client program is running. This parameter has been discarded and does not take effect. To use this parameter, you can configure it in the <b>java.util.logging</b> attribute file or system attributes.</li> <li>● <b>allowEncodingChanges</b>: Boolean type. If this parameter is set to <b>true</b>, the character set type can be changed. This parameter is used together with <b>characterEncoding=CHARSET</b> to set the character set. The two parameters are separated by ampersands (&amp;). The value of <b>characterEncoding</b> can be <b>UTF8</b>, <b>GBK</b>, <b>LATIN1</b>, or <b>GB18030</b>. The default value is <b>false</b>.</li> </ul> <p><b>NOTE</b> When the database whose character set is GB18030_2022 is connected, setting <b>characterEncoding</b> to <b>GB18030_2022</b> does not take effect and UTF8 is used by default. You need to set <b>characterEncoding</b> to <b>GB18030</b> so that the GB18030_2022 characters on the server can be properly parsed.</p> <ul style="list-style-type: none"> <li>● <b>currentSchema</b>: string type. You need to specify a schema in <b>search-path</b>. If the schema name contains special characters except letters, digits, and underscores (<code>_</code>), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (,). Schemas containing special characters also need to be enclosed in quotation marks.</li> </ul>

Parameter	Description
	<p>Example: <code>currentSchema=schema_a,"schema-b","schema/c"</code>.</p> <ul style="list-style-type: none"> <li>● <b>hostRecheckSeconds</b>: integer type. After JDBC attempts to connect to a host, the host status is saved: connection success or connection failure. This status is trusted within the duration specified by <b>hostRecheckSeconds</b>. After the duration expires, the status becomes invalid. The default value is 10 seconds.</li> <li>● <b>ssl</b>: Boolean type. It specifies a connection in SSL mode. When <b>ssl</b> is set to <b>true</b>, the NonValidatingFactory channel and certificate mode are supported.             <ol style="list-style-type: none"> <li>1. For the NonValidatingFactory channel, configure the username and password and set <b>SSL</b> to <b>true</b>.</li> <li>2. In certification mode, configure the client certificate, key, and root certificate, and set <b>SSL</b> to <b>true</b>.</li> </ol> </li> <li>● <b>sslmode</b>: string type. It specifies the SSL authentication mode. The value can be <b>disable</b>, <b>allow</b>, <b>prefer</b>, <b>require</b>, <b>verify-ca</b>, or <b>verify-full</b>.             <ul style="list-style-type: none"> <li>– <b>disable</b>: SSL connection is disabled.</li> <li>– <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li> <li>– <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li> <li>– <b>require</b>: The system attempts to set up an SSL connection. If there is a CA file, the system performs verification as if the parameter was set to <b>verify-ca</b>.</li> <li>– <b>verify-ca</b>: attempts to set up an SSL connection and checks whether the server certificate is issued by a trusted CA.</li> <li>– <b>verify-full</b>: The system attempts to set up an SSL connection, checks whether the server certificate is issued by a trusted CA, and checks whether the host name of the server is the same as that in the certificate.</li> </ul> </li> <li>● <b>sslcert</b>: string type. It specifies the complete path of the certificate file. The type of the client and server certificates is <b>End Entity</b>.</li> <li>● <b>sslkey</b>: string type. It specifies the complete path of the key file. Convert the client certificate to the DER format.  <pre>openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt</pre> </li> <li>● <b>sslrootcert</b>: string type. It specifies the name of the SSL root certificate. The root certificate type is CA.</li> <li>● <b>sslpassword</b>: string type. It is provided for ConsoleCallbackHandler.</li> <li>● <b>sslpasswordcallback</b>: string type. It specifies the class name of the SSL password provider. The default value is <b>org.postgresql.ssl.jdbc4.LibPQFactory.ConsoleCallbackHandler</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>● <b>sslfactory</b>: string type. It specifies the class name used by SSLSocketFactory to establish an SSL connection.</li> <li>● <b>sslfactoryarg</b>: string type. The value is an optional parameter of the constructor function of the sslfactory class. (This parameter is not recommended.)</li> <li>● <b>sslhostnameverifier</b>: string type. It specifies the class name of the host name verifier. The API must implement javax.net.ssl.HostnameVerifier. The default value is <b>org.postgresql.ssl.PGjdbcHostnameVerifier</b>.</li> <li>● <b>loginTimeout</b>: integer type. It specifies the waiting time for establishing the database connection, in seconds. When multiple IP addresses are configured in the URL, if the time for obtaining the connection exceeds the value of this parameter, the connection fails and the subsequent IP addresses are not tried. The default value is <b>0</b>.</li> <li>● <b>connectTimeout</b>: integer type. It specifies the timeout interval for connecting to a server. If the time taken to connect to a server exceeds the value specified, the connection is interrupted. The unit of the timeout interval is second. The value <b>0</b> indicates that the timeout mechanism does not take effect. When multiple IP addresses are configured in the URL, this parameter indicates the timeout interval for connecting to a single IP address. The default value is <b>0</b>.</li> <li>● <b>socketTimeout</b>: integer type. It specifies the timeout interval for a socket read operation. If the time taken to read data from a server exceeds the value specified, the connection is closed. The unit of the timeout interval is second. The default value <b>0</b> indicates that the timeout mechanism does not take effect.</li> <li>● <b>socketTimeoutInConnecting</b>: integer type. It specifies the timeout interval for a socket read operation during the connection establishment. If the time taken to read data from the server exceeds this value, it searches for the next node for connection. The unit of the timeout interval is second. The default value is <b>5s</b>.</li> <li>● <b>statementTimeout</b>: integer type. It specifies the timeout interval for executing a statement in a connection. If the execution time of a statement exceeds this value, the statement execution is canceled. The unit of the timeout interval is millisecond. The default value <b>0</b> indicates that the timeout mechanism does not take effect.</li> <li>● <b>driverInfoMode</b>: string type. This parameter controls the output mode of the driver description information. The value can be <b>postgresql</b> or <b>gaussdb</b>. The default value is <b>postgresql</b>, indicating that the driver description related to PostgreSQL is displayed. If this parameter is set to <b>gaussdb</b>, the driver description related to GaussDB is displayed.</li> <li>● <b>cancelSignalTimeout</b>: integer type. Cancel messages may cause a block. It controls <b>connectTimeout</b> and <b>socketTimeout</b> in a cancel</li> </ul>

Parameter	Description
	<p>command. The unit of the timeout interval is second. The default value is 10 seconds.</p> <ul style="list-style-type: none"> <li>● <b>tcpKeepAlive</b>: Boolean type. It is used to enable or disable TCP keepalive detection. The default value is <b>false</b>.</li> <li>● <b>logUnclosedConnections</b>: Boolean type. The client may leak a connection object because it does not call the connection object's close() method. These objects will be collected as garbage and finalized using the finalize() method. If the caller ignores this operation, this method closes the connection. The default value is <b>false</b>.</li> <li>● <b>assumeMinServerVersion</b>: string type. The client sends a request to set a floating point. This parameter specifies the version of the server to connect, for example, <b>assumeMinServerVersion=9.0</b>. This parameter can reduce the number of packets to send during connection setup.</li> <li>● <b>ApplicationName</b>: string type. It specifies the name of the JDBC driver that is being connected. You can query the <b>pg_stat_activity</b> table on the primary database node to view information about the client that is being connected. The JDBC driver name is displayed in the <b>application_name</b> column. The default value is <b>PostgreSQL JDBC Driver</b>.</li> <li>● <b>connectionExtraInfo</b>: Boolean type. This parameter specifies whether the driver reports the driver deployment path and process owner to the database. The value can be <b>true</b> or <b>false</b>. The default value is <b>false</b>. If <b>connectionExtraInfo</b> is set to <b>true</b>, the JDBC driver reports the driver deployment path, process owner, and URL connection configuration information to the database and displays the information in the <b>connection_info</b> parameter. In this case, you can query the information from PG_STAT_ACTIVITY.</li> <li>● <b>autosave</b>: string type. The value can be <b>always</b>, <b>never</b>, or <b>conservative</b>. It specifies the action that the driver should perform upon a query failure. If <b>autosave</b> is set to <b>always</b>, the JDBC driver sets a savepoint before each query and rolls back to the savepoint if the query fails. If <b>autosave</b> is set to <b>never</b>, there is no savepoint. If <b>autosave</b> is set to <b>conservative</b>, a savepoint is set for each query. However, the system rolls back and retries only when there is an invalid statement. The default value is <b>never</b>.</li> <li>● <b>protocolVersion</b>: integer type. It specifies the connection protocol version. Only versions 1 and 3 are supported. If it is set to <b>1</b>, only the V1 server is connected. If it is set to <b>3</b>, MD5 encryption is used. You must need to set the GUC parameter <b>password_encryption_type</b> to <b>1</b> to change the database encryption mode. After the database is restarted, create a user who uses MD5 encryption to encrypt passwords. In addition, modify the <b>pg_hba.conf</b> file to change the client connection mode to MD5 and log in as a new user (not recommended).</li> </ul>

Parameter	Description
	<p><b>NOTE</b> The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.</p> <ul style="list-style-type: none"> <li>• <b>prepareThreshold</b>: integer type. This parameter specifies the time when the parse statement is sent. The default value is <b>5</b>. It takes a long time to parse an SQL statement for the first time, but a short time to parse SQL statements later because of cache. If a session runs an SQL statement multiple consecutive times and the number of execution times exceeds the value of <b>prepareThreshold</b>, JDBC does not send the parse command to the SQL statement.</li> <li>• <b>preparedStatementCacheQueries</b>: integer type. It specifies the number of queries cached in each connection. The default value is <b>256</b>. If more than 256 different queries are used in the <code>prepareStatement()</code> call, the least recently used query cache will be discarded. The value <b>0</b> indicates that the cache function is disabled.</li> <li>• <b>preparedStatementCacheSizeMiB</b>: integer type. This parameter specifies the maximum cache size of each connection, in MB. The default value is <b>5</b>. If the size of the cached queries exceeds 5 MB, the least recently used query cache will be discarded. The value <b>0</b> indicates that the cache function is disabled.</li> <li>• <b>databaseMetadataCacheFields</b>: integer type. The default value is <b>65536</b>. This parameter specifies the maximum cache size of each connection. The value <b>0</b> indicates that the cache function is disabled.</li> <li>• <b>databaseMetadataCacheFieldsMiB</b>: integer type. The default value is <b>5</b>. This parameter specifies the maximum cache size of each connection, in MB. The value <b>0</b> indicates that the cache function is disabled.</li> <li>• <b>stringtype</b>: string type. The options are <b>false</b>, <b>"unspecified"</b>, and <b>"varchar"</b>. It specifies the type of the <b>PreparedStatement</b> parameter used by the <code>setString()</code> method. If <b>stringtype</b> is set to <b>VARCHAR</b> (default value), these parameters are sent to the server as varchar parameters. If <b>stringtype</b> is set to <b>unspecified</b>, these parameters are sent to the server as an untyped value, and the server attempts to infer their appropriate type.</li> <li>• <b>batchMode</b>: string type. It specifies whether to connect the database in batch mode. The default value is <b>on</b>, indicating that the batch mode is enabled. If <b>batchMode</b> is set to <b>on</b>, the returned result is <code>[count, 0, 0...0]</code>. The first element in the array is the total number of records affected in batches. If <b>batchMode</b> is set to <b>off</b>, the returned result is <code>[1, 1, 1..1]</code>. Each element in the array corresponds to the number of affected records in a single modification.</li> <li>• <b>fetchsize</b>: integer type. It specifies the default <b>fetchsize</b> for statements in the created connection. The default value is <b>0</b>,</li> </ul>

Parameter	Description
	<p>indicating that all results are obtained at a time. It is equivalent to <b>defaultRowFetchSize</b>.</p> <ul style="list-style-type: none"> <li>● <b>rewriteBatchedInserts</b>: Boolean type. During batch import, set this parameter to <b>true</b> to combine <i>N</i> insertion statements into one: <b>insert into TABLE_NAME values(values1, ..., valuesN), ..., (values1, ..., valuesN)</b>. To use this parameter, set <b>batchMode</b> to <b>off</b>. The default value is <b>false</b>.</li> <li>● <b>unknownLength</b>: integer type. The default value is <b>Integer.MAX_VALUE</b>. This parameter specifies the length of the unknown length type when the data of some PostgreSQL types (such as TEXT) is returned by functions such as <code>ResultSetMetaData.getColumnDisplaySize</code> and <code>ResultSetMetaData.getPrecision</code>.</li> <li>● <b>uppercaseAttributeName</b>: Boolean type. The default value is <b>false</b> (disabled). The value can also be <b>true</b> (enabled). If this parameter is enabled, the query result of the API for obtaining metadata is converted to uppercase letters. The application scenario is as follows: All metadata stored in the database is in lowercase, but the metadata in uppercase must be used as the input and output parameters. For details about the involved APIs, see <a href="#">java.sql.DatabaseMetaData</a> and <a href="#">java.sql.ResultSetMetaData</a>.</li> <li>● <b>defaultRowFetchSize</b>: integer type. It specifies the number of rows read by fetch in <code>ResultSet</code> at a time. Limiting the number of rows read each time in a database access request can avoid unnecessary memory consumption, thereby avoiding out of memory exception. The default value is <b>0</b>, indicating that all rows are obtained at a time in <code>ResultSet</code>. This parameter cannot be set to a negative value.</li> <li>● <b>binaryTransfer</b>: Boolean type. This parameter specifies whether data is sent and received in binary format. The default value is <b>false</b>.</li> <li>● <b>binaryTransferEnable</b>: string type. It specifies types for which binary transmission is enabled. Every two types are separated by commas (,). You can select either the OID or name, for example, <code>binaryTransferEnable=Integer4_ARRAY,Integer8_ARRAY</code>. For example, if the OID name is <b>BLOB</b> and the OID number is <b>88</b>, you can configure the OID as follows: <b>binaryTransferEnable=BLOB</b> or <b>binaryTransferEnable=88</b></li> <li>● <b>binaryTransferDisable</b>: string type. It specifies types for which binary transmission is disabled. Every two types are separated by commas (,). You can select either the OID or name. It overwrites the setting of <b>binaryTransferEnable</b>.</li> <li>● <b>blobMode</b>: string type. It sets the <code>setBinaryStream</code> method to assign values to different types of data. The value <b>on</b> indicates that values are assigned to BLOB data. The value <b>off</b> indicates that values are assigned to bytea data. The default value is <b>on</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>● <b>socketFactory</b>: string type. It specifies the name of the class used to create a socket connection with the server. This class must implement the javax.net.SocketFactory API and define a constructor with no parameter or a single string parameter.</li> <li>● <b>socketFactoryArg</b>: string type. The value is an optional parameter of the constructor function of the socketFactory class and is not recommended.</li> <li>● <b>receiveBufferSize</b>: integer type. It is used to set <b>SO_RCVBUF</b> on the connection stream.</li> <li>● <b>sendBufferSize</b>: integer type. It is used to set <b>SO_SNDBUF</b> on the connection stream.</li> <li>● <b>preferQueryMode</b>: string type. The value can be "extended", "extendedForPrepared", "extendedCacheEverything", or "simple". It specifies the query mode. In <b>simple</b> mode, the query is executed without parsing or binding. In <b>extended</b> mode, the query is executed and bound. The <b>extendedForPrepared</b> mode is used for prepared statement extension. In <b>extendedCacheEverything</b> mode, each statement is cached.</li> <li>● <b>targetServerType</b>: string type. This parameter is used to identify the primary DN and standby DN by querying whether a DN allows the write operation in the URL connection string. The default value is <b>any</b>. The value can be "any", "master", "slave", "preferSlave", or "clusterMainNode". <ul style="list-style-type: none"> <li>– <b>master</b>: attempts to connect to a primary node in the URL connection string. If the primary node cannot be found, an exception is thrown.</li> <li>– <b>slave</b>: attempts to connect to a standby node in the URL connection string. If the primary node cannot be found, an exception is thrown.</li> <li>– <b>preferSlave</b>: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN.</li> <li>– <b>any</b>: attempts to connect to any DN in the URL connection string.</li> <li>– <b>clusterMainNode</b>: attempts to connect to the primary node or main standby node (primary DR node) in the URL string. If the primary node or main standby node cannot be found, an exception is thrown.</li> </ul> </li> <li>● <b>priorityServers</b>: integer type. This value is used to specify the first <i>n</i> nodes configured in the URL as the primary database instance to be connected preferentially. The default value is <b>NULL</b>. The value is a number greater than 0 and less than the number of DNs configured in the URL. It is used in streaming DR scenarios. Example: <b>jdbc:postgresql://host1:port1,host2:port2,host3:port3,host4:port4,/database?priorityServers=2</b>. That is, <b>host1</b> and <b>host2</b> are primary database</li> </ul>

Parameter	Description
	<p>instance nodes, and <b>host3</b> and <b>host4</b> are DR database instance nodes.</p> <ul style="list-style-type: none"> <li>● <b>forceTargetServerSlave</b>: Boolean type. It specifies whether to enable the function of forcibly connecting to the standby node and forbid the existing connections to be used on the standby node that is promoted to primary during the primary/standby switchover of the database instance. The default value is <b>false</b>, indicating that the function of forcibly connecting to the standby node is disabled. <b>true</b>: The function of forcibly connecting to the standby node is enabled.</li> <li>● <b>traceInterfaceClass</b>: string type. The default value is <b>NULL</b>, which is used to obtain the implementation class of <b>traceld</b>. The value is the fully qualified name of the implementation class of the org.postgresql.log.Tracer API that implements the method for obtaining <b>traceld</b>.</li> <li>● <b>use_boolean</b>: Boolean type. It is used to set the OID type bound to the setBoolean method in extended mode. The default value is <b>false</b>, indicating that the int2 type is bound. The value <b>true</b> indicates that the Boolean type is bound.</li> <li>● <b>allowReadOnly</b>: Boolean type. This parameter specifies whether the read-only mode is allowed. The default value is <b>true</b>, indicating that the read-only mode is allowed. If this parameter is set to <b>false</b>, the read-only mode is disabled.</li> <li>● <b>TLSCiphersSupported</b>: string type. It is used to set the supported TLS encryption suite. The default value is <b>TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384</b>.</li> <li>● <b>stripTrailingZeros</b>: Boolean type. The default value is <b>false</b>. If the value is <b>true</b>, trailing 0s of the numeric type are removed. It is valid only for <b>ResultSet.getObject(int columnIndex)</b>.</li> <li>● <b>enableTimeZone</b>: Boolean type. The default value is <b>true</b>. This parameter specifies whether to enable the time zone setting on the server. The value <b>true</b> indicates that the JVM time zone is obtained to specify the database time zone. The value <b>false</b> indicates that the database time zone is used.</li> <li>● <b>loadBalanceHosts</b>: Boolean type. In the default mode (disabled), multiple hosts specified in the URL are connected in default sequence. If load balancing is enabled, the shuffle algorithm is used to randomly select a host from the candidate hosts to establish a connection. In a centralized environment, ensure that no write operation is in services when using this parameter.</li> <li>● <b>oracleCompatible</b>: string type. The default value is <b>false</b>. This is used to set the A-compatible features of driver APIs. The options are as follows:</li> </ul>

Parameter	Description
	<ol style="list-style-type: none"> <li>1. <b>true</b> or <b>on</b>: All A-compatible features of drivers are enabled.</li> <li>2. <b>false</b> or <b>off</b>: All A-compatible features of drivers are disabled.</li> <li>3. <b>"tag1,tag2,tag3"</b>: Some A-compatible features of drivers are enabled. You can configure one or more tags separated by commas (,). Each tag corresponds to an A-compatible feature. Currently, the following tags are supported: <ul style="list-style-type: none"> <li>- <code>getProcedureColumns</code>: The behavior of the <code>DatabaseMetaData#getProcedureColumns</code> API is compatible with behavior A.</li> <li>- <code>batchInsertAffectedRows</code>: After <code>reWriteBatchedInserts</code> is enabled, the result returned by the <code>Statement#executeBatch</code> API is compatible with behavior A.</li> </ul> <ul style="list-style-type: none"> <li>• <b>printSqlInLog</b>: Boolean type. It specifies whether to output SQL statements in exception information or logs. The value is <b>true</b> (enabled) or <b>false</b> (disabled). The default value is <b>true</b>.</li> </ul> </li> </ol>
user	Database user.
password	Password of the database user.

 NOTE

After the **uppercaseAttributeName** parameter is enabled, if the database contains metadata with a mixture of uppercase and lowercase letters, only the metadata in lowercase letters can be queried and output in uppercase letters. Before using the metadata, ensure that the metadata is stored in lowercase letters to prevent data errors.

## Examples

### Example 1: Connect to a database.

// The following code encapsulates database connection operations into an API. The database can then be connected using an authorized username and a password.

```
public static Connection getConnect(String username, String passwd)
{
    // Driver class.
    String driver = "org.postgresql.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres";
    Connection conn = null;

    try
    {
        // Load the driver.
        Class.forName(driver);
    }
    catch( Exception e )
    {
        e.printStackTrace();
        return null;
    }
}
```

```
try
{
    // Create a connection.
    conn = DriverManager.getConnection(sourceURL, username, passwd);
    System.out.println("Connection succeed!");
}
catch(Exception e)
{
    e.printStackTrace();
    return null;
}

return conn;
}
```

Example 2: Use the Properties object as a parameter to create a connection.

```
// The following code uses the Properties object as a parameter to establish a connection:
public static Connection getConnectUseProp(String username, String passwd)
{
    // Driver class.
    String driver = "org.postgresql.Driver";
    // Database connection descriptor.
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres";
    Connection conn = null;
    Properties info = new Properties();

    try
    {
        // Load the driver.
        Class.forName(driver);
    }
    catch( Exception e )
    {
        e.printStackTrace();
        return null;
    }

    try
    {
        info.setProperty("user", username);
        info.setProperty("password", passwd);
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL, info);
        System.out.println("Connection succeed!");
    }
    catch(Exception e)
    {
        e.printStackTrace();
        return null;
    }

    return conn;
}
```

For details about common parameters, see [Common JDBC Parameters](#).

### 5.3.5 Connecting to a Database (Using SSL)

When establishing connections to the GaussDB server using JDBC, you can enable SSL connections to encrypt client and server communications for security of sensitive data transmission on the Internet.

This section describes how applications configure the client in SSL mode through JDBC. For details about how to configure the server, contact the administrator.

To use the method described in this section, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

## Configuring the Client

To configure the client, perform the following steps:

Upload the certificate files **client.key.pk8**, **client.crt**, and **cacert.pem** generated in section "Configuring the Server" to the client.

### Example 1: Using the NonValidatingFactory Channel

#### NOTE

Select either example 1 or example 2.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:postgresql://$ip:$port/postgres";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");

        urlProps.setProperty("sslfactory", "org.postgresql.ssl.NonValidatingFactory");
        urlProps.setProperty("user", userName);
        urlProps.setProperty("password", password);
        urlProps.setProperty("ssl", "true");

        try {
            Class.forName("org.postgresql.Driver").newInstance();
        } catch (Exception e) {
            e.printStackTrace();
        }
        try {
            Connection conn;
            conn = DriverManager.getConnection(urls,urlProps);
            conn.close();
        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

### Example 2: Using a Certificate

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
public class SSL{
    public static void main(String[] args) {
        Properties urlProps = new Properties();
        String urls = "jdbc:postgresql://$ip:$port/postgres";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

```
urlProps.setProperty("sslcert", "client.crt");
urlProps.setProperty("sslkey", "client.key.pk8");
urlProps.setProperty("sslrootcert", "cacert.pem");
urlProps.setProperty("user", userName);
urlProps.setProperty("ssl", "true");
/* sslmode can be set to require, verify-ca, or verify-full. Select one from the following three
examples: */
/* ===== Example 2.1: Set sslmode to require to use the certificate for authentication.
*/
urlProps.setProperty("sslmode", "require");
/* ===== Example 2.2: Set sslmode to verify-ca to use the certificate for
authentication. */
urlProps.setProperty("sslmode", "verify-ca");
/* ===== Example 2.3: Set sslmode to verify-full to use the certificate (in the Linux
OS) for authentication. */
urls = "jdbc:postgresql://world:8000/postgres";
urlProps.setProperty("sslmode", "verify-full");

try {
    Class.forName("org.postgresql.Driver").newInstance();
} catch (Exception e) {
    e.printStackTrace();
}
try {
    Connection conn;
    conn = DriverManager.getConnection(urls,urlProps);
    conn.close();
} catch (Exception e) {
    e.printStackTrace();
}
}
/**
 * Note: Convert the client key to the DER format.
 * openssl pkcs8 -topk8 -outform DER -in client.key -out client.key.pk8 -nocrypt
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-MD5-DES
 * openssl pkcs8 -topk8 -inform PEM -in client.key -outform DER -out client.key.der -v1 PBE-SHA1-3DES
 * The preceding algorithms are not recommended due to their low security.
 * If the customer needs to use a higher-level private key encryption algorithm, the following private key
encryption algorithms can be used after the BouncyCastle or a third-party private key is used to decrypt the
password package:
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 AES128
 * openssl pkcs8 -in client.key -topk8 -outform DER -out client.key.der -v2 aes-256-cbc -iter 1000000
 * openssl pkcs8 -in client.key -topk8 -out client.key.der -outform Der -v2 aes-256-cbc -v2prf
hmacWithSHA512
 * Enable BouncyCastle: Introduce the bcpkix-jdk15on.jar package for projects that use JDBC. The
recommended version is 1.65 or later.
 */
```

**NOTICE**

When JDBC establishes a connection in SSL mode, a strong random number is obtained on the client. During the connection establishment, the error information shown in the figure may be displayed.

```

```

The random number generation on the client is too slow to meet product requirements. The entropy source is insufficient. As a result, the service fails to be started. This problem exists in some Linux environments.

Recommended solution: Start the `haveged` service on the client and increase the entropy value of the system entropy pool to improve the speed of reading random numbers. The startup command is as follows:

```
systemctl start haveged
```

### 5.3.6 Connecting to a Database (Using UDS)

The Unix domain socket is used for data exchange between different processes on the same host. You can add `unixsocket` to obtain the socket factory.

The `unixsocket-core-XXX.jar`, `unixsocket-common-XXX.jar`, and `unixsocket-native-common-XXX.jar` JAR packages need to be referenced. In addition, you need to add `socketFactory=org.newsclub.net.unix.AFUNIXSocketFactory $FactoryArg&socketFactoryArg=[path-to-the-unix-socket]` to the URL connection string.

Example:

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Properties;

public class Test {
    public static void main(String[] args) {
        String driver = "org.postgresql.Driver";
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");
```

```
Connection conn;
try {
    Class.forName(driver).newInstance();
    Properties properties = new Properties();
    properties.setProperty("user", userName);
    properties.setProperty("password", password);
    conn = DriverManager.getConnection("jdbc:postgresql://$ip.$port/postgres?
socketFactory=org.newsclub" +
    ".net.unix" +
    ".AFUNIXSocketFactory$FactoryArg&socketFactoryArg=/data/tmp/.s.PGSQL.8000",
    properties);
    System.out.println("Connection Successful!");
    Statement statement = conn.createStatement();
    statement.executeQuery("select 1");
} catch (Exception e) {
    e.printStackTrace();
}
}
```

#### NOTICE

- Set the **socketFactoryArg** parameter based on the actual path. The value must be the same as that of the GUC parameter **unix\_socket\_directory**.
- The connection host name must be set to **localhost**.

## 5.3.7 Running SQL Statements

### Running a Common SQL Statement

To enable an application to operate data in the database by running SQL statements (statements that do not need to transfer parameters), perform the following operations:

Operations such as SELECT, UPDATE, INSERT, and DELETE can be performed on XML data.

#### Step 1 Create a statement object by calling the createStatement method in Connection.

```
// There will be security risks if the username and password used for authentication are directly written into
code. It is recommended that the username and password be stored in the configuration file or
environment variables (the password must be stored in ciphertext and decrypted when being used) to
ensure security.
// In this example, the username and password are stored in environment variables. Before running this
example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
Statement stmt = conn.createStatement();
```

#### Step 2 Run the SQL statement by calling the executeUpdate method in Statement.

```
int rc = stmt.executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");
```

 NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. The VACUUM operation is not supported in a transaction block. If one of the statements fails, the entire request will be rolled back.
- Use semicolons (;) to separate statements. Stored procedures, functions, and anonymous blocks do not support multi-statement execution. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the semicolons (;) cannot be used to separate statements in this scenario.
- The slash (/) can be used as the terminator for creating a single stored procedure, function, anonymous block, or package body. When **preferQueryMode** is set to **simple**, the statement does not execute the parsing logic, and the slash (/) cannot be used as the terminator in this scenario.
- When **prepareThreshold** is set to **1**, each SQL statement executed by the statement is cached because cached statements are not evicted by default (default value of **preferQueryMode**). As a result, memory bloat may occur. In this case, set **preferQueryMode** to **extendedCacheEverything** to evict cached statements.

**Step 3** Close the statement object.

```
stmt.close();
```

----End

## Running a Prepared SQL Statement

Prepared statements are compiled and optimized once but can be used in different scenarios by assigning multiple values. Using prepared statements improves execution efficiency. If you want to run a statement for several times, use a precompiled statement. Perform the following operations:

**Step 1** Create a prepared statement object by calling the `prepareStatement` method in `Connection`.

```
PreparedStatement pstmt = con.prepareStatement("UPDATE customer_t1 SET c_customer_name = ?  
WHERE c_customer_sk = 1");
```

**Step 2** Set parameters by calling the `setShort` method in `PreparedStatement`.

```
pstmt.setShort(1, (short)2);
```

---

 CAUTION

After binding parameters are set in `PreparedStatement`, a B packet or U packet is constructed and sent to the server when the SQL statement is executed. However, the maximum length of a B packet or U packet cannot exceed 1023 MB. If the data bound at a time is too large, an exception may occur because the packet is too long. Therefore, when setting binding parameters in `PreparedStatement`, you need to evaluate and control the size of the bound data to avoid exceeding the upper limit of the packet.

**Step 3** Run the prepared statement by calling the `executeUpdate` method in `PreparedStatement`.

```
int rowcount = pstmt.executeUpdate();
```

**Step 4** Close the prepared statement object by calling the `close` method in `PreparedStatement`.

```
pstmt.close();
```

----End

## Calling a Stored Procedure

To call an existing stored procedure through JDBC in GaussDB, perform the following operations:

**Step 1** Create a call statement object by calling the `prepareCall` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into
// code. It is recommended that the username and password be stored in the configuration file or
// environment variables (the password must be stored in ciphertext and decrypted when being used) to
// ensure security.
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
// environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection myConn = DriverManager.getConnection("url",userName,password);
CallableStatement cstmt = myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
```

**Step 2** Set parameters by calling the `setInt` method in `CallableStatement`.

```
cstmt.setInt(2, 50);
cstmt.setInt(1, 20);
cstmt.setInt(3, 90);
```

**Step 3** Register an output parameter by calling the `registerOutParameter` method in `CallableStatement`.

```
cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
```

**Step 4** Call the stored procedure by calling the `execute` method in `CallableStatement`.

```
cstmt.execute();
```

**Step 5** Obtain the output parameter by calling the `getInt` method in `CallableStatement`.

```
int out = cstmt.getInt(4); // Obtain the OUT parameter.
```

Example:

```
// The following stored procedure (containing the OUT parameter) has been created:
create or replace procedure testproc
(
  psv_in1 in integer,
  psv_in2 in integer,
  psv_inout in out integer
)
as
begin
  psv_inout := psv_in1 + psv_in2 + psv_inout;
end;
/
```

**Step 6** Close the call statement by calling the `close` method in `CallableStatement`.

```
cstmt.close();
```

 NOTE

- Many database classes such as Connection, Statement, and ResultSet have a close() method. Close these classes after using their objects. Closing Connection will close all the related Statements, and closing a Statement will close its ResultSet.
- Some JDBC drivers support named parameters, which can be used to set parameters by name rather than sequence. If a parameter has the default value, you do not need to specify any parameter value but can use the default value directly. Even though the parameter sequence changes during a stored procedure, the application does not need to be modified. Currently, the GaussDB JDBC driver does not support this method.
- GaussDB does not support functions containing OUT parameters, or stored procedures and function parameters containing default values.
- When you bind parameters in `myConn.prepareCall("{? = CALL TESTPROC(?,?,?)}")` during a stored procedure calling, you can bind parameters and register the first parameter as the output parameter according to the placeholder sequence or the fourth parameter as the output parameter according to the parameter sequence in the stored procedure. The preceding example registers the fourth parameter.

## NOTICE

- If JDBC is used to call a stored procedure whose returned value is a cursor, the returned cursor cannot be used.
- A stored procedure and an SQL statement must be run separately.
- Output parameters must be registered for parameters of the inout type in the stored procedure.

---

----End

## Calling a Stored Procedure When Overloading Is Enabled in Oracle-Compatible Mode

Set `behavior_compat_options` to `'proc_outparam_override'`, and then perform the following steps to call the stored procedure based on JDBC:

**Step 1** Create a call statement object by calling the `prepareCall` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
CallableStatement cs = conn.prepareCall("{ CALL TEST_PROC(?,?,?) }");
```

**Step 2** Set parameters by calling the `setInt` method in `CallableStatement`.

```
PGobject pGobject = new PGobject();
pGobject.setType("public.compfoo"); // Set the composite type name. The format is "schema.typename".
pGobject.setValue("1,demo"); // Bind the value of the composite type. The format is "(value1,value2)".
cs.setObject(1, pGobject);
```

**Step 3** Register an output parameter by calling the `registerOutParameter` method in `CallableStatement`.

```
// Register an OUT parameter of the composite type. The format is "schema.typename".
cs.registerOutParameter(2, Types.STRUCT, "public.compfoo");
```

```
// Register an OUT parameter of the table type. The format is "schema.typename".
cs.registerOutParameter(3, Types.ARRAY, "public.compfoo_table");
```

**Step 4** Call the stored procedure by calling the execute method in CallableStatement.

```
cs.execute();
```

**Step 5** Obtain the output parameter by calling the getObject method in CallableStatement.

```
// The returned structure is of the user-defined type.
PGObject result = (PGObject)cs.getObject(2); // Obtain the out parameter.
result.getValue(); // Obtain the string value of the composite type.
result.getArrayValue(); // Obtain the array values of the composite type and sort the values according to
the sequence of columns of the composite type.
result.getStruct(); // Obtain the subtype names of the composite type and sort them according to the
creation sequence.
result.getAttributes(); // Return the object constructed from data in each column of the user-defined type.
For the array and table types, PgArray is returned. For the user-defined type, PGObject is encapsulated. For
other types of data, a character string is returned.
// The returned result is of the table type.
PgArray pgArray = (PgArray) cs.getObject(3);
ResultSet rs = pgArray.getResultSet();
while (rs.next()) {
    rs.getObject(2); // Object constructed from data in each row of the table type
}
```

#### NOTICE

If the table type of the output parameter is user-defined, for example, defined by running **create type compfooTable is table of compfoo**, the received return object is PgArray. In addition, the object obtained by **rs.getObject(2)** is also PgArray. In this case, the data of each column of the compfoo type cannot be obtained. To obtain the data, you must execute **getPGObject()** to obtain PGObject first.

**Step 6** Close the call statement by calling the close method in CallableStatement.

```
cs.close();
```

#### NOTE

- After the Oracle-compatible mode is enabled, you must use the **{call proc\_name(?,?,?)}** format to call a stored procedure and use the **{? = call func\_name(?,?)}** format to call a function. The question mark (?) on the left of the equal mark is the placeholder for the return value of the function and is used to register the return value of the function.
- After **behavior\_compat\_options** is set to **'proc\_outparam\_override'**, the service needs to re-establish a connection. Otherwise, the stored procedures and functions cannot be correctly called.
- If a function or stored procedure contains a composite type, bind and register parameters in the schema.typename format.

----End

Example:

```
// Create a composite data type in the database.
CREATE TYPE compfoo AS (f1 int, f3 text);
// The following stored procedure (containing the OUT parameter) has been created:
create or replace procedure test_proc
(
    psv_in in compfoo,
    psv_out out compfoo,
    table_out out compfoo_table
)
```

```
as
begin
  psv_out := psv_in;
  table_out:=compfoo_table();
  table_out.extend(2);
  table_out(1):=psv_out;
  table_out(2):=psv_out;
end;
/
// Create the table type in the database.
create type compfoo_table is table of compfoo;
```

## Batch Processing

When a prepared statement processes multiple pieces of similar data, the database creates only one execution plan. This improves compilation and optimization efficiency. Perform the following operations:

- Step 1** Create a prepared statement object by calling the `prepareStatement` method in `Connection`.

```
// There will be security risks if the username and password used for authentication are directly written into
code. It is recommended that the username and password be stored in the configuration file or
environment variables (the password must be stored in ciphertext and decrypted when being used) to
ensure security.
// In this example, the username and password are stored in environment variables. Before running this
example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
environment (set the environment variable names based on the actual situation).
String userName = System.getenv("EXAMPLE_USERNAME_ENV");
String password = System.getenv("EXAMPLE_PASSWORD_ENV");
Connection conn = DriverManager.getConnection("url",userName,password);
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?)");
```

- Step 2** Call `setShort` to set parameters for each piece of data, and call `addBatch` to confirm that the setting is complete.

```
pstmt.setShort(1, (short)2);
pstmt.addBatch();
```

- Step 3** Perform batch processing by calling the `executeBatch` method in `PreparedStatement`.

```
int[] rowcount = pstmt.executeBatch();
```

- Step 4** Close the prepared statement object by calling the `close` method in `PreparedStatement`.

```
pstmt.close();
```

### NOTE

Do not terminate a batch processing action when it is ongoing; otherwise, database performance will deteriorate. Therefore, disable automatic commit during batch processing. Manually commit several rows at a time. The statement for disabling automatic commit is `conn.setAutoCommit(false)`.

----End

## 5.3.8 Processing Data in a Result Set

### Setting a Result Set Type

Different types of result sets apply to different application scenarios. Applications select proper types of result sets based on requirements. Before running an SQL statement, you must create a statement object. Some methods of creating

statement objects can set the type of a result set. [Table 5-5](#) lists result set parameters. The related Connection methods are as follows:

```
// Create a Statement object. This object will generate a ResultSet object with a specified type and
concurrency.
createStatement(int resultSetType, int resultSetConcurrency);

// Create a PreparedStatement object. This object will generate a ResultSet object with a specified type and
concurrency.
prepareStatement(String sql, int resultSetType, int resultSetConcurrency);

// Create a CallableStatement object. This object will generate a ResultSet object with a specified type and
concurrency.
prepareCall(String sql, int resultSetType, int resultSetConcurrency);
```

**Table 5-5** Result set types

Parameter	Description
resultSetType	<p>Type of a result set. There are three types of result sets:</p> <ul style="list-style-type: none"> <li>• <b>ResultSet.TYPE_FORWARD_ONLY:</b> The ResultSet object can only be navigated forward. It is the default value.</li> <li>• <b>ResultSet.TYPE_SCROLL_SENSITIVE:</b> You can view the modified result by scrolling to the modified row.</li> <li>• <b>ResultSet.TYPE_SCROLL_INSENSITIVE:</b> The ResultSet object is insensitive to changes in the underlying data source.</li> </ul> <p><b>NOTE</b> After a result set has obtained data from the database, the result set is insensitive to data changes made by other transactions, even if the result set type is <b>ResultSet.TYPE_SCROLL_SENSITIVE</b>. To obtain up-to-date data of the record pointed by the cursor from the database, call the <code>refreshRow()</code> method in a ResultSet object.</p>
resultSetConcurrency	<p>Concurrency type of a result set. There are two types of concurrency.</p> <ul style="list-style-type: none"> <li>• <b>ResultSet.CONCUR_READ_ONLY:</b> Data in a result set cannot be updated except that an updated statement has been created in the result set data.</li> <li>• <b>ResultSet.CONCUR_UPDATEABLE:</b> changeable result set. The concurrency type for a result set object can be updated if the result set is scrollable.</li> </ul>

## Positioning a Cursor in a Result Set

ResultSet objects include a cursor pointing to the current data row. The cursor is initially positioned before the first row. The `next` method moves the cursor to the next row from its current position. When a ResultSet object does not have a next row, a call to this method returns **false**. Therefore, this method is used in the while loop for result set iteration. However, the JDBC driver provides more cursor positioning methods for scrollable result sets, which allows positioning cursor in the specified row. [Table 5-6](#) describes these methods.

**Table 5-6** Methods for positioning a cursor in a result set

Method	Description
next()	Moves cursor to the next row from its current position.
previous()	Moves cursor to the previous row from its current position.
beforeFirst()	Places cursor before the first row.
afterLast()	Places cursor after the last row.
first()	Places cursor to the first row.
last()	Places cursor to the last row.
absolute(int)	Places cursor to a specified row.
relative(int)	Moves the row specified by the forward parameter (that is, the value is <b>1</b> , which is equivalent to next()) or backward (that is, the value is <b>-1</b> , which is equivalent to previous()).

## Obtaining the Cursor Position from a Result Set

This cursor positioning method can be used to change the cursor position for a scrollable result set. The JDBC driver provides a method to obtain the cursor position in a result set. [Table 5-7](#) describes these methods.

**Table 5-7** Methods for obtaining a cursor position in a result set

Method	Description
isFirst()	Checks whether it is in the first row.
isLast()	Checks whether it is in the last row.
isBeforeFirst()	Checks whether it is before the first row.
isAfterLast()	Checks whether it is after the last row.
getRow()	Obtains its current row number.

## Obtaining Data from a Result Set

ResultSet objects provide a variety of methods to obtain data from a result set. [Table 5-8](#) describes the common methods for obtaining data. If you want to know more about other methods, see JDK official documents.

**Table 5-8** Common methods for obtaining data from a result set

Method	Description
<code>int getInt(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as an integer.
<code>int getInt(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as an integer.
<code>String getString(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as a string.
<code>String getString(String columnLabel)</code>	Retrieves the value of the column designated by a column label in the current row as a string.
<code>Date getDate(int columnIndex)</code>	Retrieves the value of the column designated by a column index in the current row as a date.
<code>Date getDate(String columnLabel)</code>	Retrieves the value of the column designated by a column name in the current row as a date.

### 5.3.9 Closing a Connection

After you complete required data operations in a database, close the database connection.

Call the close method to close the database connection.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.  
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).  
String userName = System.getenv("EXAMPLE_USERNAME_ENV");  
String password = System.getenv("EXAMPLE_PASSWORD_ENV");  
Connection conn = DriverManager.getConnection(sourceURL, userName, password);  
conn.close();
```

### 5.3.10 Log Management

The GaussDB JDBC driver uses log records to help solve problems when the GaussDB JDBC driver is used in applications. GaussDB JDBC supports the following log management methods:

1. Use the SLF4J log framework for interconnecting with applications.
2. Use the JdkLogger log framework for interconnecting with applications.

SLF4J and JdkLogger are mainstream frameworks for Java application log management in the industry. For details about how to use these frameworks, see

the official documents (SLF4J: <http://www.slf4j.org/manual.html>; JdkLogger: <https://docs.oracle.com/javase/8/docs/technotes/guides/logging/overview.html>).

Method 1: Use the SLF4J log framework for interconnecting with applications.

When a connection is set up, **logger=Slf4JLogger** is configured in the URL.

The SLF4J may be implemented by using Log4j or Log4j2. When the Log4j is used to implement the SLF4J, the following JAR packages need to be added: **log4j-\*.jar**, **slf4j-api-\*.jar**, and **slf4j-log4j-\*.jar** (\* varies according to versions), and configuration file **log4j.properties**. If the Log4j2 is used to implement the SLF4J, you need to add the following JAR packages: **log4j-api-\*.jar**, **log4j-core-\*.jar**, **log4j-slf4j18-impl-\*.jar**, and **slf4j-api-alpha1.jar** (\* varies according to versions), and configuration file **log4j2.xml**.

This method supports log management and control. The SLF4J can implement powerful log management and control functions through related configurations in files. This method is recommended.

---

**CAUTION**

This method depends on the general SLF4J APIs, such as **org.slf4j.LoggerFactory.getLogger(String name)**, **org.slf4j.Logger.debug(String var1)**, **org.slf4j.Logger.info(String var1)**, **org.slf4j.Logger.warn(String warn)**, and **org.slf4j.Logger.warn(String warn)**. If these APIs are changed, logs cannot be recorded.

---

Example:

```
public static Connection GetConnection(String username, String passwd){
    String sourceURL = "jdbc:postgresql://$ip:$port/postgres?logger=Slf4JLogger";
    Connection conn = null;

    try{
        // Create a connection.
        conn = DriverManager.getConnection(sourceURL,username,passwd);
        System.out.println("Connection succeed!");
    }catch (Exception e){
        e.printStackTrace();
        return null;
    }
    return conn;
}
```

Example of **log4j.properties**:

```
log4j.logger.org.postgresql=ALL, log_gsjdbc

# Default file output configuration
log4j.appender.log_gsjdbc=org.apache.log4j.RollingFileAppender
log4j.appender.log_gsjdbc.Append=true
log4j.appender.log_gsjdbc.File=gsjdbc.log
log4j.appender.log_gsjdbc.Threshold=TRACE
log4j.appender.log_gsjdbc.MaxFileSize=10MB
log4j.appender.log_gsjdbc.MaxBackupIndex=5
log4j.appender.log_gsjdbc.layout=org.apache.log4j.PatternLayout
log4j.appender.log_gsjdbc.layout.ConversionPattern=%d %p %t %c - %m%n
log4j.appender.log_gsjdbc.File.Encoding = UTF-8
```

Example of **log4j2.xml**:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration status="OFF">
  <appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </Console>
    <File name="FileTest" fileName="test.log">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
    </File>
    <!-- JDBC driver log file output configuration. Log rewinding is supported. When the log size exceeds
10 MB, a new file is created. The new file is named in the format of yyyy-mm-dd-file ID. -->
    <RollingFile name="RollingFileJdbc" fileName="gsjdbc.log" filePattern="%d{yyyy-MM-dd}-%i.log">
      <PatternLayout pattern="%d %p %t %c - %m%n"/>
      <Policies>
        <SizeBasedTriggeringPolicy size="10 MB"/>
      </Policies>
    </RollingFile>
  </appenders>
  <loggers>
    <root level="all">
      <appender-ref ref="Console"/>
      <appender-ref ref="FileTest"/>
    </root>
    <!-- JDBC driver logs. The log level is all. All logs can be viewed and exported to the gsjdbc.log file. -->
    <logger name="org.postgresql" level="all" additivity="false">
      <appender-ref ref="RollingFileJdbc"/>
    </logger>
  </loggers>
</configuration>
```

Method 2: Use the JdkLogger log framework for interconnecting with applications.

The default Java logging framework stores its configurations in a file named **logging.properties**. Java installs the global configuration file in the folder in the Java installation directory. The **logging.properties** file can also be created and stored with a single project.

Configuration example of **logging.properties**:

```
# Specify the processing program as a file.
handlers= java.util.logging.FileHandler

# Specify the default global log level.
.level= ALL

# Specify the log output control standard.
java.util.logging.FileHandler.level=ALL
java.util.logging.FileHandler.pattern = gsjdbc.log
java.util.logging.FileHandler.limit = 500000
java.util.logging.FileHandler.count = 30
java.util.logging.FileHandler.formatter = java.util.logging.SimpleFormatter
java.util.logging.FileHandler.append=false
```

Code example:

```
System.setProperty("java.util.logging.FileHandler.pattern", "jdbc.log");
FileHandler fileHandler = new FileHandler(System.getProperty("java.util.logging.FileHandler.pattern"));
Formatter formatter = new SimpleFormatter();
fileHandler.setFormatter(formatter);
Logger logger = Logger.getLogger("org.postgresql");
logger.addHandler(fileHandler);
logger.setLevel(Level.ALL);
logger.setUseParentHandlers(false);
```

## Link Trace Function

The GaussDB JDBC driver provides the application-to-database link trace function to associate discrete SQL statements on the database side with application

requests. This function requires application developers to implement the `org.postgresql.log.Tracer` API class and specify the permission name of the API implementation class in the URL.

URL example:

```
String URL = "jdbc:postgresql://$ip:$port/postgres?tracelInterfaceClass=xxx.xxx.xxx.OpenGaussTracelImpl";
```

The `org.postgresql.log.Tracer` API class is defined as follows:

```
public interface Tracer {  
    // Retrieves the value of tracel.  
    String getTracelId();  
}
```

Example of the `org.postgresql.log.Tracer` API implementation class:

```
import org.postgresql.log.Tracer;  
  
public class OpenGaussTracelImpl implements Tracer {  
    private static MDC mdc = new MDC();  
  
    private final String TRACE_ID_KEY = "tracelId";  
  
    public void set(String tracelId) {  
        mdc.put(TRACE_ID_KEY, tracelId);  
    }  
  
    public void reset() {  
        mdc.clear();  
    }  
  
    @Override  
    public String getTracelId() {  
        return mdc.get(TRACE_ID_KEY);  
    }  
}
```

Example of context mapping which is used to store trace IDs generated for different requests:

```
import java.util.HashMap;  
  
public class MDC {  
    static final private ThreadLocal<HashMap<String, String>> threadLocal = new ThreadLocal<>();  
  
    public void put(String key, String val) {  
        if (key == null || val == null) {  
            throw new IllegalArgumentException("key or val cannot be null");  
        } else {  
            if (threadLocal.get() == null) {  
                threadLocal.set(new HashMap<>());  
            }  
            threadLocal.get().put(key, val);  
        }  
    }  
  
    public String get(String key) {  
        if (key == null) {  
            throw new IllegalArgumentException("key cannot be null");  
        } else if (threadLocal.get() == null) {  
            return null;  
        } else {  
            return threadLocal.get().get(key);  
        }  
    }  
  
    public void clear() {  
        if (threadLocal.get() == null) {  
            return;  
        } else {  
            threadLocal.get().clear();  
        }  
    }  
}
```

```
}  
}  
}
```

#### Example of using **traceld**:

```
String traceld = UUID.randomUUID().toString().replaceAll("-", "");  
openGaussTrace.set(traceld);  
pstmt = con.prepareStatement("select * from test_trace_id where id = ?");  
pstmt.setInt(1, 1);  
pstmt.execute();  
pstmt = con.prepareStatement("insert into test_trace_id values(?,?)");  
pstmt.setInt(1, 2);  
pstmt.setString(2, "test");  
pstmt.execute();  
openGaussTrace.reset();
```

#### NOTE

- When the link trace function is used, the link function at the application layer is guaranteed by services.
- The application must expose the API for obtaining **traceld** to the JDBC and configure the API implementation class to the JDBC connection string.
- SQL statements of the same request must use the same **traceld**.
- The value of **traceld** transferred by the application cannot exceed 32 bytes. Otherwise, the extra bytes will be truncated.

## 5.3.11 Examples: Common Operations

### Example 1: Creating a Database Connection, Creating a Table, and Inserting Data

This example illustrates how to develop applications based on GaussDB JDBC APIs. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

```
//DBtest.java  
// This example illustrates the main processes of JDBC-based development, covering database connection  
// creation, table creation, and data insertion.  
// There will be security risks if the username and password used for authentication are directly written into  
// code. It is recommended that the username and password be stored in the configuration file or  
// environment variables (the password must be stored in ciphertext and decrypted when being used) to  
// ensure security.  
// In this example, the username and password are stored in environment variables. Before running this  
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local  
// environment (set the environment variable names based on the actual situation).  
  
import java.sql.Connection;  
import java.sql.DriverManager;  
import java.sql.PreparedStatement;  
import java.sql.SQLException;  
import java.sql.Statement;  
import java.sql.CallableStatement;  
import java.sql.Types;  
  
public class DBTest {  
  
    // Create a database connection.  
    public static Connection getConnection(String username, String passwd) {  
        String driver = "org.postgresql.Driver";  
        String sourceURL = "jdbc:postgresql://$ip:$port/postgres";  
        Connection conn = null;  
        try {  
            // Load the database driver.  
            Class.forName(driver).newInstance();  

```

```
} catch (Exception e) {
    e.printStackTrace();
    return null;
}

try {
    // Create a database connection.
    conn = DriverManager.getConnection(sourceURL, username, passwd);
    System.out.println("Connection succeed!");
} catch (Exception e) {
    e.printStackTrace();
    return null;
}

return conn;
};

// Run a common SQL statement to create table customer_t1.
public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();

        // Run a common SQL statement.
        int rc = stmt
            .executeUpdate("CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));");

        stmt.close();
    } catch (SQLException e) {
        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }
}

// Run a prepared statement to insert data in batches.
public static void BatchInsertData(Connection conn) {
    PreparedStatement pst = null;

    try {
        // Generate a prepared statement.
        pst = conn.prepareStatement("INSERT INTO customer_t1 VALUES (?,?)");
        for (int i = 0; i < 3; i++) {
            // Add parameters.
            pst.setInt(1, i);
            pst.setString(2, "data " + i);
            pst.addBatch();
        }
        // Perform batch processing.
        pst.executeBatch();
        pst.close();
    } catch (SQLException e) {
        if (pst != null) {
            try {
                pst.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }
}
```

```
// Run a prepared statement to update data.
public static void ExecPreparedSQL(Connection conn) {
    PreparedStatement pstmt = null;
    try {
        pstmt = conn
            .prepareStatement("UPDATE customer_t1 SET c_customer_name = ? WHERE c_customer_sk = 1");
        pstmt.setString(1, "new Data");
        int rowcount = pstmt.executeUpdate();
        pstmt.close();
    } catch (SQLException e) {
        if (pstmt != null) {
            try {
                pstmt.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }
}

// Create a stored procedure.
public static void CreateCallable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();
        // Create a function to return the sum of the three input values.
        stmt.execute("create or replace procedure testproc \n" +
            "\n" +
            "    psv_in1 in integer,\n" +
            "    psv_in2 in integer,\n" +
            "    psv_inout inout integer\n" +
            ")\n" +
            "as\n" +
            "begin\n" +
            "    psv_inout := psv_in1 + psv_in2 + psv_inout;\n" +
            "end;\n" +
            "/");
    } catch (SQLException e) {
        throw new RuntimeException(e);
    } finally {
        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException e) {
                throw new RuntimeException(e);
            }
        }
    }
}

// Run a stored procedure.
public static void ExecCallableSQL(Connection conn) {
    CallableStatement cstmt = null;
    try {
        // The stored procedure TESTPROC must be created in advance.
        cstmt=conn.prepareCall("{? = CALL TESTPROC(?,?,?)}");
        cstmt.setInt(2, 50);
        cstmt.setInt(1, 20);
        cstmt.setInt(3, 90);
        cstmt.registerOutParameter(4, Types.INTEGER); // Register an OUT parameter of the integer type.
        cstmt.execute();
        int out = cstmt.getInt(4); // Obtain the OUT parameter.
        System.out.println("The CallableStatment TESTPROC returns:"+out);
        cstmt.close();
    } catch (SQLException e) {
        if (cstmt != null) {
            try {
                cstmt.close();
            }
        }
    }
}
```

```
    } catch (SQLException e1) {
        e1.printStackTrace();
    }
    }
    e.printStackTrace();
}
}

/**
 * Main process. Call static methods one by one.
 * @param args
 */
public static void main(String[] args) {
    // Create a database connection.
    String userName = System.getenv("EXAMPLE_USERNAME_ENV");
    String password = System.getenv("EXAMPLE_PASSWORD_ENV");
    Connection conn = GetConnection(uesrName, password);

    // Create a table.
    CreateTable(conn);

    // Insert data in batches.
    BatchInsertData(conn);

    // Run a prepared statement to update data.
    ExecPreparedSQL(conn);

    // Create a stored procedure.
    CreateCallable(conn);

    // Run a stored procedure.
    ExecCallableSQL(conn);

    // Close the connection to the database.
    try {
        conn.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
}
```

## Example 2: High Client Memory Usage

In this example, **setFetchSize** adjusts the memory usage of the client by using the database cursor to obtain server data in batches. It may increase network interaction and damage some performance.

The cursor is valid within a transaction. Therefore, disable automatic commit and then manually commit the code.

```
// Disable automatic commit.
conn.setAutoCommit(false);

// Create a table.
Statement st = conn.createStatement();
st.execute("create table mytable (cal1 int);");

// Insert 200 rows of data into the table.
PreparedStatement pstmt = conn.prepareStatement("insert into mytable values (?)");
for (int i = 0; i < 200; i++) {
    pstmt.setInt(1, i + 1);
    pstmt.addBatch();
}
pstmt.executeBatch();
```

```
conn.commit();
pstmt.close();

// Open the cursor and obtain 50 rows of data each time.
st.setFetchSize(50);
ResultSet rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("a row was returned.");
}
conn.commit();
rs.close();

// Disable the server cursor.
st.setFetchSize(0);
rs = st.executeQuery("SELECT * FROM mytable");
while (rs.next())
{
    System.out.print("many rows were returned.");
}
conn.commit();
rs.close();

// Close the statement.
st.close();
conn.close();
```

Enable automatic commit.

```
conn.setAutoCommit(true);
```

### Example 3: Using Common Data Types

```
// Example of the bit type. Note that the value range of the bit type is [0,1].
Statement st = conn.createStatement();
String sqlstr = "create or replace function fun_1()\n" +
    "returns bit AS $$\n" +
    "select col_bit from t_bit limit 1;\n" +
    "$$\n" +
    "LANGUAGE SQL;";
st.execute(sqlstr);
CallableStatement c = conn.prepareCall("{ ? = call fun_1() }");
// Register the output type, which is a bit string.
c.registerOutParameter(1, Types.BIT);
c.execute();
// Use the Boolean type to obtain the result.
System.out.println(c.getBoolean(1));

// Example of using the money type
// Example of using a column of the money type in the table structure.
st.execute("create table t_money(col1 money)");
PreparedStatement pstmt = conn.prepareStatement("insert into t_money values(?)");
// Use PGOBJECT to assign a value. The value range is [-92233720368547758.08,92233720368547758.07].
PGObject minMoney = new PGObject();
minMoney.setType("money");
minMoney.setValue("-92233720368547758.08");
pstmt.setObject(1, minMoney);
pstmt.execute();
// Use PGMONEY to assign a value. The value range is [-9999999.99,9999999.99].
pstmt.setObject(1,new PGMoney(9999999.99));
pstmt.execute();

// Example of using the function whose return value is money.
st.execute("create or replace function func_money() " +
    "return money " +
    "as declare " +
    "var1 money; " +
    "begin " +
    " select col1 into var1 from t_money limit 1; " +
```

```
        " return var1; " +  
        "end;");  
CallableStatement cs = conn.prepareCall("{? = call func_money()}");  
cs.registerOutParameter(1,Types.DOUBLE);  
cs.execute();  
cs.getObject(1);
```

## Example 4: Obtaining the Driver Version

```
Driver.getGSVersion();
```

### 5.3.12 Example: Retrying SQL Queries for Applications

If the primary database node is faulty and cannot be restored within 10s, GaussDB automatically switches the standby database node to the active state to ensure the normal running of the database. Jobs running during the failover will fail and those started after the failover will not be affected. To prevent upper-layer services from being affected by the failover, refer to this example to construct an SQL retry mechanism at the service layer. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

```
// There will be security risks if the username and password used for authentication are directly written into  
// code. It is recommended that the username and password be stored in the configuration file or  
// environment variables (the password must be stored in ciphertext and decrypted when being used) to  
// ensure security.  
// In this example, the username and password are stored in environment variables. Before running this  
// example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local  
// environment (set the environment variable names based on the actual situation).  
import java.sql.Connection;  
import java.sql.DriverManager;  
import java.sql.PreparedStatement;  
import java.sql.ResultSet;  
import java.sql.SQLException;  
import java.sql.Statement;  
  
class ExitHandler extends Thread {  
    private Statement cancel_stmt = null;  
  
    public ExitHandler(Statement stmt) {  
        super("Exit Handler");  
        this.cancel_stmt = stmt;  
    }  
    public void run() {  
        System.out.println("exit handle");  
        try {  
            this.cancel_stmt.cancel();  
        } catch (SQLException e) {  
            System.out.println("cancel query failed.");  
            e.printStackTrace();  
        }  
    }  
}  
  
public class SQLRetry {  
    // Create a database connection.  
    public static Connection GetConnection(String username, String passwd) {  
        String driver = "org.postgresql.Driver";  
        String sourceURL = "jdbc:postgresql://$ip:$port/postgres";  
        Connection conn = null;  
        try {  
            // Load the database driver.  
            Class.forName(driver).newInstance();  
        } catch (Exception e) {  
            e.printStackTrace();  
            return null;  
        }  
    }  
}
```

```
}

try {
    // Create a database connection.
    conn = DriverManager.getConnection(sourceURL, username, passwd);
    System.out.println("Connection succeed!");
} catch (Exception e) {
    e.printStackTrace();
    return null;
}

return conn;
}

// Run a common SQL statement to create the jdbc_test1 table.
public static void CreateTable(Connection conn) {
    Statement stmt = null;
    try {
        stmt = conn.createStatement();

        Runtime.getRuntime().addShutdownHook(new ExitHandler(stmt));

        // Run a common SQL statement.
        int rc2 = stmt
            .executeUpdate("DROP TABLE if exists jdbc_test1;");

        int rc1 = stmt
            .executeUpdate("CREATE TABLE jdbc_test1(col1 INTEGER, col2 VARCHAR(10));");

        stmt.close();
    } catch (SQLException e) {
        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException e1) {
                e1.printStackTrace();
            }
        }
        e.printStackTrace();
    }

### 5.3.13 Example: Importing and Exporting Data Through Local Files

When Java is used for secondary development based on GaussDB, you can use the CopyManager API to export data from the database to a local file or import a local file to the database by streaming. The file can be in CSV or TEXT format.

The example is as follows. Load the GaussDB JDBC driver before executing it. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).
import java.sql.Connection;
import java.sql.DriverManager;
import java.io.IOException;
import java.io.FileInputStream;
import java.io.FileOutputStream;
import java.sql.SQLException;
import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;

public class Copy{

    public static void main(String[] args)
    {
        String urls = new String("jdbc:postgresql://$ip:$port/postgres"); // Database URL
        String username = System.getenv("EXAMPLE_USERNAME_ENV"); // Username
        String password = System.getenv("EXAMPLE_PASSWORD_ENV"); // Password
        String tablename = new String("migration_table"); // Table information
        String tablename1 = new String("migration_table_1"); // Table information
        String driver = "org.postgresql.Driver";
        Connection conn = null;

        try {
            Class.forName(driver);
            conn = DriverManager.getConnection(urls, username, password);
        } catch (ClassNotFoundException e) {
            e.printStackTrace(System.out);
        } catch (SQLException e) {
            e.printStackTrace(System.out);
        }
    }
}
```

```
// Export the query result of SELECT * FROM migration_table to the local file d:/data.txt.
try {
    copyToFile(conn, "d:/data.txt", "(SELECT * FROM migration_table)");
} catch (SQLException e) {

e.printStackTrace();
} catch (IOException e) {

e.printStackTrace();
}
// Import data from the d:/data.txt file to the migration_table_1 table.
try {
    copyFromFile(conn, "d:/data.txt", tablename1);
} catch (SQLException e) {
    e.printStackTrace();
} catch (IOException e) {

e.printStackTrace();
}

// Export the data from the migration_table_1 table to the d:/data1.txt file.
try {
    copyToFile(conn, "d:/data1.txt", tablename1);
} catch (SQLException e) {

e.printStackTrace();
} catch (IOException e) {

e.printStackTrace();
}
}
}
// Use copyIn to import data from a file to the database.
public static void copyFromFile(Connection connection, String filePath, String tableName)
    throws SQLException, IOException {

    FileInputStream fileInputStream = null;

    try {
        CopyManager copyManager = new CopyManager((BaseConnection)connection);
        fileInputStream = new FileInputStream(filePath);
        copyManager.copyIn("COPY " + tableName + " FROM STDIN", fileInputStream);
    } finally {
        if (fileInputStream != null) {
            try {
                fileInputStream.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }
}

// Use copyOut to export data from the database to a file.
public static void copyToFile(Connection connection, String filePath, String tableOrQuery)
    throws SQLException, IOException {

    FileOutputStream fileOutputStream = null;

    try {
        CopyManager copyManager = new CopyManager((BaseConnection)connection);
        fileOutputStream = new FileOutputStream(filePath);
        copyManager.copyOut("COPY " + tableOrQuery + " TO STDOUT", fileOutputStream);
    } finally {
        if (fileOutputStream != null) {
            try {
                fileOutputStream.close();
            } catch (IOException e) {
```

```
        e.printStackTrace();
    }
}
}
```

### 5.3.14 Example: Migrating Data from MY

This example shows how to use CopyManager to migrate data from MY to GaussDB. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.

// In this example, the username and password are stored in environment variables. Before running this example, set environment variables *EXAMPLE\_USERNAME\_ENV* and *EXAMPLE\_PASSWORD\_ENV* in the local environment (set the environment variable names based on the actual situation).

```
import java.io.StringReader;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;
```

```
import org.postgresql.copy.CopyManager;
import org.postgresql.core.BaseConnection;
```

```
public class Migration{
```

```
    public static void main(String[] args) {
        String url = new String("jdbc:postgresql://$ip:$port/postgres"); // Database URL
        String user = System.getenv("EXAMPLE_USERNAME_ENV"); // GaussDB username
        String pass = System.getenv("EXAMPLE_PASSWORD_ENV"); // GaussDB password
        String tablename = new String("migration_table"); // Table information
        String delimiter = new String("|"); // Delimiter
        String encoding = new String("UTF8"); // Character set
        String driver = "org.postgresql.Driver";
        StringBuffer buffer = new StringBuffer(); // Buffer to store formatted data

        try {
            // Obtain the query result set of the source database.
            ResultSet rs = getDataSet();

            // Traverse the result set and obtain records row by row.
            // The values of columns in each record are separated by the specified delimiter and end with a
            // linefeed, forming strings.
            // Add the strings to the buffer.
            while (rs.next()) {
                buffer.append(rs.getString(1) + delimiter
                    + rs.getString(2) + delimiter
                    + rs.getString(3) + delimiter
                    + rs.getString(4)
                    + "\n");
            }
            rs.close();

            try {
                // Connect to the target database.
                Class.forName(driver);
                Connection conn = DriverManager.getConnection(url, user, pass);
                BaseConnection baseConn = (BaseConnection) conn;
                baseConn.setAutoCommit(false);

                // Initialize the table.
```

```
String sql = "Copy " + tablename + " from STDIN DELIMITER " + "'" + delimiter + "'" + "
ENCODING " + "'" + encoding + "'";

// Commit data in the buffer.
CopyManager cp = new CopyManager(baseConn);
StringReader reader = new StringReader(buffer.toString());
cp.copyIn(sql, reader);
baseConn.commit();
reader.close();
baseConn.close();
} catch (ClassNotFoundException e) {
    e.printStackTrace(System.out);
} catch (SQLException e) {
    e.printStackTrace(System.out);
}
}

} catch (Exception e) {
    e.printStackTrace();
}
}

//*****
// Return the query result set from the source database.
//*****
private static ResultSet getDataSet() {
    ResultSet rs = null;
    try {
        Class.forName("com.MY.jdbc.Driver").newInstance();
        String userName = System.getenv("EXAMPLE_USERNAME_ENV");
        String password = System.getenv("EXAMPLE_PASSWORD_ENV");
        Connection conn = DriverManager.getConnection("jdbc:MY://$ip:$port/database?
useSSL=false&allowPublicKeyRetrieval=true", uesrName, password);
        Statement stmt = conn.createStatement();
        rs = stmt.executeQuery("select * from migration_table");
    } catch (SQLException e) {
        e.printStackTrace();
    } catch (Exception e) {
        e.printStackTrace();
    }
    return rs;
}
}
```

### 5.3.15 Example: Logical Replication Code

The example demonstrates how to use the logical replication function through the JDBC APIs. Before executing the example, load the driver. For details about how to obtain and load the driver, see [JDBC Package, Driver Class, and Environment Class](#).

For details about the configuration options of logical replication, see section "Logical Replication > Logical Decoding" in *Feature Guide*. In addition, the following configuration items are added for streaming decoding tools such as JDBC:

1. Decoding thread concurrency

Set **parallel-decode-num** to specify the number of decoder threads for parallel decoding. The value is an integer ranging from 1 to 20. The value **1** indicates that decoding is performed based on the original serial logic. Other values indicate that parallel decoding is enabled. The default value is **1**. When this parameter is set to **1**, do not configure the following options: **decode-style**, **sending-batch**, and **parallel-queue-size**.

2. Decoding format

Configure **decode-style** to specify the decoding format. The value can be 'j', 't' or 'b' of the char type, indicating the JSON, text, or binary format, respectively. The default value is 'b', indicating binary decoding. This option is set only when parallel decoding is allowed and binary decoding is supported only in the parallel decoding scenario. For the JSON and text formats corresponding to the binary format, in the decoding result sent in batches, the uint32 consisting of the first four bytes of each decoding statement indicates the total number of bytes of the statement (the four bytes occupied by the uint32 are excluded, and 0 indicates that the decoding of this batch ends). The 8-byte uint64 indicates the corresponding LSN (**begin** corresponds to **first\_lsn**, **commit** corresponds to **end\_lsn**, and other values correspond to the LSN of the statement).

 NOTE

The binary encoding rules are as follows:

1. The first four bytes represent the total number of bytes of the decoding result of statements following the statement-level delimiter letter P (excluded) or the batch end character F (excluded). If the value is **0**, the decoding of this batch ends.
2. The next eight bytes (uint64) indicate the corresponding LSN (**begin** corresponds to **first\_lsn**, **commit** corresponds to **end\_lsn**, and other values correspond to the LSN of the statement).
3. The next one-byte letter can be **B**, **C**, **I**, **U**, or **D**, representing BEGIN, COMMIT, INSERT, UPDATE, or DELETE.
4. If **B** is used in the step 3:
  1. The next eight bytes (uint64) indicate the CSN.
  2. The next eight bytes (uint64) indicate **first\_lsn**.
  3. (Optional) If the next 1-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length for committing the transaction. The following characters with the same length are the timestamp character string.
  4. (Optional) If the next one-byte letter is **N**, the following four bytes (uint32) indicate the length of the transaction username. The following characters with the same length are the transaction username.
  5. Because there may still be a decoding statement subsequently, a 1-byte letter **P** or **F** is used as a separator between statements. **P** indicates that there are still decoded statements in this batch, and **F** indicates that decoding in this batch is complete.
5. If the letter described in 3 is **C**:
  1. (Optional) If the next 1-byte letter is **X**, the following eight bytes (uint64) indicate XID.
  2. (Optional) If the next 1-byte letter is **T**, the following four bytes (uint32) indicate the timestamp length. The following characters with the same length are the timestamp character string.
  3. When logs are sent in batches, decoding results of other transactions may still exist after a COMMIT log is decoded. If the next 1-byte letter is **P**, the batch still needs to be decoded. If the letter is **F**, the batch decoding ends.
6. If the letter described in 3 is **I**, **U**, or **D**:
  1. The following two bytes (uint16) indicate the length of the schema name.
  2. The schema name is read based on the preceding length.
  3. The following two bytes (uint16) indicate the length of the table name.
  4. The table name is read based on the preceding length.
  5. (Optional) If the next 1-byte letter is **N**, it indicates a new tuple. If the letter is **O**, it indicates an old tuple. In this case, the new tuple is sent first.
    1. The following two bytes (uint16) indicate the number of columns to be decoded for the tuple, which is recorded as **attrnum**.
    2. The following procedure is repeated for *attrnum* times:
      1. The next two bytes (uint16) indicate the length of the column name.
      2. The column name is read based on the preceding length.
      3. The following four bytes (uint32) indicate the OID of the current column type.
      4. The next four bytes (uint32) indicate the length of the value (stored in the character string format) in the current column. If the value is **0xFFFFFFFF**, it indicates null. If the value is **0**, it indicates a character string whose length is 0.
      5. The column value is read based on the preceding length.

6. Because there may still be a decoding statement after, if the next one-byte letter is **P**, it indicates that the batch still needs to be decoded, and if the next one-byte letter is **F**, it indicates that decoding of the batch ends.
3. Decoding only on the standby node  
Configure the **standby-connection** option to specify whether to perform decoding only on the standby node. The value is of the Boolean type (**0** or **1**). The value **true** (or **1**) indicates that only the standby node can be connected for decoding. When the primary node is connected for decoding, an error is reported and the system exits. The value **false** (or **0**) indicates that there is no restriction. The default value is **false** (or **0**).
4. Batch sending  
Configure **sending-batch** to specify whether to send results in batches. The value is an integer ranging from 0 to 1. The value **0** indicates that decoding results are sent one by one. The value **1** indicates that decoding results are sent in batches when the accumulated size of decoding results reaches 1 MB. The default value is **0**. This parameter can be set only during parallel decoding. In the scenario where batch sending is enabled, if the decoding format is 'j' or 't', before each original decoding statement, a uint32 type is added indicating the length of the decoding result (excluding the current uint32 type), and a uint64 type is added, indicating the LSN corresponding to the current decoding result.
5. Length of the parallel decoding queue  
Configure **parallel-queue-size** to specify the length of the queue for interaction among parallel logical decoding threads. The value ranges from 2 to 1024 and must be a power of 2. The default value is **128**. The queue length is positively correlated with the memory usage during decoding.
6. Memory threshold for logical decoding  
The **max-txn-in-memory** configuration item specifies the memory threshold for caching the intermediate decoding result of a single transaction, in MB. The value ranges from 0 to 100 during serial decoding. The default value is **0**, indicating that the memory usage is not controlled. The **max-reorderbuffer-in-memory** configuration item specifies the memory threshold for caching intermediate decoding results of all transactions, in GB. The value ranges from 0 to 100 during serial decoding. The default value is **0**, indicating that the memory usage is not controlled. When the memory usage exceeds the threshold, intermediate decoding results are written into a temporary file during decoding, affecting the logical decoding performance.
7. Logical decoding sending timeout threshold  
The **sender-timeout** configuration item specifies the heartbeat timeout threshold between the kernel and client. If no message is received from the client within the period, the logical decoding stops and disconnects from the client. The unit is ms, and the value range is [0,2147483647]. The default value depends on the value of the GUC parameter **logical\_sender\_timeout**.
8. User blacklist options for logical decoding  
Use the user blacklist for logical decoding. The transaction operations of blacklisted users are filtered from the logical decoding result. The options are as follows:
  - a. **exclude-userids**: specifies the OIDs of blacklisted users. Multiple OIDs are separated by commas (.). The system does not check whether the user OIDs exist.

- b. **exclude-users**: specifies blacklisted usernames. Multiple usernames are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
  - c. **dynamic-resolution**: specifies whether to dynamically parse blacklisted usernames. The default value is **true**. If the parameter is set to **false**, an error is reported and the logical decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**. If the parameter is set to **true**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.
9. Output options for transaction logical logs
- a. **include-xids**: specifies whether the BEGIN logical log of a transaction outputs the transaction ID. The default value is **true**.
  - b. **include-timestamp**: specifies whether the BEGIN logical log of a transaction outputs the time when the transaction is committed. The default value is **false**.
  - c. **include-user**: specifies whether the BEGIN logical log of a transaction outputs the username of the transaction. The default value is **false**. The username of a transaction refers to the authorized user, that is, the login user who executes the session corresponding to the transaction. The username does not change during the execution of the transaction.
10. By default, **socketTimeout** of the logical decoding connection is set to **10s**. When the primary node is overloaded during decoding on the standby node, the connection may be closed due to timeout. You can set **withStatusInterval(10000,TimeUnit.MILLISECONDS)** to adjust the timeout interval.
11. Heartbeat log output option
- enable-heartbeat**: specifies whether to generate heartbeat logs. The default value is **false**.

 **NOTE**

If the heartbeat log output option is enabled, heartbeat logs will be generated. The heartbeat logs can be in the binary or TEXT/JSON format. For a binary heartbeat log message, it starts with a character 'h' and then the heartbeat log content: an 8-byte uint64 LSN indicating the end position of WAL reading when the heartbeat logical log is sent, an 8-byte uint64 LSN indicating the location of the WAL that has been flushed to disks when the heartbeat logical log is sent, and an 8-byte int64 timestamp (starting from January 1, 1970) indicating the timestamp when the latest decoded transaction log or checkpoint log is generated; then, it ends with character 'F'. TEXT/JSON heartbeat log messages that are sent in batches end with '0'. There is no such terminator for each TEXT/JSON heartbeat log message. The message content is transmitted in big-endian mode. The following figure shows the format.

Binary format (batch sending and non-batch sending)	uint32 len	uint64 lsn	'h'	uint64 latest_decode_lsn	uint64 latest_flush_lsn	int64 latest_decode_time	'F'
text/json + batch sending	uint32 len	uint64 lsn	char* "HeartBeat:latest_decode_lsn:XX,latest_flush_lsn:XX,latest_decoded_wal_time:XX"				'0'
text/json + non-batch sending	char* "HeartBeat:latest_decode_lsn:XX,latest_flush_lsn:XX,latest_decoded_wal_time:XX"						

The decoding performance (Xlog consumption) is greater than or equal to 100 Mbps in the following standard parallel decoding scenario: 16-core CPU, 128 GB memory, network bandwidth > 200 Mbps, 10 to 100 columns in a table, 0.1 KB to 1 KB data in a single row, INSERT as main DML operations, less than 4096 statements in a single transaction, **parallel-decode-num** set to **8**, decoding format as **'b'**, and batch sending function enabled. To ensure that the decoding performance meets the requirements and minimize the impact on services, you are advised to set up only one parallel decoding connection on a standby node to ensure that the CPU, memory, and bandwidth resources are sufficient.

**Note:** The logical replication class `PGReplicationStream` is a non-thread-safe class. Concurrent calls may cause data exceptions.

```
// There will be security risks if the username and password used for authentication are directly written into code. It is recommended that the username and password be stored in the configuration file or environment variables (the password must be stored in ciphertext and decrypted when being used) to ensure security.
```

```
// In this example, the username and password are stored in environment variables. Before running this example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local environment (set the environment variable names based on the actual situation).

        int TEST_MODE_START_REPL = 2;  
        // Test mode: Delete a logical replication slot.  
        int TEST_MODE_DROP_SLOT = 3;  
        // Enable different test modes.  
        int testMode = TEST_MODE_START_REPL;  
  
        try {  
            Class.forName(driver);  
        } catch (Exception e) {  
            e.printStackTrace();  
            return;  
        }  
  
        try {  
            Properties properties = new Properties();  
            PGProperty.USER.set(properties, System.getenv("EXAMPLE_USERNAME_ENV"));  
            PGProperty.PASSWORD.set(properties, System.getenv("EXAMPLE_PASSWORD_ENV"));  
            // For logical replication, the following three attributes are mandatory:  
            PGProperty.ASSUME_MIN_SERVER_VERSION.set(properties, "9.4");
```

```
PGProperty.REPLICATION.set(properties, "database");
PGProperty.PREFER_QUERY_MODE.set(properties, "simple");
conn = (PgConnection) DriverManager.getConnection(sourceURL, properties);
System.out.println("connection success!");

if(testMode == TEST_MODE_CREATE_SLOT){
    conn.getReplicationAPI()
        .createReplicationSlot()
        .logical()
        .withSlotName("replication_slot") // If the character string contains uppercase letters, the
uppercase letters are automatically converted to lowercase letters.
        .withOutputPlugin("mppdb_decoding")
        .make();
} else if(testMode == TEST_MODE_START_REPL) {
    // Create a replication slot before enabling this mode.
    LogSequenceNumber waitLSN = LogSequenceNumber.valueOf("6F/E3C53568");
    PGReplicationStream stream = conn
        .getReplicationAPI()
        .replicationStream()
        .logical()
        .withSlotName("replication_slot")
        .withSlotOption("include-xids", false)
        .withSlotOption("skip-empty-xacts", true)
        .withStartPosition(waitLSN)
        .withSlotOption("parallel-decode-num", 10) // Decoding thread concurrency
        .withSlotOption("white-table-list", "public.t1,public.t2") // Whitelist
        .withSlotOption("standby-connection", true) // Forcible standby decoding
        .withSlotOption("decode-style", "t") // Decoding format
        .withSlotOption("sending-batch", 0) // Sending decoding results in batches
        .withSlotOption("max-txn-in-memory", 100) // The memory threshold for flushing a single
decoding transaction to disks is 100 MB.
        .withSlotOption("max-reorderbuffer-in-memory", 50) // The total memory threshold for
flushing decoding transactions that are being handled to disks is 50 GB.
        .withSlotOption("exclude-users", 'userA') // The logical log of the transaction executed by
user A is not returned.
        .withSlotOption("include-user", true) // The BEGIN logical log of the transaction contains
the username.
        .withSlotOption("enable-heartbeat", true) // Enable the heartbeat log output option.
        .start();
    while (true) {
        ByteBuffer byteBuffer = stream.readPending();

        if (byteBuffer == null) {
            TimeUnit.MILLISECONDS.sleep(10L);
            continue;
        }

        int offset = byteBuffer.arrayOffset();
        byte[] source = byteBuffer.array();
        int length = source.length - offset;
        System.out.println(new String(source, offset, length));

        // If the LSN needs to be flushed, call the following APIs based on the service requirements:
        //LogSequenceNumber lastRecv = stream.getLastReceiveLSN();
        //stream.setFlushedLSN(lastRecv);
        //stream.forceUpdateStatus();

    }
} else if(testMode == TEST_MODE_DROP_SLOT){
    conn.getReplicationAPI()
        .dropReplicationSlot("replication_slot");
}
} catch (Exception e) {
    e.printStackTrace();
    return;
}
}
```

Example of the decoding result in text format (that is, 't' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
table public t1 INSERT: a[integer]:1 b[integer]:2 c[text]:'hello'
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
table public t1 UPDATE: old-key: a[integer]:1 new-tuple: a[integer]:1 b[integer]:5 c[text]:'hello'
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
table public t1 DELETE: a[integer]:1
COMMIT XID: 15506
```

Example of the decoding result in JSON format (that is, 'j' format):

```
BEGIN CSN: 2014 first_lsn: 0/2816A28
{"table_name":"public.t1","op_type":"INSERT","columns_name":["a","b","c"],"columns_type":
["integer","integer","text"],"columns_val":["1","1","hello"],"old_keys_name":[],"old_keys_type":
[],"old_keys_val":[]}
COMMIT XID: 15504
BEGIN CSN: 2015 first_lsn: 0/2816C20
{"table_name":"public.t1","op_type":"UPDATE","columns_name":["a","b","c"],"columns_type":
["integer","integer","text"],"columns_val":["1","5","hello"],"old_keys_name":["a"],"old_keys_type":
["integer"],"old_keys_val":["1"]}
COMMIT XID: 15505
BEGIN CSN: 2016 first_lsn: 0/2816D60
{"table_name":"public.t1","op_type":"DELETE","columns_name":[],"columns_type":[],"columns_val":
[],"old_keys_name":["a"],"old_keys_type":["integer"],"old_keys_val":["1"]}
COMMIT XID: 15506
```

### 5.3.16 Example: Parameters for Connecting to the Database in Different Scenarios

#### NOTE

In the example, **host:port** represents a node, where **host** indicates the name or IP address of the server where the database resides, and **port** indicates the port number of the server where the database resides.

#### DR

A customer has two database instances. Database instance A is the production database instance, and database instance B is the DR database instance. When the customer performs a DR switchover, database instance A is demoted to the DR database instance, and database instance B is promoted the production database instance. In this case, to avoid application restart or re-release caused by modifications on the configuration file, the customer can write database instances A and B to the connection string when initializing the configuration file. If the primary database instance cannot be connected, the driver attempts to connect to the DR database instance. For example, database instance A consists of *node1*, *node2*, and *node3*, and database instance B consists of *node4*, *node5*, and *node6*.

The URL can be configured as follows:

```
jdbc:postgresql://node1,node2,node3,node4,node5,node6/database?priorityServers=3
```

If you want to connect to both the primary cluster and hosts in the primary cluster, set **targetServerType** to **master**. The URL can be configured as follows:

```
jdbc:postgresql://node1,node2,node3,node4,node5,node6/database?
priorityServers=3&targetServerType=master
```

#### Load Balancing

A customer has a centralized database instance that consists of one primary node and two standby nodes, that is, *node1*, *node2*, and *node3*. *node1* is the primary node, and *node2* and *node3* are the standby nodes.

If the customer wants to evenly distribute the connections established on the same application to three nodes, the URL can be configured as follows:

```
jdbc:postgresql://node1,node2,node3/database?loadBalanceHosts=true
```

### CAUTION

When **loadBalanceHosts** is used, if the connection is established on the standby DN, write operations cannot be performed. If read and write operations are required, do not set this parameter.

## Automatic Selection of the Primary Node

A customer has a centralized database instance that consists of one primary node and two standby nodes, that is, *node1*, *node2*, and *node3*. *node1* is the primary node, and *node2* and *node3* are the standby nodes.

If the customer requires that the application connection be established on the primary DN and a new primary node be automatically selected to establish the connection during the primary/standby switchover, configure the URL as follows:

```
jdbc:postgresql://node1,node2,node3/database?targetServerType=master
```

## Log Diagnosis

If a customer encounters slow data import or some errors that are difficult to analyze, the trace log function can be enabled for diagnosis. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?loggerLevel=trace
```

## High Performance

A customer may execute the same SQL statement for multiple times with different input parameters. To improve the execution efficiency, the **prepareThreshold** parameter can be enabled to avoid repeatedly generating execution plans. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?prepareThreshold=5
```

A customer queries 10 million data records at a time. To prevent memory overflow caused by simultaneous return of the data records, the **defaultRowFetchSize** parameter can be used. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?defaultRowFetchSize=50000
```

A customer needs to insert 10 million data records in batches. To improve efficiency, the **batchMode** parameter can be used. The URL can be configured as follows:

```
jdbc:postgresql://node1/database?batchMode=on
```

## Case Conversion

In Oracle, metadata is stored in uppercase letters by default. In GaussDB, metadata is stored in lowercase letters by default. Therefore, after the metadata is

migrated from Oracle to GaussDB, the uppercase letters changes to lowercase letters. If the original service involves the processing of uppercase metadata, you can enable this parameter. However, you are advised to modify the service code instead of using this method to solve the problem. If you have to use this function, ensure that the metadata in the current database is in lowercase to avoid problems.

```
jdbc:postgresql://node1/database?uppercaseAttributeName=true
```

The APIs involved in DatabaseMetaData can be directly called based on input parameters. The methods of calling the APIs involved in ResultSetMetaData are as follows:

```
Statement stmt = conn.createStatement();
ResultSet rs = stmt.executeQuery("select * from test_supplier");
ResultSetMetaData rsmd = rs.getMetaData();
for (int i = 1; i <= rsmd.getColumnCount(); i++) {
    System.out.println(rsmd.getColumnLabel(i) + " " + rsmd.getColumnName(i));
}
```

## 5.3.17 JDBC API Reference

This section describes common JDBC interfaces. For more interfaces, check JDK1.8 (software package) and JDBC 4.2.

### 5.3.17.1 java.sql.Connection

java.sql.Connection is an API for connecting to a database.

**Table 5-9** Support status for java.sql.Connection

Method Name	Return Type	Support JDBC 4
abort(Executor executor)	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
commit()	void	Yes
createArrayOf(String typeName, Object[] elements)	Array	Yes
createBlob()	Blob	Yes
createClob()	Clob	Yes
createSQLXML()	SQLXML	Yes
createStatement()	Statement	Yes
createStatement(int resultSetType, int resultSetConcurrency)	Statement	Yes

Method Name	Return Type	Support JDBC 4
createStatement(int resultSetType, int resultSetConcurrency, int resultSetHoldability)	Statement	Yes
getAutoCommit()	Boolean	Yes
getCatalog()	String	Yes
getClientInfo()	Properties	Yes
getClientInfo(String name)	String	Yes
getHoldability()	int	Yes
getMetaData()	DatabaseMetaData	Yes
getNetworkTimeout()	int	Yes
getSchema()	String	Yes
getTransactionIsolation()	int	Yes
getTypeMap()	Map<String,Class<?>>	Yes
getWarnings()	SQLWarning	Yes
isClosed()	Boolean	Yes
isReadOnly()	Boolean	Yes
isValid(int timeout)	Boolean	Yes
nativeSQL(String sql)	String	Yes
prepareCall(String sql)	CallableStatement	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency)	CallableStatement	Yes
prepareCall(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	CallableStatement	Yes
prepareStatement(String sql)	PreparedStatement	Yes
prepareStatement(String sql, int autoGeneratedKeys)	PreparedStatement	Yes
prepareStatement(String sql, int[] columnIndexes)	PreparedStatement	Yes
prepareStatement(String sql, int resultSetType, int resultSetConcurrency)	PreparedStatement	Yes

Method Name	Return Type	Support JDBC 4
prepareStatement(String sql, int resultSetType, int resultSetConcurrency, int resultSetHoldability)	PreparedStatement	Yes
prepareStatement(String sql, String[] columnNames)	PreparedStatement	Yes
releaseSavepoint(Savepoint savepoint)	void	Yes
rollback()	void	Yes
rollback(Savepoint savepoint)	void	Yes
setAutoCommit(boolean autoCommit)	void	Yes
setClientInfo(Properties properties)	void	Yes
setClientInfo(String name,String value)	void	Yes
setHoldability(int holdability)	void	Yes
setNetworkTimeout(Executor executor, int milliseconds)	void	Yes
setReadOnly(boolean readOnly)	void	Yes
setSavepoint()	Savepoint	Yes
setSavepoint(String name)	Savepoint	Yes
setSchema(String schema)	void	Yes
setTransactionIsolation(int level)	void	Yes
setTypeMap(Map<String,Class<?>> map)	void	Yes

**NOTICE**

The autocommit mode is used by default within the API. If you disable it by running **setAutoCommit(false)**, all the statements executed later will be packaged in explicit transactions, and you cannot execute statements that cannot be executed within transactions.

### 5.3.17.2 java.sql.CallableStatement

java.sql.CallableStatement is an API for executing stored procedures.

**Table 5-10** Support status for java.sql.CallableStatement

Method Name	Return Type	Support JDBC 4
getArray(int parameterIndex)	Array	Yes
getBigDecimal(int parameterIndex)	BigDecimal	Yes
getBlob(int parameterIndex)	Blob	Yes
getBoolean(int parameterIndex)	Boolean	Yes
getByte(int parameterIndex)	byte	Yes
getBytes(int parameterIndex)	byte[]	Yes
getClob(int parameterIndex)	Clob	Yes
getDate(int parameterIndex)	Date	Yes
getDate(int parameterIndex, Calendar cal)	Date	Yes
getDouble(int parameterIndex)	double	Yes
getFloat(int parameterIndex)	float	Yes
getInt(int parameterIndex)	int	Yes
getLong(int parameterIndex)	long	Yes
getObject(int parameterIndex)	Object	Yes
getObject(int parameterIndex, Class<T> type)	Object	Yes
getShort(int parameterIndex)	short	Yes
getSQLXML(int parameterIndex)	SQLXML	Yes
getString(int parameterIndex)	String	Yes
getNString(int parameterIndex)	String	Yes
getTime(int parameterIndex)	Time	Yes

Method Name	Return Type	Support JDBC 4
getTime(int parameterIndex, Calendar cal)	Time	Yes
getTimestamp(int parameterIndex)	Timestamp	Yes
getTimestamp(int parameterIndex, Calendar cal)	Timestamp	Yes
registerOutParameter(int parameterIndex, int type)	void	Yes
registerOutParameter(int parameterIndex, int sqlType, int type)	void	Yes
wasNull()	Boolean	Yes

 **NOTE**

- The batch operation of statements containing OUT parameter is not allowed.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, and setFetchSize.
- The following methods are inherited from java.sql.PreparedStatement: addBatch, clearParameters, execute, executeQuery, executeUpdate, getMetaData, setBigDecimal, setBoolean, setByte, setBytes, setDate, setDouble, setFloat, setInt, setLong, setNull, setObject, setString, setTime, and setTimestamp.
- The registerOutParameter(int parameterIndex, int sqlType, int type) method is used only to register the composite data type.

### 5.3.17.3 java.sql.DatabaseMetaData

java.sql.DatabaseMetaData is an API for defining database objects.

**Table 5-11** Support status for java.sql.DatabaseMetaData

Method Name	Return Type	Support JDBC 4
allProceduresAreCallable()	Boolean	Yes
allTablesAreSelectable()	Boolean	Yes
autoCommitFailureClosesAllResultSets()	Boolean	Yes
dataDefinitionCausesTransactionCommit()	Boolean	Yes
dataDefinitionIgnoredInTransactions()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
deletesAreDetected(int type)	Boolean	Yes
doesMaxRowSizeIncludeBlobs()	Boolean	Yes
generatedKeyAlwaysReturned()	Boolean	Yes
getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)	ResultSet	Yes
getCatalogs()	ResultSet	Yes
getCatalogSeparator()	String	Yes
getCatalogTerm()	String	Yes
getClientInfoProperties()	ResultSet	Yes
getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)	ResultSet	Yes
getConnection()	Connection	Yes
getCrossReference(String parentCatalog, String parentSchema, String parentTable, String foreignCatalog, String foreignSchema, String foreignTable)	ResultSet	Yes
getDefaultTransactionIsolation()	int	Yes
getExportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getExtraNameCharacters()	String	Yes
getFunctionColumns(String catalog, String schemaPattern, String functionNamePattern, String columnNamePattern)	ResultSet	Yes
getFunctions(String catalog, String schemaPattern, String functionNamePattern)	ResultSet	Yes

Method Name	Return Type	Support JDBC 4
getIdentifierQuoteString()	String	Yes
getImportedKeys(String catalog, String schema, String table)	ResultSet	Yes
getIndexInfo(String catalog, String schema, String table, boolean unique, boolean approximate)	ResultSet	Yes
getMaxBinaryLiteralLength()	int	Yes
getMaxCatalogNameLength()	int	Yes
getMaxCharLiteralLength()	int	Yes
getMaxColumnNameLength()	int	Yes
getMaxColumnsInGroupBy()	int	Yes
getMaxColumnsInIndex()	int	Yes
getMaxColumnsInOrderBy()	int	Yes
getMaxColumnsInSelect()	int	Yes
getMaxColumnsInTable()	int	Yes
getMaxConnections()	int	Yes
getMaxCursorNameLength()	int	Yes
getMaxIndexLength()	int	Yes
getMaxLogicalLobSize()	default long	Yes
getMaxProcedureNameLength()	int	Yes
getMaxRowSize()	int	Yes
getMaxSchemaNameLength()	int	Yes
getMaxStatementLength()	int	Yes
getMaxStatements()	int	Yes
getMaxTableNameLength()	int	Yes
getMaxTablesInSelect()	int	Yes
getMaxUserNameLength()	int	Yes
getNumericFunctions()	String	Yes

Method Name	Return Type	Support JDBC 4
getPrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getPartitionTablePrimaryKeys(String catalog, String schema, String table)	ResultSet	Yes
getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)	ResultSet	Yes
getProcedures(String catalog, String schemaPattern, String procedureNamePattern)	ResultSet	Yes
getProcedureTerm()	String	Yes
getSchemas()	ResultSet	Yes
getSchemas(String catalog, String schemaPattern)	ResultSet	Yes
getSchemaTerm()	String	Yes
getSearchStringEscape()	String	Yes
getSQLKeywords()	String	Yes
getSQLStateType()	int	Yes
getStringFunctions()	String	Yes
getSystemFunctions()	String	Yes
getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)	ResultSet	Yes
getTimeDateFunctions()	String	Yes
getTypeInfo()	ResultSet	Yes
getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)	ResultSet	Yes
getURL()	String	Yes

Method Name	Return Type	Support JDBC 4
getVersionColumns(String catalog, String schema, String table)	ResultSet	Yes
insertsAreDetected(int type)	Boolean	Yes
locatorsUpdateCopy()	Boolean	Yes
othersDeletesAreVisible(int type)	Boolean	Yes
othersInsertsAreVisible(int type)	Boolean	Yes
othersUpdatesAreVisible(int type)	Boolean	Yes
ownDeletesAreVisible(int type)	Boolean	Yes
ownInsertsAreVisible(int type)	Boolean	Yes
ownUpdatesAreVisible(int type)	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
storesMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
supportsBatchUpdates()	Boolean	Yes
supportsCatalogsInDataManipulation()	Boolean	Yes
supportsCatalogsInIndexDefinitions()	Boolean	Yes
supportsCatalogsInPrivilegeDefinitions()	Boolean	Yes
supportsCatalogsInProcedureCalls()	Boolean	Yes
supportsCatalogsInTableDefinitions()	Boolean	Yes
supportsCorrelatedSubqueries()	Boolean	Yes
supportsDataDefinitionAndDataManipulationTransactions()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsDataManipulation-TransactionsOnly()	Boolean	Yes
supportsGetGeneratedKeys()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
supportsMultipleOpenResults()	Boolean	Yes
supportsNamedParameters()	Boolean	Yes
supportsOpenCursorsAcrossCommit()	Boolean	Yes
supportsOpenCursorsAcrossRollback()	Boolean	Yes
supportsOpenStatementsAcrossCommit()	Boolean	Yes
supportsOpenStatementsAcrossRollback()	Boolean	Yes
supportsPositionedDelete()	Boolean	Yes
supportsPositionedUpdate()	Boolean	Yes
supportsRefCursors()	Boolean	Yes
supportsResultSetConcurrency(int type, int concurrency)	Boolean	Yes
supportsResultSetType(int type)	Boolean	Yes
supportsSchemasInIndexDefinitions()	Boolean	Yes
supportsSchemasInPrivilegeDefinitions()	Boolean	Yes
supportsSchemasInProcedureCalls()	Boolean	Yes
supportsSchemasInTableDefinitions()	Boolean	Yes
supportsSelectForUpdate()	Boolean	Yes
supportsStatementPooling()	Boolean	Yes
supportsStoredFunctionsUsingCallSyntax()	Boolean	Yes
supportsStoredProcedures()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsSubqueriesInComparisons()	Boolean	Yes
supportsSubqueriesInExists()	Boolean	Yes
supportsSubqueriesInIns()	Boolean	Yes
supportsSubqueriesInQuantifieds()	Boolean	Yes
supportsTransactionIsolationLevel(int level)	Boolean	Yes
supportsTransactions()	Boolean	Yes
supportsUnion()	Boolean	Yes
supportsUnionAll()	Boolean	Yes
updatesAreDetected(int type)	Boolean	Yes
getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)	ResultSet	Yes
getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)	ResultSet	Yes
getTableTypes()	ResultSet	Yes
getUserName()	String	Yes
isReadOnly()	Boolean	Yes
nullsAreSortedHigh()	Boolean	Yes
nullsAreSortedLow()	Boolean	Yes
nullsAreSortedAtStart()	Boolean	Yes
nullsAreSortedAtEnd()	Boolean	Yes
getDatabaseProductName()	String	Yes
getDatabaseProductVersion()	String	Yes
getDriverName()	String	Yes
getDriverVersion()	String	Yes
getDriverMajorVersion()	int	Yes

Method Name	Return Type	Support JDBC 4
getDriverMinorVersion()	int	Yes
usesLocalFiles()	Boolean	Yes
usesLocalFilePerTable()	Boolean	Yes
supportsMixedCaseIdentifiers()	Boolean	Yes
storesUpperCaseIdentifiers()	Boolean	Yes
storesLowerCaseIdentifiers()	Boolean	Yes
supportsMixedCaseQuotedIdentifiers()	Boolean	Yes
storesUpperCaseQuotedIdentifiers()	Boolean	Yes
storesLowerCaseQuotedIdentifiers()	Boolean	Yes
storesMixedCaseQuotedIdentifiers()	Boolean	Yes
supportsAlterTableWithAddColumn()	Boolean	Yes
supportsAlterTableWithDropColumn()	Boolean	Yes
supportsColumnAliasing()	Boolean	Yes
nullPlusNonNullsNull()	Boolean	Yes
supportsConvert()	Boolean	Yes
supportsConvert(int fromType, int toType)	Boolean	Yes
supportsTableCorrelationNames()	Boolean	Yes
supportsDifferentTableCorrelationNames()	Boolean	Yes
supportsExpressionsInOrderBy()	Boolean	Yes
supportsOrderByUnrelated()	Boolean	Yes
supportsGroupBy()	Boolean	Yes
supportsGroupByUnrelated()	Boolean	Yes
supportsGroupByBeyondSelect()	Boolean	Yes

Method Name	Return Type	Support JDBC 4
supportsLikeEscapeClause()	Boolean	Yes
supportsMultipleResultSets()	Boolean	Yes
supportsMultipleTransactions()	Boolean	Yes
supportsNonNullableColumns()	Boolean	Yes
supportsMinimumSQLGrammar()	Boolean	Yes
supportsCoreSQLGrammar()	Boolean	Yes
supportsExtendedSQLGrammar()	Boolean	Yes
supportsANSI92EntryLevelSQL()	Boolean	Yes
supportsANSI92IntermediateSQL()	Boolean	Yes
supportsANSI92FullSQL()	Boolean	Yes
supportsIntegrityEnhancementFacility()	Boolean	Yes
supportsOuterJoins()	Boolean	Yes
supportsFullOuterJoins()	Boolean	Yes
supportsLimitedOuterJoins()	Boolean	Yes
isCatalogAtStart()	Boolean	Yes
supportsSchemasInDataManipulation()	Boolean	Yes
supportsSavepoints()	Boolean	Yes
supportsResultSetHoldability(int holdability)	Boolean	Yes
getResultSetHoldability()	int	Yes
getDatabaseMajorVersion()	int	Yes
getDatabaseMinorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes
getJDBCMajorVersion()	int	Yes
getJDBCMinorVersion()	int	Yes

 NOTE

If the value of **uppercaseAttributeName** is **true**, the following APIs convert the query result to uppercase letters. The conversion range is the same as that of the **toUpperCase** method in Java.

- `public ResultSet getProcedures(String catalog, String schemaPattern, String procedureNamePattern)`
- `public ResultSet getProcedureColumns(String catalog, String schemaPattern, String procedureNamePattern, String columnNamePattern)`
- `public ResultSet getTables(String catalog, String schemaPattern, String tableNamePattern, String[] types)`
- `public ResultSet getSchemas(String catalog, String schemaPattern)`
- `public ResultSet getColumns(String catalog, String schemaPattern, String tableNamePattern, String columnNamePattern)`
- `public ResultSet getColumnPrivileges(String catalog, String schema, String table, String columnNamePattern)`
- `public ResultSet getTablePrivileges(String catalog, String schemaPattern, String tableNamePattern)`
- `public ResultSet getBestRowIdentifier(String catalog, String schema, String table, int scope, boolean nullable)`
- `public ResultSet getPrimaryKeys(String catalog, String schema, String table)`
- `protected ResultSet getImportedExportedKeys(String primaryCatalog, String primarySchema, String primaryTable, String foreignCatalog, String foreignSchema, String foreignTable)`
- `public ResultSet getIndexInfo(String catalog, String schema, String tableName, boolean unique, boolean approximate)`
- `public ResultSet getUDTs(String catalog, String schemaPattern, String typeNamePattern, int[] types)`
- `public ResultSet getFunctions(String catalog, String schemaPattern, String functionNamePattern)`

 CAUTION

The `getPartitionTablePrimaryKeys(String catalog, String schema, String table)` API is used to obtain the primary key column of a partitioned table that contains global indexes. An example is as follows:

```
PgDatabaseMetaData dbmd = (PgDatabaseMetaData)conn.getMetaData();
dbmd.getPartitionTablePrimaryKeys("catalogName", "schemaName", "tableName");
```

### 5.3.17.4 java.sql.Driver

`java.sql.Driver` is a database driver API.

**Table 5-12** Support status for `java.sql.Driver`

Method Name	Return Type	Support JDBC 4
<code>acceptsURL(String url)</code>	Boolean	Yes
<code>connect(String url, Properties info)</code>	Connection	Yes
<code>jdbcCompliant()</code>	Boolean	Yes

Method Name	Return Type	Support JDBC 4
getMajorVersion()	int	Yes
getMinorVersion()	int	Yes
getParentLogger()	Logger	Yes
getPropertyInfo(String url, Properties info)	DriverPropertyInfo[]	Yes

### 5.3.17.5 java.sql.PreparedStatement

java.sql.PreparedStatement is an API for preparing statements.

**Table 5-13** Support status for java.sql.PreparedStatement

Method Name	Return Type	Support JDBC 4
clearParameters()	void	Yes
execute()	Boolean	Yes
executeQuery()	ResultSet	Yes
executeUpdate()	int	Yes
executeLargeUpdate()	long	No
getMetaData()	ResultSetMetaData	Yes
getParameterMetaData()	ParameterMetaData	Yes
setArray(int parameterIndex, Array x)	void	Yes
setAsciiStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, int length)	void	Yes
setBinaryStream(int parameterIndex, InputStream x, long length)	void	Yes

Method Name	Return Type	Support JDBC 4
setBlob(int parameterIndex, InputStream inputStream)	void	Yes
setBlob(int parameterIndex, InputStream inputStream, long length)	void	Yes
setBlob(int parameterIndex, Blob x)	void	Yes
setCharacterStream(int parameterIndex, Reader reader)	void	Yes
setCharacterStream(int parameterIndex, Reader reader, int length)	void	Yes
setClob(int parameterIndex, Reader reader)	void	Yes
setClob(int parameterIndex, Reader reader, long length)	void	Yes
setClob(int parameterIndex, Clob x)	void	Yes
setDate(int parameterIndex, Date x, Calendar cal)	void	Yes
setNull(int parameterIndex, int sqlType)	void	Yes
setNull(int parameterIndex, int sqlType, String typeName)	void	Yes
setObject(int parameterIndex, Object x)	void	Yes
setObject(int parameterIndex, Object x, int targetSqlType)	void	Yes

Method Name	Return Type	Support JDBC 4
setObject(int parameterIndex, Object x, int targetSqlType, int scaleOrLength)	void	Yes
setSQLXML(int parameterIndex, SQLXML xmlObject)	void	Yes
setTime(int parameterIndex, Time x)	void	Yes
setTime(int parameterIndex, Time x, Calendar cal)	void	Yes
setTimestamp(int parameterIndex, Timestamp x)	void	Yes
setTimestamp(int parameterIndex, Timestamp x, Calendar cal)	void	Yes
setUnicodeStream(int parameterIndex, InputStream x, int length)	void	Yes
setURL(int parameterIndex, URL x)	void	Yes
setBoolean(int parameterIndex, boolean x)	void	Yes
setBigDecimal(int parameterIndex, BigDecimal x)	void	Yes
setByte(int parameterIndex, byte x)	void	Yes
setBytes(int parameterIndex, byte[] x)	void	Yes
setDate(int parameterIndex, Date x)	void	Yes
setDouble(int parameterIndex, double x)	void	Yes

Method Name	Return Type	Support JDBC 4
setFloat(int parameterIndex, float x)	void	Yes
setInt(int parameterIndex, int x)	void	Yes
setLong(int parameterIndex, long x)	void	Yes
setShort(int parameterIndex, short x)	void	Yes
setString(int parameterIndex, String x)	void	Yes
setNString(int parameterIndex, String x)	void	Yes
addBatch()	void	Yes
executeBatch()	int[]	Yes

 **NOTE**

- Execute addBatch() and execute() only after executing clearBatch().
- Batch is not cleared by calling executeBatch(). Clear batch by explicitly calling clearBatch().
- After bounded variables of a batch are added, if you want to reuse these values, you do not need to use set\*() again. Instead, add a batch.
- The following methods are inherited from java.sql.Statement: close, execute, executeQuery, executeUpdate, getConnection, getResultSet, getUpdateCount, isClosed, setMaxRows, and setFetchSize.
- The executeLargeUpdate() method can only be used in JDBC 4.2 or later.

### 5.3.17.6 java.sql.ResultSet

java.sql.ResultSet is an execution result set API.

**Table 5-14** Support status for java.sql.ResultSet

Method Name	Return Type	Support JDBC 4
absolute(int row)	Boolean	Yes
afterLast()	void	Yes
beforeFirst()	void	Yes
cancelRowUpdates()	void	Yes

Method Name	Return Type	Support JDBC 4
clearWarnings()	void	Yes
close()	void	Yes
deleteRow()	void	Yes
findColumn(String columnLabel)	int	Yes
first()	Boolean	Yes
getArray(int columnIndex)	Array	Yes
getArray(String columnLabel)	Array	Yes
getAsciiStream(int columnIndex)	InputStream	Yes
getAsciiStream(String columnLabel)	InputStream	Yes
getBigDecimal(int columnIndex)	BigDecimal	Yes
getBigDecimal(String columnLabel)	BigDecimal	Yes
getBinaryStream(int columnIndex)	InputStream	Yes
getBinaryStream(String columnLabel)	InputStream	Yes
getBlob(int columnIndex)	Blob	Yes
getBlob(String columnLabel)	Blob	Yes
getBoolean(int columnIndex)	Boolean	Yes
getBoolean(String columnLabel)	Boolean	Yes
getByte(int columnIndex)	byte	Yes
getBytes(int columnIndex)	byte[]	Yes
getByte(String columnLabel)	byte	Yes
getBytes(String columnLabel)	byte[]	Yes

Method Name	Return Type	Support JDBC 4
getCharacterStream(int columnIndex)	Reader	Yes
getCharacterStream(String columnLabel)	Reader	Yes
getClob(int columnIndex)	Clob	Yes
getClob(String columnLabel)	Clob	Yes
getConcurrency()	int	Yes
getCursorName()	String	Yes
getDate(int columnIndex)	Date	Yes
getDate(int columnIndex, Calendar cal)	Date	Yes
getDate(String columnLabel)	Date	Yes
getDate(String columnLabel, Calendar cal)	Date	Yes
getDouble(int columnIndex)	double	Yes
getDouble(String columnLabel)	double	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getFloat(int columnIndex)	float	Yes
getFloat(String columnLabel)	float	Yes
getInt(int columnIndex)	int	Yes
getInt(String columnLabel)	int	Yes
getLong(int columnIndex)	long	Yes
getLong(String columnLabel)	long	Yes
getMetaData()	ResultSetMetaData	Yes
getObject(int columnIndex)	Object	Yes

Method Name	Return Type	Support JDBC 4
getObject(int columnIndex, Class<T> type)	<T> T	Yes
getObject(int columnIndex, Map<String,Class<?>> map)	Object	Yes
getObject(String columnLabel)	Object	Yes
getObject(String columnLabel, Class<T> type)	<T> T	Yes
getObject(String columnLabel, Map<String,Class<?>> map)	Object	Yes
getRow()	int	Yes
getShort(int columnIndex)	short	Yes
getShort(String columnLabel)	short	Yes
getSQLXML(int columnIndex)	SQLXML	Yes
getSQLXML(String columnLabel)	SQLXML	Yes
getStatement()	Statement	Yes
getString(int columnIndex)	String	Yes
getString(String columnLabel)	String	Yes
getNString(int columnIndex)	String	Yes
getNString(String columnLabel)	String	Yes
getTime(int columnIndex)	Time	Yes
getTime(int columnIndex, Calendar cal)	Time	Yes
getTime(String columnLabel)	Time	Yes

Method Name	Return Type	Support JDBC 4
getTime(String columnLabel, Calendar cal)	Time	Yes
getTimestamp(int columnIndex)	Timestamp	Yes
getTimestamp(int columnIndex, Calendar cal)	Timestamp	Yes
getTimestamp(String columnLabel)	Timestamp	Yes
getTimestamp(String columnLabel, Calendar cal)	Timestamp	Yes
getType()	int	Yes
getWarnings()	SQLWarning	Yes
insertRow()	void	Yes
isAfterLast()	Boolean	Yes
isBeforeFirst()	Boolean	Yes
isClosed()	Boolean	Yes
isFirst()	Boolean	Yes
isLast()	Boolean	Yes
last()	Boolean	Yes
moveToCurrentRow()	void	Yes
moveToInsertRow()	void	Yes
next()	Boolean	Yes
previous()	Boolean	Yes
refreshRow()	void	Yes
relative(int rows)	Boolean	Yes
rowDeleted()	Boolean	Yes
rowInserted()	Boolean	Yes
rowUpdated()	Boolean	Yes
setFetchDirection(int direction)	void	Yes
setFetchSize(int rows)	void	Yes

Method Name	Return Type	Support JDBC 4
updateArray(int columnIndex, Array x)	void	Yes
updateArray(String columnLabel, Array x)	void	Yes
updateAsciiStream(int columnIndex, InputStream x, int length)	void	Yes
updateAsciiStream(String columnLabel, InputStream x, int length)	void	Yes
updateBigDecimal(int columnIndex, BigDecimal x)	void	Yes
updateBigDecimal(String columnLabel, BigDecimal x)	void	Yes
updateBinaryStream(int columnIndex, InputStream x, int length)	void	Yes
updateBinaryStream(String columnLabel, InputStream x, int length)	void	Yes
updateBoolean(int columnIndex, boolean x)	void	Yes
updateBoolean(String columnLabel, boolean x)	void	Yes
updateByte(int columnIndex, byte x)	void	Yes
updateByte(String columnLabel, byte x)	void	Yes
updateBytes(int columnIndex, byte[] x)	void	Yes
updateBytes(String columnLabel, byte[] x)	void	Yes
updateCharacterStream(int columnIndex, Reader x, int length)	void	Yes

Method Name	Return Type	Support JDBC 4
updateCharacterStream(String columnLabel, Reader reader, int length)	void	Yes
updateDate(int columnIndex, Date x)	void	Yes
updateDate(String columnLabel, Date x)	void	Yes
updateDouble(int columnIndex, double x)	void	Yes
updateDouble(String columnLabel, double x)	void	Yes
updateFloat(int columnIndex, float x)	void	Yes
updateFloat(String columnLabel, float x)	void	Yes
updateInt(int columnIndex, int x)	void	Yes
updateInt(String columnLabel, int x)	void	Yes
updateLong(int columnIndex, long x)	void	Yes
updateLong(String columnLabel, long x)	void	Yes
updateNull(int columnIndex)	void	Yes
updateNull(String columnLabel)	void	Yes
updateObject(int columnIndex, Object x)	void	Yes
updateObject(int columnIndex, Object x, int scaleOrLength)	void	Yes
updateObject(String columnLabel, Object x)	void	Yes
updateObject(String columnLabel, Object x, int scaleOrLength)	void	Yes
updateRow()	void	Yes

Method Name	Return Type	Support JDBC 4
updateShort(int columnIndex, short x)	void	Yes
updateShort(String columnLabel, short x)	void	Yes
updateSQLXML(int columnIndex, SQLXML xmlObject)	void	Yes
updateSQLXML(String columnLabel, SQLXML xmlObject)	void	Yes
updateString(int columnIndex, String x)	void	Yes
updateString(String columnLabel, String x)	void	Yes
updateTime(int columnIndex, Time x)	void	Yes
updateTime(String columnLabel, Time x)	void	Yes
updateTimestamp(int columnIndex, Timestamp x)	void	Yes
updateTimestamp(String columnLabel, Timestamp x)	void	Yes
wasNull()	Boolean	Yes

 **NOTE**

- One statement cannot have multiple open ResultSets.
- The cursor that is used for traversing the ResultSet cannot be open after being committed.

### 5.3.17.7 java.sql.ResultSetMetaData

java.sql.ResultSetMetaData describes the information about ResultSet objects.

**Table 5-15** Support status for java.sql.ResultSetMetaData

Method Name	Return Type	Support JDBC 4
getCatalogName(int column)	String	Yes

Method Name	Return Type	Support JDBC 4
getColumnClassName(int column)	String	Yes
getColumnCount()	int	Yes
getColumnDisplaySize(int column)	int	Yes
getColumnLabel(int column)	String	Yes
getColumnName(int column)	String	Yes
getColumnType(int column)	int	Yes
getColumnTypeName(int column)	String	Yes
getPrecision(int column)	int	Yes
getScale(int column)	int	Yes
getSchemaName(int column)	String	Yes
getTableName(int column)	String	Yes
isAutoIncrement(int column)	Boolean	Yes
isCaseSensitive(int column)	Boolean	Yes
isCurrency(int column)	Boolean	Yes
isDefinitelyWritable(int column)	Boolean	Yes
isNullable(int column)	int	Yes
isReadOnly(int column)	Boolean	Yes
isSearchable(int column)	Boolean	Yes
isSigned(int column)	Boolean	Yes
isWritable(int column)	Boolean	Yes

 **NOTE**

When **uppercaseAttributeName** is set to **true**, the following APIs convert the query result to uppercase letters. The conversion range is 26 English letters.

- public String getColumnName(int column)
- public String getColumnLabel(int column)

### 5.3.17.8 java.sql.Statement

java.sql.Statement is an SQL statement API.

**Table 5-16** Support status for java.sql.Statement

Method Name	Return Type	Support JDBC 4
addBatch(String sql)	void	Yes
clearBatch()	void	Yes
clearWarnings()	void	Yes
close()	void	Yes
closeOnCompletion()	void	Yes
execute(String sql)	Boolean	Yes
execute(String sql, int autoGeneratedKeys)	Boolean	Yes
execute(String sql, int[] columnIndexes)	Boolean	Yes
execute(String sql, String[] columnNames)	Boolean	Yes
executeBatch()	Boolean	Yes
executeQuery(String sql)	ResultSet	Yes
executeUpdate(String sql)	int	Yes
executeUpdate(String sql, int autoGeneratedKeys)	int	Yes
executeUpdate(String sql, int[] columnIndexes)	int	Yes
executeUpdate(String sql, String[] columnNames)	int	Yes
getConnection()	Connection	Yes
getFetchDirection()	int	Yes
getFetchSize()	int	Yes
getGeneratedKeys()	ResultSet	Yes
getMaxFieldSize()	int	Yes

Method Name	Return Type	Support JDBC 4
getMaxRows()	int	Yes
getMoreResults()	Boolean	Yes
getMoreResults(int current)	Boolean	Yes
getResultSet()	ResultSet	Yes
getResultSetConcurrency()	int	Yes
getResultSetHoldability()	int	Yes
getResultSetType()	int	Yes
getQueryTimeout()	int	Yes
getUpdateCount()	int	Yes
getWarnings()	SQLWarning	Yes
isClosed()	Boolean	Yes
isCloseOnCompletion()	Boolean	Yes
isPoolable()	Boolean	Yes
setCursorName(String name)	void	Yes
setEscapeProcessing(boolean enable)	void	Yes
setFetchDirection(int direction)	void	Yes
setMaxFieldSize(int max)	void	Yes
setMaxRows(int max)	void	Yes
setPoolable(boolean poolable)	void	Yes
setQueryTimeout(int seconds)	void	Yes
setFetchSize(int rows)	void	Yes
cancel()	void	Yes
executeLargeUpdate(String sql)	long	No
getLargeUpdateCount()	long	No

Method Name	Return Type	Support JDBC 4
executeLargeBatch()	long	No
executeLargeUpdate(String sql, int autoGeneratedKeys)	long	No
executeLargeUpdate(String sql, int[] columnIndexes)	long	No
executeLargeUpdate(String sql, String[] columnNames)	long	No

 NOTE

- Using setFetchSize can reduce the memory occupied by result sets on the client. Result sets are packaged into cursors and segmented for processing, which will increase the communication traffic between the database and the client, affecting performance.
- Database cursors are valid only within their transactions. If **setFetchSize** is set, set **setAutoCommit(false)** and commit transactions on the connection to flush service data to a database.
- The LargeUpdate method can only be used in JDBC 4.2 or later.

### 5.3.17.9 javax.sql.ConnectionPoolDataSource

This section describes **javax.sql.ConnectionPoolDataSource**, the API for data source connection pools.

**Table 5-17** Support status for javax.sql.ConnectionPoolDataSource

Method Name	Return Type	JDBC 4 Is Supported Or Not
getPooledConnection()	PooledConnection	Yes
getPooledConnection(String user,String password)	PooledConnection	Yes

### 5.3.17.10 javax.sql.DataSource

This section describes **javax.sql.DataSource**, the interface for data sources.

**Table 5-18** Support status for javax.sql.DataSource

Method Name	Return Type	Support JDBC 4
getConnection()	Connection	Yes
getConnection(String username,String password)	Connection	Yes
getLoginTimeout()	int	Yes
getLogWriter()	PrintWriter	Yes
setLoginTimeout(int seconds)	void	Yes
setLogWriter(PrintWriter out)	void	Yes

### 5.3.17.11 javax.sql.PooledConnection

This section describes **javax.sql.PooledConnection**, the connection API created by a connection pool.

**Table 5-19** Support status for javax.sql.PooledConnection

Method Name	Return Type	JDBC 4 Is Supported Or Not
addConnectionEventListener (ConnectionEventListener listener)	void	Yes
close()	void	Yes
getConnection()	Connection	Yes
removeConnectionEventListener (ConnectionEventListener listener)	void	Yes

### 5.3.17.12 javax.naming.Context

This section describes **javax.naming.Context**, the context interface for connection configuration.

**Table 5-20** Support status for javax.naming.Context

Method Name	Return Type	Support JDBC 4
bind(Name name, Object obj)	void	Yes
bind(String name, Object obj)	void	Yes

Method Name	Return Type	Support JDBC 4
lookup(Name name)	Object	Yes
lookup(String name)	Object	Yes
rebind(Name name, Object obj)	void	Yes
rebind(String name, Object obj)	void	Yes
rename(Name oldName, Name newName)	void	Yes
rename(String oldName, String newName)	void	Yes
unbind(Name name)	void	Yes
unbind(String name)	void	Yes

### 5.3.17.13 javax.naming.spi.InitialContextFactory

This section describes **javax.naming.spi.InitialContextFactory**, the initial context factory interface.

**Table 5-21** Support status for javax.naming.spi.InitialContextFactory

Method Name	Return Type	Support JDBC 4
getInitialContext(Hashtable<?,?> environment)	Context	Yes

### 5.3.17.14 CopyManager

CopyManager is an API class provided by the JDBC driver in GaussDB. It is used to import data to GaussDB in batches.

#### Inheritance Relationship of CopyManager

The CopyManager class is in the **org.postgresql.copy** package and inherits the java.lang.Object class. The declaration of the class is as follows:

```
public class CopyManager
extends Object
```

#### Construction Method

```
public CopyManager(BaseConnection connection)
throws SQLException
```

## Common Methods

**Table 5-22** Common methods of CopyManager

Return Value	Method	Description	throws
CopyIn	copyIn(String sql)	-	SQLException
long	copyIn(String sql, InputStream from)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from InputStream.	SQLException,IOE xception
long	copyIn(String sql, InputStream from, int bufferSize)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from InputStream.	SQLException,IOE xception
long	copyIn(String sql, Reader from)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from Reader.	SQLException,IOE xception
long	copyIn(String sql, Reader from, int bufferSize)	Uses <b>COPY FROM STDIN</b> to quickly load data to tables in the database from Reader.	SQLException,IOE xception
CopyOut	copyOut(String sql)	-	SQLException
long	copyOut(String sql, OutputStream to)	Sends the result set of <b>COPY TO STDOUT</b> from the database to the OutputStream class.	SQLException,IOE xception
long	copyOut(String sql, Writer to)	Sends the result set of <b>COPY TO STDOUT</b> from the database to the Writer class.	SQLException,IOE xception

### 5.3.17.15 PGReplicationConnection

PGReplicationConnection is an API class provided by the JDBC driver in GaussDB. It is used to implement functions related to logical replication.

#### Inheritance Relationship of PGReplicationConnection

PGReplicationConnection is a logical replication interface. Its implementation class is PGReplicationConnectionImpl, which is in the **org.postgresql.replication** package. The declaration of the class is as follows:

```
public class PGReplicationConnection implements PGReplicationConnection
```

#### Construction Method

```
public PGReplicationConnection(BaseConnection connection)
```

#### Common Methods

**Table 5-23** Common methods of PGReplicationConnection

Return Value	Method	Description	Throws
ChainedCreateReplicationSlotBuilder	createReplicationSlot()	Creates a logical replication slot. Only LSN-based logical replication slots can be created. For details about how to create CSN-based logical replication slots, see the SQL function <code>pg_create_logical_replication_slot</code> for logical replication.	-
void	dropReplicationSlot(String slotName)	Deletes a logical replication slot.	SQLException,IOE xception
ChainedStreamBuilder	replicationStream()	Enables logical replication.	-

### 5.3.17.16 PGReplicationStream

PGReplicationStream is an API class provided by the GaussDB JDBC driver. It is used to operate logical replication streams.

## Inheritance Relationship of PGReplicationStream

PGReplicationStream is a logical replication API. Its implementation class is V3PGReplicationStream, which is in the **org.postgresql.core.v3.replication** package. The declaration of the class is as follows:

```
public class V3PGReplicationStream implements PGReplicationStream
```

## Constructor Method

```
public V3PGReplicationStream(CopyDual copyDual, LogSequenceNumber startLSN, long updateIntervalMs, ReplicationType replicationType)
```

## Common Methods

Table 5-24 Common methods of PGReplicationConnection

Return Value	Method	Description	throws
void	close()	Ends the logical replication and releases resources.	SQLException
void	forceUpdateStatus()	Forcibly sends the LSN status received, flushed, and applied last time to the backend.	SQLException
LogSequenceNumber	getLastAppliedLSN()	Obtains the LSN when the primary node replays logs last time.	-
LogSequenceNumber	getLastFlushedLSN()	Obtains the LSN flushed by the primary node last time, that is, the LSN pushed by the current logical decoding.	-
LogSequenceNumber	getLastReceiveLSN()	Obtains the last received LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots).	-
boolean	isClosed()	Determines whether the replication stream is disabled.	-
ByteBuffer	read()	Reads the next WAL record from the backend. If the data cannot be read, this method blocks the I/O read.	SQLException

Return Value	Method	Description	throws
ByteBuffer	readPending()	Reads the next WAL record from the backend. If the data cannot be read, this method does not block the I/O read.	SQLException
void	setAppliedLSN(LogSequenceNumber applied)	Sets the applied LSN.	-
void	setFlushedLSN(LogSequenceNumber flushed)	Updates the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots), which is sent to the backend at the next update to update the LSN (for LSN-based replication slots) or CSN (for CSN-based replication slots) on the server.	-

### 5.3.17.17 ChainedStreamBuilder

ChainedStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to build replication streams.

#### Inheritance Relationship of ChainedStreamBuilder

ChainedStreamBuilder is a logical replication API. Its implementation class is ReplicationStreamBuilder, which is in the **org.postgresql.replication.fluent** package. The declaration of the class is as follows:

```
public class ReplicationStreamBuilder implements ChainedStreamBuilder
```

#### Constructor Method

```
public ReplicationStreamBuilder(final BaseConnection connection)
```

## Common Methods

**Table 5-25** Common methods of ReplicationStreamBuilder

Return Value	Method	Description	throws
ChainedLogicalStreamBuilder	logical()	Creates a logical replication stream.	-
ChainedPhysicalStreamBuilder	physical()	Creates a physical replication stream.	-

### 5.3.17.18 ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API class provided by the GaussDB JDBC driver. It is used to specify common parameters for logical and physical replication.

### Inheritance Relationship of ChainedCommonStreamBuilder

ChainedCommonStreamBuilder is an API for logical replication. The implementation abstract class is AbstractCreateSlotBuilder. The inheritance class is LogicalCreateSlotBuilder which is in the **org.postgresql.replication.fluent.logical** package. The declaration of this class is as follows:

```
public class LogicalCreateSlotBuilder
    extends AbstractCreateSlotBuilder<ChainedLogicalCreateSlotBuilder>
    implements ChainedLogicalCreateSlotBuilder
```

### Constructor Method

```
public LogicalCreateSlotBuilder(BaseConnection connection)
```

## Common Methods

**Table 5-26** Common methods of LogicalCreateSlotBuilder

Return Value	Method	Description	throws
T	withSlotName(String slotName)	Specifies the name of a replication slot.	-
ChainedLogicalCreateSlotBuilder	withOutputPlugin(String outputPlugin)	Plug-in name. Currently, mppdb_decoding is supported.	-

Return Value	Method	Description	throws
void	make()	Creates a slot with the specified parameters in the database.	SQLException
ChainedLogicalCreateSlotBuilder	self()	Returns the implementation of ChainedLogicalCreateSlotBuilder.	-

### 5.3.17.19 PGobject

**Table 5-27** Common PGobject Methods

Return value	Method	Description	throws
Object[]	getStruct()	Obtains the subtype names of the composite type and sorts them according to the creation sequence.	-
String	getValue()	Obtains the string value of the composite type.	-
String[]	getArrayValue()	Obtains the array values of the composite type and sorts the values according to the sequence of columns of the composite type.	-
Object[]	getAttributes()	Obtains the array values of the composite type. If the columns are of the table or array type, PgArray is returned. If the columns are of the composite type, PGobject is returned. For other types, a string value is returned.	SQLException

### 5.3.18 Common JDBC Parameters

#### targetServerType

**Principle:** If the value is **master**, it attempts to connect to the IP addresses configured in the string in sequence until the primary node in the cluster is connected.

If the value is **slave**, it attempts to connect to the IP addresses configured in the string in sequence until the standby node in the cluster is connected. The query statement is **select local\_role, db\_state from pg\_stat\_get\_stream\_replications()**.

**Suggestion:** You are advised to set this parameter to **master** for services with write operations to ensure that the primary node can be properly connected after a primary/standby switchover. However, if the standby node is not completely promoted to primary during the primary/standby switchover, the connection cannot be established. As a result, service statements cannot be executed.

## hostRecheckSeconds

**Principle:** Specifies the period during which the DN list stored in JDBC remains trusted. Within this period, the DN list is directly read from the host addresses stored in JDBC. After that (or the primary node fails to be connected within the specified period), the node status in the DN list is updated and other IP addresses are connected.

**Suggestion:** The default value is **10s**. You are advised to adjust the value based on service requirements. This parameter is used together with the **targetServerType** parameter.

## allowReadOnly

**Principle:** Checks whether the transaction access mode can be modified through **setReadOnly**. If the value is **true**, the transaction access mode can be modified. If the value is **false**, the transaction access mode cannot be modified through this API. To modify the transaction access mode, execute the statements: SET SESSION CHARACTERISTICS AS TRANSACTION + READ ONLY / READ WRITE.

**Suggestion:** The default value **true** is recommended.

## fetchsize

**Principle:** After **fetchsize** is set to  $n$  and the database server executes a query, JDBC communicates with the server when the caller executes **resultset.next()**, fetches  $n$  pieces of data to the JDBC client, and returns the first piece of data to the caller. When the caller fetches the  $(n+1)$ th data record, the caller fetches data from the database server again.

**Function:** Prevents the database from transmitting all results to the client at a time, which exhausts the memory resources of the client.

**Suggestion:** You are advised to set this parameter based on the amount of data queried by services and the memory of the client. When setting **fetchsize**, disable automatic commit (set **autocommit** to **false**). Otherwise, the setting of **fetchsize** does not take effect.

## defaultRowFetchSize

**Function:** The default value of **fetchsize** is **0**. Setting **defaultRowFetchSize** will change the default value of **fetchsize**.

## batchMode

**Function:** This parameter specifies whether to connect the database in batch mode. The default value is **on**. After the function is enabled, the batch update performance is improved, and the return value is also batch updated. For example, if three data records are inserted in batches, the return value is **[3,0,0]** when the function is enabled, and the return value is **[1,1,1]** when the function is disabled.

**Suggestion:** If the service framework (such as hibernate) checks the return value during batch update, you can set this parameter to solve the problem.

## loginTimeout

**Function:** Controls the time for establishing a connection with the database. The time includes **connectTimeout** and **socketTimeout**. If the time elapsed exceeds the threshold, the connection exits. The calculation formula is as follows:

**loginTimeout** = **connectTimeout** x Number of nodes + Connection authentication time + Initialization statement execution time.

**Suggestion:** After this parameter is set, an asynchronous thread is started each time a connection is established. If there are a large number of connections, the pressure on the client may increase. If this parameter needs to be set, you are advised to set it to 3 x **connectTimeout** in centralized environment to prevent connection failures when the network is abnormal and the third IP address is the IP address of the primary node. The default value is **0**.

---

### NOTICE

This parameter sets the time for attempting to connect to all IP addresses in a list. If this parameter is set to a small value, the subsequent IP addresses in the list may fail to be connected. For example, if three IP addresses are set, **loginTimeout** is set to **5s**, and it takes 5s to connect to the first two IP addresses, the third IP address cannot be connected. In a centralized environment, the last IP address is the IP address of the primary node. As a result, the automatic search for the primary node may fail.

---

## cancelSignalTimeout

**Function:** Cancel messages may cause a block. This parameter controls **connectTimeout** and **socketTimeout** in a cancel command, in seconds. It is used to prevent timeout detection from being performed when the connection is canceled due to timeout.

**Suggestion:** The default value is **10s**. You are advised to adjust the value based on service requirements.

## connectTimeout

**Function:** Controls the socket timeout threshold during connection setup. In this case, this timeout threshold is the time when the JDBC connects to the database through the socket, not the time when the connection object is returned. If the time elapsed exceeds the threshold, JDBC searches for the next IP address.

**Suggestion:** This parameter determines the maximum timeout interval for establishing a TCP connection on each node. If a network fault occurs on a node, it attempts to connect to the node until the time specified by **connectTimeout** elapses, and then attempts to connect to the next node. Considering the network jitter and delay, you are advised to set this parameter to **3s**.

## socketTimeout

**Function:** Controls the timeout threshold of socket operations. If the time of executing service statements or reading data streams from the network exceeds the threshold (that is, when the statement execution time exceeds the specified threshold and no data is returned), the connection is interrupted.

**Suggestion:** This parameter specifies the maximum execution time of a single SQL statement. If the execution time of a single SQL statement exceeds the value of this parameter, an error is reported and the statement exits. You are advised to set this parameter based on service characteristics. If this parameter is not set, the default value **0** is used, indicating that the execution of SQL statement does not time out.

## socketTimeoutInConnecting

**Function:** Controls the socket operation timeout value during connection establishment. If the time of reading data streams from the network exceeds the threshold, it attempts to search for the next node for connection.

**Suggestion:** This parameter affects only the socket timeout value during the connection establishment. If this parameter is not set, the default value **5s** is used.

## autosave

**Function:** If the value is **always**, you can set a savepoint before each statement in a transaction. If an error is reported during statement execution in a transaction, the system returns to the latest savepoint. In this way, subsequent statements in the transaction can be properly executed and committed. The default value is **never**.

**Suggestion:** You are advised not to set this parameter to avoid severe performance deterioration.

## currentSchema

**Function:** Specifies the schema of the current connection. If this parameter is not set, the default schema is the username used for the connection.

**Suggestion:** You are advised to set this parameter to the schema where the service data is located. If the schema name contains special characters except letters, digits, and underscores (`_`), you are advised to enclose the schema name in quotation marks. Note that the schema name is case sensitive after quotation marks are added. If multiple schemas need to be configured, separate them with commas (`,`). Schemas containing special characters also need to be enclosed in quotation marks.

## prepareThreshold

**Function:** The default value is **5**. If an SQL statement is executed for multiple consecutive times in a session and the number of execution times specified by **prepareThreshold** is reached, JDBC does not send the PARSE command to the SQL statement but caches the SQL statement to improve the execution speed.

**Suggestion:** The default value is **5**. Adjust the value based on service requirements.

## preparedStatementCacheQueries

**Function:** Specifies the number of queries cached in each connection. The default value is **256**. If more than 256 different queries are used in the **prepareStatement()** call, the least recently used query cache will be discarded.

**Suggestion:** The default value is **256**. Adjust the value based on service requirements. This parameter is used together with **prepareThreshold**.

## blobMode

**Function:** Sets the **setBinaryStream** method to assign values to different types of data. The value **on** indicates that values are assigned to BLOB data. The value **off** indicates that values are assigned to bytea data. The default value is **on**. For example, you can assign values to parameters in the **preparestatement** and **callablestatement** objects.

**Suggestion:** The default value is **true**.

## setAutocommit

**Function:** If the value is **true**, a transaction is automatically started when each statement is executed. After the execution is complete, the transaction is automatically committed. That is, each statement is a transaction. If the value is **false**, a transaction is automatically started. However, you need to manually commit the transaction.

**Suggestion:** Adjust the value based on service characteristics. If autocommit needs to be disabled for performance or other purposes, the application must ensure that transactions can be committed. For example, explicitly commit translations after specifying service SQL statements. Particularly, ensure that all transactions are committed before the client exits.

## 5.3.19 Troubleshooting

### 5.3.19.1 Incorrect batchMode Settings

#### Symptom

Set the URL parameters **batchMode** to **on** and **rewriteBatchedInserts** to **true**, and use JDBC to insert data in batches. As a result, an exception is thrown, indicating that the number of bound parameters is inconsistent with the number of parameters required by the statement.

bind message supplies \* parameters, but prepared statement "" requires \*

**Example 1:**

```
// conn is a created connection object. The URL parameters for creating the connection contain
// &batchMode=on&rewriteBatchedInserts=true.
// Bind parameters in batches and then execute the statement. The number of bound parameters does not
// match the number of columns in the rewritten INSERT statement. As a result, an exception is thrown.
// java.sql.BatchUpdateException: bind message supplies 3 parameters, but prepared statement "" requires 6
PreparedStatement stmt = conn.prepareStatement("insert into test_tbl values (?, ?, ?)");

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.setInt(1, 1);
stmt.setString(2, "aaa");
stmt.setString(3, "bbbb");
stmt.addBatch();

stmt.executeBatch();
```

**Cause Analysis**

When **rewriteBatchedInserts** is set to **true**, the batch statement combines multiple SQL statements into one. As a result, the number of reserved parameter columns in the statement changes. If **batchMode** is set to **on**, parameters are bound based on the SQL statements before combination. As a result, the number of bound parameters is inconsistent with the number of parameters required by the statement.

**Solution**

If **rewriteBatchedInserts** is set to **true**, set **batchMode** to **off**.

**5.3.20 Mapping for JDBC Data Types**

The index relationships among data types, Java variable types, and JDBC types are as follows:

Compatibility Mode	Gauss Kernel Data Type	Java Variable Type	JDBC Type Index
A/B	oid	java.lang.Long	java.sql.Types.BIGINT
A/B	numeric	java.math.BigDecimal	java.sql.Types.NUMERIC
A/B	tinyint	java.lang.Integer	java.sql.Types.TINYINT
A/B	smallint	java.lang.Integer	java.sql.Types.SMALLINT
A/B	bigint	java.lang.Long	java.sql.Types.BIGINT
A/B	float4	java.lang.Float	java.sql.Types.REAL

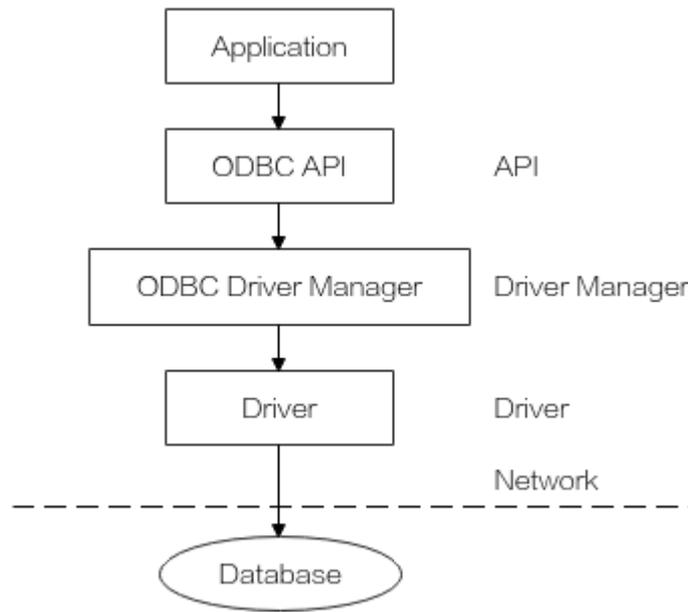

Compatibility Mode	Gauss Kernel Data Type	Java Variable Type	JDBC Type Index
A/B	float8	java.lang.Double	java.sql.Types.DOUBLE
A/B	char	java.lang.String	java.sql.Types.CHAR
A/B	character	java.lang.String	java.sql.Types.CHAR
A/B	bpchar	java.lang.String	java.sql.Types.CHAR
A/B	character varying	java.lang.String	java.sql.Types.VARCHAR
A/B	varchar	java.lang.String	java.sql.Types.VARCHAR
A/B	text	java.lang.String	java.sql.Types.VARCHAR
A/B	name	java.lang.String	java.sql.Types.VARCHAR
A/B	bytea	byte[]	java.sql.Types.BINARY
A/B	blob	java.sql.Blob	java.sql.Types.BLOB
A/B	clob	java.sql.Clob	java.sql.Types.CLOB
A/B	boolean	java.lang.Boolean	java.sql.Types.BIT
B	date	java.sql.Date	java.sql.Types.DATE
A/B	time	java.sql.Time	java.sql.Types.TIME
A/B	timetz	java.sql.Time	java.sql.Types.TIME
A/B	timestamp	java.sql.Timestamp	java.sql.Types.TIMESTAMP
A/B	smalldatetime	java.sql.Timestamp	java.sql.Types.TIMESTAMP
A/B	timestampz	java.sql.Timestamp	java.sql.Types.TIMESTAMP
A/B	refcursor	java.sql.ResultSet	java.sql.Types.REF_CURSOR java.sql.Types.OTHER -10

## 5.4 Development Based on ODBC

Open Database Connectivity (ODBC) is a Microsoft API for accessing databases based on the X/OPEN CLI. Applications interact with the database through the APIs provided by ODBC, which enhances their portability, scalability, and maintainability.

**Figure 5-2** shows the system structure of ODBC.

**Figure 5-2** ODBC system structure

GaussDB supports ODBC in the following environments.

**Table 5-28** OSs Supported by ODBC

OS	Platform
EulerOS 2.5	x86_64
EulerOS 2.9	Arm64
EulerOS 2.10	x86_64
EulerOS 2.10	Arm64
Windows 7	x86_32
Windows 7	x86_64
Windows Server 2008	x86_32
Windows Server 2008	x86_64
Kylin V10	x86_64
Kylin V10	Arm64
UnionTech V20	x86_64
UnionTech V20	Arm64

The ODBC Driver Manager running on Unix or Linux can be unixODBC or iODBC. unixODBC-2.3.7 is used as the component for connecting to the database.

Windows has a native ODBC Driver Manager. You can locate **Data Sources (ODBC)** by choosing **Control Panel > Administrative Tools**.

 NOTE

The current database ODBC driver is based on an open-source version and may be incompatible with data types tinyint, smalldatetime, nvarchar, and nvarchar2.

## 5.4.1 ODBC Packages, Dependent Libraries, and Header Files

### ODBC Package for the Linux OS

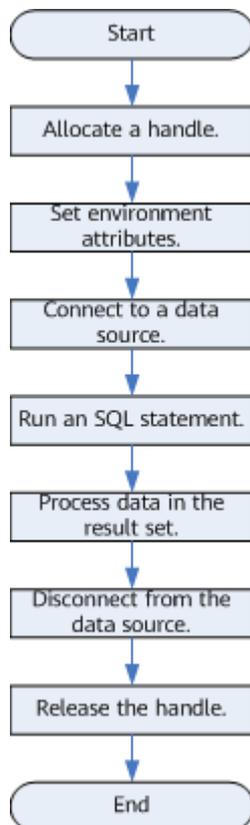

Obtain the package from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Odbc.tar.gz**. In the Linux OS, header files (including **sql.h** and **sqlext.h**) and the library (**libodbc.so**) are required in application development. These header files and library can be obtained from the unixODBC-2.3.7 installation package.

### ODBC Package for the Windows OS

Obtain the package from the release package **GaussDB-Kernel\_Database version number\_Windows\_Odbc\_X86.tar.gz** (32-bit) or **GaussDB-Kernel\_Database version number\_Windows\_Odbc\_X64.tar.gz** (64-bit). In the Windows OS, the required header files and library files are system-resident.

## 5.4.2 Development Process

Figure 5-3 ODBC-based application development process

## APIs Involved in the Development Process

**Table 5-29** API description

Function	API
Allocate a handle.	<b>SQLAllocHandle</b> is a generic function for allocating a handle. It can replace the following functions: <ul style="list-style-type: none"> <li>• <b>SQLAllocEnv</b>: allocates an environment handle.</li> <li>• <b>SQLAllocConnect</b>: allocates a connection handle.</li> <li>• <b>SQLAllocStmt</b>: allocates a statement handle.</li> </ul>
Set environment attributes.	<b>SQLSetEnvAttr</b>
Set connection attributes.	<b>SQLSetConnectAttr</b>
Set statement attributes.	<b>SQLSetStmtAttr</b>
Connect to a data source.	<b>SQLConnect</b>
Bind a buffer to a column in the result set.	<b>SQLBindCol</b>
Bind the parameter marker of an SQL statement to a buffer.	<b>SQLBindParameter</b>
Return the error message of the last operation.	<b>SQLGetDiagRec</b>
Prepare an SQL statement for execution.	<b>SQLPrepare</b>
Run a prepared SQL statement.	<b>SQLExecute</b>
Run an SQL statement directly.	<b>SQLExecDirect</b>
Fetch the next row (or rows) from the result set.	<b>SQLFetch</b>
Return data in a column of the result set.	<b>SQLGetData</b>
Get the column information from a result set.	<b>SQLColAttribute</b>
Disconnect from a data source.	<b>SQLDisconnect</b>

Function	API
Release a handle.	<p><b>SQLFreeHandle</b> is a generic function for releasing a handle. It can replace the following functions:</p> <ul style="list-style-type: none"><li>• <b>SQLFreeEnv</b>: releases an environment handle.</li><li>• <b>SQLFreeConnect</b>: releases a connection handle.</li><li>• <b>SQLFreeStmt</b>: releases a statement handle.</li></ul>

#### NOTE

- If an execution request (not in a transaction block) received in the database contains multiple statements, the request is packed into a transaction. If one of the statements fails, the entire request will be rolled back.
- ODBC connects applications to the database and delivers the SQL statements sent by an application to the database. It does not parse the SQL syntax. Therefore, when confidential information (such as a plaintext password) is written into the SQL statement sent by an application, the confidential information is exposed in the driver log.

### 5.4.3 Configuring a Data Source in the Linux OS

The ODBC DRIVER (**psqlodbcw.so**) provided by GaussDB can be used after it has been configured in a data source. To configure a data source, you must configure the **odbc.ini** and **odbcinst.ini** files on the server. The two files are generated during the unixODBC compilation and installation, and are saved in the **/usr/local/etc** directory by default.

#### Procedure

**Step 1** Obtain the source code package of unixODBC by clicking the following link:

Download address: <https://gitee.com/src-openeuler/unixODBC/blob/openEuler-22.03-LTS-SP1/unixODBC-2.3.7.tar.gz>.

After the download, verify the integrity based on the integrity verification algorithm provided by the community.

**Step 2** Install unixODBC. It does not matter if unixODBC of another version has been installed.

For example, install unixODBC-2.3.7.

```
tar zxvf unixODBC-2.3.7.tar.gz
cd unixODBC-2.3.7
```

```
./configure --enable-gui=no # To perform compilation on an Arm server, add the configure parameter --  
build=aarch64-unknown-linux-gnu.  
make  
# The installation may require root permissions.  
make install
```

 NOTE

- Currently, unixODBC-2.2.1 is not supported.
- By default, it is installed in the **/usr/local** directory. The data source file is generated in the **/usr/local/etc** directory, and the library file is generated in the **/usr/local/lib** directory.
- You can compile unixODBC with the **--enable-fastvalidate=yes** option to achieve higher performance. However, this option may cause an application that passes an invalid handle to the ODBC API to fail instead of returning an SQL\_INVALID\_HANDLE error.

**Step 3** Replace the GaussDB client driver.

Decompress **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Odbc.tar.gz**. After the decompression, the **lib** and **odbc** folders are generated. The **odbc** folder contains another **lib** folder. Copy all dynamic libraries in the **/lib** and **/odbc/lib** folders to the **/usr/local/lib** directory.

**Step 4** Configure a data source.

1. Configure the ODBC driver file.

Add the following content to the **/usr/local/etc/odbcinst.ini** file:

```
[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

For descriptions of the parameters in the **odbcinst.ini** file, see [Table 5-30](#).

**Table 5-30** odbcinst.ini configuration parameters

Parameter	Description	Example
[DriverName]	Driver name, corresponding to Driver in DSN.	[DRIVER_N]
Driver64	Path of the dynamic driver library.	Driver64=/usr/local/lib/psqlodbcw.so
setup	Driver installation path, which is the same as the dynamic library path in Driver64.	setup=/usr/local/lib/psqlodbcw.so

2. Configure the data source file.

Add the following content to the **/usr/local/etc/odbc.ini** file:

```
[MPPODBC]
Driver=GaussMPP
Servername=127.0.0.1 (database server IP address)
Database=postgres (database name)
Username=omm (database username)
Password= (database user password)
Port=8000 (database listening port)
Sslmode = allow
```

For descriptions of the parameters in the **odbc.ini** file, see [Table 5-31](#).

**Table 5-31** odbc.ini configuration parameters

Parameter	Description	Example
[DSN]	Data source name.	[MPPODBC]
Driver	Driver name, corresponding to DriverName in <b>odbcinst.ini</b> .	Driver = DRIVER_N
Servename	Server IP address. Multiple IP addresses can be configured.	Servename=127.0.0.1
Database	Name of the database to connect.	Database = postgres
Username	Database username.	Username = omm

Parameter	Description	Example
Password	<p>Database user password.</p> <p><b>NOTE</b> After a user establishes a connection, the ODBC driver automatically clears their password stored in memory.</p> <p>However, if this parameter is configured, unixODBC will cache data source files, which may cause the password to be stored in the memory for a long time.</p> <p>When you connect to an application, you are advised to send your password through an API instead of writing it in a data source configuration file. After the connection has been established, immediately clear the memory segment where your password is stored.</p> <p><b>CAUTION</b> The password in the configuration file must comply with the following HTTP rules:</p> <ol style="list-style-type: none"> <li>1. Characters must comply with the URL encoding specifications. For example, the exclamation mark (!) must be written as %21, and the percent sign (%) must be written as %25. Therefore, pay attention to the characters.</li> <li>2. A plus sign (+) will be replaced by a space.</li> </ol>	Password=*****
Port	Port number of the server.	Port = 8000
Sslmode	Specifies whether to enable SSL.	Sslmode = allow

Parameter	Description	Example
Debug	If this parameter is set to <b>1</b> , the <b>mylog</b> file of the PostgreSQL ODBC driver will be printed. The directory generated for storing logs is <b>/tmp/</b> . If this parameter is set to <b>0</b> , no directory is generated.	Debug = 1
UseServerSidePrepare	Specifies whether to enable the extended query protocol for the database.  The value can be <b>0</b> or <b>1</b> . The default value is <b>1</b> , indicating that the extended query protocol is enabled.	UseServerSidePrepare = 1
UseBatchProtocol	Specifies whether to enable the batch query protocol. If it is enabled, DML performance can be improved. The value can be <b>0</b> or <b>1</b> (default).  <ul style="list-style-type: none"> <li>- If this parameter is set to <b>0</b>, the batch query protocol is disabled (mainly for communication with earlier database versions).</li> <li>- If this parameter is set to <b>1</b> and <b>support_batch_bind</b> is set to <b>on</b>, the batch query protocol is enabled.</li> </ul>	UseBatchProtocol = 1
ForExtensionConnector	This parameter specifies whether the savepoint is sent. The default value is <b>1</b> . If the value is <b>0</b> , the savepoint is sent. If the value is <b>1</b> , the savepoint is not sent.	ForExtensionConnector = 1

Parameter	Description	Example
ConnectionExtraInfo	<p>Specifies whether to display the driver deployment path and process owner in the GUC parameter <b>connection_info</b>.</p> <p><b>NOTE</b> The default value is <b>0</b>. If this parameter is set to <b>1</b>, the ODBC driver reports the driver deployment path and process owner to the database and displays the information in the GUC parameter <b>connection_info</b>. In this case, you can query the information from <a href="#">PG_STAT_ACTIVITY</a>.</p>	ConnectionExtraInfo = 1
BoolAsChar	If this parameter is set to <b>Yes</b> , the Boolean value is mapped to the SQL_CHAR type. If this parameter is not set, the value is mapped to the SQL_BIT type.	BoolsAsChar = Yes
RowVersioning	When an attempt is made to update a row of data, setting this parameter to <b>Yes</b> allows the application to detect whether the data has been modified by other users.	RowVersioning = Yes
ShowSystemTables	By default, the driver regards the system table as a common SQL table.	ShowSystemTables = Yes

Parameter	Description	Example
MaxCacheQueries	<p>Controls the number of precompiled statements cached for each connection. If this parameter is set to <b>0</b>, the precompiled statement cache pool is disabled on the client. If this parameter is set to a value greater than 4096, the value <b>4096</b> is used. If the number of executed statements exceeds the upper limit specified by <b>MaxCacheQueries</b>, the least recently used statements are eliminated. The default value is <b>0</b>.</p>	MaxCacheQueries=128
MaxCacheSizeMiB	<p>Controls the total size of precompiled statements cached for each connection. This parameter takes effect when the value of <b>MaxCacheQueries</b> is greater than 0. If the total size of cached statements is greater than the value of <b>MaxCacheSizeMiB</b>, the least recently used statements are eliminated. If this parameter is set to a value greater than 4096, the value <b>4096</b> is used. The unit is MB. The default value is <b>1</b>.</p>	MaxCacheSizeMiB=10

Parameter	Description	Example
TcpUserTimeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the <b>TCP_USER_TIMEOUT</b> socket option. <b>0</b> indicates that the default value is used. Ignore this parameter for Unix-domain connections. The unit is millisecond. The default value is <b>0</b> .	TcpUserTimeout=5000

[Table 3 Sslmode options](#) describes the valid values of **Sslmode**.

**Table 5-32** Sslmode options

Sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified.

Sslmode	Whether SSL Encryption Is Enabled	Description
verify-full	Yes	SSL connection is required. In addition to the check scope specified by <b>verify-ca</b> , the system checks whether the name of the host where the database resides is the same as that in the certificate. GaussDB does not support this mode.

**Step 5** (Optional) Contact the administrator to generate an SSL certificate. This step and step **Step 6** are required only when the server and client are connected in SSL mode. Skip the two steps if the non-SSL connection mode is used.

**Step 6** (Optional) Contact the administrator to replace the SSL certificate.

**Step 7** Enable the SSL mode. For details, contact the administrator.

**Step 8** Configure the database server. For details, contact the administrator.

**Step 9** Configure the environment variables on the client.

```
vim ~/.bashrc
```

Add the following information to the configuration file:

```
export LD_LIBRARY_PATH=/usr/local/lib:$LD_LIBRARY_PATH
export ODBC_SYSINI=/usr/local/etc
export ODBCINI=/usr/local/etc/odbc.ini
```

**Step 10** Make the setting take effect.

```
source ~/.bashrc
```

----End

## Verifying the Data Source Configuration

After the installation, the generated binary file is stored in the **/usr/bin** directory. You can run the **isql -v MPP\_ODBC** command (*MPP\_ODBC* is the data source name).

- If the following information is displayed, the configuration is correct and the connection succeeds:

```
+-----+
| Connected!          |
|                    |
| sql-statement      |
| help [tablename]   |
| quit               |
|                    |
+-----+
```

- If error information is displayed, the configuration is incorrect. Check the configuration.

## FAQs

- [UnixODBC][Driver Manager]Can't open lib 'xxx/xxx/psqlodbcw.so' : file not found.

Possible causes:

- The path configured in the **odbcinst.ini** file is incorrect.  
Run **ls** to check the path in the error information, ensuring that the **psqlodbcw.so** file exists and you have execution permissions on it.
- The dependent library of **psqlodbcw.so** does not exist or is not in system environment variables.  
Run the **ldd** command to check the path in the error information. If the unixODBC library such as **libodbc.so.1** is missing, reconfigure unixODBC according to the procedure, ensure that the **lib** directory in the installation path is added to **LD\_LIBRARY\_PATH**. If other libraries do not exist, add the **lib** directory under the ODBC driver package to **LD\_LIBRARY\_PATH**.
- [UnixODBC]connect to server failed: no such file or directory  
Possible causes:
  - An incorrect or unreachable database IP address or port was configured.  
Check the **Servername** and **Port** configuration items in data sources.
  - Server monitoring is improper.  
If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.
  - Firewall and network gatekeeper settings are improper.  
Check firewall settings, and ensure that the database communication port is trusted.  
Check to ensure network gatekeeper settings are proper (if any).
- [unixODBC]The password-stored method is not supported.  
Possible causes:  
The **sslmode** configuration item is not configured in the data sources.  
Solution:  
Set the configuration item to **allow** or a higher level. For details, see [Table 5-32](#).
- Server common name "xxxx" does not match host name "xxxxx"  
Possible causes:  
When **verify-full** is used for SSL encryption, the driver checks whether the host name in certificates is the same as the actual one.  
Solution:  
To solve this problem, use **verify-ca** to stop checking host names, or generate a set of CA certificates containing the actual host names.
- Driver's SQLAllocHandle on SQL\_HANDLE\_DBC failed  
Possible causes:  
The executable file (such as the **isql** tool of unixODBC) and the database driver (**psqlodbcw.so**) depend on different library versions of ODBC, such as **libodbc.so.1** and **libodbc.so.2**. You can verify this problem by using the following method:

```
ldd `which isql` | grep odbc  
ldd psqlodbcw.so | grep odbc
```

If the suffix digits of the outputs **libodbc.so** are different or indicate different physical disk files, this problem exists. Both **isql** and **psqlodbcw.so** require

**libodbc.so** to be loaded. If they load different physical files, two sets of function lists with the same name are generated in a visible domain (the **libodbc.so.\*** function export lists of unixODBC are the same). This results in conflicts and the database driver cannot be loaded.

Solution:

Uninstall the unnecessary unixODBC, such as **libodbc.so.2**, and create a soft link with the same name and the **.so.2** suffix for the remaining **libodbc.so.1** library.

- FATAL: Forbid remote connection with trust method!

For security purposes, the primary database node forbids access from other nodes in the database without authentication.

To access the primary database node from inside the database, deploy the ODBC program on the host where the primary database node is located and set the server address to **127.0.0.1**. It is recommended that the service system be deployed outside the database. Otherwise, the database performance may be affected.

- [unixODBC][Driver Manager]Invalid attribute value

The unixODBC version may not be the recommended one. You are advised to run the **odbcinst --version** command to check the unixODBC version in the environment.

- authentication method 10 not supported.

If this error occurs on an open-source client, the cause may be:

The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

#### NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In **pg\_hba.conf** of the target primary database node, the authentication mode is set to **gss** for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to **sha256** and try again. For details, see [Step 8](#).

- isql: error while loading shared libraries:xxx

The dynamic library does not exist in the environment. You need to install the corresponding library.

## 5.4.4 Configuring a Data Source in the Windows OS

Configure an ODBC data source using the ODBC data source manager preinstalled in the Windows OS.

### Procedure

**Step 1** Replace the GaussDB client driver.

Decompress **GaussDB-Kernel\_Database version number\_Windows\_Odbc.tar.gz** and click **psqlodbc.exe** (32-bit) to install the driver. Decompress the **GaussDB-Kernel\_Database version number\_Windows\_Odbc\_X64.tar.gz** (64-bit) driver package or **GaussDB-Kernel\_Database version number\_Windows\_Odbc\_X64.tar.gz** (32-bit) driver package, and click **gsqlodbc.exe** to install the driver.

**Step 2** Open the driver manager.

When configuring the data source, use the ODBC driver manager corresponding to the ODBC version. If the 64-bit ODBC driver is used, the 64-bit ODBC driver manager must be used. Assume that the OS is installed on drive C (if the OS is installed on another drive, change the path accordingly):

- If you want to use 32-bit ODBC driver manager in a 64-bit OS, open **C:\Windows\SysWOW64\odbcad32.exe**. Do not choose **Control Panel > Administrative Tools > Data Sources (ODBC)**.

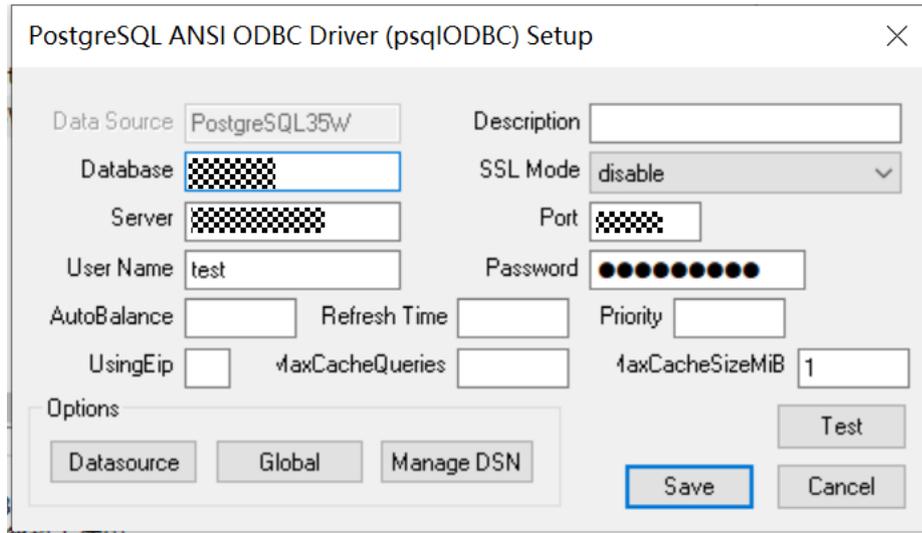

#### NOTE

WoW64 is short for Windows 32-bit on Windows 64-bit. **C:\Windows\SysWOW64\** stores the 32-bit environment on a 64-bit system. **C:\Windows\System32\** stores the environment consistent with the current OS. For technical details, see Windows technical documents.

- For a 32-bit OS, open **C:\Windows\System32\odbcad32.exe** or choose **Computer > Control Panel > Administrative Tools > Data Sources (ODBC)** to open Driver Manager.
- For a 64-bit OS, choose **Control Panel > Administrative Tools > Data Sources (ODBC)** to enable driver management.

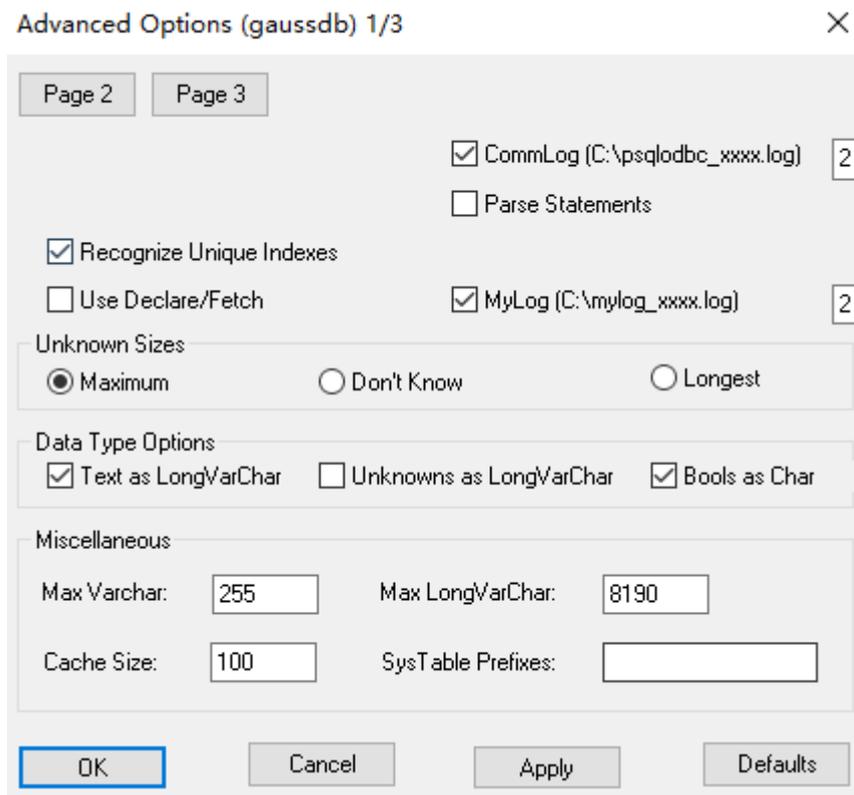

**Step 3** Configure a data source.

On the **User DSN** tab, click **Add** and choose **PostgreSQL Unicode** for setup.

For details about the parameters, see [Configuring a Data Source in the Linux OS](#).

You can click **Datasource** to configure whether to print logs.

**NOTICE**

The entered username and password will be recorded in the Windows registry and you do not need to enter them again when connecting to the database next time. For security purposes, you are advised to delete sensitive information before clicking **Save** and enter the required username and password again when using ODBC APIs to connect to the database.

**Step 4** Enable the SSL mode.

Change the value of **SSL Mode** in Step 2 to **require**.

**Table 5-33** sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required and whether the database has a trusted certificate will be verified. Currently, Windows ODBC does not support the certificate-based authentication.
verify-full	Yes	SSL connection is required. In addition to the check scope specified by <b>verify-ca</b> , the system checks whether the name of the host where the database resides is the same as that in the certificate. Currently, Windows ODBC does not support the certificate-based authentication.

**Step 5** Configure a GaussDB server. For details, contact the administrator.

**Step 6** Restart the database instance.

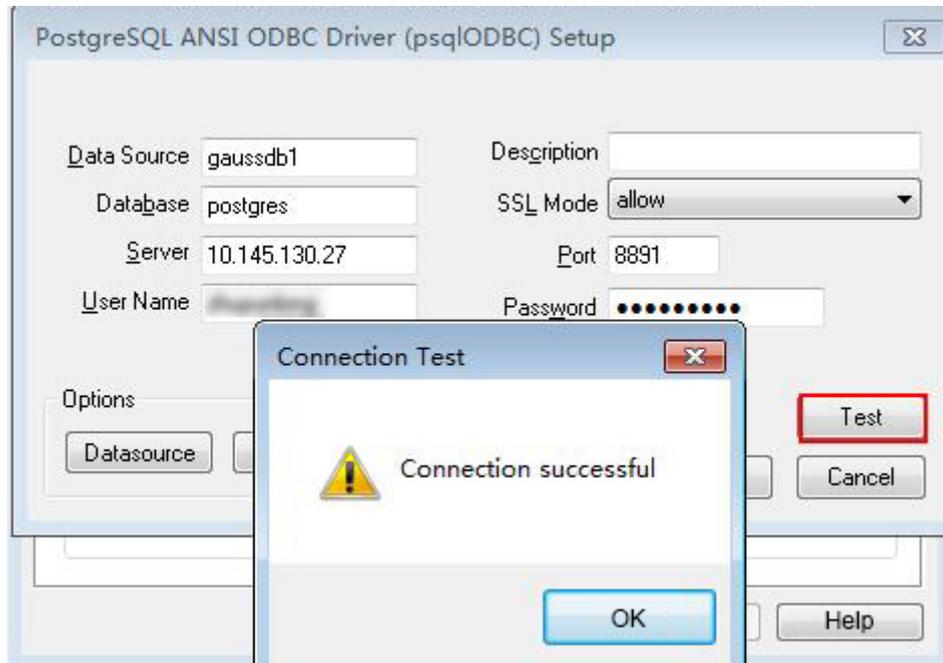

```
gs_om -t stop
gs_om -t start
```

----End

## Verifying the Data Source Configuration

Click **Test**.

- If the following information is displayed, the configuration is correct and the connection succeeds.

- If error information is displayed, the configuration is incorrect. Check the configuration.

## FAQs

- connect to server failed: no such file or directory  
Possible causes:
  - An incorrect or unreachable database IP address or port was configured.  
Check the **Servername** and **Port** configuration items in data sources.
  - Server monitoring is improper.  
If **Servername** and **Port** are correctly configured, ensure the proper network adapter and port are monitored by following the database server configurations in the procedure in this section.
  - Firewall and network gatekeeper settings are improper.  
Check firewall settings, and ensure that the database communication port is trusted.  
Check to ensure network gatekeeper settings are proper (if any).
- The password-stored method is not supported.  
Possible causes:
  - sslmode** is not configured for the data source. Set this configuration item to **allow** or a higher level to enable SSL connections. For details on **sslmode**, see [Table 5-33](#).
- authentication method 10 not supported.

If this error occurs on an open-source client, the cause may be:

The database stores only the SHA-256 hash of the password, but the open-source client supports only MD5 hashes.

#### NOTE

- The database stores the hashes of user passwords instead of actual passwords.
- If a password is updated or a user is created, both types of hashes will be stored, compatible with open-source authentication protocols.
- An MD5 hash can only be generated using the original password, but the password cannot be obtained by reversing its SHA-256 hash. Passwords in the source version will only have SHA-256 hashes and not support MD5 authentication.
- The MD5 encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.

To solve this problem, you can update the user password (see [ALTER USER](#)) or create a user (see [CREATE USER](#)) having the same permissions as the faulty user.

- unsupported frontend protocol 3.51: server supports 1.0 to 3.0

The database version is too early or the database is an open-source database. Use the driver of the required version to connect to the database.

- FATAL: GSS authentication method is not allowed because XXXX user password is not disabled.

In `pg_hba.conf` of the target DN, the authentication mode is set to `gss` for authenticating the IP address of the current client. However, this authentication algorithm cannot authenticate clients. Change the authentication algorithm to `sha256` and try again. For details, see [Step 5](#).

## 5.4.5 Example: Common Functions and Batch Binding

### Examples

- Example of the command for compiling ODBC application code in Windows:  

```
gcc odbctest.c -o odbctest -lodb32
```

Run the following command:

```
./odbctest.exe
```
- Example of the command for compiling ODBC application code in Linux:  

```
gcc odbctest.c -o odbctest -lodb
```

Run the following command:

```
./odbctest
```
- If `sql.h` or API cannot be found during compilation, manually connect to the header file and dynamic library of unixODBC.  

```
gcc -I /home/omm/unixodbc/include -L /home/omm/unixodbc/lib odbctest.c -o odbctest -lodb
```

### Code for Common Functions

```
// The example shows how to obtain data from GaussDB through ODBC.
// DBtest.c (compile with: libodbc.so)
#ifdef WIN32
#include <windows.h>
#else
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
```

```
SQLHENV    V_OD_Env;    // Handle ODBC environment
SQLHSTMT   V_OD_hstmt; // Handle statement
SQLHDBC    V_OD_hdbc;  // Handle connection
char       typename[100];
SQLINTEGER value = 100;
SQLINTEGER V_OD_erg,V_OD_buffer,V_OD_err,V_OD_id;
int main(int argc,char *argv[])
{
    // 1. Allocate an environment handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_ENV,SQL_NULL_HANDLE,&V_OD_Env);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        printf("Error AllocHandle\n");
        exit(0);
    }
    // 2. Set environment attributes (version information).
    SQLSetEnvAttr(V_OD_Env, SQL_ATTR_ODBC_VERSION, (void*)SQL_OV_ODBC3, 0);
    // 3. Allocate a connection handle.
    V_OD_erg = SQLAllocHandle(SQL_HANDLE_DBC, V_OD_Env, &V_OD_hdbc);
    if ((V_OD_erg != SQL_SUCCESS) && (V_OD_erg != SQL_SUCCESS_WITH_INFO))
    {
        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    // In this example, the username and password are stored in environment variables. Before running this
    // example, set environment variables EXAMPLE_USERNAME_ENV and EXAMPLE_PASSWORD_ENV in the local
    // environment (set the environment variable names based on the actual situation).
    char *userName;
    userName = getenv("EXAMPLE_USERNAME_ENV");
    char *password;
    password = getenv("EXAMPLE_PASSWORD_ENV");
    // 4. Set connection attributes.
    SQLSetConnectAttr(V_OD_hdbc, SQL_ATTR_AUTOCOMMIT, (SQLPOINTER *)SQL_AUTOCOMMIT_ON,
0);
    // 5. Connect to the data source. userName and password indicate the username and password for
    // connecting to the database, respectively.
    // If the username and password have been set in the odbc.ini file, you can retain "". However, you are
    // advised not to do so because the username and password will be disclosed if the permission for odbc.ini is
    // abused.
    V_OD_erg = SQLConnect(V_OD_hdbc, (SQLCHAR*) "gaussdb", SQL_NTS,

        SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
        exit(0);
    }
    printf("Connected !\n");
    // 6. Set statement attributes.
    SQLSetStmtAttr(V_OD_hstmt,SQL_ATTR_QUERY_TIMEOUT,(SQLPOINTER *)3,0);
    // 7. Allocate a statement handle.
    SQLAllocHandle(SQL_HANDLE_STMT, V_OD_hdbc, &V_OD_hstmt);
    // 8. Run SQL statements.
    SQLExecDirect(V_OD_hstmt,"drop table IF EXISTS customer_t1",SQL_NTS);
    SQLExecDirect(V_OD_hstmt,"CREATE TABLE customer_t1(c_customer_sk INTEGER, c_customer_name
VARCHAR(32));",SQL_NTS);
    SQLExecDirect(V_OD_hstmt,"insert into customer_t1 values(25,'li')",SQL_NTS);
    // 9. Prepare for execution.
    SQLPrepare(V_OD_hstmt,"insert into customer_t1 values(?)",SQL_NTS);
    // 10. Bind parameters.
    SQLBindParameter(V_OD_hstmt,1,SQL_PARAM_INPUT,SQL_C_SLONG,SQL_INTEGER,0,0,
        &value,0,NULL);
    // 11. Run prepared statements.
    SQLExecute(V_OD_hstmt);
    SQLExecDirect(V_OD_hstmt,"select c_customer_sk from customer_t1",SQL_NTS);
    // 12. Obtain attributes of a specific column in the result set.
    SQLColAttribute(V_OD_hstmt,1,SQL_DESC_TYPE,typename,100,NULL,NULL);
    printf("SQLColAttribute %s\n",typename);
    // 13. Bind the result set.
```

```
SQLBindCol(V_OD_hstmt,1,SQL_C_SLONG, (SQLPOINTER)&V_OD_buffer,150,
           (SQLLEN *)&V_OD_err);
// 14. Obtain data in the result set by executing SQLFetch.
V_OD_erg=SQLFetch(V_OD_hstmt);
// 15. Obtain and return data by executing SQLGetData.
while(V_OD_erg != SQL_NO_DATA)
{
    SQLGetData(V_OD_hstmt,1,SQL_C_SLONG,(SQLPOINTER)&V_OD_id,0,NULL);
    printf("SQLGetData ----ID = %d\n",V_OD_id);
    V_OD_erg=SQLFetch(V_OD_hstmt);
};
printf("Done !\n");
// 16. Disconnect data source connections and release handles.
SQLFreeHandle(SQL_HANDLE_STMT,V_OD_hstmt);
SQLDisconnect(V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_DBC,V_OD_hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, V_OD_Env);
return(0);
}
```

## Code for Batch Processing

```
/******
* Enable UseBatchProtocol in the data source and set the database parameter support_batch_bind
* to on.
* The CHECK_ERROR command is used to check and print error information.
* This example is used to interactively obtain the DSN, data volume to be processed, and volume of ignored
data from users, and insert required data into the test_odbc_batch_insert table.

```

## 5.4.6 Typical Application Scenarios and Configurations

### Log Diagnosis

ODBC logs are classified into unixODBC driver manager logs and psqLODBC driver logs. The former is used to trace whether the application API is successfully executed, and the latter is used to locate problems based on DFX logs generated during underlying implementation.

The unixODBC log needs to be configured in the **odbcinst.ini** file:

```
[ODBC]
Trace=Yes
TraceFile=/path/to/odbctrace.log

[GaussMPP]
Driver64=/usr/local/lib/psqlodbcw.so
setup=/usr/local/lib/psqlodbcw.so
```

For gsqlODBC logs, you only need to add the following content to **odbc.ini**:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
Debug=1 (Enable the debug log function of the driver.)
```

#### NOTE

The unixODBC logs are generated in the path configured by **TraceFile**. The psqLODBC generates the **mylog\_XXX.log** file in the **/tmp/** directory.

## High Performance

If a large amount of data needs to be inserted, you are advised to perform the following operations:

- You need to set **UseBatchProtocol** to **1** in the **odbc.ini** file and **support\_batch\_bind** to **on** in the database.
- The ODBC program binding type must be the same as that in the database.
- The character set of the client is the same as that of the database.
- The transaction is committed manually.

**odbc.ini** configuration file:

```
[gaussdb]
Driver=GaussMPP
Servername=10.10.0.13 (database server IP address)
...
UseBatchProtocol=1 (enabled by default)
ConnSettings=set client_encoding=UTF8 (Set the character code on the client to be the same as that on the server.)
```

Binding type case:

```
#ifndef WIN32
#include <windows.h>
#endif
#include <stdio.h>
#include <stdlib.h>
#include <sql.h>
#include <sqlext.h>
#include <string.h>
#include <sys/time.h>

#define MESSAGE_BUFFER_LEN 128
SQLHANDLE h_env = NULL;
SQLHANDLE h_conn = NULL;
SQLHANDLE h_stmt = NULL;
void print_error()
{
    SQLCHAR Sqlstate[SQL_SQLSTATE_SIZE+1];
    SQLINTEGER NativeError;
    SQLCHAR MessageText[MESSAGE_BUFFER_LEN];
    SQLSMALLINT TextLength;

}
```

#### NOTE

In the preceding example, the **number** column is defined. When the SQLBindParameter API is called, the performance of binding SQL\_NUMERIC is higher than that of SQL\_LONG. If char is used, the data type needs to be converted when data is inserted to the database server, causing a performance bottleneck.

## Automatic Primary/Standby Switchover

### Example Scenario

If a database instance is configured with one primary DN and multiple standby DNs, write the IP addresses of all DNs into the configuration file. ODBC automatically searches for the primary DN and establishes a connection with it. When a primary/standby switchover occurs, ODBC can also connect to the new primary DN.

## ODBC Constraints

- ODBC does not support read on the standby node.
- ODBC does not support user-defined types and does not support user-defined parameters in stored procedures.

## 5.4.7 ODBC Interface Reference

The ODBC interface is a set of API functions provided to users. This chapter describes its common interfaces. For details on other interfaces, see "ODBC Programmer's Reference" at MSDN ([https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms714177(v=vs.85).aspx)).

### 5.4.7.1 SQLAllocEnv

In ODBC 3.x, SQLAllocEnv (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

### 5.4.7.2 SQLAllocConnect

In ODBC 3.x, SQLAllocConnect (an ODBC 2.x function) was deprecated and replaced by SQLAllocHandle. For details, see [SQLAllocHandle](#).

### 5.4.7.3 SQLAllocHandle

#### Description

Allocates environment, connection, statement, or descriptor handles. This function replaces the deprecated ODBC 2.x functions SQLAllocEnv, SQLAllocConnect, and SQLAllocStmt.

#### Prototype

```
SQLRETURN SQLAllocHandle(SQLSMALLINT HandleType,
                        SQLHANDLE InputHandle,
                        SQLHANDLE *OutputHandlePtr);
```

#### Parameters

Table 5-34 SQLAllocHandle parameters

Keyword	Description
HandleType	Type of handle to be allocated by SQLAllocHandle. The value must be one of the following: <ul style="list-style-type: none"> <li>• <b>SQL_HANDLE_ENV</b> (environment handle)</li> <li>• <b>SQL_HANDLE_DBC</b> (connection handle)</li> <li>• <b>SQL_HANDLE_STMT</b> (statement handle)</li> <li>• <b>SQL_HANDLE_DESC</b> (descriptor handle)</li> </ul> The handle allocation sequence is: environment handle > connection handle > statement handle. A later allocated handle depends on a previously allocated handle.
InputHandle	Existing handle to use as a context for the new handle being allocated. <ul style="list-style-type: none"> <li>• If <b>HandleType</b> is set to <b>SQL_HANDLE_ENV</b>, this parameter is set to <b>SQL_NULL_HANDLE</b>.</li> <li>• If <b>HandleType</b> is set to <b>SQL_HANDLE_DBC</b>, this parameter value must be an environment handle.</li> <li>• If <b>HandleType</b> is set to <b>SQL_HANDLE_STMT</b> or <b>SQL_HANDLE_DESC</b>, this parameter value must be a connection handle.</li> </ul>
OutputHandlePtr	<b>Output parameter:</b> Pointer to a buffer that stores the returned handle in the newly allocated data structure.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.

- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLAllocHandle` returns **SQL\_ERROR** when it is used to allocate a non-environment handle, it sets **OutputHandlePtr** to **SQL\_NULL\_HDBC**, **SQL\_NULL\_HSTMT**, or **SQL\_NULL\_HDESC**. The application can then call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to the value of **IntputHandle**, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.4 SQLAllocStmt

In ODBC 3.x, `SQLAllocStmt` was deprecated and replaced by `SQLAllocHandle`. For details, see [SQLAllocHandle](#).

### 5.4.7.5 SQLBindCol

## Description

Binds application data buffers to columns in a result set.

## Prototype

```
SQLRETURN SQLBindCol(SQLHSTMT StatementHandle,
                    SQLUSMALLINT ColumnNumber,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

## Parameters

**Table 5-35** SQLBindCol parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Number of the column to be bound. The column number starts with 0 and increases in ascending order. Column 0 is the bookmark column. If no bookmark column is set, column numbers start with 1.
TargetType	C data type in the buffer.

Keyword	Description
TargetValuePtr	<b>Output parameter:</b> pointer to the buffer bound with the column. The SQLFetch function returns data in the buffer. If this parameter is a null pointer, <b>StrLen_or_IndPtr</b> is a valid value.
BufferLength	Length of the buffer pointed to by <b>TargetValuePtr</b> , in bytes.
StrLen_or_IndPtr	<b>Output parameter:</b> pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If SQLBindCol returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.6 SQLBindParameter

## Description

Binds parameter markers in an SQL statement to a buffer.

## Prototype

```
SQLRETURN SQLBindParameter(SQLHSTMT StatementHandle,
    SQLSMALLINT ParameterNumber,
    SQLSMALLINT InputOutputType,
    SQLSMALLINT ValuetType,
    SQLSMALLINT ParameterType,
    SQLULEN ColumnSize,
    SQLSMALLINT DecimalDigits,
    SQLPOINTER ParameterValuePtr,
    SQLLEN BufferLength,
    SQLLEN *StrLen_or_IndPtr);
```

## Parameters

**Table 5-36** SQLBindParameter

Keyword	Description
StatementHandle	Statement handle.
ParameterNumber	Parameter marker number, starting with 1 and increasing in ascending order.
InputOutputType	Input/output type of the parameter.
ValueType	C data type of the parameter.
ParameterType	SQL data type of the parameter.
ColumnSize	Size of the column or expression of the corresponding parameter marker.
DecimalDigits	Decimal digit of the column or the expression of the corresponding parameter marker.
ParameterValuePtr	Pointer to the storage parameter buffer.
BufferLength	Length of the <b>ParameterValuePtr</b> buffer in bytes.
StrLen_or_IndPtr	Pointer to the length or indicator of the buffer. If the value is null, no length or indicator is used.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLBindParameter` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.7 SQLColAttribute

#### Description

Returns the descriptor information about a column in the result set.

#### Prototype

```
SQLRETURN SQLColAttribute(SQLHSTMT StatementHandle,
    SQLUSMALLINT ColumnNumber,
    SQLUSMALLINT FieldIdentifier,
    SQLPOINTER CharacterAttributePtr,
    SQLSMALLINT BufferLength,
    SQLSMALLINT *StringLengthPtr,
    SQLLEN *NumericAttributePtr);
```

#### Parameters

**Table 5-37** SQLColAttribute parameters

Keyword	Description
StatementHandle	Statement handle.
ColumnNumber	Column number of the field to be queried, starting with 1 and increasing in ascending order.
FieldIdentifier	Field identifier of <b>ColumnNumber</b> in IRD.
CharacterAttributePtr	<b>Output parameter:</b> pointer to the buffer that returns the <b>FieldIdentifier</b> value.
BufferLength	<ul style="list-style-type: none"> <li>Indicates the length of the buffer if <b>FieldIdentifier</b> is an ODBC-defined field and <b>CharacterAttributePtr</b> points to a string or a binary buffer.</li> <li>Ignore this parameter if <b>FieldIdentifier</b> is an ODBC-defined field and <b>CharacterAttributePtr</b> points to an integer.</li> </ul>
StringLengthPtr	<b>Output parameter:</b> pointer to a buffer in which the total number of valid bytes (for string data) is stored in <b>*CharacterAttributePtr</b> . Ignore the value of <b>BufferLength</b> if the data is not a string.
NumericAttributePtr	<b>Output parameter:</b> pointer to an integer buffer in which the value of <b>FieldIdentifier</b> in the <b>ColumnNumber</b> row of the IRD is returned.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.

- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLColAttribute` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.8 SQLConnect

## Description

Establishes a connection between a driver and a data source. After the connection is established, the connection handle can be used to access all information about the data source, including its application operating status, transaction processing status, and error information.

## Prototype

```
SQLRETURN SQLConnect(SQLHDBC ConnectionHandle,
    SQLCHAR *ServerName,
    SQLSMALLINT NameLength1,
    SQLCHAR *UserName,
    SQLSMALLINT NameLength2,
    SQLCHAR *Authentication,
    SQLSMALLINT NameLength3);
```

## Parameters

**Table 5-38** SQLConnect parameters

Keyword	Description
ConnectionHandle	Connection handle, obtained from <code>SQLAllocHandle</code> .
ServerName	Name of the data source to connect.
NameLength1	Length of <b>ServerName</b> .
UserName	Username of the database in the data source.
NameLength2	Length of <b>UserName</b> .
Authentication	User password of the database in the data source.

Keyword	Description
NameLength3	Length of <b>Authentication</b> .

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If SQLConnect returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.9 SQLDisconnect

#### Description

Closes the connection associated with a database connection handle.

#### Prototype

```
SQLRETURN SQLDisconnect(SQLHDBC ConnectionHandle);
```

#### Parameters

**Table 5-39** SQLDisconnect parameter

Keyword	Description
ConnectionHandle	Connection handle, obtained from SQLAllocHandle.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.

- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLDisconnect` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.10 SQLExecDirect

#### Description

Executes a prepared statement specified in this parameter. `SQLExecDirect` is the fastest method for executing only one SQL statement at a time.

#### Prototype

```
SQLRETURN SQLExecDirect(SQLHSTMT StatementHandle,
                        SQLCHAR *StatementText,
                        SQLINTEGER TextLength);
```

#### Parameters

**Table 5-40** SQLExecDirect parameters

Keyword	Description
StatementHandle	Statement handle, obtained from <code>SQLAllocHandle</code> .
StatementText	SQL statement to be executed. Multiple statements cannot be executed at a time.
TextLength	Length of <b>StatementText</b> .

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_NEED\_DATA** indicates that parameters provided before executing the SQL statement are insufficient.

- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.

## Precautions

If `SQLExecDirect` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call `SQLGetDiagRec`, with `HandleType` and `Handle` set to **SQL\_HANDLE\_STMT** and `StatementHandle`, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.11 SQLExecute

## Description

If a statement contains a parameter marker, the `SQLExecute` function uses the current value of the parameter marker to execute a prepared SQL statement.

## Prototype

```
SQLRETURN SQLExecute(SQLHSTMT StatementHandle);
```

## Parameters

**Table 5-41** SQLExecute parameter

Keyword	Description
StatementHandle	Statement handle to be executed.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_NEED\_DATA** indicates that parameters provided before executing the SQL statement are insufficient.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.

- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If `SQLExecute` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call `SQLGetDiagRec`, with `HandleType` and `Handle` set to **SQL\_HANDLE\_STMT** and `StatementHandle`, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.12 SQLFetch

#### Description

Advances the cursor to the next row of the result set and retrieves any bound columns.

#### Prototype

```
SQLRETURN SQLFetch(SQLHSTMT StatementHandle);
```

#### Parameters

Table 5-42 SQLFetch parameter

Keyword	Description
StatementHandle	Statement handle, obtained from <code>SQLAllocHandle</code> .

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If SQLFetch returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.13 SQLFreeStmt

In ODBC 3.x, SQLFreeStmt (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

### 5.4.7.14 SQLFreeConnect

In ODBC 3.x, SQLFreeConnect (an ODBC 2.x function) was deprecated and replaced by SQLFreeHandle. For details, see [SQLFreeHandle](#).

### 5.4.7.15 SQLFreeHandle

#### Description

Releases resources associated with a specific environment, connection, or statement handle. It replaces the ODBC 2.x functions: SQLFreeEnv, SQLFreeConnect, and SQLFreeStmt.

#### Prototype

```
SQLRETURN SQLFreeHandle(SQLSMALLINT HandleType,
                        SQLHANDLE Handle);
```

#### Parameters

**Table 5-43** SQLFreeHandle parameters

Keyword	Description
HandleType	Type of handle to be freed by SQLFreeHandle. The value must be one of the following: <ul style="list-style-type: none"> <li>• <b>SQL_HANDLE_ENV</b></li> <li>• <b>SQL_HANDLE_DBC</b></li> <li>• <b>SQL_HANDLE_STMT</b></li> <li>• <b>SQL_HANDLE_DESC</b></li> </ul> If none of them is the value of <b>HandleType</b> , SQLFreeHandle returns <b>SQL_INVALID_HANDLE</b> .
Handle	Name of the handle to be freed.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLFreeHandle` returns **SQL\_ERROR**, the handle is still valid.

## Examples

See [Examples](#).

### 5.4.7.16 SQLFreeEnv

In ODBC 3.x, `SQLFreeEnv` (an ODBC 2.x function) was deprecated and replaced by `SQLFreeHandle`. For details, see [SQLFreeHandle](#).

### 5.4.7.17 SQLPrepare

## Description

Prepares an SQL statement to be executed.

Note that the prepared statements sent by ODBC do not support the kernel reuse plan. As a result, a new plan needs to be generated for each execution, causing high CPU usage. If services have requirements on plan reuse, you are advised to use the JDBC client.

## Prototype

```
SQLRETURN SQLPrepare(SQLHSTMT StatementHandle,
                    SQLCHAR *StatementText,
                    SQLINTEGER TextLength);
```

## Parameters

**Table 5-44** SQLPrepare parameters

Keyword	Description
StatementHandle	Statement handle.
StatementText	SQL text string.
TextLength	Length of <b>StatementText</b> .

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If SQLPrepare returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.18 SQLGetData

## Description

SQLGetData is used to retrieve data for a single column in the result set. It can be called multiple times to partially retrieve variable-length data.

## Prototype

```
SQLRETURN SQLGetData(SQLHSTMT StatementHandle,
                    SQLUSMALLINT Col_or_Param_Num,
                    SQLSMALLINT TargetType,
                    SQLPOINTER TargetValuePtr,
                    SQLLEN BufferLength,
                    SQLLEN *StrLen_or_IndPtr);
```

## Parameters

**Table 5-45** SQLGetData parameters

Keyword	Description
StatementHandle	Statement handle, obtained from SQLAllocHandle.
Col_or_Param_Num	Column number for which the data retrieval is requested. The column number starts with 1 and increases in ascending order. The number of the bookmark column is 0.

Keyword	Description
TargetType	C data type in the TargetValuePtr buffer. If <b>TargetType</b> is <b>SQL_ARD_TYPE</b> , the driver uses the data type of the <b>SQL_DESC_CONCISE_TYPE</b> field in ARD. If it is <b>SQL_C_DEFAULT</b> , the driver selects a default data type according to the source SQL data type.
TargetValuePtr	<b>Output parameter:</b> pointer to the pointer that points to the buffer where the data is located.
BufferLength	Size of the buffer pointed to by <b>TargetValuePtr</b> .
StrLen_or_IndPtr	<b>Output parameter:</b> pointer to the buffer where the length or identifier value is returned.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_NO\_DATA** indicates that the SQL statement does not return a result set.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.
- **SQL\_STILL\_EXECUTING** indicates that the statement is being executed.

## Precautions

If SQLGetData returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call [SQLGetDiagRec](#), with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.19 SQLGetDiagRec

## Description

Returns the current values of multiple fields in a diagnostic record that contains error, warning, and status information.

## Prototype

```
SQLRETURN SQLGetDiagRec(SQLSMALLINT HandleType
                        SQLHANDLE Handle,
```

```

SQLSMALLINT  RecNumber,
SQLCHAR      *SQLState,
SQLINTEGER   *NativeErrorPtr,
SQLCHAR      *MessageText,
SQLSMALLINT  BufferLength
SQLSMALLINT  *TextLengthPtr);
    
```

## Parameters

**Table 5-46** SQLGetDiagRec parameters

Keyword	Description
HandleType	Handle-type identifier that describes the type of handle for which diagnostics are desired. The value must be one of the following: <ul style="list-style-type: none"> <li>SQL_HANDLE_ENV</li> <li>SQL_HANDLE_DBC</li> <li>SQL_HANDLE_STMT</li> <li>SQL_HANDLE_DESC</li> </ul>
Handle	Handle for the diagnostic data structure. Its type is indicated by <b>HandleType</b> . If <b>HandleType</b> is set to <b>SQL_HANDLE_ENV</b> , <b>Handle</b> may indicate a shared or non-shared environment handle.
RecNumber	Status record from which the application seeks information. Status records are numbered from 1.
SQLState	<b>Output parameter:</b> pointer to a buffer that saves the 5-character <b>SQLSTATE</b> code pertaining to <b>RecNumber</b> .
NativeErrorPtr	<b>Output parameter:</b> pointer to a buffer that saves the native error code.
MessageText	Pointer to a buffer that saves text strings of diagnostic information.
BufferLength	Length of <b>MessageText</b> .
TextLengthPtr	<b>Output parameter:</b> pointer to the buffer, the total number of bytes in the returned <b>MessageText</b> . If the number of bytes available to return is greater than <b>BufferLength</b> , then the diagnostics information text in <b>MessageText</b> is truncated to <b>BufferLength</b> minus the length of the null termination character.

## Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.

- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

SQLGetDiagRec does not release diagnostic records for itself. It uses the following return values to report execution results:

- **SQL\_SUCCESS** indicates that the function successfully returns diagnostic information.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that the **MessageText** buffer is too small to hold the requested diagnostic information. No diagnostic records are generated.
- **SQL\_INVALID\_HANDLE** indicates that the handle indicated by **HandType** and **Handle** is an invalid handle.
- **SQL\_ERROR** indicates that the value of **RecNumber** is less than or equal to 0 or the value of **BufferLength** is less than 0.

If an ODBC function returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, you can call SQLGetDiagRec to obtain the **SQLSTATE** value. [Table 2 SQLSTATE values](#) lists the possible **SQLSTATE** values.

**Table 5-47** SQLSTATE values

SQLSTATE	Error	Description
HY000	General error.	An error occurs when there is no specific SQLSTATE.
HY001	Memory allocation error.	The driver is unable to allocate memory required to support execution or completion of the function.
HY008	Operation canceled.	SQLCancel is called to terminate the statement execution, but the StatementHandle function is still called.
HY010	Function sequence error.	The function is called prior to sending data to data parameters or columns being executed.
HY013	Memory management error.	The function fails to be called. The error may be caused by low memory conditions.
HYT01	Connection timeout.	The timeout period expired before the application was able to connect to the data source.
IM001	Function not supported by the driver.	The called function is not supported by the StatementHandle driver.

## Examples

See [Examples](#).

### 5.4.7.20 SQLSetConnectAttr

#### Description

Sets connection attributes.

#### Prototype

```
SQLRETURN SQLSetConnectAttr(SQLHDBC ConnectionHandle
                             SQLINTEGER Attribute,
                             SQLPOINTER ValuePtr,
                             SQLINTEGER StringLength);
```

#### Parameters

**Table 5-48** SQLSetConnectAttr parameters

Keyword	Description
ConnectionHandle	Connection handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and can be a 32-bit unsigned integer value or a null-terminated string. If the <b>ValuePtr</b> parameter is driver-specific value, it may be a signed integer.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

#### Precautions

If `SQLSetConnectAttr` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call `SQLGetDiagRec`, with **HandleType** and **Handle** set to **SQL\_HANDLE\_DBC** and **ConnectionHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.21 SQLSetEnvAttr

#### Description

Sets environment attributes.

#### Prototype

```
SQLRETURN SQLSetEnvAttr(SQLHENV EnvironmentHandle,
                        SQLINTEGER Attribute,
                        SQLPOINTER ValuePtr,
                        SQLINTEGER StringLength);
```

#### Parameters

**Table 5-49** SQLSetEnvAttr parameters

Keyword	Description
EnvironmentHandle	Environment handle.
Attribute	Environment attribute to be set. The value must be one of the following: <ul style="list-style-type: none"> <li>• <b>SQL_ATTR_ODBC_VERSION</b>: ODBC version</li> <li>• <b>SQL_CONNECTION_POOLING</b>: connection pool attribute</li> <li>• <b>SQL_OUTPUT_NTS</b>: string type returned by the driver</li> </ul>
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and can be a 32-bit integer value or a null-terminated string.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

#### Return Values

- **SQL\_SUCCESS** indicates that the call succeeded.
- **SQL\_SUCCESS\_WITH\_INFO** indicates that some warning information is displayed.
- **SQL\_ERROR** indicates major errors, such as memory allocation and connection failures.
- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLSetEnvAttr` returns `SQL_ERROR` or `SQL_SUCCESS_WITH_INFO`, the application can call `SQLGetDiagRec`, set `HandleType` and `Handle` to `SQL_HANDLE_ENV` and `EnvironmentHandle`, and obtain the `SQLSTATE` value. The `SQLSTATE` value provides the detailed function calling information.

## Examples

See [Examples](#).

### 5.4.7.22 SQLSetStmtAttr

## Description

Sets attributes related to a statement.

## Prototype

```
SQLRETURN SQLSetStmtAttr(SQLHSTMT StatementHandle
                          SQLINTEGER Attribute,
                          SQLPOINTER ValuePtr,
                          SQLINTEGER StringLength);
```

## Parameters

**Table 5-50** SQLSetStmtAttr parameters

Keyword	Description
StatementHandle	Statement handle.
Attribute	Attribute to set.
ValuePtr	Pointer to the <b>Attribute</b> value. <b>ValuePtr</b> depends on the <b>Attribute</b> value, and can be a 32-bit unsigned integer value or a pointer to a null-terminated string, a binary buffer, or a driver-specified value. If the <b>ValuePtr</b> parameter is driver-specific value, it may be a signed integer.
StringLength	If <b>ValuePtr</b> points to a string or a binary buffer, <b>StringLength</b> is the length of <b>*ValuePtr</b> . If <b>ValuePtr</b> points to an integer, <b>StringLength</b> is ignored.

## Return Values

- `SQL_SUCCESS` indicates that the call succeeded.
- `SQL_SUCCESS_WITH_INFO` indicates that some warning information is displayed.
- `SQL_ERROR` indicates major errors, such as memory allocation and connection failures.

- **SQL\_INVALID\_HANDLE** indicates that invalid handles were called. This value may also be returned by other APIs.

## Precautions

If `SQLSetStmtAttr` returns **SQL\_ERROR** or **SQL\_SUCCESS\_WITH\_INFO**, the application can call **SQLGetDiagRec**, with **HandleType** and **Handle** set to **SQL\_HANDLE\_STMT** and **StatementHandle**, respectively, to obtain the **SQLSTATE** value. The **SQLSTATE** value provides the detailed function calling information.

## Examples

See [Examples](#).

# 5.5 Development Based on libpq

libpq is a C application programming interface to GaussDB. libpq contains a set of library functions that allow client programs to send query requests to the GaussDB servers and obtain query results. It is also the underlying engine of other GaussDB APIs, such as ODBC. This chapter provides examples to show how to write code using libpq.

## 5.5.1 libpq Package, Dependent Library, and Header File

Obtain the libpq package, dependent library, and header files from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Libpq.tar.gz**. Client programs that use libpq must include the header file **libpq-fe.h** and must connect to the libpq library.

## 5.5.2 Development Process

To compile and develop source programs based on libpq, perform the following steps:

1. Decompress the **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Libpq.tar.gz** file. The required header file is stored in the **include** folder, and the **lib** folder contains the required libpq library file.

### NOTE

In addition to **libpq-fe.h**, the **include** folder contains the header files **postgres\_ext.h**, **gs\_thread.h**, and **gs\_threadlocal.h** by default. These three header files are the dependency files of **libpq-fe.h**.

2. Develop the source program **testlibpq.c**. The source code file needs to reference the header file provided by libpq.

Example: `#include <libpq-fe.h>`

3. To compile the libpq source program by running **gcc**, use the **-I directory** option to provide the installation location of the header file. (Sometimes the compiler looks for the default directory, so this option can be ignored.)

`gcc -I (Directory where the header file is located) -L (Directory where the libpq library is located) testlibq.c -lpq`

Example:

```
gcc -I $(GAUSSHOME)/include/libpq -L $(GAUSSHOME)/lib -lpq testlibpq.c -o testlibpq
```

4. If the makefile is used, add the following option to variables *CPPFLAGS*, *LDLFLAGS*, and *LIBS*:

```
CPPFLAGS += -I (Directory of the header file)
LDLFLAGS += -L (Directory of the libpq library)
LIBS += -lpq
```

Example:

```
CPPFLAGS += -I$(GAUSSHOME)/include/libpq
LDLFLAGS += -L$(GAUSSHOME)/lib
```

## 5.5.3 Examples

### Code for Common Functions

Example 1:

```
/*
 * testlibpq.c
 * Note: testlibpq.c source program provides basic and common application scenarios of libpq.
 * The PQconnectdb, PQexec, PQntuples, and PQfinish APIs provided by libpq are used to establish database
 * connections, execute SQL statements, obtain returned results, and clear resources.
 */
#include <stdio.h>
#include <stdlib.h>
#include <libpq-fe.h>
#include <string.h>

static void
exit_nicely(PGconn *conn)
{
    PQfinish(conn);
    exit(1);
}

int
main(int argc, char **argv)
{
    /* The values of variables such as user and passwd must be read from environment variables or
    * configuration files. Environment variables need to be configured as required. If no environment variable is
    * used, a character string can be directly assigned. */
    const char *conninfo;
    PGconn *conn;
    PGresult *res;
    int nFields;
    int i,j;
    char *passwd = getenv("EXAMPLE_PASSWD_ENV");
    char *port = getenv("EXAMPLE_PORT_ENV");
    char *host = getenv("EXAMPLE_HOST_ENV");
    char *username = getenv("EXAMPLE_USERNAME_ENV");
    char *dbname = getenv("EXAMPLE_DBNAME_ENV");

    /*
    * This value is used when the user provides the value of the conninfo character string in the command
    * line.
    * Otherwise, the environment variables or the default values
    * are used for all other connection parameters.
    */
    if (argc > 1)
        conninfo = argv[1];
    else {
        sprintf(conninfo,
            "dbname=%s port=%s host=%s application=test connect_timeout=5 sslmode=allow user=%s
            password=%s",

}
```

## 5.5.4 libpq API Reference

### 5.5.4.1 Database Connection Control Functions

There are database connection control functions for controlling the connections to database servers. An application can connect to multiple servers at a time. For example, a client connects to multiple databases. Each connection is represented by a PGconn object, which is obtained from the function PQconnectdb, PQconnectdbParams, or PQsetdbLogin. Note that these functions will always return a non-null object pointer, unless memory allocation fails. The API for establishing a connection is stored in the PGconn object. The PQstatus function can be called to check the return value for a successful connection.

#### 5.5.4.1.1 PQconnectdbParams

##### Description

Establishes a new connection with the database server.

##### Prototype

```
PGconn* PQconnectdbParams(const char* const* keywords, const char* const* values, int expand_dbname);
```

##### Parameters

**Table 5-51** PQconnectdbParams parameters

Keyword	Description
keywords	An array of strings, each of which is a keyword.
values	Value assigned to each keyword.
expand_dbname	When <b>expand_dbname</b> is non-zero, the <b>dbname</b> keyword value can be recognized as a connection string. Only <b>dbname</b> that first appears is expanded in this way, and any subsequent <b>dbname</b> value is treated as a database name.

##### Return Values

**PGconn \*** points to the object pointer that contains a connection. The memory is allocated by the function internally.

##### Precautions

This function establishes a new database connection using the parameters taken from two NULL-terminated arrays. Unlike PQsetdbLogin, the parameter set can be

extended without changing the function signature. Therefore, use of this function (or its non-blocking analogs `PQconnectStartParams` and `PQconnectPoll`) is preferred for new application programming.

### 5.5.4.1.2 PQconnectdb

#### Description

Establishes a new connection with the database server.

#### Prototype

```
PGconn* PQconnectdb(const char* conninfo);
```

#### Parameters

Table 5-52 PQconnectdb parameter

Keyword	Description
conninfo	Connection string. For details about the columns in the string, see <a href="#">Connection Parameters</a> .

#### Return Values

**PGconn \*** points to the object pointer that contains a connection. The memory is allocated by the function internally.

#### Precautions

- This function establishes a new database connection using the parameters taken from the string **conninfo**.
- The input parameter can be empty, indicating that all default parameters can be used. It can contain one or more values separated by spaces or contain a URL.

### 5.5.4.1.3 PQconninfoParse

#### Description

Returns parsed connection options based on the connection.

#### Prototype

```
PQconninfoOption* PQconninfoParse(const char* conninfo, char** errmsg);
```

## Parameters

Table 5-53

Keyword	Description
conninfo	Passed string. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URL.
errmsg	Error information.

## Return Values

PQconninfoOption pointers

### 5.5.4.1.4 PQconnectStart

#### Description

Establishes a non-blocking connection with the database server.

#### Prototype

```
PGconn* PQconnectStart(const char* conninfo);
```

#### Parameters

Table 5-54

Keyword	Description
conninfo	String of connection information. This parameter can be left empty. In this case, the default value is used. It can contain one or more values separated by spaces or contain a URL.

## Return Values

PGconn pointers

### 5.5.4.1.5 PQerrorMessage

#### Function

Returns error information on a connection.

#### Prototype

```
char* PQerrorMessage(const PGconn* conn);
```

## Parameter

Table 5-55

Keyword	Parameter Description
conn	Connection handle.

## Return Value

char pointers

### 5.5.4.1.6 PQsetdbLogin

## Description

Establishes a new connection with the database server.

## Prototype

```
PGconn* PQsetdbLogin(const char* pghost, const char* pgport, const char* pgoptions, const char* pgtty,
const char* dbName, const char* login, const char* pwd);
```

## Parameters

Table 5-56 PQsetdbLogin parameters

Keyword	Description
pghost	Name of the host to be connected. For details, see the <b>host</b> column described in <a href="#">Connection Parameters</a> .
pgport	Port number of the host server. For details, see the <b>port</b> column described in <a href="#">Connection Parameters</a> .
pgoptions	Command-line options to be sent to the server during running. For details, see the <b>options</b> column described in <a href="#">Connection Parameters</a> .
pgtty	Ignored. (Previously, this option declares the output direction of server logs.)
dbName	Name of the database to be connected. For details, see the <b>dbname</b> column described in <a href="#">Connection Parameters</a> .
login	Username for connection. For details, see the <b>user</b> column described in <a href="#">Connection Parameters</a> .
pwd	Password used for authentication during connection. For details, see the <b>password</b> column described in <a href="#">Connection Parameters</a> .

## Return Values

**PGconn \*** points to the object pointer that contains a connection. The memory is allocated by the function internally.

## Precautions

- This function is the predecessor of PQconnectdb with a fixed set of parameters. When an undefined parameter is called, its default value is used. Write NULL or an empty string for any one of the fixed parameters that is to be defaulted.
- If the **dbName** value contains an equal sign (=) or a valid prefix in the connection URL, it is taken as a conninfo string and passed to PQconnectdb, and the remaining parameters are consistent with PQconnectdbParams parameters.

### 5.5.4.1.7 PQfinish

## Function

Closes the connection to the server and releases the memory used by the PGconn object.

## Prototype

```
void PQfinish(PGconn* conn);
```

## Parameter

Table 5-57 PQfinish parameter

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.

## Precautions

If the server connection attempt fails (as indicated by PQstatus), the application should call PQfinish to release the memory used by the PGconn object. The PGconn pointer must not be used again after PQfinish has been called.

## Example

For details, see [Examples](#).

### 5.5.4.1.8 PQreset

## Function

Resets the communication port to the server.

## Prototype

```
void PQreset(PGconn* conn);
```

## Parameter

**Table 5-58** PQreset parameter

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.

## Precautions

This function will close the connection to the server and attempt to establish a new connection to the same server by using all the parameters previously used. This function is applicable to fault recovery after a connection exception occurs.

### 5.5.4.1.9 PQstatus

## Description

Returns the connection status.

## Prototype

```
ConnStatusType PQstatus(const PGconn *conn);
```

## Parameters

**Table 5-59** PQstatus parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

## Return Values

**ConnStatusType** indicates the connection status. The enumerated values are as follows:

```
CONNECTION_STARTED
Waiting for the connection to be established.

CONNECTION_MADE
Connection succeeded; waiting to send

CONNECTION_AWAITING_RESPONSE
Waiting for a response from the server.

CONNECTION_AUTH_OK
```

Authentication received; waiting for backend startup to complete.

CONNECTION\_SSL\_STARTUP  
Negotiating SSL encryption.

CONNECTION\_SETENV  
Negotiating environment-driven parameter settings.

CONNECTION\_OK  
Normal connection.

CONNECTION\_BAD  
Failed connection.

## Precautions

The connection status can be one of the preceding values. After the asynchronous connection procedure is complete, only two of them, **CONNECTION\_OK** and **CONNECTION\_BAD**, can return. **CONNECTION\_OK** indicates that the connection to the database is normal. **CONNECTION\_BAD** indicates that the connection to the database fails. Generally, the normal state remains until PQfinish is called. However, a communication failure may cause the connection status to become to **CONNECTION\_BAD** before the connection procedure is complete. In this case, the application can attempt to call PQreset to restore the communication.

## Examples

For details, see [Examples](#).

### 5.5.4.2 Database Statement Execution Functions

After the connection to the database server is successfully established, you can use the functions described in this section to execute SQL queries and commands.

#### 5.5.4.2.1 PQclear

### Description

Releases the storage associated with PGresult. Any query result should be released by PQclear when it is no longer needed.

### Prototype

```
void PQclear(PGresult* res);
```

### Parameters

**Table 5-60** PQclear parameter

Keyword	Description
res	Object pointer that contains the query result.

## Precautions

PGresult is not automatically released. That is, it does not disappear when a new query is submitted or even if you close the connection. To delete it, you must call PQclear. Otherwise, memory leakage occurs.

### 5.5.4.2.2 PQexec

## Function

Commits a command to the server and waits for the result.

## Prototype

```
PGresult* PQexec(PGconn* conn, const char* query);
```

## Parameter

**Table 5-61** PQexec parameters

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.
command	Query string to be executed.

## Return Value

**PGresult** indicates the object pointer that contains the query result.

## Precautions

The PQresultStatus function should be called to check the return value for any errors (including the value of a null pointer, in which **PGRES\_FATAL\_ERROR** will be returned). The PQerrorMessage function can be called to obtain more information about such errors.

---

### NOTICE

The command string can contain multiple SQL commands separated by semicolons (;). Multiple queries sent in a PQexec call are processed in one transaction, unless there are specific BEGIN/COMMIT commands in the query string to divide the string into multiple transactions. Note that the returned PGresult structure describes only the result of the last command executed from the string. If a command fails, the string processing stops and the returned PGresult describes the error condition.

---

## Example

For details, see [Examples](#).

### 5.5.4.2.3 PQexecParams

## Description

Runs a command to bind parameters.

## Prototype

```
PGresult* PQexecParams(PGconn* conn,  
    const char* command,  
    int nParams,  
    const Oid* paramTypes,  
    const char* const* paramValues,  
    const int* paramLengths,  
    const int* paramFormats,  
    int resultFormat);
```

## Parameters

**Table 5-62** PQexecParams parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
paramTypes	Types of parameters to be bound.
paramValues	Values of parameters to be bound.
paramLengths	Parameter lengths.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

## Return Values

PGresult pointers

### 5.5.4.2.4 PQexecParamsBatch

## Description

Runs a command to bind batches of parameters.

## Prototype

```
PGresult* PQexecParamsBatch(PGconn* conn,  
    const char* command,
```

```
int nParams,
int nBatch,
const Oid* paramTypes,
const char* const* paramValues,
const int* paramLengths,
const int* paramFormats,
int resultFormat);
```

## Parameters

**Table 5-63** PQexecParamsBatch parameters

Keyword	Description
conn	Connection handle.
command	SQL text string.
nParams	Number of parameters to be bound.
nBatch	Number of batch operations.
paramTypes	Types of parameters to be bound.
paramValues	Values of parameters to be bound.
paramLengths	Parameter lengths.
paramFormats	Parameter formats (text or binary).
resultFormat	Result format (text or binary).

## Return Values

PGresult pointers

### 5.5.4.2.5 PQexecPrepared

## Function

PQexecPrepared is used to send a request to execute a prepared statement with given parameters and wait for the result.

## Prototype

```
PGresult* PQexecPrepared(PGconn* conn,
const char* stmtName,
int nParams,
const char* const* paramValues,
const int* paramLengths,
const int* paramFormats,
int resultFormat);
```

## Parameter

**Table 5-64** PQexecPrepared parameters

Keyword	Parameter Description
conn	Connection handle.
stmtName	<i>stmt</i> name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.
nParams	Parameter quantity.
paramValues	Actual values of parameters.
paramLengths	Actual data lengths of parameters.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

## Return Value

PGresult pointers

### 5.5.4.2.6 PQexecPreparedBatch

## Function

PQexecPreparedBatch is used to send a request to execute a prepared statement with batches of given parameters and wait for the result.

## Prototype

```
PGresult* PQexecPreparedBatch(PGconn* conn,
    const char* stmtName,
    int nParams,
    int nBatchCount,
    const char* const* paramValues,
    const int* paramLengths,
    const int* paramFormats,
    int resultFormat);
```

## Parameter

**Table 5-65** PQexecPreparedBatch parameters

Keyword	Parameter Description
conn	Connection handle.
stmtName	<i>stmt</i> name, which can be set to "" or NULL to reference an unnamed statement. Otherwise, it must be the name of an existing prepared statement.

Keyword	Parameter Description
nParams	Parameter quantity.
nBatchCount	Number of batches.
paramValues	Actual values of parameters.
paramLengths	Actual data lengths of parameters.
paramFormats	Parameter formats (text or binary).
resultFormat	Return result format (text or binary).

## Return Value

PGresult pointers

### 5.5.4.2.7 PQfname

## Function

PQfname is used to return the column name associated with the given column number. Column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

## Prototype

```
char *PQfname(const PGresult *res,
             int column_number);
```

## Parameter

**Table 5-66** PQfname parameters

Keyword	Parameter Description
res	Operation result handle.
column_number	Number of columns.

## Return Value

char pointers

## Example

For details, see [Examples](#).

### 5.5.4.2.8 PQgetvalue

#### Function

PQgetvalue is used to return a single field value of one row of a PGresult. Row and column numbers start from 0. The caller should not release the result directly. The result will be released when the associated PGresult handle is passed to PQclear.

#### Prototype

```
char *PQgetvalue(const PGresult *res,  
                int row_number,  
                int column_number);
```

#### Parameter

**Table 5-67** PQgetvalue parameters

Keyword	Parameter Description
res	Operation result handle.
row_number	Number of rows.
column_number	Number of columns.

#### Return Value

For data in text format, the value returned by PQgetvalue is a null-terminated string representation of the field value.

For binary data, the value is a binary representation determined by the typsend and typreceive functions of the data type.

If this field is left blank, an empty string is returned.

#### Example

For details, see [Examples](#).

### 5.5.4.2.9 PQnfields

#### Function

PQnfields is used to return the number of columns (fields) in each row of the query result.

#### Prototype

```
int PQnfields(const PGresult *res);
```

## Parameter

**Table 5-68** PQnfields parameters

Keyword	Parameter Description
res	Operation result handle.

## Return Value

Value of the int type

## Example

For details, see [Examples](#).

### 5.5.4.2.10 PQntuples

## Function

Returns the number of rows (tuples) in the query result.

## Prototype

```
int PQntuples(const PGresult* res);
```

---

**NOTICE**

PQntuples returns an integer result. An overflow may occur if the return value is out of the value range allowed in a 32-bit OS.

---

## Parameter

**Table 5-69** PQntuples parameters

Keyword	Parameter Description
res	Operation result handle.

## Return Value

Value of the int type

## Examples

For details, see [Examples](#).

### 5.5.4.2.11 PQprepare

#### Description

Commits a request to create a prepared statement with given parameters and waits for completion.

#### Prototype

```
PGresult* PQprepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

#### Parameters

**Table 5-70** PQprepare parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of <b>stmt</b> to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

#### Return Values

**PGresult** indicates the object pointer that contains the query result.

#### Precautions

- PQprepare creates a prepared statement for later execution with PQexecPrepared. This function allows commands to be repeatedly executed, without being parsed and planned each time they are executed. PQprepare is supported only in protocol 3.0 or later. It will fail when protocol 2.0 is used.
- This function creates a prepared statement named **stmtName** from the query string, which must contain an SQL command. **stmtName** can be "" to create an unnamed statement. In this case, any pre-existing unnamed statement will be automatically replaced. Otherwise, this is an error if the statement name has been defined in the current session. If any parameters are used, they are referred to in the query as \$1, \$2, and so on. **nParams** is the number of parameters for which types are pre-specified in the array paramTypes[]. (The array pointer can be **NULL** when **nParams** is 0.) paramTypes[] specifies the data types to be assigned to the parameter symbols by OID. If **paramTypes** is **NULL**, or any element in the array is 0, the server assigns a data type to the parameter symbol in the same way as it does for an untyped literal string. In addition, the query can use parameter symbols whose numbers are greater than **nParams**. Data types of these symbols will also be inferred.

**NOTICE**

You can also execute the **SQLPREPARE** statement to create a prepared statement that is used with PQexecPrepared. Although there is no libpq function of deleting a prepared statement, the **SQL DEALLOCATE** statement can be used for this purpose.

## Examples

For details, see [Examples](#).

### 5.5.4.2.12 PQresultStatus

#### Function

Returns the result status of a command.

#### Prototype

```
ExecStatusType PQresultStatus(const PGresult* res);
```

#### Parameter

**Table 5-71** PQresultStatus parameter

Keyword	Parameter Description
res	Object pointer that contains the query result.

#### Return Value

**PQresultStatus** indicates the command execution status. The enumerated values are as follows:

PQresultStatus can return one of the following values:

**PGRES\_EMPTY\_QUERY**

The string sent to the server was empty.

**PGRES\_COMMAND\_OK**

A command that does not return data was successfully executed.

**PGRES\_TUPLES\_OK**

A query (such as SELECT or SHOW) that returns data was successfully executed.

**PGRES\_COPY\_OUT**

Copy Out (from the server) data transfer started.

**PGRES\_COPY\_IN**

Copy In (to the server) data transfer started.

**PGRES\_BAD\_RESPONSE**

The response from the server cannot be understood.

**PGRES\_NONFATAL\_ERROR**

A non-fatal error (notification or warning) occurred.

```
PGRES_FATAL_ERROR
A fatal error occurred.

PGRES_COPY_BOTH
Copy In/Out (to and from the server) data transfer started. This state occurs only in streaming replication.

PGRES_SINGLE_TUPLE
PGresult contains a result tuple from the current command. This state occurs in a single-row query.
```

## Precautions

- Note that the SELECT command that happens to retrieve zero rows still returns **PGRES\_TUPLES\_OK**. **PGRES\_COMMAND\_OK** is used for commands that can never return rows (such as INSERT or UPDATE, without return clauses). The result status **PGRES\_EMPTY\_QUERY** might indicate a bug in the client software.
- The result status **PGRES\_NONFATAL\_ERROR** will never be returned directly by PQexec or other query execution functions. Instead, such results will be passed to the notice processor.

## Example

For details, see [Examples](#).

### 5.5.4.3 Functions for Asynchronous Command Processing

The PQexec function is adequate for committing commands in common, synchronous applications. However, it has several defects, which may be important to some users:

- PQexec waits for the end of the command, but the application may have other work to do (for example, maintaining a user interface). In this case, PQexec would not want to be blocked to wait for the response.
- As the client application is suspended while waiting for the result, it is difficult for the application to determine whether to cancel the ongoing command.
- PQexec can return only one PGresult structure. If the committed command string contains multiple SQL commands, all the PGresult structures except the last PGresult are discarded by PQexec.
- PQexec always collects the entire result of the command and caches it in a PGresult. Although this mode simplifies the error handling logic for applications, it is impractical for results that contain multiple rows.

Applications that do not want to be restricted by these limitations can use the following functions that PQexec is built from: PQsendQuery and PQgetResult. The functions PQsendQueryParams, PQsendPrepare, and PQsendQueryPrepared can also be used with PQgetResult.

#### 5.5.4.3.1 PQsendQuery

### Description

Commits a command to the server without waiting for the result. If the query is successful, **1** is returned. Otherwise, **0** is returned.

## Prototype

```
int PQsendQuery(PGconn*conn, const char* query);
```

## Parameters

**Table 5-72** PQsendQuery parameters

Keyword	Description
conn	Points to the object pointer that contains the connection information.
query	Query string to be executed.

## Return Values

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

After PQsendQuery is successfully called, call PQgetResult one or more times to obtain the results. PQsendQuery cannot be called again (on the same connection) until PQgetResult returns a null pointer, indicating that the command execution is complete.

### 5.5.4.3.2 PQsendQueryParams

## Function

PQsendQueryParams is used to submit a command and separate parameters to the server without waiting for the result.

## Prototype

```
int PQsendQueryParams(PGconn* conn, const char* command, int nParams, const Oid* paramTypes, const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

## Parameter

**Table 5-73** PQsendQueryParams parameters

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.
command	Query string to be executed.
nParams	Parameter quantity.

Keyword	Parameter Description
paramTypes	Parameter type.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

This function is equivalent to PQsendQuery. The only difference is that query parameters can be specified separately from the query string. The parameter processing of this function is similar to that of PQexecParams. It cannot work on connections using protocol v2.0, and it allows only one command to appear in the query string.

### 5.5.4.3 PQsendPrepare

## Function

PQsendPrepare is used to send a request to create a prepared statement with given parameters, without waiting for completion.

## Prototype

```
int PQsendPrepare(PGconn* conn, const char* stmtName, const char* query, int nParams, const Oid* paramTypes);
```

## Parameters

**Table 5-74** PQsendPrepare parameters

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of <b>stmt</b> to be executed.
query	Query string to be executed.
nParams	Parameter quantity.
paramTypes	Array of the parameter type.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

PQsendPrepare is an asynchronous version of PQprepare. If it can dispatch a request, **1** is returned. Otherwise, **0** is returned. After a successful calling of PQsendPrepare, call PQgetResult to check whether the server successfully created the prepared statement. PQsendPrepare parameters are handled in the same way as PQprepare parameters. Like PQprepare, PQsendPrepare cannot work on connections using protocol 2.0.

## Example

For details, see [Examples](#).

### 5.5.4.3.4 PQsendQueryPrepared

## Function

PQsendQueryPrepared is used to send a request to execute a prepared statement with given parameters, without waiting for the result.

## Prototype

```
int PQsendQueryPrepared(PGconn* conn, const char* stmtName, int nParams, const char* const* paramValues, const int* paramLengths, const int* paramFormats, int resultFormat);
```

## Parameters

**Table 5-75** PQsendQueryPrepared parameters

Keyword	Parameter Description
conn	Points to the object pointer that contains the connection information.
stmtName	Name of <b>stmt</b> to be executed.
nParams	Parameter quantity.
paramValues	Parameter value.
paramLengths	Parameter length.
paramFormats	Parameter format.
resultFormat	Result format.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **conn->errorMessage**.

## Precautions

PQsendQueryPrepared is similar to PQsendQueryParams, but the command to be executed is specified by naming a previously-prepared statement, instead of providing a query string. PQsendQueryPrepared parameters are handled in the same way as PQexecPrepared parameters. Like PQexecPrepared, it cannot work on connections using protocol v2.0.

### 5.5.4.3.5 PQflush

## Description

Flushes any queued output data to the server.

## Prototype

```
int PQflush(PGconn* conn);
```

## Parameters

**Table 5-76** PQflush parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

## Return Values

**int** indicates the execution result. If the operation is successful (or the send queue is empty), **0** is returned. If the operation fails, **-1** is returned. If all data in the send queue fails to be sent, **1** is returned. (This case occurs only when the connection is non-blocking.) The failure cause is stored in **conn->error\_message**.

## Precautions

Call PQflush after sending any command or data over a non-blocking connection. If **1** is returned, wait for the socket to become read- or write-ready. If the socket becomes write-ready, call PQflush again. If the socket becomes read-ready, call PQconsumeInput and then call PQflush again. Repeat the operation until the value **0** is returned for PQflush. (It is necessary to check for read-ready and drain the input using PQconsumeInput. This is because the server can block trying to send us data, for example, notification messages, and will not read our data until we read it.) Once PQflush returns **0**, wait for the socket to be read-ready and then read the response as described above.

### 5.5.4.4 Functions for Canceling Queries in Progress

A client application can use the functions described in this section to cancel a command that is still being processed by the server.

#### 5.5.4.4.1 PQgetCancel

##### Description

Creates a data structure that contains the information required to cancel a command issued through a specific database connection.

##### Prototype

```
PGcancel* PQgetCancel(PGconn* conn);
```

##### Parameters

Table 5-77 PQgetCancel parameter

Keyword	Description
conn	Points to the object pointer that contains the connection information.

##### Return Values

**PGcancel** points to the object pointer that contains the cancel information.

##### Precautions

PQgetCancel creates a PGcancel object for a given PGconn connection object. If the given connection object (**conn**) is NULL or an invalid connection, it will return NULL. The PGcancel object is an opaque structure that cannot be directly accessed by applications. It can be transferred only to PQcancel or PQfreeCancel.

#### 5.5.4.4.2 PQfreeCancel

##### Function

PQfreeCancel is used to release the data structure created by PQgetCancel.

##### Prototype

```
void PQfreeCancel(PGcancel* cancel);
```

## Parameter

Table 5-78 PQfreeCancel parameter

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.

## Precautions

PQfreeCancel releases a data object previously created by PQgetCancel.

### 5.5.4.4.3 PQcancel

## Function

PQcancel is used to request the server to abandon processing of the current command.

## Prototype

```
int PQcancel(PGcancel* cancel, char* errbuf, int errbufsize);
```

## Parameter

Table 5-79 PQcancel parameters

Keyword	Parameter Description
cancel	Points to the object pointer that contains the cancel information.
errbuf	Buffer for storing error information.
errbufsize	Size of the buffer for storing error information.

## Return Value

**int** indicates the execution result. **1** indicates successful execution and **0** indicates an execution failure. The failure cause is stored in **errbuf**.

## Precautions

- Successful sending does not guarantee that the request will have any effect. If the cancellation is valid, the current command is terminated early and an error is returned. If the cancellation fails (for example, because the server has processed the command), no result is returned.
- If **errbuf** is a local variable in a signal handler, you can safely call PQcancel from the signal handler. For PQcancel, the PGcancel object is read-only, so it

can also be called from a thread that is separate from the thread that is operating the PGconn object.

## Example

For details, see [Examples](#).

## 5.5.5 Connection Parameters

**Table 5-80** Connection parameters

Parameter	Description
host	<p>Name of the host to connect to. If the host name starts with a slash (/), Unix domain socket communications instead of TCP/IP communications are used. The value is the directory where the socket file is stored. If <b>host</b> is not specified, the default behavior is to connect to the Unix-domain socket in the <b>/tmp</b> directory (or the socket directory specified during database installation). On a machine without a Unix-domain socket, the default behavior is to connect to <b>localhost</b>.</p> <p>You can specify multiple host names by using a character string separated by commas (.). Multiple host names can be specified.</p>
hostaddr	<p>IP address of the host to connect to. The value is in standard IPv4 address format, for example, 172.28.40.9. If the machine supports IPv6, IPv6 address can also be used. If a non-null string is specified, TCP/IP communications are used.</p> <p>You can specify multiple IP addresses by using a character string separated by commas (.). Multiple IP addresses can be specified.</p> <p>Replacing <b>host</b> with <b>hostaddr</b> can prevent applications from querying host names, which may be important for applications with time constraints. However, a host name is required for GSSAPI or SSPI authentication methods. Therefore, the following rules are used:</p> <ol style="list-style-type: none"> <li>1. If <b>host</b> is specified but <b>hostaddr</b> is not, a query for the host name will be executed.</li> <li>2. If <b>hostaddr</b> is specified but <b>host</b> is not, the value of <b>hostaddr</b> is the server network address. If the host name is required for authentication, the connection attempt fails.</li> <li>3. If both <b>host</b> and <b>hostaddr</b> are specified, the value of <b>hostaddr</b> is the server network address. The value of <b>host</b> is ignored unless it is required by authentication, in which case it is used as the host name.</li> </ol> <p><b>NOTICE</b></p> <ul style="list-style-type: none"> <li>• If <b>host</b> is not the server name in the network address specified by <b>hostaddr</b>, the authentication may fail.</li> <li>• If neither <b>host</b> nor <b>hostaddr</b> is specified, libpq will use a local Unix domain socket for connection. If the machine does not have a Unix domain socket, it will attempt to connect to <b>localhost</b>.</li> </ul>

Parameter	Description
port	Port number of the host server, or the socket file name extension for Unix-domain connections. You can specify multiple port numbers by using a character string separated by commas (.). Multiple port numbers can be specified.
user	Name of the user to be connected. By default, the username is the same as the OS name of the user running the application.
dbname	Database name. The default value is the same as the username.
password	Password to be used if the server requires password authentication.
connect_timeout	Maximum timeout period of the connection, in seconds (written as a decimal integer string). The value <b>0</b> or null indicates infinity. You are advised not to set the connection timeout period to a value less than 2 seconds.
client_encoding	Client encoding for the connection. In addition to the values accepted by the corresponding server options, you can use <b>auto</b> to determine the correct encoding from the current environment in the client (the <i>LC_CTYPE</i> environment variable in the Unix system).
tty	This parameter can be ignored. (This parameter was used to specify the location to which the debugging output of the server was sent).
options	Adds command-line options to send to the server at runtime.
application_name	Specifies the current user identity for the <b>application_name</b> parameter.
fallback_application_name	Specifies a backup value for the <b>application_name</b> parameter. This value is used if no value is set for <b>application_name</b> through a connection parameter or the <i>PGAPPNAME</i> environment variable. In a common tool program, if you set a default name but do not want the default name to be overwritten by the user, you can specify a backup value.
keepalives	Specifies whether TCP keepalive is enabled on the client side. The default value is <b>1</b> , indicating that the function is enabled. The value <b>0</b> indicates that the function is disabled. Ignore this parameter for Unix-domain connections.
keepalives_idle	The number of seconds of inactivity after which TCP should send a keepalive message to the server. The value <b>0</b> indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.

Parameter	Description
keepalives_interval	The number of seconds after which a TCP keepalive message that is not acknowledged by the server should be retransmitted. The value <b>0</b> indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.
keepalives_count	Controls the number of times that keepalive messages are sent through TCP. The value <b>0</b> indicates that the default value is used. Ignore this parameter for Unix-domain connections or if keep-alive is disabled.
tcp_user_timeout	Specifies the maximum duration for which transmitted data can remain unacknowledged before the TCP connection is forcibly closed on an OS that supports the <b>TCP_USER_TIMEOUT</b> socket option. The value <b>0</b> indicates that the default value is used. Ignore this parameter for Unix-domain connections.
rw_timeout	Sets the read and write timeout interval of the client connection.
sslmode	Specifies whether to enable SSL encryption. <ul style="list-style-type: none"> <li>• <b>disable</b>: SSL connection is disabled.</li> <li>• <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li> <li>• <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li> <li>• <b>require</b>: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.</li> <li>• <b>verify-ca</b>: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication.</li> <li>• <b>verify-full</b>: SSL connection is required. Currently, Windows ODBC does not support certificate-based authentication.</li> </ul>
sslcompression	If this parameter is set to <b>1</b> (default value), the data transmitted over the SSL connection is compressed (this requires that the OpenSSL version be 0.9.8 or later). If it is set to <b>0</b> , compression will be disabled (this requires OpenSSL 1.0.0 or later). If a connection without SSL is established, this parameter is ignored. If the OpenSSL version in use does not support this parameter, it will also be ignored. Compression takes up CPU time, but it increases throughput when the bottleneck is the network. If CPU performance is a limiting factor, disabling compression can improve response time and throughput.
sslcert	This parameter specifies the file name of the client SSL certificate. If no SSL connection is established, this parameter is ignored.

Parameter	Description
sslkey	This parameter specifies the location of the key used for the client certificate. It can specify a key obtained from an external "engine" (the engine is a loadable module of OpenSSL). The description of an external engine should consist of a colon-separated engine name and an engine-related key identifier. If no SSL connection is established, this parameter is ignored.
sslrootcert	This parameter specifies the name of a file that contains the SSL Certificate Authority (CA) certificate. If the file exists, the system authenticates the server certificate issued by one of these authorities.
sslcr	This parameter specifies the file name of the SSL Certificate Revocation List (CRL). If a certificate listed in this file exists, the server certificate authentication will be rejected.
requirepeer	This parameter specifies the OS user of the server, for example, <b>requirepeer=postgres</b> . When a Unix domain socket connection is established, if this parameter is set, the client checks whether the server process is running under the specified username at the beginning of the connection. If not, the connection will be interrupted by an error. This parameter can be used to provide server authentication similar to that of the SSL certificate on TCP/IP connections. (Note that if the Unix domain socket is in <b>/tmp</b> or another public writable location, any user can start a server for listening to the location. Use this parameter to ensure that you are connected to a server that is run by a trusted user.) This option is supported only on platforms that implement the peer authentication method.
krbsrvname	This parameter specifies the Kerberos service name used for GSSAPI authentication. For successful Kerberos authentication, this value must match the service name specified in the server configuration.
gsslib	This parameter specifies the GSS library used for GSSAPI authentication. It is used only in the Windows OS. If this parameter is set to <b>gssapi</b> , the libpq is forced to use the GSSAPI library to replace the default SSPI for authentication.
service	This parameter specifies the name of the service for which the additional parameter is used. It specifies a service name in <b>pg_service.conf</b> that holds the additional connection parameters. This allows the application to specify only one service name so that the connection parameters can be centrally maintained.
authtype	<b>authtype</b> is no longer used, so it is marked as a parameter not to be displayed. It is retained in an array so as not to reject the <b>conninfo</b> string from old applications that might still try to set it.
remote_node_name	Specifies the name of the remote node connected to the local node.

Parameter	Description
localhost	Specifies the local host in a connection channel.
localport	Specifies the local port in a connection channel.
fencedUdfRPCMode	Specifies whether the fenced UDF RPC protocol uses Unix domain sockets or special socket file names. The default value is <b>0</b> , indicating that the Unix domain socket mode is used and the file type is <code>.s.PGSQL.%d</code> . To use the fenced UDF mode, set this parameter to <b>1</b> . In this case, the file type is <code>.s.fencedMaster_unixdomain</code> .
replication	<p>Specifies whether the connection should use replication protocols instead of common protocols. Protocols with this parameter configured are internal protocols used for PostgreSQL replication connections and tools such as <b>pg_basebackup</b>, while they can also be used by third-party applications. The following values, which are case-insensitive, are supported:</p> <ul style="list-style-type: none"> <li>• <b>true, on, yes, and 1</b>: Specify that the physical replication mode is connected.</li> <li>• <b>database</b>: Specifies that the logical replication mode and the database specified by <b>dbname</b> are connected.</li> <li>• <b>false, off, no, and 0</b>: Specify that the connection is a regular connection, which is the default behavior.</li> </ul> <p>In physical or logical replication mode, only simple query protocols can be used.</p>
backend_version	Specifies the backend version to be passed to the remote end.
prototype	Sets the current protocol level. The default value is <b>PROTO_TCP</b> .
enable_ce	Specifies whether a client is allowed to connect to a fully-encrypted database. The default value is <b>0</b> . To enable the basic capability of encrypted equality query, change the value to <b>1</b> .
connection_info	<p>The value of <b>connection_info</b> is a JSON character string consisting of <b>driver_name</b>, <b>driver_version</b>, <b>driver_path</b>, and <b>os_user</b>.</p> <p>If the value is not null, use <b>connection_info</b> and ignore <b>connectionExtraInf</b>.</p> <p>If the value is null, a connection information string related to <b>libpq</b> is generated. When <b>connectionExtraInf</b> is set to <b>false</b>, the value of <b>connection_info</b> consists of only <b>driver_name</b> and <b>driver_version</b>.</p>
connectionExtraInf	Specifies whether the value of <b>connection_info</b> contains extension information. The default value is <b>0</b> . If the value contains other information, set this parameter to <b>1</b> .

Parameter	Description
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting <b>target_session_attrs</b> are as follows:</p> <ul style="list-style-type: none"> <li>• <b>any</b>: All types of hosts can be connected.</li> <li>• <b>read-write</b>: The connection is set up only when the connected host is readable and writable.</li> <li>• <b>read-only</b>: Only readable hosts can be connected.</li> <li>• <b>primary</b> (default value): Only the primary node in the primary/standby systems can be connected.</li> <li>• <b>standby</b>: Only the standby node in the primary/standby systems can be connected.</li> <li>• <b>prefer-standby</b>: The system first attempts to find a standby node for connection. If all hosts in the <b>hosts</b> list fail to be connected, try the <b>any</b> mode.</li> </ul>

## 5.6 Psycopg-based Development

Psycopg is a Python API used to execute SQL statements and provides a unified access API for GaussDB. Applications can perform data operations based on psycopg. Psycopg2 is the encapsulation of libpq and is implemented using the C language, which is efficient and secure. It provides cursors on both clients and servers, asynchronous communication and notification, and the COPY TO and COPY FROM functions. It supports multiple types of Python out-of-the-box and adapts to GaussDB data types. Through the flexible object adaptation system, you can extend and customize the adaptation. Psycopg2 is compatible with Unicode.

GaussDB supports the psycopg2 feature and allows psycopg2 to be connected in SSL mode.

**Table 5-81** Platforms supported by psycopg

OS	Platform	Python Version
EulerOS 2.5	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.8.5
EulerOS 2.9	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.7.4
EulerOS 2.10, Kylin V10, and UnionTech20	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.7.9
EulerOS 2.11 and SUSE 12.5	<ul style="list-style-type: none"> <li>• Arm64</li> <li>• x86_64</li> </ul>	3.9.11

**NOTICE**

During psychopg2 compilation, OpenSSL of GaussDB is linked. OpenSSL of GaussDB may be incompatible with OpenSSL of the OS. If incompatibility occurs, for example, "version 'OPENSSL\_1\_1\_1f' not found" is displayed, use the environment variable `LD_LIBRARY_PATH` to isolate the OpenSSL provided by the OS and the OpenSSL on which GaussDB depends.

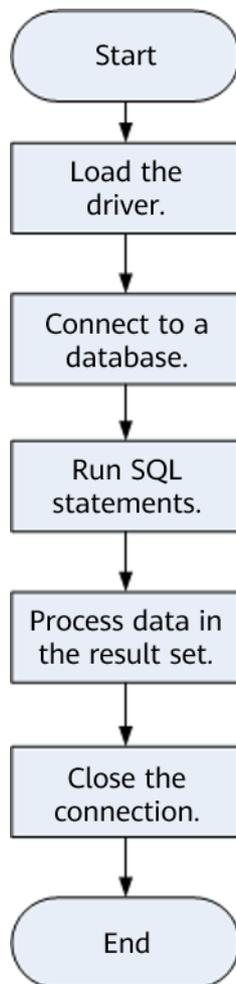

For example, when the application software **client.py** that calls psychopg2 is executed, the environment variable is explicitly assigned to the application software.

```
export LD_LIBRARY_PATH=/path/to/gaussdb/libs:$LD_LIBRARY_PATH python client.py
```

In the preceding command, **/path/to/psychopg2/lib** indicates the directory where the OpenSSL library on which GaussDB depends is located. Change it as required.

### 5.6.1 Development Process

Figure 5-4 Application development process based on psychopg2

## 5.6.2 Development Procedure

**Step 1** Prepare related drivers and dependent libraries. Obtain them from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Python.tar.gz**.

After the decompression, the following folders are generated:

- **psycopg2**: **psycopg2** library file
- **lib**: **lib** library file

**Step 2** Load the driver.

- Before using the driver, perform the following operations:
  - a. Decompress the driver package of the corresponding version.  

```
tar zxvf xxxx-Python.tar.gz
```
  - b. Copy **psycopg2** to the **site-packages** folder in the Python installation directory as the **root** user.  

```
su root
cp psycopg2 $(python3 -c 'import site; print(site.getsitepackages()[0])') -r
```
  - c. Change the **psycopg2** directory permission to **755**.  

```
chmod 755 $(python3 -c 'import site; print(site.getsitepackages()[0])')/psycopg2 -R
```
  - d. Add the **psycopg2** directory to the environment variable **\$PYTHONPATH** and validate it.  

```
export PYTHONPATH=$(python3 -c 'import site; print(site.getsitepackages()[0])'):$PYTHONPATH
```
  - e. For non-database users, configure the **lib** directory in **LD\_LIBRARY\_PATH** after decompression.  

```
export LD_LIBRARY_PATH=path/to/lib:$LD_LIBRARY_PATH
```
- Load a database driver before creating a database connection.  

```
import psycopg2
```

**Step 3** Connect to a database.

Connect to the database in non-SSL mode.

1. Use the `psycopg2.connect` function to obtain the connection object.
2. Use the connection object to create a cursor object.

Connect to the database in SSL mode.

When you use `psycopy2` to connect to the GaussDB server, you can enable SSL to encrypt the communication between the client and server. To enable SSL, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

1. Use the `.ini` file (the **configparser** package of Python can parse this type of configuration file) to save the configuration information about the database connection.
2. Add SSL connection parameters **sslmode**, **sslcert**, **sslkey**, and **sslrootcert** to the connection options.
  - a. **sslmode**: For details about the options, see [Table 5-82](#).
  - b. **sslcert**: client certificate path.
  - c. **sslkey**: client key path.
  - d. **sslrootcert**: root certificate path.

3. Use the `psycopg2.connect` function to obtain the connection object.
4. Use the connection object to create a cursor object.

**CAUTION**

To use SSL to connect to the database, ensure that the Python interpreter is compiled in the mode of generating a dynamic link library (.so) file. You can perform the following steps to check the connection mode of the Python interpreter:

1. Run the **import ssl** command in the Python interpreter to import SSL.
2. Run the **ps ux** command to query the PID of the Python interpreter. Assume that the PID is **\*\*\*\*\***.
3. In the Python interpreter CLI, run the **pmap -p \*\*\*\*\* | grep ssl** command and check whether the command output contains the path related to **libssl.so**. If yes, the Python interpreter is compiled in dynamic link mode.

**Table 5-82** sslmode options

sslmode	Whether SSL Encryption Is Enabled	Description
disable	No	SSL connection is not enabled.
allow	Possible	If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.
prefer	Possible	If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.
require	Yes	SSL connection is required, but only data is encrypted. However, authenticity of the database server will not be verified.
verify-ca	Yes	SSL connection is required, and the validity of the server CA must be verified.
verify-full	Yes	The SSL connection must be enabled, which is not supported by GaussDB currently.

**Step 4** Run SQL statements.

1. Construct an operation statement and use `%s` as a placeholder. During execution, `psycopg2` will replace the placeholder with the parameter value. You can add the `RETURNING` clause to obtain the automatically generated column values.

2. Use the `cursor.execute` method to execute one row of SQL statement, and use the `cursor.executemany` method to execute multiple rows of SQL statements.

**Step 5** Process the result set.

1. `cursor.fetchone()`: fetches the next row in a query result set and returns a sequence. If no data is available, null is returned.
2. `cursor.fetchall()`: fetches all remaining rows in a query result and returns a list. An empty list is returned when no rows are available.

 **NOTE**

For database-specific data types, such as `tinyint`, the corresponding columns in the query result are character strings.

**Step 6** Close the connection.

After you complete required data operations in a database, close the database connection. Call the close method such as `connection.close()` to close the connection.

 **CAUTION**

This method closes the database connection and does not automatically call `commit()`. If you just close the database connection without calling `commit()` first, changes will be lost.

----End

## 5.6.3 Examples: Common Operations

```
import psycopg2
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

# Create a connection object.
conn=psycopg2.connect(database="database", user=user, password=password, host="localhost", port=port)
cur=conn.cursor() # Create a pointer object.

# Create a connection object (using SSL).
conn = psycopg2.connect(dbname="database", user=user, password=password, host="localhost", port=port,
    sslmode="verify-ca", sslcert="client.crt", sslkey="client.key", sslrootcert="cacert.pem")
Note: If sslcert, sslkey, and sslrootcert are not set, the following files in the .postgresql directory of the
current user are used by default: client.crt, client.key, and root.crt.

# Create a table.
cur.execute("CREATE TABLE student(id integer,name varchar,sex varchar);")

# Insert data.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(1,'Aspirin','M'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(2,'Taxol','F'))
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(3,'Dixheral','M'))

# Insert data in batches.
stus = ((4,'John','M'),(5,'Alice','F'),(6,'Peter','M'))
cur.executemany("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",stus)
```

```
# Obtain the result.
cur.execute('SELECT * FROM student')
results=cur.fetchall()
print (results)

# Perform a commit.
conn.commit()

# Insert a data record.
cur.execute("INSERT INTO student(id,name,sex) VALUES(%s,%s,%s)",(7,'Lucy','F'))

# Perform a rollback.
conn.rollback()

# Close the connection.
cur.close()
conn.close()

# Common connection modes of psycopg2.
conn = psycopg2.connect(dbname="dbname", user=user, password=password, host="localhost", port=port)
conn = psycopg2.connect(f"dbname={dbname} user={user} password={password} host=localhost port={port}")

# Use logs.
import logging
import psycopg2
from psycopg2.extras import LoggingConnection
import os

# Obtain the username and password from environment variables.
user = os.getenv('user')
password = os.getenv('password')

logging.basicConfig(level=logging.DEBUG) # Log level
logger = logging.getLogger(__name__)

db_settings = {
    "user": user,
    "password": password,
    "host": "localhost",
    "database": "dbname",
    "port": port
}

# LoggingConnection records all SQL statements by default. You can filter unnecessary or sensitive SQL
statements. Example of filtering password-related SQL statements:
class SelfLoggingConnection(LoggingConnection):

    def filter(self, msg, curs):
        if db_settings['password'] in msg.decode():
            return b'queries containing the password will not be recorded'
        return msg

conn = psycopg2.connect(connection_factory=SelfLoggingConnection, **db_settings)
conn.initialize(logger)
```

**CAUTION**

- By default, **LoggingConnection** records all SQL information and does not anonymize sensitive information. You can use the filter function to define the output SQL content.
- The log function is an additional function provided by psycopg2 for developers to explicitly debug full SQL statements. By default, the log function is not used. This function prints SQL statements before psycopg2 executes SQL statements. However, the SQL statements can be printed only when the log level is **DEBUG**. This function is not a default function. It is used only when there are special requirements. You are advised not to use this function unless there are special requirements. For details, visit <https://www.psycopg.org/docs/extras.html?highlight=loggingconnection>.

## 5.6.4 Psycopg API Reference

Psycopg APIs are a set of methods provided for users. This section describes some common APIs.

### 5.6.4.1 psycopg2.connect()

#### Description

This method creates a database session and returns a new connection object.

#### Prototype

```
import os
conn=psycopg2.connect(dbname="test",user=os.getenv('user'),password=os.getenv('password'),host="127.0.0.1",port="5432")
```

#### Parameters

**Table 5-83** psycopg2.connect parameters

Keyword	Description
dbname	Database name.
user	Username.
password	Password.
host	IP address of the database. You can specify multiple IP addresses and separate them with commas (,). By default, the Unix domain socket is used.
port	Connection port number. The default value is <b>5432</b> . If the host has multiple IP addresses and the port numbers are the same, specify one port number. Otherwise, the port numbers must correspond to the IP addresses one by one and are separated by commas (,).

Keyword	Description
sslmode	SSL mode, which is used for SSL connection.
sslcert	Path of the client certificate, which is used for SSL connection.
sslkey	Path of the client key, which is used for SSL connection.
sslrootcert	Path of the root certificate, which is used for SSL connection.
hostaddr	IP address of the database.
connect_timeout	Client connection timeout interval.
client_encoding	Encoding format of the client.
application_name	Value of <b>application_name</b> .
fallback_application_name	Rollback value of <b>application_name</b> .
keepalives	Specifies whether to enable the TCP connection on the client. The value can be <b>1</b> (enabled) or <b>0</b> (disabled). The default value is <b>1</b> . If the Unix domain socket connection is used, ignore this parameter.
options	Specifies the command line options sent to the server when the connection starts.
keepalives_idle	Describes inactivity before keepalive messages are sent to the server. If keepalive messages are disabled, ignore this parameter.
keepalives_interval	Specifies whether keepalive messages that are not confirmed by the server need to be resent. If keepalive messages are disabled, ignore this parameter.
keepalives_count	Specifies the number of TCP connections that may be lost before the client is disconnected from the server.
replication	Specifies that the connection uses the replication protocol instead of the common protocol.
requiressl	Supports the SSL mode.
sslcompression	Specifies the SSL compression. If this parameter is set to <b>1</b> , the data sent through the SSL connection is compressed. If this parameter is set to <b>0</b> , compression is disabled. If no SSL connection is established, ignore this parameter.
sslcrl	Specifies the path of the CRL, which is used to check whether the SSL server certificate is available.
requirepeer	Specifies the OS username of the server.

Keyword	Description
target_session_attrs	<p>Specifies the type of the host to be connected. The connection is successful only when the host type is the same as the configured value. This parameter is verified only when multiple IP addresses are specified. The rules for setting <b>target_session_attrs</b> are as follows:</p> <ul style="list-style-type: none"> <li>• <b>any</b>: All types of hosts can be connected.</li> <li>• <b>read-write</b>: The connection is set up only when the connected host is readable and writable.</li> <li>• <b>read-only</b>: Only readable hosts can be connected.</li> <li>• <b>primary</b> (default value): Only the primary node in the primary/standby systems can be connected.</li> <li>• <b>standby</b>: Only the standby node in the primary/standby systems can be connected.</li> <li>• <b>prefer-standby</b>: The system first attempts to find a standby node for connection. If all hosts in the <b>hosts</b> list fail to be connected, try the <b>any</b> mode.</li> </ul>

## Return Values

Connection object (for connecting to a database instance)

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.2 connection.cursor()

## Function

This method returns a new cursor object.

## Prototype

```
cursor(name=None, cursor_factory=None, scrollable=None, withhold=False)
```

## Parameter

**Table 5-84** connection.cursor parameters

Keyword	Description
name	Cursor name. The default value is <b>None</b> .
cursor_factory	Creates a non-standard cursor. The default value is <b>None</b> .
scrollable	Sets the SCROLL option. The default value is <b>None</b> .

Keyword	Description
withhold	Sets the HOLD option. The default value is <b>False</b> .

## Return Value

Cursor object (used for cursors that are programmed using Python in the entire database)

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.3 cursor.execute(query,vars\_list)

## Function

This method executes the parameterized SQL statements (that is, placeholders instead of SQL literals). The pycogp2 module supports placeholders marked with %s.

## Prototype

```
cursor.execute(query,vars_list)
```

## Parameters

**Table 5-85** cursor.execute parameters

Keyword	Description
query	SQL statement to be executed.
vars_list	Variable list, which matches the %s placeholder in the query.

## Return Value

None

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.4 cursor.executemany(query,vars\_list)

## Function

This method executes an SQL command against all parameter sequences or mappings found in the sequence SQL.

## Prototype

```
curosr.executemany(query,vars_list)
```

## Parameter

**Table 5-86** curosr.executemany parameters

Keyword	Description
query	SQL statement that you want to execute.
vars_list	Variable list, which matches the %s placeholder in the query.

## Return Value

None

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.5 connection.commit()

## Description

This method commits the currently pending transaction to the database.

---

 **CAUTION**

By default, Psycopg opens a transaction before executing the first command. If **commit()** is not called, the effect of any data operation will be lost.

---

## Prototype

```
connection.commit()
```

## Parameters

None

## Return Values

None

## Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.6 connection.rollback()

#### Function

This method rolls back the current pending transaction.

---

**CAUTION**

If you close the connection using **close()** but do not commit the change using **commit()**, an implicit rollback will be performed.

---

#### Prototype

```
connection.rollback()
```

#### Parameter

None

#### Return Value

None

#### Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.7 cursor.fetchone()

#### Function

This method extracts the next row of the query result set and returns a tuple.

#### Prototype

```
cursor.fetchone()
```

#### Parameter

None

#### Return Value

A single tuple is the first result in the result set. If no more data is available, **None** is returned.

#### Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.8 cursor.fetchall()

#### Function

This method obtains all the (remaining) rows of the query result and returns them as a list of tuples.

#### Prototype

```
cursor.fetchall()
```

#### Parameter

None

#### Return Value

Tuple list, which contains all results of the result set. An empty list is returned when no rows are available.

#### Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.9 cursor.close()

#### Function

This method closes the cursor of the current connection.

#### Prototype

```
cursor.close()
```

#### Parameter

None

#### Return Value

None

#### Examples

For details, see [Examples: Common Operations](#).

### 5.6.4.10 connection.close()

#### Function

This method closes the database connection.

---

 **CAUTION**

This method closes the database connection and does not automatically call **commit()**. If you just close the database connection without calling **commit()** first, changes will be lost.

---

## Prototype

```
connection.close()
```

## Parameter

None

## Return Value

None

## Examples

For details, see [Examples: Common Operations](#).

# 5.7 Development Based on the Go Driver

## 5.7.1 Setting Up the Go Driver Environment

### Go Driver Package

Obtain the package from the release package **GaussDB-Kernel\_Database version number\_OS version number\_64bit\_Go.tar.gz**. Decompress the package to obtain the Go driver source code package.

---

**NOTICE**

The Go driver package provided by the database depends on Go 1.13 or later.

---

### Environment Class

- **Configure the Go environment.**

You need to configure the following parameters in the environment variables:

- **GO111MODULE**: Set **GO111MODULE** to **on** when installing the Go driver by importing a file online. If you do not want to reconstruct the **go mod** project, set **GO111MODULE** to **off** and manually download the dependency package. The dependency package must be at the same level as the driver root directory and service code.
- **GOPROXY**: When importing data online, you need to configure the path that contains the Go driver package.

- You can configure other Go environment variables based on your scenario parameters.

Run the **go env** command to view the Go environment variable configuration result and check whether the Go version is 1.13 or later.

- **Install the Go driver.**

- Download the Go driver package to the local host. The Go driver repository address is <https://open.codehub.huawei.com/OpenSourceCenter/openGauss-connector-go-pq/>.
- Go to the root path of the Go driver code and run the **go mod tidy** command to download related dependencies. You need to configure **GOPATH=\${Path for storing the Go driver dependency package}** in the environment variables.
- If the dependencies have been downloaded to the local host, you can add a line "Replace the Go driver package with the local Go driver package address through replace" to **go.mod**, indicating that all import Go driver packages in the code are stored in the local path and the dependencies are not downloaded from the proxy.

---

 **CAUTION**

When you run the **go mod tidy** command to download dependencies, some of them may be downloaded as an earlier version. If the earlier version has vulnerabilities, you can change the dependency version in the **go.mod** file and update the dependency to the version after the vulnerability is fixed to avoid risks.

---

## Driver Class

When creating a database connection, you need to enter the database driver name **gaussdb**.

---

**NOTICE**

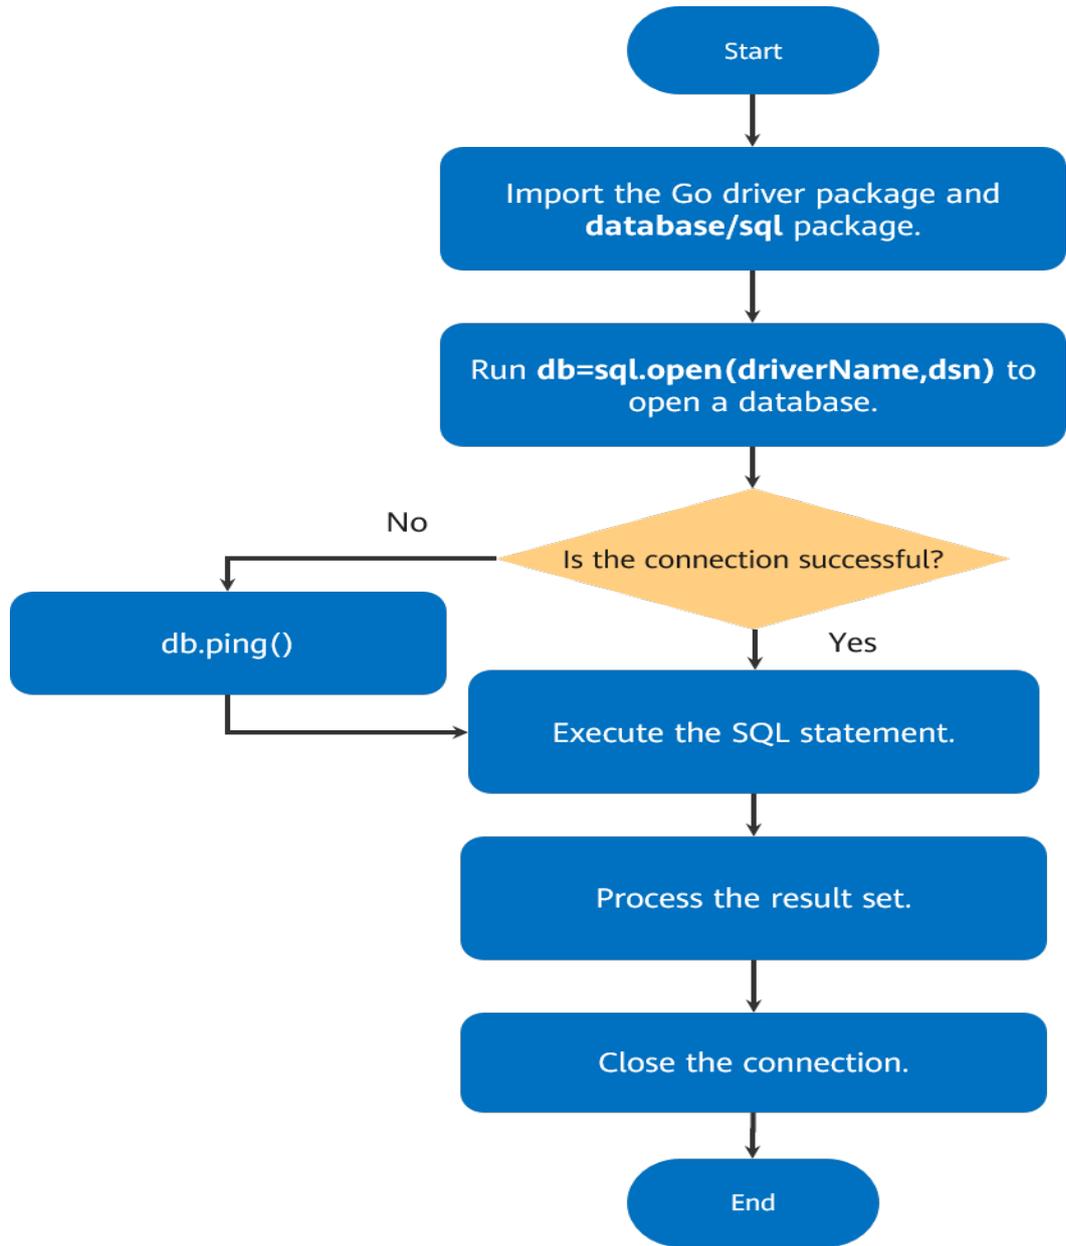

The Go driver provided by the database does not adapt to mature ORM frameworks (such as XORM) in the industry. As such, the driver name input during database connection creation must be compatible with Postgres and PostgreSQL. The Go driver of the database cannot coexist with that of PostgreSQL.

---

## 5.7.2 Development Process

The Go driver of the database complies with the rule of the Go language third-party library. You only need to import the driver to the application program and save the driver code in the directory specified by **GOPATH**.

Figure 5-5 Application development process based on Go

### 5.7.3 Connecting to a Database

When you call the standard SQL API open of the Go language to create a database connection, a connected object is returned to transfer the driver name and description string.

#### Function Prototype

The Go driver provides the following method to generate a database connection object:

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Parameter description:

- **driverName** indicates the driver name. The database driver name is **opengauss**, which is compatible with Postgres.
- **dataSourceName** indicates the data source to be connected. The value can be in DSN or URL format.
  - DSN format: key1 = value1 key2 = value2... Different groups of keywords are separated by space. The space on the left and right of the equal sign (=) is optional.
  - URL format: driverName://[userspec@][hostspec][/dbname][?paramspec]

In the preceding information, **driverName** indicates the driver name. The database driver name is "opengauss", which is compatible with "postgres" and "postgresql".

**userspec** indicates user[:password]. When a URL is used for connection, the password cannot contain separators in the URL string. If the password contains separators, the DSN format is recommended.

**hostspec** indicates [host][:port][, ...].

**dbname** indicates the database name. You are not allowed to remotely log in to the database as an initial user.

**paramspec** indicates name=value[&...].

**NOTICE**

- In the DSN format, if there are multiple IP addresses:
  - When the value of **num(ip)** is the same as that of **num(port)**, the IP address matches the port number.
  - When the value of **num(ip)** is greater than that of **num(port)**, the IP address that cannot match the port number matches the first port number. For example, the matching condition of **host = ip1, ip2, ip3 port = port1, port2** is **ip1:port1, ip2:port2, ip3:port1**.
  - When the value of **num(ip)** is smaller than that of **num(port)**, the extra port numbers are discarded. For example, the matching condition of **host = ip1, ip2, ip3 port = port1, port2, port3, port4** is **ip1:port1, ip2:port2, ip3:port3**.
- In the URL format, if there are multiple IP addresses:
  - In the URL, *ip:port* must appear in pairs, that is, the value of **num(ip)** is the same as that of **num(port)**. Use commas (,) to separate multiple pairs.
  - The URL contains only multiple IP addresses. The port number is specified by the environment variable or uses the default value **5432**.

**Parameters**

**Table 5-87** Database connection parameters

Parameter	Description
-----------	-------------

host	IP address of the host server, which can also be specified by the environment variable <code>PGHOST</code>
port	Port number of the host server, which can also be specified by the environment variable <code>PGPORT</code>
dbname	Database name, which can also be specified by the environment variable <code>PGDATABASE</code>
user	Username to be connected, which can also be specified by the environment variable <code>PGUSER</code>
password	Password of the user to be connected
connect_timeout	Timeout interval for connecting to the server, which can also be specified by the environment variable <code>PGCONNECT_TIMEOUT</code>
sslmode	SSL encryption mode, which can also be specified by the environment variable <code>PGSSLMODE</code> Value range: <ul style="list-style-type: none"><li>• <b>disable</b>: SSL connection is disabled.</li><li>• <b>allow</b>: If the database server requires SSL connection, SSL connection can be enabled. However, authenticity of the database server will not be verified.</li><li>• <b>prefer</b>: If the database supports SSL connection, SSL connection is preferred. However, authenticity of the database server will not be verified.</li><li>• <b>require</b>: SSL connection is required and data is encrypted. However, authenticity of the database server will not be verified.</li><li>• <b>verify-ca</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA is verified.</li><li>• <b>verify-full</b>: SSL connection is required, and whether the server certificate is issued by a trusted CA and whether the host name of the server is the same as that in the certificate are verified.</li></ul>
sslkey	Key location of the client certificate. If SSL connection is required and this parameter is not specified, you can set the environment variable <code>PGSSLKEY</code> to specify the location.
sslcert	File name of the client SSL certificate, which can also be specified by the environment variable <code>PGSSLCERT</code>
sslrootcert	Name of the file that contains the SSL CA certificate, which can also be specified by the environment variable <code>PGSSLROOTCERT</code>
sslcrll	File name of the SSL CRL. If a certificate listed in this file exists, the server certificate authentication will be rejected and the connection will fail. The value can also be specified by the environment variable <code>PGSSLCRL</code> .

sslpassword	<p>Passphrase used to decrypt a key into plaintext. If this parameter is specified, the SSL key is an encrypted file. Currently, the SSL key supports DES encryption and AES encryption.</p> <p><b>NOTE</b> The DES encryption algorithm has lower security and poses security risks. Therefore, you are advised to use a more secure encryption algorithm.</p>
disable_prepared_binary_result	<p>The value of this parameter is a string. If it is set to <b>yes</b>, the connection should not use the binary format when the query results are received from prepared statements. This parameter is used only for debugging.</p> <p>Value range: <b>yes</b> and <b>no</b>.</p>
binary_parameters	<p>Specifies whether <b>[]byte</b> is always sent in binary format. The value is a string. Value range: <b>yes</b> and <b>no</b>. If this parameter is set to <b>yes</b>, you are advised to bind parameters based on <b>[]byte</b> to reduce internal type conversion.</p>
target_session_attrs	<p>Connection type of the database, which can also be specified by the environment variable <i>PGTARGETSESSIONATTRS</i>. This parameter is used to identify the primary and standby nodes. There are six value options, namely, <b>any</b>, <b>master</b>, <b>slave</b>, <b>preferSlave</b>, <b>read-write</b>, and <b>read-only</b>. The default value is <b>any</b>.</p> <ul style="list-style-type: none"> <li>• <b>any</b>: attempts to connect to any DN in the URL connection string.</li> <li>• <b>master</b>: attempts to connect to a primary node in the URL connection string. If the primary node cannot be found, an exception is thrown.</li> <li>• <b>slave</b>: attempts to connect to a standby node in the URL connection string. If the standby node cannot be found, an exception is thrown.</li> <li>• <b>preferSlave</b>: attempts to connect to a standby DN (if available) in the URL connection string. Otherwise, it connects to the primary DN.</li> <li>• <b>read-write</b>: specifies that only the primary node can be connected.</li> <li>• <b>read-only</b>: specifies that only the standby node can be connected.</li> </ul>
loggerLevel	<p>Log level, which is used to print debugging information. The value can also be specified by the environment variable <i>PGLOGGERLEVEL</i>.</p> <p>The value can be <b>trace</b>, <b>debug</b>, <b>info</b>, <b>warn</b>, <b>error</b>, or <b>none</b>, in descending order of priority.</p>
application_name	<p>Name of the Go driver that is being connected. The default value is <b>go-driver</b>. You are advised not to configure this parameter.</p>

RuntimeParams	Runtime parameter to be set to the session default value on a connection, for example, <b>search_path</b> , <b>application_name</b> , or <b>timezone</b> . For details about the parameters, see the default settings of the client connection. You can run the <b>SHOW</b> command to check whether the parameters are set successfully.
enable_ce	Encrypted database function. <b>enable_ce=1</b> indicates that the Go driver supports the basic capability of encrypted equality query.

### Example 1:

// A single IP address and a single port (ip:port) are used as an example. In this example, the username and password are stored in environment variables. Before running this example, set environment variables in the local environment (set the environment variable name based on the actual situation).

```
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
    password := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + password + "
    dbname=postgres sslmode=disable" // DSN connection string
    //str := "opengauss://" + username + ":" + password + "@" + hostip + ":" + port + "/postgres?
    sslmode=disable" // URL connection string
    db, err := sql.Open("opengauss", str)
    if err != nil {
        log.Fatal(err)
    }
    defer db.Close()

    err = db.Ping()
    if err != nil {
        log.Fatal(err)
    }

    sqls := []string {
        "drop table if exists testExec",
        "create table testExec(f1 int, f2 varchar(20), f3 number, f4 timestamptz, f5 boolean)",
        "insert into testExec values(1, 'abcdefg', 123.3, '2022-02-08 10:30:43.31 +08', true)",
        "insert into testExec values(:f1, :f2, :f3, :f4, :f5)",
    }

    inF1 := []int{2, 3, 4, 5, 6}
    inF2 := []string{"hello world", "Huawei", "Beijing 2022 Winter Olympics", "nanjing", "Research Center"}
    inF3 := []float64{641.43, 431.54, 5423.52, 665537.63, 6503.1}
    inF4 := []time.Time{
        time.Date(2022, 2, 8, 10, 35, 43, 623431, time.Local),
        time.Date(2022, 2, 10, 19, 11, 54, 353431, time.Local),
        time.Date(2022, 2, 12, 6, 11, 15, 636431, time.Local),
        time.Date(2022, 2, 14, 4, 51, 22, 747653, time.Local),
        time.Date(2022, 2, 16, 13, 45, 55, 674636, time.Local),
    }
    inF5 := []bool{false, true, false, true, true}

    for _, s := range sqls {
        if strings.Contains(s, ":f") {
            for i, _ := range inF1 {
                _, err := db.Exec(s, inF1[i], inF2[i], inF3[i], inF4[i], inF5[i])
                if err != nil {

```

```
    log.Fatal(err)
  }
} else {

}
```

## 5.7.4 Connecting to a Database (Using SSL)

The Go driver supports SSL connections to the database. After the SSL mode is enabled, if the Go driver connects to the database server in SSL mode, the Go driver uses the standard TLS 1.3 protocol by default, and the TLS version must be 1.2 or later. This section describes how applications configure the client in SSL mode through the Go driver. For details about how to configure the server, contact the administrator. To use the method described in this section, you must have the server certificate, client certificate, and private key files. For details on how to obtain these files, see related documents and commands of OpenSSL.

### NOTE

In SSL-based certificate authentication mode, you do not need to specify the user password in the connection string.

## Configuring the Client

Upload the **client.key**, **client.crt**, and **ca-cert.pem** files generated during server configuration to the client. For details about server configuration, contact the administrator.

### Example 1:

```
// Mutual authentication is used as an example. In this example, the username and password are stored in  
// environment variables. Before running this example, set environment variables in the local environment (set  
// the environment variable name based on the actual situation).  
func main() {  
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment  
    // variable.  
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment  
    // variable.  
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the  
    // environment variable.  
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the  
    // environment variable.  
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the  
    // environment variable.  
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "  
    sslcert=certs/client.crt sslkey=certs/client.key sslpassword=" + sslpasswd  
    parameters := []string {  
        "sslmode=require",  
        "sslmode=verify-ca sslrootcert=certs/ca-cert.pem",  
    }  
  
    for _, param := range parameters {  
        db, err := sql.Open("opengauss", dsnStr+param)  
        if err != nil {  
            log.Fatal(err)  
        }  
    }  
  
    var f1 int  
    err = db.QueryRow("select 1").Scan(&f1)  
    if err != nil {  
        log.Fatal(err)  
    } else {  
        fmt.Printf("RESULT: select 1: %d\n", f1)  
    }  
}
```

```
db.Close()
}
}
```

### Example 2:

```
// For example, verify sslpassword. In this example, the username and password are stored in environment
// variables. Before running this example, set environment variables in the local environment (set the
// environment variable name based on the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    // variable.
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    // variable.
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
    // environment variable.
    passwd := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
    // environment variable.
    dsnStr := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
    dbname=postgres"
    sslpasswd := os.Getenv("GOSSLPASSWD") // GOSSLPASSWD indicates the passphrase written into the
    // environment variable.
    connStrs := []string {
        " sslmode=verify-ca sslcert=certs/client_rsa.crt sslkey=certs/client_rsa.key sslpassword=" + sslpasswd + "
        sslrootcert=certs/cacert_rsa.pem",
        " sslmode=verify-ca sslcert=certs/client_ecdsa.crt sslkey=certs/client_ecdsa.key sslpassword=" + sslpasswd +
        " sslrootcert=certs/cacert_ecdsa.pem",
    }
    for _, connStr := range connStrs {
        db, err := sql.Open("opengauss", dsnStr + connStr)
        if err != nil {
            log.Fatal(err)
        }
        var f1 int
        err = db.QueryRow("select 1").Scan(&f1)
        if err != nil {
            if !strings.HasPrefix(err.Error(), "connect failed.") {
                log.Fatal(err)
            }
        }
    }
    db.Close()
}
```

## 5.7.5 Go APIs

### 5.7.5.1 sql.Open

The following table describes sql.Open.

Method	Description	Return Value
Open(driverName, dataSourceName string)	Opens a database based on a specified database driver and the dedicated data source of the driver.	*DB and error

For details about the **driverName** and **dataSourceName** parameters, see [Connecting to a Database](#).

### 5.7.5.2 type DB

The following table describes type DB.

Method	Description	Return Value
(db *DB)Begin()	Starts a transaction. The isolation level of the transaction is determined by the driver.	*Tx and error
(db *DB)BeginTx(ctx context.Context, opts *TxOptions)	Starts a transaction with a specified transaction isolation level. A specified context is used until the transaction is committed or rolled back. If the context is canceled, the SQL package rolls back the transaction.	*Tx and error
(db *DB)Close()	Closes the database and releases all the opened resources.	error
(db *DB)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(db *DB)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(db *DB)Ping()	Checks whether the database connection is still valid and establishes a connection if necessary.	error
(db *DB)PingContext(ctx context.Context)	Checks whether the database connection is still valid in a specified context and establishes a connection if necessary.	error
(db *DB)Prepare(query string)	Creates a prepared statement for subsequent queries or executions.	*Stmt and error
(db *DB)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions in a specified context.	*Stmt and error
(db *DB)Query(query string, args ...interface{})	Executes a query and returns multiple rows of data.	*Rows and error
(db *DB)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query and returns multiple rows of data in a specified context.	*Rows and error

(db *DB)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(db *DB)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row

 **NOTE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in **type Rows**. If the result is not obtained through the Next() API, unexpected errors may occur.

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> .
opts	Transaction isolation level and transaction access mode. The transaction isolation level (opts.Isolation) supports sql.LevelReadUncommitted, sql.LevelReadCommitted, sql.LevelRepeatableRead, and sql.LevelSerializable. The transaction access mode (opts.ReadOnly) can be true (read only) or false (read write).

## Examples

```
// In this example, the username and password are stored in environment variables. Before running this
// example, set environment variables in the local environment (set the environment variable names based on
// the actual situation).
func main() {
    hostip := os.Getenv("GOHOSTIP") // GOHOSTIP indicates the IP address written into the environment
    port := os.Getenv("GOPORT") // GOPORT indicates the port number written into the environment
    username := os.Getenv("GOUSRNAME") // GOUSRNAME indicates the username written into the
    password := os.Getenv("GOPASSWD") // GOPASSWD indicates the user password written into the
```

```

environment variable.
str := "host=" + hostip + " port=" + port + " user=" + username + " password=" + passwd + "
dbname=postgres sslmode=disable"
db, err:= sql.Open("opengauss", str)
if err != nil {
    log.Fatal(err)
}
defer db.Close()

err = db.Ping()
if err != nil {
    log.Fatal(err)
}

    _ err = db.Exec("drop table if exists testuser.test")
    _ err = db.Exec("create table test(id int, name char(10))")

    // Binding by location
    _ err = db.Exec("insert into test(id, name) values(:1, :2)", 1, "Zhang San")
if err != nil {
    log.Fatal(err)
}

    // Binding by name
    _ err = db.Exec("insert into test(id, name) values(:id, :name)", sql.Named("id", 1), sql.Named("name",
"Zhang San"))
if err != nil {
    log.Fatal(err)
}
}

```

### 5.7.5.3 type Stmt

The following table describes type Stmt.

Method	Description	Return Value
(s *Stmt)Close()	Closes a specified prepared statement.	error

<code>(s *Stmt)Exec(args ...interface{})</code>	Executes a prepared statement with specified parameters and returns a <b>Result</b> value. The Prepare-Bind-Execute (PBE) feature is supported. PBE is a method of sending and executing queries. The CN can receive PBE packets through complex query protocols to execute statements.	Result and error
---	---	------------------

	<p><b>NOTE</b></p> <ol style="list-style-type: none"><li>1. The placeholder of a precompiled statement can be a dollar sign (\$) or a question mark (?).</li><li>2. The number of placeholders in a precompiled statement is determined by the database. When the number of table columns exceeds the database limit or does not match the number of current table columns, the server returns an error.</li><li>3. Batch PBE processing supports addition, deletion, and modification. During the batch operation, the maximum length of a U packet is limited to 1 GB minus 1 byte, that is, 0x3fffffff bytes. If the length exceeds the limit, "bind message length XXX too long. This can be caused by very large or incorrect length specifications on InputStream parameters" will be reported.</li><li>4. When a record is inserted, the performance of PBE deteriorates greatly compared with that of a single-query statement (conn.simpleExec). Therefore, you are advised to use single-query statements, rather than the PBE statement.</li><li>5. After the underlying error processing of the driver is reconstructed, the PBE performance decreases by less than 5%.</li></ol>	
--	---	--

(s *Stmt)ExecContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns a <b>Result</b> value.	Result and error
(s *Stmt)Query(args ...interface{})	Executes a prepared statement with specified parameters and returns <b>*Rows</b> as the query result.	*Rows and error
(s *Stmt)QueryContext(ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns <b>*Rows</b> as the query result.	*Rows and error
(s *Stmt)QueryRow(args ...interface{})	Executes a prepared statement with specified parameters and returns <b>*Row</b> as the result.	*Row
(s *Stmt)QueryRowContext (ctx context.Context, args ...interface{})	Executes a prepared statement with specified parameters in a specified context and returns <b>*Row</b> as the result.	*Row

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> in section "type DB."

### NOTE

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in [type Rows](#). If the result is not obtained through the Next() API, unexpected errors may occur.

### 5.7.5.4 type Tx

The following table describes type Tx.

Method	Description	Return Value
(tx *Tx)Commit()	Commits a transaction.	error
(tx *Tx)Exec(query string, args ...interface{})	Performs an operation that does not return rows of data.	Result and error
(tx *Tx)ExecContext(ctx context.Context, query string, args ...interface{})	Performs an operation that does not return rows of data in a specified context.	Result and error
(tx *Tx)Prepare(query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.	*Stmt and error
(tx *Tx)PrepareContext(ctx context.Context, query string)	Creates a prepared statement for subsequent queries or executions. The returned statement is executed within a transaction and cannot be used when the transaction is committed or rolled back.  The specified context will be used in the preparation phase, not in the transaction execution phase. The statement returned by this method will be executed in the transaction context.	*Stmt and error
(tx *Tx)Query(query string, args ...interface{})	Executes a query that returns rows of data.	*Rows and error
(tx *Tx)QueryContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns rows of data in a specified context.	*Rows and error

(tx *Tx)QueryRow(query string, args ...interface{})	Executes a query that returns only one row of data.	*Row
(tx *Tx)QueryRowContext(ctx context.Context, query string, args ...interface{})	Executes a query that returns only one row of data in a specified context.	*Row
(tx *Tx) Rollback()	Rolls back a transaction.	error
(tx *Tx)Stmt(stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement.  Example: str, err := db.Prepare("insert into t1 values(:1, :2)") tx, err := db.Begin() res, err := tx.Stmt(str).Exec(1, "aaa")	*Stmt
(tx *Tx)StmtContext(ctx context.Context, stmt *Stmt)	Returns a transaction-specific prepared statement for an existing statement in a specified context.	*Stmt

 **NOTE**

1. The Query(), QueryContext(), QueryRow(), and QueryRowContext() APIs are usually used in query statements, such as SELECT. The Exec() API is used for executing operation statements. If query APIs are used to execute non-query statements, the execution result may be unexpected. Therefore, you are advised not to use the query APIs to execute non-query statements, such as UPDATE and INSERT.
2. The result of executing a query statement using a query API needs to be obtained through the Next() API in [type Rows](#). If the result is not obtained through the Next() API, unexpected errors may occur.

## Parameters

Parameter	Description
ctx	Specified context.
query	Executed SQL statement.
args	Parameter that needs to be bound to the executed SQL statement. Binding by location and binding by name are supported. For details, see <a href="#">Examples</a> in section "type DB."
stmt	Existing prepared statement, which is generally the prepared statement returned by the PREPARE statement

### 5.7.5.5 type Rows

The following table describes type Rows.

Method	Description	Return Value
(rs *Rows)Close()	Closes <b>Rows</b> to stop the iteration of the data set.	error
(rs *Rows)ColumnTypes()	Returns column information.	[]*ColumnType and error
(rs *Rows)Columns()	Returns the name of each column.	[]string and error
(rs *Rows)Err()	Returns any errors that occur during iteration.	error
(rs *Rows)Next()	Prepares the next data row to be read with the Scan method. If there is an additional result set, <b>true</b> is returned. Otherwise, <b>false</b> is returned.	boolean
(rs *Rows)Scan(dest ...interface{})	Copies the columns of the current iterated row of data to the value specified by <b>dest</b> .	error
(rs *Rows)NextResultSet()	Specifies whether there is an additional result set.	boolean

### Parameters

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

### 5.7.5.6 type Row

The following table describes type Row.

Method	Description	Return Value
(r *Row)Scan(dest ...interface{})	Copies the columns in the current row of data to the value specified by <b>dest</b> .	error
(r *Row)Err()	Returns errors that occur during execution.	error

## Parameter Description

Parameter	Description
dest	The column to be queried needs to be copied to the value specified by this parameter.

### 5.7.5.7 type ColumnType

The following table describes type ColumnType.

Method	Description	Return Value
(ci *ColumnType)DatabaseTypeName()	Returns the name of the column-type database system. If an empty string is returned, driver-type names are not supported.	error
(ci *ColumnType)DecimalSize()	Returns the scale and precision of the decimal type. If the value of <b>ok</b> is <b>false</b> , the specified type is unavailable or not supported.	precision, scale int64, ok boolean
(ci *ColumnType)Length()	Returns the length of the data column type. If the value of <b>ok</b> is <b>false</b> , the specified type does not have a length.	length int64, ok boolean
(ci *ColumnType)ScanType()	Returns a Go type that can be used for scanning by using Rows.Scan.	reflect.Type
(ci *ColumnType)Name()	Returns the name of a data column.	string

### 5.7.5.8 type Result

The following table describes type Result.

Method	Description	Return Value
(res Result)RowsAffected()	Returns the number of rows affected by the INSERT, DELETE, UPDATE, SELECT, MOVE, FETCH, and COPY operations.	int64 and error

## 5.8 ECPG-based Development

Embedded SQL C Preprocessor (ECPG) for GaussDB Kernel is an embedded SQL preprocessor for C programs. An embedded SQL program consists of code written in an ordinary programming language, in this case C, mixed with SQL commands in specially marked sections. To build the program, the source code (\*.pgc) is first passed through the embedded SQL preprocessor, which converts it to an ordinary C program (\*.c), and afterwards it can be processed by a C compiler. Converted ECPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the GaussDB Kernel server using the normal frontend-backend protocol.

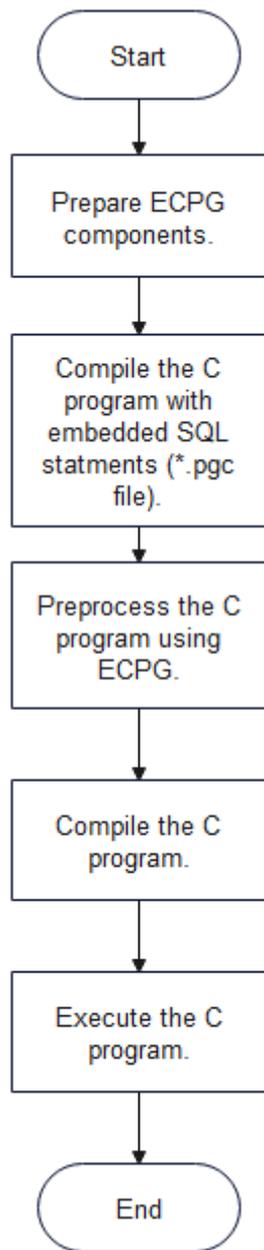

Programs written for the embedded SQL interface are normal C programs with special code inserted to perform database-related actions. This special code always has the form:

```
EXEC SQL ...;
```

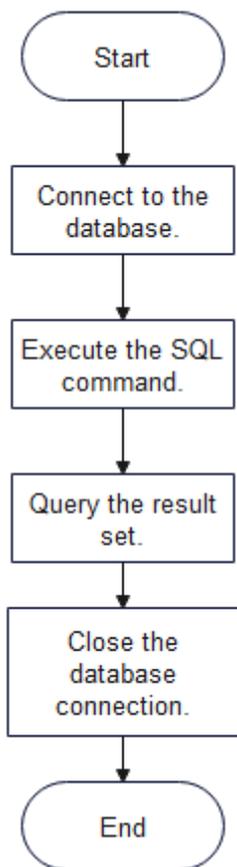

These statements syntactically take the place of a C statement. Depending on the particular statement, they can appear at the global level or within a function. Embedded SQL statements follow the case-sensitivity rules of normal SQL code, and allow nested C code-style comments (part of the SQL standard). However, the C part of the program follows the standards of the C program and does not support nested comments.

## 5.8.1 Development Process

Figure 5-6 ECPG-based development process

**Figure 5-7** Embedded SQL-C program development process

## 5.8.2 ecpg Components

- Platforms supported by ecpg

**Table 5-88** Platforms supported by ecpg

OS	Platform
EulerOS V2.0SP5	x86_64
EulerOS V2.0SP9	Arm64

- ecpg components
  - ecpg: an executable binary file used to preprocess C programs with embedded SQL statements.
  - libecpg: dynamic library provided by ecpg to implement connections, SQL statements, and transactions, including **libecpg.so**, **libecpg.so.6**, and **libecpg.so.6.4**. It is referenced by the **-lecpg** parameter during C program compilation and execution.
  - libpgtypes: dynamic library provided by ecpg for operating data of the numeric, date, timestamp, and interval types, including **libpgtypes.so**, **libecpg.so.6**, and **libecpg.so.6.4**. The library is referenced by the **-lpgtypes** parameter during C program compilation and execution.

- Paths for obtaining ecpg components
  - ecpg binary file: `$GAUSSHOME/bin`
  - Dynamic library on which ecpg depends: `$GAUSSHOME/lib`
  - Header file required by ecpg: `$GAUSSHOME/include/ecpg`

## 5.8.3 ecpg Preprocessing and Compiling

Prepare C programs with embedded SQL statements with the extension .pgc. ecpg converts them into C programs that can be compiled by the C compiler.

The generated C program is compiled into an executable file by the compiler. The executable file is run to enable the client program to access the database. For details, see [Examples](#).

- ecpg preprocessing and C compilation process
  - a. Preprocessing: `ecpg -I $GAUSSHOME/include -o test.c test.pgc`  
To execute ecpg preprocessing, run the following command:  
`ecpg [OPTION]...`  
The options are as follows:
    - **-o OUTFILE**: writes the result to OUTFILE, which is a C file.
    - **-I DIRECTORY**: path of the header file.
    - **-c**: automatically generates a C file.
    - **--version**: checks the current ecpg version.
  - b. Compilation: `gcc -I $GAUSSHOME/include/ecpg -I $GAUSSHOME/include -I $GAUSSHOME/include/postgresql/server/ -L $GAUSSHOME/lib -lecpg -lrt -lpq -lpqtypes -lpthread test_ecpg.c -o test_ecpg`
  - c. Execution: `./test`

### NOTICE

- ecpg is a compilation preprocessing tool. If an error message is displayed indicating that the related header file or function implementation cannot be found during preprocessing or compilation, you can specify the header file or link the dynamic library as required.
- ecpg requires compilation preprocessing tools such as GCC and ld. You are advised to use GCC 7.3.0.
- Other dynamic libraries and header files on which ecpg depends are usually stored in `$GAUSSHOME/include/libpq` and `$GAUSSHOME/include`.
- Common dynamic library dependencies during compilation include: `-lpq`, `-lpq_ce`, and `-lpthread`. If the libpq communications library is required during development, connect to `-lpq` and `-lpq_ce`. If the multi-thread connection is required during development, connect to `-lpthread`.

## 5.8.4 Managing Database Connections

This section describes how to establish and switch a database connection.

### 5.8.4.1 Connecting to a Database

Connect to a database.

```
EXEC SQL CONNECT TO target [AS connection-name] [USER user-name];
```

The target can be declared using the following methods. The italic part is a variable. Change it based on the actual situation.

- *dbname[@hostname][:port]*
- *tcp:postgresql://hostname[:port][/dbname][?options]*
- *unix:postgresql://hostname[:port][/dbname][?options]*
- An SQL string containing one of the above forms

There are also different ways to specify the username:

- *username/password*
- *username SQLIDENTIFIED BY password*
- *username USING password*

As mentioned above, the **username** and **password** parameters can be an SQL identifier, an SQL string, or a reference to a character variable.

**connection\_name** indicates the connection name. If a program uses only one connection, you can omit it. The most recently opened connection becomes the current connection.

Example:

```
#include <stdlib.h>
EXEC SQL CONNECT TO mydb@sql.mydomain.com;

EXEC SQL CONNECT TO unix:postgresql://sql.mydomain.com/mydb AS myconnection USER username;

EXEC SQL BEGIN DECLARE SECTION;
/* The values of target, user, and passwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
const char *target = getenv("EXAMPLE_TARGET_ENV");
const char *user = getenv("EXAMPLE_USERNAME_ENV");
const char *passwd = getenv("EXAMPLE_PASSWD_ENV");
EXEC SQL END DECLARE SECTION;
...
EXEC SQL CONNECT TO :target USER :user USING :passwd;
/* or EXEC SQL CONNECT TO :target USER :user/:passwd; */
```

For details about the complete example, see the connection syntax example in [CONNECT](#).

#### NOTE

- In the last form, character variables are referenced. For details about how to reference C variables in SQL statements, see [Host Variables](#).
- The format of the connection target is not described in the SQL standard. Therefore, to develop a portable application, you can use the method in the last example to encapsulate the connection target string into a variable.

**NOTICE**

- If **ip-port** is specified in the connection statement, username and password must be specified. This rule is determined by the GaussDB Kernel communication authentication. If **ip-port** is not specified, the local *\$PGPORT* (UDS) is used for communication.
- If the SSL protocol is used for connection, run the **tcp:postgresql://hostname[:port]/[dbname][?options]** command and set **sslmode** to **disable** \require in **options**.

### 5.8.4.2 Managing Connections

SQL statements in embedded SQL programs are by default executed on the current connection, that is, the most recently opened one. If an application needs to manage multiple connections, use either of the following methods:

- **Method 1: Explicitly select a connection for each SQL statement.**  
EXEC SQL AT connection-name SELECT ...;  
This method is particularly suitable if the application needs to use several connections in mixed order.  
If the application uses multiple threads of execution, they cannot share a connection concurrently. You must either explicitly control access to the connection (using mutexes) or use a connection for each thread.
- **Method 2: Execute a statement to switch the connection.**  
EXEC SQL SET CONNECTION connection-name;  
This method is particularly suitable if many statements are executed on the same connection.

An example of managing connections is as follows:

```
#include <stdio.h>
EXEC SQL BEGIN DECLARE SECTION;
char dbname[1024];
EXEC SQL END DECLARE SECTION;

int main()
{
    EXEC SQL CONNECT TO testdb1 AS con1 USER testuser;
    EXEC SQL CONNECT TO testdb2 AS con2 USER testuser;
    EXEC SQL CONNECT TO testdb3 AS con3 USER testuser;

    /* This query will be executed in the most recently opened database testdb3. */
    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb3)\n", dbname);

    /* Use AT to run a query in testdb2. */
    EXEC SQL AT con2 SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb2)\n", dbname);

    /* Switch to connection to testdb1. */
    EXEC SQL SET CONNECTION con1;

    EXEC SQL SELECT current_database() INTO :dbname;
    printf("current=%s (should be testdb1)\n", dbname);

    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output:

```
current=testdb3 (should be testdb3)
current=testdb2 (should be testdb2)
current=testdb1 (should be testdb1)
```

#### NOTICE

- In multi-thread mode, different threads cannot use the same connection name. The connection name of each thread must be unique.
- A connection must be established and closed in the same process or thread.

## 5.8.5 Running SQL Commands

The format of embedded SQL commands is EXEC SQL [Command]. In embedded SQL applications, you can run common standard SQL statements supported by GaussDB Kernel or extended SQL statements provided by ECPG. Currently, features or syntaxes such as stored procedures, packages, anonymous blocks, and flashback are not supported.

### 5.8.5.1 Executing SQL Statements

#### Step 1 Create a table.

```
EXEC SQL CREATE TABLE foo (a int, b varchar);
```

#### Step 2 Insert a row.

```
EXEC SQL INSERT INTO foo VALUES (5, 'abc');
```

#### Step 3 Delete a row.

```
EXEC SQL DELETE FROM foo WHERE a = 5;
```

#### Step 4 Update table data.

```
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
```

#### Step 5 Query data in a single row.

```
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
```

----End

A complete example is as follows:

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main ()
{
    ECPGdebug (1, stderr);

    EXEC SQL BEGIN DECLARE SECTION;
    int var_a;
    EXEC SQL END DECLARE SECTION;

    EXEC SQL CONNECT TO postgres;
    // Create a table.
    EXEC SQL CREATE TABLE foo (a int, b varchar);
    // Insert data.
    EXEC SQL INSERT INTO foo VALUES (5, 'abc');
    EXEC SQL INSERT INTO foo VALUES (6, 'def');
    EXEC SQL INSERT INTO foo VALUES (7, 'ghi');
```

```
// Delete a row.
EXEC SQL DELETE FROM foo WHERE a = 5;
// Update table data.
EXEC SQL UPDATE foo SET b = 'gdp' WHERE a = 7;
// Query table data in a single row.
EXEC SQL SELECT a INTO :var_a FROM foo WHERE b = 'def';
// Print the query results.
printf("select res is %d\n", var_a);

EXEC SQL DISCONNECT;

return 0;
}
```

### 5.8.5.2 Using Cursors

To retrieve a result set holding multiple rows, an application has to declare a cursor and fetch each row from the cursor.

**Step 1** Declare a cursor.

```
EXEC SQL DECLARE c CURSOR FOR select * from tb1;
```

**Step 2** Open a cursor.

```
EXEC SQL OPEN c;
```

**Step 3** Fetch a row of data from a cursor.

```
EXEC SQL FETCH 1 in c into :a, :str;
```

**Step 4** Close a cursor.

```
EXEC SQL CLOSE c;
```

----End

For details about how to use cursors, see [DECLARE](#). For details about the [FETCH](#) command, see [FETCH](#).

A complete example is as follows:

```
#include <string.h>
#include <stdlib.h>

int main(void)
{
    exec sql begin declare section;
        int *a = NULL;
        char *str = NULL;
    exec sql end declare section;

    int count = 0;
    exec sql connect to postgres ;
    exec sql set autocommit to off;
    exec sql begin;
    exec sql drop table if exists tb1;
    exec sql create table tb1(id int, info text);
    exec sql insert into tb1 (id, info) select generate_series(1, 100000), 'test';
    exec sql select count(*) into :a from tb1;
    printf ("a is %d\n", *a);
    exec sql commit;

    // Define a cursor.
    exec sql declare c cursor for select * from tb1;
    // Open the cursor.
    exec sql open c;
    exec sql whenever not found do break;
    while(1) {
        // Capture data.
        exec sql fetch 1 in c into :a, :str;
```

```
count++;
if (count == 100000) {
    printf("Fetch res: a is %d, str is %s", *a, str);
}
}
// Close the cursor.
exec sql close c;
exec sql set autocommit to on;
exec sql drop table tb1;
exec sql disconnect;

ECPGfree_auto_mem();
return 0;
```

### 5.8.5.3 Managing Transactions

In the default mode, statements are committed only when EXEC SQL COMMIT is issued. The embedded SQL interface also supports autocommit of transactions by executing the **EXEC SQL SET AUTOCOMMIT TO ON** statement. In autocommit mode, each command is automatically committed unless it is inside an explicit transaction block. This mode can be explicitly turned off by using **EXEC SQL SET AUTOCOMMIT TO OFF**.

Common transaction management commands are as follows:

- **EXEC SQL COMMIT**: commits an ongoing transaction.
- **EXEC SQL ROLLBACK**: rolls back an ongoing transaction.
- **EXEC SQL SET AUTOCOMMIT TO ON**: enables the autocommit mode.
- **SET AUTOCOMMIT TO OFF**: disables the autocommit mode. This is the default mode.

### 5.8.5.4 Prepared Statements

Prepared statements can be used when the value passed to an SQL statement is unknown at compile time or the same statement will be used multiple times.

- Statements are prepared using the **PREPARE** command. For the values that are not known yet, use the placeholder (?).  
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg\_database WHERE oid = ?";
- If a statement returns a single row, the application can call EXECUTE after PREPARE to execute the statement, supplying the actual values for the placeholders with a USING clause:  
EXEC SQL EXECUTE stmt1 INTO :dboid, :dbname USING 1;
- If a statement returns multiple rows, the application can use a cursor declared based on the prepared statement. To bind input parameters, the cursor must be opened with a USING clause:  
EXEC SQL PREPARE stmt1 FROM "SELECT oid, datname FROM pg\_database WHERE oid > ?";  
EXEC SQL DECLARE foo\_bar CURSOR FOR stmt1;  
/\* When the end of the result set is reached, exit the while loop. \*/  
EXEC SQL WHENEVER NOT FOUND DO BREAK;  
EXEC SQL OPEN foo\_bar USING 100;  
...  
while (1)  
{  
 EXEC SQL FETCH NEXT FROM foo\_bar INTO :dboid, :dbname;  
 ...  
}  
EXEC SQL CLOSE foo\_bar;
- When a prepared statement is no longer needed, it should be deallocated.

```
EXEC SQL DEALLOCATE PREPARE name;
```

## 5.8.5.5 Embedded SQL Commands

### 5.8.5.5.1 ALLOCATE DESCRIPTOR

#### Function

Allocates a newly named SQL descriptor area.

#### Syntax

```
ALLOCATE DESCRIPTOR name
```

#### Parameters

**name**

Name of an SQL descriptor, case sensitive. This can be an SQL identifier or a host variable.

#### Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;
```

#### Helpful Links

[DEALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), [SET DESCRIPTOR](#)

### 5.8.5.5.2 CONNECT

#### Description

Establishes a connection between the client and the SQL server.

#### Syntax

```
CONNECT TO connection_target [ AS connection_name ] [ USER connection_user ]
```

#### Parameters

- **connection\_target**  
Specifies the target server to be connected in one of the following formats:
  - [ *database\_name* ] [ @ *host* ] [ : *port* ]: connection over TCP/IP.
  - unix: postgresql://*host* [ : *port* ] / [ *database\_name* ] [ ? *connection\_option* ]: connection over Unix domain sockets.
  - tcp: postgresql://*host* [ : *port* ] / [ *database\_name* ] [ ? *connection\_option* ]: connection over TCP/IP.
  - **SQL string constant**: one of the preceding forms.
- **connection\_name**  
An optional identifier used for the connection, which can be referenced in other commands. It can be an SQL identifier or a host variable.

- **connection\_user**

Username for database connection.

You can use *user\_name/password*, *user\_name SQLIDENTIFIED BY password*, or *user\_name USING password* to specify the username and password.

The username and password can be SQL identifiers, string constants, or host variables.

 **NOTE**

In the preceding parameters, the information in italics refers to variables. Replace them based on the actual situation.

## Examples

Here are several variants of specifying connection parameters:

```
EXEC SQL CONNECT TO "connectdb" AS main;
EXEC SQL CONNECT TO "connectdb" AS second;
EXEC SQL CONNECT TO 'connectdb' AS main;
EXEC SQL CONNECT TO REGRESSDB1 as main;
EXEC SQL CONNECT TO connectdb AS :id;
EXEC SQL CONNECT TO connectdb AS main USER connectuser/connectdb;
EXEC SQL CONNECT TO connectdb AS main USER connectuser USING "connectdb";
EXEC SQL CONNECT TO connectdb AS main;
EXEC SQL CONNECT TO tcp:postgresql://localhost/connectdb USER connectuser IDENTIFIED BY connectpw;
EXEC SQL CONNECT TO tcp:postgresql://localhost:$PORT/connectdb USER connectuser SQLIDENTIFIED BY connectpw;
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser SQLIDENTIFIED BY "connectpw";
EXEC SQL CONNECT TO unix:postgresql://localhost/connectdb USER connectuser USING "connectpw";
```

Example of using the connection syntax:

```
#include <stdlib.h>
#include <string.h>
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    // Define the host by defining columns such as database and password required by the connection string.
    // The actual values are read from environment variables or configuration files. Environment variables need to
    // be configured as required. If no environment variable is used, a character string can be directly assigned.
    exec sql begin declare section;
        const int max_str_len = 200;
        char db[max_str_len] = getenv("EXAMPLE_DATABASENAME_ENV");
        char pw[max_str_len] = getenv("EXAMPLE_PASSWD_ENV");
        char new_pw[max_str_len] = getenv("EXAMPLE_NEW_PASSWD_ENV");
    exec sql end declare section;

    // Print debug logs.
    ECPGdebug(1, stderr);

    // The connection statement involves the database, username, and password. The user must be created
    // in advance and have related operation permissions.

    // Connection mode: EXEC SQL CONNECT TO [ database_name ] [ @host ] [ :port ] [ USER
    connection_user ]
    // Case 1: Use the default local connection mode to connect to the postgres database.
    exec sql connect to postgres;
    // Case 2: Use the default local connection mode to connect to the postgres database. The connection
    // alias is conn1.
    exec sql connect to postgres as conn1;
    // Case 3: Use the ip+port mode (localhost indicates the local IP address listened by the database, and
    // $PORT indicates the listening port of the database) to connect to the connectdb database, specify the
    // database alias, and specify the user password.
```

```
exec sql connect to connectdb@localhost:$PORT as conn2 user connectuser using :pw;
// Case 4: Use the ip+port mode (127.0.0.1 indicates the local address listened by the database, and
$PORT indicates the listening port of the database) to connect to the connectdb database, specify the
database alias, and specify the user password.
exec sql connect to connectdb@127.0.0.1:$PORT as conn3 user connectuser sqlidentified by :pw;
// Case 5: Close the connection to the database.
exec sql disconnect postgres;
exec sql disconnect conn1;
exec sql disconnect conn2;
exec sql disconnect conn3;

// Connection mode: EXEC SQL CONNECT TO <tcp|unix>:<gaussdb|postgresql>://host
[ :port ]/[ database_name ] [ ?connection_option ]
// Case 1: Replace the URL variables with the host variables pw and db.
strcpy(pw, new_pw);
strcpy(db, "tcp:postgresql://localhost/connectdb");
exec sql connect to :db user connectuser using :pw;
// Case 2: 127.0.0.1 indicates the IP address listened by the database, and connectdb indicates the
database.
exec sql connect to tcp:postgresql://127.0.0.1/connectdb as conn4 user connectuser using :pw;
// Case 3: 127.0.0.1 indicates the IP address listened by the database, connectdb indicates the database,
and connect_timeout=14 indicates the connection string configuration parameter.
exec sql connect to tcp:gaussdb://localhost/connectdb?connect_timeout=14 as conn5 user connectuser
sqlidentified by :pw;
// Case 4: Close all connections.
exec sql close all;

// Connect to the database and execute the service.
exec sql connect to tcp:postgresql://127.0.0.1/connectdb as conn4 user connectuser using :pw;
exec sql set autocommit = on;
exec sql create table t1(a int);
exec sql insert into t1 values(1),(2);
exec sql select a from t1 where a > 1;
exec sql drop table t1;
exec sql disconnect current;
return 0;
}
```

Example of using a host variable to specify connection parameters:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
/* The values of dbname, user, and pwd must be read from environment variables or configuration files.
Environment variables need to be configured as required. If no environment variable is used, a character
string can be directly assigned. */
char *dbname = getenv("EXAMPLE_DBNAME_ENV"); /* Database name */
char *user = getenv("EXAMPLE_USERNAME_ENV"); /* Username for connection */
char *pwd = getenv("EXAMPLE_PASSWD_ENV"); /* Password */
char *connection = "tcp:postgresql://localhost:$PORT/testdb"; /* Connection string */
char ver[256]; /* Buffer for storing version strings */
EXEC SQL END DECLARE SECTION;

ECPGdebug(1, stderr);
EXEC SQL CONNECT TO :dbname;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
EXEC SQL CONNECT TO :connection USER :user USING :pwd;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL SELECT version() INTO :ver;
EXEC SQL DISCONNECT;

printf("version: %s\n", ver);
```

```
return 0;  
}
```

## Helpful Links

[DISCONNECT](#), [SET CONNECTION](#)

### 5.8.5.5.3 DEALLOCATE DESCRIPTOR

#### Function

Deallocates a SQL descriptor area.

#### Syntax

```
DEALLOCATE DESCRIPTOR name
```

#### Parameters

**name**

Name of an SQL descriptor, case sensitive. This can be an SQL identifier or a host variable.

#### Examples

```
DEALLOCATE DESCRIPTOR mydesc;
```

## Helpful Links

[DEALLOCATE DESCRIPTOR](#), [GET DESCRIPTOR](#), [SET DESCRIPTOR](#)

### 5.8.5.5.4 DECLARE

#### Description

Declares a cursor for iterating over the result set of a prepared statement. This command is slightly semantically different from the SQL command **DECLARE**: Whereas the latter executes a query and prepares the result set for retrieval, this embedded SQL command merely declares a name as a "loop variable" for iterating over the result set of a query; the actual execution happens when the cursor is opened with the **OPEN** command.

#### Syntax

```
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR  
prepared_name  
DECLARE cursor_name [ BINARY ] [ NO SCROLL ] CURSOR [ { WITH | WITHOUT } HOLD ] FOR query
```

#### Parameters

- **cursor\_name**  
Cursor name, which is case sensitive. It can be an SQL identifier or a host variable.
- **prepared\_name**

Name of the prepared query, which can be an SQL identifier or a host variable.

- **query**  
A SELECT command for providing the rows to be returned by the cursor.

 **NOTE**

For details about the cursor options, see [DECLARE](#).

## Examples

Examples of declaring a cursor used for query:

```
EXEC SQL DECLARE C CURSOR FOR SELECT * FROM My_Table;  
EXEC SQL DECLARE C CURSOR FOR SELECT Item1 FROM T;  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT version();
```

Example of declaring a cursor for a prepared statement:

```
EXEC SQL PREPARE stmt1 AS SELECT version();  
EXEC SQL DECLARE cur1 CURSOR FOR stmt1;
```

## Helpful Links

[OPEN](#)

### 5.8.5.5.5 DESCRIBE

## Function

Retrieves metadata information for the result columns contained in prepared statements.

## Syntax

```
DESCRIBE [ OUTPUT ] prepared_name USING SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO SQL DESCRIPTOR descriptor_name  
DESCRIBE [ OUTPUT ] prepared_name INTO sqllda_name
```

## Parameters

- **prepared\_name**  
Name of a prepared statement, which can be an SQL identifier or a host variable.
- **descriptor\_name**  
Descriptor name, which is case sensitive. It can be an SQL identifier or a host variable.
- **sqllda\_name**  
Name of an SQLDA variable.

## Examples

```
EXEC SQL ALLOCATE DESCRIPTOR mydesc;  
EXEC SQL PREPARE stmt1 FROM :sql_stmt;  
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :charvar = NAME;  
EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
```

## Helpful Links

[ALLOCATE DESCRIPTOR, GET DESCRIPTOR](#)

### 5.8.5.5.6 DISCONNECT

## Function

Closes one or all database connections.

## Syntax

```
DISCONNECT connection_name  
DISCONNECT [ CURRENT ]  
DISCONNECT DEFAULT  
DISCONNECT ALL
```

## Parameters

- **connection\_name**  
Name of the database connection established by the CONNECT command.
- **current**  
Closes the current connection, which can be a recently opened connection or a connection set by the SET CONNECTION command. This is also the default if no parameter is passed to the DISCONNECT command.
- **default**  
Closes the default connection.
- **all**  
Closes all open connections.

## Examples

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
  
int main(void)  
{  
    /* Create the testdb database in advance. */  
    EXEC SQL CONNECT TO testdb AS DEFAULT USER testuser;  
    EXEC SQL CONNECT TO testdb AS con1 USER testuser;  
    EXEC SQL CONNECT TO testdb AS con2 USER testuser;  
    EXEC SQL CONNECT TO testdb AS con3 USER testuser;  
    EXEC SQL DISCONNECT CURRENT; /* Close connection 3. */  
    EXEC SQL DISCONNECT DEFAULT; /* Close the default connection. */  
    EXEC SQL DISCONNECT ALL; /* Close connections 2 and 1. */  
    return 0;  
}
```

## Helpful Links

[CONNECT, SET CONNECTION](#)

### 5.8.5.5.7 EXECUTE IMMEDIATE

#### Function

Immediately prepares and executes a dynamically specified SQL statement without retrieving result rows.

#### Syntax

```
EXECUTE IMMEDIATE string
```

#### Parameters

##### string

A C string or host variable that contains the SQL statement to be executed.

#### Examples

The following is an example of executing the INSERT statement using EXECUTE IMMEDIATE and a host variable named **command**:

```
printf(command, "INSERT INTO test (name, amount, letter) VALUES ('r1', 1, 'f');  
EXEC SQL EXECUTE IMMEDIATE :command;
```

### 5.8.5.5.8 GET DESCRIPTOR

#### Function

Retrieves information about a query result set and stores it into host variables. A descriptor area is typically populated using FETCH or SELECT before using this command to transfer the information into host language variables. This command can be in either of the following formats:

- Retrieves the descriptor "header" items, which applies to the result set in its entirety.
- Retrieves information about a particular column, requiring the column number as additional parameter.

#### Syntax

```
GET DESCRIPTOR descriptor_name VALUE column_number :cvariable = descriptor_item [ , ... ]  
GET DESCRIPTOR descriptor_name:cvariable = descriptor_header_item [ , ... ]
```

#### Parameters

- **descriptor\_name**  
Descriptor name.
- **descriptor\_header\_item**  
Identifies which header item is to be retrieved. Currently, only COUNT that is used to obtain the number of columns in the result set is supported.
- **column\_number**  
Number of the column about which information is to be retrieved. The count starts at 1.

- **descriptor\_item**  
Identifies which information item about a column is to be retrieved.
- **cvariable**  
A host variable that will receive the data retrieved from the descriptor area.

## Examples

Retrieve the number of columns in a result set.

```
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
```

Retrieve the data length in the first column.

```
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
```

Retrieve the data body of the second column as a string.

```
EXEC SQL GET DESCRIPTOR d VALUE 2 :d_data = DATA;
```

Execute **SELECT current\_database()**; The number of columns, column data length, and column data are displayed.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    int d_count;
    char d_data[1024];
    int d_returned_octet_length;
EXEC SQL END DECLARE SECTION;
EXEC SQL CONNECT TO testdb AS con1 USER testuser;
EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
EXEC SQL ALLOCATE DESCRIPTOR d;

/* Declare and open a cursor, and allocate a descriptor to the cursor. */
EXEC SQL DECLARE cur CURSOR FOR SELECT current_database();
EXEC SQL OPEN cur;
EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;

/* Obtain the total number of columns. */
EXEC SQL GET DESCRIPTOR d :d_count = COUNT;
printf("d_count = %d\n", d_count);

/* Obtain the length of a returned column. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_returned_octet_length = RETURNED_OCTET_LENGTH;
printf("d_returned_octet_length = %d\n", d_returned_octet_length);

/* Fetch the returned column as a string. */
EXEC SQL GET DESCRIPTOR d VALUE 1 :d_data = DATA;
printf("d_data = %s\n", d_data);

/* Closed */
EXEC SQL CLOSE cur;
EXEC SQL COMMIT;

EXEC SQL DEALLOCATE DESCRIPTOR d;
EXEC SQL DISCONNECT ALL;
return 0;
}
```

The following is the command output.

```
d_count          = 1
d_returned_octet_length = 6
d_data          = testdb
```

## Helpful Links

[ALLOCATE DESCRIPTOR](#), [DEALLOCATE DESCRIPTOR](#), and [SET DESCRIPTOR](#)

### 5.8.5.5.9 OPEN

## Description

Opens a cursor and optionally binds actual values to placeholders in the cursor declaration. The cursor must have been declared using the **DECLARE** command. Executing the **OPEN** command triggers the query on the server.

## Syntax

```
OPEN cursor_name  
OPEN cursor_name USING value [, ... ]  
OPEN cursor_name USING SQL DESCRIPTOR descriptor_name
```

## Parameters

- **cursor\_name**  
Name of the cursor to be opened. It can be an SQL identifier or a host variable.
- **value**  
A value that is to be bound to a placeholder in the cursor declaration. It can be an SQL constant, a host variable, or a host variable with an indicator.
- **descriptor\_name**  
Name of the descriptor that contains the value to be bound to the placeholder in the cursor declaration. It can be an SQL identifier or a host variable.

## Examples

```
EXEC SQL OPEN a;  
EXEC SQL OPEN d USING 1, 'test';  
EXEC SQL OPEN c1 USING SQL DESCRIPTOR mydesc;  
EXEC SQL OPEN :curname1;
```

## Helpful Links

[DECLARE](#)

### 5.8.5.5.10 PREPARE

## Description

Prepares the statement to be executed.

## Syntax

```
PREPARE name FROM string
```

## Parameters

- **name**  
An identifier for the prepared query.
- **string**  
A C string or host variable that contains a prepared statement, which can be SELECT, INSERT, UPDATE, or DELETE.

## Examples

```
char *stmt = "SELECT * FROM test1 WHERE a = ? AND b = ?";  
EXEC SQL ALLOCATE DESCRIPTOR outdesc;  
EXEC SQL PREPARE foo FROM :stmt;  
EXEC SQL EXECUTE foo USING SQL DESCRIPTOR indesc INTO SQL DESCRIPTOR outdesc;
```

### NOTICE

The PREPARE statement provided by ecpg is not equivalent to the PREPARE syntax provided by the kernel. Example:

GaussDB Kernel kernel syntax:

```
PREPARE name [ ( data_type [, ...] ) ] AS statement
```

Embedded SQL statement:

```
EXEC SQL PREPARE I (int, int) AS INSERT INTO T VALUES ( $1, $2 );  
EXEC SQL EXECUTE I(1, 2);
```

When the preceding statement is executed, an error message "too few arguments on" is reported. ecpg provides a dynamic SQL statement to solve the problem in the **PREPARE name [ ( data\_type [, ...] ) ] AS statement** syntax scenario.

Example of using dynamic SQL syntax rules to solve the preceding problem:

```
EXEC SQL PREPARE I AS INSERT INTO T VALUES ( $1, $2 );  
EXEC SQL EXECUTE I using 1, 2;
```

### 5.8.5.5.11 SET AUTOCOMMIT

#### Function

Sets the autocommit behavior of the current database session. By default, embedded SQL programs do not automatically commit, so you need to explicitly issue COMMIT. This command can change the session to the automatic commit mode so that each individual statement is implicitly committed.

#### Syntax

```
SET AUTOCOMMIT { = | TO } { ON | OFF }
```

### 5.8.5.5.12 SET CONNECTION

#### Function

Sets a database connection.

#### Syntax

```
SET CONNECTION [ TO | = ] connection_name
```

## Parameters

- **connection\_name**  
Name of a database connection established by the CONNECT command.

## Examples

```
EXEC SQL SET CONNECTION TO con2;  
EXEC SQL SET CONNECTION = con1;
```

## Helpful Links

[CONNECT](#), [DISCONNECT](#)

### 5.8.5.5.13 SET DESCRIPTOR

## Description

Populates an SQL descriptor area, which is usually used to bind parameters in a prepared query execution. This command can be in either of the following formats:

- Applies to the descriptor "header", which is independent of specific data.
- Assigns a value to specific data identified by a number.

## Syntax

```
SET DESCRIPTOR descriptor_name descriptor_header_item = value [, ... ]  
SET DESCRIPTOR descriptor_name VALUE number descriptor_item = value [, ...]
```

## Parameters

- **descriptor\_name**  
SQL descriptor name.
- **descriptor\_header\_item**  
Identifies the header information item to be set. Currently, only COUNT that can be used to set the number of descriptor items is supported.
- **number**  
Number of descriptor items to be set. The count starts at 1.
- **descriptor\_item**  
Identifies which descriptor item is to be set. Currently, only DATA, TYPE, and LENGTH are supported.
- **value**  
Value to be stored in the descriptor item. The value can be an SQL constant or a host variable.

## Examples

```
EXEC SQL SET DESCRIPTOR indesc COUNT = 1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = 2;  
EXEC SQL SET DESCRIPTOR indesc VALUE 1 DATA = :val1;  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val1, DATA = 'some string';  
EXEC SQL SET DESCRIPTOR indesc VALUE 2 INDICATOR = :val2null, DATA = :val2;
```

## Helpful Links

[DEALLOCATE DESCRIPTOR, GET DESCRIPTOR, SET DESCRIPTOR](#)

### 5.8.5.5.14 TYPE

#### Function

Defines a new data type. This command is identified only when `ecpg` is run with the `-c` option.

#### Syntax

```
TYPE type_name IS ctype
```

#### Parameters

##### **type\_name**

Data type name.

##### **ctype**

C type description.

#### Examples

```
EXEC SQL TYPE customer IS
struct
{
    varchar name[50];
    int    phone;
};

EXEC SQL TYPE cust_ind IS
struct ind
{
    short name_ind;
    short phone_ind;
};

EXEC SQL TYPE c IS char reference;
EXEC SQL TYPE ind IS union { int integer; short smallint; };
EXEC SQL TYPE intarray IS int[AMOUNT];
EXEC SQL TYPE str IS varchar[BUFFERSIZ];
EXEC SQL TYPE string IS char[11];
```

Example of using EXEC SQL TYPE (note that the `-c` parameter needs to be added in the `ecpg` preprocessing phase when the following example is used):

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

EXEC SQL WHENEVER SQLERROR SQLPRINT;
EXEC SQL TYPE tt IS
struct
{
    varchar v[256];
    int    i;
};
EXEC SQL TYPE tt_ind IS
struct ind {
    short v_ind;
```

```
    short i_ind;
};

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    tt t;
    tt_ind t_ind;
EXEC SQL END DECLARE SECTION;
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL SELECT current_database(), 256 INTO :t_ind LIMIT 1;

    printf("t.v = %s\n", t.v.arr);
    printf("t.i = %d\n", t.i);

    printf("t_ind.v_ind = %d\n", t_ind.v_ind);
    printf("t_ind.i_ind = %d\n", t_ind.i_ind);

    EXEC SQL DISCONNECT con1;

    return 0;
}
```

The output of this example is as follows.

```
t.v = testdb
t.i = 256
t_ind.v_ind = 0
t_ind.i_ind = 0
```

### 5.8.5.5.15 VAR

## Function

Assigns a new C data type to a host variable. The host variable must have been declared in a DECLARE segment.

#### NOTE

- Exercise caution when using VAR. Using VAR to change the data type may cause the memory address to be invalid. As a result, the data variable is invalid and the value cannot be assigned.
- If the data type has been defined in the host variable DECLARE segment, you do not need to use the VAR statement.

## Syntax

```
VAR varname IS ctype
```

## Parameters

- **varname**  
Name of a C variable.
- **ctype**  
C type description.

## Examples

```
EXEC SQL BEGIN DECLARE SECTION;
    short a;
EXEC SQL END DECLARE SECTION;
EXEC SQL VAR a IS int;
```

### 5.8.5.5.16 WHENEVER

#### Description

Defines a behavior that is called when an SQL execution exception occurs (row not found, SQL alarm, or error).

#### Syntax

```
WHENEVER { NOT FOUND | SQLERROR | SQLWARNING } action
```

#### Parameters

For details about the parameter description, see [Setting Callbacks](#).

#### Examples

```
EXEC SQL WHENEVER NOT FOUND CONTINUE;
EXEC SQL WHENEVER NOT FOUND DO BREAK;
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLWARNING DO warn();
EXEC SQL WHENEVER SQLERROR sqlprint;
EXEC SQL WHENEVER SQLERROR SQLCALL print2();
EXEC SQL WHENEVER SQLERROR DO handle_error("select");
EXEC SQL WHENEVER SQLERROR DO sqlnotice(NULL, NONO);
EXEC SQL WHENEVER SQLERROR DO sqlprint();
EXEC SQL WHENEVER SQLERROR GOTO error_label;
EXEC SQL WHENEVER SQLERROR STOP;
```

Use `WHENEVER NOT FOUND BREAK` to handle the looping of the result set.

```
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

int main(void)
{
    EXEC SQL CONNECT TO testdb AS con1;
    EXEC SQL SELECT pg_catalog.set_config('search_path', '', false); EXEC SQL COMMIT;
    EXEC SQL ALLOCATE DESCRIPTOR d;
    EXEC SQL DECLARE cur CURSOR FOR SELECT current_database(), 'hoge', 256;
    EXEC SQL OPEN cur;

    /* When the end of the result set is reached, exit the loop. */
    EXEC SQL WHENEVER NOT FOUND DO BREAK;

    while (1)
    {
        EXEC SQL FETCH NEXT FROM cur INTO SQL DESCRIPTOR d;
        ...
    }
    EXEC SQL CLOSE cur;
    EXEC SQL COMMIT;
    EXEC SQL DEALLOCATE DESCRIPTOR d;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

## 5.8.6 Querying the Result Set

- The `SELECT` statement that returns the result of a single row can be directly executed using `EXEC SQL`. For details, see [Executing SQL Statements](#).

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);

/* The query result is in a single row. :num is the host variable. */
EXEC SQL SELECT number1 INTO :num FROM test_table WHERE number2 = 1;
```

- To process a multi-row result set, you must use a cursor. For details, see [Using Cursors](#). (In special cases, an application can fetch multiple rows of results at a time and write them to the host variable of the array type. For details, see [Host Variables with Non-Primitive Types](#).)

Example:

```
/* Create a table and insert data. */
EXEC SQL CREATE TABLE test_table (number1 integer, number2 integer);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (2, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (3, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (4, 1);
EXEC SQL INSERT INTO test_table (number1, number2) VALUES (5, 1);

/* Define the host variable. */
EXEC SQL BEGIN DECLARE SECTION;
int v1;
int v2;
EXEC SQL END DECLARE SECTION;

/* Declare a cursor. */
EXEC SQL DECLARE test_bar CURSOR FOR SELECT number1, number2 FROM test_table ORDER BY
number1;
/* Open the cursor. */
EXEC SQL OPEN test_bar;
/* When the cursor reaches the end of the result set, exit the loop. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
/* Obtain the query result set. */
while(1)
{
EXEC SQL FETCH NEXT FROM test_bar INTO :v1, :v2;
printf("number1 = %d, number2 = %d\n",v1,v2);
}
/* Close the cursor. */
EXEC SQL CLOSE test_bar;
```

## 5.8.7 Closing a Database Connection

Close the database connection after the database is used.

Close a connection.

```
EXEC SQL DISCONNECT [connection];
```

Declare the connection by using the following methods:

- connection-name
- default
- current
- all

## 5.8.8 Host Variables

This section describes how to use host variables to pass data between C programs and embedded SQL programs. In C programs with embedded SQL statements, we use the C language as the host language and regard EXEC SQL [Command] statements as embedded SQL statements of the host language. Therefore, variables used for embedded SQL statements in C programs are called host variables.

### 5.8.8.1 Overview

Passing data between a C program and SQL statements is particularly simple in embedded SQL. Instead of having the program paste data into the statements, you can simply write the name of a C variable into the SQL statement, prefixed by a colon. The following is an example.

```
EXEC SQL INSERT INTO sometable VALUES (:v1, 'foo', :v2);
```

This statement references two C variables named v1 and v2 and uses a regular SQL string, indicating that you are not restricted to use one kind of data or the other.

### 5.8.8.2 DECLARE Section

To implement data interaction between a C program with embedded SQL statements and a database, for example, to pass parameters in a query of the C program to the database, or to pass data from the database back to the program, the C variables that are intended to contain this data need to be declared in specially marked sections, so that the embedded SQL preprocessor is made aware of them.

This section starts with:

```
EXEC SQL BEGIN DECLARE SECTION;
```

And ends with:

```
EXEC SQL END DECLARE SECTION;
```

Between them, there must be regular C variable declarations. An example is as follows:

```
int x = 4;  
char foo[16], bar[16];
```

#### NOTICE

- The type of the host variables declared between the start and end of the marked section must be one of the supported data types. For details, see [Table 5-89](#).
- You can also declare variables with the following syntax which implicitly creates a DECLARE section: EXEC SQL int i = 4.
- Variables that are not intended to be used in SQL commands can be declared normally outside these special sections.
- The definition of a structure or union also must be listed inside a DECLARE section. Otherwise, the preprocessor cannot process these types.

### 5.8.8.3 Retrieving Query Results

To retrieve the results of a query, embedded SQL provides special variants of the usual commands **SELECT** and **FETCH**. These commands have a special INTO clause that specifies which host variables the retrieved values are to be stored in. **SELECT** is used for a query that returns only a single row, and **FETCH** is used for a query that returns multiple rows, using a cursor.

- Here is an example using the command **SELECT**:

```

/*
 * Assume a table:
 * CREATE TABLE test1 (a int, b varchar(50));
 */
EXEC SQL BEGIN DECLARE SECTION;
  int v1;
  VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL SELECT a, b INTO :v1, :v2 FROM test;

```

The INTO clause appears between the SELECT list and the FROM clause. The number of elements in the SELECT list and the list after INTO (also called the target list) must be equal.

- Here is an example using the command **FETCH**:

```

EXEC SQL BEGIN DECLARE SECTION;
  int v1;
  VARCHAR v2;
EXEC SQL END DECLARE SECTION;

...

EXEC SQL DECLARE foo CURSOR FOR SELECT a, b FROM test;
...
do
{
  ...
  EXEC SQL FETCH NEXT FROM foo INTO :v1, :v2;
  ...
} while (...);

```

The INTO clause appears after all SQL clauses.

### 5.8.8.4 Type Mapping

When ecpg applications exchange values between the GaussDB Kernel server and the C program, such as when retrieving query results from the server or executing SQL statements with input parameters, the values need to be converted between GaussDB Kernel data types and host language variable types (C language data types, concretely). There are two data types available: Simple GaussDB Kernel data types, such as integer and text, can be directly read and written by applications. Other GaussDB Kernel data types, such as timestamp and numeric, can be accessed only by using special library functions. For details, see [ECPG API Reference](#).

**Table 5-89** Mapping between GaussDB Kernel data types and C variable types

GaussDB Kernel Data Type	Host Variable Type
smallint	short
integer	int
bigint	long long int
boolean	boolean
character( <i>n</i> ), varchar( <i>n</i> ), text	char[ <i>n</i> +1], VARCHAR[ <i>n</i> +1]
double precision	double

GaussDB Kernel Data Type	Host Variable Type
real	float
smallserial	short
serial	int
bigserial	long long int
oid	unsigned int
name	char[NAMEDATALEN]
date	date [a]
timestamp	timestamp [a]
interval	interval [a]
decimal	decimal [a]
numeric	numeric [a]

 **NOTE**

[a] This type can be accessed through [Accessing Special Data Types](#).

**NOTICE**

- Currently, only basic data types of the C language can be used or combined. The string data type in the C++ language cannot be used as the host variable type.
- Currently, ecpg maps only common data types of GaussDB Kernel SQL. For details about the supported data types, see [Table 5-89](#).

### 5.8.8.5 Handling Character Strings

To handle SQL character string data types, such as varchar and text, there are two possible methods to declare the host variables.

1. Method 1: Use char[] (a char string), which is the most common method for processing character data in C programs.

```
EXEC SQL BEGIN DECLARE SECTION;  
char str[50];  
EXEC SQL END DECLARE SECTION;
```

Note that you have to take care of the length yourself. If you use this host variable as the target variable of a query which returns a string with more than 49 characters, a buffer overflow occurs.

2. Method 2: Use the VARCHAR type, which is a special type provided by ecpg. The definition on an array of type VARCHAR is converted into a named struct for every variable. The statement is as follows:

```
VARCHAR var[180];
```

It will be converted into:

```
struct varchar_var
{
    int len;
    char arr[180];
} var;
```

To store a string in a VARCHAR host variable, the host variable has to be declared as a string including the zero-byte terminator. **arr** stores the string including a terminating zero byte. **len** stores the length of the string stored in **arr** without the terminating zero byte. The terminator is not included when the length is calculated. When a host variable is used as input for a query, if the values of **strlen(arr)** and **len** are different, the shorter one is used.

---

**CAUTION**

- VARCHAR can be written in upper or lower case, but not in mixed case.
  - char and VARCHAR host variables can also hold values of other SQL types, which will be stored in their string forms.
- 

### 5.8.8.6 Host Variables with Non-Primitive Types

Non-primitive host variables can be arrays, typedefs, structures, and pointers.

- Arrays

There are two use cases for arrays as host variables. The first case is to store some text strings in `char[]` or `VARCHAR[]`. The second case is to retrieve multiple rows from a query result without using a cursor. Without an array, to process a query result consisting of multiple rows, it is required to use a cursor and the **FETCH** command. But with array host variables, multiple rows can be received at once. The length of the array has to be defined to be able to accommodate all rows, otherwise a buffer overflow will occur.

For example, scan the `pg_database` system catalog and display the OIDs and names of all available databases.

```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
    EXEC SQL BEGIN DECLARE SECTION;
    int dbid[8];
    char dbname[8][16];
    int i;
    EXEC SQL END DECLARE SECTION;

    memset(dbname, 0, sizeof(char)* 16 * 8);
    memset(dbid, 0, sizeof(int) * 8);
    * Connect to the testdb database. The testdb database must be created in advance. */
    EXEC SQL CONNECT TO testdb;
    /* Retrieve multiple rows to arrays at a time. */
    EXEC SQL SELECT oid,datname INTO :dbid, :dbname FROM pg_database;
    for (i = 0; i < 8; i++)
        printf("oid=%d, dbname=%s\n", dbid[i], dbname[i]);
    EXEC SQL COMMIT;
    EXEC SQL DISCONNECT ALL;
    return 0;
}
```

Example output (the exact value depends on the local environment):

```
oid=1, dbname=template1
oid=11510, dbname=template0
oid=11511, dbname=postgres
oid=313780, dbname=testdb
oid=0, dbname=
oid=0, dbname=
oid=0, dbname=
```

- Structures

A structure whose member names match the column names of a query result, can be used to retrieve multiple columns at once. The structure enables handling multiple column values in a single host variable.

The following example retrieves OIDs, names, and sizes of the available databases from the `pg_database` system catalog and using the `pg_database_size()` function. In this example, a structure variable `dbinfo_t` with members whose names match each column in the `SELECT` result is used to retrieve one result row without putting multiple host variables in the `FETCH` statement.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
    long long int size;
} dbinfo_t;

dbinfo_t dbval;
EXEC SQL END DECLARE SECTION;
memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Fetch multiple columns into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :dbval;
    /* Print the members of the structure. */
    printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, dbval.size);
}
EXEC SQL CLOSE cur1;
```

Example output (the exact value depends on the local environment):

```
oid=1, datname=template1, size=4324580
oid=11510, datname=template0, size=4243460
oid=11511, datname=postgres, size=4324580
oid=313780, datname=testdb, size=8183012
```

Structure host variables "absorb" as many columns in the query result as the structure columns. Additional columns can be allocated to other host variables. The above program could also be restructured like this, with the **size** variable outside the structure:

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
{
    int oid;
    char datname[65];
} dbinfo_t;

dbinfo_t dbval;
```

```
long long int size;
EXEC SQL END DECLARE SECTION;

memset(&dbval, 0, sizeof(dbinfo_t));

EXEC SQL DECLARE cur1 CURSOR FOR SELECT oid, datname, pg_database_size(oid) AS size FROM
pg_database;
EXEC SQL OPEN cur1;

/* Exit the while loop when the end of the result set is reached. */
EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
/* Fetch multiple columns into one structure. */
EXEC SQL FETCH FROM cur1 INTO :dbval, :size;
/* Print the members of the structure. */
printf("oid=%d, datname=%s, size=%lld\n", dbval.oid, dbval.datname, size);
}

EXEC SQL CLOSE cur1;
```

- **typedef**

Use the `typedef` keyword to map new types to existing types.

```
EXEC SQL BEGIN DECLARE SECTION;
typedef char mychartype[40];
typedef long serial_t;
EXEC SQL END DECLARE SECTION;
```

You can also run the following command:

```
EXEC SQL TYPE serial_t IS long;
```

This declaration does not need to be part of a `DECLARE` section.

- **Pointers**

You can declare pointers to the most common types.

```
EXEC SQL BEGIN DECLARE SECTION;
int *intp;
char **charp;
EXEC SQL END DECLARE SECTION;
```

### 5.8.8.7 Accessing Special Data Types

ecpg supports the numeric, decimal, date, timestamp, and interval data types. These data types cannot be mapped to primitive host variable types because they have a complex internal structure. Applications deal with these types by declaring host variables in special types and accessing them using functions in the `pgtypes` library. For details about the functions in the `pgtypes` library, see [ECPG API Reference](#).

- **timestamp,date**

First, the program must include the header file for the timestamp type.

```
#include <pgtypes_timestamp.h>
```

Then, declare a host variable of the timestamp type in the `DECLARE` section.

```
EXEC SQL BEGIN DECLARE SECTION;
timestamp ts;
EXEC SQL END DECLARE SECTION;
```

After the value is read to the host variable, the `pgtypes` library function is used for processing. In the following example, the `PGTYPEStimestamp_to_asc()` function is used to convert the **timestamp** value to the text format:

```
EXEC SQL SELECT now()::timestamp INTO :ts;
printf("ts = %s\n", PGTYPEStimestamp_to_asc(ts));
```

Example output:

```
ts = 2022-06-27 18:03:56.949343
```

In addition, the date type can be processed in the same way. The program must contain the **pgtypes\_data.h** header file, declare a host variable as the date type, and use the `PGTYPEdata_to_asc()` function to convert the variable to the text format.

- interval

The handling of the interval type is also similar to the timestamp and date types. However, to allocate memory for an interval type value explicitly, the memory space for the variable must be allocated from the heap memory.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_interval.h>
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    interval *in;
EXEC SQL END DECLARE SECTION;
    /* Connect to the testdb database. The testdb database must be created in advance.*/
EXEC SQL CONNECT TO testdb;
    in = PGTYPEinterval_new();
EXEC SQL SELECT '1 min'::interval INTO :in;
    printf("interval = %s\n", PGTYPEinterval_to_asc(in));
    PGTYPEinterval_free(in);
EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
    return 0;
}
```

- numeric,decimal

The handling of the numeric and decimal types is similar to the interval type: It requires defining a pointer, allocating some memory space from the heap, and accessing the variable using the `pgtypes` library functions.

Example:

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_numeric.h>
EXEC SQL WHENEVER SQLERROR STOP;
int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    numeric *num;
    numeric *num2;
    decimal *dec;
EXEC SQL END DECLARE SECTION;

    /* Connect to the testdb database. The testdb database must be created in advance.*/
EXEC SQL CONNECT TO testdb;

    num = PGTYPEnumeric_new();
    dec = PGYPESdecimal_new();

EXEC SQL SELECT 12.345::numeric(4,2), 23.456::decimal(4,2) INTO :num, :dec;
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 0));
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 1));
    printf("numeric = %s\n", PGTYPEnumeric_to_asc(num, 2));
    /* Convert decimal to numeric to show a decimal value. */
    num2 = PGTYPEnumeric_new();
    PGTYPEnumeric_from_decimal(dec, num2);
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 0));
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 1));
    printf("decimal = %s\n", PGTYPEnumeric_to_asc(num2, 2));
    PGTYPEnumeric_free(num2);
    PGYPESdecimal_free(dec);
}
```

```
PGTYPESnumeric_free(num);  
  
EXEC SQL COMMIT;  
EXEC SQL DISCONNECT ALL;  
return 0;  
}
```

### 5.8.8.8 Handling Non-Primitive SQL Data Types

This section describes how to handle non-scalar and user-defined SQL-level data types in ecpg applications. Note that this is distinct from the handling of host variables of non-primitive types described in [Host Variables with Non-Primitive Types](#).

- Arrays

Multi-dimensional SQL-level arrays are not directly supported in ecpg. One-dimensional SQL-level arrays can be mapped into C array host variables and vice-versa. However, when creating a statement, ecpg does not know the types of the columns, so that it cannot check if a C array is input into a corresponding SQL-level array. When processing the output of an SQL statement, ecpg has to check if both are arrays.

If a query accesses elements of an array separately, a host variable with a type that can be mapped to the element type should be used. For example, if a column type is array of integer, a host variable of type int can be used. Also if the element type is varchar or text, a host variable of type char[] or VARCHAR[] can be used.

Example:

```
CREATE TABLE t3 (  
  ii integer[]  
);  
testdb=> SELECT * FROM t3;  
  ii  
-----  
{1,2,3,4,5}  
(1 row)
```

The following example retrieves the fourth element of an array and stores it in a host variable of the int type:

```
EXEC SQL BEGIN DECLARE SECTION;  
  int ii;  
EXEC SQL END DECLARE SECTION;  
  
EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[4] FROM t3;  
EXEC SQL OPEN cur1;  
  
EXEC SQL WHENEVER NOT FOUND DO BREAK;  
  
while (1)  
{  
  EXEC SQL FETCH FROM cur1 INTO :ii ;  
  printf("ii=%d\n", ii);  
}  
EXEC SQL CLOSE cur1;
```

Example output:

```
ii=4
```

To map multiple array elements to the multiple elements in an array type host variable, each element of the array column and each element of the host variable array must be managed separately. Example:

```
EXEC SQL BEGIN DECLARE SECTION;  
  int ii_a[8];
```

```
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii[1], ii[2], ii[3], ii[4] FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
  EXEC SQL FETCH FROM cur1 INTO :ii_a[0], :ii_a[1], :ii_a[2], :ii_a[3];
  ...
}
```

**Note:**

```
EXEC SQL BEGIN DECLARE SECTION;
  int ii_a[8];
EXEC SQL END DECLARE SECTION;

EXEC SQL DECLARE cur1 CURSOR FOR SELECT ii FROM t3;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
  /* Error */
  EXEC SQL FETCH FROM cur1 INTO :ii_a;
  ...
}
```

It does not work out because you cannot map an array type column to an array host variable directly.

- Composite types

Composite types are not directly supported in ecpg. For example, you cannot declare member variables as date type in a structure. However, you can access each attribute separately or use the external string representation.

In the following example, each attribute can be accessed separately:

```
CREATE TYPE comp_t AS (intval integer, textval varchar(32));
CREATE TABLE t4 (compval comp_t);
INSERT INTO t4 VALUES ( (256, 'PostgreSQL') );
```

The following program retrieves data from the example table by selecting each attribute of the `comp_t` type separately:

```
EXEC SQL BEGIN DECLARE SECTION;
  int intval;
  varchar textval[33];
EXEC SQL END DECLARE SECTION;

/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
  /* Fetch each element of the composite type column into host variables. */
  EXEC SQL FETCH FROM cur1 INTO :intval, :textval;
  printf("intval=%d, textval=%s\n", intval, textval.arr);
}
EXEC SQL CLOSE cur1;
```

The host variables storing values in the **FETCH** command can be gathered into one structure. For more details about the host variables in the structure form, see [Handling Character Strings](#). In the following example, the two host variables, `intval` and `textval`, become members of the `comp_t` structure, and the structure is specified in the **FETCH** command:

```
EXEC SQL BEGIN DECLARE SECTION;
typedef struct
```

```
{
    int intval;
    varchar textval[33];
} comp_t;
comp_t compval;
EXEC SQL END DECLARE SECTION;

/* Put each element of the composite type column in the SELECT list. */
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).intval, (compval).textval FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;
while (1)
{
    /* Put all values in the SELECT list into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :compval;
    printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
EXEC SQL CLOSE cur1;
```

Although a structure is used in the **FETCH** command, the attribute names in the **SELECT** clause are specified one by one. This can be enhanced by using a **\*** to ask for all attributes of the composite type value. For example:

```
...
EXEC SQL DECLARE cur1 CURSOR FOR SELECT (compval).* FROM t4;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    /* Put all values in the SELECT list into one structure. */
    EXEC SQL FETCH FROM cur1 INTO :compval;
    printf("intval=%d, textval=%s\n", compval.intval, compval.textval.arr);
}
...
```

In this way, composite types can be mapped into structures, even though `ecpg` does not understand the composite type itself.

- User-defined base types

When `ecpg` uses host variables to store query results, only the data types provided by `ecpg` are supported. User-defined data types are not supported. Data types created using `CREATE TYPE` cannot be mapped using host variables.

However, you can use external string representations and host variables of the `char[]` or `VARCHAR[]` type to handle user-defined types.

The external string representation of that type is `(%lf,%lf)`, which is defined in function `complex_in()`. The following example inserts complex type values **(1,1)** and **(3,3)** into columns **a** and **b** and then queries them from the table:

```
EXEC SQL BEGIN DECLARE SECTION;
    varchar a[64];
    varchar b[64];
EXEC SQL END DECLARE SECTION;
EXEC SQL INSERT INTO test_complex VALUES ('(1,1)', '(3,3)');
EXEC SQL DECLARE cur1 CURSOR FOR SELECT a, b FROM test_complex;
EXEC SQL OPEN cur1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH FROM cur1 INTO :a, :b;
    printf("a=%s, b=%s\n", a.arr, b.arr);
}
EXEC SQL CLOSE cur1;
```

Example output:  
a=(1,1), b=(3,3)

## 5.8.9 Executing Dynamic SQL Statements

In most cases, the SQL statements executed by an application are known when the application is written. However, in some cases, SQL statements are constructed at run time or provided by external sources. In these cases, the SQL statements cannot be directly embedded into the C source code, but dynamic SQL statements allow you to call the provided SQL statements in a string variable.

### 5.8.9.1 Executing a Statement Without a Result Set

An example of running the **EXECUTE IMMEDIATE** command is as follows:

```
EXEC SQL BEGIN DECLARE SECTION;  
const char *stmt = "CREATE TABLE test1 (...);";  
EXEC SQL END DECLARE SECTION;  
EXEC SQL EXECUTE IMMEDIATE :stmt;
```

**EXECUTE IMMEDIATE** can be used for SQL statements that do not return a result set, such as DDL, INSERT, UPDATE, and DELETE statements. However, statements for retrieving data, such as SELECT statements, cannot be executed in this way.

### 5.8.9.2 Executing a Statement with Input Parameters

Prepare a normal statement and execute a specific version of it by replacing its parameters (with question marks). Use the EXECUTE statement to execute the prepared statement by specifying parameters in the USING clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;  
const char *stmt = "INSERT INTO test1 VALUES(?, ?);";  
EXEC SQL END DECLARE SECTION;  
/* PREPARE Prepare a statement for execution. */  
EXEC SQL PREPARE mystmt FROM :stmt;  
...  
/* Single quotation marks are valid characters. If a character string is used, use double quotation marks.*/  
EXEC SQL EXECUTE mystmt USING 42, 'foobar';  
  
/* When you no longer need a prepared statement, you should deallocate it.*/  
EXEC SQL DEALLOCATE PREPARE name;
```

### 5.8.9.3 Executing a Statement with a Result Set

EXECUTE can be used to execute SQL statements with a result set. To save the result, add an INTO clause. Example:

```
EXEC SQL BEGIN DECLARE SECTION;  
const char *stmt = "SELECT a, b, c FROM test1 WHERE a > ?";  
int v1, v2;  
VARCHAR v3[50];  
EXEC SQL END DECLARE SECTION;  
  
EXEC SQL PREPARE mystmt FROM :stmt;  
...  
EXEC SQL EXECUTE mystmt INTO :v1, :v2, :v3 USING 37;
```

#### NOTE

The EXECUTE statement supports the INTO and USING clauses.

If a query may return multiple result rows, use cursors. For details about cursors, see [Using Cursors](#). Example:

```
EXEC SQL BEGIN DECLARE SECTION;
char dbaname[128];
char datname[128];
char *stmt = "SELECT u.username as dbaname, d.datname "
            " FROM pg_database d, pg_user u "
            " WHERE d.datdba = u.usesysid";
EXEC SQL END DECLARE SECTION;

EXEC SQL CONNECT TO testdb AS con1 USER testuser;

EXEC SQL PREPARE stmt1 FROM :stmt;

EXEC SQL DECLARE cursor1 CURSOR FOR stmt1;
EXEC SQL OPEN cursor1;

EXEC SQL WHENEVER NOT FOUND DO BREAK;

while (1)
{
    EXEC SQL FETCH cursor1 INTO :dbaname, :datname;
    printf("dbaname=%s, datname=%s\n", dbaname, datname);
}
EXEC SQL CLOSE cursor1;

EXEC SQL COMMIT;
EXEC SQL DISCONNECT ALL;
```

## 5.8.10 Error Handling

There are two non-exclusive methods to handle errors and warnings in an embedded SQL program:

- Callbacks can be configured to handle errors or warnings using the `WHENEVER` command.
- Detailed information about the errors or warnings can be obtained from the `sqlca` variable.

### 5.8.10.1 Setting Callbacks

One simple method to catch errors and warnings is to set a specific action to be executed whenever a particular condition occurs. To set the callback, run the following command:

```
EXEC SQL WHENEVER condition action;
```

**condition** can be one of the following:

- **SQLERROR**: The specified action is called whenever an error occurs during the execution of an SQL statement.
- **SQLWARNING**: The specified action is called whenever a warning occurs during the execution of an SQL statement.
- **NOT FOUND**: The specified action is called whenever an SQL statement retrieves or affects zero rows.

**action** can be one of the following:

- **CONTINUE**: ignores the callback error condition and continues the execution. It is usually used to stop a break condition. This is the default value.
- **GOTO label/GO TO label**: jumps to a specified label (using the C goto statement).
- **SQLPRINT**: prints a message to the standard error.

- **STOP:** calls `exit(1)` to terminate the program.
- **DO BREAK:** executes the C statement `BREAK`. This statement is used only in loops or switch statements.

Example:

```
/* It prints a simple message when a warning occurs and aborts the program when an error happens. */
EXEC SQL WHENEVER SQLWARNING SQLPRINT;
EXEC SQL WHENEVER SQLERROR STOP;
```

## NOTICE

- The statement `EXEC SQL WHENEVER` is a directive of the SQL preprocessor, not a C statement. The error or warning actions that it sets apply to all embedded SQL statements that appear below the point where the handler is set, unless a different action was set for the same condition between the first `EXEC SQL WHENEVER` and the SQL statement causing the condition, regardless of the flow of control in the C program. Therefore, neither of the following C programs can achieve the expected effect:

```
/*
 * ERROR
 */
int main(int argc, char *argv[])
{
    ...
    if (verbose) {
        EXEC SQL WHENEVER SQLWARNING SQLPRINT;
    }
    ...
    EXEC SQL SELECT ...;
    ...
}
/*
 * ERROR
 */
int main(int argc, char *argv[])
{
    ...
    set_error_handler();
    ...
    EXEC SQL SELECT ...;
    ...
}
static void set_error_handler(void)
{
    EXEC SQL WHENEVER SQLERROR STOP;
}
```

- `DO BREAK` can be used only in the `while`, `for`, and `switch` scenarios. After `DO BREAK` is used, use the `CONTINUE` statement to ignore it.

### 5.8.10.2 sqlca

The embedded SQL API provides a global variable *sqlca* (short for SQL communication area). *sqlca* covers warnings and errors. If multiple warnings or errors occur during the execution of a statement, then *sqlca* will only contain information about the last one. In a multithreaded program, every thread automatically gets its own copy of *sqlca*.

The data structure is as follows:

```
struct
{
```

```
char sqlcaid[8];
long sqlabc;
long sqlcode;
struct
{
    int sqlerrml;
    char sqlerrmc[SQLERRMC_LEN];
} sqlerrm;
char sqlerrp[8];
long sqlerrd[6];
char sqlwarn[8];
char sqlstate[5];
} sqlca;
```

If no error occurred in the last SQL statement, **sqlca.sqlcode** will be **0** and **sqlca.sqlstate** will be **00000**. If a warning or error occurred, then **sqlca.sqlcode** will be negative and **sqlca.sqlstate** will be different from **00000**. For details about the values of **SQLSTATE** and **SQLCODE**, see [SQLSTATE and SQLCODE](#).

If the last SQL statement was successful, then **sqlca.sqlerrd[1]** contains the OID of the processed row, if applicable, and **sqlca.sqlerrd[2]** contains the number of processed or returned rows, if applicable to the command.

In case of an error or warning, **sqlca.sqlerrm.sqlerrmc** will contain a string that describes the error. **sqlca.sqlerrm.sqlerrml** contains the length of the error message that is stored in **sqlca.sqlerrm.sqlerrmc**, that is, the result of **strlen()**. Note that some messages are too long to fit in the fixed-size **sqlerrmc** array; they will be truncated.

When a warning is generated, **sqlca.sqlwarn[2]** is set to **W**.

The fields **sqlcaid**, **sqlcab**, **sqlerrp**, and the remaining elements of **sqlerrd** and **sqlwarn** currently contain no useful information.

#### Example:

```
/* Integrate WHENEVER and sqlca to implement error handling. */
EXEC SQL WHENEVER SQLERROR SQLCALL print_sqlca();

void print_sqlca()
{
    fprintf(stderr, "==== sqlca ====\n");
    fprintf(stderr, "sqlcode: %ld\n", sqlca.sqlcode);
    fprintf(stderr, "sqlerrm.sqlerrml: %d\n", sqlca.sqlerrm.sqlerrml);
    fprintf(stderr, "sqlerrm.sqlerrmc: %s\n", sqlca.sqlerrm.sqlerrmc);
    fprintf(stderr, "sqlerrd: %ld %ld %ld %ld %ld %ld\n", sqlca.sqlerrd[0], sqlca.sqlerrd[1], sqlca.sqlerrd[2],
        sqlca.sqlerrd[3], sqlca.sqlerrd[4], sqlca.sqlerrd[5]);
    fprintf(stderr, "sqlwarn: %d %d %d %d %d %d %d %d\n", sqlca.sqlwarn[0], sqlca.sqlwarn[1],
        sqlca.sqlwarn[2],
        sqlca.sqlwarn[3], sqlca.sqlwarn[4], sqlca.sqlwarn[5],
        sqlca.sqlwarn[6], sqlca.sqlwarn[7]);
    fprintf(stderr, "sqlstate: %5s\n", sqlca.sqlstate);
    fprintf(stderr, "=====\n");
}
```

The output is similar to the following (here is a misspelled table name):

```
==== sqlca ====
sqlcode: -400
sqlerrm.sqlerrml: 49
sqlerrm.sqlerrmc: relation "pg_databasep" does not exist on line 38
sqlerrd: 0 0 0 0 0 0
sqlwarn: 0 0 0 0 0 0 0 0
sqlstate: 42P01
=====
```

### 5.8.10.3 SQLSTATE and SQLCODE

SQLSTATE is a five-character array. The five characters contain digits or upper-case letters that represent codes of various error and warning conditions. SQLSTATE has a hierarchical scheme: the first two characters indicate the general class of the condition, the last three characters indicate a subclass of the general condition. For example, the code 00000 indicates the success state.

SQLCODE is a simple integer. The value 0 indicates success, a positive value indicates success with additional information, a negative value indicates an error. The SQL standard only defines the positive value +100, which indicates that the last command returned or affected zero rows, and no specific negative values.

**Table 5-90** Mapping between SQLSTATE and SQLCODE

SQLCODE Value	SQLSTATE Value	Description
0 (ECPG_NO_ERROR)	SQLSTATE 00000	Indicates no error.
100 (ECPG_NOT_FOUND)	SQLSTATE 02000	<p>This is a harmless condition indicating that the last command retrieved or processed zero rows, or that you are at the end of the cursor.</p> <p>When processing a cursor in a loop, you could use this code as a way to detect when to abort the loop. An example is as follows:</p> <pre>while (1) { EXEC SQL FETCH ... ; if (sqlca.sqlcode == ECPG_NOT_FOUND) break; }</pre> <p>Actually, WHENEVER NOT FOUND DO BREAK effectively does this internally, so there is usually no advantage in writing this out explicitly.</p>
-12 (ECPG_OUT_OF_MEMORY)	SQLSTATE YE001	Indicates that your virtual memory is exhausted. The numeric value is defined as <b>-ENOMEM</b> .
-200 (ECPG_UNSUPPORTED)	SQLSTATE YE000	Indicates that the preprocessor has generated something that the library does not know about.
-201 (ECPG_TOO_MANY_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified more host variables than the command expected.
-202 (ECPG_TOO_FEW_ARGUMENTS)	SQLSTATE 07001 or 07002	Indicates that the command specified fewer host variables than the command expected.

SQLCODE Value	SQLSTATE Value	Description
-203 (ECPG_TOO_MANY_MATCHES)	SQLSTATE 21000	Indicates that a query has returned multiple rows, but the statement is ready to store only one result row.
-204 (ECPG_INT_FORMAT)	SQLSTATE 42804	The host variable is of the int type and the data in the database is of a different type and contains a value that cannot be interpreted as an int. The library uses strtol() for this conversion.
-205 (ECPG_UINT_FORMAT)	SQLSTATE 42804	The host variable is of the unsigned int type and the data in the database is of a different type and contains a value that cannot be interpreted as an unsigned int. The library uses strtoul() for this conversion.
-206 (ECPG_FLOAT_FORMAT)	SQLSTATE 42804	The host variable is of the float type and the data in the database is of another type and contains a value that cannot be interpreted as a float value. The library uses strtod() for this conversion.
-207 (ECPG_NUMERIC_FORMAT)	SQLSTATE 42804	The host variable is of the numeric type and the data in the database is of another type and contains a value that cannot be interpreted as a numeric value.
-208 (ECPG_INTERVAL_FORMAT)	SQLSTATE 42804	The host variable is of the interval type and the data in the database is of another type and contains a value that cannot be interpreted as an interval value.
-209 (ECPG_DATE_FORMAT)	SQLSTATE 42804	The host variable is of the date type and the data in the database is of another type and contains a value that cannot be interpreted as a date value.
-210 (ECPG_TIMESTAMP_FORMAT)	SQLSTATE 42804	The host variable is of the timestamp type and the data in the database is of another type and contains a value that cannot be interpreted as a timestamp value.
-211 (ECPG_CONVERT_BOOL)	SQLSTATE 42804	The host variable is of the Boolean type, but the data in the database is neither 't' nor 'f'.
-212 (ECPG_EMPTY)	SQLSTATE YE000	The statement sent to the SQL server was empty. (This usually does not occur in an embedded SQL program, so it may point to an internal error.)

SQLCODE Value	SQLSTATE Value	Description
-213 (ECPG_MISSING_INDICATOR)	SQLSTATE 22002	A null value was returned and no null indicator variable was provided.
-214 (ECPG_NO_ARRAY)	SQLSTATE 42804	An ordinary variable was used in a place that requires an array.
-215 (ECPG_DATA_NOT_ARRAY)	SQLSTATE 42804	The database returned an ordinary variable in a place that requires array value.
-216 (ECPG_ARRAY_INSERT)	SQLSTATE 42804	The value cannot be inserted into the array.
-220 (ECPG_NO_CONN)	SQLSTATE 08003	The program tried to access a connection that does not exist.
-221 (ECPG_NOT_CONN)	SQLSTATE YE000	The program tried to access a connection that does exist but is not open. (This is an internal error.)
-230 (ECPG_INVALID_STMT)	SQLSTATE 26000	The statement you are trying to use has not been prepared.
-239 (ECPG_INFORMIX_DUPLICATE_KEY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-240 (ECPG_UNKNOWN_DESCRIPTOR)	SQLSTATE 33000	The specified descriptor was not found. The statement you are trying to use has not been prepared.
-241 (ECPG_INVALID_DESCRIPTOR_INDEX)	SQLSTATE 07009	The specified descriptor was out of range.
-242 (ECPG_UNKNOWN_DESCRIPTOR_ITEM)	SQLSTATE YE000	An invalid descriptor item was requested. (This is an internal error.)
-243 (ECPG_VAR_NOT_NUMERIC)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a numeric value and the host variable was not numeric.
-244 (ECPG_VAR_NOT_CHARACTER)	SQLSTATE 07006	During the execution of a dynamic statement, the database returned a non-numeric value and the host variable was numeric.

SQLCODE Value	SQLSTATE Value	Description
-284 (ECPG_INFORMIX_S UBSELECT_NOT_ON E)	SQLSTATE 21000	The result of the subquery was not a single row.
-400 (ECPG_PGSQL)	-	Some error caused by the SQL server. This message contains an error message from the SQL server.
-401 (ECPG_TRANS)	SQLSTATE 08007	The SQL server notified that the transaction cannot be started, committed, or rolled back.
-402 (ECPG_CONNECT)	SQLSTATE 08001	The connection attempt to the database did not succeed.
-403 (ECPG_DUPLICATE_K EY)	SQLSTATE 23505	Duplicate key error, violation of unique constraint.
-404 (ECPG_SUBSELECT_ NOT_ONE)	SQLSTATE 21000	The result of the subquery was not a single row.
-602 (ECPG_WARNING_U NKNOWN_PORTAL)	SQLSTATE 34000	An invalid cursor name was specified.
-603 (ECPG_WARNING_IN _TRANSACTION)	SQLSTATE 25001	A transaction is in progress.
-604 (ECPG_WARNING_N O_TRANSACTION)	SQLSTATE 25P01	There is no active (in-progress) transaction.
-605 (ECPG_WARNING_P ORTAL_EXISTS)	SQLSTATE 42P03	An existing cursor name was specified.

 CAUTION

- The SQLSTATE codes 22002, 07001, 07002, 07006, 07009, 33000, 42601, 42804, 42P03, YE000 and YE001 are newly added to ecpg for embedded SQL statements. Other SQLSTATE codes are inherited from the kernel SQLSTATE codes.
- If the value of **SQLSCODE** is **-400**, ecpg detects that the kernel server returns an error. The error code of the kernel SQLSTATE is used.

## 5.8.11 Preprocessor Directives

This section describes the preprocessing instructions provided by ECPG. The preprocessing instructions are used to process program instructions for macro definition, file inclusion, and conditional compilation.

### 5.8.11.1 Including Files

To include an external file in an embedded SQL program, use the following statements:

```
EXEC SQL INCLUDE filename;  
EXEC SQL INCLUDE <filename>;  
EXEC SQL INCLUDE "filename";
```

#### NOTE

- ECPG searches for files in the following sequence:
  1. Current directory
  2. /usr/local/include
  3. GaussDB Kernel directory, which is defined at build time
  4. /usr/include
- When **EXEC SQL INCLUDE** *"filename"* is used, only the current directory is searched.
- In each directory, ECPG will first look for the file name as given, and if not found will append .h to the file name and try again (unless the specified file name already has that suffix).
- The file name is case sensitive.

### 5.8.11.2 Directives: ifdef, ifndef, else, elif, and endif

ecpg provides ifdef, ifndef, else, elif, and endif conditional compilation instructions. During preprocessing, different parts of the program are compiled based on different conditions. When using the program, you need to add the EXEC SQL prefix keyword.

Example:

```
EXEC SQL ifndef TZVAR;  
EXEC SQL SET TIMEZONE TO 'GMT';  
EXEC SQL elif TZNAME;  
EXEC SQL SET TIMEZONE TO TZNAME;  
EXEC SQL else;  
EXEC SQL SET TIMEZONE TO TZVAR;  
EXEC SQL endif;
```

### 5.8.11.3 Directives: define and undef

Similar to the directive **#define** that is known from C, embedded SQL has a similar concept.

```
EXEC SQL DEFINE name;  
EXEC SQL DEFINE name value;  
EXEC SQL UNDEF name;
```

Example:

```
/* Define a name. */  
EXEC SQL DEFINE HAVE_FEATURE;  
  
/* Define constants. */  
EXEC SQL DEFINE MYNUMBER 12;  
EXEC SQL DEFINE MYSTRING 'abc';
```

```
/* Use undef to remove a previous definition. */  
EXEC SQL UNDEF MYNUMBER;
```

You can also use the C versions **#define** and **#undef** in your embedded SQL program. The difference is where your defined values get evaluated. If you use **EXEC SQL DEFINE**, then `ecpg` evaluates the definitions and substitutes the values. In the following example, `ecpg` does the substitution and the compiler will never see any name or identifier **MYNUMBER**:

```
EXEC SQL DEFINE MYNUMBER 12;  
...  
EXEC SQL UPDATE Tbl SET col = MYNUMBER;
```

#### NOTICE

Note that you cannot use **#define** for a constant that you are going to use in an embedded SQL query because in this case the embedded SQL precompiler is not able to see this declaration.

## 5.8.12 Using Library Functions

- `ECPGdebug(int on, FILE *stream)`: If the first parameter of the function is not 0, the debug log function is enabled. The second parameter indicates the standard output stream of the log to be printed. Debug logs are executed on the standard output stream. The logs contain all input SQL statements and results from the GaussDB Kernel server.

Example:

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
#include "sqlca.h"  
  
int main()  
{  
    ECPGdebug(1, stderr);  
    EXEC SQL CONNECT postgres;  
    EXEC SQL SET AUTOCOMMIT TO ON;  
    EXEC SQL CREATE TABLE T1(a int);  
    return (0);  
}
```

- `ECPGget_PGconn(const char *connection_name)`: returns the database connection handle identified by the given name. If `connection_name` is set to **NULL**, the current connection handle is returned. If no connection handle can be identified, the function returns **NULL**.

Example:

```
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
#include "sqlca.h"  
  
int main()  
{  
    ECPGdebug(1, stderr);  
    EXEC SQL CONNECT TO postgres as con1;  
    EXEC SQL SET AUTOCOMMIT TO ON;  
    EXEC SQL DROP TABLE IF EXISTS T1;  
    PGconn *conn;  
    conn = ECPGget_PGconn("con1");  
    printf("conn = %p\n", conn);  
}
```

```
conn = ECPGget_PGconn(NULL);
printf("conn = %p\n", conn);
EXEC SQL CREATE TABLE T1(a int);
return (0);
}
```

- `ECPGtransactionStatus(const char *connection_name)`: returns the current transaction status of the `connection_name` connection. The possible return values are as follows:

```
PQTRANS_IDLE, /* connection idle */
PQTRANS_ACTIVE, /* command in progress */
PQTRANS_INTRANS, /* idle, within transaction block */
PQTRANS_INERROR, /* idle, within failed transaction */
PQTRANS_UNKNOWN /* cannot determine status */
```

**Example:**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    ECPGdebug(1, stderr);
    EXEC SQL CONNECT TO postgres as con1;
    EXEC SQL DROP TABLE IF EXISTS T1;
    int a = ECPGtransactionStatus("con1");
    printf("%d\n", a);
    EXEC SQL CREATE TABLE T1(a int);
    EXEC SQL COMMIT;
    return (0);
}
```

- `ECPGfree_auto_mem()`: releases all memory allocated for output host variables. This function is called (return\exit) when the program ends.

**Example:**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "sqlca.h"

int main()
{
    EXEC SQL BEGIN DECLARE SECTION;
    int *ip1=0;
    char **cp2=0;
    int *ipointer1=0;
    int *ipointer2=0;
    int colnum;
    EXEC SQL END DECLARE SECTION;
    int i;

    ECPGdebug(1, stderr);

    EXEC SQL WHENEVER SQLERROR DO sqlprint();
    EXEC SQL CONNECT TO REGRESSDB1;

    EXEC SQL SET DATESTYLE TO postgres;

    EXEC SQL CREATE TABLE test (a int, b text);
    EXEC SQL INSERT INTO test VALUES (1, 'one');
    EXEC SQL INSERT INTO test VALUES (2, 'two');
    EXEC SQL INSERT INTO test VALUES (NULL, 'three');
    EXEC SQL INSERT INTO test VALUES (NULL, NULL);

    EXEC SQL ALLOCATE DESCRIPTOR mydesc;
    EXEC SQL SELECT * INTO SQL DESCRIPTOR mydesc FROM test;
    EXEC SQL GET DESCRIPTOR mydesc :colnum=COUNT;
    EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :ip1=DATA, :ipointer1=INDICATOR;
```

```
EXEC SQL GET DESCRIPTOR mydesc VALUE 2 :cp2=DATA, :ipointer2=INDICATOR;

printf("Result (%d columns):\n", colnum);
for (i=0;i < sqlca.sqlerrd[2];++i)
{
    if (ipointer1[i]) printf("NULL, ");
    else printf("%d, ",ip1[i]);

    if (ipointer2[i]) printf("NULL, ");
    else printf("%s", cp2[i]);
    printf("\n");
}
ECPGfree_auto_mem();
printf("\n");

EXEC SQL DEALLOCATE DESCRIPTOR mydesc;
EXEC SQL ROLLBACK;
EXEC SQL DISCONNECT;
return 0;
}
```

## 5.8.13 SQL Descriptor Area

An SQL descriptor area (SQLDA) is a more sophisticated method for processing the result of a SELECT, FETCH or a DESCRIBE statement. An SQLDA groups the data of one row of data together with metadata items into one data structure. `ecpg` provides two ways to use descriptor areas: named SQLDA and C-structure SQLDA.

### 5.8.13.1 Named SQLDA

A named SQLDA consists of a header and one or more item descriptor areas. The header contains information concerning the entire descriptor area, and each item descriptor area describes a column in the result row.

- Before using an SQLDA, you need to allocate it.  
`EXEC SQL ALLOCATE DESCRIPTOR identifier;`
- When you no longer need the SQLDA, deallocate it in time.  
`EXEC SQL DEALLOCATE DESCRIPTOR identifier;`
- To use a descriptor area, declare it using the INTO clause.  
`EXEC SQL FETCH NEXT FROM mycursor INTO SQL DESCRIPTOR mydesc;`

If the result set is empty, the descriptor area still contains the metadata from the query.

- For a prepared query that has not been executed, you can use DESCRIBE to obtain the metadata of its result set.

```
EXEC SQL BEGIN DECLARE SECTION;
char *sql_stmt = "SELECT * FROM table1";
EXEC SQL END DECLARE SECTION;

EXEC SQL PREPARE stmt1 FROM :sql_stmt;
EXEC SQL DESCRIBE stmt1 INTO SQL DESCRIPTOR mydesc;
```

In DESCRIBE and FETCH statements, the INTO and USING keywords are used similarly: they produce a result set and metadata in a descriptor area.

- Retrieve the value in a descriptor area from the header and store it into a host variable.  
`EXEC SQL GET DESCRIPTOR name :hostvar = field;`
- Currently, only one header descriptor area **COUNT** is defined, which tells how many item descriptor areas exist (that is, how many columns are contained in

the result). The host variable must be of the integer type. Retrieve a specific value from the item descriptor area.

```
EXEC SQL GET DESCRIPTOR name VALUE num :hostvar = field;
```

**num** can be a character integer or a host variable that contains an integer.

Possible data types are as follows:

- CARDINALITY (integer): number of rows in the result set
  - DATA: actual data item (therefore, the data type of this field depends on the query)
  - DATETIME\_INTERVAL\_CODE (integer): When **TYPE** is **9**, **DATETIME\_INTERVAL\_CODE** will have a value of **1** for DATE, **2** for TIME, **3** for TIMESTAMP, **4** for TIME WITH TIME ZONE, or **5** for TIMESTAMP WITH TIME ZONE.
  - INDICATOR (integer): indicator (indicating a null value or a value truncation)
  - LENGTH (integer): data length in characters
  - NAME(string): column name
  - OCTET\_LENGTH (integer): length of the character representation of the data in bytes
  - PRECISION (integer): precision (for the numeric type)
  - RETURNED\_LENGTH (integer): data length in characters
  - RETURNED\_OCTET\_LENGTH (integer): length of the character representation of the data in bytes
  - SCALE (integer): ratio (for the numeric type)
  - TYPE (integer): numeric code of the data type of the column
- Retrieve the column value and store it in a host variable.  

```
EXEC SQL GET DESCRIPTOR mydesc VALUE num :hostvar = field
```

**num** can be a character integer or a host variable that contains an integer.

Possible columns are as follows:

- DATA
  - Actual data item (the data type of this column depends on the query)
  - NAME(string)
  - Field name
- Manually create a descriptor area to provide input parameters for a query or cursor.  

```
EXEC SQL SET DESCRIPTOR name VALUE numfield = :hostvar;
```
  - Retrieve multiple rows of records in a FETCH statement and use a host variable of the array type to store data.  

```
EXEC SQL BEGIN DECLARE SECTION;  
int id[5];  
EXEC SQL END DECLARE SECTION;  
EXEC SQL FETCH 5 FROM mycursor INTO SQL DESCRIPTOR mydesc;  
EXEC SQL GET DESCRIPTOR mydesc VALUE 1 :id = DATA;
```

### 5.8.13.2 C-Structure SQLDA

SQLDA is a C language structure used to store a query result set. A structure stores a record of a result set.

```
EXEC SQL include sqllda.h;
sqllda_t      *mysqllda;
EXEC SQL FETCH 3 FROM mycursor INTO DESCRIPTOR mysqllda;
```

Note that the SQL keyword is omitted. The paragraphs about the use cases of the INTO and USING keywords in section [Named SQLDA](#) also apply here. In a DESCRIBE statement, if the INTO keyword is used, the DESCRIPTOR keyword can be omitted.

```
EXEC SQL DESCRIBE prepared_statement INTO mysqllda;
```

- Procedure
  - a. Prepare a query and declare a cursor for it.
  - b. Declare an SQLDA for the result row.
  - c. Declare SQLDA for input parameters, initialize parameters, and allocate memory.
  - d. Open a cursor with the input SQLDA.
  - e. Fetch rows from the cursor and store them in the output SQLDA.
  - f. Read the value from the output SQLDA to the host variable.
  - g. Close the cursor.
  - h. Deallocate the memory allocated to the SQLDA.
- There are three types of SQLDA data structures: sqllda\_t, sqlvar\_t, and struct sqlname.

a. sqllda\_t

The definition of sqllda\_t is as follows:

```
struct sqllda_struct
{
    char      sqldaid[8];
    long      sqldabc;
    short     sqln;
    short     sqld;
    struct sqllda_struct *desc_next;
    struct sqlvar_struct sqlvar[1];
};
typedef struct sqllda_struct sqllda_t;
```

The structure members are described as follows:

- **sqldaid**: contains a string "SQLDA".
  - **sqldabc**: contains the size (in bytes) of the allocated space.
  - **sqln**: contains the number of input parameters for a parameterized query in case it is passed into OPEN, DECLARE or EXECUTE statements using the USING keyword. When it is used as the output of a SELECT, EXECUTE, or FETCH statement, its value is the same as that of **sqld**.
  - **sqld**: contains the number of fields in a result set.
  - **desc\_next**: If the query returns more than one record, multiple linked SQLDA structures are returned, and **desc\_next** holds a pointer to the next SQLDA structure in the list.
  - **sqlvar**: indicates the array of the columns in the result set.
- b. sqlvar\_t

The structure type `sqlvar_t` holds a column value and metadata (such as type and length). The definition of this type is as follows:

```
struct sqlvar_struct
{
    short    sqltype;
    short    sqllen;
    char     *sqldata;
    short    *sqlind;
    struct sqlname sqlname;
};
typedef struct sqlvar_struct sqlvar_t;
```

The structure members are described as follows:

- **sqltype**: contains the type identifier of the field.
- **sqllen**: contains the binary length of the field, for example, 4 bytes for `ECPGt_int`.
- **sqldata**: points to the data. For details about the data format, see [Type Mapping](#).
- **sqlind**: points to a null indicator. The value **0** indicates not null, and the value **-1** indicates null.
- **sqlname**: indicates the name of the field.

c. `struct sqlname`

A `struct sqlname` structure holds a column name. It is treated as a member of the `sqlvar_t` structure. The definition of this type is as follows:

```
#define NAMEDATALEN 64
struct sqlname
{
    short    length;
    char     data[NAMEDATALEN];
};
```

The structure members are described as follows:

- **length**: contains the length of the field name.
  - **data**: contains the actual field name.
- Use an `SQLDA` to retrieve a result set.  
The general procedure for retrieving a query result set through an `SQLDA` is as follows:
    - a. Declare an `sqlda_t` structure to receive the result set.
    - b. Execute the **FETCH**, **EXECUTE**, or **DESCRIBE** command to process a query for which an `SQLDA` has been declared.
    - c. Check the number of records in the result set by looking at `sqln`, a member of the `sqlda_t` structure.
    - d. Fetch the values of each column from `sqlvar[0]`, `sqlvar[1]`, ..., members of the `sqlda_t` structure.
    - e. Go to next row (`sqlda_t`) by following the `desc_next` pointer, a member of the `sqlda_t` structure.
    - f. Repeat the preceding steps as required.

Example:

```
/* Declare an sqlda_t structure to receive the result set. */
sqlda_t *sqlda1;
```

```
/* Next, specify an SQLDA in a command. This is an example of the FETCH command. */
EXEC SQL FETCH NEXT FROM cur1 INTO DESCRIPTOR sqlda1;
/* Run a loop to retrieve rows along the linked list. */
sqlda_t *cur_sqlda;
for (cur_sqlda = sqlda1;
     cur_sqlda != NULL;
     cur_sqlda = cur_sqlda->desc_next)
{
    ...
}
/* Inside the loop, run another loop to retrieve the data of each column in the row (sqlvar_t). */
for (i = 0; i < cur_sqlda->sqln; i++)
{
    sqlvar_t v = cur_sqlda->sqlvar[i];
    char *sqldata = v.sqldata;
    short sqlen = v.sqlen;
    ...
}
/* To fetch the values of a column, check the value of the sqltype member of the sqlvar_t structure.
Then, switch to an appropriate method based on the column type to copy data from the sqlvar field
to a host variable. */
char var_buf[1024];
switch (v.sqltype)
{
    case ECPGt_char:
        memset(&var_buf, 0, sizeof(var_buf));
        memcpy(&var_buf, sqldata, (sizeof(var_buf) <= sqlen ? sizeof(var_buf) - 1 : sqlen));
        break;

    case ECPGt_int:
        memcpy(&intval, sqldata, sqlen);
        snprintf(var_buf, sizeof(var_buf), "%d", intval);
        break;
    ...
}
```

- Use an SQLDA to pass query parameters.

The general procedure for passing input parameters to a prepared query using an SQLDA is as follows:

- a. Create a prepared query (prepared statement).
- b. Declare an sqlda\_t structure as an SQLDA.
- c. Allocate a memory area for the SQLDA.
- d. Set (copy) the input values in the allocated memory.
- e. Open a cursor declaring the SQLDA.

#### Example:

```
/* First, create a prepared statement. */
EXEC SQL BEGIN DECLARE SECTION;
    char query[1024] = "SELECT d.oid, * FROM pg_database d, pg_stat_database s WHERE d.oid =
s.datid AND (d.datname = ? OR d.oid = ?)";
EXEC SQL END DECLARE SECTION;
    EXEC SQL PREPARE stmt1 FROM :query;

/* Allocate memory for an SQLDA and set the number of input parameters in the sqln member
variable of the sqlda_t structure.
* When the prepared query requires two or more input parameters, the application must allocate
extra memory space. The space size is calculated as follows: (Number of parameters - 1) x
sizeof(sqlvar_t).
* The example here shows how to allocate memory space for two input parameters.
*/
sqlda_t *sqlda2;
sqlda2 = (sqlda_t *) malloc(sizeof(sqlda_t) + sizeof(sqlvar_t));
memset(sqlda2, 0, sizeof(sqlda_t) + sizeof(sqlvar_t));
sqlda2->sqln = 2; /* Number of input variables */
/* After memory allocation, store the parameter values into the sqlvar[] array. (This is same array
```

```
used for retrieving column values when the SQLDA is receiving a result set.)
 * In this example, the input parameters are postgres (string type) and 1 (integer type). */
sqlda2->sqlvar[0].sqltype = ECPGt_char;
sqlda2->sqlvar[0].sqldata = "postgres";
sqlda2->sqlvar[0].sqlllen = 8;
int intval = 1;
sqlda2->sqlvar[1].sqltype = ECPGt_int;
sqlda2->sqlvar[1].sqldata = (char *) &intval;
sqlda2->sqlvar[1].sqlllen = sizeof(intval);
/* Input parameters are passed to the prepared statement by opening a cursor and declaring the
SQLDA that has been created. */
EXEC SQL OPEN cur1 USING DESCRIPTOR sqlda2;
/* Finally, the allocated memory must be explicitly released after you use the input SQLDA, which is
different from the SQLDA used to receive query results. */
free(sqlda2);
```

## 5.8.14 Examples

### ecpg Example Code

```
#include <locale.h>
#include <string.h>
#include <stdlib.h>

exec sql whenever sqlerror sqlprint;
exec sql include sqlca;

int main(void)
{
EXEC SQL BEGIN DECLARE SECTION;
    char *temp_str = (char *)malloc(11);
EXEC SQL END DECLARE SECTION;

    ECPGdebug(1, stderr);

    exec sql connect to postgres;

    /* Enable the automatic commit function. You do not need to manually commit the exec sql command. */
    exec sql set autocommit = on;
    exec sql drop table if exists test_t;
    /* Create a table and insert data. */
    exec sql create table test_t(f float, i int, a int[10], mstr char(10));
    exec sql insert into test_t(f, i, a, mstr) values(1.01,1,'{0,1,2,3,4,5,6,7,8,9}', 'China');

    /* Disable the automatic commit function. The following SQL statements for inserting data must be
    manually committed: */
    exec sql set autocommit = off;
    exec sql insert into test_t(f, i, a, mstr) values(2.01,2,'{0,1,2,3,4,5,6,7,8,9}', 'USA');
    exec sql commit;

    exec sql insert into test_t(f, i, a, mstr) values(3.01,3,'{0,1,2,3,4,5,6,7,8,9}', 'AUS');
    exec sql insert into test_t(f, i, a, mstr) values(4.01,4,'{0,1,2,3,4,5,6,7,8,9}', 'JAP');
    exec sql commit;

EXEC SQL BEGIN DECLARE SECTION;
    int a[10] = {9,8,7,6,5,4,3,2,1,0};
    int id = 6;
EXEC SQL END DECLARE SECTION;

    /* Fetch data from the host variable and insert the data into the table. The type of the host variable is
    the same as that defined in the table. */
    strcpy(temp_str, "RUS");
    exec sql insert into test_t(f, i, a, mstr) values(5.01,5,;a;temp_str);
    exec sql commit;

    exec sql set autocommit = on;
    exec sql begin;
    exec sql insert into test_t(f, i, a, mstr) values(6.01,;id,;a,;SIG);
```

```
exec sql commit;
exec sql set autocommit = off;

exec sql begin declare section;
float ff;
char tmp_text[25] = "klmnopqrst";
exec sql end declare section;

exec sql set autocommit = on;
exec sql begin work;

printf("Found ff=%f tmp_text=%10.10s\n", ff, tmp_text);

/* Example of a conditional query statement */
exec sql select f, mstr into :ff,:tmp_text from test_t where f > (select f from test_t where i = 4 or i < 0)
order by a limit 1;
printf("Found ff=%f tmp_text=%10.10s\n", ff, tmp_text);

exec sql select f, mstr into :ff,:tmp_text from test_t where mstr = 'JAP' order by i;
printf("Found ff=%f tmp_text=%10.10s\n", ff, tmp_text);

exec sql select f, mstr into :ff,:tmp_text from test_t order by i DESC limit 1;
printf("Found ff=%f tmp_text=%10.10s\n", ff, tmp_text);

exec sql select f, mstr into :ff,:tmp_text from test_t order by mstr limit 1;
printf("Found ff=%f tmp_text=%10.10s\n", ff, tmp_text);

exec sql select count(f), a into :ff,:tmp_text from test_t where i > 2 group by a limit 1;
printf("Found ff=%f tmp_text=%20.30s\n", ff, tmp_text);

exec sql select count(f), a into :ff,:tmp_text from test_t where i > 3 group by a order by a limit 1;
printf("Found ff=%f tmp_text=%20.30s\n", ff, tmp_text);

exec sql select sum(f), a into :ff,:tmp_text from test_t where i > 2 group by a order by a limit 1;
printf("Found ff=%f tmp_text=%20.30s\n", ff, tmp_text);

exec sql select distinct a into :tmp_text from test_t order by a limit 1;

exec sql drop table test_t;

exec sql commit;
/* Release the connection and release the memory allocated to the host variable. */
exec sql disconnect;
free(temp_str);

return 0;
}
```

## Example Code of the pgtypes Library Function

Example 1: Use library functions to perform different operations on time and date types. For details, see [Using Library Functions](#).

```
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <limits.h>
#include <pgtypes_date.h>
#include <pgtypes_timestamp.h>

char *dates[] = { "19990108foobar",
                  "19990108 foobar",
                  "1999-01-08 foobar",
                  "January 8, 1999",
                  "1999-01-08",
                  "1/8/1999",
                  "1/18/1999",
                  "01/02/03",
                  "1999-Jan-08",
```

```
        "Jan-08-1999",
        "08-Jan-1999",
        "99-Jan-08",
        "08-Jan-99",
        "08-Jan-06",
        "Jan-08-99",
        "19990108",
        "990108",
        "1999.008",
        "J2451187",
        "January 8, 99 BC",
        NULL
    };

/* The value cannot conflict with the value of times of libc. */
static char *times[] = { "0:04",
    "1:59 PDT",
    "13:24:40 -8:00",
    "13:24:40.495+3",
    NULL
};

char *intervals[] = { "1 minute",
    "1 12:59:10",
    "2 day 12 hour 59 minute 10 second",
    "1 days 12 hrs 59 mins 10 secs",
    "1 days 1 hours 1 minutes 1 seconds",
    "1 year 59 mins",
    "1 year 59 mins foobar",
    NULL
};

int main(void)
{
    exec sql begin declare section;
        date date1;
        timestamp ts1, ts2;
        char *text;
        interval *i1;
        date *dc;
    exec sql end declare section;

    int i, j;
    char *endptr;

    ECPGdebug(1, stderr);

    /* Parse a timestamp from its textual representation and convert the date into a character string. */
    ts1 = PGTYPEStimestamp_from_asc("2003-12-04 17:34:29", NULL);
    text = PGTYPEStimestamp_to_asc(ts1);

    printf("timestamp: %s\n", text);
    free(text);

    /* Extract the date part from the timestamp. */
    date1 = PGTYPEStimestamp_to_date(ts1);
    dc = PGTYPEStimestamp_to_date_new(date1);
    *dc = date1;
    /* Return the textual representation of a date variable. */
    text = PGTYPEStimestamp_to_date_asc(*dc);
    printf("Date of timestamp: %s\n", text);
    free(text);
    PGTYPEStimestamp_to_date_free(dc);

    for (i = 0; dates[i]; i++)
    {
        bool err = false;
        /* Parse a date from the textual representation of the date. */
        date1 = PGTYPEStimestamp_to_date_asc(dates[i], &endptr);
```

```
if (date1 == INT_MIN) {
    err = true;
}
/* Return the textual representation of a date variable. */
text = PGTYPEdate_to_asc(date1);
printf("Date[%d]: %s (%c - %c)\n",
       i, err ? "-" : text,
       endptr ? 'N' : 'Y',
       err ? 'T' : 'F');
free(text);
if (!err)
{
    for (j = 0; times[j]; j++)
    {
        int length = strlen(dates[i]) + 1 + strlen(times[j]) + 1;
        char* t = (char *)malloc(length);
        sprintf(t, "%s %s", dates[i], times[j]);
        /* Parse a timestamp from its textual representation and convert the date into a character string.
*/
        ts1 = PGTYPEstimestamp_from_asc(t, NULL);
        text = PGTYPEstimestamp_to_asc(ts1);
        if (i != 19 || j != 3)
            printf("TS[%d,%d]: %s\n", i, j, errno ? "-" : text);
        free(text);
        free(t);
    }
}

/* Parse a timestamp from its textual representation. */
ts1 = PGTYPEstimestamp_from_asc("2004-04-04 23:23:23", NULL);

for (i = 0; intervals[i]; i++)
{
    interval *ic;
    /* Parse an interval from its textual representation. */
    i1 = PGTYPEsinterval_from_asc(intervals[i], &endptr);
    if (*endptr)
        printf("endptr set to %s\n", endptr);
    if (!i1)
    {
        printf("Error parsing interval %d\n", i);
        continue;
    }
    /* Add an interval variable to the timestamp variable. */
    j = PGTYPEstimestamp_add_interval(&ts1, i1, &ts2);
    if (j < 0)
        continue;
    /* Convert a variable of the interval type to the text format. */
    text = PGTYPEsinterval_to_asc(i1);
    printf("interval[%d]: %s\n", i, text ? text : "-");
    free(text);

    /* Return a pointer to an allocated interval variable. */
    ic = PGTYPEsinterval_new();
    /* Copy a variable of the interval type. */
    PGTYPEsinterval_copy(i1, ic);
    /* Convert a variable of the interval type to the text format. */
    text = PGTYPEsinterval_to_asc(i1);
    printf("interval_copy[%d]: %s\n", i, text ? text : "-");
    free(text);
    /* Release the memory that has been allocated to an interval variable. */
    PGTYPEsinterval_free(ic);
    PGTYPEsinterval_free(i1);
}

return (0);
}
```

Example 2: Use the pgtypes library function to perform different operations on the numeric type.

```
#include <stdio.h>
#include <stdlib.h>
#include <pgtypes_numeric.h>
#include <pgtypes_error.h>
#include <decimal.h>

char* nums[] = { "2E394", "-2", ".794", "3.44", "592.49E21", "-32.84e4",
                "2E-394", ".1E-2", "+.0", "-592.49E-07", "+32.84e-4",
                ".500001", "-.5000001",
                "1234567890123456789012345678.91", /* A 30-bit number should be converted into a decimal
number.*/

## 5.8.15 ECPG API Reference

The ECPG API reference describes the data type-related interfaces provided by the pgtypes library for users to use in embedded SQL-C programs. The pgtypes library maps SQL data types to C data types and provides some interfaces to implement basic functions and calculations.

### 5.8.15.1 Interval Type

[Table 5-91](#) lists the common APIs for interval data provided by ecpg.

**Table 5-91** Common interval type APIs

API	Description	Remarks
interval* PGTYPEinterval_new(void)	Returns a pointer to an allocated interval variable.	This function creates an interval variable on the heap. The return value is of the interval* type.
void PGTYPEinterval_free(interval* inval)	Releases the memory that has been allocated to an interval variable.	This function releases the memory allocated to the interval* variable created by the PGTYPEinterval_new function.
interval* PGTYPEinterval_from_asc(char* str, char** endptr)	Parses an interval from its textual representation.	This function parses the input string <b>str</b> and returns a pointer to an allocated interval variable. Currently, <b>ecpg</b> parses the entire character string and does not support storing the address of the first invalid character in <b>*endptr</b> . You can set <b>endptr</b> to <b>NULL</b> .
char* PGTYPEinterval_to_asc(interval* span)	Converts a variable of the interval type into its textual representation.	This function converts the interval variable to which the span points into a char*.
int PGTYPEinterval_copy(interval* intvlsrc, interval* intvldest)	Copies a variable of the interval type.	This function copies the interval variable that intvlsrc points to into the variable that intvldest points to.

## Examples

For details, see [Examples](#).

### 5.8.15.2 Numeric Type

[Table 5-92](#) lists the common APIs for numeric (numeric or decimal) data provided by **ecpg**.

**Table 5-92** Common numeric type APIs

API	Description	Remarks
numeric* PGTYPESnumeric_new(vo id)	Requests a pointer to a newly allocated numeric variable.	This function creates a numeric variable on the heap. The return value is of the numeric* type.
decimal* PGTYPESdecimal_new(vo id)	Requests a pointer to a newly allocated decimal variable.	This function creates a decimal variable on the heap. The return value is of the decimal* type.
void PGTYPESnumeric_free(nu meric* var)	Frees the memory of a variable of the numeric type.	This function frees a numeric* variable created by using the PGTYPESnumeric_new function.
void PGTYPESdecimal_free(de cimal*)	Frees the memory of a variable of the decimal type.	This function frees a decimal* variable created by using the PGTYPESdecimal_new function.
numeric* PGTYPESnumeric_from_a sc(char* str, char** endptr)	Converts a string to the numeric type.	For example, the valid formats are -2, .794, +3.44, 592.49E07 or -32.84e-4. If the value could be parsed successfully, a valid pointer is returned; otherwise, a null pointer is returned. ecpg only parses complete character strings. Currently, ecpg does not support storing the address of the first invalid character in *endptr. However, endptr can be set to null.
char* PGTYPESnumeric_to_asc( numeric* num, int dscale)	Returns a pointer to a string allocated by malloc that contains the string representation of the numeric type num.	The numeric value will be printed using dscale decimal places and will be rounded if necessary.

API	Description	Remarks
int PGTYPESnumeric_add(nu meric* var1, numeric* var2, numeric* result)	Adds two numeric variables to the third numeric variable.	This function adds the variables <i>var1</i> and <i>var2</i> to the result variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_sub(nu meric* var1, numeric* var2, numeric* result)	Subtracts two numeric variables and returns the result to the third numeric variable.	This function subtracts <i>var2</i> from <i>var1</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_mul(nu meric* var1, numeric* var2, numeric* result)	Multiplies two numeric variables and returns the result to the third numeric variable.	This function multiplies variables <i>var1</i> and <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_div(nu meric* var1, numeric* var2, numeric* result)	Divides two numeric variables and returns the result to the third numeric variable.	This function divides variable <i>var1</i> by variable <i>var2</i> . The result of this operation is stored in the variable <i>result</i> . The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_cmp(n umeric* var1, numeric* var2)	Compares two numeric variables.	This function compares two numeric variables. If an error occurs, <i>INT_MAX</i> is returned. On success, this function returns one of the following three possible results: <ul style="list-style-type: none"> <li>• If <i>var1</i> is greater than <i>var2</i>, <b>1</b> is returned.</li> <li>• If <i>var1</i> is smaller than <i>var2</i>, <b>-1</b> is returned.</li> <li>• If <i>var1</i> and <i>var2</i> are equal, <b>0</b> is returned.</li> </ul>

API	Description	Remarks
int PGTYPESnumeric_from_int(signed int int_val, numeric* var)	Converts an int variable into a numeric variable.	This function accepts a signed int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.
int PGTYPESnumeric_from_long(signed long int long_val, numeric* var)	Converts a long int variable into a numeric variable.	This function accepts a long int variable and stores it in the numeric variable <i>var</i> . The function returns <b>0</b> on success and <b>-1</b> in case of failure.
int PGTYPESnumeric_copy(numeric* src, numeric* dst)	Copies a numeric variable to another one.	This function copies the value of the variable that <b>src</b> points to into the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_from_double(double d, numeric* dst)	Converts a double-precision variable into a numeric variable.	This function accepts a double-precision variable and stores the result in the variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error.
int PGTYPESnumeric_to_double(numeric* nv, double* dp)	Converts a numeric variable into a double-precision variable.	This function converts the numeric value in the variable that <b>nv</b> points to into a double-precision variable that <b>dp</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .

API	Description	Remarks
int PGTYPE numeric_to_int( numeric* nv, int* ip)	Converts a numeric variable into an int variable.	This function converts the numeric value in the variable that <b>nv</b> points to into an int variable that <b>ip</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .
int PGTYPE numeric_to_long( numeric* nv, long* ip)	Converts a numeric variable into a long int variable.	This function converts the numeric value in the variable that <b>nv</b> points to into a long int variable that <b>ip</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .
int PGTYPE numeric_to_decimal( numeric* src, decimal* dst)	Converts a numeric variable into a decimal variable.	This function converts the numeric value in the variable that <b>src</b> points to into a decimal variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow). When overflow occurs, the global variable <b>errno</b> is additionally set to <b>PGTYPES_NUM_OVERFLOW</b> .

API	Description	Remarks
int PGTYPESnumeric_from_d ecimal(decimal* src, numeric* dst)	Converts a decimal variable into a numeric variable.	This function converts the decimal value in the variable that <b>src</b> points to into a numeric variable that <b>dst</b> points to. The function returns <b>0</b> on success and <b>-1</b> in case of error (or overflow).

## Examples

For details, see [Examples](#).

### 5.8.15.3 Date Type

[Table 5-93](#) lists the common date type APIs provided by ecpg.

**Table 5-93** Common date type APIs

API	Description	Remarks
date* PGTYPESdate_new(void)	Returns a pointer to an allocated date variable.	This function creates a date variable on the heap. The return value is of the date* type.
void PGTYPESdate_free(date*)	Releases the memory that has been allocated to a date variable.	Frees a date* variable created using the PGTYPESdate_free function.

API	Description	Remarks
<p>date PGTYPESdate_from_asc(char* str, char** endptr)</p>	<p>Parses a date from its textual representation.</p>	<p>This function accepts a C string <b>str</b> and a pointer to a C string <b>endptr</b>. <b>ecpg</b> converts the date expressed in text into a character string. Currently, ECPG does not support storing the address of the first invalid character in <b>*endptr</b>. However, <b>endptr</b> can be set to null.</p> <p>Note that the function always assumes MDY-formatted dates and there is currently no variable to change that within <b>ecpg</b>.</p>
<p>char* PGTYPESdate_to_asc(date dDate)</p>	<p>Returns the textual representation of a date variable.</p>	<p>This function accepts the date <b>dDate</b> as its unique parameter. It will output the date in the YYYY-MM-DD format.</p>
<p>date PGTYPESdate_from_timestamp(timestamp dt)</p>	<p>Extracts the date part from a timestamp.</p>	<p>This function accepts a timestamp as its unique parameter and returns the extracted date part from the timestamp.</p>
<p>void PGTYPESdate_julmdy(date jd, int* mdy)</p>	<p>Extracts the values of day, month, and year from a variable of the date type.</p>	<p>This function accepts the date <b>jd</b> and a pointer to an array of three integer values <b>mdy</b>. The variable name indicates the sequence. <b>mdy[0]</b> indicates the month, <b>mdy[1]</b> indicates the day, and <b>mdy[2]</b> indicates the year.</p>

API	Description	Remarks
void PGTYPEdate_mdyjul(int * mdy, date* jdate)	Creates a date using the specified integer value.	This function accepts an array consisting of three integers ( <b>mdy</b> ) as its first parameter. The three integers are used to indicate the day, month, and year, respectively. The second parameter is a pointer to a variable of the date type, which is used to store the result of the operation.
int PGTYPEdate_dayofweek(date d)	Returns a number indicating the day of a week for a date value.	This function accepts the date variable <b>d</b> as its unique parameter and returns an integer indicating the day of the week.
void PGTYPEdate_today(date * d)	Returns the current date.	This function accepts a pointer to a date variable <b>d</b> and sets the parameter to the current date. <ul style="list-style-type: none"> <li>● <b>0</b>: Sunday</li> <li>● <b>1</b>: Monday</li> <li>● <b>2</b>: Tuesday</li> <li>● <b>3</b>: Wednesday</li> <li>● <b>4</b>: Thursday</li> <li>● <b>5</b>: Friday</li> <li>● <b>6</b>: Saturday</li> </ul>

API	Description	Remarks
int PGTYPEdate_defmt_asc( date* d, const char* fmt, char* str)	Converts a C char* string to a value of the date type using a format mask.	This function accepts a pointer <b>d</b> pointing to a date value for storing the operation result, a format mask <b>fmt</b> for parsing the date, and a C char* string <b>str</b> containing the textual representation of the date. The textual representation is expected to match the format mask. However, you do not need to have a 1:1 mapping of the string to the format mask. The function only analyzes the sequential order and looks for the literals "yy" or "yyyy" that indicate the position of the year, "mm" indicating the position of the month and "dd" indicating the position of the day.  Example of valid input (fmt, str): yy/mm/dd 1994, February 3rd

API	Description	Remarks
int PGTYPEdate_fmt_asc( t dDate, const char* fmtstring, char* outbuf)	Converts a variable of the date type into its textual representation using a format mask.	This function accepts the date <b>dDate</b> to be converted, the format mask <b>fmtstring</b> , and the string <b>outbuf</b> of the textual representation of the date to be saved.  The function returns <b>0</b> on success and a negative value in case of error.  Example of valid input: 112359 //mmddy 59/11/23 //yy/mm/dd Nov.23,1959 //mmm.dd,yyyy Mon,Nov.23,1959 // ddd,mmm.dd,yyyy  Format: <ul style="list-style-type: none"> <li>• <b>dd</b>: indicates the day of a month.</li> <li>• <b>mm</b>: indicates the month of a year.</li> <li>• <b>yy</b>: indicates a two-digit year.</li> <li>• <b>yyyy</b>: indicates a four-digit year.</li> <li>• <b>ddd</b>: indicates the day of a week.</li> <li>• <b>mmm</b>: indicates the month.</li> </ul>

## Examples

For details, see [Examples](#).

### 5.8.15.4 Timestamp Type

[Table 5-94](#) lists the common APIs for timestamp data provided by ecpg.

**Table 5-94** Common timestamp type APIs

API	Description	Remarks
timestamp PGTYPEStimestamp_from_asc(char *str, char **endptr)	Parses a timestamp from its textual representation into a timestamp variable.	This function accepts a string <b>str</b> to parse and a pointer to a C char* <b>endptr</b> . It returns the parsed timestamp on success and <b>PGTYPEStimestamp</b> in case of error. In addition, <b>errno</b> is set to <b>PGTYPEStimestamp</b> when an error occurs.  The valid input of <b>PGTYPEStimestamp_from_asc</b> is as follows: 1999-01-08 04:05:06 January 8 04:05:06 1999 PST 1999-Jan-08 04:05:06.789-8 1999-01-08 04:05:06.789 (time zone specifier ignored) J2451187 04:05-08:00 1999-01-08 04:05:00 (time zone specifier ignored)
char *PGTYPEStimestamp_to_asc(timestamp tstamp)	Converts a date to a C char* string.	This function accepts the timestamp <b>tstamp</b> as its unique parameter and returns an allocated string containing the textual representation of the timestamp. The result must be released using <b>PGTYPEStimestamp_free()</b> .
void PGTYPEStimestamp_current(timestamp *ts)	Returns the current timestamp.	This function obtains the current timestamp and saves it to the timestamp variable that <b>ts</b> points to.

API	Description	Remarks
<p>int PGTYPEStimestamp_fmt_asc(timestamp *ts, char *output, int str_len, char *fmtstr)</p>	<p>Converts a timestamp variable into a C char* using a format mask.</p>	<p>This function accepts a pointer pointing to the timestamp <b>ts</b> to be converted, a pointer pointing to the output buffer <b>output</b>, the maximum length allocated to the output buffer <b>str_len</b>, and the format mask <b>fmtstr</b> for conversion as its parameters.</p> <p>The function returns <b>0</b> on success and a negative value in case of error.</p>
<p>int PGTYPEStimestamp_sub(timestamp *ts1, timestamp *ts2, interval *iv)</p>	<p>Subtracts a timestamp from another timestamp and saves the result in an interval variable.</p>	<p>This function subtracts the timestamp variable that <b>ts2</b> points to from the timestamp variable that <b>ts1</b> points to, and stores the result in the interval variable that <b>iv</b> points to.</p> <p>The function returns <b>0</b> on success and a negative value in case of error.</p>
<p>int PGTYPEStimestamp_defmt_asc(char *str, char *fmt, timestamp *d)</p>	<p>Parses the timestamp value from its textual representation using a format mask.</p>	<p>This function accepts a timestamp textual representation placed in the variable <b>str</b> and a format mask placed in the variable <b>fmt</b> that will be used for conversion. The result will be stored in the variable that <b>d</b> points to.</p> <p>If the format mask <b>fmt</b> is null, the function rolls back to use the default format <b>mask %Y- %m- %d %H: %M: %S</b>.</p>

API	Description	Remarks
int PGTYPEtimestamp_add_ interval(timestamp *tin, interval *span, timestamp *tout)	Adds an interval variable to a timestamp variable.	This function accepts a pointer <b>tin</b> pointing to the timestamp variable and a pointer <b>span</b> pointing to the interval variable. It adds the interval to the timestamp and then saves the result timestamp in the variable that <b>tout</b> points to.  The function returns <b>0</b> on success and a negative value in case of error.
int PGTYPEtimestamp_sub_ interval(timestamp* tin, interval* span, timestamp* tout)	Subtracts an interval variable from a timestamp variable.	This function subtracts the interval variable that <b>span</b> points to from the timestamp variable that <b>tin</b> points to, and then saves the result in the variable that <b>tout</b> points to.  The function returns <b>0</b> on success and a negative value in case of error.

## Examples

For details, see [Examples](#).

## 5.9 Debugging

To control the output of log files and better understand the operating status of the database, modify specific configuration parameters in the **postgresql.conf** file in the instance data directory.

[Table 5-95](#) describes the adjustable configuration parameters.

**Table 5-95** Configuration parameters

Parameter	Description	Value Range	Remarks
client_min_messages	Level of messages to be sent to clients.	<ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• LOG</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>NOTICE</b>	Messages of the set level or lower will be sent to clients. The lower the level is, the fewer the messages will be sent.
log_min_messages	Level of messages to be recorded in server logs.	<ul style="list-style-type: none"> <li>• DEBUG5</li> <li>• DEBUG4</li> <li>• DEBUG3</li> <li>• DEBUG2</li> <li>• DEBUG1</li> <li>• INFO</li> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• LOG</li> <li>• FATAL</li> <li>• PANIC</li> </ul> Default value: <b>WARNING</b>	Messages higher than the set level will be recorded in logs. The higher the level is, the fewer the server logs will be recorded.

Parameter	Description	Value Range	Remarks
log_min_error_statement	Level of SQL error statements to be recorded in server logs.	<ul style="list-style-type: none"> <li>DEBUG5</li> <li>DEBUG4</li> <li>DEBUG3</li> <li>DEBUG2</li> <li>DEBUG1</li> <li>INFO</li> <li>NOTICE</li> <li>WARNING</li> <li>ERROR</li> <li>FATAL</li> <li>PANIC</li> </ul> Default value: ERROR	SQL error statements of the set level or higher will be recorded in server logs. Only a system administrator is allowed to modify this parameter.
log_min_duration_statement	Minimum execution duration of a statement. If the execution duration of a statement is equal to or longer than the set milliseconds, the statement and its duration will be recorded in logs. Enabling this function can help you track the query attempts to be optimized.	INT type Default value: <b>30min</b> Unit: millisecond	The value <b>-1</b> indicates that the function is disabled. Only a system administrator is allowed to modify this parameter.
log_connections/ log_disconnections	Specifies whether to record a server log message when each session is connected or disconnected.	<ul style="list-style-type: none"> <li><b>on</b>: The system records a log server when each session is connected or disconnected.</li> <li><b>off</b>: The system does not record a log server when each session is connected or disconnected.</li> </ul> Default value: <b>off</b>	-

Parameter	Description	Value Range	Remarks
log_duration	Specifies whether to record the duration of each executed statement.	<ul style="list-style-type: none"> <li>● <b>on</b>: The system records the duration of each executed statement.</li> <li>● <b>off</b>: The system does not record the duration of each executed statement.</li> </ul> Default value: <b>off</b>	Only a system administrator is allowed to modify this parameter.
log_statement	SQL statements to be recorded in logs.	<ul style="list-style-type: none"> <li>● <b>none</b>: The system does not record any SQL statements.</li> <li>● <b>ddl</b>: The system records data definition statements.</li> <li>● <b>mod</b>: The system records data definition statements and data operation statements.</li> <li>● <b>all</b>: The system records all statements.</li> </ul> Default value: <b>none</b>	Only a system administrator is allowed to modify this parameter.
log_hostname	Specifies whether to record host names.	<ul style="list-style-type: none"> <li>● <b>on</b>: The system records host names.</li> <li>● <b>off</b>: The system does not record host names.</li> </ul> Default value: <b>off</b>	By default, connection logs only record the IP addresses of connected hosts. With this function, the host names will also be recorded.  This parameter has an impact on viewing audit results, <a href="#">GS_SESSION_MEMORY_DETAIL</a> , <a href="#">PG_STAT_ACTIVITY</a> , and the GUC parameter <a href="#">log_line_prefix</a> .

**Table 5-96** describes the preceding parameter levels.

**Table 5-96** Description of log level parameters

Level	Description
DEBUG[1-5]	Provides information that can be used by developers. Level 1 is the lowest level whereas level 5 is the highest level.
INFO	Provides information about users' hidden requests, for example, information about the VACUUM VERBOSE process.
NOTICE	Provides information that may be important to users, for example, truncations of long identifiers or indexes created as a part of a primary key.
WARNING	Provides warning information for users, for example, COMMIT out of transaction blocks.
ERROR	Reports an error that causes a command to terminate.
LOG	Reports information that administrators may be interested in, for example, the activity levels of check points.
FATAL	Reports the reason that causes a session to terminate.
PANIC	Reports the reason that causes all sessions to terminate.

# 6 SQL Optimization

---

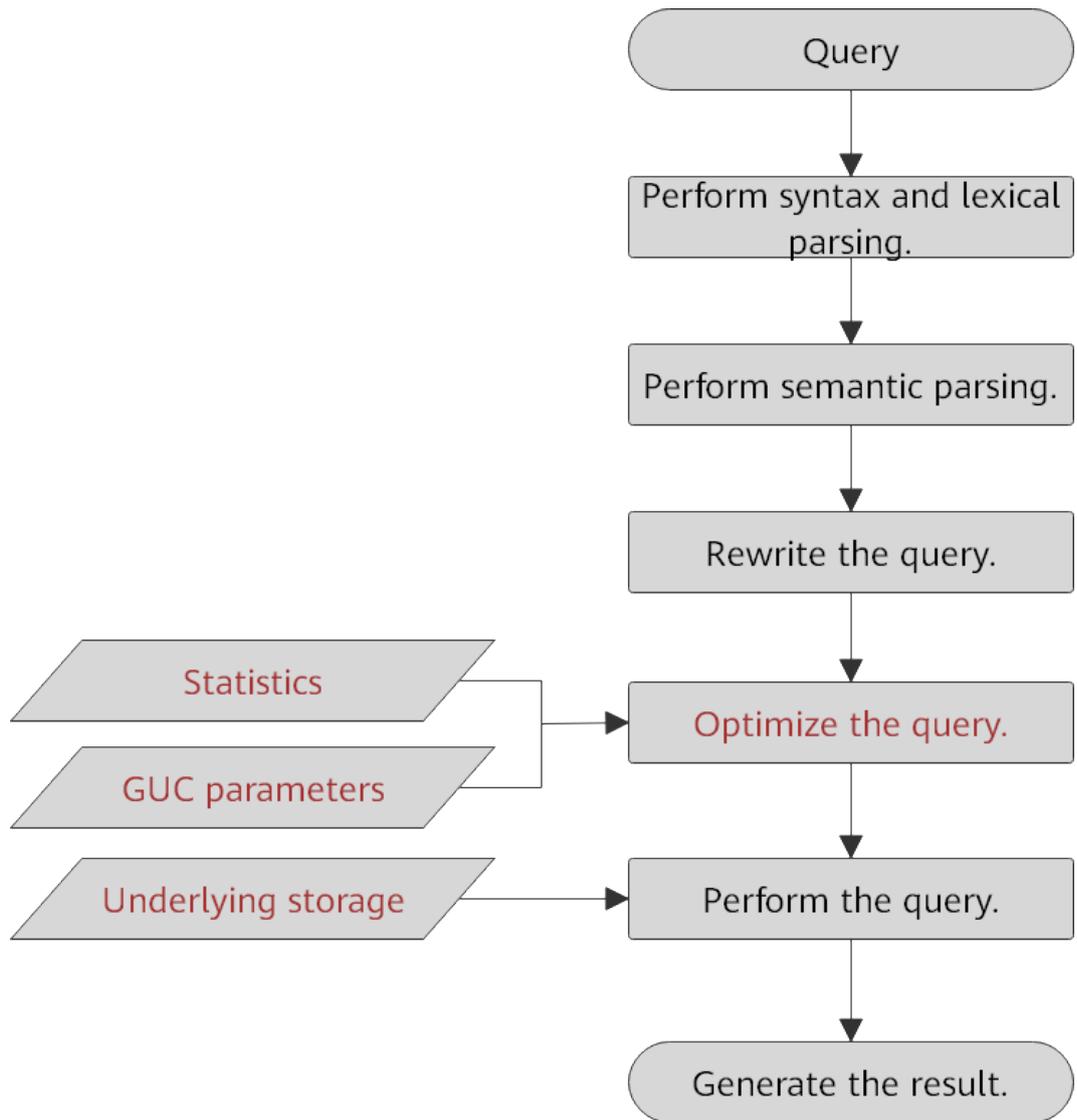

The aim of SQL optimization is to maximize the utilization of resources, including CPU, memory, and disk I/O. All optimization methods are intended for resource utilization. To maximize resource utilization is to run SQL statements as efficiently as possible to achieve the highest performance at a lower cost. For example, when performing a typical point query, you can use a combination of Seq Scan and filter (that is, read each tuple and match the point query condition). You can also use Index Scan, which can implement the query at a lower cost but achieve the same effect.

You can determine a proper database deployment solution and table definition based on hardware resources and service characteristics. This is the basis of meeting performance requirements. The following performance tuning sections assume that you have finished installation based on a proper database solution in the software installation guide and performed database design based on the guide for database design and development.

## 6.1 Query Execution Process

The process from receiving SQL statements to the statement execution by the SQL engine is shown in [Figure 6-1](#) and described in [Table 6-1](#). The texts in red are steps where database administrators can optimize queries.

**Figure 6-1** Execution process of query-related SQL statements by the SQL engine

**Table 6-1** Execution process of query-related SQL statements by the SQL engine

Step	Description
1. Perform syntax and lexical parsing.	Converts the input SQL statements from the string data type to the formatted structure stmt based on the specified SQL statement rules.
2. Perform semantic parsing.	Converts the formatted structure obtained from the previous step into objects that can be recognized by the database.
3. Rewrite the query statements.	Converts the output of the previous step into the structure that optimizes the query execution.

Step	Description
4. Optimize the query.	Determines the execution mode of SQL statements (the execution plan) based on the result obtained from the previous step and the internal database statistics. For details about how the internal database statistics and GUC parameters affect the query optimization (execution plan), see <a href="#">Optimizing Queries Using Statistics</a> and <a href="#">Optimizing Queries Using GUC Parameters</a> .
5. Perform the query.	Executes the SQL statements based on the execution path specified in the previous step. Selecting a proper underlying storage mode improves the query execution efficiency.

## Optimizing Queries Using Statistics

The GaussDB optimizer is a typical cost-based optimization (CBO). By using CBO, the database calculates the number of tuples and the execution cost for each execution step under each execution plan based on the number of table tuples, column width, NULL record ratio, and characteristic values, such as distinct, MCV, and HB values, and certain cost calculation methods. The database then selects the execution plan that takes the lowest cost for the overall execution or for the return of the first tuple. These characteristic values are the statistics, which is the core for optimizing a query. Accurate statistics helps the analyzer select the most appropriate query plan. Generally, you can collect statistics of a table or that of some columns in a table using ANALYZE. You are advised to periodically execute ANALYZE or execute it immediately after you modified most contents in a table.

## Optimizing Queries Using GUC Parameters

Optimizing queries aims to select an efficient execution mode.

Take the following SQL statement as an example:

```
select count(1)
from customer inner join store_sales on (ss_customer_sk = c_customer_sk);
```

During execution of **customer inner join store\_sales**, GaussDB supports nested loop, merge join, and hash join. The optimizer estimates the result set size and the execution cost of each join mode based on the statistics on the **customer** and **store\_sales** tables. It then compares the costs and selects the one costing the least.

As mentioned above, the execution cost is calculated based on certain methods and statistics. If the actual execution cost cannot be accurately estimated, you need to optimize the execution plan by setting GUC parameters. For example, the **random\_page\_cost** parameter indicates the optimizer's calculation of the cost of a non-sequentially-fetched disk page. The default value is **4**. When the random read speed of a machine disk (for example, an SSD) is high, you can decrease the value of this parameter. After the change, the cost of index scanning is reduced, and the index scanning mode is preferred when a plan is generated.

## Optimizing Queries by Rewriting SQL Statements

Besides the preceding methods that improve the performance of the execution plan generated by the SQL engine, database administrators can also enhance SQL statement performance by rewriting SQL statements while retaining the original service logic based on the execution mechanism of the database and abundant practices.

This requires that database administrators know the customer services well and have professional knowledge of SQL statements. Below chapters will describe some common SQL rewriting scenarios.

## 6.2 Introduction to the SQL Execution Plan

### 6.2.1 Overview

The SQL execution plan is a node tree, which displays detailed procedure when GaussDB runs an SQL statement. A database operator indicates one step.

You can run the **EXPLAIN** command to view the execution plan generated for each query by an optimizer. The output of EXPLAIN has one row for each execution node, showing the basic node type and the cost estimation that the optimizer made for the execution of this node, as shown below.

```
gaussdb=# explain select * from t1,t2 where t1.c1 = t2.c2;
          QUERY PLAN
-----
Hash Join (cost=23.73..341.30 rows=16217 width=180)
  Hash Cond: (t1.c1 = t2.c2)
    -> Seq Scan on t1 (cost=0.00..122.17 rows=5317 width=76)
    -> Hash (cost=16.10..16.10 rows=610 width=104)
        -> Seq Scan on t2 (cost=0.00..16.10 rows=610 width=104)
(5 rows)
```

- Nodes at the bottom level are scan nodes. They scan tables and return raw rows. The types of scan nodes (sequential scans and index scans) vary depending on the table access methods. Objects scanned by the bottom layer nodes may not be row-store data (not directly read from a table), such as VALUES clauses and functions that return rows, which have their own types of scan nodes.
- If the query requires join, aggregation, sorting, or other operations on the raw rows, there will be other nodes above the scan nodes to perform these operations. In addition, there is more than one way to perform these operations, so different types of execution nodes may be displayed here.
- The first row (the upper-layer node) estimates the total execution cost of the execution plan. Such an estimate indicates the value that the optimizer tries to minimize.

### Execution Plan Display Format

GaussDB provides four display formats: normal, pretty, summary, and run.

- normal: indicates that the default printing format is used.

- `pretty`: indicates that the new plan display format improved by GaussDB is used. The new format contains a plan node ID, directly and effectively analyzing performance.
- `summary`: indicates that the printing information analysis is added based on the `pretty` format.
- `run`: indicates that the information based on the summary format is exported as a CSV file for further analysis.

An example of an execution plan using the `pretty` format is as follows:

```
gaussdb=# explain select * from t1,t2 where t1.c1=t2.c2;
id | operation | E-rows | E-width | E-costs
-----+-----+-----+-----+-----
 1 | -> Hash Join (2,3) | 23091 | 16 | 58.353..355.674
 2 | -> Seq Scan on t1 | 2149 | 8 | 0.000..31.490
 3 | -> Hash | 2149 | 8 | 31.490..31.490
 4 | -> Seq Scan on t2 | 2149 | 8 | 0.000..31.490
(4 rows)

Predicate Information (identified by plan id)
-----
 1 --Hash Join (2,3)
    Hash Cond: (t1.c1 = t2.c2)
(2 rows)
```

You can change the display format of execution plans by setting the GUC parameter `explain_perf_mode`. The following uses the `pretty` format by default.

## Execution Plan Information

In addition to setting different display formats for an execution plan, you can use different EXPLAIN syntax to display execution plan information in detail. The following lists the common EXPLAIN syntax. For details about more EXPLAIN syntax, see [EXPLAIN](#).

- `EXPLAIN statement`: only generates an execution plan and does not execute. The `statement` indicates SQL statements.
- `EXPLAIN ANALYZE statement`: generates and executes an execution plan, and displays the execution summary. Then actual execution time statistics are added to the display, including the total elapsed time expended within each plan node (in milliseconds) and the total number of rows it actually returned.
- `EXPLAIN PERFORMANCE statement`: generates and executes the execution plan, and displays all execution information.

To measure the run time cost of each node in the execution plan, the current execution of `EXPLAIN ANALYZE` or `EXPLAIN PERFORMANCE` adds profiling overhead to query execution. Running `EXPLAIN ANALYZE` or `EXPLAIN PERFORMANCE` on a query sometimes takes longer time than executing the query normally. The amount of time that exceeds depends on the complexity of the query itself and the platform used.

Therefore, if an SQL statement is not finished after being running for a long time, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, execute the `EXPLAIN ANALYZE` or `EXPLAIN PERFORMANCE` statement to check the execution plan and information to locate the fault.

## 6.2.2 Description

As described in [Overview](#), EXPLAIN displays the execution plan, but will not actually run SQL statements. EXPLAIN ANALYZE and EXPLAIN PERFORMANCE both will actually run SQL statements and return the execution information. This section describes the execution plan and execution information in detail.

### Execution Plans

The following SQL statement is used as an example:

```
SELECT * FROM t1, t2 WHERE t1.c1 = t2.c2;
```

Run the **EXPLAIN** command and the output is as follows:

```
gaussdb=# EXPLAIN SELECT * FROM t1,t2 WHERE t1.c1 = t2.c2;
          QUERY PLAN
-----
Hash Join (cost=23.73..341.30 rows=16217 width=180)
  Hash Cond: (t1.c1 = t2.c2)
    -> Seq Scan on t1 (cost=0.00..122.17 rows=5317 width=76)
    -> Hash (cost=16.10..16.10 rows=610 width=104)
        -> Seq Scan on t2 (cost=0.00..16.10 rows=610 width=104)
(5 rows)
```

**Interpretation of the execution plan level (vertical):**

1. Layer 1: **Seq Scan on t2**

The table scan operator scans the table **t2** using **Seq Scan**. At this layer, data in the table **t2** is read from a buffer or disk, and then transferred to the upper-layer node for calculation.

2. Layer 2: **Hash**

Hash operator. It is used to calculate the hash value of the operator transferred from the lower layer for subsequent hash join operations.

3. Layer 3: **Seq Scan on t1**

The table scan operator scans the table **t1** using **Seq Scan**. At this layer, data in the table **t1** is read from a buffer or disk, and then transferred to the upper-layer node for hash join calculation.

4. Layer 4: **Hash Join**

Join operator. It is used to join data in the **t1** and **t2** tables using the hash join method and output the result data.

**Keywords in the execution plan:**

1. Table access modes

- Seq Scan  
Scans all rows of the table in sequence.
- Index Scan

The optimizer uses a two-step plan: the child plan node visits an index to find the locations of rows matching the index condition, and then the upper plan node actually fetches those rows from the table itself. Fetching rows separately is much more expensive than reading them sequentially, but because not all pages of the table have to be visited, this is still cheaper than a sequential scan. The upper-layer planning node sorts index-identified rows based on their physical locations before reading them. This minimizes the independent capturing overhead.

If there are separate indexes on multiple columns referenced in WHERE, the optimizer might choose to use an AND or OR combination of the indexes. However, this requires the visiting of both indexes, so it is not necessarily a win compared to using just one index and treating the other condition as a filter.

The following index scans featured with different sorting mechanisms are involved:

- Bitmap index scan  
Fetches data pages using a bitmap.
- Index scan using index\_name  
Uses simple index search, which fetches data from an index table in the sequence of index keys. This mode is commonly used when only a small amount of data needs to be fetched from a large data table or when the ORDER BY condition is used to match the index sequence to reduce the sorting time.
- Index-Only Scan  
Scans the index that contains all required data, instead of referencing a table.
- Bitmap Heap Scan  
Reads pages from bitmaps created by other operations and filters out the rows that do not meet the conditions. Bitmap heap scan can avoid random I/Os and accelerate read speed.
- TID Scan  
Scans a table by a tuple ID.
- Index Ctid Scan  
Scans a table based on the CTID index.
- CTE Scan  
Specifies that CTE evaluates subquery operations and stores query results as a temporary table. The temporary table is scanned by the CTE Scan operator.
- Foreign Scan  
Reads data from a remote data source.
- Function Scan  
Obtains result sets returned by functions and returns them as the rows read from tables.
- Sample Scan  
Queries and returns sampled data.
- Subquery Scan  
Reads subquery results.
- Values Scan  
Reads constants as part of the **VALUES** command.
- WorkTable Scan  
Scans a work table. Data is read in the middle of an operation which is usually a recursive operation declared using WITH RECURSIVE.

## 2. Table connection modes

### – Nested Loop

A nested loop is used for queries that have a smaller dataset connected. In a nested loop join, the foreign table drives the internal table and each row returned from the foreign table should have a matching row in the internal table. The returned result set of all queries should be less than 10,000. The table that returns a smaller subset will work as a foreign table, and indexes are recommended for connection columns of the internal table.

### – (Sonic) Hash Join

A hash join is used for large tables. The optimizer uses a hash join, in which rows of one table are entered into an in-memory hash table, after which the other table is scanned and the hash table is probed for matches to each row. Sonic and non-Sonic hash joins differ in their hash table structures, which do not affect the execution result set.

### – Merge Join

In most cases, the execution performance of a merge join is lower than that of a hash join. However, if the source data has been pre-sorted and no more sorting is needed during the merge join, its performance excels.

## 3. Operators

### – sort

Sorts the result set.

### – filter

The EXPLAIN output shows the WHERE clause being applied as a filter condition attached to the Seq Scan plan node. This means that the plan node checks the condition for each row it scans, and returns only the ones that meet the condition. The estimated number of output rows has been reduced because of the WHERE clause. However, the scan will still have to visit all 10,000 rows, as a result, the cost is not decreased. It increases a bit (by 10,000 x **cpu\_operator\_cost**) to reflect the extra CPU time spent on checking the WHERE condition.

### – LIMIT

Limits the number of output execution results. If a LIMIT condition is added, not all rows are retrieved.

### – Append

Appends sub-operation results.

### – Aggregate

Aggregates the results generated from querying rows. It can be an aggregation of statements such as GROUP BY, UNION, and SELECT DISTINCT.

### – BitmapAnd

Specifies the AND operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

### – BitmapOr

Specifies the OR operation of a bitmap, which is used to form a bitmap that matches more complex conditions.

- Gather  
Gathers data of parallel threads.
- Group  
Groups rows to perform the GROUP BY operation.
- GroupAggregate  
Aggregates the pre-sorted rows of the GROUP BY operation.
- Hash  
Hashes rows for the parent query. It is usually used to perform the JOIN operation.
- HashAggregate  
Aggregates the result rows of GROUP BY by using a hash table.
- Merge Append  
Merges subquery results in a way that preserves the sort order. It can be used to merge sorted rows in a table partition.
- ProjectSet  
Executes a function on the returned result set.
- Recursive Union  
Performs a union operation on all steps of a recursive function.
- SetOp  
Specifies a set operation, such as INTERSECT or EXCEPT.
- Unique  
Removes duplicates from an ordered result set.
- HashSetOp  
Specifies a strategy for set operations such as INTERSECT or EXCEPT. It uses Append to avoid pre-sorted input.
- LockRows  
Locks problematic rows to prevent other queries from writing, but allows reading.
- Materialize  
Stores subquery results in the memory so that the parent query can quickly access and obtain the subquery results.
- Result  
Returns a value (such as a hard-coded value) without scanning.
- WindowAgg  
Specifies a window aggregate function, which is generally triggered by the OVER statement.
- Merge  
Performs a merge operation.
- StartWith Operator  
Specifies the hierarchical query operator, which is used to perform recursive query operations.
- Rownum

- Filters the row number in the query result. It usually appears in the ROWNUM clause.
- Index Cond  
Specifies the index scan conditions.
- Unpivot  
Specifies a transpose operator.
- 4. Partition pruning
  - Iterations  
Specifies the number of iterations performed by the partition iteration operator on level-1 partitions. If **PART** is displayed, dynamic pruning is used.  
  
For example, **Iterations: 4** indicates that the iteration operator needs to traverse four level-1 partitions. **Iterations: PART** indicates that the number of level-1 partitions to be traversed is determined by parameter conditions of the partition key.
  - Selected Partitions  
Specifies the selected level-1 partitions for pruning. **m..n** indicates that partitions **m** to **n** are selected. Multiple inconsecutive partitions are separated by commas (,).  
  
For example, **Selected Partitions: 2..4,7** indicates that partitions 2, 3, 4, and 7 are selected.
  - Sub Iterations  
Specifies the number of iterations performed by the partition iteration operator on level-2 partitions. If **PART** is displayed, dynamic pruning is used.  
  
For example, **Sub Iterations: 4** indicates that the iteration operator needs to traverse four level-2 partitions. **Iterations: PART** indicates that the number of level-2 partitions to be traversed is determined by parameter conditions of the partition key.
  - Selected Subpartitions  
Specifies the selected level-2 partitions for pruning, which is in the format like: level-1 partition number:level-2 partition number.  
  
For example, **Selected Subpartitions: 2:1 3:2** indicates that level-2 partition 1 of the second level-1 partition and level-2 partition 2 of the third level-1 partition are selected. **Selected Subpartitions: ALL** indicates that all level-2 partitions are selected.
- 5. Other keywords
  - Partitioned  
Indicates operations on a specific partition.
  - Partition Iterator  
Partition iterator, which usually indicates that a subquery is an operation on a partition.
  - InitPlan  
Indicates a non-related subplan.

## Execution Information

The execution result of the following SQL statement in pretty mode is used as an example:

```
gaussdb=# select sum(t2.c1) from t1,t2 where t1.c1=t2.c2 group by t1.c2;
```

The output of running EXPLAIN PERFORMANCE is as follows:

```
gaussdb=# explain performance select sum(t2.c1) from t1,t2 where t1.c1=t2.c2 group by t1.c2;
id | operation | A-time | A-rows | E-rows | E-distinct | Peak Memory | A-width | E-width | E-costs
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | -> HashAggregate | 0.574 | 0 | 200 | | 29KB | | 8 |
396.113..398.113
2 | -> Hash Join (3,4) | 0.358 | 0 | 18915 | 200, 200 | 12KB | | 8 |
53.763..301.538
3 | -> Seq Scan on public.t1 | 0.037 | 1 | 1945 | | 22KB | | 8 | 0.000..29.450
4 | -> Hash | 0.038 | 0 | 1945 | | 264KB | | 8 | 29.450..29.450
5 | -> Seq Scan on public.t2 | 0.029 | 30 | 1945 | | 22KB | | 8 | 0.000..29.450
(5 rows)
```

===== Query Summary =====
-----
Datanode executor start time: 0.180 ms
Datanode executor run time: 0.590 ms
Datanode executor end time: 0.051 ms
Planner runtime: 0.366 ms
Query Id: 844424930141239
Total runtime: 0.866 ms
(6 rows)
```

In the preceding example, the execution information consists of the following parts:

1. The plan is displayed as a table, which contains 11 columns: **id**, **operation**, **A-time**, **A-rows**, **E-rows**, **E-distinct**, **Peak Memory**, **E-memory**, **A-width**, **E-width**, and **E-costs**. The meanings of the plan-type columns (**id**, **operation**, or columns started with **E**) are the same as those when EXPLAIN is executed. For details, see [Execution Plans](#). The meanings of **A-time**, **A-rows**, **E-distinct**, **Peak Memory**, and **A-width** are described as follows:
  - **A-time**: execution completion time of the current operator.
  - **A-rows**: number of actual output tuples of the operator
  - **E-distinct**: estimated distinct value of the Hash Join operator.
  - **Peak Memory**: peak memory used by the operator during execution.
  - **A-width**: actual tuple width in each row of the current operator. This parameter is valid only for heavy memory operators, including (Vec)HashJoin, (Vec)HashAgg, (Vec)HashSetOp, (Vec)Sort, and (Vec)Materialize. The (Vec)HashJoin calculation width is the width of its right subtree operator and will be displayed on the right subtree.
2. **Predicate Information (identified by plan id)**:  
This part displays the static information that does not change in the plan execution process, such as some join conditions and filter information.
3. **Memory Information (identified by plan id)**:  
This part displays the memory usage information printed by certain operators (mainly Hash and Sort), including **peak memory**, **control memory**, **operator memory**, **width**, **auto spread num**, and **early spilled**; and spill details, including **spill Time(s)**, **inner/outer partition spill num**, **temp file num**, **spilled data volume**, and **written disk IO** [*min*, *max*].
4. **Targetlist Information (identified by plan id)**:  
This part displays the target columns provided by each operator.
5. **DataNode Information (identified by plan id)**:  
This part displays the execution time, CPU, and buffer usage of each operator.

6. ===== Query Summary =====:

This part displays the total execution time and network traffic, including the maximum and minimum execution time in the initialization and end phases, available system memory when the current statement is executed, and estimated statement memory.

## 6.3 Optimization Process

You can analyze slow SQL statements to optimize them.

### Procedure

- Step 1** Collect all table statistics associated with the SQL statements. In a database, statistics indicate the source data of a plan generated by an optimizer. If no collection statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance. According to past experience, about 10% performance problems occurred because no statistics are collected. For details, see [Updating Statistics](#).
- Step 2** View the execution plan to find out the cause. If the SQL statements have been running for a long period of time and not ended, run the **EXPLAIN** command to view the execution plan and then locate the fault. If the SQL statement has been properly executed, run the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to check the execution plan and information to locate the fault. For details about the execution plan, see [Introduction to the SQL Execution Plan](#).
- Step 3** Review and modify a table definition by referring to [Reviewing and Modifying a Table Definition](#).
- Step 4** For details about **EXPLAIN** or **EXPLAIN PERFORMANCE**, the reason why SQL statements are slowly located, and how to solve this problem, see [Typical SQL Optimization Methods](#).
- Step 5** Generally, some SQL statements can be converted to its equivalent statements in all or certain scenarios by rewriting queries. SQL statements are simpler after they are rewritten. Some execution steps can be simplified to improve the performance. Query rewriting methods are universal in all databases. [Experience in Rewriting SQL Statements](#) describes several tuning methods by rewriting SQL statements.
- Step 6** If the root cause of slow SQL statements cannot be analyzed using the preceding methods, you can use the plan trace feature to analyze the root cause of slow SQL statements. For details, see [Introduction to Plan Trace](#).

----End

## 6.4 Updating Statistics

In a database, statistics indicate the source data of a plan generated by an optimizer. If no statistics are available or out of date, the execution plan may seriously deteriorate, leading to low performance.

## Context

The ANALYZE statement collects statistic about table contents in databases, which will be stored in the PG\_STATISTIC system catalog. Then, the query optimizer uses the statistics to work out the most efficient execution plan.

After executing batch insertions and deletions, you are advised to run the **ANALYZE** statement on the table or the entire library to update statistics. By default, 30,000 rows of statistics are sampled. That is, the default value of the GUC parameter **default\_statistics\_target** is **100**. If the total number of rows in the table exceeds 1,600,000, you are advised to set **default\_statistics\_target** to **-2**, indicating that 2% of the statistics are collected.

For an intermediate table generated during the execution of a batch script or stored procedure, you also need to run the **ANALYZE** statement.

If there are multiple inter-related columns in a table and the conditions or grouping operations based on these columns are involved in the query, collect statistics about these columns so that the query optimizer can accurately estimate the number of rows and generate an effective execution plan.

## Procedure

Run the following commands to update the statistics about a table or the entire database:

```
ANALYZE tablename;           -- Update statistics about a table.  
ANALYZE;                       -- Update statistics about the entire database.
```

Run the following statements to perform statistics-related operations on multiple columns:

```
ANALYZE tablename ((column_1, column_2));           -- Collect statistics about column_1 and  
column_2 of tablename.  
  
ALTER TABLE tablename ADD STATISTICS ((column_1, column_2)); -- Declare statistics about column_1  
and column_2 of tablename.  
ANALYZE tablename;           -- Collect statistics about one or more columns.  
  
ALTER TABLE tablename DELETE STATISTICS ((column_1, column_2)); -- Delete statistics about column_1  
and column_2 of tablename or their statistics declaration.
```

### NOTICE

After the statistics are declared for multiple columns by running the **ALTER TABLE *tablename* ADD STATISTICS** statement, the system collects the statistics about these columns next time **ANALYZE** is performed on the table or the entire database.

To collect the statistics, run the **ANALYZE** statement.

### NOTE

Use **EXPLAIN** to show the execution plan of each SQL statement. If **rows=10** (the default value, probably indicating that the table has not been analyzed) is displayed in the **SEQ SCAN** output of a table, execute the ANALYZE statement for this table.

## 6.5 Reviewing and Modifying a Table Definition

### 6.5.1 Overview

To properly define a table, you must:

1. **Reduce the data volume scanned** by using the partition pruning mechanism.
2. **Minimize random I/Os** by using clustering.

The table definition is created during the database design and is reviewed and modified during the SQL statement optimization.

### 6.5.2 Using Partitioned Tables

Partitioning refers to splitting what is logically one large table into smaller physical pieces based on specific schemes. The table based on the logic is called a partitioned table, and a physical piece is called a partition. Data is stored in physical partitions not the logical table. A partitioned table has the following advantages over an ordinary table:

1. High query performance: You can specify partitions when querying partitioned tables, improving query efficiency.
2. High availability: If a certain partition in a partitioned table is faulty, data in the other partitions is still available.
3. Easy maintenance: To fix a partitioned table having a faulty partition, you only need to fix the partition.

Partitioned tables supported by the GaussDB database are level-1 and level-2 partitioned tables. Level-1 partitioned tables include range partitioned tables, interval partitioned tables, list partitioned tables, and hash partitioned tables. Level-2 partitioned tables include nine combinations of any two of range partitioned tables, list partitioned tables, and hash partitioned tables.

- Range partitioned table: Data in different ranges is mapped to different partitions. The range is determined by the partition key specified during the partitioned table creation. The partition key is usually a date. For example, sales data is partitioned by month.
- Interval partitioned table: a special type of range partitioned tables. Compared with range partitioned tables, interval value definition is added. When no matching partition can be found for an inserted record, a partition can be automatically created based on the interval value.
- List partitioned table: Key values contained in the data are stored in different partitions, and the data is mapped to each partition in sequence. The key values contained in the partitions are specified when the partitioned table is created.
- Hash partitioned table: Data is mapped to each partition based on the internal hash algorithm. The number of partitions is specified when the partitioned table is created.
- Level-2 partitioned table: a partitioned table obtained by randomly combining range partitioning, list partitioning, and hash partitioning. Both level-1 and level-2 partitions can be defined in the preceding three ways.

## 6.5.3 Selecting a Data Type

Use the following principles to select efficient data types:

1. **Select data types that facilitate data calculation.**

Generally, the calculation of integers (including common comparison calculations, such as =, >, <, ≥, ≤, and ≠ and GROUP BY) is more efficient than that of strings and floating point numbers.

2. **Select data types with a short length.**

Data types with short length reduce both the data file size and the memory used for computing, improving the I/O and computing performance. For example, use **SMALLINT** instead of **INT**, and **INT** instead of **BIGINT**.

3. **Use the same data type for a join.**

You are advised to use the same data type for a join. To join columns with different data types, the database needs to convert them to the same type, which leads to additional performance overheads.

## 6.6 Typical SQL Optimization Methods

SQL optimization involves continuous analysis and trying. Queries are run before they are used for services to determine whether the performance meets requirements. If it does not, queries will be optimized by [checking the execution plan](#) and identifying the causes. Then, the queries will be run and optimized again until they meet the requirements.

### 6.6.1 Optimizing SQL Self-Diagnosis

Performance issues may occur when you query data or run the **INSERT**, **DELETE**, **UPDATE**, or **CREATE TABLE AS** statement. In this case, you can query the **warning** column in the [PG\\_CONTROL\\_GROUP\\_CONFIG](#) and [GS\\_SESSION\\_MEMORY\\_DETAIL](#) views to obtain reference for performance optimization.

Alarms that can trigger SQL self diagnosis depend on the settings of the GUC parameter **resource\_track\_level**. If **resource\_track\_level** is set to **query**, alarms about the failures in collecting column statistics and pushing down SQL statements will trigger the diagnosis. If **resource\_track\_level** is set to **operator**, all alarms will trigger the diagnosis.

Whether a SQL plan will be diagnosed depends on the settings of the GUC parameter **resource\_track\_cost**. A SQL plan will be diagnosed only if its execution cost is greater than **resource\_track\_cost**. You can use the **EXPLAIN** keyword to check the plan execution cost.

The SQL self-diagnosis function is affected by the **enable\_analyze\_check** parameter. Ensure that the function is enabled before using it.

If a large number of statements are executed, certain data may fail to be collected due to memory control. In this case, you can increase the value of **instr\_unique\_sql\_count**.

## Alarms

Currently, performance alarms will be reported when statistics about one or multiple columns are not collected.

An alarm will be reported if some column statistics are not collected. For details about the optimization, see [Updating Statistics](#) and [Optimizing Statistics](#).

Example alarms:

No statistics about a table are not collected.

```
Statistic Not Collect:  
  schema_test.t1
```

The statistics about a single column are not collected.

```
Statistic Not Collect:  
  schema_test.t2(c1,c2)
```

The statistics about multiple columns are not collected.

```
Statistic Not Collect:  
  schema_test.t3((c1,c2))
```

The statistics about a single column and multiple columns are not collected.

```
Statistic Not Collect:  
  schema_test.t4(c1,c2)  schema_test.t4((c1,c2))
```

## Restrictions

1. An alarm contains a maximum of 2048 characters. If the length of an alarm exceeds this value (for example, a large number of long table names and column names are displayed in the alarm when their statistics are not collected), a warning instead of an alarm will be reported.  
WARNING, "Planner issue report is truncated, the rest of planner issues will be skipped"
2. If a query statement contains the **Limit** operator, alarms of operators lower than **Limit** will not be reported.

## 6.6.2 Optimizing Subqueries

### Context

When an application runs an SQL statement to operate the database, a large number of subqueries are used because they are more clear than table join. Especially in complicated query statements, subqueries have more complete and independent semantics, which makes SQL statements clearer and easier to understand. Therefore, subqueries are widely used.

In GaussDB, subqueries can also be called sublinks based on the location of subqueries in SQL statements.

- Subquery: corresponds to a range table (RangeTblEntry) in the query parse tree. That is, a subquery is a SELECT statement following immediately after the FROM keyword.
- Sublink: corresponds to an expression in the query parsing tree. That is, a sublink is a statement in the WHERE or ON clause or in the target list.

In conclusion, a subquery is a RangeTblEntry and a sublink is an expression in the query parsing tree. A sublink can be found in constraint conditions and expressions. In GaussDB, sublinks can be classified into the following types:

- exist\_sublink: corresponds to the **EXIST** and **NOT EXIST** statements.
- any\_sublink: corresponds to the *op* ANY(SELECT...) statement. *op* can be the <, >, or = operator. IN/NOT IN (SELECT...) also belongs to this type.
- all\_sublink: corresponds to the *op* ALL(SELECT...) statement. *op* can be the <, >, or = operator.
- rowcompare\_sublink: corresponds to the RECORD *op* (SELECT...) statement.
- expr\_sublink: corresponds to the (SELECT with a single target list item...) statement.
- array\_sublink: corresponds to the ARRAY(SELECT...) statement.
- cte\_sublink: corresponds to the WITH(...) query statement.

The exist\_sublink and any\_sublink are pulled up by the optimization engine of GaussDB. In addition, expr\_sublink can also be pulled up. However, because of the flexible use of subqueries in SQL statements, complex subqueries may affect query performance. If you do not want to pull up expr\_sublink, set the GUC parameter **rewrite\_rule**. Subqueries are classified into non-correlated subqueries and correlated subqueries.

- **Non-correlated subqueries**

The execution of a subquery is independent from attributes of the outer query. In this way, a subquery can be executed before outer queries.

Example:

```
gaussdb=# select t1.c1,t1.c2
from t1
where t1.c1 in (
  select c2
  from t2
  where t2.c2 IN (2,3,4)
);

```

QUERY PLAN

---

```
Hash Join
Hash Cond: (t1.c1 = t2.c2)
-> Seq Scan on t1
  Filter: (c1 = ANY ('{2,3,4}'::integer[]))
-> Hash
  -> HashAggregate
      Group By Key: t2.c2
      -> Seq Scan on t2
          Filter: (c2 = ANY ('{2,3,4}'::integer[]))
(9 rows)
```

- **Correlated subqueries**

The execution of a subquery depends on some attributes (used as AND conditions of the subquery) of outer queries. In the following example, **t1.c1** in the **t2.c1 = t1.c1** condition is a correlated attribute. Such a subquery depends on outer queries and needs to be executed once for each outer query.

Example:

```
gaussdb=# select t1.c1,t1.c2
from t1
where t1.c1 in (
```

```

select c2
from t2
where t2.c1 = t1.c1 AND t2.c2 in (2,3,4)
);
          QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: ((c1 = t1.c1) AND (c2 = ANY ('{2,3,4}'::integer[])))
(5 rows)
    
```

## Sublink Optimization on GaussDB

To optimize a sublink, a subquery is pulled up to join with tables in outer queries. You can run the EXPLAIN statement to check whether a sublink is converted into such a plan.

Example:

```

gaussdb=# explain select t1.c1, t1.c2 from t1 where t1.c1 in(select c2 from t2 where t2.c1 = t1.c1);
          QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: (c1 = t1.c1)
(5 rows)
    
```

- **Sublink-release scenarios supported by GaussDB**

- Pulling up the IN sublink
  - The subquery cannot contain columns in the outer query (columns in more outer queries are allowed).
  - The subquery cannot contain volatile functions.

Example:

```

select t1.c1,t1.c2
from t1
where t1.c1 in (
  select c2
  from t2
  where t2.c1 = 1
);
    
```

```

          QUERY PLAN
-----
Streaming (type: GATHER)
  Node/s: All datanodes
  -> Nested Loop Semi Join
      Join Filter: (t1.c1 = t2.c2)
      -> Seq Scan on t1
      -> Materialize
          -> Streaming(type: REDISTRIBUTE)
              Spawn on: datanode1
              -> Seq Scan on t2
                  Filter: (c1 = 1)
(10 rows)
    
```

Replace the execution plan on the right of the arrow with the following execution plan:

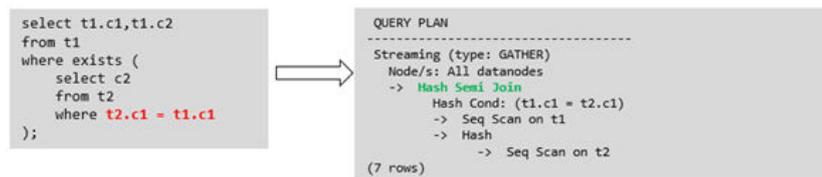

```

          QUERY PLAN
-----
Hash Join
  Hash Cond: (t1.c1 = t2.c2)
  -> Seq Scan on t1
  -> Hash
      -> HashAggregate
          Group By Key: t2.c2
          -> Seq Scan on t2
              Filter: (c1 = 1)
(8 rows)
    
```

- Pulling up the EXISTS sublink  
The WHERE clause must contain a column in the outer query. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The subquery must contain the FROM clause.
- The subquery cannot contain the WITH clause.
- The subquery cannot contain aggregate functions.
- The subquery cannot contain a SET, SORT, LIMIT, WindowAgg, or HAVING operation.
- The subquery cannot contain volatile functions.

Example:

Replace the execution plan on the right of the arrow with the following execution plan:

```

QUERY PLAN
-----
Hash Join
Hash Cond: (t1.c1 = t2.c1)
-> Seq Scan on t1
-> Hash
    -> HashAggregate
        Group By Key: t2.c1
        -> Seq Scan on t2
(7 rows)
    
```

- Pulling up an equivalent correlated query containing aggregate functions  
The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. Other restrictions are as follows:

- The columns in the expression in the WHERE condition of the subquery must exist in tables.
- After the SELECT keyword of the subquery, there must be only one output column. The output column must be an aggregate function (for example, MAX), and the parameter (for example, **t2.c2**) of the aggregate function cannot be columns of a table (for example, **t1**) in outer queries. The aggregate function cannot be COUNT.

For example, the following subquery can be pulled up:

```

select * from t1 where c1 >(
    select max(t2.c1) from t2 where t2.c1=t1.c1
);
    
```

The following subquery cannot be pulled up because the subquery has no aggregate function:

```
select * from t1 where c1 >(
    select t2.c1 from t2 where t2.c1=t1.c1
);
```

The following subquery cannot be pulled up because the subquery has two output columns:

```
select * from t1 where (c1,c2) >(
    select max(t2.c1),min(t2.c2) from t2 where t2.c1=t1.c1
);
```

- The subquery must be a FROM clause.
- The subquery cannot contain a GROUP BY, HAVING, or SET operation.
- The subquery can only be an inner join.

For example, the following subquery cannot be pulled up:

```
select * from t1 where c1 >(
    select max(t2.c1) from t2 full join t3 on (t2.c2=t3.c2) where t2.c1=t1.c1
);
```

- The target list of the subquery cannot contain the function that returns a set.
- The WHERE condition of the subquery must contain a column from the outer query. Equivalence comparison must be performed between this column and related columns in tables of the subquery. These conditions must be connected using AND. Other parts of the subquery cannot contain the column. For example, the following innermost sublink can be pulled up:

```
select * from t3 where t3.c1=(
    select t1.c1
    from t1 where c1 >(
        select max(t2.c1) from t2 where t2.c1=t1.c1
    ));
```

If another condition is added to the subquery in the previous example, the subquery cannot be pulled up because the subquery references to the column in the outer query. Example:

```
select * from t3 where t3.c1=(
    select t1.c1
    from t1 where c1 >(
        select max(t2.c1) from t2 where t2.c1=t1.c1 and t3.c1>t2.c2
    ));
```

– Pulling up a sublink in the OR clause

If the WHERE condition contains an EXIST correlated sublink connected by OR:

Example:

```
select a, c from t1
where t1.a = (select avg(a) from t3 where t1.b = t3.b) or
exists (select * from t4 where t1.c = t4.c);
```

The process of pulling up such a sublink is as follows:

- i. Extract **opExpr** from the OR clause in the WHERE condition. The value is **t1.a = (select avg(a) from t3 where t1.b = t3.b)**.
- ii. The **opExpr** contains a subquery. If the subquery can be pulled up, the subquery is rewritten as **select avg(a), t3.b from t3 group by t3.b**, generating the NOT NULL condition **t3.b is not null**. The

**opExpr** is replaced by this NOT NULL condition. In this case, the SQL statement changes to:

```
select a, c
from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on (t1.a = avg
and t1.b = t3.b)
where t3.b is not null or exists (select * from t4 where t1.c = t4.c);
```

- iii. Extract the **EXISTS** sublink **exists (select \* from t4 where t1.c = t4.c)** from the OR clause to check whether the sublink can be pulled up. If it can be pulled up, the subquery is converted into **select t4.c from t4 group by t4.c**, generating the NOT NULL condition **t4.c is not null**. In this case, the SQL statement changes to:

```
select t1.a, t1.c from t1 left join (select avg(a) avg, t3.b from t3 group by t3.b) as t3 on
(t1.a = avg and t1.b = t3.b) left join (select t5.c from t5 group by t5.c) as t5 on (t1.c =
t5.c) where t3.b is not null or t5.c is not null;
```

- **Sublink-release scenarios not supported by GaussDB**

Except the sublinks described above, all the other sublinks cannot be pulled up. In this case, a join subquery is planned as the combination of subplans and broadcast. As a result, if inner tables have a large amount of data, query performance may be poor.

If a correlated subquery joins with two tables in outer queries, the subquery cannot be pulled up. You need to change the parent query into a WITH clause and then perform the join.

Example:

```
select distinct t1.a, t2.a
from t1 left join t2 on t1.a=t2.a and not exists (select a,b from test1 where test1.a=t1.a and
test1.b=t2.a);
```

The outer query is changed into:

```
with temp as
(
    select * from (select t1.a as a, t2.a as b from t1 left join t2 on t1.a=t2.a)
)
select distinct a,b
from temp
where not exists (select a,b from test1 where temp.a=test1.a and temp.b=test1.b);
```

- The subquery (without COUNT) in the target list cannot be pulled up.

Example:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
```

The execution plan is as follows:

```
gaussdb=# explain (costs off)
select (select c2 from t2 where t1.c1 = t2.c1) ssq, t1.c2
from t1
where t1.c2 > 10;
QUERY PLAN
-----
Seq Scan on t1
  Filter: (c2 > 10)
  SubPlan 1
    -> Seq Scan on t2
        Filter: (t1.c1 = c1)
(5 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met.

Therefore, use a right outer join to join **t2** and **t1** so that the SSQ can return padding values when the condition **t1.c1=t2.c1** is not met.

 NOTE

ScalarSubQuery (SSQ) and Correlated-ScalarSubQuery (CSSQ) are described as follows:

- SSQ: a sublink that returns a scalar value of a single row with a single column
- CSSQ: an SSQ containing correlation conditions

The preceding SQL statement can be changed into:

```
with ssq as
(
  select * from t1 where t1.c2 >10
)
select t2.c2,ssq.c2 from t2 right join ssq on ssq.c1 = t2.c1;
```

The execution plan after the change is as follows:

```
QUERY PLAN
-----
Hash Right Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
    -> Seq Scan on t1
        Filter: (c2 > 10)
(6 rows)
```

In the preceding example, the SSQ in the target list is pulled up to right join, preventing poor performance caused by the plan involving subplans when the table (**t2**) in the subquery is too large.

- The subquery (with COUNT) in the target list cannot be pulled up.

Example:

```
select (select count(*) from t2 where t2.c1=t1.c1) cnt, t1.c1, t3.c1
from t1,t3
where t1.c1=t3.c1 order by cnt, t1.c1;
```

The execution plan is as follows:

```
QUERY PLAN
-----
Sort
Sort Key: ((SubPlan 1)), t1.c1
-> Hash Join
Hash Cond: (t1.c1 = t3.c1)
-> Seq Scan on t1
-> Hash
    -> Seq Scan on t3
SubPlan 1
-> Aggregate
    -> Seq Scan on t2
        Filter: (c1 = t1.c1)
(11 rows)
```

The correlated subquery is displayed in the target list (query return list). Values need to be returned even if the condition **t1.c1=t2.c1** is not met. Therefore, use left outer join to join **T1** and **T2** so that SSQ can return padding values when the condition **t1.c1=t2.c1** is not met. However, COUNT is used, which requires that **0** is returned when the condition is not met. Therefore, case-when NULL then 0 else count(\*) can be used.

The preceding SQL statement can be changed into:

```
with ssq as
(
  select count(*) cnt, c1 from t2 group by c1
```

```
)
select case when
      ssq.cnt is null then 0
      else ssq.cnt
      end cnt, t1.c1, t3.c1
from t1 left join ssq on ssq.c1 = t1.c1,t3
where t1.c1 = t3.c1
order by ssq.cnt, t1.c1;
```

The execution plan after the change is as follows:

```
-----
QUERY PLAN
-----
Sort
  Sort Key: ssq.cnt, t1.c1
  CTE ssq
    -> HashAggregate
      Group By Key: t2.c1
      -> Seq Scan on t2
    -> Hash Join
      Hash Cond: (t1.c1 = t3.c1)
      -> Hash Left Join
        Hash Cond: (t1.c1 = ssq.c1)
        -> Seq Scan on t1
        -> Hash
          -> CTE Scan on ssq
      -> Hash
        -> Seq Scan on t3
(15 rows)
```

- Non-equivalent correlated subqueries cannot be pulled up.

Example:

```
select t1.c1, t1.c2
from t1
where t1.c1 = (select agg() from t2.c2 > t1.c2);
```

Non-equivalent correlated sublinks cannot be pulled up. You can perform join twice (one CorrelationKey and one rownum self-join) to rewrite the statement.

You can rewrite the statement in either of the following ways:

- Subquery rewriting
 

```
select t1.c1, t1.c2
from t1, (
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
) dt /* derived table */
where t1.rowid = dt.rowid AND t1.c1 = dt.aggref;
```

- CTE rewriting
 

```
WITH dt as
(
  select t1.rowid, agg() aggref
  from t1,t2
  where t1.c2 > t2.c2 group by t1.rowid
)
select t1.c1, t1.c2
from t1, dt
where t1.rowid = dt.rowid AND
t1.c1 = dt.aggref;
```

**NOTICE**

- If the AGG type is COUNT(\*), **0** is used for data padding when **CASE-WHEN** is not matched. If the type is not COUNT(\*), **NULL** is used.
- CTE rewriting works better by using sharescan.

## More Optimization Examples

Example: Modify the SELECT statement by modifying the subquery to a join relationship between the main table and the parent query or modifying the subquery to improve the query performance. Ensure that the subquery to be used is semantically correct.

```
gaussdb=# explain (costs off) select * from t1 where t1.c1 in (select t2.c1 from t2 where t1.c1 = t2.c2);
QUERY PLAN
-----
Seq Scan on t1
  Filter: (SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2
        Filter: (t1.c1 = c2)
(5 rows)
```

In the preceding example, a subplan is used. To remove the subplan, you can modify the statement as follows:

```
gaussdb=# explain (costs off) select * from t1 where exists (select t2.c1 from t2 where t1.c1 = t2.c2 and t1.c1 = t2.c1);
QUERY PLAN
-----
Hash Join
  Hash Cond: (t1.c1 = t2.c2)
  -> Seq Scan on t1
  -> Hash
    -> HashAggregate
        Group By Key: t2.c2, t2.c1
    -> Seq Scan on t2
        Filter: (c2 = c1)
(8 rows)
```

In this way, the subplan is replaced by the hash-join between the two tables, greatly improving the execution efficiency.

## 6.6.3 Optimizing Statistics

### Context

GaussDB generates optimal execution plans based on the cost estimation. Optimizers need to estimate the number of data rows and the cost based on statistics collected using ANALYZE. Therefore, the statistics is vital for the estimation of the number of rows and cost. Global statistics are collected using ANALYZE: **relpages** and **reltuples** in the pg\_class table; **stadistinct**, **stanullfrac**, **stanumbersN**, **stavaluesN**, and **histogram\_bounds** in the pg\_statistic table.

### Example 1: Poor Query Performance Due to the Lack of Statistics

In most cases, the lack of statistics about tables or columns involved in the query greatly affects the query performance.

The table structure is as follows:

```
CREATE TABLE LINEITEM
(
  L_ORDERKEY      BIGINT      NOT NULL
, L_PARTKEY      BIGINT      NOT NULL
, L_SUPPKEY      BIGINT      NOT NULL
, L_LINENUMBER   BIGINT      NOT NULL
, L_QUANTITY     DECIMAL(15,2) NOT NULL
, L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL
, L_DISCOUNT    DECIMAL(15,2) NOT NULL
, L_TAX          DECIMAL(15,2) NOT NULL
, L_RETURNFLAG   CHAR(1)     NOT NULL
, L_LINESTATUS   CHAR(1)     NOT NULL
, L_SHIPDATE     DATE        NOT NULL
, L_COMMITDATE   DATE        NOT NULL
, L_RECEIPTDATE  DATE        NOT NULL
, L_SHIPINSTRUCT CHAR(25)    NOT NULL
, L_SHIPMODE     CHAR(10)    NOT NULL
, L_COMMENT      VARCHAR(44) NOT NULL
);

CREATE TABLE ORDERS
(
  O_ORDERKEY      BIGINT      NOT NULL
, O_CUSTKEY       BIGINT      NOT NULL
, O_ORDERSTATUS   CHAR(1)     NOT NULL
, O_TOTALPRICE    DECIMAL(15,2) NOT NULL
, O_ORDERDATE     DATE        NOT NULL
, O_ORDERPRIORITY CHAR(15)    NOT NULL
, O_CLERK         CHAR(15)    NOT NULL
, O_SHIPPRIORITY  BIGINT      NOT NULL
, O_COMMENT       VARCHAR(79) NOT NULL
);
```

The query statements are as follows:

```
explain verbose select
count(*) as numwait
from
lineitem l1,
orders
where
o_orderkey = l1.l_orderkey
and o_orderstatus = 'F'
and l1.l_receiptdate > l1.l_commitdate
and not exists (
select
*
from
lineitem l3
where
l3.l_orderkey = l1.l_orderkey
and l3.l_suppkey <> l1.l_suppkey
and l3.l_receiptdate > l3.l_commitdate
)
order by
numwait desc;
```

If such an issue occurs, you can use the following methods to check whether statistics in tables or columns has been collected using ANALYZE.

1. Execute EXPLAIN VERBOSE to analyze the execution plan and check the warning information:

```
WARNING:Statistics in some tables or columns(public.lineitem.l_receiptdate,
public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey,
public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
HINT:Do analyze for them in order to generate optimized plan.
```

2. Check whether the following information exists in the log file in the **pg\_log** directory. If it does, the poor query performance was caused by the lack of statistics in some tables or columns.

```
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] LOG:Statistics in some tables or columns(public.lineitem.l_receiptdate, public.lineitem.l_commitdate, public.lineitem.l_orderkey, public.lineitem.l_suppkey, public.orders.o_orderstatus, public.orders.o_orderkey) are not collected.
2017-06-14 17:28:30.336 CST 140644024579856 20971684 [BACKEND] HINT:Do analyze for them in order to generate optimized plan.
```

By using any of the preceding methods, you can identify tables or columns whose statistics have not been collected using ANALYZE. You can execute ANALYZE to warnings or tables and columns recorded in logs to resolve the problem.

## 6.6.4 Optimizing Operators

### Context

A query statement needs to go through multiple operator procedures to generate the final result. Sometimes, the overall query performance deteriorates due to long execution time of certain operators, which are regarded as bottleneck operators. In this case, you need to execute the **EXPLAIN ANALYZE** or **EXPLAIN PERFORMANCE** command to view the bottleneck operators, and then perform optimization.

For example, in the following execution process, the execution time of the Hashagg operator accounts for about 66%  $[(51016-13535)/56476 \approx 66\%]$  of the total execution time. Therefore, the Hashagg operator is the bottleneck operator for this query. Optimize this operator first.

id	operation	A-time	A-rows	E-rows	Peak Memory	E-memory	A-width	E-width	E-costs
1	Row Adapter	56476.397	10000000	237060	19KB			20	2093222.75
2	Vector Streaming (type: GATHER)	55664.220	10000000	237060	243KB			20	2093222.75
3	Vector Hash Aggregate	[55124.685, 55132.180]	10000000	237060	[29349KB, 29441KB]	16MB	[20, 20]	20	20918406.50
4	Vector Streaming (type: REDISTRIBUTE)	[52519.781, 53709.779]	339264604	4856184	[1219KB, 1219KB]	1MB		20	10461210.85
5	Vector Hash Aggregate	[25675.616, 25676.424]	339264604	4856184	[71285KB, 716894KB]	16MB	[20, 20]	20	10461210.85
6	Vector Partition Iterator	[9035.202, 13565.884]	97000000	935838097	[9KB, 9KB]	1MB		20	10195891.68
7	Partitioned CStore Scan on xuj1.e_mp_day_energy_mv_1	[9015.645, 13535.346]	97000000	935838097	[845KB, 845KB]	1MB		20	10195891.68

### Examples

Example 1: Scan the base table. For queries requiring large volume of data filtering, such as point queries or queries that need range scanning, a full table scan using SeqScan will take a long time. To facilitate scanning, you can create indexes on the condition column and select IndexScan for index scanning.

```
gaussdb=# explain (analyze on, costs off) select * from t1 where c1=10004;
```

id	operation	A-time	A-rows	Peak Memory	A-width
1	Seq Scan on t1	2053.069	7	64KB	

Predicate Information (identified by plan id)

```
1 --Seq Scan on t1
  Filter: (c1 = 10004)
  Rows Removed by Filter: 110000
```

```
(3 rows)
gaussdb=# create index idx on t1(c1);
CREATE INDEX
```

```
gaussdb=# explain (analyze on, costs off) select * from t1 where c1=10004;
```

id	operation	A-time	A-rows	Peak Memory	A-width
1	Index Scan using idx on t1	0.227	7	77KB	

```
(1 row)

Predicate Information (identified by plan id)
-----
 1 --Index Scan using idx on t1
   Index Cond: (c1 = 10004)
(2 rows)
```

In this example, the full table scan filters large amounts of data and returns 7 records. After an index has been created on the **c1** column, the scanning efficiency is significantly boosted and the duration of IndexScan is reduced from 2s to 0.2 ms.

Example 2: If NestLoop is used for joining tables with a large number of rows, the join may take a long time. In the following example, NestLoop takes 27s. If **enable\_mergejoin** is set to **off** to disable merge join and **enable\_nestloop** is set to **off** to disable NestLoop so that the optimizer selects hash join, the join duration is reduced to 2s.

```
gaussdb=# explain analyze select count(*) from t1,t2 where t1.c1=t2.c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-width | E-
costs
-----+-----+-----+-----+-----+-----+-----+-----
 1 | -> Aggregate | 27544.545 | 1 | 1 | 15KB | | 8 | 1046289.218..1046289.228
 2 | -> Nested Loop (3,4) | 27544.028 | 1992 | 3133 | 8KB | | 0 | 0.000..1046281.385
 3 | -> Seq Scan on t1 | 2043.884 | 110007 | 118967 | 61KB | | 4 | 0.000..157587.670
 4 | -> Materialize | 6877.119 | 54783486 | 498 | 65KB | | 4 | 0.000..11.470
 5 | -> Seq Scan on t2 | 0.430 | 498 | 498 | 57KB | | 4 | 0.000..8.980
(5 rows)
```

After the parameters are set:

```
gaussdb=# set enable_mergejoin=off;
SET
gaussdb=# set enable_nestloop=off;
SET
gaussdb=# explain analyze select count(*) from t1,t2 where t1.c1=t2.c2;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-width | E-
costs
-----+-----+-----+-----+-----+-----+-----+-----
 1 | -> Aggregate | 2103.025 | 1 | 1 | 15KB | | 8 | 158088.164..158088.174
 2 | -> Hash Join (3,4) | 2102.536 | 1992 | 3133 | 10KB | | 0 | 15.205..158080.331
 3 | -> Seq Scan on t1 | 2063.595 | 110007 | 118967 | 61KB | | 4 | 0.000..157587.670
 4 | -> Hash | 0.753 | 498 | 498 | 296KB | | 4 | 8.980..8.980
 5 | -> Seq Scan on t2 | 0.480 | 498 | 498 | 57KB | | 4 | 0.000..8.980
(5 rows)
```

3. Generally, query performance can be improved by selecting **HashAgg**. If **Sort** and **GroupAgg** are used for a large result set, you need to set **enable\_sort** to **off**. **HashAgg** consumes less time than **Sort** and **GroupAgg**.

```
gaussdb=# explain analyze select count(*) from t1 group by c1;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-width | E-
costs
-----+-----+-----+-----+-----+-----+-----+-----
 1 | -> GroupAggregate | 2417.004 | 60000 | 18909 | 17KB | | 12 |
167616.708..168698.051
 2 | -> Sort | 2304.329 | 200016 | 118967 | 26466KB | | 4 | 167616.708..167914.126
 3 | -> Seq Scan on t1 | 2125.464 | 200016 | 118967 | 58KB | | 4 | 0.000..157587.670
(3 rows)
```

After the parameters are set:

```
gaussdb=# set enable_sort=off;
SET
gaussdb=# explain analyze select count(*) from t1 group by c1;
id | operation | A-time | A-rows | E-rows | Peak Memory | A-width | E-width | E-
costs
```

```

+-----+-----+-----+-----+-----+-----+-----+-----+
1 | -> HashAggregate | 2324.062 | 60000 | 39912 | 10066KB | | | 4 | 159297.545..159696.665
2 | -> Seq Scan on t1 | 2131.319 | 200016 | 193303 | 58KB | | | 4 | 0.000..158331.030
(2 rows)

```

## 6.7 Experience in Rewriting SQL Statements

Based on the SQL execution mechanism and a large number of practices, SQL statements can be optimized by following certain rules to enable the database to execute SQL statements more quickly and obtain correct results. You can comply with these rules to improve service query efficiency.

- Replace **UNION** with **UNION ALL**.

**UNION** eliminates duplicate rows while merging two result sets but **UNION ALL** merges the two result sets without deduplication. Therefore, replace **UNION** with **UNION ALL** if you are sure that the two result sets do not contain duplicate rows based on the service logic.

- Add **NOT NULL** to the join columns.

If there are many NULL values in the **JOIN** columns, you can add the filter criterion **IS NOT NULL** to filter data in advance to improve the **JOIN** efficiency.

- Convert **NOT IN** to **NOT EXISTS**.

**nestloop anti join** must be used to implement **NOT IN**, and **hash anti join** is required for **NOT EXISTS**. If no NULL value exists in the **JOIN** columns, **NOT IN** is equivalent to **NOT EXISTS**. Therefore, if you are sure that no NULL value exists, you can convert **NOT IN** to **NOT EXISTS** to generate **hash join** and to improve the query performance.

As shown in the following statement, the **t2.d2** column does not contain null values (it is set to **NOT NULL**) and **NOT EXISTS** is used for the query.

```
SELECT * FROM t1 WHERE NOT EXISTS (SELECT * FROM t2 WHERE t1.c1=t2.d2);
```

The generated execution plan is as follows:

```

QUERY PLAN
-----
Hash Anti Join
Hash Cond: (t1.c1 = t2.d2)
-> Seq Scan on t1
-> Hash
-> Seq Scan on t2
(5 rows)

```

- Use **hashagg**.

If a plan involving groupAgg and SORT operations generated by the **GROUP BY** statement is poor in performance, you can set **work\_mem** to a larger value to generate a **hashagg** plan, which does not require sorting and improves the performance.

- Replace functions with **CASE** statements.

The GaussDB performance greatly deteriorates if a large number of functions are called. In this case, you can change the pushdown functions to **CASE** statements.

- Do not use functions or expressions for indexes.

Using functions or expressions for indexes stops indexing. Instead, it enables scanning on the full table.

- Do not use the !=, <, or > operator, NULL, OR, or implicit parameter conversion in WHERE clauses.
- If the values of >= and <= are the same in WHERE condition, change the condition to = because range equivalence class derivation is not supported currently.

For example, change **SELECT \* FROM t1 WHERE c1 >= 1 AND c1 <= 1** to **SELECT \* FROM t1 WHERE c1 = 1**.

For range queries, the optimizer has a larger error when calculating selectivity than equivalent queries. Therefore, change range queries to equivalent queries as much as possible.

- Split complex SQL statements.  
You can split an SQL statement into several ones and save the execution result to a temporary table if the SQL statement is too complex to be tuned using the solutions above, including but not limited to the following scenarios:
  - The same subquery is involved in multiple SQL statements of a job and the subquery contains large amounts of data.
  - Incorrect plan cost causes a small hash bucket of subquery. For example, the actual number of rows is 10 million, but only 1000 rows are in hash bucket.
  - Functions such as **substr** and **to\_number** cause incorrect measures for subqueries containing large amounts of data.

## 6.8 Configuring Key Parameters for SQL Tuning

This section describes key configuration parameters of the primary database node, which affect GaussDB SQL tuning. Contact the administrator to configure parameters.

**Table 6-2** Parameters of the primary database node

Parameter/ Reference Value	Description
enable_nestloop=on	<p>Specifies how the optimizer uses Nest Loop Join. If this parameter is set to <b>on</b>, the optimizer preferentially uses Nest Loop Join. If it is set to <b>off</b>, the optimizer preferentially uses other methods, if any.</p> <p><b>NOTE</b> If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: SET enable_nestloop to off;</p> <p>By default, this parameter is set to <b>on</b>. Change the value as required. Generally, among the three join modes (Nested Loop, Merge Join, and Hash Join), Nested Loop is applicable to scenarios with small data volume or indexes, and Hash Join is applicable to big data analysis scenarios.</p>

Parameter/ Reference Value	Description
enable_bitmapscan=on	<p>Specifies whether the optimizer uses bitmap scan. If the value is <b>on</b>, bitmap scan is used. If the value is <b>off</b>, it is not used.</p> <p><b>NOTE</b> If you only want to temporarily change the value of this parameter during the current database connection (that is, the current session), execute the following SQL statement: SET enable_bitmapscan to off;</p> <p>The bitmap scan applies only in the query condition <b>where a &gt; 1 and b &gt; 1</b> and indexes are created on columns <b>a</b> and <b>b</b>. However, the performance of bitmapscan is sometimes inferior to that of indexscan. During tuning, if the query performance is poor and bitmapscan operators are in the execution plan, set this parameter to <b>off</b> and check whether the performance is improved.</p>
enable_hashagg=on	Specifies whether the optimizer uses hash aggregate plans.
enable_hashjoin=on	Specifies whether the optimizer uses hash join plans.
enable_mergejoin=on	Specifies whether the optimizer uses merge join plans.
enable_indexscan=on	Specifies whether the optimizer uses index scan plans.
enable_indexonlyscan=on	Specifies whether the optimizer uses index-only scan plans.
enable_seqscan=on	Specifies whether the optimizer uses sequential scan plans. It is impossible to suppress sequential scans entirely, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.
enable_sort=on	Specifies the optimizer sorting order. It is impossible to fully suppress explicit sorting, but setting this variable to <b>off</b> encourages the optimizer to choose other methods if available.
rewrite_rule	Specifies whether the optimizer enables the LAZYAGG, MAGICSET, PARTIALPUSH, DISABLEREP, UNIQUECHECK, INTARGETLIST, PREDPUSH, PREDPUSHFORCE, PREDPUSHNORMAL, DISABLE_PULLUP_EXPR_SUBLINK, SUBLINK_PULLUP_ENHANCED, DISABLE_PULLUP_NOT_IN_SUBLINK, DISABLE_ROWNUM_PUSHDOWN, or DISABLE_WINDOWAGG_PUSHDOWN rewriting rule.

Parameter/ Reference Value	Description
sql_beta_feature	Specifies whether the optimizer enables the following functions: SEL_SEMI_POISSON, SEL_EXPR_INSTR, PARAM_PATH_GEN, RAND_COST_OPT, PARAM_PATH_OPT, PAGE_EST_OPT, CANONICAL_PATHKEY, PREDPUSH_SAME_LEVEL, PARTITION_FDW_ON, DISABLE_BITMAP_COST_WITH_LOSSY_PAGES, ENABLE_UPSERT_EXECUTE_GPLAN, and DISABLE_FASTPATH_INSERT.
var_eq_const_selectivity	Specifies whether the optimizer uses histograms to calculate the selectivity of integer constants.
partition_page_estimation	Specifies whether to optimize page estimation of partitioned table pages based on the pruning result. Only the partitioned table pages and local index pages are included. The global index pages are not included. The estimation formula is as follows:  Number of pages after estimation = Total number of pages in the partitioned table x (Number of partitions after pruning/Total number of partitions)
partition_iterator_elimination	Specifies whether to eliminate the partition iteration operators to improve execution efficiency when the partition pruning result of a partitioned table is a partition.

Parameter/ Reference Value	Description
enable_functional_dependency	<p>Specifies whether functional dependency statistics are used.</p> <p>Setting this parameter to <b>on</b> will enable the following functions:</p> <ol style="list-style-type: none"> <li>1. The statistics about multiple columns generated by ANALYZE contain functional dependency statistics.</li> <li>2. Function dependency statistics are used to calculate the selectivity.</li> </ol> <p>Setting this parameter to <b>off</b>, the two functions do not take effect, that is:</p> <ol style="list-style-type: none"> <li>1. The statistics about multiple columns generated by ANALYZE do not contain functional dependency statistics.</li> <li>2. Function dependency statistics are not used to calculate the selectivity.</li> </ol> <p><b>NOTE</b> The concept of functional dependency comes from the relational database normal form, which indicates the functional relationship between attributes. The concept of functional dependency statistics derives from the preceding concept. It indicates the ratio of the data volume that meets the functional relationship to the total data volume. Functional dependency statistics are a type of multi-column statistics, which can be used to improve the accuracy of selectivity estimation.</p> <p>Functional dependency statistics are applicable to the <b>where a = 1 and b = 1</b> condition, in which <b>a</b> and <b>b</b> must be attributes of the same table subject to equivalent constraints and the constraints are connected by AND. There are at least two constraints.</p>
enable_seqscan_fusion	Specifies whether to enable the sequential scan noise floor elimination function.
enable_inner_unique_opt	Specifies whether the optimizer uses Inner Unique.

## 6.9 Hint-based Tuning

### 6.9.1 Plan Hint Optimization

In plan hints, you can specify a join order, join and scan operations, and the number of rows in a result to tune an execution plan, improving query performance.

GaussDB also provides the SQL patch function. You can create an SQL patch to make hints take effect without modifying service statements.

## Description

Plan hints are specified in the following format after keywords such as SELECT, INSERT, UPDATE, DELETE, and MERGE:

```
/*+ <plan hint>*/
```

You can specify multiple hints for a query plan and separate them with spaces. A hint specified for a query plan does not apply to its subquery plans. To specify a hint for a subquery, add the hint following the SELECT of this subquery.

Example:

```
select /*+ <plan_hint1> <plan_hint2> */ * from t1, (select /*+ <plan_hint3> */ * from t2) where 1=1;
```

In the preceding command, *<plan\_hint1>* and *<plan\_hint2>* are the hints of a query, and *<plan\_hint3>* is the hint of its subquery.

You can use the EXPLAIN syntax to analyze the plan hint optimization effect. You can use EXPLAIN to view the plan of the target SQL statement after the plan hint is used and check whether the plan meets the requirements to verify the plan hint effect. EXPLAIN has multiple plan display modes, which are controlled by **explain\_perf\_mode**. In some examples in this section, **explain\_perf\_mode** is set to **pretty** to display complete plan information. In some examples, **explain\_perf\_mode** is set to **normal** to simplify the output information.

---

### NOTICE

If a hint is specified in the **CREATE VIEW** statement, the hint will be applied each time this view is used.

If the random plan function is enabled (**plan\_mode\_seed** is set to a value other than 0), the specified hint will not be used.

---

## Scope

Currently, the following hints are supported:

- Join order hints (**leading**).
- Join operation hints, excluding the **semi join**, **anti join**, and **unique plan** hints.
- Rows hints.
- Stream operation hints.
- Scan operation hints, supporting only the **tablescan**, **indexscan**, and **indexonlyscan** hints
- Sublink name hints.
- Hints specifying not to expand subqueries.
- Hints for internal table materialization.
- **Bitmapscan** hints
- Hints of the Agg method

## Precautions

Hints do not support **Sort**, **Setop**, or **Subplan**.

## Example

The following are the statements (used in most examples in this section) and the original plan without hints for comparing the methods supported by Plan Hint:

```
create table t1(c1 int, c2 int, c3 int);
create table t2(c1 int, c2 int, c3 int);
create table t3(c1 int, c2 int, c3 int);
create index it1 on t1(c1,c2);
create index it2 on t2(c1,c2);
create index it3 on t1(c3,c2);
create table store
(
  s_store_sk          integer          not null,
  s_store_id         char(16)         not null,
  s_rec_start_date   date              ,

(23 rows)

```

## 6.9.2 Hint Specifying the Query Block Where the Hint Is Located

### Description

This function allows users to use @queryblock in hints to implement block-level hint control. Users can specify the query block to which the hint takes effect. For example, you can specify the hint of an inner query block in the outer query block.

## Syntax

Add **@queryblock** at the beginning of the hint parameter. **Hint\_SEPC** is a specific hint.

```
Hint_SEPC([@queryblock])
```

## Parameters

**Hint\_SEPC** is the hint name, and **@queryblock** can be left empty. If **@queryblock** is left empty, the hint takes effect in the current query block declared by the hint. If **@queryblock** is left empty and **Hint\_SPEC** has no parameter, use **Hint\_SPEC** instead of **Hint\_SPEC()**. Parentheses are unnecessary. The following describes how to name a query block and how to make a hint take effect. Some hints do not take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

- Query the name of a query block.

Each query block must have a name, so as to accurately specify a hint. There are two naming methods: user-specified and system-specified.

- You can use the blockname hint to specify the block to be queried. For details, see [Sublink Name Hints](#).
- If no alias is specified for a query block, the default block name is automatically generated based on the processing sequence. Generally, the default alias of each query block consists of the first three letters of the query block name, \$, and the number of the query block. For example, the alias of the first SELECT query block is **sel\$1**. In pretty mode, you can use the explain method with a specified block name to view the name of the query block where the processing operator of each table is located.

```
gaussdb=# set explain_perf_mode = pretty;
SET
gaussdb=# explain (blockname on,costs off) select * from t1, (select c1 from t2 group by c1) sub1
where t1.c1 = sub1.c1;
id |          operation          | Query Block
-----+-----+-----
 1 | -> Hash Join (2,3)          | sel$1
 2 | -> Seq Scan on t1@"sel$1"   | sel$1
 3 | -> Hash                     |
 4 | -> HashAggregate           | sel$2
 5 | -> Seq Scan on t2@"sel$2" | sel$2
(5 rows)
```

You can see that Seq Scan of **t2** is located in the **sel\$2** query block.

- **@queryblock** specifies the query block.

For the preceding example, if you want to modify the indexscan mode in **t2**, run the following command:

```
select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1, (select c1 from t2 group by c1) sub1 where
t1.c1 = sub1.c1;
```

Both indexscan and tablescan are scan hints. For details about scan hints, see [Scan Operation Hints](#). You can specify the hint of indexscan(**@sel\$2 t2**) in the **sel\$1** query block to move the hint to the **sel\$2** query block. The hint takes effect for **t2**. If the **sel\$2** query block is promoted **sel\$1** during subsequent rewriting, the hint is also promoted together to **sel\$1** and continues to take effect for **t2**.

```
gaussdb=# explain (blockname on,costs off) select /*+indexscan(@sel$2 t2) tablescan(t1)*/ * from t1,
(select c1 from t2 group by c1) sub1 where t1.c1 = sub1.c1;
```

id	operation	Query Block
1	-> Hash Join (2,3)	sel\$1
2	-> Seq Scan on t1@sel\$1	sel\$1
3	-> Hash	
4	-> Group	sel\$2
5	-> Index Only Scan using it2 on t2@sel\$2	sel\$2

(5 rows)

**CAUTION**

Sometimes, query rewriting in the optimizer phase expands some query blocks. As a result, the plan does not display related query blocks in the explain method. The hint specifies a query block based on the name of the query block before the optimizer phase. If a query block to be queried may be expanded in the planning phase, you can add the `no_expand` hint (see [Hints Specifying Not to Expand Subqueries](#)) to prevent it from being expanded.

1. The `sel$2` query block is a simple query. The optimizer performs query rewriting during subsequent processing, and `t1` is promoted to `sel$1` for processing. Therefore, the operation in the `sel$2` query block is not displayed in the plan.

```
gaussdb=# explain (blockname on,costs off) select * from t2, (select c1 from t1 where t1.c3 = 2)
sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Hash Join (2,3) | sel$1
2 | -> Seq Scan on t2@"sel$1" | sel$1
3 | -> Hash |
4 | -> Bitmap Heap Scan on t1@"sel$2" | sel$1
5 | -> Bitmap Index Scan using it3 |
(5 rows)
```

2. The `sel$2` query block is a simple query. During subsequent processing, the optimizer skips query rewriting because of the `no_expand` hint, and `t1` is still processed in the original query block.

```
gaussdb=# explain (blockname on,costs off) select * from t2, (select /*+ no_expand*/ c1 from t1
where t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Hash Join (2,3) | sel$1
2 | -> Seq Scan on t2@"sel$1" | sel$1
3 | -> Hash |
4 | -> Bitmap Heap Scan on t1@"sel$2" | sel$2
5 | -> Bitmap Index Scan using it3 |
(5 rows)
```

3. Because `t1` is processed in the `sel$2` query block after the `no_expand` hint is added, you can use `@sel$2` to specify the query block for the hint.

```
gaussdb=# explain (blockname on,costs off) select /*+ indexscan(@sel$2 t1)*/ * from t2, (select c1
from t1 where t1.c3 = 2) sub1 where t2.c1 = sub1.c1;
id | operation | Query Block
-----+-----+-----
1 | -> Hash Join (2,3) | sel$1
2 | -> Seq Scan on t2@"sel$1" | sel$1
3 | -> Hash |
4 | -> Index Scan using it3 on t1@"sel$2" | sel$1
(4 rows)
```

4. The query block number in the view depends on the sequence of the statement using the view. Therefore, do not use hints to specify query blocks when creating a view. The behavior is uncontrollable.

```
gaussdb=# create view v1 as select /*+ no_expand */ c1 from t1 where c1 in (select /*+ no_expand
*/ c1 from t2 where t2.c3=4 );
CREATE VIEW
gaussdb=# explain (blockname on,costs off) select * from v1;
id | operation | Query Block
-----+-----+-----
1 | -> Seq Scan on t1@"sel$2" | sel$2
2 | -> Seq Scan on t2@"sel$3" [1, SubPlan 1] | sel$3
(2 rows)

Predicate Information (identified by plan id)
-----
```

```
1 --Seq Scan on t1@"sel$2"
  Filter: (hashed SubPlan 1)
2 --Seq Scan on t2@"sel$3"
  Filter: (c3 = 4)
(4 rows)
```

In this case, the statements in **v1** belong to **sel\$2** and **sel\$3**.

- Some hints do not take effect only at the outermost layer and cannot be specified using **@queryblock**. For details, see the syntax description of each hint.

## 6.9.3 Hint Specifying the Query Block and Schema of a Table

### Description

In a query, the table name can be duplicate in different query blocks and different schemas. Therefore, when specifying a table in a query, you can use a hint to specify the query block and schema where the table is located to avoid ambiguity. This function is applicable to all hints whose table names need to be specified.

### Syntax

When specifying a table using a hint, specify a schema using a period (*schema*) and a query block using the at sign (*@queryblock*). Both the schema and query block can be left empty.

```
[schema.]relnam[@queryblock]
```

### Parameters

- relnam** indicates the name of the table in the query. If the table has an alias, use the alias first. In this case, **relnam** is set to the alias. If the table name contains special characters, such as at sign (@) and period (.), **relnam** must be enclosed in double quotation marks (") to avoid conflict with the declaration of the query block and schema names. For example, if the table name is **relnametest@1**, enter "**relnametest@1**".
- schema** indicates the schema where the table is located. It can be left empty. If no schema is specified, the hint searches all schemas for **relnam**.
- queryblock** indicates the query block where the table is located. It can be left empty. If no query block is specified, the hint searches all query blocks for **relnam**.

### Example

- t1** of **sel\$2** is promoted to **sel\$1** for processing, and **t1** is unclear.

```
gaussdb=# explain(blockname on,costs off) select /*+ indexscan(t1)*/ * from t1, (select c2 from t1
where c1=1) tt1 where t1.c1 = tt1.c2;
WARNING: Error hint: IndexScan(t1), relation name "t1" is ambiguous.
...
```

- t1@sel\$2** is specified to perform indexscan on **t1** of **sel\$2** (Index Cond: (c1 = 1)).

```
gaussdb=# explain(blockname on,costs off) select /*+ indexscan(t1@sel$2)*/ * from t1, (select c2 from
t1 where c1=1) tt1 where t1.c1 = tt1.c2;
id | operation | Query Block
-----+-----+-----
1 | -> Hash Join (2,3) | sel$1
```

```
2 | -> Seq Scan on t1@"sel$1" | sel$1
3 | -> Hash |
4 | -> Index Only Scan using it1 on t1@"sel$2" | sel$1
(4 rows)

Predicate Information (identified by plan id)
-----
1 --Hash Join (2,3)
   Hash Cond: (public.t1.c1 = public.t1.c2)
4 --Index Only Scan using it1 on t1@"sel$2"
   Index Cond: (c1 = 1)
(4 rows)
```

## 6.9.4 Join Order Hints

### Description

These hints specify the join order and outer/inner tables.

### Syntax

- Specify only the join order.

```
leading([@queryblock] join_table_list)
```

- Specify the join order and outer/inner tables. The outer/inner tables are specified by the outermost parentheses.

```
leading([@queryblock] (join_table_list))
```

### Parameters

*join\_table\_list* specifies the tables to be joined. The values can be table names or table aliases. If a subquery is pulled up, the value can also be the subquery alias. Separate the values with spaces. You can add parentheses to specify the join priorities of tables.

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.

---

#### NOTICE

A table name or alias can only be a string without a schema name.

An alias (if any) is used to represent a table.

---

To prevent semantic errors, tables in the list must meet the following requirements:

- The tables must exist in the query or its subquery to be pulled up.
- The table names must be unique in the query or subquery to be pulled up. If they are not, their aliases must be unique.
- A table appears only once in the list.
- An alias (if any) is used to represent a table.

For example:

**leading(t1 t2 t3 t4 t5):** t1, t2, t3, t4, and t5 are joined. The join sequence and outer/inner tables are not specified.

**leading((t1 t2 t3 t4 t5)):** t1, t2, t3, t4, and t5 are joined in sequence. The table on the right is used as the inner table in each join.

**leading(t1 (t2 t3 t4) t5):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1 and t5, and the outer/inner tables are not specified.

**leading((t1 (t2 t3 t4) t5)):** First, t2, t3, and t4 are joined and the outer/inner tables are not specified. Then, the result is joined with t1, and (t2 t3 t4) is used as the inner table. Finally, the result is joined with t5, and t5 is used as the inner table.

**leading((t1 (t2 t3) t4 t5) leading((t3 t2))):** First, t2 and t3 are joined and t2 is used as the inner table. Then, the result is joined with t1, and (t2 t3) is used as the inner table. Finally, the result is joined with t4 and then t5, and the table on the right in each join is used as the inner table.

## Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ leading((((store_sales store) promotion) item) customer) ad2) store_returns) leading((store
store_sales)*/ i_product_name product_name ...
```

First, **store\_sales** and **store** are joined and **store\_sales** is the inner table. Then, the result is joined with **promotion**, **item**, **customer**, **ad2**, and **store\_returns** in sequence. The optimized plan is as follows.

```
WARNING: Duplicated or conflict hint: Leading(store_sales store), will be discarded.
QUERY PLAN
-----
HashAggregate (cost=55.24..55.25 rows=1 width=880)
  Group By Key: item_i_product_name, item_i_item_sk, store_s_store_name, store_s_zip, ad2.ca_street_number, ad2.ca_street_name, ad2.ca_city, ad2.ca_zip
  -> Nested Loop (cost=29.93..50.21 rows=1 width=776)
    -> Nested Loop (cost=29.93..54.80 rows=1 width=784)
      -> Nested Loop (cost=29.93..54.11 rows=1 width=424)
        -> Nested Loop (cost=29.93..53.70 rows=1 width=424)
          Join Filter: (store_sales.ss_item_sk = item_i_item_sk)
          -> Seq Scan on item (cost=1.00..11.16 rows=1 width=208)
            Filter: ((i_current_price >= 35::numeric) AND (i_current_price <= 45::numeric) AND (i_current_price <= 50::numeric) AND (i_color
= ANY ('{maroon,burnished,dia,steel,navajo,chocolate}'::bpchar)))
          -> Hash Join (cost=70.93..41.99 rows=44 width=216)
            Hash Cond: (promotion.p_promo_sk = store_sales.ss_promo_sk)
            -> Seq Scan on promotion (cost=0.00..11.12 rows=118 width=4)
            -> Hash (cost=29.00..29.00 rows=74 width=220)
              -> Hash Join (cost=17.61..29.00 rows=74 width=220)
                Hash Cond: (store_s_store_sk = store_sales.ss_store_sk)
                -> Seq Scan on store (cost=0.00..10.44 rows=44 width=166)
                -> Hash (cost=13.88..13.88 rows=338 width=62)
                  -> Seq Scan on store_sales (cost=0.00..13.38 rows=338 width=62)
                  -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
                    Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
                  -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
                    Index Cond: (ca_address_sk = customer.c_current_addr_sk)
                  -> Index Only Scan using store_returns_pkey on store_returns (cost=0.00..0.41 rows=1 width=8)
                    Index Cond: ((sr_item_sk = store_sales.ss_item_sk) AND (sr_ticket_number = store_sales.ss_ticket_number))
(24 rows)
```

For details about the warning at the top of the plan, see [Hint Errors, Conflicts, and Other Warnings](#).

## 6.9.5 Join Operation Hints

### Description

These hints specify the join method, which can be nested loop join, hash join, or merge join.

### Syntax

```
[no] nestloop|hashjoin|mergejoin([@queryblock] table_list)
```

## Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **no** indicates that the specified hint will not be used for a join.
- *table\_list* specifies the tables to be joined. The values are the same as those of **join\_table\_list** but contain no parentheses.

For example:

**no nestloop(t1 t2 t3):** **nestloop** is not used for joining **t1**, **t2**, and **t3**. The three tables may be joined in either of the two ways: Join **t2** and **t3**, and then **t1**; join **t1** and **t2**, and then **t3**. This hint takes effect only for the last join. If necessary, you can hint other joins. For example, you can add **no nestloop(t2 t3)** to join **t2** and **t3** first and to forbid the use of **nestloop**.

## Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ nestloop(store_sales store_returns item) */ i_product_name product_name ...
```

**nestloop** is used for the last join between **store\_sales**, **store\_returns**, and **item**. The optimized plan is as follows:

```

QUERY PLAN
-----
HashAggregate (cost=23.52..23.53 rows=1 width=880)
  Group By Key: item_i_product_name, item_i_item_sk, store_s_store_name, store_s_zip, ad2.ca_street_number, ad2.ca_street_name, ad2.ca_city, ad2.ca_zip
  -> Nested Loop (cost=4.27..23.49 rows=1 width=766)
    -> Nested Loop (cost=4.27..22.89 rows=1 width=416)
      -> Nested Loop (cost=4.27..22.39 rows=1 width=420)
        -> Nested Loop (cost=4.27..21.98 rows=1 width=420)
          -> Nested Loop (cost=4.27..21.57 rows=1 width=262)
            Join Filter: (item_i_item_sk = store_sales_ss_item_sk)
            -> Nested Loop (cost=4.27..20.78 rows=2 width=210)
              -> Seq Scan on item (cost=0.00..11.16 rows=1 width=208)
                Filter: ((i_current_price <= 45::numeric) AND (i_current_price >= 96::numeric) AND (i_current_price <= 50::numeric) AND (i_color = ANY ('{maroon,burnished,dim,steel,navajo,chocolate}':bpchar)))
              -> Bitmap Heap Scan on store_returns (cost=4.27..9.61 rows=2 width=8)
                Recheck Cond: (sr_item_sk = item_i_item_sk)
                -> Bitmap Index Scan on store_returns_pkey (cost=0.00..4.27 rows=2 width=0)
                  Index Cond: (sr_item_sk = item_i_item_sk)
            -> Index Scan using store_sales_pkey on store_sales (cost=0.00..0.39 rows=1 width=82)
              Index Cond: ((ss_item_sk = store_returns_sr_item_sk) AND ((ss_ticket_number = store_returns_sr_ticket_number)))
          -> Index Scan using store_pkey on store (cost=0.00..0.40 rows=1 width=166)
            Index Cond: (s_store_sk = store_sales_ss_store_sk)
        -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
          Index Cond: (c_customer_sk = store_sales_ss_customer_sk)
      -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
        Index Cond: (p_promo_sk = store_sales_ss_promo_sk)
    -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
      Index Cond: (ca_address_sk = customer_c_current_addr_sk)
  (25 rows)
    
```

## 6.9.6 Rows Hints

### Description

These hints specify the number of rows in an intermediate result set. Both absolute values and relative values are supported.

### Syntax

```
rows( [@queryblock] table_list #|+|-* const)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **#**, **+**, **-**, and **\*** are operators used for hinting the estimation. **#** indicates that the original estimation is used without any calculation. **+**, **-**, and **\*** indicate

that the original estimation is calculated using these operators. The minimum calculation result is 1. *table\_list* specifies the tables to be joined. The values are the same as those of *table\_list* in [Join Operation Hints](#).

- *const* can be any non-negative number and supports scientific notation.

For example:

**rows(t1 #5):** The result set of **t1** is five rows.

**rows(t1 t2 t3 \*1000):** The result set of joined **t1**, **t2**, and **t3** is multiplied by 1000.

## Suggestion

- The hint using **\*** for two tables is recommended. This hint will be triggered if the two tables appear on two sides of a join. For example, if the hint is **rows(t1 t2 \* 3)**, the join result of **(t1 t3 t4)** and **(t2 t5 t6)** will be multiplied by 3 because **t1** and **t2** appear on both sides of the join.
- **rows** hints can be specified for the result sets of a single table, multiple tables, function tables, and subquery scan tables.

## Example

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ rows(store_sales store_returns *50) */ i_product_name product_name ...
```

Multiply the result set of joined **store\_sales** and **store\_returns** by 50. The optimized plan is as follows:

```

QUERY PLAN
-----
HashAggregate (cost=23.52..23.53 rows=1 width=880)
  Group By Key: item_i_product_name, item_i_item_sk, store_s_store_name, store_s_zip, ad2_ca_street_number, ad2_ca_street_name, ad2_ca_city, ad2_ca_zip
  -> Nested Loop (cost=4.27..22.49 rows=1 width=776)
    -> Nested Loop (cost=4.27..22.80 rows=1 width=416)
      -> Nested Loop (cost=4.27..22.39 rows=1 width=420)
        -> Nested Loop (cost=4.27..21.98 rows=1 width=420)
          -> Nested Loop (cost=4.27..21.57 rows=1 width=262)
            Join Filter: (item_i_item_sk = store_sales.ss_item_sk)
            -> Nested Loop (cost=4.27..20.78 rows=1 width=19)
              -> Seq Scan on item (cost=0.00..11.16 rows=1 width=208)
                Filters: ((i_current_price >= 35::numeric) AND (i_current_price <= 45::numeric) AND (i_current_price >= 50::numeric) AND (i_color = ANY ('{maroon,burnished,dim,steel,navajo,chocolate}'::bpchar[])))
              -> Bitmap Heap Scan on store_returns (cost=4.27..9.61 rows=2 width=8)
                Recheck Cond: (sr_item_sk = item_i_item_sk)
                -> Bitmap Index Scan on store_returns_pkey (cost=0.00..4.27 rows=2 width=0)
                  Index Cond: (sr_item_sk = item_i_item_sk)
            -> Index Scan using store_sales_pkey on store_sales (cost=0.00..0.38 rows=1 width=62)
              Index Cond: ((ss_item_sk = store_returns.sr_item_sk) AND (ss_ticket_number = store_returns.sr_ticket_number))
            -> Index Scan using store_pkey on store (cost=0.00..0.40 rows=1 width=166)
              Index Cond: (s_store_sk = store_sales.ss_store_sk)
          -> Index Scan using customer_pkey on customer (cost=0.00..0.40 rows=1 width=8)
            Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
        -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
          Index Cond: (p_promo_sk = store_sales.ss_promo_sk)
      -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.68 rows=1 width=368)
        Index Cond: (ca_address_sk = customer.c_current_addr_sk)
  (25 rows)

```

## 6.9.7 Stream Operation Hints

### Description

A method of using stream in a parallel execution plan is specified. The value can be **broadcast** or **redistribute**, indicating that data is broadcast or redistributed.

### Syntax

```
[no] broadcast|redistribute([@queryblock] table_list)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.

- **broadcast** and **redistribute**
  - **no** specifies that the specified hint will not be used for a stream operation.
  - **table\_list** specifies one or more tables on which the stream operation is performed. Multiple tables are separated by spaces. For example, `broadcast(t1)` and `broadcast(t1 t2)`.

## Examples

```
CREATE TABLE stream_t1(a int, b int);
INSERT INTO stream_t1 VALUES(generate_series(1, 1000000), generate_series(1, 1000000));
ANALYZE stream_t1;
CREATE TABLE stream_t2(a int, b int);
INSERT INTO stream_t2 VALUES(generate_series(1, 10000), generate_series(1, 10000));
ANALYZE stream_t2;
SET query_dop = 4;
EXPLAIN (COSTS OFF) SELECT/*+ BROADCAST(stream_t1)*/ * FROM stream_t1 JOIN stream_t2 ON
(stream_t1.a = stream_t2.a);
      QUERY PLAN
-----
Streaming(type: LOCAL GATHER dop: 1/4)
-> Hash Join
   Hash Cond: (stream_t1.a = stream_t2.a)
-> Streaming(type: BROADCAST dop: 4/4)
   -> Seq Scan on stream_t1
-> Hash
   -> Streaming(type: LOCAL ROUNDROBIN dop: 4/1)
       -> Seq Scan on stream_t2
(8 rows)
-- Specify an execution plan to broadcast stream_t2.
EXPLAIN (COSTS OFF) SELECT/*+ BROADCAST(stream_t2)*/ * FROM stream_t1 JOIN stream_t2 ON
(stream_t1.a = stream_t2.a);
      QUERY PLAN
-----
Streaming(type: LOCAL GATHER dop: 1/4)
-> Hash Join
   Hash Cond: (stream_t1.a = stream_t2.a)
-> Seq Scan on stream_t1
-> Hash
   -> Streaming(type: BROADCAST dop: 4/1)
       -> Seq Scan on stream_t2
(7 rows)
-- The data of stream_t2 is broadcast and then joined with stream_t1. In this example, four concurrent
requests are enabled, and a table is broadcast to other threads for parallel hash join. The size of table
stream_t2 is smaller than that of table stream_t1. Therefore, broadcasting table t2 brings lower
performance overhead.
```

Note: Stream hints take effect only when parallel execution plans are generated.

## 6.9.8 Scan Operation Hints

### Description

These hints specify a scan operation, which can be **tablescan**, **indexscan**, or **indexonlyscan**.

### Syntax

```
[no] tablescan|indexscan|indexonlyscan( [@queryblock] table [index])
```

## Parameters

- **no** indicates that the specified hint will not be used for a join.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- *table* specifies the table to be scanned. You can specify only one table. Use a table alias (if any) instead of a table name.
- *index* indicates the index for **indexscan** or **indexonlyscan**. You can specify only one index.

### NOTE

- **indexscan** and **indexonlyscan** hints can be used only when the specified index belongs to the table.
- Scan operation hints can be used for row-store tables, HDFS tables, and subquery tables. HDFS internal tables include base tables and delta tables. The delta tables are invisible to users. Therefore, scan operation hints are used only for base tables.
- The index-only scan plan can be generated by the index scan hint, but the index-only hint can generate only the index-only plan.
- When index scan is compatible with index-only scan, some plan changes may occur. For example, **cost\_model\_version** is added for escape. This parameter can be used to determine whether index scan is compatible with index-only scan. Index scan is compatible with index-only scan when the parameter value is greater than 2 or equal to 0.

## Example

To specify an index-based hint for a scan, create an index named **i** on the **i\_item\_sk** column of the **item** table.

```
create index i on item(i_item_sk);
```

Hint the query plan in [Example](#) as follows:

```
explain
select /*+ indexscan(item i) */ i_product_name product_name ...
```

**item** is scanned based on an index. The optimized plan is as follows.

```

QUERY PLAN
-----
HashAggregate (cost=38.79..38.80 rows=1 width=880)
  Group By Keys: item_i_product_name, item_i_item_sk, store_s_store_name, store_s_zip, ad2_ca_street_number, ad2_ca_street_name, ad2_ca_city, ad2_ca_zip
  -> Nested Loop (cost=18.45..38.76 rows=1 width=776)
    -> Nested Loop (cost=18.45..38.07 rows=1 width=416)
      -> Nested Loop (cost=18.45..37.66 rows=1 width=420)
        -> Nested Loop (cost=18.45..37.25 rows=1 width=420)
          -> Nested Loop (cost=18.45..36.84 rows=1 width=202)
            Join Filter: (store_sales.ss_item_sk = item_i_item_sk)
            -> Hash Join (cost=18.45..35.62 rows=3 width=62)
              Hash Cond: ((store_returns.sr_item_sk = store_sales.ss_item_sk) AND (store_returns.sr_ticket_number = store_sales.ss_ticket_number))
              -> Seq Scan on store_returns (cost=0.00..14.08 rows=408 width=8)
              -> Hash (cost=13.38..13.38 rows=338 width=62)
                -> Seq Scan on store_sales (cost=0.00..13.38 rows=338 width=62)
                -> Index Scan using i on item (cost=0.00..0.40 rows=1 width=208)
                  Index Cond: (i_item_sk = store_returns.sr_item_sk)
                  Filter: ((i_current_price >= 35::numeric) AND (i_current_price <= 45::numeric) AND (i_current_price <= 50::numeric) AND (i_color = ANY ('{maroon,burnished,dia,steel,navajo,chocolate}::bpchar[])))
            -> Index Scan using customer_sk on customer (cost=0.00..0.40 rows=1 width=166)
              Index Cond: (c_customer_sk = store_sales.ss_customer_sk)
          -> Index Only Scan using promotion_pkey on promotion (cost=0.00..0.40 rows=1 width=4)
            Index Cond: (p_promo_sk = store_sales.ss_promo_sk)
        -> Index Scan using customer_address_pkey on customer_address ad2 (cost=0.00..0.08 rows=1 width=368)
          Index Cond: (ca_address_sk = customer.c_current_addr_sk)
(24 rows)

```

In a centralized environment, when GSI hints are used, an alarm is reported indicating that GSI hints are not supported. Example:

```

-- Create a table.
CREATE TABLE gsi_test(a int, b int);
CREATE INDEX gsi_test_idx on gsi_test(a);
-- Use indexes.
EXPLAIN SELECT /*+ GSI(gsi_test gsi_test_idx) */ * FROM gsi_test where b = 1;
WARNING: LINE 1: unsupport distributed hint at 'gsi'

```

```

QUERY PLAN
-----
Seq Scan on gsi_test (cost=0.00..36.86 rows=11 width=8)
  Filter: (b = 1)
(2 rows)

In a centralized environment, when GSI table hints are used, an alarm is reported
indicating that GSI table hints are not supported. Example:
EXPLAIN SELECT /*+ GSITABLE(gsi_test gsi_test_idx) */ * FROM gsi_test where b = 1;
WARNING: LINE 1: unsupport distributed hint at 'gsitable'
QUERY PLAN
-----
Seq Scan on gsi_test (cost=0.00..36.86 rows=11 width=8)
  Filter: (b = 1)
(2 rows)

```

## 6.9.9 Sublink Name Hints

### Description

These hints specify the name of a sublink block.

### Syntax

```
blockname ( [@queryblock] table)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **table** specifies the name you have specified for a sublink block.

#### NOTE

- The **blockname** hint is used by an outer query only when the corresponding sublink is not pulled up. Currently, only the **Agg** equivalent join, **IN**, and **EXISTS** sublinks can be pulled up. This hint is usually used together with the hints described in the previous sections.
- The subquery after the **FROM** keyword is hinted by using the subquery alias. In this case, **blockname** becomes invalid.
- If a sublink contains multiple tables, the tables will be joined with the outer-query tables in a random sequence after the sublink is pulled up. In this case, **blockname** also becomes invalid.

### Examples

```
explain select /*+nestloop(store_sales tt) */ * from store_sales where ss_item_sk in (select /*
+blockname(tt)*/ i_item_sk from item group by 1);
```

**tt** indicates the sublink block name. After being pulled up, the sublink is joined with the outer-query table **store\_sales** by using **nestloop**. The optimized plan is as follows:

```

QUERY PLAN
-----
Nested Loop (cost=10.53..68.39 rows=169 width=212)
-> HashAggregate (cost=10.53..10.95 rows=42 width=4)
  Group By Key: item.i_item_sk
  -> Seq Scan on item (cost=0.00..10.42 rows=42 width=4)
  -> Index Scan using store_sales_pkey on store_sales (cost=0.00..1.34 rows=2 width=212)
     Index Cond: (ss_item_sk = item.i_item_sk)
(6 rows)

```

 CAUTION

When the **blockname** hint is specified using **@queryblock** instead of taking effect in the current query block, for example, **blockname(@sel\$2 new\_qb\_name)**, other hints cannot be specified using **@new\_qb\_name**. In this case, **new\_qb\_name** is only used as the name of the sublink and can be specified using hints.

- The following specifies block **bn2** using **blockname(@sel\$2 bn2)**. As a result, **TableScan(@bn2 t2)** cannot find the queryblock by using **@bn2**. The query block should be specified by using **@sel\$2**. The following specifies block **bn3** using the **blockname(bn3)** hint. The hint takes effect in the current query block and changes the name of the query block. Therefore, **tablescan(@bn3 t3@bn3)** can find the query block specified by using **@bn3**.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) tablescan(@bn2 t2) tablescan(@sel$2 t2@bn2)
indexscan(@sel$2 t2@sel$2) tablescan(@bn3 t3@bn3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1
from t2 where t2.c2 = 1 group by 1) and c3 in ( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2
= 1 group by 1);
WARNING: hint: TableScan(@bn2 t2) does not match any query block
WARNING: Error hint: TableScan(@"sel$2" t2@bn2), relation name "t2@bn2" is not found.
```

- The following specifies the sublink block **bn2** by using **blockname(@sel\$2 bn2)**. When the sublink is promoted, **hashjoin(t1 bn2)** can be used to specify the operation of the promoted sublink.

```
gaussdb=# explain select /*+ blockname(@sel$2 bn2) hashjoin(t1 bn2) nestloop(t1 bn3) nestloop(t1
sel$3)*/ c2 from t1 where c1 in ( select /*+ */t2.c1 from t2 where t2.c2 = 1 group by 1) and c3 in
( select /*+ blockname(bn3)*/t3.c3 from t3 where t3.c2 = 1 group by 1);
WARNING: Duplicated or conflict hint: NestLoop(t1 "sel$3"), will be discarded.
```

## 6.9.10 Hint Errors, Conflicts, and Other Warnings

Plan hints change an execution plan. You can run **EXPLAIN** to view the changes.

Hints containing errors are invalid and do not affect statement execution. The errors will be displayed in different ways based on statement types. Hint errors in an **EXPLAIN** statement are displayed as a warning on the interface. Hint errors in other statements will be recorded in debug1-level logs containing the **PLANHINT** keyword.

Hint error types are as follows:

- Syntax errors

An error will be reported if the syntax tree fails to be reduced. The No. of the row generating an error is displayed in the error details.

For example, the hint keyword is incorrect, no table or only one table is specified in the **leading** or **join** hint, or no tables are specified in other hints. The parsing of a hint is terminated immediately after a syntax error is detected. Only the hints that have been parsed successfully are valid.

For example:

```
leading((t1 t2)) nestloop(t1) rows(t1 t2 #10)
```

The syntax of **nestloop(t1)** is wrong and its parsing is terminated. Only **leading(t1 t2)** that has been successfully parsed before **nestloop(t1)** is valid.

- Semantic errors

- An error will be reported if the specified tables do not exist, multiple tables are found based on the hint setting, or a table is used more than once in the **leading** or **join** hint.

- An error will be reported if the index specified in a scan hint does not exist.
- If multiple tables with the same name exist after a subquery is pulled up and some of them need to be hinted, add aliases for them to avoid name duplication.
- Duplicated or conflicted hints

If hint duplication or conflicts occur, only the first hint takes effect. A message will be displayed to describe the situation.

- Hint duplication indicates that a hint is used more than once in the same query, for example, **nestloop(t1 t2) nestloop(t1 t2)**.
- A hint conflict indicates that the functions of two hints with the same table list conflict with each other.

For example, if **nestloop (t1 t2) hashjoin (t1 t2)** is used, **hashjoin (t1 t2)** becomes invalid. **nestloop(t1 t2)** does not conflict with **no mergejoin(t1 t2)**.

---

#### NOTICE

The table list in the **leading** hint is disassembled. For example, **leading ((t1 t2 t3))** will be disassembled as **leading((t1 t2)) leading(((t1 t2) t3))**, which will conflict with **leading((t2 t1))** (if any). In this case, the latter **leading(t2 t1)** becomes invalid. If two hints use duplicated table lists and only one of them has the specified outer/inner table, the one without a specified outer/inner table becomes invalid.

---

- A hint becomes invalid after a sublink is pulled up.  
In this case, a message will be displayed. Generally, such invalidation occurs when a sublink contains multiple tables to be joined. After the sublink is pulled up, the tables will not be join members.
- Hints are not used.
  - If a **hashjoin** or **mergejoin** hint is specified for non-equivalent joins, it will not be used.
  - If an **indexscan** or **indexonlyscan** hint is specified for a table that does not have an index, it will not be used.
  - If an **indexscan** or **indexonlyscan** hint is specified for a full-table scan, it will not be used. Generally, index paths are generated only when filtering conditions are used on index columns. Indexes are not used during a full table scan.
  - If an **indexonlyscan** hint is specified when the output or predicate condition column does not contain only indexes, it will not be used.
  - In equivalent joins, only the joins containing equivalence conditions are valid. Therefore, the **leading**, **join**, and **rows** hints specified for the joins without an equivalence condition will not be used. For example, **t1**, **t2**, and **t3** are to be joined, and the join between **t1** and **t3** does not contain an equivalence condition. In this case, **leading(t1 t3)** will not be used.
  - If no sublink is pulled up, the specified **blockname** hint will not be used.

## 6.9.11 Optimizer GUC Parameter Hints

### Description

Sets GUC parameters related to query optimization. The settings take effect during the query execution. For details about the application scenarios of hints, see the description of each GUC parameter.

### Syntax

```
set( [@queryblock] param value)
```

### Parameters

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). It can be omitted, indicating that the hint takes effect in the current query block. This hint takes effect only when it specifies the outermost query block.
- **param** indicates the parameter name.
- **value** indicates the value of a parameter.
- Currently, the following parameters can be set and take effect by using Hint:
  - Boolean  
enable\_bitmapscan, enable\_hashagg, enable\_hashjoin, enable\_indexscan, enable\_indexonlyscan, enable\_material, enable\_mergejoin, enable\_nestloop, enable\_index\_nestloop, enable\_seqscan, enable\_sort, enable\_tidscan, partition\_iterator\_elimination, partition\_page\_estimation, enable\_functional\_dependency, var\_eq\_const\_selectivity, and enable\_inner\_unique\_opt
  - Integer type  
**query\_dop**
  - Floating point  
cost\_weight\_index, default\_limit\_rows, seq\_page\_cost, random\_page\_cost, cpu\_tuple\_cost, cpu\_index\_tuple\_cost, cpu\_operator\_cost, and effective\_cache\_size

#### NOTE

- If you set a parameter that is not in the whitelist and the parameter value is invalid or the hint syntax is incorrect, the query execution is not affected. Run **explain(verbose on)**. An error message is displayed, indicating that hint parsing fails.
- The GUC parameter hint takes effect only in the outermost query. That is, the GUC parameter hint in the subquery does not take effect.
- The GUC parameter hint in the view definition does not take effect.
- In the CREATE TABLE ... AS ... statement, the outermost GUC parameter hint takes effect.

## 6.9.12 Hint for Selecting the Custom Plan or Generic Plan

### Function

For query statements and DML statements executed in PBE mode, the optimizer generates a custom plan or generic plan based on factors such as rules, costs, and

parameters. You can use the hint of **use\_cplan** or **use\_gplan** to specify the plan to execute.

## Syntax

- To select the custom plan, run the following statement:  
use\_cplan
- To select the generic plan, run the following statement:  
use\_gplan

### NOTE

- For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
- This hint has a higher priority than cost-based selection and the **plan\_cache\_mode** parameter. That is, this hint does not take effect for statements for which **plan\_cache\_mode** cannot be forcibly set to specify an execution mode.

## Examples

Forcibly use the custom plan.

```
create table t (a int, b int, c int);
prepare p as select /*+ use_cplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the actual value of the input parameter, that is, the plan is a custom plan.

```
QUERY PLAN
-----
Seq Scan on t (cost=0.00..34.31 rows=10 width=12)
  Filter: (a = 1)
(2 rows)
```

Forcibly use the generic plan.

```
deallocate p;
prepare p as select /*+ use_gplan */ * from t where a = $1;
explain execute p(1);
```

In the following plan, the filtering condition is the input parameter to be added. That is, the plan is a generic plan.

```
QUERY PLAN
-----
Seq Scan on t (cost=0.00..34.31 rows=10 width=12)
  Filter: (a = $1)
(2 rows)
```

## 6.9.13 Hints Specifying Not to Expand Subqueries

### Function

When the database optimizes the query logic, some subqueries can be promoted to the upper layer to avoid nested execution. However, for some subqueries that have a low selection rate and can use indexes to filter access pages, nested

execution does not cause too much performance deterioration, while after the promotion, the query search scope is expanded, which may cause performance deterioration. In this case, you can use the **no\_expand** hint for debugging. This hint is not recommended in most cases.

## Syntax

```
no_expand[(@queryblock)]
```

## Parameter Description

For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block. If it is not specified, **no\_expand** does not have parentheses ().

## Example

Normal query execution:

```
explain select * from t1 where t1.c1 in (select t2.c1 from t2);
```

Plan

```
QUERY PLAN
-----
Hash Join (cost=38.81..92.58 rows=972 width=12)
  Hash Cond: (t1.c1 = t2.c1)
    -> Seq Scan on t1 (cost=0.00..29.45 rows=1945 width=12)
    -> Hash (cost=36.31..36.31 rows=200 width=4)
        -> HashAggregate (cost=34.31..36.31 rows=200 width=4)
            Group By Key: t2.c1
            -> Seq Scan on t2 (cost=0.00..29.45 rows=1945 width=4)
(7 rows)
```

After **no\_expand** is added:

```
explain select * from t1 where t1.c1 in (select /*+ no_expand*/ t2.c1 from t2);
```

Plan

```
QUERY PLAN
-----
Seq Scan on t1 (cost=34.31..68.62 rows=972 width=12)
  Filter: (hashed SubPlan 1)
  SubPlan 1
    -> Seq Scan on t2 (cost=0.00..29.45 rows=1945 width=4)
(4 rows)
```

## 6.9.14 Hint Specifying Not to Use Global Plan Cache

### Function

When global plan cache is enabled, you can use the **no\_gpc** hint to force a single query statement not to share the plan cache globally. Only the plan cache within the current session lifecycle is retained.

## Syntax

```
no_gpc
```

### NOTE

This parameter takes effect only for statements executed by PBE when **enable\_global\_plancache** is set to **on**.

## Example

```
gaussdb=# deallocate all;
DEALLOCATE ALL
gaussdb=# prepare p1 as insert /*+ no_gpc*/ into t1 select c1,c2 from t2 where c1=$1;
PREPARE
gaussdb=# execute p1(3);
INSERT 0 1
gaussdb=# select * from dbperf.global_plancache_status where schema_name='public' order by 1,2;
 nodename | query | refcount | valid | databaseid | schema_name | params_num | func_id | pkg_id | stmt_id
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

No result exists in the **dbperf.global\_plancache\_status** view, that is, no plan is cached globally.

## 6.9.15 Hint of Parameterized Paths at the Same Level

### Description

The **predpush\_same\_level** and **nestloop\_index** hints are used to specify the generation of parameterized paths between tables or materialized views at the same level.

### Syntax

```
predpush_same_level(src, dest)
predpush_same_level(src1 src2 ..., dest)
[no] nestloop_index([@queryblock] dest[, index_list]) -- With indexes
[no] nestloop_index([@queryblock] dest[, (src1 src2 ...)]) -- With tables
```

### NOTE

The **predpush\_same\_level** parameter takes effect only when the **predpushforce** option in **rewrite\_rule** is enabled.

**nestloop\_index** has no requirement on **rewrite\_rule**.

### Parameters

- **no** indicates that the parameterized path of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **dest** is the target table of the parameterized path, that is, the table where the indexes are located.
- **src** is the parameter table of the parameterized path.
- **index\_list** is the index sequence used by the parameterized path, which consists of character strings separated by spaces.

## Examples

### 1. Examples of nestloop\_index:

- Transfer **t2.c1** and **t3.c2** of **t2** and **t3** to the **t1** table for index scanning (parameterized path).

```
gaussdb=# explain (costs off) select /*+nestloop_index(t1,(t2 t3)) */ from t1,t2,t3 where t1.c1 = t2.c1 and t1.c2 = t3.c2;
```

QUERY PLAN

```
-----
Nested Loop
-> Seq Scan on t3
-> Nested Loop
   -> Seq Scan on t2
   -> Index Scan using it1 on t1
       Index Cond: ((c1 = t2.c1) AND (c2 = t3.c2))
(6 rows)
```

- Perform an index scan on **it1** of the **t1** table (parameterized path).

```
gaussdb=# explain (costs off) select /*+NestLoop_Index(t1,it1) */ from t1,t2 where t1.c1 = t2.c1;
```

QUERY PLAN

```
-----
Nested Loop
-> Seq Scan on t2
-> Index Scan using it1 on t1
   Index Cond: (c1 = t2.c1)
(4 rows)
```

### 2. Example of predpush\_same\_level:

- Prepare parameters.

```
gaussdb=# set rewrite_rule = 'predpushforce';
SET
```

- View the plan.

```
gaussdb=# explain select * from t1, t2 where t1.c1 = t2.c1;
```

QUERY PLAN

```
-----
Hash Join (cost=53.76..301.54 rows=18915 width=24)
Hash Cond: (t1.c1 = t2.c1)
-> Seq Scan on t1 (cost=0.00..29.45 rows=1945 width=12)
-> Hash (cost=29.45..29.45 rows=1945 width=12)
   -> Seq Scan on t2 (cost=0.00..29.45 rows=1945 width=12)
(5 rows)
```

- The filter condition **t1.c1 = t2.c1** is displayed on **Join**. In this case, **predpush\_same\_level(t1, t2)** can be used to push the condition down to the scan operator of **t2**.

```
gaussdb=# explain select /*+predpush_same_level(t1, t2)*/ * from t1, t2 where t1.c1 = t2.c1;
```

QUERY PLAN

```
-----
Nested Loop (cost=0.00..1143.20 rows=18915 width=24)
-> Seq Scan on t1 (cost=0.00..29.45 rows=1945 width=12)
-> Index Scan using it2 on t2 (cost=0.00..0.47 rows=10 width=12)
   Index Cond: (c1 = t1.c1)
(4 rows)
```

### NOTICE

- You can specify multiple **src** parameters in the same condition.
- If the specified **src** and **dest** conditions do not exist or do not meet the parameterized path requirements, this hint does not take effect.
- If a stream operator exists on the **dest** scanning operator, this hint does not take effect.

## 6.9.16 Hint for Setting Slow SQL Control Rules

### Description

Users can set the execution time, maximum execution time, and maximum IOPS for SQL statements marked as slow SQL statements.

### Syntax

```
wlmrule("time_limit,max_execute_time,max_iops")
```

#### NOTE

This parameter is valid only for SELECT statements executed by non-sysadmin or non-monitoradmin users when **enable\_thread\_pool** is set to **on**.

- **time\_limit**: execution time of an SQL statement marked as a slow SQL statement. The value ranges from 0 to *INT\_MAX*.
- **max\_execute\_time**: maximum execution time of an SQL statement. If the execution time exceeds the value of this parameter, the SQL statement is forcibly canceled and exits. The value ranges from **0** to *INT\_MAX*. If the value of **max\_execute\_time** is less than or equal to the value of **time\_limit**, the rule does not take effect.
- **max\_iops**: maximum IOPS of an SQL statement marked as a slow SQL statement. This parameter is valid only when **use\_workload\_manager** is set to **on**. The IOPS limit applies logical I/O control. For details about the definition of IOPS, see the definition of **io\_control\_unit**. The value can be **Low**, **Medium**, **High**, **None**, or 0 to *INT\_MAX*.

### Examples

```
select /*+ wlmrule("100,500,1") */ * from t2 order by b limit 1;
```

It indicates that the execution time of the current statement marked as a slow SQL statement is 100 ms, the maximum execution time is 500 ms, and the maximum IOPS is 1.

## 6.9.17 Hint for Adaptive Plan Selection

### Description

For query statements and DML statements executed in PBE mode, you can add the **choose\_adaptive\_gplan** hint to the query to trigger adaptive plan selection.

### Syntax

Enable adaptive plan selection for query:  
`choose_adaptive_gplan`

 NOTE

- For SQL statements that are executed in non-PBE mode, setting this hint does not affect the execution mode.
- This hint takes effect only when the GUC parameter **enable\_cachedplan\_mgr** is set to **on**.

## Examples

```
prepare k as select /*+ choose_adaptive_gplan */ * from t1 where c1=$1 and c2=$2 and c3=$3 and c4=$4;
```

## 6.9.18 Hint for Materializing a Sub-plan Result

### Function

You can materialize a sub-plan result to temporarily store the query record. This hint is used only in the INSERT statement.

When the INSERT INTO ... SELECT statement is used to insert a large amount of data with multiple duplicate rows, the index needs to be compared for multiple times. As a result, the execution takes a long time. This hint is used to materialize the results of subplans and temporarily store query records to reduce the number of index comparisons and shorten the statement execution time.

### Syntax

```
material_subplan
```

### Examples

Create a table and insert data into the table.

```
create table test_mt_sub(a int, b int) with(storage_type = ustore);
create index on test_mt_sub(a);
create table test_src_mt_sub(a int, b int);
insert into test_src_mt_sub values(generate_series(1,10), generate_series(1,100000));
```

Normal INSERT INTO...SELECT statement:

```
insert into test_mt_sub select /*+ nestloop(test_src_mt_sub t1)*/ * from test_src_mt_sub where
notexists(select 1 from test_mt_sub t1 where t1.a = test_src_mt_sub.a);
```

The execution plan is as follows:

```
QUERY PLAN
-----
Insert on test_mt_sub
-> Nested Loop Anti Join
   -> Seq Scan on test_src_mt_sub
   -> Index Only Scan using test_mt_sub_a_idx on test_mt_sub t1
       Index Cond: (a = test_src_mt_sub.a)
(5 rows)
```

Use the material\_subplan hint operator:

```
insert /*+ material_subplan*/ into test_mt_sub select /*+ nestloop(test_src_mt_sub t1)*/ * from
test_src_mt_sub where not exists(select 1 from test_mt_sub t1 where t1.a = test_src_mt_sub.a);
```

The execution plan is as follows:

```
QUERY PLAN
-----
Insert on test_mt_sub
-> Materialize
   -> Nested Loop Anti Join
```

```
-> Seq Scan on test_src_mt_sub  
-> Index Only Scan using test_mt_sub_a_idx on test_mt_sub t1  
    Index Cond: (a = test_src_mt_sub.a)  
(6 rows)
```

## 6.9.19 Bitmap Scan Hints

### Function

These hints generate a bitmap scan path by using the specified index on the target table. The path that meets the hint requirement is selected from the paths that can be generated by the optimizer.

### Syntax

```
[no] bitmapscan([@queryblock] table [index_list])
```

### Parameter Description

- **no** indicates that the scan of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **table** indicates the target table of the bitmap scan.
- **index\_list** indicates the index used by the bitmap scan.

### Example

```
gaussdb=# explain(costs off) select /*+ BitmapScan(t1 it1 it3)*/ from t1 where (t1.c1 = 5 or t1.c2=6) or  
(t1.c3=3 or t1.c2=7);  
          QUERY PLAN  
-----  
Bitmap Heap Scan on t1  
  Recheck Cond: ((c1 = 5) OR (c2 = 6) OR (c3 = 3) OR (c2 = 7))  
-> BitmapOr  
  -> Bitmap Index Scan on it1  
      Index Cond: (c1 = 5)  
  -> Bitmap Index Scan on it3  
      Index Cond: (c2 = 6)  
  -> Bitmap Index Scan on it3  
      Index Cond: (c3 = 3)  
  -> Bitmap Index Scan on it3  
      Index Cond: (c2 = 7)  
(11 rows)
```

#### NOTE

The path that meets the bitmap scan hint is selected from the existing index paths. Because the index path construction space is large and the optimizer prunes the paths, if any index path is not generated, the path cannot be constructed.

## 6.9.20 Hint for Inner Table Materialization During Join

### Function

These hints materialize inner tables when specifying the inner tables to be joined.

## Syntax

```
[no] materialize_inner([@queryblock] inner_table_list)
```

## Parameter Description

- **no** indicates that the materialization of hints is not used.
- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block.
- **inner\_table\_list**: a list of inner tables to be materialized during the join operation. The value is a character string separated by spaces.

## Example

Table **t1** is an inner table to be materialized, and the result of (t1 t2) is materialized as a joined inner table.

```
gaussdb=# explain (costs off) select /*+materialize_inner(t1) materialize_inner(t1 t2)*/ * from t1,t2,t3
where t1.c3 = t2.c3 and t2.c2=t3.c2 and t1.c2=5;
          QUERY PLAN
-----
Nested Loop
Join Filter: (t2.c2 = t3.c2)
-> Seq Scan on t3
-> Materialize
   -> Nested Loop
       Join Filter: (t1.c3 = t2.c3)
       -> Seq Scan on t2
       -> Materialize
           -> Bitmap Heap Scan on t1
               Recheck Cond: (c2 = 5)
               -> Bitmap Index Scan on it3
                   Index Cond: (c2 = 5)
(12 rows)
```

## 6.9.21 AGG Hint

### Function

You can specify the AGG method when performing the AGG algorithm.

### Syntax

```
use_hash_agg[@queryblock], use_sort_agg[@queryblock]
```

## Parameter Description

- For details about **@queryblock**, see [Hint Specifying the Query Block Where the Hint Is Located](#). This parameter can be omitted, indicating that it takes effect in the current query block. If it is not specified, the hint does not have parentheses ().

## Example

1. Use hash aggregation.
 

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_hash_agg */ t1.c1 from
t1,t3 where t1.c1=t3.c1 group by 1);
          QUERY PLAN
```

```
-----
Hash Semi Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
    -> HashAggregate
        Group By Key: t1.c1
    -> Hash Join
        Hash Cond: (t1.c1 = t3.c1)
        -> Seq Scan on t1
        -> Hash
            -> Seq Scan on t3
(11 rows)
```

2. Use `use_sort_agg` for aggregation and then perform merge join.

```
gaussdb=# explain (costs off) select c1 from t2 where c1 in( select /*+ use_sort_agg */ t1.c1 from t1,t3
where t1.c1=t3.c1 group by 1);
QUERY PLAN
```

```
-----
Hash Semi Join
Hash Cond: (t2.c1 = t1.c1)
-> Seq Scan on t2
-> Hash
    -> Group

## 6.10 Introduction to Plan Trace

### NOTICE

1. This feature is used by database kernel developers for in-depth analysis of slow SQL statements. It is not recommended that non-kernel developers use this feature.
2. After this feature is enabled, optimizer information is recorded in the system catalog during DML execution. As a result, the original read transaction becomes a write transaction, and functions that must be executed in the read transaction, such as `pg_create_logical_replication_slot`, cannot be executed.

You can use the plan trace feature to view the optimization process of a query plan. In the plan trace, you can view key information such as the path calculation process, path selection process, and path elimination process in the plan to help analyze the root cause of slow SQL statements. This feature can be used in either of the following ways:

```
-- Prepare tables.
CREATE TABLE tb_a(c1 int);
CREATE TABLE tb_b(c1 int);
CREATE INDEX tb_a_idx_c1 ON tb_a(c1);
CREATE INDEX idx_b ON tb_b(c1);
```

**Method 1:** Use the GUC parameter `enable_plan_trace` to enable the plan trace feature. The procedure is as follows:

**Step 1** Enable the plan trace GUC function.

```
set enable_plan_trace = on;
```

**Step 2** Run the service SQL statement. For example, the service SQL statement is as follows:

```
select * from tb_a a, tb_b b where a.c1 = b.c1 and a.c1=1;
```

**Step 3** View the newly generated plan trace in the gs\_my\_plan\_trace view.

```
select * from gs_my_plan_trace order by modifydate limit 1;
```

Generally, plan trace records are large. If gsql is used to connect to the database, you are advised to run the \x command to change the display mode of gsql query results to **Expanded**.

The plan trace records are usually large. Therefore, only fragments of the key trace execution result of this example are provided.

Fragment 1: In the trace, you can view the SQL statement and plan that are being executed.

```
query_id | 69e138356181711a21de1211f639892b
query    | select * from tb_a a, tb_b b where a.c1 = b.c1 and a.c1=1;
unique_sql_id | 3388945134
plan     | Datanode Name: datanode
         | Nested Loop (cost=0.00..10.75 rows=144 width=8)
         | -> Index Only Scan using tb_a_idx_c1 on tb_a a (cost=0.00..4.46 rows=12 width=4)
         |     Index Cond: (c1 = '***')
         | -> Materialize (cost=0.00..4.52 rows=12 width=4)
         |     -> Index Only Scan using idx_b on tb_b b (cost=0.00..4.46 rows=12 width=4)
         |         Index Cond: (c1 = '***')
```

Fragment 2: In the trace, you can view the key GUC parameters used by the current SQL statement.

```
plan_trace | [key_guc]
           | enable_pbe_optimization=1
           | plan_cache_mode=0
           | random_page_cost=4.000
           | enable_hashjoin=1
           | enable_mergejoin=1
           | enable_nestloop=1
           | enable_seqscan=1
           | effective_cache_size=16385
           | work_mem=65536
           | default_statistics_target=100
           | cost_param=0
           | =[key_guc]=
```

Fragment 3: In the trace, you can view the process of calculating the path cost of the current SQL query plan.

```
| [btcostestimate]
| cal: num_sa_scans,1.000000
| cal: num_index_tuples=mtree_selectivity * index_tuples,48.629630,0.004863,10000.000000
| cal: num_index_tuples = rint(num_index_tuples / num_sa_scans),49.000000
|
| [adt_genericcostestimate]
| input: loop_count,1.000000 num_index_tuples,49.000000 index_total_pages,37.000000
| cal: num_sa_scans,1.000000 idx_local_tuples,10000.000000
| cal: index_selectivity,0.004863
| cal: num_index_pages=ceil(num_index_tuples/idx_local_tuples * index_total_pages),1.000000
| cal: num_scans=num_sa_scans * loop_count,1.000000
| cal: index_total_cost=num_index_pages * spc_random_page_cost,4.000000
| cal: index_total_cost += num_index_tuples * num_sa_scans * (cpu_index_tuple_cost +
qual_op_cost),4.367500
| cal: index_total_cost += num_sa_scans * 100.0 * cpu_operator_cost,4.617500
```

```

|=[adt_genericcostestimate]=
|=[btccostestimate]=
    
```

Fragment 4: In the trace, you can see the elimination process of the base table path: 1. The old path is eliminated. 2. Reasons why the old path was eliminated; 3. Information about the new path.

```

| An old path is removed with cost = 881.806443 .. 932.541443; rows = 49.000000
| The old path and the comparison results are:
| {
|   old pathid=00000005 Cost = NewBetter | PathKeys = Equal | BMS =
|   Rows = Equal
| }
Equal
| A new path is accepted with cost = 284.629750 .. 341.718970; rows = 49.000000
| The detail information of the new path:
| {
|   HashJoin(1:tb_a 2:tb_b ) pathid=00000011 hasparam=0 rows=49 multiple=1.000000
tuples=0.00 rpages=0.00 ipages=0.00 selec=0.00000000 ml=0 iscost=1 lossy=0 uidx=0) dop=1
cost=284.63..341.72 hint 0 trace_id=#3##4##11# clauses: a.id = b.id(norm_
    
```

Fragment 5: In the trace, you can see the elimination process of the join path: 1. The old path is eliminated. 2. Reasons why the old path was eliminated; 3. Information about the new path.

```

| An old path is removed with cost = 4.629750 .. 7591.045220; rows = 49.000000
| The old path and the comparison results are:
| {
|   old pathid=00000008 Cost = Equal | PathKeys = Equal | BMS =
|   Rows = Equal
|   Small fuzzy factor is used!
| }
Equal
| A new path is accepted with cost = 4.629750 .. 7566.167720; rows = 49.000000
| The detail information of the new path:
| {
|   NestLoop(1:tb_a 2:tb_b ) pathid=00000014 hasparam=0 rows=49 multiple=1.000000
tuples=0.00 rpages=0.00 ipages=0.00 selec=0.00000000 ml=0 iscost=1 lossy=0 uidx=0) dop=1
cost=4.63..7566.17 hint 0 trace_id=#4##13##14# clauses: a.id = b.id(norm_
|   Small fuzzy factor is used!
    
```

The trace information is easy to understand and is not described here. The personnel who use this feature need to analyze the trace information by themselves.

----End

**Method 2:** Use the system function `gs_plan_trace_watch_sqlid` to enable the plan trace feature. The procedure is as follows:

**Step 1** Obtain the unique SQL ID of the SQL statement from the `dbperf.statement` system catalog. For example, run the following SQL statement to obtain the unique SQL ID:

```

select * from dbperf.statement where query like '%tb_a%';
    
```

The value of `unique_sql_id` in the command output is as follows:

```

node_name      | datanode1
node_id        | 0
user_name      | qiunc
user_id        | 10
unique_sql_id  | 1921680825
query          | select * from tb_a a, tb_b b where a.id=b.id and a.c1=?;
n_calls        | 3
min_elapse_time | 8880
max_elapse_time | 12371
total_elapse_time | 32036
    
```

**Step 2** A user with the sysadmin permission calls the `gs_plan_trace_watch_sqlid` function to listen to the unique SQL ID. Example:

```
select gs_plan_trace_watch_sqlid(1921680825);
```

**Step 3** If no plan trace is generated for the unique SQL ID, the unique SQL ID is saved in a memory list. You can use the `gs_plan_trace_show_sqlids()` function to view the unique SQL ID list of the plan trace to be collected. An example SQL statement is as follows:

```
select gs_plan_trace_show_sqlids();
```

The execution result of the SQL statement is as follows:

```
-[ RECORD 1 ]-----+-----  
gs_plan_trace_show_sqlids | 1921680825,
```

**Step 4** If you run the following SQL statement:

```
select * from tb_a a, tb_b b where a.id=b.id and a.c1=1;
```

You can also generate plan trace records for the SQL statement.

---

#### NOTICE

Only users with the sysadmin, opradmin, or monadmin permission can call the `gs_plan_trace_watch_sqlid` and `gs_plan_trace_show_sqlids` functions. If a common user executes the SQL statement with the unique SQL ID listened by the administrator, the common user can use the `gs_my_plan_trace` view to view the plan trace generated by the common user.

---

----End

---

#### NOTICE

Generally, plan trace records are large. You need to clear them in a timely manner. Otherwise, a large amount of disk space is occupied. You can use the `gs_plan_trace_delete` function to delete the plan trace records generated by yourself.

For example, run the following SQL statement:

```
select gs_plan_trace_delete(TIMESTAMPTZ '2023-01-10 17:16:42.652543+08')
```

You can delete all plan trace records earlier than or equal to the 2023-01-10 17:16:42.652543+08 for the current user. In this way, each user can delete its own plan trace data.

---

## 6.11 Tuning with SQL PATCH

SQL PATCH is designed for database administrators (DBAs), O&M personnel, and other roles who need to optimize SQL statements. If performance problems caused by poor plans of service statements are identified through other O&M views or fault locating methods, you can create an SQL patch to optimize service statements based on hints. Currently, the following hints are supported: number of rows, scanning mode, join mode, join sequence, PBE custom/generic plan selection, statement-level parameter setting, and parameterized path. In addition,

in case that services are unavailable due to internal system errors that are triggered by specific statements, you can create SQL patches to rectify single-point failures without changing service statements. In this way, errors can be reported in advance to avoid greater loss.

## Feature Constraints

1. Patches can be created only by unique SQL ID. If unique SQL IDs conflict, SQL patches that are used for hint-based optimization may affect performance but do not affect semantic correctness.
2. Only hints that do not change SQL semantics can be used as patches. SQL rewriting is not supported.
3. This tool is not applicable to logical backup and restoration.
4. The patch validity cannot be verified during patch creation. If the patch hint has syntax or semantic errors, the query execution is not affected.
5. Only the initial user, O&M administrator, monitoring administrator, and system administrator have the permission to perform this operation.
6. Patches are not shared between databases. When creating SQL patches, you need to connect to the target database.
7. In the centralized deployment scenario where the standby node is readable, you must specify the primary node to run the SQL PATCH command to create, modify, or delete functions and the standby node to report errors.
8. There is a delay in synchronizing an SQL patch to the standby node. The patch takes effect after the standby node replays related logs.
9. SQL patches in a stored procedure and global SQL patches cannot coexist.
10. SQL patches cannot be used for precompiled statements that are executed using the PREPARE + EXECUTE syntax.
11. It is not recommended that the SQL patches be used in the database for a long time. It should be used only as a workaround. If the database service is unavailable due to a kernel fault triggered by a specific statement or SQL hints are used for performance tuning, you must rectify the service fault or upgrade the kernel as soon as possible. After the upgrade, the method of generating unique SQL IDs may change. Therefore, the workaround may become invalid.
12. Currently, except DML statements, unique SQL IDs of SQL statements (such as CREATE TABLE) are generated by hashing the statement text. Therefore, SQL PATCH is sensitive to uppercase and lowercase letters, spaces, and linefeeds. That is, even statements of different texts have the same semantics, you still need to create different SQL patches for them. For DML operations, SQL PATCH can take effect for the same statement with different input parameters, regardless of uppercase letters, lowercase letters, and spaces.

## Example

The SQL patch is implemented based on the unique SQL ID. Therefore, you need to enable related O&M parameters (**enable\_resource\_track = on**, **instr\_unique\_sql\_count > 0**) for the SQL patch to take effect. The unique SQL ID can be obtained from both the WDR and slow SQL view. You need to specify the unique SQL ID when creating the SQL patch. For SQL statements in a stored

procedure, you need to set **instr\_unique\_sql\_track\_type** to 'all' and query unique SQL ID in the `dbe_perf.statement_history` view.

The following provides simple examples:

Scenario 1: Use SQL PATCH to optimize specific statements based on hints.

```
gaussdb=# create table hint_t1(a int, b int, c int);
CREATE TABLE
gaussdb=# create index on hint_t1(a);
CREATE INDEX
gaussdb=# insert into hint_t1 values(1,1,1);
INSERT 0 1
gaussdb=# set track_stmt_stat_level = 'L1,L1'; -- Enable full SQL statistics.
SET
gaussdb=# set explain_perf_mode = normal;
SET
gaussdb=# select * from hint_t1 t1 where t1.a = 1; -- Execute the SQL statement.
 a | b | c
---+---+---
 1 | 1 | 1
(1 row)
gaussdb=# \x --Switch to the extended display mode to facilitate plan observation.
Expanded display is on.
gaussdb=# select unique_query_id, query, query_plan from dbe_perf.statement_history where query like
'%hint_t1%'; -- Obtain the query plan and unique SQL ID.
-[ RECORD 1 ]-----
unique_query_id | 2311517824
query           | select * from hint_t1 t1 where t1.a = ?;
query_plan      | Datanode Name: sgnode
                | Bitmap Heap Scan on hint_t1 t1 (cost=4.33..14.88 rows=10 width=12)
                |   Recheck Cond: (a = '****')
                |   -> Bitmap Index Scan on hint_t1_a_idx (cost=0.00..4.33 rows=10 width=0)
                |       Index Cond: (a = '****')
gaussdb=# \x
Expanded display is off.
gaussdb=# select * from dbe_sql_util.create_hint_sql_patch('patch1', 2311517824, 'indexscan(t1)'); -- Specify
a hint patch for the specified unique SQL ID.
 create_hint_sql_patch
-----
 t
(1 row)

gaussdb=# explain select * from hint_t1 t1 where t1.a = 1; -- Check whether the hint takes effect.
NOTICE: Plan influenced by SQL hint patch
          QUERY PLAN
-----
 [Bypass]
 Index Scan using hint_t1_a_idx on hint_t1 t1 (cost=0.00..32.43 rows=10 width=12)
   Index Cond: (a = 1)
(3 rows)
gaussdb=# select * from hint_t1 t1 where t1.a = 1; -- Execute the statement again.
 a | b | c
---+---+---
 1 | 1 | 1
(1 row)
gaussdb=# \x
Expanded display is on.
gaussdb=# select unique_query_id, query, query_plan from dbe_perf.statement_history where query like
'%hint_t1%'; -- The query plan has been changed.
-[ RECORD 1 ]-----
unique_query_id | 2311517824
query           | select * from hint_t1 t1 where t1.a = ?;
query_plan      | Datanode Name: sgnode
                | Bitmap Heap Scan on hint_t1 t1 (cost=4.33..15.70 rows=10 p-time=0 p-rows=0 width=12)
                |   Recheck Cond: (a = '****')
                |   -> Bitmap Index Scan on hint_t1_a_idx (cost=0.00..4.33 rows=10 p-time=0 p-rows=0 width=0)
```

```

      |          Index Cond: (a = '****')
      |
-[ RECORD 2 ]---+-----
unique_query_id | 2311517824
query           | select * from hint_t1 t1 where t1.a = ?;
query_plan      | Datanode Name: sgnode
                | Index Scan using hint_t1_a_idx on hint_t1 t1 (cost=0.00..8.27 rows=1 p-time=0 p-rows=0
width=12)
                |          Index Cond: (a = '****')
    
```

Scenario 2: Run the SQL PATCH command to report an error for a specific statement in advance.

```

gaussdb=# select * from db_sql_util.drop_sql_patch('patch1'); -- Delete patch 1.
drop_sql_patch
-----
t
(1 row)
gaussdb=# select * from db_sql_util.create_abort_sql_patch('patch2', 2311517824); -- Create an abort
patch for the statement of the unique SQL ID.
create_abort_sql_patch
-----
t
(1 row)

gaussdb=# select * from hint_t1 t1 where t1.a = 1; -- An error is reported in advance when the statement is
executed again.
ERROR: Statement 2578396627 canceled by abort patch patch2
    
```

Scenario 3: Create an SQLpatch for the SQL statements in the stored procedure.

```

gaussdb=# create table test_proc_patch(a int,b int);
CREATE TABLE
gaussdb=# insert into test_proc_patch values(1,2);
INSERT 0 1
gaussdb=# create index test_a on test_proc_patch(a);
CREATE INDEX
gaussdb=# create procedure mypro() as num int;
gaussdb$# begin
gaussdb$# select b into num from test_proc_patch where a = 1;
gaussdb$# end;
gaussdb$# /
CREATE PROCEDURE
gaussdb=# set track_stmt_stat_level = 'L0,L1'; -- Open the statistics information.
SET
gaussdb=# select b from test_proc_patch where a = 1;
 b
---
 2
(1 row)
gaussdb=# call mypro();
 mypro
-----
(1 row)
gaussdb=# set track_stmt_stat_level = 'OFF,L0'; -- Temporarily disable the function of recording statistics.
SET
gaussdb=# select unique_query_id, query, query_plan, parent_unique_sql_id from
db_perf.statement_history where query like '%call mypro();%' or query like '%test_proc_patch%';
 unique_query_id |          query           |          query_plan           |
parent_unique_sql_id
-----+-----
+-----+-----
      2859505004 | select b from test_proc_patch where a = ?; | Datanode Name:
sgnode           |          +|          0

## Helpful Links

The following table lists the system catalogs and interface functions related to SQL PATCH.

**Table 6-3** System catalogs and interface functions related to SQL PATCH

Name		Description
System catalog	<a href="#">GS_SQL_PATCH</a>	<b>GS_SQL_PATCH</b> records the status information about all SQL patches.
Interface function <a href="#">DBE_SQL_UTIL</a> Schema	<a href="#">DBE_SQL_UTIL.create_hint_sql_patch</a>	<b>create_hint_sql_patch</b> creates hint SQL patches and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.create_abort_sql_patch</a>	<b>create_abort_sql_patch</b> creates abort SQL patches and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.drop_sql_patch</a>	<b>drop_sql_patch</b> deletes SQL patches from the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.enable_sql_patch</a>	<b>enable_sql_patch</b> enables SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.disable_sql_patch</a>	<b>disable_sql_patch</b> disables SQL patches on the connected CN and returns whether the execution is successful.
	<a href="#">DBE_SQL_UTIL.show_sql_patch</a>	<b>show_sql_patch</b> displays the SQL patch corresponding to a specified patch name and returns the running result.
	<a href="#">DBE_SQL_UTIL.create_hint_sql_patch</a>	<b>create_hint_sql_patch</b> creates hint SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of <b>parent_unique_sql_id</b> can be used to limit the effective range of the hint patch.

Name		Description
	<a href="#">DBE_SQL_UTIL.create_abort_sql_patch</a>	<b>create_abort_sql_patch</b> creates abort SQL patches and returns whether the execution is successful. This function is an overloaded function of the original function. The value of <b>parent_unique_sql_id</b> can be used to limit the effective range of the abort patch.

## 6.12 Optimization Cases

### 6.12.1 Case: Modifying the GUC Parameter `rewrite_rule`

`rewrite_rule` contains multiple query rewriting rules: `magicset`, `uniquecheck`, `intargetlist`, and `predpush`. The following describes the application scenarios of some important rules:

#### Preparing the Case Environment

To demonstrate rule application scenarios, you need to prepare the following table creation statements:

```
-- Clean the environment.
DROP SCHEMA IF EXISTS rewrite_rule_guc_test CASCADE;
CREATE SCHEMA rewrite_rule_guc_test;
SET current_schema=rewrite_rule_guc_test;
-- Create a test table.
CREATE TABLE t(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t1(c1 INT, c2 INT, c3 INT, c4 INT);
CREATE TABLE t2(c1 INT, c2 INT, c3 INT, c4 INT);
```

#### `intargetlist`: Target Column Subquery Performance Improvement

The query performance can be greatly improved by converting the subquery in the target column to JOIN. The following is an example:

```
gaussdb=# set rewrite_rule='none';
SET
gaussdb=# EXPLAIN (verbose on, costs off) SELECT c1,(SELECT avg(c2) FROM t2 WHERE t2.c2=t1.c2)
FROM t1 WHERE t1.c1<100 ORDER BY t1.c2;
          QUERY PLAN
-----
Sort
  Output: t1.c1, ((SubPlan 1)), t1.c2
  Sort Key: t1.c2
  -> Seq Scan on public.t1
    Output: t1.c1, (SubPlan 1), t1.c2
    Filter: (t1.c1 < 100)
    SubPlan 1
      -> Aggregate
        Output: avg(t2.c2)
        -> Seq Scan on public.t2
          Output: t2.c1, t2.c2
          Filter: (t2.c2 = t1.c2)
(12 rows)
```

Because the subquery (**select avg(c2) from t2 where t2.c2=t1.c2**) in the target column cannot be pulled up, execution of the subquery is triggered each time a row of data of **t1** is scanned, and the query efficiency is low. If the **intargetlist** parameter is enabled, the subquery is converted to JOIN to improve the query performance.

```
gaussdb=# set rewrite_rule='intargetlist';
SET
gaussdb=# explain (verbose on, costs off) select c1,(select avg(c2) from t2 where t2.c2=t1.c2) from t1
where t1.c1<100 order by t1.c2;
QUERY PLAN
-----
Sort
  Output: t1.c1, (avg(t2.c2)), t1.c2
  Sort Key: t1.c2
  -> Hash Left Join
    Output: t1.c1, (avg(t2.c2)), t1.c2
    Hash Cond: (t1.c2 = t2.c2)
    -> Seq Scan on public.t1
      Output: t1.c1, t1.c2
      Filter: (t1.c1 < 100)
    -> Hash
      Output: (avg(t2.c2)), t2.c2
      -> HashAggregate
        Output: avg(t2.c2), t2.c2
        Group By Key: t2.c2
        -> Seq Scan on public.t2
          Output: t2.c2
(16 rows)
```

## uniquecheck: Performance Improvement of Subqueries Without Aggregate Functions

Ensure that each condition has only one line of output. The subqueries with aggregate functions can be automatically pulled up. For subqueries without aggregate functions, the following is an example:

```
select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
```

Rewrite as follows:

```
select t1.c1 from t1 join (select t2.c1 from t2 where t2.c1 is not null group by t2.c1(unique check)) tt(c1) on
tt.c1=t1.c1;
```

Note that unique check in the preceding SQL statement indicates that **t2.c1** needs to be checked. If the SQL statement is abnormal, the SQL statement cannot be directly executed. To ensure semantic equivalence, the subquery **tt** must ensure that each **group by t2.c1** has only one line of output. Enable the **uniquecheck** query rewriting parameter to ensure that the query can be pulled up and equivalent. If more than one row of data is output at run time, an error is reported.

```
gaussdb=# set rewrite_rule='uniquecheck';
SET
gaussdb=# explain verbose select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c1);
QUERY PLAN
-----
Hash Join (cost=43.36..104.40 rows=2149 distinct=[200, 200] width=4)
  Output: t1.c1
  Hash Cond: (t1.c1 = subquery."?column?")
  -> Seq Scan on public.t1 (cost=0.00..31.49 rows=2149 width=4)
    Output: t1.c1, t1.c2
  -> Hash (cost=40.86..40.86 rows=200 width=8)
    Output: subquery."?column?", subquery.c1
```

```

-> Subquery Scan on subquery (cost=36.86..40.86 rows=200 width=8)
   Output: subquery."?column?", subquery.c1
   -> HashAggregate (cost=36.86..38.86 rows=200 width=4)
      Output: t2.c1, t2.c1
      Group By Key: t2.c1
      Filter: (t2.c1 IS NOT NULL)
      Unique Check Required
      -> Seq Scan on public.t2 (cost=0.00..31.49 rows=2149 width=4)
         Output: t2.c1
(16 rows)

```

Note: Because **group by t2.c1 unique check** occurs before the filter condition **t2.c1=t1.c1**, an error may be reported after the query that does not report an error is rewritten. An example is as follows:

There are tables **t1** and **t2**. The data in the tables is as follows:

```

gaussdb=# select * from t1 order by c2;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
(3 rows)
gaussdb=# select * from t2 order by c2;
 c1 | c2
----+----
  1 |  1
  2 |  2
  3 |  3
  4 |  4
  4 |  4
  5 |  5
(6 rows)

```

Disable and enable the **uniquecheck** parameter for comparison. After the parameter is enabled, an error is reported.

```

gaussdb=# select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
 c1
----
  1
  2
  3
(3 rows)
gaussdb=# set rewrite_rule='uniquecheck';
SET
gaussdb=# select t1.c1 from t1 where t1.c1 = (select t2.c1 from t2 where t1.c1=t2.c2) ;
ERROR: more than one row returned by a subquery used as an expression

```

## Parameter lazyagg: Eliminating the Aggregation Operation in a Subquery

The aggregation operation in a subquery is eliminated to improve the query efficiency. An example is as follows:

```

gaussdb=# set rewrite_rule =none;
SET
gaussdb=# EXPLAIN (costs off) SELECT t.c2, sum(cc) FROM (SELECT c2, sum(c3) AS cc FROM t1 GROUP BY
c2) s1, t WHERE s1.c2=t.c2 GROUP BY t.c2 ORDER BY 1,2;
          QUERY PLAN
-----
Sort
  Sort Key: t.c2, (sum(s1.cc))
  -> HashAggregate
    Group By Key: t.c2
    -> Hash Join
      Hash Cond: (t.c2 = s1.c2)

```

```

-> Seq Scan on t
-> Hash
  -> Subquery Scan on s1
    -> HashAggregate
        Group By Key: t1.c2
    -> Seq Scan on t1
(12 rows)

```

A subquery and the outer query have the same GROUP BY condition. The two-layer aggregation operation may lower down the query efficiency. Enable the **lazyagg** parameter to eliminate the aggregation operation in the subquery and improve the query performance.

```

gaussdb=# set rewrite_rule = lazyagg;
SET
gaussdb=# explain (costs off) select t.b, sum(cc) from (select b, sum(c) as cc from t1 group by b) s1, t
where s1.b=t.b group by t.b order by 1,2;
QUERY PLAN
-----
Sort
Sort Key: t.b, (sum((t1.c)::bigint))
-> HashAggregate
  Group By Key: t.b
  -> Hash Join
    Hash Cond: (t1.b = t.b)
    -> Seq Scan on t1
    -> Hash
      -> Seq Scan on t
(9 rows)

```

## Pushing Conditions from the Main Query to a Subquery

Associate a subquery with the aggregation operator with the main query in advance. An example is as follows:

```

gaussdb=# set rewrite_rule = none;
SET
gaussdb=# EXPLAIN (costs off) SELECT t1 FROM t1 WHERE t1.c2 = 10 AND t1.c3 < (SELECT sum(c3) FROM
t2 WHERE t1.c1 = t2.c1);
QUERY PLAN
-----
Hash Join
Hash Cond: (t2.c1 = t1.c1)
Join Filter: (t1.c3 < (sum(t2.c3)))
-> HashAggregate
  Group By Key: t2.c1
  -> Seq Scan on t2
-> Hash
  -> Seq Scan on t1
    Filter: (c2 = 10)
(9 rows)

```

In this case, the join columns of the subquery are grouped and aggregated, and then the subquery is joined with the main query. This reduces repeated scanning of related sublinks and improves query efficiency. After the rewriting parameters are modified, the plan is changed as follows:

```

gaussdb=# set rewrite_rule = magicset;
SET
gaussdb=# explain (costs off) SELECT t1 FROM t1 WHERE t1.c2 = 10 AND t1.c3 < (SELECT sum(c3) FROM
t2 WHERE t1.c1 = t2.c1);
QUERY PLAN
-----
Hash Join
Hash Cond: (t2.c1 = rewrite_rule_guc_test.t1.c1)
Join Filter: (rewrite_rule_guc_test.t1.c3 < (sum(t2.c3)))
-> HashAggregate

```

```

Group By Key: t2.c1
-> Hash Join
  Hash Cond: (t2.c1 = rewrite_rule_guc_test.t1.c1)
  -> Seq Scan on t2
  -> Hash
    -> HashAggregate
      Group By Key: rewrite_rule_guc_test.t1.c1
      -> Seq Scan on t1
      Filter: (c2 = 10)
-> Hash
  -> Seq Scan on t1
  Filter: (c2 = 10)
(16 rows)

```

## 6.12.2 Case: Creating an Appropriate Index

### Symptom

Query the information about all personnel in the sales department.

```

-- Create a table.
CREATE TABLE staffs (staff_id NUMBER(6) NOT NULL, first_name VARCHAR2(20), last_name
VARCHAR2(25), employment_id VARCHAR2(10), section_id NUMBER(4), state_name VARCHAR2(10), city
VARCHAR2(10));
CREATE TABLE sections(section_id NUMBER(4), place_id NUMBER(4), section_name VARCHAR2(20));
CREATE TABLE states(state_id NUMBER(4));
CREATE TABLE places(place_id NUMBER(4), state_id NUMBER(4));
-- Query before optimization.
EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;
-- Query after optimization.
CREATE INDEX loc_id_pk ON places(place_id);
CREATE INDEX state_c_id_pk ON states(state_id);

EXPLAIN SELECT staff_id,first_name,last_name,employment_id,state_name,city
FROM staffs,sections,states,places
WHERE sections.section_name='Sales'
AND staffs.section_id = sections.section_id
AND sections.place_id = places.place_id
AND places.state_id = states.state_id
ORDER BY staff_id;

```

### Optimization Analysis

The original execution plan is as follows before creating the **places.place\_id** and **states.state\_id** indexes:

```

-----
QUERY PLAN
-----
Sort  (cost=125.25..126.34 rows=438 width=254)
  Sort Key: staffs.staff_id
  -> Hash Join  (cost=64.91..106.03 rows=438 width=254)
    Hash Cond: (states.state_id = places.state_id)
    -> Seq Scan on states  (cost=0.00..29.45 rows=1945 width=12)
    -> Hash  (cost=64.35..64.35 rows=45 width=266)
      -> Hash Join  (cost=33.09..64.35 rows=45 width=266)
        Hash Cond: (places.place_id = sections.place_id)
        -> Seq Scan on places  (cost=0.00..25.13 rows=1513 width=24)
        -> Hash  (cost=33.02..33.02 rows=6 width=266)
          -> Hash Join  (cost=19.16..33.02 rows=6 width=266)
            Hash Cond: (staffs.section_id = sections.section_id)

```

```

-> Seq Scan on staffs (cost=0.00..12.76 rows=276 width=266)
-> Hash (cost=19.11..19.11 rows=4 width=24)
    -> Seq Scan on sections (cost=0.00..19.11 rows=4 width=24)
        Filter: ((section_name)::text = 'Sales'::text)
(16 rows)

```

The optimized execution plan is as follows (two indexes have been created on the **places.place\_id** and **states.state\_id** columns):

```

QUERY PLAN
-----
Sort (cost=107.40..108.49 rows=438 width=254)
  Sort Key: staffs.staff_id
  -> Hash Join (cost=35.37..88.18 rows=438 width=254)
    Hash Cond: (sections.section_id = staffs.section_id)
    -> Nested Loop (cost=19.16..66.85 rows=292 width=12)
      -> Hash Join (cost=19.16..50.27 rows=30 width=24)
        Hash Cond: (places.place_id = sections.place_id)
        -> Seq Scan on places (cost=0.00..25.13 rows=1513 width=24)
        -> Hash (cost=19.11..19.11 rows=4 width=24)
            -> Seq Scan on sections (cost=0.00..19.11 rows=4 width=24)
                Filter: ((section_name)::text = 'Sales'::text)
            -> Index Only Scan using state_c_id_pk on states (cost=0.00..0.45 rows=10 width=12)
                Index Cond: (state_id = places.state_id)
        -> Hash (cost=12.76..12.76 rows=276 width=266)
            -> Seq Scan on staffs (cost=0.00..12.76 rows=276 width=266)
(15 rows)

```

### 6.12.3 Case: Adding NOT NULL for the JOIN Column

```
SELECT * FROM join_a a JOIN join_b b ON a.b = b.b;
```

The execution plan is as follows:

```

QUERY PLAN
-----
Hash Join (cost=58.35..14677.69 rows=1074607 width=16) (actual time=23.374..23.384 rows=10 loops=1)
  Hash Cond: (a.b = b.b)
  -> Seq Scan on join_a a (cost=0.00..2248.10 rows=100010 width=8) (actual time=0.495..12.551 rows=100010 loops=1)
  -> Hash (cost=31.49..31.49 rows=2149 width=8) (actual time=0.614..0.614 rows=1000 loops=1)
      Buckets: 32768 Batches: 1 Memory Usage: 40kB
      -> Seq Scan on join_b b (cost=0.00..31.49 rows=2149 width=8) (actual time=0.009..0.183 rows=1000 loops=1)
  Total runtime: 23.716 ms
(7 rows)

```

### Optimization Analysis

1. According to the execution plan, the sequential scan phase is time consuming.
2. Therefore, you are advised to manually add **NOT NULL** for the **JOIN** column in the statement, as shown below:

```

SELECT
*
SELECT * FROM join_a a JOIN join_b b ON a.b = b.b where a.b IS NOT NULL;

```

The execution plan is as follows:

```

QUERY PLAN
-----
Hash Join (cost=58.22..14560.97 rows=1063762 width=16) (actual time=13.237..13.247 rows=10 loops=1)
  Hash Cond: (a.b = b.b)
  -> Seq Scan on join_a a (cost=0.00..2248.10 rows=99510 width=8) (actual time=12.417..12.422 rows=10 loops=1)
      Filter: (b IS NOT NULL)
      Rows Removed by Filter: 100000
  -> Hash (cost=31.49..31.49 rows=2138 width=8) (actual time=0.566..0.566 rows=1000 loops=1)

```

```

Buckets: 32768 Batches: 1 Memory Usage: 40kB
-> Seq Scan on join_b b (cost=0.00..31.49 rows=2138 width=8) (actual time=0.011..0.229
rows=1000 loops=1)
    Filter: (b IS NOT NULL)
    Total runtime: 13.556 ms
(10 rows)
    
```

## 6.12.4 Case: Modifying a Partitioned Table

### Symptom

In the following simple SQL statements, the performance bottlenecks exist in the scan operation on the **normal\_date** table.

```

-----
QUERY PLAN
-----
Seq Scan on normal_date (cost=0.00..259.00 rows=30 width=12) (actual time=0.100..3.466 rows=30
loops=1)
    Filter: (("time" >= '2022-09-01 00:00:00'::timestamp without time zone) AND ("time" <= '2022-10-01
00:00:00'::timestamp without time zone))
    Rows Removed by Filter: 9970
    Total runtime: 3.587 ms
(4 rows)
    
```

### Optimization Analysis

Obviously, there are date features in the **time** column of table data in the service layer, and this meet the features of a partitioned table. Replan the table definition of the **normal\_date** table. Set the **time** column as a partition key, and month as an interval unit. Define the partitioned table **normal\_date\_part**. The modified result is as follows, and the performance is improved by nearly 10 times.

```

-----
QUERY PLAN
-----
Partition Iterator (cost=0.00..480.00 rows=30 width=12) (actual time=0.038..0.085 rows=30 loops=1)
    Iterations: 2
    -> Partitioned Seq Scan on normal_date_part (cost=0.00..480.00 rows=30 width=12) (actual
time=0.049..0.063 rows=30 loops=2)
        Filter: (("time" >= '2022-09-01 00:00:00'::timestamp without time zone) AND ("time" <= '2022-10-01
00:00:00'::timestamp without time zone))
        Rows Removed by Filter: 31
        Selected Partitions: 3..4
    Total runtime: 0.360 ms
(7 rows)
    
```

## 6.12.5 Case: Rewriting SQL and Deleting Subqueries (1)

### Symptom

```

select
  1,
  (select count(*) from normal_date n where n.id = a.id) as GZCS
from normal_date a;
    
```

This SQL performance is poor. SubPlan exists in the execution plan as follows:

```

-----
QUERY PLAN
-----
Seq Scan on normal_date a (cost=0.00..888118.42 rows=5129 width=4) (actual time=2.394..22194.907
rows=10000 loops=1)
    
```

```

SubPlan 1
-> Aggregate (cost=173.12..173.12 rows=1 width=8) (actual time=22179.496..22179.942 rows=10000
loops=10000)
-> Seq Scan on normal_date n (cost=0.00..173.11 rows=1 width=0) (actual
time=11279.349..22159.608 rows=10000 loops=10000)
Filter: (id = a.id)
Rows Removed by Filter: 99990000
Total runtime: 22196.415 ms
(7 rows)
    
```

## Optimization

The core of this optimization is to eliminate subqueries. Based on the service scenario analysis, *a.id* is not null. In terms of SQL syntax, you can rewrite the SQL statement as follows:

```

select
count(*)
from normal_date n, normal_date a
where n.id = a.id
group by a.id;
    
```

The plan is as follows:

```

                                QUERY PLAN
-----
HashAggregate (cost=480.86..532.15 rows=5129 width=12) (actual time=21.539..24.356 rows=10000
loops=1)
  Group By Key: a.id
  -> Hash Join (cost=224.40..455.22 rows=5129 width=4) (actual time=6.402..13.484 rows=10000 loops=1)
    Hash Cond: (n.id = a.id)
    -> Seq Scan on normal_date n (cost=0.00..160.29 rows=5129 width=4) (actual time=0.087..1.459
rows=10000 loops=1)
    -> Hash (cost=160.29..160.29 rows=5129 width=4) (actual time=6.065..6.065 rows=10000 loops=1)
      Buckets: 32768 Batches: 1 Memory Usage: 352kB
      -> Seq Scan on normal_date a (cost=0.00..160.29 rows=5129 width=4) (actual time=0.046..2.738
rows=10000 loops=1)
  Total runtime: 26.844 ms
(9 rows)
    
```

### NOTE

To ensure that the modified statements have the same functions, **NOT NULL** is added to *normal\_date.id*.

## 6.12.6 Case: Rewriting SQL Statements and Deleting in-clause

### Symptom

in-clause/any-clause is a common SQL statement constraint. Sometimes, the clause following **in** or **any** is a constant. For example:

```
select count(1) from calc_empfyc_c1_result_tmp_t1 where ls_pid_cusr1 in ('20120405', '20130405');
```

Or

```
select count(1) from calc_empfyc_c1_result_tmp_t1 where ls_pid_cusr1 in any('20120405', '20130405');
```

Sometimes, the **in** or **any** clause is used as follows:

```
SELECT *FROM test1 t1, test2 t2WHERE t1.a = any(values(t2.a),(t2.b));
```

**a** and **b** are two columns in **t2**, and "**t1.a = any(values(t2.ba,(t2.b))**" is equivalent to "**t1.a = t2.a or t1.a = t2.b**".

Therefore, join-condition is essentially an inequality, and nestloop must be used for this unequal join operation. The corresponding execution plan is as follows:

```

QUERY PLAN
-----
---
Nested Loop (cost=0.00..138614.38 rows=2309100 width=16) (actual time=0.152..19225.483 rows=1000
loops=1)
  Join Filter: (SubPlan 1)
  Rows Removed by Join Filter: 999000
  -> Seq Scan on test1 t1 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.021..3.309 rows=1000
loops=1)
  -> Materialize (cost=0.00..42.23 rows=2149 width=8) (actual time=0.331..1265.810 rows=1000000
loops=1000)
    -> Seq Scan on test2 t2 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.013..0.268 rows=1000
loops=1)
    SubPlan 1
      -> Values Scan on ""VALUES"" (cost=0.00..0.03 rows=2 width=4) (actual time=2890.741..7372.739
rows=1999000 loops=1000000)
  Total runtime: 19227.328 ms
(9 rows)

```

## Optimization

The test result shows that both result sets are too large. As a result, nestloop is time-consuming with more than one hour to return results. Therefore, the key to performance optimization is to eliminate nestloop, using more efficient hash join. From the perspective of semantic equivalence, the SQL statements can be written as follows:

```

SELECT
*
FROM (
  SELECT * FROM test1 t1, test2 t2 WHERE t1.a = t2.a
  UNION
  SELECT * FROM test1 t1, test2 t2 WHERE t1.a = t2.b
);

```

The optimized SQL query consists of two equivalent join subqueries, and each subquery can be used for hash join in this scenario. The optimized execution plan is as follows:

```

QUERY PLAN
-----
---
HashAggregate (cost=1634.99..2096.81 rows=46182 width=16) (actual time=6.369..6.772 rows=1000
loops=1)
  Group By Key: t1.a, t1.b, t2.a, t2.b
  -> Append (cost=58.35..1173.17 rows=46182 width=16) (actual time=0.833..3.414 rows=2000 loops=1)
    -> Hash Join (cost=58.35..355.67 rows=23091 width=16) (actual time=0.832..1.590 rows=1000
loops=1)
      Hash Cond: (t1.a = t2.a)
      -> Seq Scan on test1 t1 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.015..0.156
rows=1000 loops=1)
      -> Hash (cost=31.49..31.49 rows=2149 width=8) (actual time=0.531..0.531 rows=1000 loops=1)
        Buckets: 32768 Batches: 1 Memory Usage: 40kB
        -> Seq Scan on test2 t2 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.010..0.199
rows=1000 loops=1)
    -> Hash Join (cost=58.35..355.67 rows=23091 width=16) (actual time=0.694..1.421 rows=1000
loops=1)
      Hash Cond: (t1.a = t2.b)
      -> Seq Scan on test1 t1 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.010..0.160
rows=1000 loops=1)
      -> Hash (cost=31.49..31.49 rows=2149 width=8) (actual time=0.524..0.524 rows=1000 loops=1)
        Buckets: 32768 Batches: 1 Memory Usage: 40kB
        -> Seq Scan on test2 t2 (cost=0.00..31.49 rows=2149 width=8) (actual time=0.008..0.177
rows=1000 loops=1)

```

Total runtime: 7.759 ms  
(16 rows)

# 7 SQL Reference

---

## 7.1 SQL

### What Is SQL?

SQL is a standard computer language used to control the access to databases and manage data in databases.

SQL provides different statements to enable you to:

- Query data.
- Insert, update, and delete rows.
- Create, replace, modify, and delete objects.
- Control the access to a database and its objects.
- Maintain the consistency and integrity of a database.

SQL consists of commands and functions that are used to manage databases and database objects. SQL can also forcibly implement the rules for data types, expressions, and texts. Therefore, [SQL Reference](#) describes data types, expressions, functions, and operators in addition to SQL syntax.

### Development of SQL Standards

The development history of SQL standards is as follows:

- 1986: ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989: ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992: ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999: ISO/IEC 9075:1999, SQL:1999 (SQL3)
- 2003: ISO/IEC 9075:2003, SQL:2003 (SQL4)
- 2011: ISO/IEC 9075:200N, SQL:2011 (SQL5)

### SQL Standards Supported by GaussDB

By default, GaussDB supports most features of SQL5.

## 7.2 Keywords

The SQL contains reserved keywords and non-reserved keywords. Standards require that reserved keywords not be used as other identifiers. Non-reserved keywords have special meanings only in a specific environment and can be used as identifiers in other environments.

---

### NOTICE

1. Currently, the non-reserved keywords have the following restrictions when being used as the identifier of a database object:
    1. It cannot be directly used as a column alias. That is, usage similar to `SELECT 1 ABORT` may cause errors.
    2. Keywords `ENTITYESCAPING`, `NOENTITYESCAPING`, and `WELLFORMED` cannot be used as identifiers of table names, column names, table aliases, column aliases, and function names if they are not enclosed in double quotation marks.
    3. The `RAW` keyword without double quotation marks cannot be used as the identifier of a table name or function name.
    4. The `SET` keyword without double quotation marks cannot be used as an identifier of a table alias. That is, usage similar to `SELECT * FROM T1 SET` may cause errors.
    5. Keywords such as `BEGIN`, `BY`, `CLOSE`, `CURSOR`, `DECLARE`, `DELETE`, `EXECUTE`, `FUNCTION`, `IF`, `IMMEDIATE`, `INSERT`, `LOOP`, `MOVE`, `OF`, `REF`, `RELEASE`, `RETURN`, `SAVEPOINT`, `STRICT`, `TYPE`, and `UPDATE` without double quotation marks cannot be used as variable names.
    6. When the `SYS_REFCURSOR` keyword is used as the identifier of a database object, if double quotation marks are not attached, a database object named **REFCURSOR** is created. If double quotation marks are attached, a database object named **SYS\_REFCURSOR** is created.
  2. Similar to the non-reserved keywords, the non-reserved (cannot be a function or type) keywords cannot be directly used as column aliases, either.
  3. The reserved keyword `CURRENT_TIMESTAMP` without double quotation marks (""") cannot be used as a function name.
- 

## Identifier Naming Conventions

Identifier naming must comply with the following rules:

- An identifier name can only contain letters, digits, underscores (`_`), and dollar signs (`$`).
- An identifier name must start with a letter or an underscore (`_`).

### NOTE

- The naming rules are recommended but not mandatory.
- In special cases, double quotation marks (") can be used to avoid special character errors.

## SQL Keywords

**Table 7-1** SQL keywords

Keyword	GaussDB	SQL:1999	SQL-92
ABORT	Non-reserved	N/A	N/A
ABS	N/A	Non-reserved	N/A

## 7.3 Data Types

A data type is a basic data attribute. Occupied storage space and allowed operations vary according to data types. Data is stored in tables in a database. Each column of a data table specifies a data type and data must be stored according to data types.

GaussDB supports implicit conversions between certain data types. For details, see [PG\\_CAST](#).

### 7.3.1 Numeric Types

[Table 7-2](#) lists all available types. For arithmetic operators and related built-in functions, see [Arithmetic Functions and Operators](#).

**Table 7-2 Integer types**

Name	Description	Storage Space	Range
TINYINT	Tiny integer, also called INT1	1 byte	0 ~ +255
SMALLINT	Small integer, also called INT2	2 bytes	-32,768 to +32,767
INTEGER	Typical choice for integers, also called INT4	4 bytes	-2,147,483,648 to +2,147,483,647
BINARY_INTEGER	Alias of INTEGER.	4 bytes	-2,147,483,648 to +2,147,483,647
BIGINT	Big integer, also called INT8	8 bytes	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807
int16	A 16-byte integer cannot be used to create tables.	16 bytes	-170,141,183,460,469,231,731,687,303,715,884,105,728 to +170,141,183,460,469,231,731,687,303,715,884,105,727

**Example:**

```
-- Create a table containing TINYINT data.
gaussdb=# CREATE TABLE int_type_t1
(
  IT_COL1 TINYINT
);

-- Insert data to the created table.
gaussdb=# INSERT INTO int_type_t1 VALUES(10);

-- View data.
gaussdb=# SELECT * FROM int_type_t1;
it_col1
-----
10
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE int_type_t1;
-- Create a table containing TINYINT, INTEGER, and BIGINT data.
gaussdb=# CREATE TABLE int_type_t2
(
  a TINYINT,
  b TINYINT,
  c INTEGER,
  d BIGINT
);

-- Insert data.
gaussdb=# INSERT INTO int_type_t2 VALUES(100, 10, 1000, 10000);

-- View data.
```

```
gaussdb=# SELECT * FROM int_type_t2;
 a | b | c | d
-----+-----
100 | 10 | 1000 | 10000
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE int_type_t2;
```

 **NOTE**

- Only numbers of the TINYINT, SMALLINT, INTEGER, BIGINT, or INT16 type, that is, integers can be stored. Saving a number with a decimal in any of the data types will result in errors.
- The INTEGER type is the common choice, as it offers the best balance between range, storage size, and performance. Generally, use the SMALLINT type only if you are sure that the value range is within the SMALLINT value range. The storage speed of INTEGER is much faster. BIGINT is used only when the range of INTEGER is not large enough.

**Table 7-3** Arbitrary precision types

Name	Description	Storage Space	Range
NUMERIC[(p[,s])], DECIMAL[(p[,s])]	The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0,p]. <b>NOTE</b> <b>p</b> indicates the total digits, and <b>s</b> indicates the decimal digit.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.
NUMBER[(p[,s])]	Alias of the NUMERIC type.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Up to 131,072 digits before the decimal point, and up to 16,383 digits after the decimal point when no precision is specified.

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE decimal_type_t1
(
  DT_COL1 DECIMAL(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO decimal_type_t1 VALUES(123456.122331);

-- Query data in the table.
gaussdb=# SELECT * FROM decimal_type_t1;
 dt_col1
-----
123456.1223
(1 row)
```

```

-- Drop the table.
gaussdb=# DROP TABLE decimal_type_t1;
-- Create a table.
gaussdb=# CREATE TABLE numeric_type_t1
(
  NT_COL1 NUMERIC(10,4)
);

-- Insert data.
gaussdb=# INSERT INTO numeric_type_t1 VALUES(123456.12354);

-- Query data in the table.
gaussdb=# SELECT * FROM numeric_type_t1;
   nt_col1
-----
123456.1235
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE numeric_type_t1;

```

 **NOTE**

- Compared to the integer types, the arbitrary precision numbers require larger storage space and have lower storage efficiency, operation efficiency, and poorer compression ratio results. The INTEGER type is the common choice when number types are defined. Arbitrary precision numbers are used when numbers exceed the maximum range indicated by the integers.
- When NUMERIC/DECIMAL is used for defining a column, you are advised to specify the precision (p) and scale (s) for the column.

**Table 7-4** Sequence integer

Name	Description	Storage Space	Range
SMALLSERIAL	Two-byte serial integer	2 bytes.	-32,768 to +32,767.
SERIAL	Four-byte serial integer	4 bytes.	-2,147,483,648 to +2,147,483,647.
BIGSERIAL	Eight-byte serial integer	8 bytes.	-9,223,372,036,854,775,808 to +9,223,372,036,854,775,807.

Name	Description	Storage Space	Range
LARGESERIAL	By default, a 16-byte auto-incrementing integer is inserted. The actual value type is the same as that of NUMERIC.	Variable-length type. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	There can be a maximum of 131072 digits before the decimal point and 16383 digits after the decimal point.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE smallserial_type_tab(a SMALLSERIAL);

-- Insert data.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO smallserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM smallserial_type_tab;
a
---
1
2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE serial_type_tab(b SERIAL);

-- Insert data.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO serial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM serial_type_tab;
b
---
1
2
(2 rows)

-- Create a table.
```

```

gaussdb=# CREATE TABLE bigserial_type_tab(c BIGSERIAL);
-- Insert data.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO bigserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM bigserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Create a table.
gaussdb=# CREATE TABLE largeserial_type_tab(c LARGESERIAL);

-- Insert data.
gaussdb=# INSERT INTO largeserial_type_tab VALUES(default);

-- Insert data again.
gaussdb=# INSERT INTO largeserial_type_tab VALUES(default);

-- View data.
gaussdb=# SELECT * FROM largeserial_type_tab;
 c
---
 1
 2
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE smallserial_type_tab;

gaussdb=# DROP TABLE serial_type_tab;

gaussdb=# DROP TABLE bigserial_type_tab;

```

 **NOTE**

SMALLSERIAL, SERIAL, BIGSERIAL, and LARGESERIAL are not real types. They are concepts used for setting a unique identifier for a table. Therefore, an integer column is created and its default value plans to be read from a sequencer. A NOT NULL constraint is used to ensure NULL is not inserted. In most cases you would also want to attach a **UNIQUE** or **PRIMARY KEY** constraint to prevent duplicate values from being inserted unexpectedly, but this is not automatic. Finally, the sequencer belongs to the column. In this case, when the column or the table is deleted, the sequencer is also deleted. Currently, you can specify a SERIAL column when creating a table or add a SERIAL column to an ordinary table in PG-compatible mode. In addition, **SERIAL** columns cannot be created in temporary tables. Because SERIAL is not a data type, columns cannot be converted to this type.

**Table 7-5** Floating point types

Name	Description	Storage Space	Range
REAL, FLOAT4	Single precision floating points, which is not very precise.	4 bytes.	-3.402E+38 to +3.402E+38, 6-digit decimal digits.

Name	Description	Storage Space	Range
DOUBLE PRECISION , FLOAT8	Double precision floating points, which is not very precise.	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
FLOAT[(p)]	Floating-point number, which is not very precise. The value range of precision (p) is [1,53].	4 bytes or 8 bytes.	<b>REAL</b> or <b>DOUBLE PRECISION</b> is selected as an internal identifier based on precision (p). If no precision is specified, <b>DOUBLE PRECISION</b> is used as the internal identifier.
BINARY_DOUBLE	Alias for DOUBLE PRECISION, compatible with Oracle.	8 bytes.	-1.79E+308 to +1.79E+308, 15-bit decimal digits.
DEC[(p[,s])]	The value range of <b>p</b> is [1,1000], and the value range of <b>s</b> is [0, <i>p</i> ].	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.
INTEGER[(p[,s])]	The value range of <b>p</b> (precision) is [1,1000], and the value range of <b>s</b> (scale) is [0, <i>p</i> ]. If the precision and scale are not specified, the precision <b>p</b> is <b>10</b> and the scale <b>s</b> is <b>0</b> by default. If the precision and scale are not specified, this type is mapped to INTEGER. If the precision and scale are specified, this type is mapped to NUMERIC.	The precision is specified by users. Every four decimal digits occupy two bytes, and an extra eight-byte overhead is added to the entire data.	Maximum 131,072 digits before the decimal point and 16,383 digits after the decimal point when the precision and scale are specified to the maximum.  If the precision and scale are not specified, the value ranges from -2,147,483,648 to +2,147,483,647.

 NOTE

In [Table 7-5](#), **p** is the precision, indicating the minimum acceptable total number of integral places, and **s** indicates the decimal digit.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE float_type_t2
(
  FT_COL1 INTEGER,
  FT_COL2 FLOAT4,
  FT_COL3 FLOAT8,
  FT_COL4 FLOAT(3),
  FT_COL5 BINARY_DOUBLE,
  FT_COL6 DECIMAL(10,4),
  FT_COL7 INTEGER(6,3)
);

-- Insert data.
gaussdb=# INSERT INTO float_type_t2 VALUES(10,10.365456,123456.1234,10.3214, 321.321, 123.123654,
123.123654);

-- View data.
gaussdb=# SELECT * FROM float_type_t2 ;
ft_col1 | ft_col2 | ft_col3 | ft_col4 | ft_col5 | ft_col6 | ft_col7
-----+-----+-----+-----+-----+-----+-----
      10 | 10.3655 | 123456.1234 | 10.3214 | 321.321 | 123.1237 | 123.124
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE float_type_t2;
```

## 7.3.2 Monetary Types

The money type stores a currency amount with fixed fractional precision.

The range shown in [Table 7-6](#) assumes there are two fractional digits. Input is accepted in a variety of formats, including integer and floating-point literals, as well as typical currency formatting, such as "\$1,000.00". Output is generally in the last format but depends on the locale.

**Table 7-6** Monetary type

Name	Description	Storage Space	Range
money	Currency amount	8 bytes	-92233720368547758.08 ~ +92233720368547758.07

Values of the numeric, int, and bigint data types can be cast to money. Conversion from the real or double precision data type to a money value can be done by casting to numeric type first, for example:

```
gaussdb=# SELECT '12.34'::float8::numeric::money;
money
-----
```

```
$12.34
(1 row)
```

However, this is not recommended. Floating point numbers should not be used to handle money due to the potential for rounding errors.

A money value can be cast to numeric without loss of precision. Conversion to other types could potentially lose precision, and must also be done in two stages:

```
gaussdb=# SELECT '52093.89'::money::numeric::float8;
float8
-----
52093.89
(1 row)
```

When a money value is divided by another money value, the result is of the double precision type (that is, the digit type instead of the money type); the currency units cancel each other out in the division.

### 7.3.3 Boolean Types

**Table 7-7** lists the Boolean types supported by GaussDB.

**Table 7-7** Boolean Types

Name	Description	Storage Space	Value
BOOLEAN	Boolean	1 byte	<ul style="list-style-type: none"> <li><b>true</b></li> <li><b>false</b></li> <li><b>null</b>: unknown</li> </ul>

- Valid literal values for the "true" state are:  
**TRUE, 't', 'true', 'y', 'yes', '1', 'TRUE', true, on**, and all non-zero values.
- Valid literal values for the "false" state include:  
**FALSE, 'f', 'false', 'n', 'no', '0', 0, 'FALSE', false, and off**.

**TRUE** and **FALSE** are standard expressions, compatible with SQL statements.

### Examples

Boolean values are displayed using the letters t and f.

```
-- Create a table.
gaussdb=# CREATE TABLE bool_type_t1
(
  BT_COL1 BOOLEAN,
  BT_COL2 TEXT
);

-- Insert data.
gaussdb=# INSERT INTO bool_type_t1 VALUES (TRUE, 'sic est');

gaussdb=# INSERT INTO bool_type_t1 VALUES (FALSE, 'non est');

-- View data.
gaussdb=# SELECT * FROM bool_type_t1;
```

```

bt_col1 | bt_col2
-----+-----
t      | sic est
f      | non est
(2 rows)

gaussdb=# SELECT * FROM bool_type_t1 WHERE bt_col1 = 't';
bt_col1 | bt_col2
-----+-----
t      | sic est
(1 row)

-- Drop the table.
gaussdb=# DROP TABLE bool_type_t1;

```

## 7.3.4 Character Types

**Table 7-8** lists the character data types supported by GaussDB. For string operators and related built-in functions, see [Character Processing Functions and Operators](#).

**Table 7-8** Character types

Name	Description	Storage Space
CHAR(n) CHARACTER(n) NCHAR(n)	Fixed-length character string. Empty characters are filled in with blank spaces. <b>n</b> indicates the string length. If it is not specified, the default precision <b>1</b> is used.	The maximum size is 10 MB.
VARCHAR(n) CHARACTER VARYING(n)	Variable-length string. In PostgreSQL-compatible mode, <b>n</b> indicates the string length. In other compatibility modes, <b>n</b> indicates the byte length.	The maximum size is 10 MB. If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes).
VARCHAR2(n)	Variable-length string. It is the alias of the VARCHAR(n) type. <b>n</b> indicates the string length.	The maximum value of <b>n</b> is <b>10485760</b> (10 MB). If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes).

Name	Description	Storage Space
NVARCHAR2(n)	Variable-length string. <b>n</b> indicates the string length.	<p>The maximum value of <b>n</b> is <b>10485760</b> (10 MB).</p> <p>If <b>n</b> is not specified, the maximum storage length is 1 GB – 85 bytes – Length of the first <i>n</i> columns. For example, the maximum length of (a int, b varchar) is 1,073,741,735 bytes (= 1 GB – 85 bytes – 4 bytes).</p>
TEXT	Variable-length string.	<p>The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the TEXT type may be less than 1 GB minus 1 byte.</p>
CLOB	Big text object. It is the alias of the TEXT type.	<p>For Astore, the maximum size is 32 TB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 32 TB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 32 TB minus 1 byte.</p> <p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the CLOB type may be less than 1 GB minus 1 byte.</p>

 NOTE

1. In addition to the restriction on the size of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte and is affected by the control header information of the column, the control header information of the tuple, and whether null fields exist in the tuple.
2. NCHAR is the alias of the bpchar type, and VARCHAR2(n) is the alias of the VARCHAR(n) type.
3. Only advanced package db\_lob supports CLOBs whose size is greater than 1 GB. System functions do not support CLOBs whose size is greater than 1 GB.
4. In A-compatible mode, the received empty string is converted to null by default.
5. GaussDB supports a maximum of 1 GB data transfer, and the maximum size of the result string returned by the function is 1 GB.

In GaussDB, there are two other fixed-length character types, as shown in [Table 7-9](#). The **name** type exists only for the storage of identifiers in the internal system catalogs and is not intended for use by general users. Its length is currently defined as 64 bytes (63 usable characters plus terminator). The type **"char"** only uses one byte of storage. It is internally used in the system catalogs as a simplistic enumeration type.

**Table 7-9** Special character types

Name	Description	Storage Space
name	Internal type for object names	64 bytes
"char"	Single-byte internal type	1 byte

## Examples

```
-- Create a table.
gaussdb=# CREATE TABLE char_type_t1
(
  CT_COL1 CHARACTER(4)
);

-- Insert data.
gaussdb=# INSERT INTO char_type_t1 VALUES ('ok');

-- Query data in the table.
gaussdb=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t1;
 ct_col1 | char_length
-----+-----
ok      |          4
(1 row)

-- Delete the table.
gaussdb=# DROP TABLE char_type_t1;

-- Create a table.
gaussdb=# CREATE TABLE char_type_t2
(
  CT_COL1 VARCHAR(5)
);

-- Insert data.
gaussdb=# INSERT INTO char_type_t2 VALUES ('ok');
gaussdb=# INSERT INTO char_type_t2 VALUES ('good');
```

```
-- Specify the type length. An error is reported if an inserted string exceeds this length.
gaussdb=# INSERT INTO char_type_t2 VALUES ('too long');
ERROR: value too long for type character varying(5)
CONTEXT: referenced column: ct_col1

-- Specify the type length. A string exceeding this length is truncated.
gaussdb=# INSERT INTO char_type_t2 VALUES ('too long'::varchar(5));

-- Query data.
gaussdb=# SELECT ct_col1, char_length(ct_col1) FROM char_type_t2;
 ct_col1 | char_length
-----+-----
ok      |          2
good   |          4
too l   |          5
(3 rows)

-- Delete data.
gaussdb=# DROP TABLE char_type_t2;
```

### 7.3.5 Binary Types

**Table 7-10** lists the binary data types supported by GaussDB.

**Table 7-10** Binary data types

Name	Description	Storage Space
BLOB	<p>Binary large object (BLOB).</p> <p>Currently, BLOB only supports the following external access APIs:</p> <ul style="list-style-type: none"> <li>DBE_LOB.GET_LENGTH</li> <li>DBE_LOB.READ</li> <li>DBE_LOB.WRITE</li> <li>DBE_LOB.WRITE_APPEND</li> <li>DBE_LOB.COPY</li> <li>DBE_LOB.ERASE</li> </ul> <p>For details about the APIs, see <a href="#">DBE_LOB</a>.</p>	<p>For Astore, the maximum size is 32 TB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 32 TB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 32 TB minus 1 byte.</p> <p>For Ustore, the maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of the BLOB type may be less than 1 GB minus 1 byte.</p>
RAW	Variable-length hexadecimal string.	<p>4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.</p>

Name	Description	Storage Space
BYTEA	Variable-length binary string.	4 bytes plus the actual binary string. The maximum size is 1 GB minus 1 byte. However, the size of the column description header and the size of the tuple (less than 1 GB minus 1 byte) where the column is located must also be considered. Therefore, the maximum size of this type may be less than 1 GB minus 1 byte.
BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as deterministic encryption, the column type is BYTEAWITHOUTORDERWITHEQUALCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1073741771 bytes (1 GB - 53 bytes).
BYTEAWITHOUTORDERCOL	Variable-length binary character string (new type for the encryption feature. If the encryption type of an encrypted column is specified as random encryption, the column type is BYTEAWITHOUTORDERCOL). The original data type is displayed when an encrypted table is printed by running the meta command.	4 bytes plus the actual binary string. The maximum value is 1073741771 bytes (1 GB - 53 bytes).
_BYTEAWITHOUTORDERWITHEQUALCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1073741771 bytes (1 GB - 53 bytes).
_BYTEAWITHOUTORDERCOL	Variable-length binary string, which is a new type for the encryption feature.	4 bytes plus the actual binary string. The maximum value is 1,073,741,771 bytes (1 GB minus 53 bytes).

 NOTE

- In addition to the size limit of each column, the total size of each tuple cannot exceed 1 GB minus 1 byte.
- BYTEAWITHOUTORDERWITHEQUALCOL, BYTEAWITHOUTORDERCOL, \_BYTEAWITHOUTORDERWITHEQUALCOL, and \_BYTEAWITHOUTORDERCOL cannot be directly used to create a table.
- RAW(*n*), where *n* indicates the recommended byte length and is not used to verify the byte length of the input raw type.
- GaussDB supports a maximum of 1 GB data transfer, and the maximum size of the result string returned by the function is 1 GB.

## Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_type_t1
(
  BT_COL1 INTEGER,
  BT_COL2 BLOB,
  BT_COL3 RAW,
  BT_COL4 BYTEA
);

-- Insert data.
gaussdb=# INSERT INTO blob_type_t1 VALUES(10,empty_blob(),
HEXTORAW('DEADBEEF'),E'\xDEADBEEF');

-- Query data in the table.
gaussdb=# SELECT * FROM blob_type_t1;
 bt_col1 | bt_col2 | bt_col3 | bt_col4
-----+-----+-----+-----
      10 |          | DEADBEEF | \xdeadbeef
(1 row)

-- Delete the table.
gaussdb=# DROP TABLE blob_type_t1;
```

## 7.3.6 Date/Time Types

[Table 7-11](#) lists the date/time types that can be used in GaussDB. For the operators and built-in functions of the types, see [Date and Time Processing Functions and Operators](#).

 NOTE

If the time format of another database is different from that of GaussDB, modify the value of the **DateStyle** parameter to keep them consistent.

**Table 7-11** Date/Time types

Name	Description	Storage Space
DATE	<p>Date.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-01-01BC</b> (4713 B.C.).</li> <li>• Maximum value: <b>5874897-12-31AD</b> (5874897 A.C.)</li> </ul> <p><b>NOTE</b> For A compatibility, the database treats empty strings as <b>NULL</b> and replaces DATE with <b>TIMESTAMP(0) WITHOUT TIME ZONE</b>.</p>	4 bytes (8 bytes in A compatibility schema)
TIME [(p)] [WITHOUT TIME ZONE]	<p>Time within one day.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>00:00:00</b>.</li> <li>• Maximum value: <b>24:00:00</b>.</li> </ul>	8 bytes
TIME [(p)] [WITH TIME ZONE]	<p>Time within one day (with time zone).</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>00:00:00+1559</b>.</li> <li>• Maximum value: <b>24:00:00</b>.</li> </ul>	12 bytes
TIMESTAMP[(p)] [WITHOUT TIME ZONE]	<p>Date and time.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.).</li> <li>• Maximum value: <b>294277-01-09AD 00:00:00.000000</b> (294277 A.D.).</li> </ul>	8 bytes

Name	Description	Storage Space
<p>TIMESTAMP[(p)] [WITH TIME ZONE]</p>	<p>Date and time (with time zone). TIMESTAMP is also called TIMESTAMPTZ.</p> <p><b>p</b> indicates the precision after the decimal point. The value ranges from <b>0</b> to <b>6</b>.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.).</li> <li>• Maximum value: <b>294277-01-09AD 00:00:00.000000</b> (294277 A.D.).</li> </ul> <p>Time zone update: In some countries or regions, the time zone information is frequently updated due to political, economic, and war factors. Therefore, the database system needs to modify the time zone file to ensure that the time is correct.</p> <p>Currently, the GaussDB time zone type involves only timestamp with timezone. When a new time zone file takes effect, the existing data is not changed, and the new data is adjusted based on the time zone file information.</p>	<p>8 bytes</p>
<p>SMALLDATETIME</p>	<p>Date and time (without time zone). The precision level is minute. 30s to 59s are rounded into one minute.</p> <ul style="list-style-type: none"> <li>• Minimum value: <b>4713-11-24BC 00:00:00.000000</b> (4713 B.C.).</li> <li>• Maximum value: <b>294277-01-09AD 00:00:00.000000</b> (294277 A.D.).</li> </ul>	<p>8 bytes</p>
<p>INTERVAL DAY (l) TO SECOND (p)</p>	<p>Specifies the time interval (<i>X</i> days <i>X</i> hours <i>X</i> minutes <i>X</i> seconds).</p> <ul style="list-style-type: none"> <li>• <b>l</b>: indicates the precision of days. The value ranges from 0 to 6. For compatibility, the precision functions are not supported.</li> <li>• <b>p</b>: indicates the precision of seconds. The value ranges from 0 to 6. The digit 0 at the end of a decimal number is not displayed.</li> </ul>	<p>16 bytes</p>

Name	Description	Storage Space
INTERVAL [FIELDS] [ (p) ]	<p>Time interval.</p> <ul style="list-style-type: none"> <li><b>FIELDS:</b> YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, DAY TO HOUR, DAY TO MINUTE, DAY TO SECOND, HOUR TO MINUTE, HOUR TO SECOND, or MINUTE TO SECOND.</li> <li><b>p:</b> indicates the precision of seconds. The value ranges from 0 to 6. <b>p</b> takes effect only when <b>FIELDS</b> is set to <b>SECOND</b>, <b>DAY TO SECOND</b>, <b>HOUR TO SECOND</b>, or <b>MINUTE TO SECOND</b>. The digit 0 at the end of a decimal number is not displayed.</li> </ul>	12 bytes
reltime	<p>Relative time interval.</p> <ul style="list-style-type: none"> <li>The format is as follows: X years X mons X days XX:XX:XX.</li> <li>The Julian calendar is used. It specifies that a year has 365.25 days and a month has 30 days. The relative time interval needs to be calculated based on the input value.</li> </ul>	4 bytes
abstime	<p>Date and time.</p> <ul style="list-style-type: none"> <li>Format: YYYY-MM-DD hh:mm:ss +timezone.</li> <li>The value range is from 1901-12-13 20:45:53 GMT to 2038-01-18 23:59:59 GMT. The precision is second.</li> </ul>	4 bytes

 **NOTE**

If the values of **a\_format\_version** and **a\_format\_dev\_version** are **10c** and **s1**, the default DATE value is determined by the following:

- Year: returned through SYSDATE
- Month: returned through SYSDATE
- Day: 01 (first day of the month)
- Hour, minute, and second: all 0

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);
```

```
-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10(1 row)

-- Delete a table.
gaussdb=# DROP TABLE date_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE time_type_tab (da time without time zone ,dai time with time zone,dfgh
timestamp without time zone,dfga timestamp with time zone, vbg smalldatetime);

-- Insert data.
gaussdb=# INSERT INTO time_type_tab VALUES ('21:21:21','21:21:21 pst','2010-12-12','2013-12-11
pst','2003-04-12 04:05:06');

-- View data.
gaussdb=# SELECT * FROM time_type_tab;
      da | dai | dfgh | dfga | vbg
-----+-----+-----+-----+-----
21:21:21 | 21:21:21-08 | 2010-12-12 00:00:00 | 2013-12-11 16:00:00+08 | 2003-04-12 04:05:00
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE time_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE day_type_tab (a int,b INTERVAL DAY(3) TO SECOND (4));

-- Insert data.
gaussdb=# INSERT INTO day_type_tab VALUES (1, INTERVAL '3' DAY);

-- View data.
gaussdb=# SELECT * FROM day_type_tab;
 a | b
---+-----
 1 | 3 days
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE day_type_tab;

-- Create a table.
gaussdb=# CREATE TABLE year_type_tab(a int, b interval year (6));

-- Insert data.
gaussdb=# INSERT INTO year_type_tab VALUES(1,interval '2' year);

-- View data.
gaussdb=# SELECT * FROM year_type_tab;
 a | b
---+-----
 1 | 2 years
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE year_type_tab;
```

## Date Inputs

Date and time input is accepted in almost any reasonable formats, including ISO 8601, SQL-compatible, and traditional Postgres. The system allows you to customize the sequence of day, month, and year in the date input. Set the **DateStyle** parameter to **MDY** to select month-day-year interpretation, **DMY** to

select day-month-year interpretation, or **YMD** to select year-month-day interpretation.

Remember that any date or time literal input needs to be enclosed with single quotation marks ('), and the syntax is as follows:

```
type [ ( p ) ] 'value'
```

The **p** that can be selected in the precision statement is an integer, indicating the number of fractional digits in the **seconds** column. [Table 7-12](#) shows the input formats of the date type.

**Table 7-12** Date input formats

Example	Description
1999-01-08	ISO 8601 (recommended format). January 8, 1999 in any format.
January 8, 1999	Unambiguous in any <b>datestyle</b> input mode
1/8/1999	January 8 in MDY format. August 1 in DMY format.
1/18/1999	January 18 in MDY format, rejected in other formats.
01/02/03	<ul style="list-style-type: none"> <li>January 2, 2003 in <b>MDY</b> mode</li> <li>February 1, 2003 in <b>DMY</b> mode</li> <li>February 3, 2001 in <b>YMD</b> mode</li> </ul>
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in <b>YMD</b> mode, else error
08-Jan-99	January 8, except error in <b>YMD</b> mode
Jan-08-99	January 8, except error in <b>YMD</b> mode
19990108	ISO 8601. January 8, 1999 in any format.
990108	ISO 8601. January 8, 1999 in any format.
1999.008	Year and day of year
J2451187	Julian date
January 8, 99 BC	Year 99 BC

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE date_type_tab(coll date);

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES (date '12-10-2010');
```

```

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10(1 row)

-- View the date format.
gaussdb=# SHOW datestyle;
DateStyle
-----
ISO, MDY
(1 row)

-- Set the date format.
gaussdb=# SET datestyle='YMD';
SET

-- Insert data.
gaussdb=# INSERT INTO date_type_tab VALUES(date '2010-12-11');

-- View data.
gaussdb=# SELECT * FROM date_type_tab;
      coll
-----
2010-12-10 2010-12-11(2 rows)

-- Delete a table.
gaussdb=# DROP TABLE date_type_tab;

```

## Time

The time-of-day types are **TIME [(p)] [WITHOUT TIME ZONE]** and **TIME [(p)] [WITH TIME ZONE]**. **TIME** alone is equivalent to **TIME WITHOUT TIME ZONE**.

If a time zone is specified in the input for **TIME WITHOUT TIME ZONE**, it is silently ignored.

For details about the time input types, see [Table 7-14](#). For details about time zone input types, see [Table 7-13](#).

**Table 7-13** Time input types

Example	Description
05:06.8	ISO 8601
4:05:06	ISO 8601
4:05	ISO 8601
040506	ISO 8601
4:05 AM	Same as 04:05. Input hours must be less than or equal to 12.
4:05 PM	Same as 16:05. Input hours must be less than or equal to 12.
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601

Example	Description
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by abbreviation
2003-04-12 04:05:06 America/ New_York	Time zone specified by full name

**Table 7-14** Time zone input types

Example	Description
PST	Abbreviation (for Pacific Standard Time)
America/New_York	Full time zone name
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST

Example:

```
gaussdb=# SELECT time '04:05:06';
time
-----
04:05:06
(1 row)

gaussdb=# SELECT time '04:05:06 PST';
time
-----
04:05:06
(1 row)

gaussdb=# SELECT time with time zone '04:05:06 PST';
timetz
-----
04:05:06-08
(1 row)
```

## Special Values

The special values supported by GaussDB are converted to common date/time values when being read. For details, see [Table 7-15](#).

**Table 7-15** Special values

Input String	Applicable Type	Description
epoch	date and timestamp	1970-01-01 00:00:00+00 (Unix system time zero)
infinity	timestamp	Later than any other timestamps
-infinity	timestamp	Earlier than any other timestamps
now	date, time, and timestamp	Start time of the current transaction
today	date and timestamp	Midnight today
tomorrow	date and timestamp	Midnight tomorrow
yesterday	date and timestamp	Midnight yesterday
allballs	time	00:00:00.00 UTC

**Example:**

```
-- Create a table.
gaussdb=# CREATE TABLE realtime_type_special(col1 varchar(20), col2 date, col3 timestamp, col4 time);

-- Insert data.
gaussdb=# INSERT INTO realtime_type_special VALUES('epoch', 'epoch', 'epoch', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('now', 'now', 'now', 'now');
gaussdb=# INSERT INTO realtime_type_special VALUES('today', 'today', 'today', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('tomorrow', 'tomorrow', 'tomorrow', NULL);
gaussdb=# INSERT INTO realtime_type_special VALUES('yesterday', 'yesterday', 'yesterday', NULL);

-- View data.
gaussdb=# SELECT * FROM realtime_type_special;
 col1 | col2 | col3 | col4
-----+-----+-----+-----
epoch | 1970-01-01 00:00:00 | 1970-01-01 00:00:00 |
now | 2023-02-27 11:38:13 | 2023-02-27 11:38:13.032815 | 11:38:13.032815
today | 2023-02-27 00:00:00 | 2023-02-27 00:00:00 |
tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
yesterday | 2023-02-26 00:00:00 | 2023-02-26 00:00:00 |
(5 rows)

gaussdb=# SELECT * FROM realtime_type_special WHERE col3 < 'infinity';
 col1 | col2 | col3 | col4
-----+-----+-----+-----
epoch | 1970-01-01 00:00:00 | 1970-01-01 00:00:00 |
now | 2023-02-27 11:38:13 | 2023-02-27 11:38:13.032815 | 11:38:13.032815
today | 2023-02-27 00:00:00 | 2023-02-27 00:00:00 |
tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
yesterday | 2023-02-26 00:00:00 | 2023-02-26 00:00:00 |
(5 rows)

gaussdb=# SELECT * FROM realtime_type_special WHERE col3 > '-infinity';
 col1 | col2 | col3 | col4
-----+-----+-----+-----
epoch | 1970-01-01 00:00:00 | 1970-01-01 00:00:00 |
now | 2023-02-27 11:38:13 | 2023-02-27 11:38:13.032815 | 11:38:13.032815
today | 2023-02-27 00:00:00 | 2023-02-27 00:00:00 |
tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
yesterday | 2023-02-26 00:00:00 | 2023-02-26 00:00:00 |
```

```
(5 rows)
gaussdb=# SELECT * FROM realtime_type_special WHERE col3 > 'now';
 col1 | col2 | col3 | col4

tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
(1 row)

gaussdb=# SELECT * FROM realtime_type_special WHERE col3 = 'today';
 col1 | col2 | col3 | col4
-----+-----+-----+-----
today | 2023-02-27 00:00:00 | 2023-02-27 00:00:00 |
(1 row)

gaussdb=# SELECT * FROM realtime_type_special WHERE col3 = 'tomorrow';
 col1 | col2 | col3 | col4
-----+-----+-----+-----
tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
(1 row)

gaussdb=# SELECT * FROM realtime_type_special WHERE col3 > 'yesterday';
 col1 | col2 | col3 | col4
-----+-----+-----+-----
now | 2023-02-27 11:38:13 | 2023-02-27 11:38:13.032815 | 11:38:13.032815
today | 2023-02-27 00:00:00 | 2023-02-27 00:00:00 |
tomorrow | 2023-02-28 00:00:00 | 2023-02-28 00:00:00 |
(3 rows)

gaussdb=# SELECT TIME 'allballs';
 time
-----
00:00:00
(1 row)

-- Delete a table.
gaussdb=# DROP TABLE realtime_type_special;
```

## Interval Input

The input of **reltime** can be any valid interval in text format. It can be a number (negative numbers and decimals are also allowed) or a specific time, which must be in SQL standard format, ISO-8601 format, or POSTGRES format. In addition, the text input needs to be enclosed with single quotation marks (').

For details about interval input, see [Table 7-16](#).

**Table 7-16** Interval input types

Input	Output	Description
60	2 mons	Numbers are used to indicate intervals. The default unit is day. Decimals and negative numbers are allowed. Particularly, a negative interval syntactically means how long before.
31.25	1 mons 1 days 06:00:00	
-365	-12 mons -5 days	

Input	Output	Description
1 years 1 mons 8 days 12:00:00	1 years 1 mons 8 days 12:00:00	Intervals are in POSTGRES format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-13 months -10 hours	-1 years -25 days -04:00:00	
-2 YEARS +5 MONTHS 10 DAYS	-1 years -6 mons -25 days -06:00:00	
P-1.1Y10M	-3 mons -5 days -06:00:00	Intervals are in ISO-8601 format. They can contain both positive and negative numbers and are case-insensitive. Output is a simplified POSTGRES interval converted from the input.
-12H	-12:00:00	

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE reltime_type_tab(col1 character(30), col2 reltime);

-- Insert data.
gaussdb=# INSERT INTO reltime_type_tab VALUES ('90', '90');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-366', '-366');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('1975.25', '1975.25');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('-2 YEARS +5 MONTHS 10 DAYS', '-2 YEARS +5 MONTHS 10 DAYS');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('30 DAYS 12:00:00', '30 DAYS 12:00:00');
gaussdb=# INSERT INTO reltime_type_tab VALUES ('P-1.1Y10M', 'P-1.1Y10M');

-- View data.
gaussdb=# SELECT * FROM reltime_type_tab;
   col1      | col2
-----+-----
 90          | 3 mons
-366        | -1 years -18:00:00
1975.25     | 5 years 4 mons 29 days
-2 YEARS +5 MONTHS 10 DAYS | -1 years -6 mons -25 days -06:00:00
30 DAYS 12:00:00 | 1 mon 12:00:00
P-1.1Y10M   | -3 mons -5 days -06:00:00
(6 rows)

-- Delete a table.
gaussdb=# DROP TABLE reltime_type_tab;
```

### 7.3.7 Geometric

**Table 7-17** lists the geometric types that can be used in GaussDB. The most fundamental type, the point, forms the basis for all of the other types.

**Table 7-17** Geometric types

Name	Storage Space	Description	Representation
point	16 bytes	Point on a plane	(x,y)
lseg	32 bytes	Finite line segment	((x1,y1),(x2,y2))
box	32 bytes	Rectangle	((x1,y1),(x2,y2))
path	16 + 16 <i>n</i> bytes	Closed path (similar to polygon)	((x1,y1),...)
path	16+16 <i>n</i> bytes	Open path	[(x1,y1),...]
polygon	40+16 <i>n</i> bytes	Polygon (similar to closed path)	((x1,y1),...)
circle	24 bytes	Circle	<(x,y),r> (center point and radius)

A rich set of functions and operators is available in GaussDB to perform various geometric operations, such as scaling, translation, rotation, and determining intersections. For details, see [Geometric Functions and Operators](#).

## Points

Points are the fundamental two-dimensional building block for geometric types. Values of the **point** type are specified using either of the following syntax:

```
( x , y )
x , y
```

**x** and **y** are the respective coordinates, as floating-point numbers. The value type of the points is float8.

Points are output using the first syntax.

Example:

```
gaussdb=# select point(1.1, 2.2);
 point
-----
(1.1,2.2)
(1 row)
```

## Line Segments

Line segments (**lseg**) are represented by pairs of points. Values of the **lseg** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ( x2 , y2 ) ]
( ( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are the end points of the line segment. The value type of the points is float8.

Line segments are output using the first syntax.

Example:

```
gaussdb=# select lseg(point(1.1, 2.2), point(3.3, 4.4));
      lseg
-----
[(1.1,2.2),(3.3,4.4)]
(1 row)
```

## Rectangles

Boxes are represented by pairs of points that are opposite corners of the box. Values of the **box** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ( x2 , y2 ) )
( x1 , y1 ) , ( x2 , y2 )
x1 , y1 , x2 , y2
```

**(x1,y1)** and **(x2,y2)** are any two opposite corners of the rectangle. The value type of the points is float8.

Rectangles are output using the second syntax.

Any two opposite corners can be supplied on input, but in this order, the values will be reordered as needed to store the upper right and lower left corners.

Example:

```
gaussdb=# select box(point(1.1, 2.2), point(3.3, 4.4));
      box
-----
(3.3,4.4),(1.1,2.2)
(1 row)
```

## Paths

Paths are represented by lists of connected points. Paths can be open, where the first and last points in the list are considered not connected, or closed, where the first and last points are considered connected.

Values of the **path** type are specified using any of the following syntaxes:

```
[ ( x1 , y1 ) , ... , ( xn , yn ) ]
( ( x1 , y1 ) , ... , ( xn , yn ) )
( x1 , y1 ) , ... , ( xn , yn )
( x1 , y1 , ... , xn , yn )
x1 , y1 , ... , xn , yn
```

The points are the end points of the line segments comprising the path. The value type of the points is float8. Square brackets ([]) indicate an open path, while parentheses (()) indicate a closed path. When the outermost parentheses are omitted, as in the third through fifth syntax, a closed path is assumed.

Paths are output using the first or second syntax.

Example:

```
gaussdb=# select path(polygon '((0,0),(1,1),(2,0)'));
      path
-----
```

```
((0,0),(1,1),(2,0))  
(1 row)
```

## Polygons

Polygons are represented by lists of points (the vertexes of the polygon). Polygons are very similar to closed paths, but are stored differently and have their own set of support functions.

Values of the **polygon** type are specified using any of the following syntaxes:

```
(( x1 , y1 ) , ... , ( xn , yn ) )  
( x1 , y1 ) , ... , ( xn , yn )  
( x1 , y1 , ... , xn , yn )  
x1 , y1 , ... , xn , yn
```

A point indicates the vertex of a polygon. The value type of a point is float8.

Polygons are output using the first syntax.

Example:

```
gaussdb=# select polygon(box '((0,0),(1,1)'));  
polygon  
-----  
((0,0),(0,1),(1,1),(1,0))  
(1 row)
```

## Circles

Circles are represented by a center point and radius. Values of the **circle** type are specified using the following syntax:

```
< ( x , y ) , r >  
(( x , y ) , r )  
( x , y ) , r  
x , y , r
```

**(x,y)** is the center point and **r** is the radius of the circle. The value type of the points is float8.

Circles are output using the first syntax.

Example:

```
gaussdb=# select circle(point(0,0),1);  
circle  
-----  
<(0,0),1>  
(1 row)
```

## 7.3.8 Network Address Types

GaussDB offers data types to store IPv4 and MAC addresses.

It is better to use these types instead of plain text types to store network addresses, because these types offer input error checking and specialized operators and functions (see [Network Address Functions and Operators](#)).

**Table 7-18** Network address types

Name	Storage Space	Description
cidr	7 or 19 bytes	IPv4 networks
inet	7 or 19 bytes	IPv4 hosts and networks
macaddr	6 bytes	MAC address

## cidr

The **cidr** type (Classless Inter-Domain Routing) holds an IPv4 network address. The format for specifying networks is **address/y** where **address** is the network represented as an IPv4 address, and **y** is the number of bits in the netmask. If **y** is omitted, it is calculated using assumptions from the older classful network numbering system, except it will be at least large enough to include all of the octets written in the input. For details, see [Table 7-19](#).

**Table 7-19** cidr type input examples

cidr Input	cidr Output	abbrev(cidr)
192.168.100.128/25	192.168.100.128/25	192.168.100.128/25
192.168/24	192.168.0.0/24	192.168.0/24
192.168/25	192.168.0.0/25	192.168.0.0/25
192.168.1	192.168.1.0/24	192.168.1/24
192.168	192.168.0.0/24	192.168.0/24
10.1.2	10.1.2.0/24	10.1.2/24
10.1	10.1.0.0/16	10.1/16
10	10.0.0.0/8	10/8
10.1.2.3/32	10.1.2.3/32	10.1.2.3/32

## inet

The **inet** type holds an IPv4 host address, and optionally its subnet, all in one field. The subnet is represented by the number of network address bits present in the host address (the "netmask"). If the netmask is 32 and the address is an IPv4 address, then the value does not indicate a subnet, only a single host.

The input format for this type is **address/y** where **address** is an IPv4 address and **y** is the number of bits in the netmask. If **y** is omitted, the subnet mask is **32** for an IPv4 address, and the value represents just a single host. On display, the **/y** portion is suppressed if the netmask specifies a single host.

The essential difference between the **inet** and **cidr** data types is that **inet** accepts values with nonzero bits to the right of the netmask, whereas **cidr** does not.

## macaddr

The **macaddr** type stores MAC addresses, known for example from Ethernet card hardware addresses (although MAC addresses are used for other purposes as well). Input is accepted in the following formats:

```
'08:00:2b:01:02:03'  
'08-00-2b-01-02-03'  
'08002b:010203'  
'08002b-010203'  
'0800.2b01.0203'  
'08002b010203'
```

These examples would all specify the same address. Upper and lower cases are accepted for the digits a through f. Output is always in the first of the forms shown.

## 7.3.9 Bit String Types

Bit strings are strings of 1's and 0's. They can be used to store bit masks.

GaussDB supports two bit string types: **bit(n)** and **bit varying(n)**. Here, *n* is a positive integer. The maximum value of *n* is **83886080**, which is equivalent to 10 MB.

The bit type data must match the length *n* exactly. An error will be reported if the data length of the storage is not matched. Data of the bit varying type is of variable length up to the maximum length *n*. Longer strings will be rejected. Writing **bit** without a length is equivalent to **bit(1)**, while bit varying without a length specification means unlimited length.

### NOTE

- If one explicitly casts a bit-string value to **bit(n)**, it will be truncated or zero-padded on the right to be exactly *n* bits, without raising an error.
- Similarly, if one explicitly casts a bit-string value to **bit varying(n)** and the value is more than *n* bits, it will be truncated on the right.
- When the ADMS platform driver version 8.1.3-200 or earlier is used, use **::bit varying** to convert the bit type. Otherwise, an error may occur.

```
-- Create a table.  
gaussdb=# CREATE TABLE bit_type_t1  
(  
  BT_COL1 INTEGER,  
  BT_COL2 BIT(3),  
  BT_COL3 BIT VARYING(5)  
);  
  
-- Insert data.  
gaussdb=# INSERT INTO bit_type_t1 VALUES(1, B'101', B'00');  
  
-- Specify the type length. An error is reported if an inserted string exceeds this length.  
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10', B'101');  
ERROR: bit string length 2 does not match type bit(3)  
CONTEXT: referenced column: bt_col2  
  
-- Specify the type length. Data is converted if it exceeds this length.  
gaussdb=# INSERT INTO bit_type_t1 VALUES(2, B'10'::bit(3), B'101');
```

```
-- View data.
gaussdb=# SELECT * FROM bit_type_t1;
 bt_col1 | bt_col2 | bt_col3
-----+-----+-----
      1 |    101 |      00
      2 |    100 |     101
(2 rows)

-- Drop the table.
gaussdb=# DROP TABLE bit_type_t1;
```

## 7.3.10 UUID

The data type UUID stores Universally Unique Identifiers (UUID) as defined by RFC 4122, ISO/IEF 9834-8:2005, and related standards. This identifier is a 128-bit quantity that is generated by an algorithm chosen to make it very unlikely that the same identifier will be generated by anyone else in the known universe using the same algorithm.

A UUID is written as a sequence of lower-case hexadecimal digits, in several groups separated by hyphens, specifically a group of 8 digits followed by three groups of 4 digits followed by a group of 12 digits, for a total of 32 digits representing the 128 bits. An example of a UUID in this standard form is:

```
a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11
```

GaussDB also accepts the following alternative forms for input: use of upper-case letters and digits, the standard format surrounded by braces, omitting some or all hyphens, adding a hyphen after any group of four digits. An example is provided as follows:

```
A0EEBC99-9C0B-4EF8-BB6D-6BB9BD380A11
{a0eebc99-9c0b-4ef8-bb6d-6bb9bd380a11}
a0eebc999c0b4ef8bb6d6bb9bd380a11
a0ee-bc99-9c0b-4ef8-bb6d-6bb9-bd38-0a11
```

Output is always in the standard form.

## 7.3.11 JSON/JSONB Types

JavaScript Object Notation (JSON) data can be a single scalar, an array, or a key-value pair object. The array and object can be called a container:

- Scalar: a number, Boolean, string, or null
- Array: defined in a pair of square brackets (`[]`), in which elements can be any type of JSON data, and are not necessarily of the same type.
- Object: defined in a pair of braces (`{}`), in which objects are stored in the format of `key:value`. Each key must be a string enclosed by a pair of double quotation marks (`""`), and its value can be any type of JSON data. In case of duplicate keys, the last key value will be used.

GaussDB offers two types for storing JSON data: JSON and JSONB. The JSON data type stores a complete copy of the input, retaining the entered spaces, duplicate keys, and sequence. The JSONB data type stores data in a decomposed binary form, removing semantic-irrelevant details and duplicate keys, and sorting key-values. Therefore, the JSONB data does not need to be parsed.

It can be found that both are of JSON type, and the same strings can be entered as input. The main difference between them is the efficiency. Because JSON data

type stores an exact copy of the input text, the data must be parsed on every execution. In contrast, JSONB data is stored in a decomposed binary form and can be processed faster, though this makes it slightly slower to input due to the conversion mechanism. In addition, because the JSONB data type is normalized, it supports more operations, for example, comparing sizes according to a specific rule. JSONB also supports indexing, which is a significant advantage.

## Input Format

An input must be a JSON-compliant string, which is enclosed in single quotation marks (').

**null (null-json):** The value can only be **null** in lowercase.

```
gaussdb=# SELECT 'null':json; -- suc
json
-----
null
(1 row)

gaussdb=# SELECT 'NULL':jsonb; -- err
ERROR: invalid input syntax for type jsonb
```

**Number (num-json):** The value can be a positive or negative integer, decimal fraction, or 0. The scientific notation is supported.

```
gaussdb=# SELECT '1':json;
json
-----
1
(1 row)

gaussdb=# SELECT '-1.5':json;
json
-----
-1.5
(1 row)

gaussdb=# SELECT '-1.5e-5':jsonb, '-1.5e+2':jsonb;
 jsonb | jsonb
-----+-----
-0.000015 | -150
(1 row)

gaussdb=# SELECT '001':json, '+15':json, 'NaN':json; -- Redundant leading zeros, plus signs (+), NaN, and
infinity are not supported.
ERROR: invalid input syntax for type json
```

**Boolean (bool-json):** The value can only be **true** or **false** in lowercase.

```
gaussdb=# SELECT 'true':json;
json
-----
true
(1 row)

gaussdb=# SELECT 'false':jsonb;
 jsonb
-----
false
(1 row)
```

**String (str-json):** The value must be a string enclosed in double quotation marks ("").

```
gaussdb=# SELECT '"a"':json;
json
```

```
-----  
"a"  
(1 row)  
  
gaussdb=# SELECT "'abc'::jsonb;  
jsonb  
-----  
"abc"  
(1 row)
```

Array (array-json): Arrays are enclosed in square brackets ([]). Elements in the array can be any valid JSON data, and are unnecessarily of the same type.

```
gaussdb=# SELECT '[1, 2, "foo", null]::json;  
json  
-----  
[1, 2, "foo", null]  
(1 row)  
  
gaussdb=# SELECT '[]::json;  
json  
-----  
[]  
(1 row)  
  
gaussdb=# SELECT '[1, 2, "foo", null, [], {}]::jsonb;  
jsonb  
-----  
[1, 2, "foo", null, [], {}]  
(1 row)
```

Object (object-json): The value is enclosed in braces ({}). The key must be a JSON-compliant string, and the value can be any valid JSON string.

```
gaussdb=# SELECT '{}::json;  
json  
-----  
{  
(1 row)  
  
gaussdb=# SELECT '{"a": 1, "b": {"a": 2, "b": null}}::json;  
json  
-----  
{"a": 1, "b": {"a": 2, "b": null}}  
(1 row)  
  
gaussdb=# SELECT '{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}::jsonb;  
jsonb  
-----  
{"foo": [true, "bar"], "tags": {"a": 1, "b": null}}  
(1 row)
```

---

**⚠ CAUTION**

- Note that **'null::json** and **null::json** are different, which are similar to the strings **str="null"** and **str=null**.
  - For numbers, when scientific notation is used, JSONB expands them, while JSON stores an exact copy of the input text.
- 

## JSONB Advanced Features

- Precautions

- It cannot be used as a partition key.
- Foreign tables are not supported.

The main difference between JSON and JSONB lies in the storage mode. JSONB stores parsed binary data, which reflects the JSON hierarchy and facilitates direct access. Therefore, JSONB has many advanced features that JSON does not have.

- Format normalization

- After the input object-json string is parsed into JSONB binary, semantically irrelevant details are naturally discarded, for example, spaces:

```
gaussdb=# SELECT ' [1, " a ", {"a" :1 }]'::jsonb;
jsonb
-----
[1, " a ", {"a": 1}]
(1 row)
```

- For object-json, duplicate key-values are deleted and only the last key-value is retained. For example:

```
gaussdb=# SELECT '{"a" : 1, "a" : 2}'::jsonb;
jsonb
-----
{"a": 2}
(1 row)
```

- For object-json, key-values will be re-sorted. The sorting rule is as follows: 1. Longer key-values are sorted last. 2. If the key-values are of the same length, the key-values with a larger ASCII code are sorted after the key-values with a smaller ASCII code:

```
gaussdb=# SELECT '{"aa" : 1, "b" : 2, "a" : 3}'::jsonb;
jsonb
-----
{"a": 3, "b": 2, "aa": 1}
(1 row)
```

- Size comparison

Format normalization ensures that only one form of JSONB data exists in the same semantics. Therefore, sizes may be compared according to a specific rule.

- First, type comparison: **object-jsonb** > **array-jsonb** > **bool-jsonb** > **num-jsonb** > **str-jsonb** > **null-jsonb**
- Content comparison if the data type is the same:
  - **str-jsonb**: The default text sorting rule of the database is used for comparison. A positive value indicates greater than, a negative value indicates less than, and 0 indicates equal.
  - **num-jsonb**: numeric comparison
  - **bool-jsonb**: **true** > **false**
  - **array-jsonb**: long elements > short elements. If the lengths are the same, compare each element in sequence.
  - **object-jsonb**: If the length of a key-value pair is longer than that of a short key-value pair, the key is compared first, and then the value is compared.

 CAUTION

For comparison within the **object-jsonb** type, the final result after format sorting is used for comparison. Therefore, the comparison result may not be intuitive compared with the direct input.

- Creating indexes, primary keys, and foreign keys

- B-tree index

B-tree indexes, primary keys, and foreign keys can be created for the JSONB type.

- Inclusion and existence

Querying whether a JSON contains some elements or whether some elements exist in a JSON is an important capability of JSONB.

-- Simple scalar/primitive values contain only the identical value.

```
gaussdb=# SELECT "'foo'::jsonb @> 'foo'::jsonb;
?column?
```

```
-----
t
(1 row)
```

-- The array on the left contains the character string on the right.

```
gaussdb=# SELECT '[1, "aa", 3]::jsonb ? 'aa';
?column?
```

```
-----
t
(1 row)
```

-- The array on the left contains all elements of the array on the right, regardless of the sequence and repetition.

```
gaussdb=# SELECT '[1, 2, 3]::jsonb @> '[1, 3, 1]::jsonb;
?column?
```

```
-----
t
(1 row)
```

-- The object-json on the left contains all key-value pairs of object-json on the right.

```
gaussdb=# SELECT '{"product": "PostgreSQL", "version": 9.4, "jsonb":true}'::jsonb @>
 '{"version":9.4}'::jsonb;
?column?
```

```
-----
t
(1 row)
```

-- The array on the left does not contain all elements of the array on the right. The three elements on the left are 1, 2, and [1,3], but the elements on the right are 1 and 3.

```
gaussdb=# SELECT '[1, 2, [1, 3]]::jsonb @> '[1, 3]::jsonb;
?column?
```

```
-----
f
(1 row)
```

```
gaussdb=# SELECT '{"foo": {"bar": "baz"}}'::jsonb @> '{"bar": "baz"}'::jsonb;
?column?
```

```
-----
f
(1 row)
```

For details about the operators, see [JSON/JSONB Functions and Operators](#).

- Functions and operators

For details about the functions and operators supported by the JSON/JSONB type, see [JSON/JSONB Functions and Operators](#).

## 7.3.12 HLL

HyperLoglog (HLL) is an approximation algorithm for efficiently counting the number of distinct values in a dataset. It features faster computing and lower space usage. You only need to store HLL data structures, instead of data sets. When new data is added to a dataset, make hash calculation on the data and insert the result to an HLL. Then, you can obtain the final result based on the HLL.

**Table 7-20** compares HLL with other algorithms.

**Table 7-20** Comparison between HLL and other algorithms

Item	Sorting Algorithm	Hash Algorithm	HLL
Time complexity	$O(n \log n)$	$O(n)$	$O(n)$
Space complexity	$O(n)$	$O(n)$	$\log(\log n)$
Error rate	0	0	$\approx 0.8\%$
Storage space requirement	Size of original data	Size of original data	The maximum size is 16 KB by default.

HLL has advantages over others in the computing speed and storage space requirement. In terms of time complexity, the sorting algorithm needs  $O(n \log n)$  time for sorting, and the hash algorithm and HLL need  $O(n)$  time for full table scanning. In terms of storage space requirements, the sorting algorithm and hash algorithm need to store raw data before collecting statistics, whereas the HLL algorithm needs to store only the HLL data structures rather than the raw data, and thereby occupying a fixed space of about 16 KB.

### NOTICE

- In the current default specifications, the maximum number of distinct values that can be calculated is about  $1.1e + 15$ , and the error rate is 0.8%. If the calculation result exceeds the maximum, the error rate of the calculation result will increase, or the calculation will fail and an error will be reported.
- When using this feature for the first time, you need to evaluate the distinct values of the service, properly select configuration parameters, and perform verification to ensure that the accuracy meets requirements.
  - By default, the distinct value is  $1.1e + 15$ . If the distinct value is NaN, you need to adjust `log2m` or use another algorithm to calculate the distinct value.
  - The hash algorithm has an extremely low probability of collision. However, you are still advised to select 2 or 3 hash seeds for verification when using the hash algorithm for the first time. If there is only a small difference between the distinct values, you can select any one of the seeds as the hash seed.

**Table 7-21** describes main HLL data structures.

**Table 7-21** Main HLL data structures

Data Type	Description
hll	The HLL header is a 27-byte field. By default, the data length ranges from 0 KB to 16 KB. The distinct value can be obtained.

When you create an HLL data type, 0 to 4 input parameters are supported. The parameter meanings and specifications are the same as those of the **hll\_empty** function. The first parameter is **log2m**, indicating the logarithm of the number of buckets, and its value ranges from 10 to 16. The second parameter is **log2explicit**, indicating the threshold in explicit mode, and its value ranges from 0 to 12. The third parameter is **log2sparse**, indicating the threshold of the Sparse mode, and its value ranges from 0 to 14. The fourth parameter is **duplicatecheck**, indicating whether to enable duplicatecheck, and its value ranges from 0 to 1. When the input parameter is set to **-1**, the default value of the HLL parameter is used. You can run the **\d** or **\d+** command to view the parameters of the HLL type.

 **NOTE**

When the HLL data type is created, the result varies depending on the input parameter behavior:

- When creating an HLL type, do not set the input parameter or set it to **-1**. Use the default value of the corresponding HLL parameter.
- If a valid value is set for the input parameter, the corresponding HLL parameter uses the input value.
- If the input value is invalid, an error is reported when the HLL type is created.

```
-- Create an HLL table without specifying input parameters.
gaussdb=# create table t1 (id integer, set hll);
gaussdb=# \d t1
      Table "public.t1"
  Column | Type      | Modifiers
-----+-----+-----
 id     | integer   |
 set    | hll       |

-- Create an HLL table, specify the first two input parameters, and use the default values for the last two
input parameters.
gaussdb=# create table t2 (id integer, set hll(12,4));
gaussdb=# \d t2
      Table "public.t2"
  Column | Type      | Modifiers
-----+-----+-----
 id     | integer   |
 set    | hll(12,4,12,0) |

-- Create an HLL table, specify the third input parameter, and use default values for other parameters.
gaussdb=# create table t3(id int, set hll(-1,-1,8,-1));
gaussdb=# \d t3
      Table "public.t3"
  Column | Type      | Modifiers
-----+-----+-----
 id     | integer   |
 set    | hll(14,10,8,0) |
```

```
-- When a user creates an HLL table and specifies an invalid input parameter, an error is reported.
gaussdb=# create table t4(id int, set hll(5,-1));
ERROR: log2m = 5 is out of range, it should be in range 10 to 16, or set -1 as default

-- Drop the created HLL table.
gaussdb=# drop table t1,t2,t3;
DROP TABLE
```

#### NOTE

When inserting an HLL object to an HLL table, ensure that the parameters of the HLL type are the same as those of the inserted object. Otherwise, an error is reported.

```
-- Create an HLL table.
gaussdb=# create table t1(id integer, set hll(14));

-- Insert an HLL object to a table. The insertion succeeds because parameter types are consistent.
gaussdb=# insert into t1 values (1, hll_empty(14,-1));

-- Insert an HLL object to a table. The insertion fails because parameter types are inconsistent.
gaussdb=# insert into t1(id, set) values (1, hll_empty(14,5));
ERROR: log2explicit does not match: source is 5 and dest is 10

-- Delete the table.
gaussdb=# drop table t1;
```

The following describes HLL application scenarios:

- Scenario 1: "Hello World"

The following example shows how to use the HLL data type:

```
-- Create an HLL table.
gaussdb=# create table helloworld (id integer, set hll);

-- Insert an empty HLL to the table.
gaussdb=# insert into helloworld(id, set) values (1, hll_empty());

-- Add a hashed integer to the HLL.
gaussdb=# update helloworld set set = hll_add(set, hll_hash_integer(12345)) where id = 1;

-- Add a hashed string to the HLL.
gaussdb=# update helloworld set set = hll_add(set, hll_hash_text('hello world')) where id = 1;

-- Obtain the number of distinct values of the HLL.
gaussdb=# select hll_cardinality(set) from helloworld where id = 1;
 hll_cardinality
-----
                2
(1 row)

-- Drop the table.
gaussdb=# drop table helloworld;
```

- Scenario 2: Collect statistics about website visitors.

The following example shows how an HLL collects statistics on the number of users visiting a website within a period of time:

```
-- Create a raw data table to show that a user has visited the website at a certain time:
gaussdb=# create table facts (
    date      date,
    user_id   integer
);

-- Create a raw data table to show that a user has visited the website at a certain time:
gaussdb=# insert into facts values ('2019-02-20', generate_series(1,100));
gaussdb=# insert into facts values ('2019-02-21', generate_series(1,200));
gaussdb=# insert into facts values ('2019-02-22', generate_series(1,300));
gaussdb=# insert into facts values ('2019-02-23', generate_series(1,400));
gaussdb=# insert into facts values ('2019-02-24', generate_series(1,500));
gaussdb=# insert into facts values ('2019-02-25', generate_series(1,600));
```

```

gaussdb=# insert into facts values ('2019-02-26', generate_series(1,700));
gaussdb=# insert into facts values ('2019-02-27', generate_series(1,800));

-- Create another table and specify an HLL column:
gaussdb=# create table daily_uniques (
  date          date UNIQUE,
  users         hll
);

-- Group data by date and insert the data into the HLL:
gaussdb=# insert into daily_uniques(date, users)
  select date, hll_add_agg(hll_hash_integer(user_id))
  from facts
  group by 1;

-- Calculate the numbers of users visiting the website every day.
gaussdb=# select date, hll_cardinality(users) from daily_uniques order by date;
  date | hll_cardinality
-----+-----
2019-02-20 |          100
2019-02-21 | 200.217913059312
2019-02-22 | 301.76494508014
2019-02-23 | 400.862858326446
2019-02-24 | 502.626933349694
2019-02-25 | 601.922606454213
2019-02-26 | 696.602316769498
2019-02-27 | 798.111731634412
(8 rows)

-- Calculate the number of users who had visited the website in the week from February 20, 2019 to
February 26, 2019.
gaussdb=# select hll_cardinality(hll_union_agg(users)) from daily_uniques where date >=
'2019-02-20'::date and date <= '2019-02-26'::date;
 hll_cardinality
-----
696.602316769498
(1 row)

-- Calculate the number of users who had visited the website yesterday but have not visited the
website today:
gaussdb=# SELECT date, (#hll_union_agg(users) OVER two_days) - #users AS lost_uniques FROM
daily_uniques WINDOW two_days AS (ORDER BY date ASC ROWS 1 PRECEDING);
-- The default compatibility (O compatibility) results are as follows:
  date          | lost_uniques
-----+-----
2019-02-20 00:00:00 |          0
2019-02-21 00:00:00 |          0
2019-02-22 00:00:00 |          0
2019-02-23 00:00:00 |          0
2019-02-24 00:00:00 |          0
2019-02-25 00:00:00 |          0
2019-02-26 00:00:00 |          0
2019-02-27 00:00:00 |          0
(8 rows)

-- Drop the table.
gaussdb=# drop table facts;
gaussdb=# drop table daily_uniques;

```

- Scenario 3: The data to be inserted does not meet the requirements of the HLL data structure.

When inserting data into a column of the HLL type, ensure that the data meets the requirements of the HLL data structure. If the data does not meet the requirements after being parsed, an error will be reported. In the following example, 'E\1234' to be inserted does not meet the requirements of the HLL data structure after being parsed. As a result, an error is reported.

```
gaussdb=# create table test(id integer, set hll);
gaussdb=# insert into test values(1, 'E\1234');
ERROR: not a hll type, size=6 is not enough
gaussdb=# drop table test;
```

## 7.3.13 Range

A range type is a data type that represents the range of a value of an element type (called the subtype of a range). For example, the range of timestamp may be used to express a time range in which a conference room is reserved. In this case, the data type is `tsrange` (short for timestamp range), and timestamp is the subtype. The subtype must have an overall order so that the element value can be clearly specified within a range, before, or after.

Range types are useful because they can express multiple element values in a single range value and can clearly express concepts such as range overlapping. The time and date range used for scheduling is the best example, as the range of an instrument are also examples of range type.

### Built-in Range

The following built-in ranges are available:

- `int4range`: integer range.
- `int8range`: bigint range.
- `numrange`: numeric range.
- `tsrange`: range of timestamp without the time zone.
- `tstzrange`: range of timestamp with the time zone
- `daterange`: date range.

In addition, you can define your own range types. For details, see [CREATE TYPE](#).

### Example

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');
-- Inclusion
SELECT int4range(10, 20) @> 3;
?column?
-----
f
(1 row)
-- Overlapping
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);
?column?
-----
t
(1 row)
-- Upper bound extraction
SELECT upper(int8range(15, 25));
upper
-----
25
(1 row)
-- Intersection set
SELECT int4range(10, 20) * int4range(15, 25);
?column?
-----
[15,20)
(1 row)
```

```
-- Empty range
SELECT isempty(numrange(1, 5));
 isempty
-----
 f
(1 row)
DROP TABLE reservation;
```

See the complete list of operators and functions on a range type in [Range Functions and Operators](#).

## Including and Excluding Bounds

Each non-empty range has two bounds, a lower bound and an upper bound. All values between the upper and lower bounds are included in the range. An inclusion bound means that the bound value itself is included in the range, while an exclusion bound means that the bound value is not included in the range.

In a textual form of a range, the inclusion lower bound is expressed as "[" and an exclusion lower bound is expressed as "(" . Similarly, one containing the upper bound is expressed as "]" and one excluding the upper bound is expressed as ")" (for details, see [Range Input/Output](#)).

The `lower_inc` and `upper_inc` functions test the upper and lower bounds of a range value, respectively.

## Infinite (Unbounded) Range

When the lower bound of a range is unbounded, it means that all values less than the upper bound are included in the range. Similarly, when the upper bound of a range is unbounded, all values greater than the lower bound are included in the range. When both the upper and lower bounds are unbounded, all values of the element type are considered within the range. The missing bounds are automatically converted to exclusions. You can think of these missing values as positive infinity or negative infinity, but they are special range type values and are considered to be positive and negative infinity values that go beyond any range element type.

Element types with the infinity values can be used as explicit bound values. For example, in the timestamp range, `[today, infinity)` does not include a special timestamp value infinity.

The `lower_inf` and `upper_inf` functions test the infinite upper and lower bounds of a range, respectively.

## Range Input/Output

The input of a range value must follow one of the following formats:

```
(lower-bound, upper-bound)
(lower-bound, upper-bound]
[lower-bound, upper-bound)
[lower-bound, upper-bound]
Empty
```

The output of a range value must follow one of the following formats:

```
[lower-bound, upper-bound)
Empty
```

Parentheses () or square brackets [] indicate whether the upper and lower bounds are excluded or included. Note that the last format is empty, which represents an empty range (a range that does not contain values).

The value of *lower-bound* can be a valid input character string of the subtype or null, indicating that there is no lower bound. Similarly, *upper-bound* can be a valid input character string of the subtype or null, indicating that there is no upper bound.

Each bound value can be referenced using the quotation marks('') character. This is necessary if the bounds value contains parentheses (), square brackets [], commas (,), quotation marks (''), or backslashes (\). Otherwise, those characters will be considered as the part of the range syntax. To put the quotation mark or backslash in a referenced bound value, put a backslash in front of it (and a pair of double quotation marks in its quoted bound value represents one quotation mark character, which is similar to the single quotation mark rule in SQL character strings). In addition, you can avoid referencing and use backslash escapes to protect all data characters, otherwise they will be used as part of the return syntax. Also, if you want to write a bound value that is an empty string, write '', indicating infinite bounds.

Spaces are allowed before and after a range value, but any space between parentheses() or square brackets[] is used as part of the upper or lower bound value (depending on the element type, the space may or may not represent a value).

Examples:

```
-- All values between 3 (included) and 7 (excluded) are included.
gaussdb=# SELECT '[3,7)::int4range;
int4range
-----
[3,7)
(1 row)
-- All values between 3 (excluded) and 7 (excluded) are included.
gaussdb=# SELECT '(3,7)::int4range;
int4range
-----
[4,7)
(1 row)
-- Only value 4 is included.
gaussdb=# SELECT '[4,4)::int4range;
int4range
-----
[4,5)
(1 row)
-- No value is included (and will be normalized to null).
gaussdb=# SELECT '[4,4)::int4range;
int4range
-----
Empty
(1 row)
```

## Constructing Range

Each range type has a constructor function with the same name. Using constructor functions is often more convenient than writing a range literal constant because it avoids extra references to bound values. Constructor functions accept two or three parameters. Two parameters form a range in the standard form, where the lower bound is included and the upper bound is excluded, and three parameters form a range according to the bound specified by the third

parameter. The third parameter must be one of the following character strings: (), [], or []. For example:

```
-- The complete format is: lower bound, upper bound, and textual parameters indicating the inclusion/
exclusion of bounds.
gaussdb=# SELECT numrange(1.0, 14.0, '[');
 numrange
-----
(1.0,14.0]
(1 row)
-- If the third parameter is ignored, it is assumed to be '['.
gaussdb=# SELECT numrange(1.0, 14.0);
 numrange
-----
[1.0,14.0)
(1 row)
-- Although '[' is specified here, the value will be converted to the standard format when displayed,
because int8range is a discrete range type.
gaussdb=# SELECT int8range(1, 14, '[');
 int8range
-----
[2,15)
(1 row)
-- Using NULL for a bound causes the range to be unbounded on that side.
gaussdb=# SELECT numrange(NULL, 2.2);
 numrange
-----
(,2.2)
(1 row)
```

## Discrete Range

A range element type has a well-defined "step" such as integer or date. In these types, if there is no valid value between two elements, they can be said to be adjacent. This is in contrast to a continuous range in which other element values can always be identified between two given values. For example, a range above the numeric type is continuous, and the range of timestamp is also continuous. (Although timestamp has limited precision and can be considered as discrete in theory, it can be considered as continuous because the step is not normally considered.)

Another way to consider discrete range types is to have a clear "next" or "previous" value for each element value. With this idea in mind, you can switch between inclusion and exclusion expressions of a range bound by replacing it with the original given next or previous element value. For example, in an integer range type, [4,8] and (3,9) represent the same set of values, but not for numeric ranges.

A discrete range type should have a *regularization* function that knows the expected step size of the element type. The regularization function can convert the equivalents of the range type to the same expression, in particular consistent with the inclusion or exclusion bounds. If you do not specify a regularization function, ranges with different formats will always be considered as unequal, even if they actually express the same set of values.

The built-in range types `int4range`, `int8range`, and `daterange` use a regularized form that includes the lower bound and excludes the upper bound, that is, []. However, user-defined range types can use other conventions.

## Defining New Range

Users can define their own range types. A common reason is to use the range on the subtype that is not provided in the built-in range type. For example, to create the range type subtype float8, run the following command:

```
CREATE TYPE floatrange AS RANGE (  
    subtype = float8,  
    subtype_diff = float8mi  
);  
SELECT '[1.234, 5.678]':floatrange;  
floatrange  
-----  
[1.234,5.678]  
(1 row)  
DROP TYPE floatrange;
```

Because float8 does not have a meaningful "step", we did not define a regularization function in this example.

Defining your own range type also allows you to specify a different subtype B-tree operator class or collection to change the sort order to determine which values fall within the given range.

If the subtype is considered to have a discrete value instead of a continuous value, the **CREATE TYPE** command should specify a canonical function. The regularization function receives an input range value and must return an equivalent range value that may have different bounds and formats. For two ranges, for example, [1, 7] and [1, 8) that represent the same value set, the output must be the same. There is no relationship between choosing which expression to use as the regularization function, as long as two values of equal value in different formats can always be mapped to the same value in the same format. In addition to adjusting the inclusion/exclusion bound format, if the expected compensation is larger than the subtype can store, a regularization function may round the bound value. For example, a range type above a timestamp might be defined as having a one-hour epoch, so the regularization function might need to round off bounds that are not multiples of an hour, or might throw an error directly.

The subtype difference function uses two subtype input values and returns a difference expressed as a float8 value (X minus Y). In the example above, we can use functions under the regular float8 subtraction operator. However, for any other subtype, some type conversion may be required. There may also be a need for innovative ideas on how to express differences as numbers. For maximum extensibility, the subtype\_diff function should agree with the sort order of the selected operator class and sort rules. That is, if the first parameter of the sort order is greater than the second parameter, the result should be a positive value.

The following is an example of the subtype\_diff function:

```
CREATE FUNCTION time_subtype_diff(x time, y time) RETURNS float8 AS 'SELECT EXTRACT(EPOCH FROM  
(x - y))' LANGUAGE sql STRICT IMMUTABLE;  
CREATE TYPE timerange AS RANGE (  
    subtype = time,  
    subtype_diff = time_subtype_diff  
);  
SELECT '[11:10, 23:00]':timerange;  
timerange  
-----  
[11:10:00,23:00:00]  
(1 row)
```

```
DROP TYPE timerange;  
DROP FUNCTION time_subtype_diff;
```

For details about how to create a range type, see [CREATE TYPE](#).

## Index

In addition, B-tree indexed can be created on table columns of the range type. For these index types, basically the only useful range operation is equivalence. Using the corresponding < and > operators, there is a B-tree sort order for range value definitions, but that order is fairly arbitrary and is often less useful in the reality. The B-tree support for range types is primarily designed to allow sorting within a query, rather than creating an index.

### 7.3.14 Object Identifier Types

Object identifiers (OIDs) are used internally by GaussDB as primary keys for various system catalogs. OIDs are not added to user-created tables by the system. The **OID** type represents an object identifier.

The **OID** type is currently implemented as an unsigned four-byte integer. So, using a user-created table's **OID** column as a primary key is discouraged.

**Table 7-22** Object identifier types

Name	Reference	Description	Example
OID	N/A	Numeric object identifier	564182
CID	N/A	Command identifier. This is the data type of the system columns <b>cmin</b> and <b>cmax</b> . Command identifiers are 32-bit quantities.	N/A
XID	N/A	A transaction identifier. This is the data type of the system columns <b>xmin</b> and <b>xmax</b> . Transaction identifiers are 64-bit quantities.	N/A
TID	N/A	Row identifier. This is the data type of the system column <b>ctid</b> . A row ID is a pair (block number, tuple index within block) that identifies the physical location of the row within its table.	N/A
REGCONFIG	pg_ts_config	Text search configuration	english

Name	Reference	Description	Example
REGDICTIONARY	pg_ts_dict	Text search dictionary	simple
REGOPER	pg_operator	Operator name	N/A
REGOPERATOR	pg_operator	Operator with argument types	*(integer,integer) or -(NONE,integer)
REGPROC	pg_proc	Function name	sum
REGPROCEDURE	pg_proc	Function with argument types	sum(int4)
REGCLASS	pg_class	Relation name	pg_type
REGTYPE	pg_type	Data type name	integer

The **OID** type is used for a column in the database system catalog.

Example:

```
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'pg_type';
oid
-----
1247
(1 row)
```

The alias type for **OID** is **REGCLASS** which allows simplified search for **OID** values.

Example:

```
gaussdb=# SELECT attrelid,attname,attypid,attstattarget FROM pg_attribute WHERE attrelid =
'pg_type'::REGCLASS;
attrelid | attname | attypid | attstattarget
-----+-----+-----+-----
1247 | xc_node_id | 23 | 0
1247 | tableoid | 26 | 0
1247 | cmax | 29 | 0
1247 | xmax | 28 | 0
1247 | cmin | 29 | 0
1247 | xmin | 28 | 0
1247 | oid | 26 | 0
1247 | ctid | 27 | 0
1247 | typname | 19 | -1
1247 | typnamespace | 26 | -1
1247 | typowner | 26 | -1
1247 | typplen | 21 | -1
1247 | typbyval | 16 | -1
1247 | typtype | 18 | -1
1247 | typcategory | 18 | -1
1247 | typispreferred | 16 | -1
1247 | typisdefined | 16 | -1
1247 | typdelim | 18 | -1
1247 | typrelid | 26 | -1
1247 | typelem | 26 | -1
1247 | typarray | 26 | -1
1247 | typinput | 24 | -1
1247 | typoutput | 24 | -1
1247 | typreceive | 24 | -1
```

1247	typsend	24	-1
1247	typmodin	24	-1
1247	typmodout	24	-1
1247	typanalyze	24	-1
1247	typalign	18	-1
1247	typstorage	18	-1
1247	typnotnull	16	-1
1247	typbasetype	26	-1
1247	typtypmod	23	-1
1247	typndims	23	-1
1247	typcollation	26	-1
1247	typdefaultbin	194	-1
1247	typdefault	25	-1
1247	typacl	1034	-1
1247	typelemmod	23	-1

(39 rows)

### 7.3.15 Pseudo-Types

GaussDB type system contains a number of special-purpose entries that are collectively called pseudo-types. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type.

Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type. [Table 7-23](#) lists all pseudo-types.

**Table 7-23** Pseudo-types

Name	Description
any	Indicates that a function accepts any input data type.
anyelement	Indicates that a function accepts any data type.
anyarray	Indicates that a function accepts any array data type.
anynonarray	Indicates that a function accepts any non-array data type.
anyenum	Indicates that a function accepts any enum data type.
anyrange	Indicates that a function accepts any range data type.
cstring	Indicates that a function accepts or returns a null-terminated C string.
internal	Indicates that a function accepts or returns a server-internal data type.
language_handler	Indicates that a procedural language call handler is declared to return <b>language_handler</b> .
fdw_handler	Indicates that a foreign-data wrapper handler is declared to return <b>fdw_handler</b> .
record	Identifies a function returning an unspecified row type.
trigger	Indicates that a trigger function is declared to return <b>trigger</b> .
void	Indicates that a function returns no value.

Name	Description
opaque	Indicates an obsolete type name that formerly served all the above purposes.

Functions coded in C (whether built in or dynamically loaded) can be declared to accept or return any of these pseudo data types. It is up to the function author to ensure that the function will behave safely when a pseudo-type is used as an argument type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. At present the procedural languages all forbid use of a pseudo-type as argument type, and allow only **void** and **record** as a result type. Some also support polymorphic functions using the **anyelement**, **anyarray**, **anynonarray**, **anyenum**, and **anyrange** types.

Each location (parameter or return value) declared as the anyelement type is allowed to have any specific actual data type, but they must all be of the same actual type in any given query.

The internal pseudo-type is used to declare functions that are meant only to be called internally by the database system, and not by direct call in an SQL query. If a function has at least one internal-type argument then it cannot be called from SQL. You are advised not to create any function that is declared to return internal unless it has at least one internal argument.

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE t1 (a int);

-- Insert two data records.
gaussdb=# INSERT INTO t1 values(1),(2);

-- Create the showall() function.
gaussdb=# CREATE OR REPLACE FUNCTION showall() RETURNS SETOF record
AS $$ SELECT count(*) from t1; $$
LANGUAGE SQL;

-- Call the showall() function.
gaussdb=# SELECT showall();
showall
-----
(2)
(1 row)

-- Delete the function.
gaussdb=# DROP FUNCTION showall();

-- Delete the table.
gaussdb=# DROP TABLE t1;
```

## 7.3.16 XML Type

The XML data type can be used to store Extensible Markup Language (XML) data. The internal format of XML is the same as that of the TEXT data type. Its advantage over storing XML data in a TEXT field is that, XML data supports

standard XML operation functions based on LIBXML2 and XML standardization check.

The XML data type can store well-formed documents as defined by the XML standard, as well as content fragments, which are defined by referencing broader "DOCUMENT NODE" XQuery and XPath data models. Roughly speaking, this means that there can be more than one top-level element or character node in a content fragment. The expression **XMLVALUE IS DOCUMENT** can be used to evaluate whether a particular XML value is a complete document or just a document fragment.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes.

The XML bottom layer uses the same data structure as the TEXT type for storage. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltest ( id int, data xml );
gaussdb=# INSERT INTO xmltest VALUES (1, 'one');
gaussdb=# INSERT INTO xmltest VALUES (2, 'two');
gaussdb=# SELECT * FROM xmltest ORDER BY 1;
 id | data
-----+-----
 1 | one
 2 | two
(2 rows)
gaussdb=# SELECT xmlconcat(xmlcomment('hello'),
                           xmlelement(NAME qux, 'xml'),
                           xmlcomment('world'));
          xmlconcat
-----+-----
<!--hello--><qux>xml</qux><!--world-->
(1 row)
gaussdb=# DROP TABLE xmltest;
```

 NOTE

- The XML type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XML operation function
  - Used as a distribution key, partition key, level-2 partition key, foreign key, primary key, or unique constraint.
  - Implicit conversion related to XML, including the conversion between strings and the XML data type
  - Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX
  - Use columns of the XML data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions including sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread
  - ODBC-related APIs with binding parameters
- The XML type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XML values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query, supporting the Astore and Ustore storage engines
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - If addition, deletion, modification, and query of user-defined composite types involve XML types that are similar to XML columns in common tables, the composite types must be inserted and modified based on the XML syntax.
  - JDBC and ODBC operations on XML data types are supported. The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XML column. You can enter an XML value using the SQL syntax and use the getSQLXML method of the ResultSet class to obtain the XML value. JDBC-related APIs with binding parameters are supported. For example, you can use the setSQLXML method in the PreparedStatement preprocessing API and the getSQLXML(int columnIndex) method in the ResultSet execution result set API.

In the API calling process, use the `java.sql.SQLXML` API class to construct an XML object, set the specified object type to `Oid.XML`, and send the type ID and XML value to the server. After obtaining the result returned from the server, call `ResultSet.getString`. Then, use the `java.sql.SQLXML` API class to construct an XML object based on the obtained character string. In this case, the system checks whether the content complies with the XML standard again. Therefore, you can also use `ResultSet.getString` to directly obtain the XML string object.

## 7.3.17 XMLType

The XMLType data type is used to store XMLType data. Currently, data is stored in character strings in the internal format. Its advantage over storing XML data in a TEXT field is that, XML data supports standard XML operation functions based on LIBXML2 and XML standardization check.

The XMLType type can store well-formed "documents" that comply with the XML standard.

The XML parser converts an XML document into an XML DOM object. The document object model (DOM) defines standard methods for accessing and manipulating documents. XML DOM defines standard methods for accessing and manipulating XML documents. XML DOM views XML documents as a tree structure. All elements can be accessed through the DOM tree. You can modify or delete their contents and create new elements. Elements, their text, and their attributes are considered as nodes. The maximum size is 1 GB.

Example:

```
gaussdb=# CREATE TABLE xmltypetest(id int, data xmltype);
gaussdb=# INSERT INTO xmltypetest VALUES (1, '<ss/>');
gaussdb=# INSERT INTO xmltypetest VALUES (2, '<xx/>');
gaussdb=# SELECT * FROM xmltypetest ORDER BY 1;
 id | data
----+-----
  1 | <ss/>
  2 | <xx/>
(2 rows)
gaussdb=# DROP TABLE xmltest;
```

 NOTE

- The XMLType type does not support the following operations:
  - Logical expressions AND, OR, and NOT
  - Input parameter of a system function that is used as a non-XMLType operation function
  - Used as a distribution key, partition key, level-2 partition key, foreign key, primary key, or unique constraint.
  - Implicit conversion related to XMLType, including the conversion between strings and the XMLType data type
  - Array expression, row expression, subquery expression, TABLE OF, and TABLE OF INDEX
  - Use columns of the XMLType data format as common indexes, unique indexes, global indexes, local indexes, and partial indexes.
  - Comparison expressions >, <, >=, <=, =, <>, !=, ^=, <=>, BETWEEN AND, IS DISTINCT FROM, and IS NOT DISTINCT FROM
  - Condition expressions DECODE, NULLIF, GREATEST, and LEAST
  - Used as DISTINCT, GROUP BY, or ORDER BY parameters
  - Aggregate functions sum, max, min, avg, list\_agg, corr, covar\_pop, covar\_samp, stddev, stddev\_pop, stddev\_samp, var\_pop, var\_samp, variance, bit\_and, bit\_or, bool\_and, bool\_or, every, regr\_avgx, regr\_avgy, regr\_count, regr\_intercept, regr\_r2, regr\_slope, regr\_sxx, regr\_sxy, regr\_syy, rank, and spread
  - ODBC-related APIs with binding parameters
- The XMLType type supports the following operations:
  - Physical backup and restoration
  - Comparison expressions IS NULL and IS NOT NULL
  - Condition expressions CASE and COALESCE
  - Global temporary tables and local temporary tables
  - Forcible type conversion
  - Expression indexes
  - Input XMLType values that comply with the XML standard
  - gs\_dump and gs\_restore
  - Parallel query. The Astore and Ustore storage engines are supported.
  - Input parameters, output parameters, customized variables, and return values of a user-defined function
  - Input parameters, output parameters, customized variables, and return values of a stored procedure, as well as stored procedures that support autonomous transactions.
  - Character processing function quote\_literal(string text) (explicitly converted to the character type) and quote\_nullable(string text) (explicitly converted to the character type)
  - Aggregate functions count, array\_agg, and checksum (explicitly converted to the character type), and string\_agg (explicitly converted to the character type)
  - If addition, deletion, modification, and query of user-defined composite types involve XMLType types that are similar to XMLType columns in common tables, the composite types must be inserted and modified based on the XMLType syntax.
  - The SELECT, UPDATE, INSERT, and DELETE operations can be performed on an XMLType column. You can enter an XMLType value using the SQL syntax.
- You can create a schema named **xmltype**. In the schema, you can create functions, but cannot use schema.func() to call functions defined in the schema.

## 7.3.18 SET Type

The SET type is a collection type that contains string members and is defined when a table column is created.

### Specifications

1. The number of members of the SET type ranges from 1 to 64. It cannot be defined as an empty set.
2. A member name can contain a maximum of 255 characters. An empty string can be used as a member name. The member name must be a character constant but cannot be a character constant obtained after calculation, for example, SET('a' || 'b', 'c').
3. The member name cannot contain commas (,) and must be unique.
4. Arrays and domain types of the SET type cannot be created.
5. The SET type is supported only when **sql\_compatibility** is set to **B**.
6. The SET type cannot be used as the partition key of a partitioned table.
7. You need to use CASCADE to drop the SET type, and the associated table columns are also dropped.
8. For a Ustore table, if the table contains columns of the SET type and the recycle bin function is enabled, the table is directly deleted instead of being moved to the recycle bin.
9. ALTER TABLE cannot be used to change a column of the SET type to another SET type.
10. When a table or a table column associated with the SET type is deleted, or a table column of the SET type is changed to another type, the SET data type is also deleted.
11. CREATE TABLE { AS | LIKE } cannot be used to create a table containing the SET type.
12. The SET type is created with table columns, and its name is a combination of column names. If a data type with the same name already exists in the schema, the SET type fails to be created.
13. The SET type can be compared with the int2, int4, int8, and text types using =, <, >, <=, >, and >=.
14. The SET type can be converted to the int2, int4, int8, float4, float8, numeric, char, varchar, text and nvarchar2 data types.

### Precautions

- The table column values of the SET type must be a subset of the set defined by the SET type. Example:

```
gaussdb=# CREATE TABLE employee (  
  name text,  
  site SET('beijing','shanghai','nanjing','wuhan')  
);
```
- The value of the **site** column must be a subset of the preceding defined set and can be an empty set. If the provided value does not exist in the members of the defined set, an error is reported. Example:

```
gaussdb=# INSERT INTO employee VALUES('zhangsan', 'nanjing,beijing');  
INSERT 0 1  
gaussdb=# INSERT INTO employee VALUES('zhangsan', 'hangzhou');
```

```
ERROR: invalid input value for set employee_site_set: 'hangzhou'
LINE 1: INSERT INTO employee VALUES('zhangsan', 'hangzhou');
          ^
CONTEXT: referenced column: site
```

- Regardless of the sequence of the member values provided by the user, the queried values of the SET type are displayed in the defined sequence after the INSERT operation is successful.

```
gaussdb=# SELECT * FROM employee;
 name | site
-----+-----
zhangsan | beijing,nanjing
(1 rows)
```

- The SET type is stored in bitmap mode. Members of the SET type are assigned different values according to the sequence in which they are defined. For example, the values of SET('beijing','shanghai','nanjing','wuhan') are as follows:

**Table 7-24** Set members and their values

Set Member	Member Value	Binary Value
'beijing'	1	0001
'shanghai'	2	0010
'nanjing'	4	0100
'wuhan'	8	1000

Therefore, if a numeric value is assigned to a column of the SET type, the value is converted to the corresponding subset. For example, the binary value corresponding to **9** is **1001**, and the corresponding subset is **'beijing,wuhan'**.

```
gaussdb=# INSERT INTO employee values('lisi', 9);
INSERT 0 1
gaussdb=# SELECT * FROM employee;
 name | site
-----+-----
zhangsan | beijing,nanjing
lisi | beijing,wuhan
(2 rows)
gaussdb=# DROP TABLE employee;
```

### 7.3.19 ACLItem

The aclitem data type is used to store object permission information. Its internal implementation is of the int type and supports the *user1=privs/user2* format.

The aclitem[] data type is an array consisting of ACL items. The supported format is {*user1 = privs1/user3, user2 = privs2/user3*}.

In the preceding command, *user1*, *user2*, and *user3* indicate the existing users or roles in the database, and *privs* indicates the permissions supported by the database. For details, see [Table 12-46](#).

Example:

```
-- Create a user.
gaussdb=# CREATE USER user1 WITH PASSWORD 'Aa123456789';
```

```
gaussdb=# CREATE USER user2 WITH PASSWORD 'Aa123456789';
gaussdb=# CREATE USER omm WITH PASSWORD 'Aa123456789';

-- Create a data table table_acl that contains three columns of the int, aclitem, and aclitem[] types.
gaussdb=# CREATE TABLE table_acl (id int,priv aclitem,privs aclitem[]);-- Insert a data record whose
content is (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (1,'user1=arw/omm','{omm=d/user2,omm=w/omm}');
-- Insert a data record whose content is (2,'user1=aw/omm','{omm=d/user2}') into the table_acl table.
gaussdb=# INSERT INTO table_acl VALUES (2,'user1=aw/omm','{omm=d/user2}');

gaussdb=# SELECT * FROM table_acl;
id | priv | privs
-----+-----+-----
 1 | user1=arw/omm | {omm=d/user2,omm=w/omm}
 2 | user1=aw/omm | {omm=d/user2}
(2 rows)

-- Delete the table and user.
gaussdb=# DROP USER user1;
gaussdb=# DROP USER user2;
gaussdb=# DROP USER omm;
gaussdb=# DROP TABLE table_acl;
```

## 7.3.20 Array Types

Array types can be used to store several elements of the same type.

### Array Type Definition

Generally, an array data type is named by adding square brackets ([]) to the end of the data type name of an array element.

Example 1: Create a table named **sal\_emp**. The table has the following columns: **name** of the text type, indicating employee names; **pay\_by\_quarter** of the integer element type, indicating an array of quarterly salaries; **phone\_numbers** of the varchar(11) element type, indicating an array of mobile numbers.

```
gaussdb=# CREATE TABLE sal_emp (
name          text,
pay_by_quarter integer[],
phone_numbers varchar(11)[]
);
gaussdb=# DROP TABLE sal_emp;
```

Example 2: Define an array type in other ways. For details about the definition method and behavior, see the comments in the example.

```
gaussdb=# CREATE TABLE sal_emp (
name          text,
pay_by_quarter1 integer[2], -- Two-dimensional array of the int type.
pay_by_quarter2 integer[3], -- One-dimensional array of the int type. The size is 3.
pay_by_quarter3 integer[3][3], -- Two-dimensional array of the int type. The size of each dimension is 3.
pay_by_quarter4 integer ARRAY, -- One-dimensional array of the int type.
pay_by_quarter5 integer ARRAY[3] -- One-dimensional array of the int type. The size is 3.
);
gaussdb=# DROP TABLE sal_emp;
```

**CAUTION**

- The definition of the number of dimensions of an array does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type and do not use multidimensional array data.
- The definition of the array size does not take effect (which does not affect the runtime behavior). You are advised to use the method described in example 1 to define the array type.
- The maximum number of dimensions of an array is 6.
- The restrictions on the number of array elements are as follows:
  1. The maximum number of elements is 134217727.
  2. The maximum storage space of all elements cannot exceed 1 GB minus 1 byte, that is, 1073741823 bytes.

## Array Constructor

An array constructor is an expression that can build array values. A simple array constructor consists of the keyword ARRAY and an expression list of array element values which are separated by commas and enclosed (,) by square brackets ([]). For example:

```
gaussdb=# SELECT ARRAY[1, 2, 3 + 4];
 array
-----
{1,2,7}
(1 row)
```

By default, the element type of an array is the common type of member expressions and is determined by the same rules as the UNION or CASE structure ([UNION, CASE, and Related Constructs](#)). You can construct an array to the desired data type through explicit type conversion. The following is an example:

```
gaussdb=# SELECT ARRAY[1, 2, 3]::varchar[];
 array
-----
{1,2,3}
(1 row)

gaussdb=# SELECT ARRAY['a', 'b', 'c'];
 array
-----
{a,b,c}
(1 row)

gaussdb=# SELECT ARRAY['a', 'b', 'c']::int[];
ERROR: invalid input syntax for integer: "a"
LINE 1: select ARRAY['a', 'b', 'c']::int[];
                   ^
CONTEXT: referenced column: array

gaussdb=# SELECT ARRAY[1::int, 'b', 'c'];
ERROR: invalid input syntax for integer: "b"
LINE 1: select ARRAY[1::int, 'b', 'c'];
                   ^
CONTEXT: referenced column: array
```

In addition to the preset basic types, the record type and table type can also be defined as array types. The following is an example:

```
gaussdb=# CREATE TYPE rec IS (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)::rec[]];
array
-----
{"(1,1)","(2,2)"}
(1 row)

gaussdb=# CREATE TABLE tab (c1 int, c2 int);
gaussdb=# SELECT ARRAY[(1, 1), (2, 2)::tab[]];
array
-----
{"(1,1)","(2,2)"}
(1 row)

gaussdb=# DROP TYPE rec;
gaussdb=# DROP TABLE tab;
```

An array must have a type. Therefore, when constructing an empty array, you must construct it as the required type. For example:

```
gaussdb=# SELECT ARRAY[]::int[];
array
-----
{}
(1 row)
```

An array can be also constructed from the result of a subquery. In this case, the array constructor consists of the keyword ARRAY and a subquery enclosed in parentheses. The subquery must return only one separate column. The generated one-dimensional array generates an element for each row of the result in the subquery. The element type matches the output column of the subquery. For example:

```
gaussdb=# SELECT ARRAY(select generate_series(1, 6));
array
-----
{1,2,3,4,5,6}
(1 row)
```

Multidimensional array values can be made by nesting array constructors. The ARRAY keyword in the inner constructor can be omitted. For example, the following two examples show the same result:

```
gaussdb=# SELECT ARRAY[ARRAY[1,2], ARRAY[3,4]];
array
-----
{{1,2},{3,4}}
(1 row)

gaussdb=# SELECT ARRAY[[1,2], [3,4]];
array
-----
{{1,2},{3,4}}
(1 row)
```

#### NOTE

- Inner constructors at the same layer must generate subarrays of the same dimension.
- Any type conversion applied to the outer ARRAY constructor is automatically applied to all inner constructors.

## String Inputs of the Array Type

To write an array value as a literal constant (constant input), enclose the element values with braces and separate them with commas. The general format of an array constant is as follows:

```
{ val1 delim val2 delim ... }
```

In the preceding format, **delim** indicates the delimiter of the element type and is recorded in the **typdelim** column in the `pg_type` catalog of the type. Each **val** can be a constant of the array element type or a subarray. For example:

```
gaussdb=# SELECT '{1, 2, 3}::int[] AS RESULT;
result
-----
{1,2,3}
(1 row)

gaussdb=# SELECT '{{1, 2, 3}, {4, 5, 6}, {7, 8, 9}}::int[] AS RESULT;
result
-----
{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

Double quotation marks can be used around any element value, and double quotation marks must be used when the element value contains special characters such as commas or braces. The following is an example:

```
gaussdb=# SELECT '{" ", "NULL", null, "\\ ", "{", "}", ", "}'::varchar[] AS RESULT;
result
-----
{" ", "NULL", NULL, "\\ ", "{", "}", ", "}
(1 row)
```

-- This example indicates that there is an array of the varchar type and there are seven varchar elements in total. The elements are as follows:

1. A character string containing a space.
2. A character string containing "NULL".
3. A character string containing NULL.
4. A character string containing a backslash (\).
5. A character string containing a left brace ({).
6. A character string containing a right brace (}).
7. A character string containing a comma (,).

#### NOTE

- For array string constant inputs, if the array element value is an empty string, contains braces, delimiters, double quotation marks, backslashes, or spaces, or matches the keyword NULL, then element inputs are enclosed in double quotation marks. An additional backslash is input if the element value contains double quotation marks or backslashes.
- The keyword NULL is case-insensitive.
- The input spaces not enclosed in double quotation marks are automatically skipped.
- You are advised to use the array constructor instead of character constants to construct array data.

## String Outputs of the Array Type

The output of an array value consists of the output of the array element type plus some modifiers indicating the array structure. These modifiers consist of braces ({}), around array values plus delimiters between adjacent items. In a multidimensional array, each dimension has its own level of braces and contains delimiters between adjacent braces at the same level.

The data of the array type contains special characters (in the following description). The following is an example of character string output:

```
gaussdb=# SELECT ARRAY[{' ', '}', 'hello, world', '', '\', ' ', NULL] AS RESULT;
array
-----
{" ", "}", "hello, world", "\\ ", "\\", " ", NULL}
(1 row)
```

 NOTE

For array string constant outputs, if the array element value is an empty string or contains braces, delimiters, double quotation marks, backslashes, or spaces, or the element is NULL, then element outputs are enclosed in double quotation marks. An additional backslash is output if the element value contains double quotation marks or backslashes. This parameter corresponds to the string constant inputs.

## Use of Array Types

The following is an example of using the array type:

```
-- Create a table with array columns and insert some data.
gaussdb=# CREATE TABLE orders (
name varchar,
items varchar[]
);
gaussdb=# INSERT INTO orders VALUES('a', ARRAY['Apple', 'Orange', 'Pear']);
gaussdb=# INSERT INTO orders VALUES('b', ARRAY['Mineral water', 'Coke', 'Sprite']);
gaussdb=# INSERT INTO orders VALUES('c', ARRAY['Mouse', 'Keyboard', 'Earphone']);
gaussdb=# INSERT INTO orders VALUES('d', '{Cabbage, Potato, Eggplant}');

-- Query data.
gaussdb=# SELECT * FROM orders ORDER BY name;
name | items
-----+-----
a | {Apple,Orange,Pear}
b | {Mineral water,Coke,Sprite}
c | {Mouse,Keyboard,Earphone}
d | {Cabbage,Potato,Eggplant}
(4 rows)

-- Access array elements.
gaussdb=# SELECT items[1] FROM orders ORDER BY name;
items
-----
Apple
Mineral water
Mouse
Cabbage
(4 rows)

-- If the accessed element exceeds the range or the accessed index is NULL, NULL is returned.
gaussdb=# SELECT items[4] FROM orders ORDER BY name;
items
-----

(4 rows)

gaussdb=# SELECT items[null] FROM orders ORDER BY name;
items
-----

(4 rows)

-- Access a subarray.
gaussdb=# SELECT items[1:2] FROM orders ORDER BY name;
items
-----
{Apple,Orange}
{Mineral water,Coke}
{Mouse,Keyboard}
```

```

{Cabbage,Potato}
(4 rows)

-- Updates the entire array.
gaussdb=# UPDATE orders SET items = ARRAY['Banana', 'Watermelon', 'Strawberry'] WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
         items
-----
{Banana,Watermelon,Strawberry}
(1 row)

-- Updates the elements of an array.
gaussdb=# UPDATE orders SET items[1] = 'Mango' WHERE name = 'a';
gaussdb=# SELECT items FROM orders WHERE name = 'a';
         items
-----
{Mango,Watermelon,Strawberry}
(1 row)

-- Updates the element fragment of an array.
gaussdb=# UPDATE orders SET items[1:2] = ARRAY['Computer','Mobile phone'] WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
         items
-----
{Computer,Mobile phone,Earphone}
(1 row)

-- Add an array element. Unassigned elements between the last element of the original array and the new
element are set to NULL.
gaussdb=# UPDATE orders SET items[4] = 'Display' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
         items
-----
{Computer,Mobile phone,Earphone,Display}
(1 row)

gaussdb=# UPDATE orders SET items[6] = 'Display 2' WHERE name = 'c';
gaussdb=# SELECT items FROM orders WHERE name = 'c';
         items
-----
{Computer,Mobile phone,Earphone,Display,NULL,Display 2}
(1 row)

```

## 7.4 Constant and Macro

[Table 7-25](#) lists the constants and macros that can be used in GaussDB.

**Table 7-25** Constant and macro

Parameter	Description	Example
CURRENT_CATALOG	Specifies the current database.	gaussdb=# SELECT CURRENT_CATALOG; current_database ----- testdb (1 row)
CURRENT_ROLE	Specifies the current user.	gaussdb=# SELECT CURRENT_ROLE; current_user ----- omm (1 row)

Parameter	Description	Example
CURRENT_SCHEMA	Specifies the current database mode.	gaussdb=# SELECT CURRENT_SCHEMA; current_schema ----- public (1 row)
CURRENT_USER	Specifies the current user.	gaussdb=# SELECT CURRENT_USER; current_user ----- omm (1 row)
LOCALTIMESTAMP	Specifies the current session time (without time zone).	gaussdb=# SELECT LOCALTIMESTAMP; timestamp ----- 2015-10-10 15:37:30.968538 (1 row)
NULL	This parameter is left blank.	N/A
SESSION_USER	Specifies the current system user.	gaussdb=# SELECT SESSION_USER; session_user ----- omm (1 row)
SYSDATE	Specifies the current system date.	gaussdb=# SELECT SYSDATE; sysdate ----- 2015-10-10 15:48:53 (1 row)
USER	Specifies the current user, also called <b>CURRENT_USER</b> .	gaussdb=# SELECT USER; current_user ----- omm (1 row)

## 7.5 Functions and Operators

Operators can be used to process one or more operands and can be placed before, after, or between operands. Results are returned after the processing.

Functions encapsulate service logic to implement specific functions. A function may or may not have parameters. After a function is executed, the result is returned.

Users can modify system functions. However, after the modification, the meaning of the functions may change, which results in disorder in system control. Therefore, users are not allowed to manually modify system functions.

 NOTE

- When the GUC parameter **behavior\_compat\_options** contains the 'enable\_funcname\_with\_argname' option, the projection alias displays the complete function.
- When the GUC parameter **enable\_volatile\_match\_index** is set to **ON** and **DBCMPATIBILITY** is set to **A**, volatile functions can match indexes. The volatile functions may not hit partial indexes. If there are implicit conversions during function execution, the volatile functions may not hit indexes. In the scenario where indexes cannot be hit, if this option is enabled, the volatile functions still cannot hit the indexes.
- When **DBCMPATIBILITY** is set to **A** and a constant or an expression that can be converted into a constant (for example, it can be an immutable function, but cannot be a stable or volatile function) is transferred during the execution of the immutable stored procedure in the SQL statement, the immutable stored procedure is not executed once per row. When the input parameter of the immutable stored procedure is a row expression, the stored procedure is executed once per row. In the SQL statements that contain UNION, UNION ALL, and ORDER BY, the number of execution times of the immutable stored procedure decreases but the stored procedure is not executed only once.

## 7.5.1 Logical Operators

The usual logical operators include AND, OR, and NOT. SQL uses a three-valued logical system with true, false, and null, which represents "unknown". Their priorities are NOT > AND > OR.

**Table 7-26** lists the calculation rules, where a and b represent logical expressions.

**Table 7-26** Operation rules

a	b	a AND b Result	a OR b Result	NOT a Result
TRUE	TRUE	TRUE	TRUE	FALSE
TRUE	FALSE	FALSE	TRUE	FALSE
TRUE	NULL	NULL	TRUE	FALSE
FALSE	FALSE	FALSE	FALSE	TRUE
FALSE	NULL	FALSE	NULL	TRUE
NULL	NULL	NULL	NULL	NULL

 NOTE

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result.
- Operations on XML data are not supported.

## 7.5.2 Comparison Operators

Comparison operators are available for the most data types and return Boolean values.

All comparison operators are binary operators. Only data types that are the same or can be implicitly converted can be compared using comparison operators.

**Table 7-27** describes comparison operators provided by GaussDB.

**Table 7-27** Comparison operators

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>, !=, or ^=	Not equal to

- Comparison operators are available for all relevant data types. All comparison operators are binary operators that returned values of Boolean type.
- The calculation priority of the inequality sign is higher than that of the equality sign. If the entered data type is different and cannot be implicitly converted, the comparison fails. For example, an expression such as **1 < 2 < 3** is invalid because the less-than sign (<) cannot be used to compare Boolean values and 3.
- Besides, each comparison operator has a corresponding function in the pg\_proc system catalog. If the value of the **proleakproof** attribute of the corresponding function is **f**, the function is not used to prevent data leakage. If a user only has the permission for a system view, but does not have the permission for the corresponding table, the query plan may not be optimal when the user searches the system view.
- This operator does not support data of the XML type.

### 7.5.3 Character Processing Functions and Operators

String functions and operators provided by GaussDB are for concatenating strings with each other, concatenating strings with non-strings, and matching the patterns of strings. Note: Except length-related functions, other functions and operators of string processing functions do not support parameters greater than 1 GB.

- `bit_length(string)`  
Description: Specifies the number of bits occupied by a string.  
Return type: int

Example:

```
gaussdb=# SELECT bit_length('world');
 bit_length
-----
         40
(1 row)
```

- `btrim(string text [, characters text])`

Description: Removes the longest string consisting only of characters in **characters** (a space by default) from the start and end of **string**.

Return type: text

Example:

```
gaussdb=# SELECT btrim('string', 'ing');
 btrim
-----
sr
(1 row)
```

- `char_length(string)` or `character_length(string)`

Description: Specifies the number of characters in a string.

Return type: int

Example:

```
gaussdb=# SELECT char_length('hello');
 char_length
-----
5
(1 row)
```

- `dump(expr[, return_fmt [, start_position [, length ] ] ])`

Description: Returns the data type code, byte length, and internal representation of the input expression. **return\_fmt** specifies the number system of the internal representation, **start\_position** specifies the byte from which the internal representation starts, and **length** indicates the length of the data to be read.

Return type: text

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `instr(text,text,int,int)`

Description: **instr(string1,string2,int1,int2)** returns the text from **int1** to **int2** in **string1**. The first **int** indicates the start position for matching, and the second **int** indicates the number of matching times.

Return type: int

Example:

```
gaussdb=# SELECT instr('abcdabcdabcd', 'bcd', 2, 2 );
 instr
-----
6
(1 row)
```

- `instrb(text,text,int,int)`

Description: **instrb(string1,string2,int1,int2)** returns the position matching **string2** in **string1** for the **int2**th time from the position specified by **int1**. **int1** indicates the start position for matching, and **int2** indicates the number of matching times. Different from the `instr` function, `instrb` is calculated in bytes and is not affected by the character set in use.

Return type: int

Example:

```
gaussdb=# SELECT instrb('abcdabcdabcd', 'bcd', 2, 2 );
 instrb
```

```
-----
        6
(1 row)
```

 **NOTE**

- This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1** in an A-compatible database.
- If the values of *int1* and *int2* are decimals, the values are truncated instead of being rounded off.

- **lengthb(text/bpchar)**

Description: Obtains the number of bytes of a specified string.

Return type: int

Example:

```
gaussdb=# SELECT lengthb('hello');
lengthb
-----
        5
(1 row)
```

- **left(str text, n int)**

Description: Returns the first *n* characters in a string. When *n* is negative, all but the last **|n|** characters are returned.

Return type: text

Example:

```
gaussdb=# SELECT left('abcde', 2);
left
-----
ab
(1 row)
```

- **length(string bytea, encoding name)**

Description: Specifies the number of characters in the string in the specified **encoding**. The string must be valid in this encoding.

Return type: int

Example:

```
gaussdb=# SELECT length('jose', 'UTF8');
length
-----
        4
(1 row)
```

 **NOTE**

If the length of the bytea type is queried and UTF8 encoding is specified, the maximum length can only be **536870888**.

- **lpad(string text, length int [, fill text])**

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

 NOTE

In the scenario where this function is in an A-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on A-compatible requirements. During the execution of the lpad function, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the left of the string.
- If the value of *length* is a decimal, the value is truncated instead of being rounded off.

- **notlike(x bytea name text, y bytea text)**

Description: Compares x and y to check whether they are inconsistent.

Return type: Boolean

Example:

```
gaussdb=# SELECT notlike(1,2);
notlike
-----
      t
(1 row)
gaussdb=# SELECT notlike(1,1);
notlike
-----
      f
(1 row)
```

- **octet\_length(string)**

Description: Specifies the number of bytes in a string.

Return type: int

Example:

```
gaussdb=# SELECT octet_length('jose');
octet_length
-----
          4
(1 row)
```

- **overlay(string placing string FROM int [for int])**

Description: Replaces substrings. **FROM int** indicates the start position of the replacement in the first string. **for int** indicates the number of characters replaced in the first string.

Return type: text

Example:

```
gaussdb=# SELECT overlay('hello' placing 'world' from 2 for 3 );
overlay
-----
hworldo
(1 row)
```

- **position(substring in string)**

Description: Specifies the position of a substring. Parameters are case-sensitive.

Return type: int. If the character string does not exist, **0** is returned.

Example:

```
gaussdb=# SELECT position('ing' in 'string');
position
-----
```

- ```

4
(1 row)

```
- pg\_client\_encoding()**

Description: Specifies the current client encoding name.

Return type: name

Example:

```

gaussdb=# SELECT pg_client_encoding();
pg_client_encoding
-----
UTF8
(1 row)

```
  - quote\_ident(string text)**

Description: Returns the given string suitably quoted to be used as an identifier in an SQL statement string (quotation marks are used as required). Quotation marks are added only if necessary (that is, if the string contains non-identifier characters or would be case-folded). Embedded quotation marks are properly doubled.

Return type: text

Example:

```

gaussdb=# SELECT quote_ident('hello world');
quote_ident
-----
"hello world"
(1 row)

```
  - quote\_literal(string text)**

Description: Returns the given string suitably quoted to be used as a string literal in an SQL statement string (quotation marks are used as required). It supports XML data that is explicitly converted to the character type.

Return type: text

Example:

```

gaussdb=# SELECT quote_literal('hello');
quote_literal
-----
'hello'
(1 row)

```

If a command similar to the following exists, the text will be escaped.

```

gaussdb=# SELECT quote_literal(E'O\hello');
quote_literal
-----
'O"hello'
(1 row)

```

If a command similar to the following exists, the backslash will be properly doubled.

```

gaussdb=# SELECT quote_literal('O\hello');
quote_literal
-----
E'O\\hello'
(1 row)

```

If the parameter is null, **NULL** is returned. If the parameter may be null, you are advised to use **quote\_nullable**.

```

gaussdb=# SELECT quote_literal(NULL);
quote_literal
-----
(1 row)

```

- `quote_literal(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
gaussdb=# SELECT quote_literal(42.5);
quote_literal
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_literal(E'O\42.5');
quote_literal
-----
'O"42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_literal('O\42.5');
quote_literal
-----
'E'O\\42.5'
(1 row)
```

- `quote_nullable(string text)`

Description: Returns the given string suitably quoted to be used as a string literal in an SQL statement string (quotation marks are used as required).

It supports XML data that is explicitly converted to the character type.

Return type: text

Example:

```
gaussdb=# SELECT quote_nullable('hello');
quote_nullable
-----
'hello'
(1 row)
```

If a command similar to the following exists, the text will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O\hello');
quote_nullable
-----
'O"hello'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\hello');
quote_nullable
-----
'E'O\\hello'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

- `quote_nullable(value anyelement)`

Description: Converts the given value to text and then quotes it as a literal.

Return type: text

Example:

```
gaussdb=# SELECT quote_nullable(42.5);
quote_nullable
-----
'42.5'
(1 row)
```

If a command similar to the following exists, the given value will be escaped.

```
gaussdb=# SELECT quote_nullable(E'O\42.5');
quote_nullable
-----
'O"42.5'
(1 row)
```

If a command similar to the following exists, the backslash will be properly doubled.

```
gaussdb=# SELECT quote_nullable('O\42.5');
quote_nullable
-----
E'O\\42.5'
(1 row)
```

If the parameter is null, **NULL** is returned.

```
gaussdb=# SELECT quote_nullable(NULL);
quote_nullable
-----
NULL
(1 row)
```

- `substring_inner(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text

Example:

```
gaussdb=# SELECT substring_inner('adcde', 2,3);
substring_inner
-----
dcd
(1 row)
```

- `substring(string [from int] [for int])`

Description: Extracts a substring. **from int** indicates the start position of the truncation. **for int** indicates the number of characters truncated.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from 2 for 3);
substring
-----
hom
(1 row)
```

- `substring(string from pattern)`

Description: Extracts substrings matching the POSIX-style regular expression. It returns the text that matches the pattern. If no match record is found, a null value is returned.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from '...$');
substring
-----
```

```
mas
(1 row)
gaussdb=# SELECT substring('foobar' from '(o(.)b)');
result
-----
o
(1 row)
gaussdb=# SELECT substring('foobar' from '(o(.)b)');
result
-----
oob
(1 row)
```

 **NOTE**

If the POSIX-style regular expression contains any parentheses, the portion of the text that matched the first parenthesized sub-expression (the one whose left parenthesis comes first) is returned. You can put parentheses around the whole expression if you want to use parentheses within it without triggering this exception.

- `substring(string from pattern for escape)`

Description: Extracts substrings matching the SQL regular expression. The declared schema must match the entire data string; otherwise, the function fails and returns a null value. To indicate the part of the schema that should be returned on success, the schema must contain two occurrences of the escape character followed by a double quotation mark ("). The text matching the portion of the pattern between these marks is returned.

Return type: text

Example:

```
gaussdb=# SELECT substring('Thomas' from '%"#"o_a#"_' for '#');
substring
-----
oma
(1 row)
```

- `rawcat(raw,raw)`

Description: Indicates the string concatenation function.

Return type: raw

Example:

```
gaussdb=# SELECT rawcat('ab','cd');
rawcat
-----
ABCD
(1 row)
```

- `regexp_like(text,text,text)`

Description: Indicates the mode matching function of a regular expression.

Return type: bool

Example:

```
gaussdb=# SELECT regexp_like('str','[ac]');
regexp_like
-----
f
(1 row)
```

- `regexp_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])`

Description: Extracts substrings from a regular expression. Its function is similar to **substr**. When a regular expression contains multiple parallel brackets, it also needs to be processed.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be extracted. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-28](#).

**Table 7-28** Options supported by flags

| Option | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'b'    | Indicates the BRE matching without extension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 'c'    | Indicates the case-sensitive matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 'e'    | Indicates the ERE matching with extension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 'i'    | Indicates the case-insensitive matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 'm'    | Indicates the multi-line matching. If <b>flags</b> contains "m", use the multi-line matching. Otherwise, use the single-line matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 'n'    | <p>The meanings of the 'n' option are related to the GUC parameter <b>behavior_compat_options</b> and the compatibility mode of the current database.</p> <ul style="list-style-type: none"> <li>• If the SQL compatibility mode of the database is A or B and the value of the GUC parameter <b>behavior_compat_options</b> contains <b>aformat_regexp_match</b>, the 'n' option indicates that "." matches the linefeed '\n'. If 'n' is not specified, "." does not match the linefeed.</li> <li>• In other cases, the "n" option has the same meaning as the "m" option.</li> </ul> |
| 'p'    | Indicates partial linefeed-sensitive matching, which is similar to the linefeed-sensitive matching ('m' or 'n') and affects "." and square bracket expression, but does not affect ^ and \$.                                                                                                                                                                                                                                                                                                                                                                                           |
| 'q'    | Indicates common character matching.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 's'    | Indicates the single-line matching. The meaning is opposite to those of 'm' and 'n'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 't'    | Indicates the compact matching. The whitespace characters match themselves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 'w'    | Indicates the reverse partial linefeed-sensitive matching. The meaning is opposite to that of 'p'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Option | Description                                                          |
|--------|----------------------------------------------------------------------|
| 'x'    | Indicates the loose matching. The whitespace characters are ignored. |

Return type: text

Example:

```
gaussdb=# SELECT regexp_substr('str','[ac]');
regexp_substr
```

-----

(1 row)

```
gaussdb=# SELECT regexp_substr('foobarbaz', 'b(..)', 3, 2) AS RESULT;
result
```

-----

baz

(1 row)

- `regexp_count(string text, pattern text [, position int [, flags text]])`

Description: obtains the number of substrings used for matching.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-28](#).

#### NOTE

When the function is in an A-compatible database, the value of **a\_format\_version** is **10c**, and the value of **a\_format\_dev\_version** is **s1**, the **pattern** parameter ending with a backslash (\) is valid.

Return type: int

Example:

```
gaussdb=# SELECT regexp_count('foobarbaz','b(..)', 5) AS RESULT;
result
```

-----

1

(1 row)

- `regexp_instr(string text, pattern text [, position int [, occurrence int [, return_opt int [, flags text]]]])`

Description: obtains the position (starting from 1) of the substring that meets the matching condition. If no substring is matched, **0** is returned.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**.

- **return\_opt**: specifies whether to return the position of the first or last character of the matched substring. This parameter is optional. If the value is **0**, the position of the first character (starting from 1) of the matched substring is returned. If the value is greater than 0, the position of the next character of the end character of the matched substring is returned. The default value is **0**.
- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-28](#).

Return type: int

Example:

```
gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 1, 0) AS RESULT;
result
-----
4
(1 row)

gaussdb=# SELECT regexp_instr('foobarbaz','b(..)', 1, 2, 0) AS RESULT;
result
-----
7
(1 row)
```

- **regexp\_matches(string text, pattern text [, flags text])**

Description: Returns all captured substrings resulting from matching a POSIX-style regular expression against **string**. If the pattern does not match, the function returns no rows. If the pattern contains no parenthesized sub-expressions, then each row returned is a single-element text array containing the substring matching the whole pattern. If the pattern contains parenthesized sub-expressions, the function returns a text array whose *n*th element is the substring matching the *n*th parenthesized sub-expression of the pattern.

The optional **flags** argument contains zero or multiple single-letter flags that change the function behavior. **i** indicates that the matching is not related to uppercase and lowercase. **g** indicates that each matched substring is replaced, instead of replacing only the first one.

#### NOTICE

If the last parameter is provided but the parameter value is an empty string (") and the SQL compatibility mode of the database is set to A, the returned result is an empty set. This is because the A compatibility mode treats the empty string (") as **NULL**. To resolve this problem, you can:

- Change the database SQL compatibility mode to C.
- Do not provide the last parameter or do not set the last parameter to an empty string.

Return type: SETOF text[]

Example:

```
gaussdb=# SELECT regexp_matches('foobarbequebaz', '(bar)(beque)');
regexp_matches
-----
{bar,beque}
```

```
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebaz', 'barbeque');
 regexp_matches
-----
{barbeque}
(1 row)
gaussdb=# SELECT regexp_matches('foobarbequebazilbarfbonk', '(b[^b]+)(b[^b]+)', 'g');
 regexp_matches
-----
{bar,beque}
{bazil,barf}
(2 rows)
```

- `regexp_split_to_array(string text, pattern text [, flags text ])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. The **regexp\_split\_to\_array** function behaves the same as **regexp\_split\_to\_table**, except that **regexp\_split\_to\_array** returns its result as an array of text.

Return type: text[]

Example:

```
gaussdb=# SELECT regexp_split_to_array('hello world', 'E\\s+');
 regexp_split_to_array
-----
{hello,world}
(1 row)
```

- `regexp_split_to_table(string text, pattern text [, flags text])`

Description: Splits **string** using a POSIX-style regular expression as the delimiter. If there is no match to the pattern, the function returns the string. If there is at least one match, for each match it returns the text from the end of the last match (or the beginning of the string) to the beginning of the match. When there are no more matches, it returns the text from the end of the last match to the end of the string.

The **flags** parameter is a text string containing zero or more single-letter flags that change the function's behavior. **i** indicates case-insensitive matching.

Return type: SETOF text

Example:

```
gaussdb=# SELECT regexp_split_to_table('hello world', 'E\\s+');
 regexp_split_to_table
-----
hello
world
(2 rows)
```

- `repeat(string text, number int)`

Description: Repeats **string** the specified number of times.

Return type: text

Example:

```
gaussdb=# SELECT repeat('Pg', 4);
 repeat
-----
PgPgPgPg
(1 row)
```

 NOTE

The maximum size of memory allocated at a time cannot exceed 1 GB due to the memory allocation mechanism of the database. Therefore, the maximum value of **number** cannot exceed  $(1 \text{ GB} - \mathbf{x})/\mathbf{lengthb}(\mathbf{string}) - 1$ . **x** indicates the length of the header information, which is usually greater than 4 bytes. The value varies among different scenarios.

- `replace(string text, from text, to text)`

Description: Replaces all occurrences in **string** of substring **from** with substring **to**.

Return type: text

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd', 'XXX');
replace
-----
abXXXefabXXXef
(1 row)
```

- `replace(string, substring)`

Description: Deletes all substrings in a string.

String type: text

Substring type: text

Return type: text

Example:

```
gaussdb=# SELECT replace('abcdefabcdef', 'cd');
replace
-----
abefabef
(1 row)
```

- `reverse(str)`

Description: Returns a reversed string (by character).

Return type: text

Example:

```
gaussdb=# SELECT reverse('abcde');
reverse
-----
edcba
(1 row)
```

- `right(str text, n int)`

Description: Returns the last *n* characters in a string. When *n* is negative, all but the first **|n|** characters are returned.

Return type: text

Example:

```
gaussdb=# SELECT right('abcde', 2);
right
-----
de
(1 row)

gaussdb=# SELECT right('abcde', -2);
right
-----
cde
(1 row)
```

- `rpad(string text, length int [, fill text])`

Description: Fills up **string** to **length** by appending the characters **fill** (a space by default). If **string** is already longer than **length**, then it is truncated.

Return type: text

 **NOTE**

In the scenario where this function is in an A-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **length** parameter indicates the display length of a character string. The display length of a single character is processed based on O-compatible requirements. During the execution of the `rpad` function, if the remaining length is 1 and the next character is of the full-width type (2 bytes), a space character is added to the right of the string.
  - If the value of *length* is a decimal, the value is truncated instead of being rounded off.
- `substrb(text,int,int)`

Description: Extracts a substring. The first **int** indicates the start position of the subtraction. The second **int** indicates the number of characters extracted.

Return type: text

Example:

```
gaussdb=# SELECT substrb('string',2,3);
substrb
-----
tri
(1 row)
```

- `substrb(text,int)`

Description: Extracts a substring. **int** indicates the start position of the extraction.

Return type: text

Example:

```
gaussdb=# SELECT substrb('string',2);
substrb
-----
tring
(1 row)
```

- `substr(bytea,from,count)`

Description: Extracts a substring from **bytea**. **from** specifies the position where the extraction starts. **count** specifies the length of the extracted substring.

Return type: text

Example:

```
gaussdb=# SELECT substr('string',2,3);
substr
-----
tri
(1 row)
```

- `string || string`

Description: Concatenates strings.

Return type: text

Example:

```
gaussdb=# SELECT 'MPP'||'DB' AS RESULT;
result
-----
MPPDB
(1 row)
```

- `string || non-string or non-string || string`  
Description: Concatenates strings and non-strings.  
Return type: text

Example:

```
gaussdb=# SELECT 'Value: '||42 AS RESULT;
result
-----
Value: 42
(1 row)
```

- `split_part(string text, delimiter text, field int)`  
Description: Splits **string** on **delimiter** and returns the **fieldth** column (counting from text of the first appeared delimiter).  
Return type: text

Example:

```
gaussdb=# SELECT split_part('abc~@~def~@~ghi', '~@~', 2);
split_part
-----
def
(1 row)
```

- `strpos(string, substring)`  
Description: Specifies the position of a substring. It is the same as **position(substring in string)**. However, the parameter sequences of them are reversed.  
Return type: int

Example:

```
gaussdb=# SELECT strpos('source', 'rc');
strpos
-----
4
(1 row)
```

- `to_hex(number int or bigint)`  
Description: Converts a number to a hexadecimal expression.  
Return type: text

Example:

```
gaussdb=# SELECT to_hex(2147483647);
to_hex
-----
7fffffff
(1 row)
```

- `translate(string text, from text, to text)`  
Description: Any character in **string** that matches a character in **from** is replaced by the corresponding character in **to**. If **from** is longer than **to**, extra characters occurred in **from** are removed.  
Return type: text

Example:

```
gaussdb=# SELECT translate('12345', '143', 'ax');
translate
```

```
-----
a2x5
(1 row)
```

- length(string)

Description: Obtains the number of characters in a string.

Return type: integer

Example:

```
gaussdb=# SELECT length('abcd');
length
-----
4
(1 row)
```

- lengthb(string)

Description: Obtains the number of characters in a string. The value depends on character sets (GBK and UTF8).

Return type: integer

Example:

```
gaussdb=# SELECT lengthb('Chinese');
lengthb
-----
7
(1 row)
```

- substr(string,from)

Description:

Extracts substrings from a string.

**from** indicates the start position of the extraction.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, all characters from **from** to the end are extracted.
- If the value of **from** is negative, the last *n* characters in the string are extracted, in which **n** indicates the absolute value of **from**.

Return type: varchar

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2);
substr
-----
BCDEF
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-2);
substr
-----
EF
(1 row)
```

- substr(string,from,count)

Description:

Extracts substrings from a string.

**from** indicates the start position of the extraction.

**count** indicates the length of the extracted substring.

- If **from** starts at 0, the value **1** is used.
- If the value of **from** is positive, extract **count** characters starting from **from**.
- If the value of **from** is negative, extract the last **n count** characters in the string, in which **n** indicates the absolute value of **from**.
- If the value of **count** is smaller than **1**, **null** is returned.

Return type: varchar

Example:

If the value of **from** is positive:

```
gaussdb=# SELECT substr('ABCDEF',2,2);
substr
-----
BC
(1 row)
```

If the value of **from** is negative:

```
gaussdb=# SELECT substr('ABCDEF',-3,2);
substr
-----
DE
(1 row)
```

- **substrb(string,from)**

Description: The functionality of this function is the same as that of **SUBSTR(string,from)**. However, the calculation unit is byte.

Return type: bytea

Example:

```
gaussdb=# SELECT substrb('ABCDEF',-2);
substrb
-----
EF
(1 row)
```

- **substrb(string,from,count)**

Description: The functionality of this function is the same as that of **SUBSTR(string,from,count)**. However, the calculation unit is byte.

Return type: bytea

Example:

```
gaussdb=# SELECT substrb('ABCDEF',2,2);
substrb
-----
BC
(1 row)
```

- **to\_single\_byte(char)**

Description: Converts all multi-byte characters in a string to single-byte characters.

Return type: text

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- **to\_multi\_byte(char)**

Description: Converts all single-byte characters in a string to multi-byte characters.

Return type: text

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `trim([leading |trailing |both] [characters] from string)`

Description: Removes the longest string containing only the characters (a space by default) from the start/end/both ends of the string.

Return type: text

Example:

```
gaussdb=# SELECT trim(BOTH 'x' FROM 'xTomxx');
 btrim
-----
 Tom
(1 row)
gaussdb=# SELECT trim(LEADING 'x' FROM 'xTomxx');
 ltrim
-----
 Tomxx
(1 row)
gaussdb=# SELECT trim(TRAILING 'x' FROM 'xTomxx');
 rtrim
-----
 xTom
(1 row)
```

- `rtrim(string [, characters])`

Description: Removes the longest string containing only characters from characters (a space by default) from the end of string.

Return type: text

Example:

```
gaussdb=# SELECT rtrim('TRIMxxxx','x');
 rtrim
-----
 TRIM
(1 row)
```

- `ltrim(string [, characters])`

Description: Removes the longest string containing only characters from characters (a space by default) from the start of string.

Return type: text

Example:

```
gaussdb=# SELECT ltrim('xxxxTRIM','x');
 ltrim
-----
 TRIM
(1 row)
```

- `upper(string)`

Description: Converts the string into the uppercase.

Return type: text

Example:

```
gaussdb=# SELECT upper('tom');
 upper
-----
 TOM
(1 row)
```

- `lower(string)`

Description: Converts the string into the lowercase.

Return type: text

Example:

```
gaussdb=# SELECT lower('TOM');
 lower
-----
 tom
(1 row)
```

- `nls_upper(string [, nlsparam])`

Description: Converts a character string to uppercase letters. You can specify a sorting rule to process special uppercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **upper**.

Return type: text

Example:

```
gaussdb=# SELECT nls_upper('große');
 nls_upper
-----
 GROBE
(1 row)
gaussdb=# SELECT nls_upper('große', 'nls_sort = XGerman');
 nls_upper
-----
 GROSSE
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `nls_lower(string [, nlsparam])`

Description: Converts a character string to lowercase letters. You can specify a sorting rule to process special lowercase conversion rules in some languages. The format of **nlsparam** is '**nls\_sort=sort\_name**', where **sort\_name** is replaced by the specific sorting rule name. When the **nlsparam** parameter is not set, this function is equivalent to **lower**.

Return type: text

Example:

```
gaussdb=# SELECT nls_lower('INDIVISIBILITY');
 nls_lower
-----
 indivisibility
(1 row)
gaussdb=# SELECT nls_lower('INDIVISIBILITY', 'nls_sort = XTurkish');
 nls_lower
-----
 indivisibility
(1 row)
```

 **NOTE**

This function can be used only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `instr(string,substring[,position,occurrence])`

Description: Queries and returns the value of the substring position that occurs the **occurrence** (1 by default) times from the **position** (1 by default) in the string.

- If the value of **position** is **0**, **0** is returned.
- If the value of **position** is negative, searches backwards from the last *n*th character in the string, in which *n* indicates the absolute value of **position**.

In this function, the calculation unit is character. One Chinese character is one character.

Return type: integer

Example:

```
gaussdb=# SELECT instr('corporate floor','or', 3);
instr
-----
      5
(1 row)
gaussdb=# SELECT instr('corporate floor','or',-3,2);
instr
-----
      2
(1 row)
```

- **initcap(string)**

Description: Capitalizes the first letter of each word in a string.

Return type: text

Example:

```
gaussdb=# SELECT initcap('hi THOMAS');
initcap
-----
Hi Thomas
(1 row)
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2** in A-compatible database, if a case-insensitive character, such as Chinese, is followed by a case-sensitive character, only the first letter of the case-sensitive character is capitalized. Therefore, you are advised to set **a\_format\_version** to **10c** and **a\_format\_dev\_version** to **s2**.

- **ascii(string)**

Description: Indicates the ASCII code of the first character in the string.

Return type: integer

Example:

```
gaussdb=# SELECT ascii('xyz');
ascii
-----
    120
(1 row)
```

- **ascii2(string)**

Description: Returns the decimal code of the first character of the input string in the database character set.

Return type: integer

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `asciistr(string)`

Description: Converts non-ASCII characters in the input string to `\XXXX`, where `XXXX` indicates the UTF-16 code unit.

Return type: `varchar`

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `unistr(string)`

Description: Converts the coding sequence in a string into the corresponding character. Other characters remain unchanged.

Return type: `text`

 NOTE

- This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.
  - The backslash (`\`) must be followed by four hexadecimal characters to indicate the coding sequence, or another backslash (`\`) indicates that a single backslash (`\`) is entered.
  - If the input parameter is of the time type, the time type is implicitly converted to the character string type.
- `vsize(expr)`

Description: Returns the number of bytes of the input expression.

Return type: `int`

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `replace(string varchar, search_string varchar, replacement_string varchar)`

Description: Replaces all **search\_string** in the string with **replacement\_string**.

Return type: `varchar`

Example:

```
gaussdb=# SELECT replace('jack and jue','j','bl');
replace
-----
black and blue
(1 row)
```

- `concat(str1,str2)`

Description: Connects `str1` and `str2` and returns the string. Note: **concat** calls the output function of the data type and the return value is immutable. As a result, the optimizer cannot calculate the result in advance when generating a plan. If there are performance requirements, you are advised to use the operator `||`.

**NOTICE**

- If **sql\_compatibility** is set to 'B' and **str1** or **str2** is set to **NULL**, the returned result is **NULL**.
- The return value of the concat function is of the variable-length type. When the concat function is compared with table data, the character string length is lost in the combination result. As a result, the comparison results are different.

Return type: varchar

Example:

```
gaussdb=# SELECT concat('Hello', ' World!');
concat
-----
Hello World!
(1 row)
gaussdb=# SELECT concat('Hello', NULL);
concat
-----
Hello
(1 row)
gaussdb=# CREATE TABLE test_space(c char(10));
CREATE TABLE
gaussdb=# CREATE TABLE test_space VALUES('a');
INSERT 0 1
-- After spaces are padded, the character string is still a fixed-length character string. It is expected
that the result can be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a ';
c
-----
a
(1 row)
-- The combination result is a variable-length character string. The comparison fails and the result
cannot be found.
gaussdb=# SELECT * FROM test_space WHERE c = 'a' || ' ';
c
---
(0 rows)
```

- **chr(integer)**

Description: For the UTF-8 character set, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

Return type: text

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an A-compatible database, the value is truncated instead of being rounded off if the value of *integer* is a decimal.

Example:

```
gaussdb=# SELECT chr(65);
chr
----
A
(1 row)
-- If the UTF-8 character set is used (the database character set has been set to UTF-8 during
database creation, the database character set cannot be reset).
gaussdb=# SELECT chr(19968);
chr
```

```
-----
chr
(1 row)
```

- `chr(cvalue int|bigint)`

Description: Converts *cvalue* to the character of the corresponding byte order and returns the character.

*cvalue* can be converted into a value of the int or bigint type. The value range is  $[0, 2^{32} - 1]$ , corresponding to the range of unsigned int. A character array consisting of one to four bytes is returned based on the value of *n*. The byte arrays returned in different character sets are the same. However, due to different encoding rules, the result of the returned character string varies depending on the character set encoding.

If the character set is a single-byte character set, an ASCII character is returned after *cvalue* mod 256.

Precautions:

- If a byte in the input *cvalue* is **0**, the output is truncated.
- If the input does not comply with the encoding rule of the current character set, an error is reported.
- If the input is **NULL** or **0**, **NULL** is returned.

Return type: text

Example:

```
gaussdb=# SELECT chr(65);
chr
-----
A
(1 row)
gaussdb=# SET a_format_version='10c';
gaussdb=# SET a_format_dev_version = 's1';
gaussdb=# SELECT chr(16705);
chr
-----
AA
(1 row)

-- The output is truncated.
gaussdb=# SELECT chr(4259905);
chr
-----
A
(1 row)
```

#### NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an A-compatible database, the `chr` function returns a character in the collation based on the input value. If the current character set for database encoding is a multi-byte character set, the return value contains one to four bytes. If the current character set for database encoding is a single-byte character set, the return value is a single byte obtained by performing the mod 256 operation on the input value. Otherwise, if the current character set for database encoding is UTF-8, the input is encoded as Unicode and a UTF-8 character is returned. For other character sets, an ASCII character is returned.

- `regexp_substr(source_char, pattern)`

Description: Extracts substrings from a regular expression. If the SQL syntax is A- and B-compatible and the value of the GUC parameter

**behavior\_compat\_options** contains **aformat\_regexp\_match**, the period (.)

cannot match the '\n' character. If **format\_regex\_match** is not contained, the period (.) matches the '\n' character by default.

Return type: text

Example:

```
gaussdb=# SELECT regexp_substr('500 Hello World, Redwood Shores, CA', '[^,]+,')
"REGEXPR_SUBSTR";
REGEXPR_SUBSTR
-----
, Redwood Shores,
(1 row)
```

- `regexp_replace(string, pattern, replacement [,flags ])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

The replacement string can contain \n, where n is 1 through 9, to indicate that the source substring matching the *n*th parenthesized sub-expression of the pattern should be inserted, and it can contain \& to indicate that the substring matching the entire pattern should be inserted.

The optional **flags** argument contains zero or multiple single-letter flags that change the function behavior. The options supported by **flags** and description are shown in [Table 7-28](#).

Return type: varchar

Example:

```
gaussdb=# SELECT regexp_replace('Thomas', '[mN]a.', 'M');
regexp_replace
-----
ThM
(1 row)
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\1Y', 'g') AS
RESULT;
result
-----
fooXarYXazY
(1 row)
```

- `repexp_replace(string text, pattern text [, replacement text [, position int [, occurrence int [, flags text]]]])`

Description: Replaces substrings matching the POSIX-style regular expression. The source string is returned unchanged if there is no match to the pattern. If there is a match, the source string is returned with the replacement string substituted for the matching substring.

Parameter description:

- **string**: source character string used for matching.
- **pattern**: regular expression pattern string used for matching.
- **replacement**: character string used to replace the matched substring. This parameter is optional. If no parameter value is specified or the parameter value is null, an empty string is used for replacement.
- **position**: start character of the source string used for matching. This parameter is optional. The default value is **1**.
- **occurrence**: sequence number of the matched substring to be replaced. This parameter is optional. The default value is **1**, indicating that the first matched substring is replaced.

- **flags**: contains zero or multiple single-letter flags that change the matching behavior of the function. This parameter is optional. The options supported by **flags** and description are shown in [Table 7-28](#).

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an A-compatible database, the default value of **occurrence** is **0**, indicating that all matched substrings are replaced. In addition, the **pattern** parameter that ends with a backslash (\) is valid.

Return type: text

Example:

```
gaussdb=# SELECT regexp_replace('foobarbaz','b(..)', E'X\1Y', 2, 2, 'n') AS RESULT;
result
-----
foobarXazY
(1 row)
```

- `concat_ws(sep text, str"any" [, str"any" [, ...] ])`

Description: Uses the first parameter as the separator, which is associated with all following parameters. The **NULL** parameter is ignored.

**NOTICE**

- If the first parameter value is **NULL**, the returned result is **NULL**.
- If the first parameter is provided but the parameter value is an empty string (") and the SQL compatibility mode of the database is set to **A**, the returned result is **NULL**. This is because the A-compatible mode treats the empty string (") as **NULL**. To resolve this problem, you can change the SQL compatibility mode of the database to B, C, or PG.

Return type: text

Example:

```
gaussdb=# SELECT concat_ws(',', 'ABCDE', 2, NULL, 22);
concat_ws
-----
ABCDE,2,22
(1 row)
```

- `nlsort(string text, sort_method text)`

Description: Returns the encoding value of a string in the sorting mode specified by **sort\_method**. The encoding value can be used for sorting and determines the sequence of the string in the sorting mode. Currently, **sort\_method** can be set to **nls\_sort=schinese\_pinyin\_m** or **nls\_sort=generic\_m\_ci**. **nls\_sort=generic\_m\_ci** supports only the case-insensitive order for English characters.

String type: text

sort\_method type: text

Return type: text

Example:

```
gaussdb=# CREATE TABLE test(a text);
gaussdb=# INSERT INTO test(a) VALUES ('abC');
gaussdb=# INSERT INTO test(a) VALUES ('abC');
gaussdb=# INSERT INTO test(a) VALUES ('abc');
```

```
gaussdb=# SELECT * FROM test ORDER BY nlssort(a,'nls_sort=schinese_pinyin_m');
 a
-----
abc
abC
abC
(3 rows)
gaussdb=# SELECT * FROM test ORDER BY nlssort(a, 'nls_sort=generic_m_ci');
 a
-----
abC
abc
abC
(3 rows)
gaussdb=# DROP TABLE test;
```

- `convert(string bytea, src_encoding name, dest_encoding name)`  
Description: Converts the string to **dest\_encoding**. **src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: bytea

Example:

```
gaussdb=# SELECT convert('text_in_utf8', 'UTF8', 'GBK');
 convert
-----
\x746578745f696e5f75746638
(1 row)
```

#### NOTE

If the rule for converting between source to target encoding (for example, GBK and LATIN1) does not exist, the string is returned without conversion. See the `pg_conversion` system catalog for details.

Example:

```
gaussdb=# SHOW server_encoding;
 server_encoding
-----
LATIN1
(1 row)

gaussdb=# SELECT convert_from('some text', 'GBK');
 convert_from
-----
some text
(1 row)

db_latin1=# SELECT convert_to('some text', 'GBK');
 convert_to
-----
\x736f6d652074657874
(1 row)

db_latin1=# SELECT convert('some text', 'GBK', 'LATIN1');
 convert
-----
\x736f6d652074657874
(1 row)
```

- `convert_from(string bytea, src_encoding name)`  
Description: Converts a string using the coding mode of the database. **src\_encoding** specifies the source code encoding. The string must be valid in this encoding.

Return type: text

Example:

```
gaussdb=# SELECT convert_from('text_in_utf8', 'UTF8');
convert_from
-----
text_in_utf8
(1 row)
```

- `convert_to(string text, dest_encoding name)`  
Description: Converts a string to **dest\_encoding**.  
Return type: bytea

Example:

```
gaussdb=# SELECT convert_to('some text', 'UTF8');
convert_to
-----
\x736f6d652074657874
(1 row)
```

- `string [NOT] LIKE pattern [ESCAPE escape-character]`

Description: Specifies the pattern matching function.

If the pattern does not include a percentage sign (%) or an underscore (\_), this mode represents itself only. In this case, the behavior of LIKE is the same as the equal operator. The underscore (\_) in the pattern matches any single character while one percentage sign (%) matches no or multiple characters.

To match with underscores (\_) or percent signs (%), corresponding characters in **pattern** must lead escape characters. The default escape character is a backward slash (\) and can be specified using the **ESCAPE** clause. To match with escape characters, enter two escape characters.

Return type: Boolean

Example:

```
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' ESCAPE '@' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'AA_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'AA@_BBCC' LIKE '%A@_B%' AS RESULT;
result
-----
t
(1 row)
```

- `REGEXP_LIKE(source_string, pattern [, match_parameter])`

Description: Indicates the mode matching function of a regular expression.

**source\_string** indicates the source string and **pattern** indicates the matching pattern of the regular expression. **match\_parameter** indicates the matching items and the values are as follows:

- 'i': case-insensitive
- 'c': case-sensitive
- 'n': allowing the metacharacter "." in a regular expression to be matched with a linefeed.
- 'm': allows **source\_string** to be regarded as multiple rows.

If **match\_parameter** is ignored, **case-sensitive** is enabled by default, "." is not matched with a linefeed, and **source\_string** is regarded as a single row.

Return type: Boolean

Example:

```
gaussdb=# SELECT regexp_like('ABC', '[A-Z]');
regexp_like
-----
t
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[D-Z]');
regexp_like
-----
f
(1 row)
gaussdb=# SELECT regexp_like('ABC', '[a-z]', 'i');
regexp_like
-----
t
(1 row)
```

- `format(formatstr text [, str"any" [, ...] ])`

Description: Formats a string.

Return type: text

Example:

```
gaussdb=# SELECT format('Hello %s, %1$s', 'World');
format
-----
Hello World, World
(1 row)
```

- `md5(string)`

Description: Encrypts a string in MD5 mode and returns a value in hexadecimal form.

 **NOTE**

The MD5 encryption algorithm is not recommended because it has lower security and poses security risks.

Return type: text

Example:

```
gaussdb=# SELECT md5('ABC');
md5
-----
902fbdd2b1df0c4f70b4a5d23525e932
(1 row)
```

- `sha(string) / sha1(string)`

Description: Encrypts a string using SHA1 and returns a hexadecimal number. The sha and sha1 functions are the same.

 **NOTE**

- The SHA1 encryption algorithm is not recommended because it has lower security and poses security risks.
- This function is valid only when GaussDB is compatible with the MY type (that is, `sql_compatibility` is set to 'B').

Return type: text

Example:

```
gaussdb=# SELECT sha('ABC');
sha
-----
3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
```

```
(1 row)
gaussdb=# SELECT sha1('ABC');
          sha1
-----
3c01bdbb26f358bab27f267924aa2c9a03fcfdb8
(1 row)
```

- sha2(string, hash\_length)

Description: Encrypts a string in SHA2 mode and returns a value in hexadecimal form.

*hash\_length*: corresponds to an SHA2 algorithm. The value can be **0** (SHA-256), **224** (SHA-224), **256** (SHA-256), **384** (SHA-384), or **512** (SHA-512). For other values, **NULL** is returned.

 **NOTE**

- The SHA-224 encryption algorithm is not recommended because it has lower security and poses security risks.
- The SHA2 function records hash plaintext in logs. Therefore, you are advised not to use this function to encrypt sensitive information such as keys.
- This function is valid only when GaussDB is B-compatible (that is, **sql\_compatibility** is set to 'B').

Return type: text

Example:

```
gaussdb=# SELECT sha2('ABC',224);
          sha2
-----
107c5072b799c4771f328304cfe1ebb375eb6ea7f35a3aa753836fad
(1 row)
gaussdb=# SELECT sha2('ABC',256);
          sha2
-----
b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
gaussdb=# SELECT sha2('ABC',0);
          sha2
-----
b5d4045c3f466fa91fe2cc6abe79232a1a57cdf104f7a26e716e0a1e2789df78
(1 row)
```

- decode(string text, format text)

Description: Decodes binary data from textual representation.

Return type: bytea

Example:

```
gaussdb=# SELECT decode('MTIzAAE=', 'base64');
          decode
-----
\x3132330001
(1 row)
```

- similar\_escape(pat text, esc text)

Description: Converts a regular expression of the SQL:2008 style to the POSIX style.

Return type: text

Example:

```
gaussdb=# SELECT similar_escape('\s+ab','2');
          similar_escape
-----
^(?!\s+ab)$
(1 row)
```

- `find_in_set(text, set)`

Description: Finds the position of a given member in a set, counting from 1. If no record is found, 0 is returned.

Return type: `int2`

Example:

```
gaussdb=# CREATE DATABASE gaussdb_b WITH DBCOMPATIBILITY 'B';
gaussdb=# \c gaussdb_b
gaussdb_b=# CREATE TABLE employee (
  name text,
  site SET('beijing','shanghai','nanjing','wuhan')
);

gaussdb_b=# INSERT INTO employee values('zhangsan', 'beijing,nanjing');
gaussdb_b=# INSERT INTO employee values('zhangsan2', 'beijing,wuhan');

gaussdb_b=# select site, find_in_set('wuhan', site) from employee;
  site      | find_in_set
-----+-----
beijing,nanjing |      0
beijing,wuhan  |      2
(2 rows)

gaussdb_b=# DROP TABLE employee;
gaussdb_b=# \c postgres
gaussdb=# DROP DATABASE gaussdb_b;
```

- `encode(data bytea, format text)`

Description: Encodes binary data into a textual representation.

Return type: `text`

Example:

```
gaussdb=# SELECT encode(E'123\000\001', 'base64');
 encode
-----
MTIzAAE=
(1 row)
```

#### NOTE

- For a string containing newline characters, for example, a string consisting of a newline character and a space, the value of **length** and **lengthb** in GaussDB is 2.
- In GaussDB, *n* in the `CHAR(n)` type indicates the number of characters. Therefore, for multiple-octet coded character sets, the length returned by the `LENGTHB` function may be longer than *n*.
- GaussDB supports multiple types of databases, including A-, B-, C-, and PG-compatible. If the database type is not specified, A is used by default. The lexical analyzer of A database is different from that of the other three databases. In A database, an empty character string is considered as **NULL**. Therefore, when a type A database is used, if an empty string is used as a parameter in the preceding character operation function, no output is displayed. For example:

```
gaussdb=# SELECT translate('12345','123','');
 translate
-----
(1 row)
```

This is because the kernel checks whether the input parameter contains **NULL** before calling the corresponding function. If yes, the kernel does not call the corresponding function. As a result, no output is displayed. In PG mode, the processing of character strings is the same as that of PostgreSQL. Therefore, the preceding problem does not occur.

## Extension Functions and Operators

- pkg\_bpchar\_opc()

Description: Serves as an extension API to add the comparison operator between bpchar and text or between text and bpchar policies, so as to solve the problem that indexes cannot be matched when data of the bpchar and text types is compared. Only the system administrator can install extensions.

### NOTICE

The extended function is for internal use only. You are advised not to use it.

Example:

The tables **logs\_nchar**, **logs\_char**, **logs\_varchar2**, and **logs\_text** are as follows:

```
/*
logs_nchar table
*/
DROP TABLE IF EXISTS logs_nchar;
CREATE TABLE logs_nchar
(
  log_id  NCHAR(16),
  log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_nchar_logid;
CREATE INDEX idx_nchar_logid ON logs_nchar(log_id);
INSERT INTO logs_nchar VALUES('FE306991300002 ', '111');
INSERT INTO logs_nchar VALUES('FE306991300003 ', '222');
INSERT INTO logs_nchar VALUES('FE306991300004 ', '222');

/*
logs_char table
*/
DROP TABLE IF EXISTS logs_char;
CREATE TABLE logs_char
(
  log_id  CHAR(16),
  log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_char_logid;
CREATE INDEX idx_char_logid ON logs_char(log_id);
INSERT INTO logs_char VALUES('FE306991300002 ', '111');
INSERT INTO logs_char VALUES('FE306991300003 ', '222');
INSERT INTO logs_char VALUES('FE306991300004 ', '222');

/*
logs_varchar2 table
*/
DROP TABLE IF EXISTS logs_varchar2;
CREATE TABLE logs_varchar2
(
  log_id  VARCHAR2(16),
  log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_varchar2_logid;
CREATE INDEX idx_varchar2_logid ON logs_varchar2(log_id);
INSERT INTO logs_varchar2 VALUES('FE306991300002 ', '111');
INSERT INTO logs_varchar2 VALUES('FE306991300003 ', '222');
INSERT INTO logs_varchar2 VALUES('FE306991300004 ', '222');

/*
logs_text table
```

```

*/
DROP TABLE IF EXISTS logs_text;
CREATE TABLE logs_text
(
  log_id text,
  log_message VARCHAR2(255) NOT NULL
);
DROP INDEX IF EXISTS idx_text_logid;
CREATE INDEX idx_text_logid ON logs_text(log_id);
INSERT INTO logs_text VALUES('FE306991300002 ', '111');
INSERT INTO logs_text VALUES('FE306991300003 ', '222');
INSERT INTO logs_text VALUES('FE306991300004 ', '222');

```

Compare the bpchar type with the text type (initial state, forward compatibility).

```

/*
If no extension is installed, when nchar and text are compared, nchar is implicitly converted to text because there is no bpchar or text index operator. That is, the fixed-length character type is converted to the variable-length character type. As a result, the execution plan changes and the index cannot be matched.
*/

```

```

gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,' ');

```

QUERY PLAN

```

-----
Seq Scan on logs_nchar (cost=0.00..11.99 rows=1 width=584)
  Filter: ((log_id)::text = 'FE306991300002 '::text)
(2 rows)

```

```

/*
The log_id column in the logs_nchar table is of nchar(16) type. The inserted data is 'FE306991300002 ', which is implicitly converted to text. During comparison, spaces are deleted, that is, 'FE306991300002'='FE306991300002 '. Therefore, the data is not matched.
*/

```

```

gaussdb=# SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,' ');
log_id | log_message
-----+-----
(0 rows)

```

Compare the bpchar type with the text type (the pkg\_bpchar\_opc extension is installed, which is A-compatible).

```

/*
The system administrator installs the pkg_bpchar_opc extension. The comparison operators of the bpchar and text types and index-related content are added to the database.
*/

```

```

gaussdb=# CREATE EXTENSION pkg_bpchar_opc;
CREATE EXTENSION

```

```

/*
In this case, when log_id is implicitly converted to the bpchar type and compared with the text type, the comparison operator and index information can be found, and the index can be matched.
*/

```

```

gaussdb=# EXPLAIN SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,' ');

```

QUERY PLAN

```

-----
[Bypass]
Index Scan using idx_nchar_logid on logs_nchar (cost=0.00..8.27 rows=1 width=584)
  Index Cond: (log_id = 'FE306991300002 '::text)
(3 rows)

```

```

gaussdb=# SELECT * FROM logs_nchar WHERE log_id = RPAD(TRIM('FE306991300002 '),16,' ');
log_id | log_message
-----+-----

```

```

FE306991300002 | 111
(1 row)

```

```

gaussdb=# DROP EXTENSION pkg_bpchar_opc;
DROP EXTENSION

```

Compare the text type with the bpchar type (initial state, forward compatibility).

```

Index Cond: (log_id = 'FE306991300002 '::bpchar)
(3 rows)
gaussdb=# DROP EXTENSION pkg_bpchar_opc;
DROP EXTENSION
```

Compare the text type with the bpchar type (initial state, forward compatibility).

```
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = t2.log_id;
log_id | log_message | log_id | log_message
-----+-----+-----+-----
FE306991300002 | 111 | FE306991300002 | 111
FE306991300003 | 222 | FE306991300003 | 222
FE306991300004 | 222 | FE306991300004 | 222
(3 rows)
gaussdb=# EXPLAIN SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = t2.log_id;
QUERY PLAN
-----
Hash Join (cost=12.99..26.15 rows=133 width=1150)
Hash Cond: ((t1.log_id)::bpchar = t2.log_id)
-> Seq Scan on logs_varchar2 t1 (cost=0.00..11.37 rows=137 width=566)
-> Hash (cost=11.33..11.33 rows=133 width=584)
-> Seq Scan on logs_char t2 (cost=0.00..11.33 rows=133 width=584)
(5 rows)
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = 'FE306991300002 '::bpchar;
log_id | log_message | log_id | log_message
-----+-----+-----+-----
FE306991300002 | 111 | FE306991300002 | 111
FE306991300002 | 111 | FE306991300003 | 222
FE306991300002 | 111 | FE306991300004 | 222
(3 rows)
```

Compare the text type with the bpchar type (the pkg\_bpchar\_opc extension is installed, which is A-compatible).

```
gaussdb=# CREATE EXTENSION pkg_bpchar_opc;
CREATE EXTENSION
/*
```

This format is not recommended. After the extension is installed, the varchar2 type of **log\_id** in the **t1** table is implicitly converted to the text type. When it is compared with the **log\_id** in the **t2** table, the char type of **log\_id** in the **t2** table is implicitly converted to the bpchar type. In this case, spaces after **log\_id** is removed by the database, that is, 'FE306991300002'='FE306991300002 '. Therefore, no data is matched.

```

*/
/*
Incorrect example:
*/
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = t2.log_id;
 log_id | log_message | log_id | log_message
-----+-----+-----+-----
(0 rows)
gaussdb=# explain SELECT * FROM logs_varchar2 t1, logs_char t2
WHERE t1.log_id = t2.log_id;
              QUERY PLAN
-----
Hash Join  (cost=12.99..26.15 rows=133 width=1150)
  Hash Cond: ((t1.log_id)::text = t2.log_id)
    -> Seq Scan on logs_varchar2 t1  (cost=0.00..11.37 rows=137
width=566)
    -> Hash  (cost=11.33..11.33 rows=133 width=584)
        -> Seq Scan on logs_char t2  (cost=0.00..11.33 rows=1
33 width=584)
(5 rows)
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = 'FE306991300002 ' ;
 log_id | log_message | log_id | log_message
-----+-----+-----+-----
FE306991300002 | 111      | FE306991300002 | 111
FE306991300002 | 111      | FE306991300003 | 222
FE306991300002 | 111      | FE306991300004 | 222
(3 rows)
*/
/*
This format is recommended to avoid the following problems: the data type of log_id in the t1 table
is converted to the text type, spaces are reserved during comparison, and data cannot be matched
when the data type of log_id in the t2 table is compared with the data type of log_id in the t1 table.
The type of t1 table is forcibly converted to the bpchar type before the extension is installed, that is,
'FE306991300002' = 'FE306991300002'. Therefore, data is matched.
*/
/*
Correct example:
*/
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id::bpchar = t2.log_id;
 log_id | log_message | log_id | log_message
-----+-----+-----+-----
FE306991300002 | 111      | FE306991300002 | 111
FE306991300003 | 222      | FE306991300003 | 222
FE306991300004 | 222      | FE306991300004 | 222
(3 rows)
*/
/*
The execution plan is the same as that before the extension is installed.
*/
gaussdb=# EXPLAIN SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id::bpchar =
t2.log_id;
              QUERY PLAN
-----
Hash Join  (cost=12.99..26.15 rows=133 width=1150)
  Hash Cond: ((t1.log_id)::bpchar = t2.log_id)
    -> Seq Scan on logs_varchar2 t1  (cost=0.00..11.37 rows=137 width=566)
    -> Hash  (cost=11.33..11.33 rows=133 width=584)
        -> Seq Scan on logs_char t2  (cost=0.00..11.33 rows=133 width=584)
(5 rows)
gaussdb=# SELECT * FROM logs_varchar2 t1, logs_char t2 WHERE t1.log_id = 'FE306991300002 ' ;
 log_id | log_message | log_id | log_message
-----+-----+-----+-----
FE306991300002 | 111      | FE306991300002 | 111
FE306991300002 | 111      | FE306991300003 | 222
FE306991300002 | 111      | FE306991300004 | 222
(3 rows)
gaussdb=# DROP EXTENSION pkg_bpchar_opc;
DROP EXTENSION

```

```
gaussdb=# DROP TABLE logs_nchar;
gaussdb=# DROP TABLE logs_char;
gaussdb=# DROP TABLE logs_varchar2;
gaussdb=# DROP TABLE logs_text;
```

 **NOTE**

- This solves the problem that data and indexes cannot be properly matched when equality matching is performed between the bpchar type (containing multiple spaces) and the text type.
- The UB-tree and B-tree are involved. The comparison symbols include >, >=, <, <=, and <>.
- The impact scope involves implicit conversion between character types. For example, when a variable-length data type is compared with a fixed-length data type, the variable-length data type is preferentially converted to the text type instead of the original bpchar type.
- The pkg\_bpchar\_opc extension is disabled by default. You can check whether the extension is enabled in the pg\_extension system catalog. If the extension data exists, the extension is enabled. If the extension data does not exist, the extension is disabled. When extension is disabled, forward compatibility is maintained. When extension is enabled, compatibility with database A is maintained. The extended function is for internal use only. You are advised not to use it.

**Table 7-29** Functions supported by pkg\_bpchar\_opc

| Name                       | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| pg_catalog.bpchar_text_lt  | Compares the bpchar type with the text type to check whether the value on the left is less than the value on the right.                |
| pg_catalog.bpchar_text_le  | Compares the bpchar type with the text type to check whether the value on the left is less than or equal to the value on the right.    |
| pg_catalog.bpchar_text_eq  | Compares the bpchar type with the text type to check whether the value on the left is equal to the value on the right.                 |
| pg_catalog.bpchar_text_ge  | Compares the bpchar type with the text type to check whether the value on the left is greater than or equal to the value on the right. |
| pg_catalog.bpchar_text_gt  | Compares the bpchar type with the text type to check whether the value on the left is greater than the value on the right.             |
| pg_catalog.bpchar_text_ne  | Compares the bpchar type with the text type to check whether the value on the left is different from the value on the right.           |
| pg_catalog.bpchar_text_cmp | Specifies that the index of the bpchar and text types supports comparison functions.                                                   |
| pg_catalog.text_bpchar_lt  | Compares the text type with the bpchar type to check whether the value on the left is less than the value on the right.                |

| Name                       | Description                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| pg_catalog.text_bpchar_le  | Compares the text type with the bpchar type to check whether the value on the left is less than or equal to the value on the right.    |
| pg_catalog.text_bpchar_eq  | Compares the text type with the bpchar type to check whether the value on the left is equal to the value on the right.                 |
| pg_catalog.text_bpchar_ge  | Compares the text type with the bpchar type to check whether the value on the left is greater than or equal to the value on the right. |
| pg_catalog.text_bpchar_gt  | Compares the text type with the bpchar type to check whether the value on the left is greater than the value on the right.             |
| pg_catalog.text_bpchar_ne  | Compares the text type with the bpchar type to check whether the value on the left is different from the value on the right.           |
| pg_catalog.text_bpchar_cmp | Specifies that the index of the text and bpchar types supports comparison functions.                                                   |
| pg_catalog.hashbpchar_text | Specifies that the hash of the bpchar and text types supports comparison functions.                                                    |
| pg_catalog.hashtextbpchar  | Specifies that the hash of the text and bpchar types supports comparison functions.                                                    |

## 7.5.4 Binary String Functions and Operators

### String Operators

SQL defines some string functions that use keywords, rather than commas, to separate arguments.

- `octet_length(string)`

Description: Specifies the number of bytes in a binary string.

Return type: int

Example:

```
gaussdb=# SELECT octet_length(E'jo\000se'::bytea) AS RESULT;
result
-----
      5
(1 row)
```

- `overlay(string placing string from int [for int])`

Description: Replaces substrings.

Return type: bytea

Example:

```
gaussdb=# SELECT overlay(E'Th\000omas'::bytea placing E'\002\003'::bytea from 2 for 3) AS
RESULT;
```

```

result
-----
\x5402036d6173
(1 row)

```

- `position(substring in string)`

Description: Specifies the location of a specified substring.

Return type: int

Example:

```

gaussdb=# SELECT position(E'\000om'::bytea in E'Th\000omas'::bytea) AS RESULT;
result
-----
3
(1 row)

```

- `substring(string [from int] [for int])`

Description: Truncates a substring.

Return type: bytea

Example:

```

gaussdb=# SELECT substring(E'Th\000omas'::bytea from 2 for 3) AS RESULT;
result
-----
\x68006f
(1 row)

```

- `substr(string, from int [, for int])`

Description: Truncates a substring.

Return type: bytea

Example:

```

gaussdb=# SELECT substr(E'Th\000omas'::bytea,2, 3) as result;
result
-----
\x68006f
(1 row)

```

- `trim([both] bytes from string)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```

gaussdb=# SELECT trim(E'\000'::bytea from E'\000Tom\000'::bytea) AS RESULT;
result
-----
\x546f6d
(1 row)

```

## Other Binary String Functions

GaussDB provides common syntax used for calling functions.

- `btrim(string bytea,bytes bytea)`

Description: Removes the longest string containing only bytes from **bytes** from the start and end of **string**.

Return type: bytea

Example:

```

gaussdb=# SELECT btrim(E'\000trim\000'::bytea, E'\000'::bytea) AS RESULT;
result

```

```
-----  
\x7472696d  
(1 row)
```

- `get_bit(string, offset)`

Description: Extracts bits from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_bit(E'Th\000omas'::bytea, 45) AS RESULT;  
result  
-----  
1  
(1 row)
```

- `get_byte(string, offset)`

Description: Extracts bytes from a string.

Return type: int

Example:

```
gaussdb=# SELECT get_byte(E'Th\000omas'::bytea, 4) AS RESULT;  
result  
-----  
109  
(1 row)
```

- `set_bit(string,offset, newvalue)`

Description: Sets bits in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_bit(E'Th\000omas'::bytea, 45, 0) AS RESULT;  
result  
-----  
\x5468006f6d4173  
(1 row)
```

- `set_byte(string,offset, newvalue)`

Description: Sets bytes in a string.

Return type: bytea

Example:

```
gaussdb=# SELECT set_byte(E'Th\000omas'::bytea, 4, 64) AS RESULT;  
result  
-----  
\x5468006f406173  
(1 row)
```

- `rawcmp`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: integer

- `raweq`

Description: Specifies the raw data type comparison function.

Parameter: raw, raw

Return type: Boolean

- `rawge`

Description: Specifies the raw data type comparison function.

- Parameter: raw, raw  
Return type: Boolean
- rawgt  
Description: Specifies the raw data type comparison function.  
Parameter: raw, raw  
Return type: Boolean
- rawin  
Description: Specifies the raw data type parsing function.  
Parameter: cstring  
Return type: bytea
- rawle  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
- rawlike  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
- rawlt  
Description: Specifies the raw data type parsing function.  
Parameter: raw, raw  
Return type: Boolean
- rawne  
Description: Compares whether the raw types are the same.  
Parameter: raw, raw  
Return type: Boolean
- rawnlike  
Description: Checks whether the raw type matches the mode.  
Parameter: raw, raw  
Return type: Boolean
- rawout  
Description: Specifies the RAW output API.  
Parameter: bytea  
Return type: cstring
- rawsend  
Description: Converts the bytea type to the binary type.  
Parameter: raw  
Return type: bytea
- rawtohex  
Description: Converts the raw format to the hexadecimal format.  
Parameter: text

Return type: text

## 7.5.5 Bit String Functions and Operators

### Bit String Operators

Aside from the usual comparison operators, the following operators can be used. Bit string operands of **&**, **|**, and **#** must be of equal length. In case of bit shifting, the original length of the string is preserved by zero padding (if necessary).

- **||**

Description: Connects bit strings.

Example:

```
gaussdb=# SELECT B'10001' || B'011' AS RESULT;
result
-----
10001011
(1 row)
```

#### NOTE

- It is recommended that a column have no more than 180 consecutive internal joins. A column with over 180 joins will be split into joined consecutive strings. Example: **str1||str2||str3||str4** is split into **(str1||str2)||str3||str4**.
- In A-compatible mode, if bit strings contain a null string, the null string is ignored and other strings are joined. In other compatibility modes, the null string is returned. Take **str1||NULL||str2** as an example. **str1str2** is returned in A-compatible mode and **NULL** is returned in other compatibility modes.

- **&**

Description: Specifies the AND operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' & B'01101' AS RESULT;
result
-----
00001
(1 row)
```

- **|**

Description: Specifies the OR operation between bit strings.

Example:

```
gaussdb=# SELECT B'10001' | B'01101' AS RESULT;
result
-----
11101
(1 row)
```

- **#**

Description: Specifies the OR operation between bit strings if they are inconsistent. If the same positions in the two bit strings are both 1 or 0, the position returns **0**.

Example:

```
gaussdb=# SELECT B'10001' # B'01101' AS RESULT;
result
-----
```

- ```
11100
(1 row)
```

• ~

Description: Specifies the NOT operation between bit strings.

Example:

```
gaussdb=# SELECT ~B'10001' AS RESULT;
result
-----
01110
(1 row)
```
- <<

Description: Shifts left in a bit string.

Example:

```
gaussdb=# SELECT B'10001' << 3 AS RESULT;
result
-----
01000
(1 row)
```
- >>

Description: Shifts right in a bit string.

Example:

```
gaussdb=# SELECT B'10001' >> 2 AS RESULT;
result
-----
00100
(1 row)
```

The following SQL-standard functions work on bit strings as well as strings: **length**, **bit\_length**, **octet\_length**, **position**, **substring**, and **overlay**.

The following functions work on bit strings as well as binary strings: **get\_bit** and **set\_bit**. When working with a bit string, these functions number the first (leftmost) bit of the string as bit 0.

In addition, it is possible to convert between integral values and type **bit**. Example:

```
gaussdb=# SELECT 44::bit(10) AS RESULT;
result
-----
0000101100
(1 row)

gaussdb=# SELECT 44::bit(3) AS RESULT;
result
-----
100
(1 row)

gaussdb=# SELECT cast(-44 as bit(12)) AS RESULT;
result
-----
111111010100
(1 row)

gaussdb=# SELECT '1110'::bit(4)::integer AS RESULT;
result
-----
14
(1 row)

gaussdb=# SELECT substring('10101111'::bit(8), 2);
substring
```

```
-----  
0101111  
(1 row)
```

**NOTE**

Casting to just "bit" means casting to bit(1), and so will deliver only the least significant bit of the integer.

## 7.5.6 Pattern Matching Operators

The database provides three independent methods for implementing pattern matching: SQL LIKE operator, SIMILAR TO operator, and POSIX-style regular expressions. Besides these basic operators, functions can be used to extract or replace matching substrings and to split a string at matching locations.

- LIKE

Description: Specifies whether the string matches the pattern string following LIKE. The LIKE expression returns true if the string matches the supplied pattern. (As expected, the NOT LIKE expression returns false if LIKE returns true, and vice versa.)

Matching rules:

- This operator can succeed only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore (\_) represents (matching) any single character. Percentage (%) indicates the wildcard character of any string.
- To match a literal underscore or percent sign, the respective character in pattern must be preceded by the escape character. The default escape character is one backslash but a different one can be selected by using the ESCAPE clause.
- To match with escape characters, enter two escape characters. For example, to write a pattern constant containing a backslash (\), you need to enter two backslashes in SQL statements.

**NOTE**

When **standard\_conforming\_strings** is set to **off**, any backslashes you write in literal string constants will need to be doubled. Therefore, writing a pattern that matches a single backslash actually involves writing four backslashes in the statement (you can avoid this by selecting a different escape character with **ESCAPE** so that the backslash is no longer a special character of **LIKE**. But the backslash is still the special character of the character text analyzer. In this case, two backslashes are required.)

In MySQL-compatible schema, it is also possible to select no escape character by writing **ESCAPE ''**. This effectively disables the escape mechanism, which makes it impossible to turn off the special meaning of underscore and percent signs in the schema.

- The keyword **ILIKE** can be used instead of **LIKE** to make the match case-insensitive.
- Operator **~~** is equivalent to **LIKE**, and operator **~~\*** corresponds to **ILIKE**.

Example:

```
gaussdb=# SELECT 'abc' LIKE 'abc' AS RESULT;  
result
```

```

-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'a%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE '_b_' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' LIKE 'c' AS RESULT;
result
-----
f
(1 row)

```

- **SIMILAR TO**

Description: Returns true or false depending on whether the pattern matches the given string. It is similar to LIKE, but differs in that it uses the regular expression understanding pattern defined by the SQL standard.

Matching rules:

- Similar to LIKE, this operator succeeds only when its pattern matches the entire string. If you want to match a sequence in any position within the string, the pattern must begin and end with a percent sign.
- The underscore ( `_` ) represents (matching) any single character. Percentage ( `%` ) indicates the wildcard character of any string.
- SIMILAR TO supports these pattern-matching metacharacters borrowed from POSIX-style regular expressions:

Metacharacter	Description
	Specifies alternation (either of two alternatives).
*	Specifies repetition of the previous item zero or more times.
+	Specifies repetition of the previous item one or more times.
?	Specifies repetition of the previous item zero or one time.
{m}	Specifies repetition of the previous item exactly <i>m</i> times.
{m,}	Specifies repetition of the previous item <i>m</i> or more times.
{m,n}	Specifies repetition of the previous item at least <i>m</i> times and does not exceed <i>n</i> times.

Metacharacter	Description
()	Specifies that parentheses () can be used to group items into a single logical item.
[...]	Specifies a character class, just as in POSIX-style regular expressions.

- d. A preamble escape character disables the special meaning of any of these metacharacters. The rules for using escape characters are the same as those for LIKE.

Regular expressions:

The **substring(string from pattern for escape)** function extracts a substring that matches an SQL regular expression pattern.

Example:

```
gaussdb=# SELECT 'abc' SIMILAR TO 'abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO 'a' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '%(b|d)%' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' SIMILAR TO '(b|c)%' AS RESULT;
result
-----
f
(1 row)
```

- POSIX-style regular expressions

Description: A regular expression is a collation that is an abbreviated definition of a set of strings (a regular set). If a string is a member of a regular expression described by a regular expression, the string matches the regular expression. POSIX-style regular expressions provide a more powerful means for pattern matching than the LIKE and SIMILAR TO operators. [Table 7-30](#) lists all available operators for pattern matching using POSIX-style regular expressions.

**Table 7-30** Regular expression match operators

Operator	Description	Example
~	Matches a regular expression, which is case-sensitive.	'thomas' ~ '.*thomas.*'

Operator	Description	Example
~*	Matches a regular expression, which is case-insensitive.	'thomas' ~* '.*Thomas.*'
!~	Does not match a regular expression, which is case-sensitive.	'thomas' !~ '.*Thomas.*'
!~*	Does not match a regular expression, which is case-insensitive.	'thomas' !~* '.*vadim.*'

Matching rules:

- a. Unlike LIKE patterns, a regular expression is allowed to match anywhere within a string, unless the regular expression is explicitly anchored to the beginning or end of the string.
- b. Besides the metacharacters mentioned above, POSIX-style regular expressions also support the following pattern matching metacharacters:

Metacharacter	Description
^	Specifies the match starting with a string.
\$	Specifies the match at the end of a string.
.	Matches any single character.

Regular expressions:

POSIX-style regular expressions support the following functions:

- The **substring(string from pattern)** function provides a method for extracting a substring that matches the POSIX-style regular expression pattern.
- The **regexp\_count(string text, pattern text [, position int [, flags text]])** function provides the function of obtaining the number of substrings that match the POSIX-style regular expression pattern.
- The **regexp\_instr(string text, pattern text [, position int [, occurrence int [, return\_opt int [, flags text]]]])** function is used to obtain the position of a substring that matches a POSIX-style regular expression pattern.
- The **regexp\_substr(string text, pattern text [, position int [, occurrence int [, flags text]]])** function provides a method to extract a substring that matches a POSIX-style regular expression pattern.
- The **regexp\_replace(string, pattern, replacement [, flags ])** function replaces the substring that matches the POSIX-style regular expression pattern with the new text.

- The **regexp\_matches(string text, pattern text [, flags text])** function returns a text array consisting of all captured substrings that match a POSIX-style regular expression pattern.
- The **regexp\_split\_to\_table(string text, pattern text [, flags text])** function splits a string using a POSIX-style regular expression pattern as a delimiter.
- The **regexp\_split\_to\_array(string text, pattern text [, flags text ])** function behaves the same as `regexp_split_to_table`, except that `regexp_split_to_array` returns its result as an array of text.

 NOTE

The regular expression split functions ignore zero-length matches, which occur at the beginning or end of a string or after the previous match. This is contrary to the strict definition of regular expression matching. The latter is implemented by **regexp\_matches**, but the former is usually the most commonly used behavior in practice.

Example:

```
gaussdb=# SELECT 'abc' ~ 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~* 'Abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' !~ 'Abc' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' !~* 'Abc' AS RESULT;
result
-----
f
(1 row)
gaussdb=# SELECT 'abc' ~ '^a' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '(b|d)' AS RESULT;
result
-----
t
(1 row)
gaussdb=# SELECT 'abc' ~ '^ (b|c)' AS RESULT;
result
-----
f
(1 row)
```

Although most regular expression searches can be executed quickly, they can still be artificially processed to require any length of time and any amount of memory. It is not recommended that you accept the regular expression search pattern from the non-security pattern source. If you must do this, you are advised to add the statement timeout limit. The search with the SIMILAR TO pattern has the same security risks as the SIMILAR TO provides many capabilities that are the same as those of the POSIX-style regular expression.

The LIKE search is much simpler than the other two options. Therefore, it is more secure to accept the non-secure pattern source search.

## 7.5.7 Arithmetic Functions and Operators

### Arithmetic Operators

- +

Description: Addition

Example:

```
gaussdb=# SELECT 2+3 AS RESULT;  
result  
-----  
5  
(1 row)
```

- -

Description: Subtraction

Example:

```
gaussdb=# SELECT 2-3 AS RESULT;  
result  
-----  
-1  
(1 row)
```

- \*

Description: Multiplication

Example:

```
gaussdb=# SELECT 2*3 AS RESULT;  
result  
-----  
6  
(1 row)
```

- /

Description: Division (The result is not rounded.)

Example:

```
gaussdb=# SELECT 4/2 AS RESULT;  
result  
-----  
2  
(1 row)  
gaussdb=# SELECT 4/3 AS RESULT;  
result  
-----  
1.3333333333333333  
(1 row)
```

- +/-

Description: Positive/Negative

Example:

```
gaussdb=# SELECT -2 AS RESULT;  
result  
-----  
-2  
(1 row)
```

- %

Description: Model (to obtain the remainder)

Example:

```
gaussdb=# SELECT 5%4 AS RESULT;  
result  
-----  
1  
(1 row)
```

- @

Description: Absolute value

Example:

```
gaussdb=# SELECT @ -5.0 AS RESULT;  
result  
-----  
5.0  
(1 row)
```

- ^

Description: Power (exponent calculation)

Example:

```
gaussdb=# SELECT 2.0^3.0 AS RESULT;  
result  
-----  
8.0000000000000000  
(1 row)
```

- |/

Description: Square root

Example:

```
gaussdb=# SELECT |/ 25.0 AS RESULT;  
result  
-----  
5  
(1 row)
```

- ||/

Description: Cubic root

Example:

```
gaussdb=# SELECT ||/ 27.0 AS RESULT;  
result  
-----  
3  
(1 row)
```

- !

Description: Factorial

Example:

```
gaussdb=# SELECT 5! AS RESULT;  
result  
-----  
120  
(1 row)
```

- !!

Description: Factorial (prefix operator)

Example:

```
gaussdb=# SELECT !!5 AS RESULT;  
result  
-----  
120  
(1 row)
```

- **&**  
Description: Binary AND  
Example:

```
gaussdb=# SELECT 91&15 AS RESULT;
result
-----
    11
(1 row)
```
- **|**  
Description: Binary OR  
Example:

```
gaussdb=# SELECT 32|3 AS RESULT;
result
-----
    35
(1 row)
```
- **#**  
Description: Binary XOR  
Example:

```
gaussdb=# SELECT 17#5 AS RESULT;
result
-----
    20
(1 row)
```
- **~**  
Description: Binary NOT  
Example:

```
gaussdb=# SELECT ~1 AS RESULT;
result
-----
   -2
(1 row)
```
- **<<**  
Description: Binary shift left  
Example:

```
gaussdb=# SELECT 1<<4 AS RESULT;
result
-----
    16
(1 row)
```
- **>>**  
Description: Binary shift right  
Example:

```
gaussdb=# SELECT 8>>2 AS RESULT;
result
-----
     2
(1 row)
```

## Arithmetic Functions

- **abs(x)**  
Description: Absolute value

Return type: same as the input

Example:

```
gaussdb=# SELECT abs(-17.4);
abs
-----
17.4
(1 row)
```

- **acos(x)**

Description: Arc cosine

Return type: double precision

Example:

```
gaussdb=# SELECT acos(-1);
acos
-----
3.14159265358979
(1 row)
```

- **asin(x)**

Description: Arc sine

Return type: double precision

Example:

```
gaussdb=# SELECT asin(0.5);
asin
-----
.523598775598299
(1 row)
```

- **atan(x)**

Description: Arc tangent

Return type: double precision

Example:

```
gaussdb=# SELECT atan(1);
atan
-----
.785398163397448
(1 row)
```

- **atan2(y, x)**

Description: Arc tangent of y/x

Return type: double precision

Example:

```
gaussdb=# SELECT atan2(2, 1);
atan2
-----
1.10714871779409
(1 row)
```

- **bitand(integer, integer)**

Description: Performs the AND (&) operation on two integers.

Return type: bigint

Example:

```
gaussdb=# SELECT bitand(127, 63);
bitand
-----
63
(1 row)
```

- **cbrt(dp)**  
Description: Cubic root  
Return type: double precision  
Example:

```
gaussdb=# SELECT cbrt(27.0);
cbrt
-----
 3
(1 row)
```
- **ceil(x)**  
Description: Minimum integer greater than or equal to the parameter  
Return type: integer  
Example:

```
gaussdb=# SELECT ceil(-42.8);
ceil
-----
-42
(1 row)
```
- **ceiling(dp or numeric)**  
Description: Minimum integer (alias of ceil) greater than or equal to the parameter  
Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.  
Example:

```
gaussdb=# SELECT ceiling(-95.3);
ceiling
-----
-95
(1 row)
```
- **cos(x)**  
Description: Cosine  
Return type: double precision  
Example:

```
gaussdb=# SELECT cos(-3.1415927);
cos
-----
-.9999999999999999
(1 row)
```
- **cosh(x)**  
Description: Hyperbolic cosine  
Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.  
Example:

```
gaussdb=# SELECT cosh(4);
cosh
-----
27.3082328360165
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- **cot(x)**  
Description: Cotangent  
Return type: double precision  
Example:

```
gaussdb=# SELECT cot(1);
      cot
-----
.642092615934331
(1 row)
```
- **degrees(dp)**  
Description: Converts radians to angles.  
Return type: double precision  
Example:

```
gaussdb=# SELECT degrees(0.5);
      degrees
-----
28.6478897565412
(1 row)
```
- **div(y numeric, x numeric)**  
Description: Integer part of y/x  
Return type: numeric  
Example:

```
gaussdb=# SELECT div(9,4);
      div
-----
      2
(1 row)
```
- **exp(x)**  
Description: Natural exponent  
Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.  
Example:

```
gaussdb=# SELECT exp(1.0);
      exp
-----
2.7182818284590452
(1 row)
```
- **floor(x)**  
Description: Not larger than the maximum integer of the parameter  
Return type: same as the input  
Example:

```
gaussdb=# SELECT floor(-42.8);
      floor
-----
      -43
(1 row)
```
- **int1(in)**  
Description: Converts the input text parameter to a value of the int1 type and returns the value.  
Return type: int1  
Example:

```
gaussdb=# SELECT int1('123');
int1
-----
123
(1 row)
gaussdb=# SELECT int1('1.1');
int1
-----
1
(1 row)
```

**NOTE**

- When **sql\_compatibility** is set to 'B', non-integer characters are automatically truncated or the value **0** is returned.
  - When **sql\_compatibility** is not set to 'B', an error message is displayed for non-integer characters, indicating that the input is invalid.
- **int2(in)**

Description: Converts the input parameter to a value of the int2 type and returns the value.

The supported input parameter types include float4, float8, int16, numeric, and text.

Return type: int2

Example:

```
gaussdb=# SELECT int2('1234');
int2
-----
1234
(1 row)
gaussdb=# SELECT int2(25.3);
int2
-----
25
(1 row)
```

**NOTE**

- When **sql\_compatibility** is set to 'B', non-integer characters are automatically truncated or the value **0** is returned.
  - When **sql\_compatibility** is not set to 'B', an error message is displayed for non-integer characters, indicating that the input is invalid.
- **int4(in)**

Description: Converts the input parameter to a value of the int4 type and returns the value.

The supported input parameter types include bit, Boolean, char, double precision, int16, numeric, real, smallint and text

Return type: int4

Example:

```
gaussdb=# SELECT int4('789');
int4
-----
789
(1 row)
gaussdb=# SELECT int4(99.9);
int4
-----
100
(1 row)
```

 NOTE

- When **sql\_compatibility** is set to 'B', non-integer characters are automatically truncated or the value **0** is returned.
- When **sql\_compatibility** is not set to 'B', an error message is displayed for non-integer characters, indicating that the input is invalid.

- **int8(in)**

Description: Converts the input parameter to a value of the int8 type and returns the value. The supported input parameter types include bit, double precision, int16, integer, numeric, oid, real, smallint, and text.

Return type: int8

Example:

```
gaussdb=# SELECT int8('789');
int8
-----
789
(1 row)
gaussdb=# SELECT int8(99.9);
int8
-----
99
(1 row)
```

 NOTE

- When **sql\_compatibility** is set to 'B', non-integer characters are automatically truncated or the value **0** is returned.
- When **sql\_compatibility** is not set to 'B', an error message is displayed for non-integer characters, indicating that the input is invalid.

- **float4(in)**

Description: Converts the input parameter to a value of the float4 type and returns the value. The supported input parameter types include bigint, double precision, int16, integer, numeric, smallint, and text.

Return type: float4

Example:

```
gaussdb=# SELECT float4('789');
float4
-----
789
(1 row)
gaussdb=# SELECT float4(99.9);
float4
-----
99.9
(1 row)
```

- **float8(in)**

Description: Converts the input parameter to a value of the float8 type and returns the value. The supported input parameter types include bigint, int16, integer, numeric, real, smallint, and text.

Return type: float8

Example:

```
gaussdb=# SELECT float8('789');
float8
-----
```

```

789
(1 row)

gaussdb=# SELECT float8(99.9);
 float8
-----
  99.9
(1 row)

```

- **int16(in)**

Description: Converts the input parameter to a value of the int16 type and returns the value. The supported input parameter types include bigint, boolean, double precision, integer, numeric, oid, real, smallint, and tinyint.

Return type: int16

Example:

```

gaussdb=# SELECT int16('789');
 int16
-----
  789
(1 row)

gaussdb=# SELECT int16(99.9);
 int16
-----
  100
(1 row)

```

- **numeric(in)**

Description: Converts the input parameter to a value of the numeric type and returns the value. The supported input parameter types include bigint, boolean, double precision, int16, integer, money, real, and smallint.

Return type: numeric

Example:

```

gaussdb=# SELECT "numeric"('789');
 numeric
-----
  789
(1 row)

gaussdb=# SELECT "numeric"(99.9);
 numeric
-----
  99.9
(1 row)

```

- **oid(in)**

Description: Converts the input parameter to a value of the oid type and returns the value. The supported input parameter types include bigint and int16.

Return type: oid

- **radians(dp)**

Description: Converts angles to radians.

Return type: double precision

Example:

```

gaussdb=# SELECT radians(45.0);
 radians
-----
.785398163397448
(1 row)

```

- **random()**  
Description: Random number between 0.0 and 1.0  
Return type: double precision  
Example:

```
gaussdb=# SELECT random();
          random
-----
.824823560658842
(1 row)
```
- **multiply(x double precision or text, y double precision or text)**  
Description: product of x and y.  
Return type: double precision  
Example:

```
gaussdb=# SELECT multiply(9.0, '3.0');
          multiply
-----
                27
(1 row)
gaussdb=# SELECT multiply('9.0', 3.0);
          multiply
-----
                27
(1 row)
```
- **ln(x)**  
Description: Natural logarithm  
Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.  
Example:

```
gaussdb=# SELECT ln(2.0);
          ln
-----
.6931471805599453
(1 row)
```
- **log(x)**  
Description: Logarithm with 10 as the base  
Return type: same as the input  
Example:

```
gaussdb=# SELECT log(100.0);
          log
-----
2.0000000000000000
(1 row)
```
- **log(b numeric, x numeric)**  
Description: Logarithm with b as the base  
Return type: numeric  
Example:

```
gaussdb=# SELECT log(2.0, 64.0);
          log
-----
6.0000000000000000
(1 row)
```
- **mod(x,y)**

Description: Remainder of x/y (model) If x equals to 0, 0 is returned.

Return type: same as the parameter type

Example:

```
gaussdb=# SELECT mod(9,4);
mod
-----
1
(1 row)
gaussdb=# SELECT mod(9,0);
mod
-----
9
(1 row)
```

- pi()

Description:  $\pi$  constant value

Return type: double precision

Example:

```
gaussdb=# SELECT pi();
pi
-----
3.14159265358979
(1 row)
```

- power(a double precision, b double precision)

Description: b power of a

Return type: double precision

Example:

```
gaussdb=# SELECT power(9.0, 3.0);
power
-----
729.0000000000000000
(1 row)
```

- remainder(x,y)

Description: Remainder of x/y. If y is 0, an error is reported.

Return type: same as the input (float4, float8, or numeric)

Example:

```
gaussdb=# SELECT remainder(11,4);
remainder
-----
-1
(1 row)
gaussdb=# SELECT remainder(9,0);
ERROR: division by zero
CONTEXT: referenced column: remainder
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- round(x)

Description: Integer closest to the input parameter

Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT round(42.4);
round
```

```
-----
42
(1 row)

gaussdb=# SELECT round(42.6);
round
-----
43
(1 row)
```

 **CAUTION**

The output of the float/double type may be **-0**. (This also occurs in functions such as trunc and ceil. When the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an A-compatible database, the returned result is **0**. The following is an example:

```
gaussdb=# SELECT round(-0.2::float8);
round
-----
-0
(1 row)
```

- **round(v numeric, s int)**

Description: **s** digits are kept after the decimal point.

Return type: numeric

Example:

```
gaussdb=# SELECT round(42.4382, 2);
round
-----
42.44
(1 row)
```

 **NOTE**

If the value of the control parameter **s** is a decimal, the value of **s** is truncated to an integer when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1** in an A-compatible database. Otherwise, the value of **s** is rounded off to an integer.

When the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1** in an A-compatible database, the round function supports round(timestamp, text) overloading. When **(text, text)** or **(text, '')** is used as the input parameter to call the round function, round(timestamp, text) is preferred.

- **setseed(dp)**

Description: Sets seed for the following random() calling (between -1.0 and 1.0, inclusive).

Return type: void

Example:

```
gaussdb=# SELECT setseed(0.54823);
setseed
-----
(1 row)
```

- **sign(x)**

Description: Returns symbols of this parameter.

Return type: **-1** indicates negative numbers. **0** indicates 0, and **1** indicates positive numbers.

Example:

```
gaussdb=# SELECT sign(-8.4);
 sign
-----
 -1
(1 row)
```

- **sin(x)**

Description: Sine

Return type: double precision

Example:

```
gaussdb=# SELECT sin(1.57079);
  sin
-----
.99999999979986
(1 row)
```

- **sinh(x)**

Description: Hyperbolic sine

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT sinh(4);
  sinh
-----
27.2899171971277
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- **sqrt(x)**

Description: Square root

Return type: dp or numeric. If implicit type conversion is not considered, the return type is the same as the input type.

Example:

```
gaussdb=# SELECT sqrt(2.0);
  sqrt
-----
1.414213562373095
(1 row)
```

- **tan(x)**

Description: Tangent

Return type: double precision

Example:

```
gaussdb=# SELECT tan(20);
  tan
-----
2.23716094422474
(1 row)
```

- **tanh(x)**

Description: Hyperbolic tangent

Return type: same as the input (double precision or numeric)

Example:

```
gaussdb=# SELECT tanh(0.1);
          tanh
-----
0.0996679946249558171183050836783521835389
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- **trunc(x)**

Description: Truncation (the integer part is retained).

Return type: same as the input

Example:

```
gaussdb=# SELECT trunc(42.8);
      trunc
-----
         42
(1 row)
```

- **trunc(v numeric, s int)**

Description: Truncates a number with **s** digits after the decimal point.

Return type: numeric

Example:

```
gaussdb=# SELECT trunc(42.4382, 2);
      trunc
-----
      42.43
(1 row)
```

 **NOTE**

In an A-compatible database, this function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is a valid value under the compatible configuration item. If the value of **s** is a decimal, the value is truncated instead of being rounded off.

- **smgrne(a smgr, b smgr)**

Description: Compares two integers of the smgr type to check whether they are different.

Return type: Boolean

- **smgreq(a smgr, b smgr)**

Description: Compares two integers of the smgr type to check whether they are equivalent.

Return type: Boolean

- **int1abs**

Description: Returns the absolute value of data of the uint8 type.

Parameter: tinyint

Return type: tinyint

- **int1and**

Description: Returns the bitwise AND result of two data records of the uint8 type.

Parameter: tinyint, tinyint

- Return type: tinyint
- **int1cmp**  
Description: Returns the comparison result of two data records of the uint8 type. If the value of the first parameter is greater, **1** is returned. If the value of the second parameter is greater, **-1** is returned. If they are the same, **0** is returned.  
Parameter: tinyint, tinyint  
Return type: integer
  - **int1div**  
Description: Returns the result of dividing two data records of the uint8 type. The result is of the float8 type.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - **int1eq**  
Description: Compares two pieces of data of the uint8 type to check whether they are the same.  
Parameter: tinyint, tinyint  
Return type: Boolean
  - **int1ge**  
Description: Determines whether the value of the first parameter is greater than or equal to the value of the second parameter in two data records of the uint8 type.  
Parameter: tinyint, tinyint  
Return type: Boolean
  - **int1gt**  
Description: Performs the greater-than operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: Boolean
  - **int1larger**  
Description: Returns the maximum value of an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - **int1le**  
Description: Performs a less-than or an equal-to operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: Boolean
  - **int1lt**  
Description: Performs a less-than operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: Boolean

- `int1smaller`  
Description: Calculates the minimum value of an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1inc`  
Description: Unsigned 1-byte integer plus 1.  
Parameter: `tinyint`  
Return type: `tinyint`
- `int1mi`  
Description: Performs a minus operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1mod`  
Description: Performs a remainder operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1mul`  
Description: Performs a multiplication operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1ne`  
Description: Performs a not-equal-to operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: Boolean
- `int1pl`  
Description: Performs an addition operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `int1um`  
Description: Returns an unsigned 2-byte integer after subtracting the opposite number from the unsigned 1-byte integer.  
Parameter: `tinyint`  
Return type: `smallint`
- `int1xor`  
Description: Performs an exclusive OR operation on an unsigned 1-byte integer.  
Parameter: `tinyint`, `tinyint`  
Return type: `tinyint`
- `cash_div_int1`  
Description: Performs a division operation on the money type.

- Parameter: money, tinyint  
Return type: money
- `cash_mul_int1`  
Description: Performs a multiplication operation on the money type.  
Parameter: money, tinyint  
Return type: money
  - `int1not`  
Description: Reverts binary bits of an unsigned 1-byte integer.  
Parameter: tinyint  
Return type: tinyint
  - `int1or`  
Description: Performs an OR operation on an unsigned 1-byte integer.  
Parameter: tinyint, tinyint  
Return type: tinyint
  - `int1shl`  
Description: Shifts an unsigned 1-byte integer leftwards by a specified number of bits.  
Parameter: tinyint, integer  
Return type: tinyint
  - `int1shr`  
Description: Shifts an unsigned 1-byte integer rightwards by a specified number of bits.  
Parameter: tinyint, integer  
Return type: tinyint
  - `width_bucket(op numeric, b1 numeric, b2 numeric, count int)`  
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.  
Return type: int  
Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
          3
(1 row)
```
  - `width_bucket(op dp, b1 dp, b2 dp, count int)`  
Description: Returns a bucket to which the operand will be assigned in an equi-depth histogram with **count** buckets, ranging from **b1** to **b2**.  
Return type: int  
Example:

```
gaussdb=# SELECT width_bucket(5.35, 0.024, 10.06, 5);
width_bucket
-----
          3
(1 row)
```
  - `analyze_tgtype_for_type(n smallint)`

Description: Parses **pg\_trigger.tgtype**, parses *n* by bit, and returns one of **before each row**, **after each row**, **before statement**, **after statement**, and **instead of**.

Return type: varchar2(16)

- analyze\_tgtype\_for\_event(*n* smallint)

Description: Parses **pg\_trigger.tgtype**, parses *n* by bit, and returns one or more of **insert**, **update**, **delete**, and **truncate**.

Return type: varchar2(246)

- nanvl(*n2*, *n1*)

Description: Two parameters are entered. The parameters must be of the numeric type or a non-numeric type that can be implicitly converted to the numeric type. If the first parameter **n2** is NaN, **n1** is returned. Otherwise, **n2** is returned.

Return value type: input parameter with a higher priority. The priority is as follows: double precision > float4 > numeric.

Example:

```
gaussdb=# SELECT nanvl('NaN', 1.1);
 nanvl
-----
 1.1
(1 row)
```

#### NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

## 7.5.8 Date and Time Processing Functions and Operators

### Date and Time Operators

For details about the time and date operators, see [Table 7-31](#).

#### NOTE

When the user uses date and time operators, explicit type prefixes are modified for corresponding operands to ensure that the operands parsed by the database are consistent with what the user expects, and no unexpected results occur.

For example, abnormal mistakes will occur in the following example without an explicit data type.

```
SELECT date '2001-10-01' - '7' AS RESULT;
```

**Table 7-31** Time and date operators

Operator	Example
+	<pre>gaussdb=# SELECT date '2001-9-28' + integer '7' AS RESULT; result ----- 2001-10-05 (1 row)</pre> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• In A compatibility mode, the query result is 2001-10-05 00:00:00.</li> <li>• In B compatibility mode (<b>sql_compatibility</b> is set to 'B', <b>b_format_version</b> is set to '5.7' and <b>b_format_dev_version</b> is set to 's1'), the query result is 2001-10-05.</li> </ul>
	<pre>gaussdb=# SELECT date '2001-09-28' + interval '1 hour' AS RESULT; result ----- 2001-09-28 01:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-09-28' + time '03:00' AS RESULT; result ----- 2001-09-28 03:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT interval '1 day' + interval '1 hour' AS RESULT; result ----- 1 day 01:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT timestamp '2001-09-28 01:00' + interval '23 hours' AS RESULT; result ----- 2001-09-29 00:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT time '01:00' + interval '3 hours' AS RESULT; result ----- 04:00:00 (1 row)</pre>
-	<pre>gaussdb=# SELECT date '2001-10-01' - date '2001-09-28' AS RESULT; result ----- 3days (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-10-01' - integer '7' AS RESULT; result ----- 2001-09-24 00:00:00 (1 row)</pre>
	<pre>gaussdb=# SELECT date '2001-09-28' - interval '1 hour' AS RESULT; result ----- 2001-09-27 23:00:00 (1 row)</pre>

Operator	Example
	<pre>gaussdb=# SELECT time '05:00' - time '03:00' AS RESULT; result ----- 02:00:00 (1 row)</pre> <pre>gaussdb=# SELECT time '05:00' - interval '2 hours' AS RESULT; result ----- 03:00:00 (1 row)</pre> <pre>gaussdb=# SELECT timestamp '2001-09-28 23:00' - interval '23 hours' AS RESULT; result ----- 2001-09-28 00:00:00 (1 row)</pre> <pre>gaussdb=# SELECT interval '1 day' - interval '1 hour' AS RESULT; result ----- 23:00:00 (1 row)</pre> <pre>gaussdb=# SELECT timestamp '2001-09-29 03:00' - timestamp '2001-09-27 12:00' AS RESULT; result ----- 1 day 15:00:00 (1 row)</pre>
*	<pre>gaussdb=# SELECT 900 * interval '1 second' AS RESULT; result ----- 00:15:00 (1 row)</pre> <pre>gaussdb=# SELECT 21 * interval '1 day' AS RESULT; result ----- 21 days (1 row)</pre> <pre>gaussdb=# SELECT double precision '3.5' * interval '1 hour' AS RESULT; result ----- 03:30:00 (1 row)</pre>
/	<pre>gaussdb=# SELECT interval '1 hour' / double precision '1.5' AS RESULT; result ----- 00:40:00 (1 row)</pre>

## Time and Date Functions

- age(timestamp, timestamp)**  
 Description: Subtracts parameters, producing a result in YYYY-MM-DD format. If the result is negative, the returned result is also negative. The input parameters can contain time zone or not.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '2001-04-10', timestamp '1957-06-13');
 age
-----
43 years 9 mons 27 days
(1 row)
```

- `age(timestamp)`

Description: Subtracts the parameter value from the system time when the current SQL statement starts to be executed. The input parameter may or may not contain a time zone.

Return type: interval

Example:

```
gaussdb=# SELECT age(timestamp '1957-06-13');
 age
-----
60 years 2 mons 18 days
(1 row)
```

- `clock_timestamp()`

Description: Returns the timestamp of the system time when the current function is called. The volatile function obtains the latest timestamp for each scan. Therefore, the result of each call in a query is different.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT clock_timestamp();
 clock_timestamp
-----
2017-09-01 16:57:36.636205+08
(1 row)
```

- `current_date`

Description: Returns the system date when the current SQL statement starts.

Return type: date

Example:

```
gaussdb=# SELECT current_date;
 date
-----
2017-09-01
(1 row)
```

#### NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2** in an A-compatible database, the return value type is timestamp.

- `current_time`

Description: Specifies the system time when the current transaction starts.

Return type: time with time zone

Example:

```
gaussdb=# SELECT current_time;
 timetz
-----
16:58:07.086215+08
(1 row)
```

- `current_timestamp`  
Description: Returns the system time when the current SQL execution starts. This is a statement-level timestamp. The returned results within the same statement remain unchanged.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT current_timestamp;
           pg_systimestamp
-----
2017-09-01 16:58:19.22173+08
(1 row)
```

- `current_timestamp(precision)`  
Description: Returns the system time when the current SQL statement is started, and rounds the microseconds of the result to the specified decimal places.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT current_timestamp(1);
           timestamptz
-----
2017-09-01 16:58:19.2+08
(1 row)
```

 **NOTE**

- When `a_format_version` is set to `10c` and `a_format_dev_version` is set to `s2` in an A-compatible database, the `precision` parameter can be an integer of the numeric type. Otherwise, only the int type is supported.
- The last digit 0 of the microsecond field is not displayed. For example, 2017-09-01 10:32:19.212000 is displayed as 2017-09-01 10:32:19.212.

- `pg_systimestamp()`  
Description: Current date and time (start of the current statement)

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_systimestamp();
           pg_systimestamp
-----
2015-10-14 11:21:28.317367+08
(1 row)
```

- `date_part(text, timestamp)`  
Description: Obtains the value of a subdomain in date or time, for example, the year or hour. It is equivalent to **extract(field from timestamp)**.

Timestamp types: abstime, date, interval, reltime, time with time zone, time without time zone, timestamp with time zone, timestamp without time zone

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('hour', timestamp '2001-02-16 20:38:40');
           date_part
-----
                20
(1 row)
```

- `date_part(text, interval)`

Description: Obtains the subdomain value of the date/time value. When obtaining the month value, if the value is greater than 12, obtain the remainder after it is divided by 12. It is equivalent to **extract(field from timestamp)**.

Return type: double precision

Example:

```
gaussdb=# SELECT date_part('month', interval '2 years 3 months');
date_part
-----
        3
(1 row)
```

- **date\_trunc(text, timestamp)**

Description: Truncates to the precision specified by **text**.

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT date_trunc('hour', timestamp '2001-02-16 20:38:40');
date_trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **trunc(timestamp)**

Description: Truncates to day by default.

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16
20:38:40');
trunc
-----
2001-02-16 00:00:00
(1 row)
```

- **trunc(arg1, arg2)**

Description: Truncates to the precision specified by **arg2**.

Type of **arg1**: interval, timestamp with time zone, timestamp without time zone

Type of **arg2**: text

Return type: interval, timestamp with time zone, timestamp without time zone

Example:

```
gaussdb=# SELECT trunc(timestamp '2001-02-16 20:38:40',
'hour');
trunc
-----
2001-02-16 20:00:00
(1 row)
```

- **round(arg1, arg2)**

Description: Rounds off to the precision specified by **arg2**.

Type of **arg1**: timestamp without time zone

Type of **arg2**: text

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT round(timestamp '2001-02-16 20:38:40',
'hour');
          round
-----
2001-02-16 21:00:00
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1** in an A-compatible database.

- **daterange(arg1, arg2)**

Description: Obtains time boundary information. The type of **arg1** and **arg2** is **date**.

Return type: daterange

Example:

```
gaussdb=# select daterange('2000-05-06','2000-08-08');
          daterange
-----
[2000-05-06,2000-08-08)
(1 row)
```

- **daterange(arg1, arg2, text)**

Description: Obtains time boundary information. The type of **arg1** and **arg2** is **date**, and the type of **text** is **text**.

Return type: daterange

Example:

```
gaussdb=# SELECT daterange('2000-05-06','2000-08-08','[]');
          daterange
-----
[2000-05-06,2000-08-09)
(1 row)
```

- **extract(field from timestamp)**

Description: Obtains the hour.

Return type: double precision

Example:

```
gaussdb=# SELECT extract(hour from timestamp '2001-02-16 20:38:40');
          date_part
-----
                20
(1 row)
```

- **extract(field from interval)**

Description: Obtains the month. If the value is greater than 12, obtain the remainder after it is divided by 12.

Return type: double precision

Example:

```
gaussdb=# SELECT extract(month from interval '2 years 3 months');
          date_part
-----
                3
(1 row)
```

- **isfinite(date)**

Description: Checks whether a date is a finite value. If yes, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(date '2001-02-16');
isfinite
-----
t
(1 row)
gaussdb=# SELECT isfinite(date 'infinity');
isfinite
-----
f
(1 row)
```

- **isfinite(timestamp)**

Description: Checks whether a timestamp is a finite value. If yes, **t** is returned. Otherwise, **f** is returned.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(timestamp '2001-02-16 21:28:30');
isfinite
-----
t
(1 row)
gaussdb=# SELECT isfinite(timestamp 'infinity');
isfinite
-----
f
(1 row)
```

- **isfinite(interval)**

Description: Checks whether the interval is a finite value. If yes, **t** is returned. Currently, **f** cannot be returned. If **'infinity'** is entered, an error is reported.

Return type: Boolean

Example:

```
gaussdb=# SELECT isfinite(interval '4 hours');
isfinite
-----
t
(1 row)
```

- **justify\_days(interval)**

Description: Adjusts intervals to 30-day time periods, which are represented as months.

Return type: interval

Example:

```
gaussdb=# SELECT justify_days(interval '35 days');
justify_days
-----
1 mon 5 days
(1 row)
```

- **justify\_hours(interval)**

Description: Sets the time interval in days (24 hours is one day).

Return type: interval

Example:

```
gaussdb=# SELECT JUSTIFY_HOURS(INTERVAL '27 HOURS');
justify_hours
-----
```

- ```
1 day 03:00:00
(1 row)
```

  - **justify\_interval(interval)**  
Description: Adjusts **interval** using **justify\_days** and **justify\_hours**.  
Return type: interval  
Example:  

```
gaussdb=# SELECT JUSTIFY_INTERVAL(INTERVAL '1 MON -1 HOUR');
justify_interval
-----
29 days 23:00:00
(1 row)
```
  - **localtime**  
Description: Specifies the system time when the current transaction starts.  
Return type: time  
Example:  

```
gaussdb=# SELECT localtime AS RESULT;
result
-----
16:05:55.664681
(1 row)
```
  - **localtimestamp**  
Description: Returns the system date and time when the current SQL query execution starts.  
Return type: timestamp  
Example:  

```
gaussdb=# SELECT localtimestamp;
timestamp
-----
2017-09-01 17:03:30.781902
(1 row)
```
  - **now()**  
Description: Returns the system date and time when the current transaction starts. The results returned in the same transaction are the same.  
Return type: timestamp with time zone  
Example:  

```
gaussdb=# SELECT now();
now
-----
2017-09-01 17:03:42.549426+08
(1 row)
```
  - **timenow()**  
Description: Returns the system date and time when the current SQL query execution starts.  
Return type: abstime  
Example:  

```
gaussdb=# SELECT timenow();
timenow
-----
2020-06-23 20:36:56+08
(1 row)
```
  - **dbtimezone**

Description: Time zone of the current database.

Return type: text

Example:

```
gaussdb=# SELECT dbtimezone;
          dbtimezone
-----
PRC
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- numtodsinterval(num, interval\_unit)

Description: Converts a number to the interval type. **num** is a numeric-typed number. **interval\_unit** is a string in the following format: 'DAY' | 'HOUR' | 'MINUTE' | 'SECOND'

You can set the GUC parameter **IntervalStyle** to **a** to be compatible with the interval output format of the function.

Return type: interval

Example:

```
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
          numtodsinterval
-----
100:00:00
(1 row)

gaussdb=# SET intervalstyle = a;
SET
gaussdb=# SELECT numtodsinterval(100, 'HOUR');
          numtodsinterval
-----
+000000004 04:00:00.000000000
(1 row)
```

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2** in an A-compatible database, an error is reported if **interval\_unit** is set to 'DAY' and **num** is set to a value greater than **1000000000**.

- numtoyminterval(num, interval\_unit)

Description: Converts a number to the interval type. **num** is a number of the numeric type, and **interval\_unit** is a string of the fixed format ('YEAR'|'MONTH').

You can set the GUC parameter **IntervalStyle** to **a** to be compatible with the interval output format of the function.

Return type: interval

Example:

```
gaussdb=# SELECT numtoyminterval(100, 'MONTH');
          numtoyminterval
-----
8 years 4 mons
(1 row)

gaussdb=# SET intervalstyle = oracle;
SET
gaussdb=# SELECT numtodsinterval(100, 'MONTH');
```

```
numtoyminterval
```

```
-----  
8-4  
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `new_time(date, timezone1,timezone2)`

Description: Returns the date and time of the time zone specified by **timezone2** when the date and time of the time zone specified by **timezone1** are date.

Return type: timestamp

Example:

```
gaussdb=# SELECT new_time('1997-10-10','AST','EST');  
new_time
```

```
-----  
1997-10-09 23:00:00  
(1 row)
```

```
gaussdb=# SELECT NEW_TIME(TO_TIMESTAMP ('10-Sep-02 14:10:10.123000','DD-Mon-RR  
HH24:MI:SS.FF'), 'AST', 'PST');
```

```
new_time  
-----  
2002-09-10 10:10:10.123  
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `sessiontimezone`

Description: Returns the time zone of the current session. There is no input parameter.

Return type: text

Example:

```
gaussdb=# SELECT SESSIONTIMEZONE;  
session_time_zone
```

```
-----  
PST8PDT  
(1 row)
```

```
gaussdb=# SELECT LOWER(SESSIONTIMEZONE);  
lower
```

```
-----  
@ 8 hours  
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

When the value of **set session time zone** is in the GMT+08:00/GMT-08:00 format, the verification fails and an error is reported. This behavior meets the expectation. If the value is 's2' and the "ERROR:invalid value for parameter "TimeZone" :\"GMT-08:00\"" error is reported when you use JDBC to create a connection, the application where the driver is located sends the same time zone parameter in GMT format to GaussDB. You can use either of the following methods to solve the problem:

Method 1: Adjust the time zone of the OS on the application side and set the local time zone to the region format, for example, Asia/Shanghai.

Method 2: Use the JDBC driver that matches the version on the application side. The JDBC driver changes the GMT time zone to a time zone format that can be identified by the database.

- `sys_extract_utc(timestamp| timestamptz)`

Description: Extracts Coordinated Universal Time (UTC, also formerly known as Greenwich Mean Time) from a date-time value with a time zone offset or time zone region name. If no time zone is specified, the date and time are associated with the session time zone. The input parameter can be in `timestamp` or `timestamp` format.

Return type: `timestamp`

Example:

```
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00');
 sys_extract_utc
-----
2000-03-28 03:30:00
(1 row)
gaussdb=# SELECT SYS_EXTRACT_UTC(TIMESTAMP '2000-03-28 11:30:00.00 -08:00');
 sys_extract_utc
-----
2000-03-28 19:30:00
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- `tz_offset('time_zone_name' | '(+/-)hh:mi' | SESSIONTIMEZONE | DBTIMEZONE)`

Description: Returns the UTC offset of the time zone indicated by the input parameter. The input parameter has the preceding four formats.

Return type: `text`

Example:

```
gaussdb=# SELECT TZ_OFFSET('US/Pacific');
 tz_offset
-----
-08:00
(1 row)
gaussdb=# SELECT TZ_OFFSET(sessiontimezone);
 tz_offset
-----
+08:00
(1 row)
```

 NOTE

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2** in an A-compatible database.

- **pg\_sleep(seconds)**

Description: Specifies the delay time of the server thread in unit of second.

Return type: void

Example:

```
gaussdb=# SELECT pg_sleep(10);
pg_sleep
-----
(1 row)
```

- **statement\_timestamp()**

Description: Current date and time (start of the current statement)

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT statement_timestamp();
statement_timestamp
-----
2017-09-01 17:04:39.119267+08
(1 row)
```

- **sysdate**

Description: Returns the system date and time when the current SQL statement is executed.

Return type: timestamp

Example:

```
gaussdb=# SELECT sysdate;
sysdate
-----
2017-09-01 17:04:49
(1 row)
```

- **current\_sysdate**

Description: Returns the system date and time when the current SQL query execution starts.

Return type: timestamp

Example:

```
gaussdb=# SELECT current_sysdate();
current_sysdate
-----
2023-06-20 20:09:02
(1 row)
```

- **timeofday()**

Description: Returns the timestamp (such as **clock\_timestamp**, but the return type is text) of the system time when the current function is called.

Return type: text

Example:

```
gaussdb=# SELECT timeofday();
timeofday
-----
Fri Sep 01 17:05:01.167506 2017 CST
(1 row)
```

- `transaction_timestamp()`

Description: Specifies the system date and time when the current transaction starts.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT transaction_timestamp();
 transaction_timestamp
-----
2017-09-01 17:05:13.534454+08
(1 row)
```

- `add_months(d,n)`

Description: Returns the time point *d* plus *n* months.

**d**: indicates the value of the timestamp type and the value that can be implicitly converted to the timestamp type.

**n**: indicates the value of the INTEGER type and the value that can be implicitly converted to the INTEGER type.

Return type: timestamp

Example:

```
gaussdb=# SELECT add_months(to_date('2017-5-29', 'yyyy-mm-dd'), 11) FROM sys_dummy;
 add_months
-----
2018-04-29 00:00:00
(1 row)
```

 **NOTE**

In the scenario where this function is in an A-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- If the calculation result is greater than 9999, an error is reported.
- If the value of *n* is a decimal, the value is truncated instead of being rounded off.

- `last_day(d)`

Description: Returns the date of the last day of the month that contains *d*.

Return type: timestamp

Example:

```
gaussdb=# SELECT last_day(to_date('2017-01-01', 'YYYY-MM-DD')) AS cal_result;
 cal_result
-----
2017-01-31 00:00:00
(1 row)
```

- `months_between(d1, d2)`

Description: Calculates the month difference between time points **d1** and **d2**. If both dates are the end of a month or are the same day, an integer is returned. Otherwise, the return value is a decimal and is calculated as 31 days per month.

Return type: numeric

Example:

```
gaussdb=# SELECT months_between(to_date('2022-10-31', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
 months_between
-----
1
(1 row)
```

```
gaussdb=# SELECT months_between(to_date('2022-10-30', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
months_between
-----
1
(1 row)
```

```
gaussdb=# SELECT months_between(to_date('2022-10-29', 'yyyy-mm-dd'), to_date('2022-09-30',
'yyyy-mm-dd'));
months_between
-----
.96774193548387096774
(1 row)
```

 **NOTE**

This function is valid only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1** in an A-compatible database.

- **next\_day(x,y)**

Description: Calculates the time of the next week y started from x.

Return type: timestamp

Example:

```
gaussdb=# SELECT next_day(timestamp '2017-05-25 00:00:00','Sunday')AS cal_result;
cal_result
-----
2017-05-28 00:00:00
(1 row)
```

- **tinterval(abstime, abstime)**

Description: Creates a time interval with two pieces of absolute time.

Return type: tinterval

Example:

```
gaussdb=# call tinterval(abstime 'May 10, 1947 23:59:12', abstime 'Mon May 1 00:30:30 1995');
tinterval
-----
["1947-05-10 23:59:12+09" "1995-05-01 00:30:30+08"]
(1 row)
```

- **tintervalend(tinterval)**

Description: Returns the end time of **tinterval**.

Return type: abstime

Example:

```
gaussdb=# SELECT tintervalend(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
tintervalend
-----
1983-10-04 23:59:12+08
(1 row)
```

- **tintervalrel(tinterval)**

Return type: tinterval

Return type: reltime

Example:

```
gaussdb=# SELECT tintervalrel(['"Sep 4, 1983 23:59:12" "Oct4, 1983 23:59:12"']);
tintervalrel
-----
1 mon
(1 row)
```

- `smalldatetime_ge`  
Description: Checks whether the value of the first parameter is greater than or equal to that of the second parameter.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: Boolean
- `smalldatetime_cmp`  
Description: Compares two `smalldatetime` values to check whether they are the same.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: integer
- `smalldatetime_eq`  
Description: Compares two `smalldatetime` values to check whether they are the same.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: Boolean
- `smalldatetime_gt`  
Description: Determines whether the first parameter is greater than the second parameter.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: Boolean
- `smalldatetime_hash`  
Description: Calculates the hash value corresponding to a timestamp.  
Parameter: `smalldatetime`  
Return type: integer
- `smalldatetime_in`  
Description: Inputs a timestamp.  
Parameter: `cstring`, `oid`, `integer`  
Return type: `smalldatetime`
- `smalldatetime_larger`  
Description: Returns a larger timestamp.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: `smalldatetime`
- `smalldatetime_le`  
Description: Checks whether the value of the first parameter is less than or equal to that of the second parameter.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: Boolean
- `smalldatetime_lt`  
Description: Determines whether the first parameter is less than the second parameter.  
Parameter: `smalldatetime`, `smalldatetime`

Return type: Boolean

- `smalldatetime_ne`  
Description: Compares two timestamps to check whether they are different.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: Boolean
- `smalldatetime_out`  
Description: Converts a timestamp into the external form.  
Parameter: `smalldatetime`  
Return type: `cstring`
- `smalldatetime_send`  
Description: Converts a timestamp to the binary format.  
Parameter: `smalldatetime`  
Return type: `bytea`
- `smalldatetime_smaller`  
Description: Returns a smaller `smalldatetime`.  
Parameter: `smalldatetime`, `smalldatetime`  
Return type: `smalldatetime`
- `smalldatetime_to_abstime`  
Description: Converts `smalldatetime` to `abstime`.  
Parameter: `smalldatetime`  
Return type: `abstime`
- `smalldatetime_to_time`  
Description: Converts `smalldatetime` to `time`.  
Parameter: `smalldatetime`  
Return type: `time without time zone`
- `smalldatetime_to_timestamp`  
Description: Converts `smalldatetime` to `timestamp`.  
Parameter: `smalldatetime`  
Return type: `timestamp without time zone`
- `smalldatetime_to_timestamptz`  
Description: Converts `smalldatetime` to `timestamptz`.  
Parameter: `smalldatetime`  
Return type: `timestamp with time zone`
- `smalldatetime_to_varchar2`  
Description: Converts `smalldatetime` to `varchar2`.  
Parameter: `smalldatetime`  
Return type: `character varying`

 NOTE

There are multiple methods for obtaining the current time. Select an appropriate API based on the actual service scenario.

1. The following APIs return values based on the start time of the current transaction:

```

CURRENT_DATE
CURRENT_TIME
CURRENT_TIME(precision)
CURRENT_TIMESTAMP(precision)
LOCALTIME
LOCALTIMESTAMP
LOCALTIME(precision)
LOCALTIMESTAMP(precision)
transaction_timestamp()
now()
    
```

The values transferred by **CURRENT\_TIME** and **CURRENT\_TIMESTAMP(precision)** contain time zone information. The values transferred by **LOCALTIME** and **LOCALTIMESTAMP** do not contain time zone information. **CURRENT\_TIME**, **LOCALTIME**, and **LOCALTIMESTAMP** can specify a precision parameter, which rounds the seconds field of the result to the decimal place. If there is no precision parameter, the result is given the full precision that can be obtained.

Because these functions all return results by the start time of the current transaction, their values do not change throughout the transaction. We think this is a feature with the purpose to allow a transaction to have a consistent concept at the "current" time, so that multiple modifications in the same transaction can maintain the same timestamp.

**transaction\_timestamp()** is equivalent to **CURRENT\_TIMESTAMP(precision)**, indicating the start time of the transaction where the current statement is located. **now()** is equivalent to **transaction\_timestamp()**.

2. The following APIs return the start time of the current statement:

```
statement_timestamp()
```

**statement\_timestamp()** returns the start time of the current statement (more accurately, the time when the last instruction is received from the client). The return values of **statement\_timestamp()** and **transaction\_timestamp()** are the same during the execution of the first instruction of a transaction, but may be different in subsequent instructions.

3. The following APIs return the actual current time when the function is called:

```
clock_timestamp()
timeofday()
```

**clock\_timestamp()** returns the actual current time, and its value changes even in the same SQL statement. Similar to **clock\_timestamp()**, **timeofday()** also returns the actual current time. However, the result of **timeofday()** is a formatted text string instead of a timestamp with time zone information.

[Table 7-32](#) shows the templates for truncating date/time values.

**Table 7-32** Truncating date/time values

| Item        | Format     | Description                                                              |
|-------------|------------|--------------------------------------------------------------------------|
| Microsecond | MICROSECON | Truncates date/time values, accurate to the microsecond (000000–999999). |
|             | US         |                                                                          |
|             | USEC       |                                                                          |
|             | USECOND    |                                                                          |

| Item        | Format     | Description                                                                                 |
|-------------|------------|---------------------------------------------------------------------------------------------|
| Millisecond | MILLISECON | Truncates date/time values, accurate to the millisecond (000–999).                          |
|             | MS         |                                                                                             |
|             | MSEC       |                                                                                             |
|             | MSECOND    |                                                                                             |
| Second      | S          | Truncates date/time values, accurate to the second (00–59).                                 |
|             | SEC        |                                                                                             |
|             | SECOND     |                                                                                             |
| Minute      | M          | Truncates date/time values, accurate to the minute (00–59).                                 |
|             | MI         |                                                                                             |
|             | MIN        |                                                                                             |

| Millennium | MIL        | Truncated or rounded off, accurate to millennium (the first day of the millennium). |
|            | MILLENNIA  |                                                                                     |
|            | MILLENNIUM |                                                                                     |

 NOTE

The behaviors of [Table 7-33](#) are valid only when the value of **a\_format\_version** is **10c** and that of **a\_format\_dev\_version** is **s1** in an A-compatible database.

- `timestamp_diff(text, timestamp, timestamp)`  
Description: Calculates the difference between two timestamps and truncates the difference to the precision specified by text.

Return type: int64

Example:

```
gaussdb=# SELECT timestamp_diff('year','2018-01-01','2020-04-01');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('month','2018-01-01','2020-04-01');
timestamp_diff
-----
         27
(1 row)
gaussdb=# SELECT timestamp_diff('quarter','2018-01-01','2020-04-01');
timestamp_diff
-----
          9
(1 row)
gaussdb=# SELECT timestamp_diff('week','2018-01-01','2020-04-01');
timestamp_diff
-----
        117
(1 row)
gaussdb=# SELECT timestamp_diff('day','2018-01-01','2020-04-01');
timestamp_diff
-----
        821
(1 row)
gaussdb=# SELECT timestamp_diff('hour','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
          2
(1 row)
gaussdb=# SELECT timestamp_diff('minute','2018-01-01 10:10:10','2018-01-01 12:12:12');
timestamp_diff
-----
        122
(1 row)
gaussdb=# SELECT timestamp_diff('second','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
        122
(1 row)
gaussdb=# SELECT timestamp_diff('microsecond','2018-01-01 10:10:10','2018-01-01 10:12:12');
timestamp_diff
-----
```

```
122000000
(1 row)
```

## TIMESTAMPDIFF

- **TIMESTAMPDIFF**(*unit*, *timestamp\_expr1*, *timestamp\_expr2*)

The **timestampdiff** function returns the result of **timestamp\_expr2** – **timestamp\_expr1** in the specified unit. **timestamp\_expr1** and **timestamp\_expr2** must be value expressions of the **timestamp**, **timestamp\_tz**, or **date** type. **unit** specifies the unit of the difference between two dates.

This function is equivalent to **timestamp\_diff(text, timestamp, timestamp)**.

### NOTE

This function is valid only when GaussDB is compatible with the MY type (that is, `dbcompatibility = 'B'`).

- **year**

Year.

```
gaussdb=# SELECT TIMESTAMPDIFF(YEAR, '2018-01-01', '2020-01-01');
timestamp_diff
-----
2
(1 row)
```

- **quarter**

Quarter.

```
gaussdb=# SELECT TIMESTAMPDIFF(QUARTER, '2018-01-01', '2020-01-01');
timestamp_diff
-----
8
(1 row)
```

- **month**

Month.

```
gaussdb=# SELECT TIMESTAMPDIFF(MONTH, '2018-01-01', '2020-01-01');
timestamp_diff
-----
24
(1 row)
```

- **week**

Week.

```
gaussdb=# SELECT TIMESTAMPDIFF(WEEK, '2018-01-01', '2020-01-01');
timestamp_diff
-----
104
(1 row)
```

- **day**

Day.

```
gaussdb=# SELECT TIMESTAMPDIFF(DAY, '2018-01-01', '2020-01-01');
timestamp_diff
-----
730
(1 row)
```

- **hour**

Hour.

```
gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-01-01 10:10:10', '2020-01-01 11:11:11');
timestamp_diff
```

- ```
-----
          1
(1 row)
```
- **minute**  
Minute.  
gaussdb=# SELECT TIMESTAMPDIFF(MINUTE, '2020-01-01 10:10:10', '2020-01-01 11:11:11');  
timestamp\_diff  
-----  
 61  
(1 row)
- **second**  
Second.  
gaussdb=# SELECT TIMESTAMPDIFF(SECOND, '2020-01-01 10:10:10', '2020-01-01 11:11:11');  
timestamp\_diff  
-----  
 3661  
(1 row)
- **microseconds**  
The second field, including fractional parts, is multiplied by 1,000,000.  
gaussdb=# SELECT TIMESTAMPDIFF(MICROSECOND, '2020-01-01 10:10:10.000000', '2020-01-01  
10:10:10.111111');  
timestamp\_diff  
-----  
 111111  
(1 row)
- **timestamp\_expr with the time zone**  
gaussdb=# SELECT TIMESTAMPDIFF(HOUR, '2020-05-01 10:10:10-01', '2020-05-01 10:10:10-03');  
timestamp\_diff  
-----  
 2  
(1 row)

## EXTRACT

- **EXTRACT(*field* FROM *source*)**  
The **extract** function retrieves fields such as year or hour from date/time values. **source** must be a value expression of the date type (**timestamp**, **time**, or **interval**). **field** is an identifier or string that selects what field to extract from the source value. The extract function returns a value of the double precision type. The following are valid **field** names:
    - **century**  
Century.  
The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0. You go from **-1** century to **1** century.  
gaussdb=# SELECT EXTRACT(CENTURY FROM TIMESTAMP '2000-12-16 12:21:13');  
date\_part  
-----  
 20  
(1 row)
    - **day**
      - For **timestamp** values, the day (of the month) field (1-31)  
gaussdb=# SELECT EXTRACT(DAY FROM TIMESTAMP '2001-02-16 20:38:40');  
date\_part

```
-----
      16
(1 row)
```

- For **interval** values, the number of days

```
gaussdb=# SELECT EXTRACT(DAY FROM INTERVAL '40 days 1 minute');
date_part
-----
      40
(1 row)
```

- decade

Year divided by 10

```
gaussdb=# SELECT EXTRACT(DECADE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
     200
(1 row)
```

- dow

Day of the week as Sunday (0) to Saturday (6)

```
gaussdb=# SELECT EXTRACT(DOW FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      5
(1 row)
```

- doy

Day of the year (1–365 or 366)

```
gaussdb=# SELECT EXTRACT(DOY FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
     47
(1 row)
```

- epoch

- For **timestamp with time zone** values, the number of seconds since 1970-01-01 00:00:00-00 UTC (can be negative).

For **date** and **timestamp** values, the number of seconds since 1970-01-01 00:00:00-00 local time.

For **interval** values, the total number of seconds in the interval.

```
gaussdb=# SELECT EXTRACT(EPOCH FROM TIMESTAMP WITH TIME ZONE '2001-02-16
20:38:40.12-08');
date_part
-----
982384720.12
(1 row)
```

```
gaussdb=# SELECT EXTRACT(EPOCH FROM INTERVAL '5 days 3 hours');
date_part
-----
     442800
(1 row)
```

- Way to convert an epoch value back to a timestamp

```
gaussdb=# SELECT TIMESTAMP WITH TIME ZONE 'epoch' + 982384720.12 * INTERVAL '1
second' AS RESULT;
result
-----
2001-02-17 12:38:40.12+08
(1 row)
```

- hour

Hour (0–23)

```
gaussdb=# SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
```

```
-----
      20
(1 row)
```

- isodow

Day of the week (1–7)

Monday is 1 and Sunday is 7.

 **NOTE**

This is identical to **dow** except for Sunday.

```
gaussdb=# SELECT EXTRACT(ISODOW FROM TIMESTAMP '2001-02-18 20:38:40');
date_part
-----
      7
(1 row)
```

- isoyear

The ISO 8601 year that the date falls in (not applicable to intervals).

Each ISO year begins with the Monday of the week containing January 4, so in early January or late December the ISO year may be different from the Gregorian year. See [week](#) for more information.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part
-----
    2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
date_part
-----
     52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part
-----
    2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
date_part
-----
      1
(1 row)
```

- microseconds

The second field, including fractional parts, is multiplied by 1,000,000.

```
gaussdb=# SELECT EXTRACT(MICROSECONDS FROM TIME '17:12:28.5');
date_part
-----
28500000
(1 row)
```

- millennium

Millennium.

Years in the 1900s are in the second millennium. The third millennium started from January 1, 2001.

```
gaussdb=# SELECT EXTRACT(MILLENNIUM FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      3
(1 row)
```

- milliseconds

Second field, including fractional parts, is multiplied by 1000. Note that this includes full seconds.

```
gaussdb=# SELECT EXTRACT(MILLISECONDS FROM TIME '17:12:28.5');
date_part
-----
      28500
(1 row)
```

- minute

Minute (0–59).

```
gaussdb=# SELECT EXTRACT(MINUTE FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
        38
(1 row)
```

- month

For **timestamp** values, the specific month in the year (1–12).

```
gaussdb=# SELECT EXTRACT(MONTH FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
         2
(1 row)
```

For **interval** values, the number of months, modulo 12 (0–11).

```
gaussdb=# SELECT EXTRACT(MONTH FROM INTERVAL '2 years 13 months');
date_part
-----
         1
(1 row)
```

- quarter

Quarter of the year (1–4) that the date is in.

```
gaussdb=# SELECT EXTRACT(QUARTER FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
         1
(1 row)
```

- second

Second field, including fractional parts (0–59).

```
gaussdb=# SELECT EXTRACT(SECOND FROM TIME '17:12:28.5');
date_part
-----
       28.5
(1 row)
```

- timezone

Time zone offset from UTC, measured in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

- timezone\_hour

Hour component of the time zone offset.

- timezone\_minute

Minute component of the time zone offset.

- week

Number of the week of the year that the day is in. By definition (ISO 8601), the first week of a year contains January 4 of that year. In other words, the first Thursday of a year is in week 1 of that year.

Because of this, it is possible for early January dates to be part of the 52nd or 53rd week of the previous year, and late December dates to be part of the 1st

week of the next year. For example, 2006-01-01 is the 52nd week of 2005, and 2006-01-02 is the first week of 2006. You are advised to use the columns **isoyear** and **week** together to ensure consistency.

```
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-01');
date_part
-----
      2005
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-01 00:00:40');
date_part
-----
       52
(1 row)
gaussdb=# SELECT EXTRACT(ISOYEAR FROM DATE '2006-01-02');
date_part
-----
      2006
(1 row)
gaussdb=# SELECT EXTRACT(WEEK FROM TIMESTAMP '2006-01-02 00:00:40');
date_part
-----
        1
(1 row)
```

- **year**  
Year field.

```
gaussdb=# SELECT EXTRACT(YEAR FROM TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
      2001
(1 row)
```

## date\_part

The `date_part` function is modeled on the traditional Ingres equivalent to the SQL-standard function `extract`:

- **date\_part('field', source)**

Note that here the **field** parameter needs to be a string value, not a name. The valid field names are the same as those for **extract**. For details, see **EXTRACT**.

Example:

```
gaussdb=# SELECT date_part('day', TIMESTAMP '2001-02-16 20:38:40');
date_part
-----
       16
(1 row)
gaussdb=# SELECT date_part('hour', INTERVAL '4 hours 3 minutes');
date_part
-----
        4
(1 row)
```

**Table 7-34** specifies the schema for formatting date and time values.

**Table 7-34** Schema for formatting date and time

Category	Format	Description
Hour	HH	Number of hours in one day (01-12)

Category	Format	Description
	HH12	Number of hours in one day (01–12)
	HH24	Number of hours in one day (00–23)
Minute	MI	Minute (00–59)
Second	SS	Second (00–59)
	FF	Microsecond (000000–999999)
	FF1	Microsecond (0-9)
	FF2	Microsecond (00-99)
	FF3	Microsecond (000-999)
	FF4	Microsecond (0000-9999)
	FF5	Microsecond (00000-99999)
	FF6	Microsecond (000000–999999)
	SSSSS	Second after midnight (0–86399)
Morning and afternoon	AM or A.M.	Morning identifier
	PM or P.M.	Afternoon identifier
Year	Y,YYY	Year with comma (with four digits or more)
	SYYYY	Year with four digits BC
	YYYY	Year (with four digits or more)
	YYY	Last three digits of a year
	YY	Last two digits of a year
	Y	Last one digit of a year
	IYYY	ISO year (with four digits or more)
	IYY	Last three digits of an ISO year
	IY	Last two digits of an ISO year
	I	Last one digit of an ISO year
	RR	Last two digits of a year (A year of the 20th century can be stored in the 21st century.)
	RRRR	Capable of receiving a year with four digits or two digits. If there are 2 digits, the value is the same as the returned value of RR. If there are 4 digits, the value is the same as YYYY.
	<ul style="list-style-type: none"> <li>• BC or B.C.</li> <li>• AD or A.D.</li> </ul>	Era indicator BC or AD

Category	Format	Description
Month	MONTH	Full spelling of a month in uppercase (9 characters are filled in if the value is empty.)
	MON	Month in abbreviated format in uppercase (with three characters)
	MM	Month (01-12)
	RM	Month in Roman numerals (I-XII; I=JAN) and uppercase
Day	DAY	Full spelling of a date in uppercase (9 characters are filled in if the value is empty.)
	DY	Day in abbreviated format in uppercase (with three characters)
	DDD	Day in a year (001-366)
	DD	Day in a month (01-31)
	D	Day in a week (1-7).
Week	W	Week in a month (1-5) (The first week starts from the first day of the month.)
	WW	Week in a year (1-53) (The first week starts from the first day of the year.)
	IW	Week in an ISO year (The first Thursday is in the first week.)
Century	CC	Century (with two digits) (The 21st century starts from 2001-01-01.)
Julian date	J	Julian date (starting from January 1 of 4712 BC)
Quarter	Q	Quarter

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1** in an A-compatible database, the date and time will be formatted in the specified pattern.

**Table 7-35** New formats for formatting date and time

Item	Format	Description
Century	SCC	Century. A hyphen (-) will be displayed before BC years.
Year	SYYYY	Returns a numeric year. A hyphen (-) will be displayed before BC years.

Item	Format	Description
	RR	Returns the two-digit year of a date.
	RRRR	Returns the four-digit year of a date.
	YEAR	Returns the year of the character type.
	SYEAR	Returns the year of the character type. A hyphen (-) will be displayed before BC years.
Date Format	DL	Returns the date in the specified long date format.
	DS	Returns the date in the specified short date format.
	TS	Returns the time in the specified time format.
Second	FF7	Microsecond (0000000-9999990)
	FF8	Microsecond (00000000-99999900)
	FF9	Microsecond (000000000-999999000)

 **NOTE**

In the table, the rules for RR to calculate years are as follows:

- If the range of the input two-digit year is between 00 and 49:  
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year are the same as the first two digits of the current year.  
If the last two digits of the current year are between 50 and 99, the first two digits of the returned year equal to the first two digits of the current year plus 1.
- If the range of the input two-digit year is between 50 and 99:  
If the last two digits of the current year are between 00 and 49, the first two digits of the returned year equal to the first two digits of the current year minus 1.  
If the last two digits of the current year are between 50 and 99, the first two digits of the returned year are the same as the first two digits of the current year.

 **NOTE**

In the scenario where this function is in an A-compatible database, the value of **a\_format\_version** is **10c**, and that of **a\_format\_dev\_version** is **s1**:

- The **to\_date** and **to\_timestamp** functions support the FX pattern (the input strictly corresponds to a pattern) and the X pattern (decimal point).
- The input pattern can appear only once, indicating that the patterns of the same information cannot appear at the same time. For example, SYYYY and BC cannot be used together.
- The pattern is case insensitive.
- You are advised to use a separator between the input and the pattern. Otherwise, the behavior may not be compatible with database O.

## 7.5.9 Type Conversion Functions

### Type Conversion Functions

- `cash_words(money)`

Description: Type conversion function, which converts money into text.

Example:

```
gaussdb=# SELECT cash_words('1.23');
           cash_words
-----
One dollar and twenty three cents
(1 row)
```

- `cast(x as y)`

Description: Converts *x* into the type specified by *y*.

Example:

```
gaussdb=# SELECT cast('22-oct-1997' as timestamp);
           timestamp
-----
1997-10-22 00:00:00
(1 row)
```

- `cast(x as y [DEFAULT z ON CONVERSION ERROR][,fmt])`

Description: Converts *x* into the type specified by *y*.

**DEFAULT z ON CONVERSION ERROR:** This parameter is optional. If the attempt to convert *x* to type *y* fails, *z* is converted to type *y* by default.

*fmt:* This parameter is optional, which can be specified when *y* is one of the following data types:

`int1/int2/int4/int8/int16/float4/float8/numeric:` The function of the optional parameter *fmt* is the same as that in the `to_number(expr [,fmt])` function.

`date/timestamp/timestamp with time zone:` The function of the optional parameter *fmt* is the same as that in the `to_date(string [,fmt])`/`to_timestamp(string [,fmt])` /`to_timestamp_tz(string [,fmt])` function.

Example:

```
gaussdb=# SELECT cast('22-ocX-1997' as timestamp DEFAULT '22-oct-1997' ON CONVERSION
ERROR, 'DD-Mon-YYYY');
           timestamp
-----
1997-10-22 00:00:00
(1 row)
```

#### NOTE

The `DEFAULT z ON CONVERSION ERROR` and *fmt* syntaxes are supported only when `a_format_version` is set to **10c** and `a_format_dev_version` is set to **s1**.

- `hextoraw(raw)`

Description: Converts a string in hexadecimal format into raw type.

Return type: raw

Example:

```
gaussdb=# SELECT hextoraw('7D');
           hextoraw
-----
7D
(1 row)
```

- numtoday(numeric)

Description: Converts values of the number type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT numtoday(2);
 numtoday
-----
 2 days
(1 row)
```

- rawtohex(string)

Description: Converts a string in binary format into hexadecimal format.

The result is the ACSII code of the input characters in hexadecimal format.

Return type: varchar

Example:

```
gaussdb=# SELECT rawtohex('1234567');
 rawtohex
-----
31323334353637
(1 row)
```

- rawtohex2(any)

Description: Converts a string in binary format into hexadecimal format.

The result is the ACSII code of the input characters in hexadecimal format.

The slash (/) can be parsed as a normal character and is not escaped.

When the input is null, the output is also null.

Return type: text

Example:

```
set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version='s2';
SET
gaussdb=# select rawtohex2('12\n?$/123/2');
 rawtohex2
-----
31325C6E3F245C3132332F32
(1 row)
```

- bit2coding(text)

Description: Reads two-byte characters, saves them based on the little-endian storage logic, parses each character into a hexadecimal ASCII code value, and converts the value into a decimal number.

Return type: int

Example:

```
gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version='s2';
SET
gaussdb=# select bit2coding('1234567890');
 bit2coding
-----
 12849
(1 row)
```

- bit4coding(text)

Description: Reads four-byte characters, saves them based on the little-endian storage logic, parses each character into a hexadecimal ASCII code value, and converts the value into a decimal number.

Return type: int

Example:

```
gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version='s2';
SET
gaussdb=# select bit4coding('1234567890');
 bit4coding
-----
875770417
(1 row)
```

- **to\_blob(raw)**

Description: Converts the RAW type to the BLOB type.

Return type: BLOB

Example:

```
gaussdb=# SELECT to_blob('0AADD343CDBBD'::RAW(10));
 to_blob
-----
00AADD343CDBBD
(1 row)
```

 **NOTE**

The **to\_blob** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_bigint(vvarchar)**

Description: Converts the character type to the bigint type.

Return type: bigint

Example:

```
gaussdb=# SELECT to_bigint('123364545554455');
 to_bigint
-----
123364545554455
(1 row)
```

- **to\_binary\_double(fmt)**

Description: Converts an expression to a value of the float8 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('12345678');
 to_binary_double
-----
12345678
(1 row)
```

- **to\_binary\_double(expr, fmt)**

Description: Converts an expression to a value of the float8 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('1,2,3', '9,9,9');
to_binary_double
-----
          123
(1 row)
```

- to\_binary\_double(expr default return\_value on conversion error)

Description: Converts an expression to a value of the float8 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: supports the number, float4, and float8 data types and numeric types that can be implicitly converted to character strings.

Note: If **expr** is not of the numeric or character type, an error is reported.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double(1e2 default 12 on conversion error);
to_binary_double
-----
          100
(1 row)
```

```
gaussdb=# SELECT to_binary_double('aa' default 12 on conversion error);
to_binary_double
-----
          12
(1 row)
```

- to\_binary\_double(expr default return\_value on conversion error, fmt)

Description: Converts an expression to a value of the float8 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float8

Example:

```
gaussdb=# SELECT to_binary_double('12-' default 10 on conversion error, '99S');
to_binary_double
-----
         -12
(1 row)
```

```
gaussdb=# SELECT to_binary_double('aa-' default 12 on conversion error, '99S');
to_binary_double
-----
          10
(1 row)
```

#### NOTE

The **to\_binary\_double** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- to\_binary\_float(expr)

Description: Converts an expression to a value of the float4 type.

**expr**: supports the number, float4, and float8 data types and character strings that can be implicitly converted to numeric types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('12345678');
to_binary_float
-----
1.23457e+07
(1 row)
```

- to\_binary\_float(expr, fmt)

Description: Converts an expression to a value of the float4 type after format matching.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('1,2,3', '9,9,9');
to_binary_float
-----
123
(1 row)
```

- to\_binary\_float(expr default return\_value on conversion error)

Description: Converts an expression to a value of the float4 type. If the conversion fails, the default value **return\_value** is returned.

**expr**: supports the number, float4, and float8 data types and numeric types that can be implicitly converted to character strings.

Note: If **expr** is not of the numeric or character type, an error is reported.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float(1e2 default 12 on conversion error);
to_binary_float
-----
100
(1 row)

gaussdb=# SELECT to_binary_float('aa' default 12 on conversion error);
to_binary_float
-----
12
(1 row)
```

- to\_binary\_float(expr default return\_value on conversion error, fmt)

Description: Converts an expression to a value of the float4 type after format matching. If the expression fails to be converted, the default value **return\_value** is returned.

**expr/fmt**: supports character strings of the char, nchar, varchar2, and nvarchar2 types. The **expr** also supports numeric types that can be implicitly converted to character types.

Return type: float4

Example:

```
gaussdb=# SELECT to_binary_float('12-' default 10 on conversion error, '99S');
to_binary_float
-----
          -12
(1 row)

gaussdb=# SELECT to_binary_float('aa-' default 12 on conversion error, '99S');
to_binary_float
-----
          10
(1 row)
```

 **NOTE**

The **to\_binary\_float** function is supported only when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s2**.

- **to\_char(datetime/interval [, fmt])**

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the VARCHAR type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-34](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char(current_timestamp,'HH12:MI:SS');
to_char
-----
10:19:26
(1 row)
gaussdb=# SELECT to_char(current_timestamp,'FMHH12:FMMI:FMSS');
to_char
-----
10:19:46
(1 row)
```

- **to\_char(double precision/real, text)**

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(125.8::real, '999D99');
to_char
-----
125.80
(1 row)
```

- **to\_char(numeric/smallint/integer/bigint/double precision/real[, fmt])**

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined

together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.). For details, see [Table 7-36](#).

- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char(1485,'9,999');
to_char
-----
1,485
(1 row)
gaussdb=# SELECT to_char( 1148.5,'9,999.999');
to_char
-----
1,148.500
(1 row)
gaussdb=# SELECT to_char(148.5,'990999.909');
to_char
-----
0148.500
(1 row)
gaussdb=# SELECT to_char(123,'XXX');
to_char
-----
7B
(1 row)
```

**Table 7-36** fmt parameter of the number type

Pattern	Description
, (comma)	Group (thousand) separator
. (period)	Decimal point
\$	\$ output to the specified position
0	Value with leading zeros
9	Value with specified digits
B	Space returned when the integer part is 0
C	Currency symbol (depending on the locale setting)
D	Decimal point (depending on the locale setting)
EEEE	Scientific notation
G	Group separator (depending on the locale setting)
L	Currency symbol (depending on the locale setting)

Pattern	Description
MI	Minus sign in the specified position (if the number is less than 0)
PR	Negative value in angle brackets
RN	Roman numeral (ranging from 1 to 3999)
S	Signed number (depending on the locale setting)
TM	Standard number in scientific notation
TM9	Standard number in scientific notation
TME	Standard number in scientific notation
U	Currency symbol (depending on the locale setting)
V	Decimal with specified number of digits shifted
PL	Plus sign in the specified position (if the number is greater than 0)
SG	Plus or minus sign in the specified position
TH or th	Ordinal number suffix

 NOTE

The *fmt* parameter can be set to **\$**, **C**, **TM**, **TM9**, **TME** or **U** only when **a\_format\_version** and **a\_format\_dev\_version** are set to **10c** and **s1**, respectively. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- `to_char(interval, text)`

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(interval '15h 2m 12s', 'HH24:MI:SS');
to_char
-----
15:02:12
(1 row)
```

- `to_char(integer, text)`

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(125, '999');
to_char
-----
125
(1 row)
```

- `to_char(set)`

Description: Converts a value of the SET type to a string.

Return value: text

Example:

```
-- site is a column of the SET type in the employee table.
gaussdb=# select to_char(site) from employee;
to_char
-----
beijing,nanjing
beijing,wuhan
(2 rows)
```

- `to_char(numeric, text)`

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(-125.8, '999D99S');
to_char
-----
125.80-
(1 row)
```

- `to_char(string)`

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the VARCHAR type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: varchar

Example:

```
gaussdb=# SELECT to_char('01110');
to_char
-----
01110
(1 row)
```

- `to_char(timestamp, text)`

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_char(current_timestamp, 'HH12:MI:SS');
to_char
-----
10:55:59
(1 row)
```

 NOTE

- The `to_char` function outputs the incorrect format (**fmt**) without change. For example, if the **fmt** is **FF10**, FF1 is matched for formatted output, and then **0** is output without change.
- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the `to_char` function reports an error for the incorrect format (**fmt**).

- `to_nchar (datetime/interval [, fmt])`

Description: Converts a DATETIME or INTERVAL value of the DATE/TIMESTAMP/TIMESTAMP WITH TIME ZONE/TIMESTAMP WITH LOCAL TIME ZONE type into the TEXT type according to the format specified by **fmt**.

- The optional parameter **fmt** allows for the following types: date, time, week, quarter, and century. Each type has a unique template. The templates can be combined together. Common templates include HH, MI, SS, YYYY, MM, and DD. For details, see [Table 7-36](#).
- A template may have a modification word. FM is a common modification word and is used to suppress the preceding zero or the following blank spaces.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(current_timestamp,'HH12:MI:SS');
to_nchar
-----
10:19:26
(1 row)
gaussdb=# SELECT to_nchar(current_timestamp,'FMHH12:FM MI:FMSS');
to_nchar
-----
10:19:46
(1 row)
```

- `to_nchar(double precision/real, text)`

Description: Converts the values of the floating point type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125.8::real, '999D99');
to_nchar
-----
125.80
(1 row)
```

- `to_nchar (numeric/smallint/integer/bigint/double precision/real[, fmt])`

Descriptions: Converts an integer or a value in floating point format into a string in specified format.

- The optional parameter *fmt* allows for the following types: decimal point, group (thousand) separator, positive/negative sign and currency sign. Each type has a unique template. The templates can be combined together. Common templates include: 9, 0, millesimal sign (,), and decimal point (.). For details, see [Table 7-36](#).
- A template can have a modification word, similar to FM. However, FM does not suppress 0 which is output according to the template.
- Use the template X or x to convert an integer value into a string in hexadecimal format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(1485,'9,999');
to_nchar
-----
1,485
(1 row)
gaussdb=# SELECT to_nchar( 1148.5,'9,999.999');
to_nchar
-----
1,148.500
(1 row)
gaussdb=# SELECT to_nchar(148.5,'990999.909');
to_nchar
-----
0148.500
(1 row)
gaussdb=# SELECT to_nchar(123,'XXX');
to_nchar
-----
7B
(1 row)
```

 **NOTE**

This function supports the \$, C, TM, TM9, TME and U patterns when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**. In addition, the **fmt** parameter cannot be set to **TH**, **PL**, or **SG** in this case.

- **to\_nchar(interval, text)**

Description: Converts the values of the time interval type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(interval '15h 2m 12s', 'HH24:MI:SS');
to_nchar
-----
15:02:12
(1 row)
```

- **to\_nchar(integer, text)**

Description: Converts the values of the integer type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(125, '999');
to_nchar
-----
125
(1 row)
```

- **to\_nchar(set)**

Description: Converts a value of the SET type to a string. The distributed system does not support the SET data type.

Return value: text

- **to\_nchar(numeric, text)**

Description: Converts the values of the numeric type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(-125.8, '999D99S');
to_nchar
-----
125.80-
(1 row)
```

- to\_nchar (string)

Description: Converts the CHAR/VARCHAR/VARCHAR2/CLOB type into the TEXT type.

If this function is used to convert data of the CLOB type, and the value to be converted exceeds the value range of the target type, an error is returned.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar('01110');
to_nchar
-----
01110
(1 row)
```

- to\_nchar(timestamp, text)

Description: Converts the values of the timestamp type into the strings in the specified format.

Return type: text

Example:

```
gaussdb=# SELECT to_nchar(current_timestamp, 'HH12:MI:SS');
to_nchar
-----
10:55:59
(1 row)
```

- to\_clob(char/nchar/varchar/varchar2/nvarchar2/text/raw)

Description: Converts the RAW type or text character set type CHAR, NCHAR, VARCHAR, VARCHAR2, NVARCHAR, NVARCHAR2, or TEXT to the CLOB type.

Return type: clob

Example:

```
gaussdb=# SELECT to_clob('ABCDEF'::RAW(10));
to_clob
-----
ABCDEF
(1 row)
gaussdb=# SELECT to_clob('hello111'::CHAR(15));
to_clob
-----
hello111
(1 row)
gaussdb=# SELECT to_clob('gauss123'::NCHAR(10));
to_clob
-----
gauss123
(1 row)
gaussdb=# SELECT to_clob('gauss234'::VARCHAR(10));
to_clob
-----
gauss234
(1 row)
gaussdb=# SELECT to_clob('gauss345'::VARCHAR2(10));
to_clob
-----
gauss345
(1 row)
```

```
gaussdb=# SELECT to_clob('gauss456'::NVARCHAR2(10));
to_clob
-----
gauss456
(1 row)
gaussdb=# SELECT to_clob('World222!'::TEXT);
to_clob
-----
World222!
(1 row)
```

- `to_date(text)`

Description: Converts values of the text type into the timestamp in the specified format. Currently, only the following two formats are supported:

- Format 1: Date without separators, for example, 20150814. The value must contain the complete year, month, and day.
- Format 2: Date with separators, for example, 2014-08-14. The separator can be any non-digit character.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT to_date('2015-08-14');
to_date
-----
2015-08-14 00:00:00
(1 row)
```

 **NOTE**

Case execution environment: The value of **a\_format\_version** is **10c**, the value of **a\_format\_dev\_version** is **s1**, and the value of **nls\_timestamp\_format** is **YYYY-MM-DD HH24:MI:SS**.

- `to_date(text, text)`

Description: Converts the values of the string type into the dates in the specified format.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date
-----
2000-12-05 00:00:00
(1 row)
```

- `to_date(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`

Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by **nls\_timestamp\_format** is used for conversion. Otherwise, the fixed format (*fmt* = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.

- *text*: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of converting *return\_value* to the DATE type is the same as that of

converting *text* to the DATE type. If *return\_value* fails to be converted to the DATE type, an error is reported.

- *fmt*: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```
gaussdb=# SELECT to_date('2015-08-14');
to_date
-----
2015-08-14 00:00:00
(1 row)
gaussdb=# SELECT to_date('05 Dec 2000', 'DD Mon YYYY');
to_date
-----
2000-12-05 00:00:00
(1 row)
gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SHOW nls_timestamp_format;
nls_timestamp_format
-----
DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)
gaussdb=# SELECT to_date('12-jan-2022' default '12-apr-2022' on conversion error);
to_date
-----
2022-01-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('12-ja-2022' default '12-apr-2022' on conversion error);
to_date
-----
2022-04-12 00:00:00
(1 row)
gaussdb=# SELECT to_date('2022-12-12' default '2022-01-01' on conversion error, 'yyyy-mm-dd');
to_date
-----
2022-12-12 00:00:00
(1 row)
```

---

**CAUTION**

- The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.
- When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, the system may not report an error if the entered year exceeds 9999. For example, the result of **to\_date('9999-12-12', 'yyyy-mm-dd hh24:mi:ss')** is **9999-09-12 12:00:00**. If the value of year exceeds 9999, the number following 9999 will be parsed as the next **fmt**. This restriction also applies to **to\_timestamp**.

- 
- **to\_number** ( *expr* [, *fmt*])

Description: Converts **expr** into a value of the NUMBER type according to the specified format.

For details about the type conversion formats, see [Table 7-37](#).

If a hexadecimal string is converted into a decimal number, the hexadecimal string can include a maximum of 16 bytes if it is to be converted into a sign-free number.

During the conversion from a hexadecimal string to a decimal digit, the format string cannot have a character other than x or X. Otherwise, an error is reported.

Return type: number

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

- `to_number(text, text)`

Description: Converts the values of the string type into the numbers in the specified format.

Return type: numeric

Example:

```
gaussdb=# SELECT to_number('12,454.8-', '99G999D9S');
to_number
-----
-12454.8
(1 row)
```

- `to_number(expr [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`

Description: Converts a string *expr* to a value of the numeric type based on the format specified by *fmt*. If *fmt* is not specified, *text* must be a character string that can be directly converted to numeric, for example, '123', '1e2'.

For details about the type conversion formats, see [Table 7-38](#).

- **expr**: an expression that can be converted into a CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT/INT/FLOAT string. If null is entered, null is returned.
- **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *expr* fails to be converted to the numeric type. Similar to *expr*, *return\_value* can be any type that can be converted to a character string. Similar to *expr*, *return\_value* is converted based on the format specified by *fmt*. The system checks whether *return\_value* fails to be converted. If *return\_value* fails to be converted, the function reports an error.
- **fmt**: This parameter is optional, which specifies the conversion format of *expr*.

If any input parameter is null, null is returned.

Return type: numeric

Example:

```
gaussdb=# SET a_format_version='10c';
gaussdb=# SET a_format_dev_version='s1';

gaussdb=# SELECT to_number('1e2');
to_number
-----
100
(1 row)
```

```

gaussdb=# SELECT to_number('123.456');
to_number
-----
 123.456
(1 row)

gaussdb=# SELECT to_number('123', '999');
to_number
-----
   123
(1 row)

gaussdb=# SELECT to_number('123-', '999MI');
to_number
-----
  -123
(1 row)

gaussdb=# SELECT to_number('123' default '456-' on conversion error, '999MI');
to_number
-----
  -456
(1 row)

```

 **NOTE**

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- **to\_timestamp(double precision)**

Description: Converts a Unix century into a timestamp.

Return type: timestamp with time zone

Example:

```

gaussdb=# SELECT to_timestamp(1284352323);
to_timestamp
-----
2010-09-13 12:32:03+08
(1 row)

```

- **to\_timestamp(string [,fmt])**

Description: Converts a string into a value of the timestamp type according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_format**.

In **to\_timestamp** in GaussDB:

- If the input year *YYYY* is 0, an error will be reported.
- If the input year *YYYY* is less than 0, specify *SYYYY* in **fmt**. The year with the value of *n* (an absolute value) BC will be output correctly.

Characters in the **fmt** must match the schema for formatting the data and time. Otherwise, an error is reported.

Return type: timestamp without time zone

Example:

```

gaussdb=# SHOW nls_timestamp_format;
nls_timestamp_format
-----
DD-Mon-YYYY HH:MI:SS.FF AM
(1 row)

gaussdb=# SELECT to_timestamp('12-sep-2014');
to_timestamp
-----

```

```

2014-09-12 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SS.FF');
to_timestamp
-----
2010-09-12 14:10:10.123
(1 row)
gaussdb=# SELECT to_timestamp('-1','YYYY');
to_timestamp
-----
0001-01-01 00:00:00 BC
(1 row)
gaussdb=# SELECT to_timestamp('98','RR');
to_timestamp
-----
1998-01-01 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('01','RR');
to_timestamp
-----
2001-01-01 00:00:00
(1 row)

```

 **NOTE**

1. When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, **fmt** supports FF[7-9]. When FF[7-9] is used, and the length of the corresponding position in the string is less than or equal to the number following FF, then, the number can be converted. However, the maximum length of the final conversion result is six digits.
  2. The result returned by the `current_timestamp` function cannot be used as a string parameter.
- `to_timestamp(text [DEFAULT return_value ON CONVERSION ERROR [, fmt]])`  
Description: Converts a string *text* into a value of the DATE type according to the format specified by *fmt*. If *fmt* is not specified, **a\_format\_version** is set to **10c**, and **a\_format\_dev\_version** is set to **s1**, the format specified by **nls\_timestamp\_format** is used for conversion. Otherwise, the fixed format (*fmt* = 'yyyy-mm-dd hh24-mi-ss') is used for conversion.
    - *text*: any expression that can be calculated to CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT string. If null is entered, null is returned.
    - **DEFAULT return\_value ON CONVERSION ERROR**: This parameter is optional, which can be used to specify the return value when *text* fails to be converted to the DATE type. The value of *return\_value* can be an expression or a bound variable that can be converted to the CHAR/VARCHAR2/NCHAR/NVARCHAR2/TEXT type or null. The method of converting *return\_value* to the timestamp type is the same as that of converting *text* to the timestamp type. If *return\_value* fails to be converted to the timestamp type, an error is reported.
    - *fmt*: This parameter is optional, which specifies the date and time model format of *text*. By default, *text* must comply with the default date format. If *fmt* is set to *J*, *text* must be an integer.

Return type: timestamp without time zone

Example:

```

gaussdb=# SET a_format_version='10c';
SET
gaussdb=# SET a_format_dev_version='s1';
SET
gaussdb=# SELECT to_timestamp('11-Sep-11' DEFAULT '12-Sep-10 14:10:10.123000' ON
CONVERSION ERROR,'DD-Mon-YY HH24:MI:SS.FF');

```

```
to_timestamp
-----
2011-09-11 00:00:00
(1 row)
gaussdb=# SELECT to_timestamp('12-Sep-10 14:10:10.123000','DD-Mon-YY HH24:MI:SSXFF');
to_timestamp
-----
2010-09-12 14:10:10.123
(1 row)
```

**NOTE**

The DEFAULT *return\_value* ON CONVERSION ERROR syntax is supported only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- `to_timestamp(text, text)`

Description: Converts values of the string type into the timestamp of the specified type.

Return type: timestamp

Example:

```
gaussdb=# SELECT to_timestamp('05 Dec 2000', 'DD Mon YYYY');
to_timestamp
-----
2000-12-05 00:00:00
(1 row)
```

- `to_timestamp_tz(text [,text])`

Description: Converts values of the string type into the timestamp of the specified type with the time zone.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 Dec 2001', 'DD Mon YYYY');
to_timestamp_tz
-----
2001-12-05 00:00:00+08:00
(1 row)
```

**NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- `to_timestamp_tz(string [DEFAULT return_value ON CONVERSION ERROR] [,fmt])`

Description: Converts a string into a value of the timestamp type with the time zone according to the format specified by **fmt**. When **fmt** is not specified, perform the conversion according to the format specified by **nls\_timestamp\_tz\_format**.

**DEFAULT return\_value ON CONVERSION ERROR:** This parameter is optional. If *string* fails to be converted to the timestamp type with time zone, *return\_value* is converted to the timestamp type with time zone.

*fmt:* This parameter is optional, which specifies the date and time model format of *string*. The setting of this parameter is the same as that in the `to_timestamp` function.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT to_timestamp_tz('05 DeX 2000' DEFAULT '05 Dec 2001' ON CONVERSION ERROR, 'DD Mon YYYY');
```

```
to_timestamp_tz
-----
2001-12-05 00:00:00+08:00
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

- **to\_dsinterval(text)**

Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_dsinterval('12 1:2:3.456');
to_dsinterval
-----
12 days 01:02:03.456
(1 row)
```

```
gaussdb=# SELECT to_dsinterval('P3DT4H5M6S');
to_dsinterval
-----
3 days 04:05:06
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

- **to\_ymininterval(text)**

Description: Converts characters to the interval type. SQL-compatible and ISO formats are supported.

Return type: interval

Example:

```
gaussdb=# SELECT to_ymininterval('1-1');
to_ymininterval
-----
1 year 1 mon
(1 row)
```

```
gaussdb=# SELECT to_ymininterval('P13Y3M4DT4H2M5S');
to_ymininterval
-----
13 years 3 mons
(1 row)
```

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

**Table 7-37** Template patterns for numeric formatting

Pattern	Description
9	Value with specified digits
0	Values with leading zeros

Pattern	Description
Period (.)	Decimal point
Comma (,)	Group (thousand) separator
PR	Negative values in angle brackets
S	Signed number (depending on the locale setting)
L	Currency symbol (depending on the locale setting)
D	Decimal point (depending on the locale setting).
G	Group separator (depending on the locale setting)
MI	Minus sign in the specified position (if the number is less than 0)
PL	Plus sign in the specified position (if the number is greater than 0)
SG	Plus or minus sign in the specified position
RN	Roman numeral (ranging from 1 to 3999)
TH or th	Ordinal number suffix
V	Decimal with specified number of digits shifted
x or X	Hexadecimal-to-decimal conversion identifier

**Table 7-38** Template patterns for to\_number formatting

Pattern	Description
9	Matches a digit. The number of digits "9" can be greater than or equal to that in the corresponding position in <i>expr</i> .
0	Strictly matches a digit. The number of digits "0" must be equal to that in <i>expr</i> .
5	Matches digit 0 or 5.
Period (.)	Decimal point in the specified position.
Comma (,)	Group (thousand) separator in the specified position. Multiple commas can be specified in <i>fmt</i> .
B	No leading sign.
PR	A negative value in angle brackets, or a positive value with no leading sign.
S	A negative value with the leading minus sign (-) or a positive value with the leading plus sign (+)

Pattern	Description
MI	A negative value with the leading minus sign (-) or a positive value with no leading sign.
\$	Leading dollar sign.
L	Local currency symbol.
C	Symbol of currency in the specified position (complying with the ISO standard).
U	Dual-currency symbol.
D	Decimal point (depending on the locale setting).
G	Group separator (complying with the ISO standard). Multiple commas can be specified in <i>fmt</i> .
RN / rn	Roman numeral (ranging from 1 to 3999). <i>to_number</i> does not support this format.
V	<i>to_number</i> does not support this format.
X / x	Conversion between hexadecimal and decimal.
TM	<i>to_number</i> does not support this format.
FM	This format can be used only at the beginning of <i>fmt</i> .
EEEE	Conversion based on the scientific notation model.

 NOTE

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**, refer to this table for the setting of *fmt*. Otherwise, refer to the previous table. The *fmt* setting complying with the ISO standard is affected by the values of **LC\_MONETARY** and **LC\_NUMERIC** parameters.

- `cast_varchar2_to_raw_for_histogram(varchar2)`  
Description: Converts from the varchar2 type to the raw type.  
Return type: raw
- `abstime_text()`  
Description: Converts abstime to text.  
Parameter: abstime  
Return type: text
- `abstime_to_smalldatetime`  
Description: Converts abstime to smalldatetime.  
Parameter: abstime  
Return type: smalldatetime
- `bigint_tid`  
Description: Converts bigint to tid.

- Parameter: bigint  
Return type: tid
- `bool_int1`  
Description: Converts Boolean to int1.  
Parameter: Boolean  
Return type: tinyint
  - `bool_int2`  
Description: Converts Boolean to int2.  
Parameter: Boolean  
Return type: smallint
  - `bool_int8`  
Description: Converts Boolean to int8.  
Parameter: Boolean  
Return type: bigint
  - `bpchar_date`  
Description: Converts a string to a date.  
Parameter: character  
Return type: date
  - `bpchar_float4`  
Description: Converts a string to float4.  
Parameter: character  
Return type: real
  - `bpchar_float8`  
Description: Converts a string to float8.  
Parameter: character  
Return type: double precision
  - `bpchar_int4`  
Description: Converts a string to int4.  
Parameter: character  
Return type: integer
  - `bpchar_int8`  
Description: Converts a string to int8.  
Parameter: character  
Return type: bigint
  - `bpchar_numeric`  
Description: Converts a string to numeric.  
Parameter: character  
Return type: numeric
  - `bpchar_timestamp`  
Description: Converts a string to a timestamp.  
Parameter: character

- Return type: timestamp without time zone
- `bpchar_to_smalldatetime`  
Description: Converts a string to smalldatetime.  
Parameter: character  
Return type: smalldatetime
  - `complex_array_in`  
Description: Converts the external `complex_array` type to the internal `anyarray` array type.  
Parameter: `cstring`, `oid`, `int2vector`  
Return type: `anyarray`
  - `date_bpchar`  
Description: Converts the date type to `bpchar`.  
Parameter: date  
Return type: character
  - `date_text`  
Description: Converts date to text.  
Parameter: date  
Return type: text
  - `date_varchar`  
Description: Converts date to `varchar`.  
Parameter: date  
Return type: character varying
  - `f4toi1`  
Description: Forcibly converts `float4` to `uint8`.  
Parameter: real  
Return type: `tinyint`
  - `f8toi1`  
Description: Forcibly converts `float8` to `uint8`.  
Parameter: double precision  
Return type: `tinyint`
  - `float4_bpchar`  
Description: Converts `float4` to `bpchar`.  
Parameter: real  
Return type: character
  - `float4_text`  
Description: Converts `float4` to text.  
Parameter: real  
Return type: text
  - `float4_varchar`  
Description: Converts `float4` to `varchar`.  
Parameter: real

- Return type: character varying
- float8\_bpchar  
Description: Converts float8 to bpchar.  
Parameter: double precision  
Return type: character
  - float8\_interval  
Description: Converts float8 to interval.  
Parameter: double precision  
Return type: interval
  - float8\_text  
Description: Converts float8 to text.  
Parameter: double precision  
Return type: text
  - float8\_varchar  
Description: Converts float8 to varchar.  
Parameter: double precision  
Return type: character varying
  - i1tof4  
Description: Converts uint8 to float4.  
Parameter: tinyint  
Return type: real
  - i1tof8  
Description: Converts uint8 to float8.  
Parameter: tinyint  
Return type: double precision
  - i1toi2  
Description: Converts uint8 to int16.  
Parameter: tinyint  
Return type: smallint
  - i1toi4  
Description: Converts uint8 to int32.  
Parameter: tinyint  
Return type: integer
  - i1toi8  
Description: Converts uint8 to int64.  
Parameter: tinyint  
Return type: bigint
  - i2toi1  
Description: Converts int16 to uint8.  
Parameter: smallint  
Return type: tinyint

- `i4toi1`  
Description: Converts int32 to uint8.  
Parameter: integer  
Return type: tinyint
- `i8toi1`  
Description: Converts int64 to uint8.  
Parameter: bigint  
Return type: tinyint
- `int1_avg_accum`  
Description: Adds the second parameter of the uint8 type to the first parameter. The first parameter is an array of the bigint type.  
Parameter: bigint[], tinyint  
Return type: bigint[]
- `int1_bool`  
Description: Converts uint8 to Boolean.  
Parameter: tinyint  
Return type: Boolean
- `int1_bpchar`  
Description: Converts uint8 to bpchar.  
Parameter: tinyint  
Return type: character
- `int1_mul_cash`  
Description: Returns the product of a parameter of the int8 type and a parameter of the cash type. The return type is cash.  
Parameter: tinyint, money  
Return type: money
- `int1_numeric`  
Description: Converts uint8 to numeric.  
Parameter: tinyint  
Return type: numeric
- `int1_nvarchar2`  
Description: Converts uint8 to nvarchar2.  
Parameter: tinyint  
Return type: nvarchar2
- `int1_text`  
Description: Converts uint8 to text.  
Parameter: tinyint  
Return type: text
- `int1_varchar`  
Description: Converts uint8 to varchar.  
Parameter: tinyint

- Return type: character varying
- `int1in`  
Description: Converts a string into an unsigned 1-byte integer.  
Parameter: `cstring`  
Return type: `tinyint`
  - `int1out`  
Description: Converts an unsigned 1-byte integer into a string.  
Parameter: `tinyint`  
Return type: `cstring`
  - `int1up`  
Description: Converts an input integer to an unsigned 1-byte integer.  
Parameter: `tinyint`  
Return type: `tinyint`
  - `int2_bool`  
Description: Converts a signed two-byte integer to the `bool` type.  
Parameter: `smallint`  
Return type: `Boolean`
  - `int2_bpchar`  
Description: Converts a signed two-byte integer to the `bpchar` type.  
Parameter: `smallint`  
Return type: `character`
  - `int2_text`  
Description: Converts a signed two-byte integer to the `text` type.  
Parameter: `smallint`  
Return type: `text`
  - `int2_varchar`  
Description: Converts a signed two-byte integer to the `varchar` type.  
Parameter: `smallint`  
Return type: `character varying`
  - `int4_bpchar`  
Description: Converts a signed four-byte integer to `bpchar`.  
Parameter: `integer`  
Return type: `character`
  - `int4_text`  
Description: Converts a signed four-byte integer to the `text` type.  
Parameter: `integer`  
Return type: `text`
  - `int4_varchar`  
Description: Converts a signed four-byte integer into `varchar`.  
Parameter: `integer`  
Return type: `character varying`

- `int8_bool`  
Description: Converts an eight-byte signed integer to a Boolean value.  
Parameter: `bigint`  
Return type: Boolean
- `int8_bpchar`  
Description: Converts an 8-byte signed integer to `bpchar`.  
Parameter: `bigint`  
Return type: character
- `int8_text`  
Description: Converts an eight-byte signed integer to the text type.  
Parameter: `bigint`  
Return type: text
- `int8_varchar`  
Description: Converts an eight-byte signed integer to `varchar`.  
Parameter: `bigint`  
Return type: character varying
- `intervaltonum`  
Description: Converts the internal data type `date` to numeric.  
Parameter: `interval`  
Return type: numeric
- `numeric_bpchar`  
Description: Converts numeric to `bpchar`.  
Parameter: `numeric`  
Return type: character
- `numeric_int1`  
Description: Converts numeric to a signed one-byte integer.  
Parameter: `numeric`  
Return type: `tinyint`
- `numeric_text`  
Description: Converts numeric to text.  
Parameter: `numeric`  
Return type: text
- `numeric_varchar`  
Description: Converts numeric to `varchar`.  
Parameter: `numeric`  
Return type: character varying
- `nvarchar2in`  
Description: Converts `c` string to `varchar`.  
Parameter: `cstring`, `oid`, `integer`  
Return type: `nvarchar2`

- `nvarchar2out`  
Description: Converts text into a c string.  
Parameter: `nvarchar2`  
Return type: `cstring`
- `nvarchar2send`  
Description: Converts varchar to binary.  
Parameter: `nvarchar2`  
Return type: `bytea`
- `oidvectorin_extend`  
Description: Converts a string to oidvector.  
Parameter: `cstring`  
Return type: `oidvector_extend`
- `oidvectorout_extend`  
Description: Converts oidvector to a string.  
Parameter: `oidvector_extend`  
Return type: `cstring`
- `oidvectorsend_extend`  
Description: Converts oidvector to a string.  
Parameter: `oidvector_extend`  
Return type: `bytea`
- `reltime_text`  
Description: Converts reltime to text.  
Parameter: `reltime`  
Return type: `text`
- `text_date`  
Description: Converts the text type to the date type.  
Parameter: `text`  
Return type: `date`
- `text_float4`  
Description: Converts text to float4.  
Parameter: `text`  
Return type: `real`
- `text_float8`  
Description: Converts the text type to float8.  
Parameter: `text`  
Return type: `double precision`
- `text_int1`  
Description: Converts the text type to int1.  
Parameter: `text`  
Return type: `tinyint`

- `text_int2`  
Description: Converts the text type to the int2 type.  
Parameter: text  
Return type: smallint
- `text_int4`  
Description: Converts the text type to int4.  
Parameter: text  
Return type: integer
- `text_int8`  
Description: Converts the text type to the int8 type.  
Parameter: text  
Return type: bigint
- `text_numeric`  
Description: Converts the text type to the numeric type.  
Parameter: text  
Return type: numeric
- `text_timestamp`  
Description: Converts the text type to the timestamp type.  
Parameter: text  
Return type: timestamp without time zone
- `time_text`  
Description: Converts the time type to the text type.  
Parameter: time without time zone  
Return type: text
- `timestamp_text`  
Description: Converts the timestamp type to the text type.  
Parameter: timestamp without time zone  
Return type: text
- `timestamp_to_smalldatetime`  
Description: Converts the timestamp type to the smalldatetime type.  
Parameter: timestamp without time zone  
Return type: smalldatetime
- `timestamp_varchar`  
Description: Converts the timestamp type to varchar.  
Parameter: timestamp without time zone  
Return type: character varying
- `timestamptz_to_smalldatetime`  
Description: Converts timestamptz to smalldatetime.  
Parameter: timestamp with time zone  
Return type: smalldatetime

- `timestampzone_text`  
Description: Converts the `timestampzone` type to the `text` type.  
Parameter: timestamp with time zone  
Return type: text
- `timetz_text`  
Description: Converts the `timetz` type to the `text` type.  
Parameter: time with time zone  
Return type: text
- `to_integer`  
Description: Converts data to the integer type.  
Parameter: character varying  
Return type: integer
- `to_interval`  
Description: Converts to the interval type.  
Parameter: character varying  
Return type: interval
- `to_numeric`  
Description: Converts to the numeric type.  
Parameter: character varying  
Return type: numeric
- `to_nvarchar2`  
Description: Converts to the `nvarchar2` type.  
Parameter: numeric  
Return type: `nvarchar2`
- `to_text`  
Description: Converts to the `text` type.  
Parameter: `smallint`  
Return type: text
- `to_ts`  
Description: Converts to the `ts` type.  
Parameter: character varying  
Return type: timestamp without time zone
- `to_varchar2`  
Description: Converts to the `varchar2` type.  
Parameter: timestamp without time zone  
Return type: character varying
- `varchar_date`  
Description: Converts `varchar` to `date`.  
Parameter: character varying  
Return type: date

- `varchar_float4`  
Description: Converts varchar to float4.  
Parameter: character varying  
Return type: real
- `varchar_float8`  
Description: Converts the varchar type to the float8 type.  
Parameter: character varying  
Return type: double precision
- `varchar_int4`  
Description: Converts the type from varchar to int4.  
Parameter: character varying  
Return type: integer
- `varchar_int8`  
Description: Converts the varchar type to the int8 type.  
Parameter: character varying  
Return type: bigint
- `varchar_numeric`  
Description: Converts varchar to numeric.  
Parameter: character varying  
Return type: numeric
- `varchar_timestamp`  
Description: Converts varchar to timestamp.  
Parameter: character varying  
Return type: timestamp without time zone
- `varchar2_to_smlldatetime`  
Description: Converts varchar2 to smlldatetime.  
Parameter: character varying  
Return type: smalldatetime
- `xidout4`  
Description: The xid output is a four-byte number.  
Parameter: xid32  
Return type: cstring
- `xidsend4`  
Description: Converts xid to the binary format.  
Parameter: xid32  
Return type: bytea
- `treat(expr AS [JSON | REF] schema.type)`  
Description: Converts expr to the type (JSON or user-defined type) specified by the keyword after AS.  
Return value type: JSON or user-defined type.  
Example:

```
gaussdb=# CREATE TABLE json_doc(data CLOB);
gaussdb=# INSERT INTO json_doc VALUES({'name':"a"});
gaussdb=# SELECT treat(data as json) FROM json_doc;
      json
-----
{"name":"a"}
(1 row)
gaussdb=# DROP TABLE json_doc;
DROP TABLE
```

- `nesttable_to_array(anynesttable)`

Description: Converts a nest-table collection type to an array type with the same elements.

Parameter: `anynesttable`

Return type: `anyarray`

Example:

```
gaussdb=# create or replace procedure p1 is
gaussdb$#   type t1 is table of int;
gaussdb$#   v1 t1 := t1(1, 2, 3);
gaussdb$#   v2 int[] := cast(v1 as int[]);
gaussdb$# begin
gaussdb$#   raise info '%', v2;
gaussdb$# end;
gaussdb$# /
CREATE PROCEDURE
gaussdb=# call p1();
INFO: {1,2,3}
p1
----
(1 row)
```

```
gaussdb=# CREATE TYPE t1 is table of int;
CREATE TYPE
gaussdb=# SELECT cast(t1(1, 2, 3) as int[]) result;
      result
-----
{1,2,3}
(1 row)
gaussdb=# DROP PROCEDURE p1;
DROP PROCEDURE

gaussdb=# DROP TYPE t1;
DROP TYPE
```

- `indexbytableint_to_array(anyindexbytable)`

Description: Converts a collection whose index type is integer to an array type with the same elements.

Parameter: `anyindexbytable`

Return type: `anyarray`

Example:

```
gaussdb=# create or replace package pkg1 is
gaussdb$#   type t1 is table of int index by int;
gaussdb$#   procedure p1();
gaussdb$# end pkg1;
gaussdb$# /
CREATE PACKAGE

gaussdb=# create or replace package body pkg1 is
gaussdb$#   procedure p1() is
gaussdb$#     v1 t1 := t1(1 => 1, 2 => 2, 3 => 3);
gaussdb$#     v2 int[];
gaussdb$#   begin
```

```

gaussdb$#      v2 := cast(v1 as int[]);
gaussdb$#      raise info '%', v2;
gaussdb$#      end;
gaussdb$# end pkg1;
gaussdb$# /
CREATE PACKAGE BODY

gaussdb=# call pkg1.p1();
INFO: {1,2,3}
 p1
----
(1 row)

gaussdb=# select indexbytableint_to_array(pkg1.t1(1 => 1, 2 => 2, 3 => 3));
indexbytableint_to_array
-----
{1,2,3}
(1 row)

gaussdb=# DROP PACKAGE pkg1;
DROP PACKAGE

```

## Encoding Type Conversion

- `convert_to_nocase(text, text)`

Description: Converts a string into a specified encoding type.

Return type: `bytea`

Example:

```

gaussdb=# SELECT convert_to_nocase('12345', 'GBK');
convert_to_nocase
-----
\x3132333435
(1 row)

```

## 7.5.10 Geometric Functions and Operators

### Geometric Operators

- +

Description: Translation

Example:

```

gaussdb=# SELECT box '((0,0),(1,1))' + point '(2.0,0)' AS RESULT;
result
-----
(3,1),(2,0)
(1 row)

```

- -

Description: Translation

Example:

```

gaussdb=# SELECT box '((0,0),(1,1))' - point '(2.0,0)' AS RESULT;
result
-----
(-1,1),(-2,0)
(1 row)

```

- \*

Description: Scaling out/Rotation

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' * point '(2.0,0)' AS RESULT;  
result  
-----  
(2,2),(0,0)  
(1 row)
```

- /  
Description: Scaling in/Rotation

Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' / point '(2.0,0)' AS RESULT;  
result  
-----  
(1,1),(0,0)  
(1 row)
```

- #  
Description: Intersection of two figures

Example:

```
gaussdb=# SELECT box '((1,-1),(-1,1))' # box '((1,1),(-2,-2))' AS RESULT;  
result  
-----  
(1,1),(-1,-1)  
(1 row)
```

- #  
Description: Number of paths or polygon vertexes

Example:

```
gaussdb=# SELECT # path '((1,0),(0,1),(-1,0))' AS RESULT;  
result  
-----  
3  
(1 row)
```

- @-@  
Description: Length or circumference

Example:

```
gaussdb=# SELECT @-@ path '((0,0),(1,0))' AS RESULT;  
result  
-----  
2  
(1 row)
```

- @@  
Description: Center of box

Example:

```
gaussdb=# SELECT @@ circle '((0,0),10)' AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- <->  
Description: Distance between the two figures

Example:

```
gaussdb=# SELECT circle '((0,0),1)' <-> circle '((5,0),1)' AS RESULT;  
result  
-----  
3  
(1 row)
```

- **&&**  
Description: Overlaps? (One point in common makes this true.)  
Example:  
gaussdb=# SELECT box '((0,0),(1,1))' && box '((0,0),(2,2))' AS RESULT;  
result  
-----  
t  
(1 row)
- **<<**  
Description: Is strictly left of (no common horizontal coordinate)?  
Example:  
gaussdb=# SELECT circle '((0,0),1)' << circle '((5,0),1)' AS RESULT;  
result  
-----  
t  
(1 row)
- **>>**  
Description: Is strictly right of (no common horizontal coordinate)?  
Example:  
gaussdb=# SELECT circle '((5,0),1)' >> circle '((0,0),1)' AS RESULT;  
result  
-----  
t  
(1 row)
- **&<**  
Description: Does not extend to the right of?  
Example:  
gaussdb=# SELECT box '((0,0),(1,1))' &< box '((0,0),(2,2))' AS RESULT;  
result  
-----  
t  
(1 row)
- **&>**  
Description: Does not extend to the left of?  
Example:  
gaussdb=# SELECT box '((0,0),(3,3))' &> box '((0,0),(2,2))' AS RESULT;  
result  
-----  
t  
(1 row)
- **<<|**  
Description: Is strictly below (no common horizontal coordinate)?  
Example:  
gaussdb=# SELECT box '((0,0),(3,3))' <<| box '((3,4),(5,5))' AS RESULT;  
result  
-----  
t  
(1 row)
- **|>>**  
Description: Is strictly above (no common horizontal coordinate)?  
Example:  
gaussdb=# SELECT box '((3,4),(5,5))' |>> box '((0,0),(3,3))' AS RESULT;  
result

- t  
(1 row)

  - &<|

Description: Does not extend above?

Example:

```
gaussdb=# SELECT box '((0,0),(1,1))' &<| box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
  - |&>

Description: Does not extend below?

Example:

```
gaussdb=# SELECT box '((0,0),(3,3))' |&> box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
  - <^

Description: Is below (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(-3,-3))' <^ box '((0,0),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
  - >^

Description: Is above (allows touching)?

Example:

```
gaussdb=# SELECT box '((0,0),(2,2))' >^ box '((0,0),(-3,-3))' AS RESULT;
result
-----
t
(1 row)
```
  - ?#

Description: Intersect?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?# box '((-2,-2),(2,2))' AS RESULT;
result
-----
t
(1 row)
```
  - ?-

Description: Is horizontal?

Example:

```
gaussdb=# SELECT ?- lseg '((-1,0),(1,0))' AS RESULT;
result
-----
t
(1 row)
```
  - ?-

Description: Are horizontally aligned?

Example:

```
gaussdb=# SELECT point '(1,0)' ?- point '(0,0)' AS RESULT;
result
-----
t
(1 row)
```

- ?|

Description: Is vertical?

Example:

```
gaussdb=# SELECT ?| lseg '((-1,0),(1,0))' AS RESULT;
result
-----
f
(1 row)
```

- ?|

Description: Are vertically aligned?

Example:

```
gaussdb=# SELECT point '(0,1)' ?| point '(0,0)' AS RESULT;
result
-----
t
(1 row)
```

- ?-|

Description: Are perpendicular?

Example:

```
gaussdb=# SELECT lseg '((0,0),(0,1))' ?-| lseg '((0,0),(1,0))' AS RESULT;
result
-----
t
(1 row)
```

- ?||

Description: Are parallel?

Example:

```
gaussdb=# SELECT lseg '((-1,0),(1,0))' ?|| lseg '((-1,2),(1,2))' AS RESULT;
result
-----
t
(1 row)
```

- @>

Description: Contains?

Example:

```
gaussdb=# SELECT circle '((0,0),2)' @> point '(1,1)' AS RESULT;
result
-----
t
(1 row)
```

- <@

Description: Contained in or on?

Example:

```
gaussdb=# SELECT point '(1,1)' <@ circle '((0,0),2)' AS RESULT;
result
-----
t
(1 row)
```

- `~=`  
Description: Specifies whether two figures are the same.

Example:

```
gaussdb=# SELECT polygon '((0,0),(1,1))' ~= polygon '((1,1),(0,0))' AS RESULT;  
result  
-----  
t  
(1 row)
```

## Geometric Functions

- `area(object)`  
Description: Area calculation  
Return type: double precision  
Example:  

```
gaussdb=# SELECT area(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
1  
(1 row)
```
- `center(object)`  
Description: Figure center calculation  
Return type: point  
Example:  

```
gaussdb=# SELECT center(box '((0,0),(1,2))') AS RESULT;  
result  
-----  
(0.5,1)  
(1 row)
```
- `diameter(circle)`  
Description: Circle diameter calculation  
Return type: double precision  
Example:  

```
gaussdb=# SELECT diameter(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
4  
(1 row)
```
- `height(box)`  
Description: Vertical size of box  
Return type: double precision  
Example:  

```
gaussdb=# SELECT height(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
1  
(1 row)
```
- `isclosed(path)`  
Description: A closed path?  
Return type: Boolean  
Example:

```
gaussdb=# SELECTisclosed(path '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
t  
(1 row)
```

- **isopen(path)**

Description: An open path?

Return type: Boolean

Example:

```
gaussdb=# SELECT isopen(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
t  
(1 row)
```

- **length(object)**

Description: Length calculation

Return type: double precision

Example:

```
gaussdb=# SELECT length(path '((-1,0),(1,0)')) AS RESULT;  
result  
-----  
4  
(1 row)
```

- **npoints(path)**

Description: Number of points in path

Return type: int

Example:

```
gaussdb=# SELECT npoints(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
3  
(1 row)
```

- **npoints(polygon)**

Description: Number of points in polygon

Return type: int

Example:

```
gaussdb=# SELECT npoints(polygon '((1,1),(0,0)')) AS RESULT;  
result  
-----  
2  
(1 row)
```

- **pclose(path)**

Description: Converts path to closed.

Return type: path

Example:

```
gaussdb=# SELECT pclose(path '[(0,0),(1,1),(2,0)]') AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

- **popen(path)**

Description: Converts path to open.

Return type: path

Example:

```
gaussdb=# SELECT popen(path '((0,0),(1,1),(2,0))) AS RESULT;  
result  
-----  
[(0,0),(1,1),(2,0)]  
(1 row)
```

- radius(circle)

Description: Circle diameter calculation

Return type: double precision

Example:

```
gaussdb=# SELECT radius(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
2  
(1 row)
```

- width(box)

Description: Horizontal size of box

Return type: double precision

Example:

```
gaussdb=# SELECT width(box '((0,0),(1,1)')) AS RESULT;  
result  
-----  
1  
(1 row)
```

## Geometric Type Conversion Functions

- box(circle)

Description: Circle to box

Return type: box

Example:

```
gaussdb=# SELECT box(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
(1.41421356237309,1.41421356237309),(-1.41421356237309,-1.41421356237309)  
(1 row)
```

- box(point, point)

Description: Points to box

Return type: box

Example:

```
gaussdb=# SELECT box(point '(0,0)', point '(1,1)') AS RESULT;  
result  
-----  
(1,1),(0,0)  
(1 row)
```

- box(polygon)

Description: Polygon to box

Return type: box

Example:

```
gaussdb=# SELECT box(polygon '((0,0),(1,1),(2,0)')) AS RESULT;  
result
```

- ```
-----
(2,1),(0,0)
(1 row)
```
- circle(box)**  
Description: Box to circle  
Return type: circle  
Example:  
gaussdb=# SELECT circle(box '((0,0),(1,1))') AS RESULT;  
result  
-----  
<(0.5,0.5),0.707106781186548>  
(1 row)
  - circle(point, double precision)**  
Description: Center and radius to circle  
Return type: circle  
Example:  
gaussdb=# SELECT circle(point '(0,0)', 2.0) AS RESULT;  
result  
-----  
<(0,0),2>  
(1 row)
  - circle(polygon)**  
Description: Polygon to circle  
Return type: circle  
Example:  
gaussdb=# SELECT circle(polygon '((0,0),(1,1),(2,0))') AS RESULT;  
result  
-----  
<(1,0.3333333333333333),0.924950591148529>  
(1 row)
  - lseg(box)**  
Description: Box diagonal to line segment  
Return type: lseg  
Example:  
gaussdb=# SELECT lseg(box '(((-1,0),(1,0))') AS RESULT;  
result  
-----  
[[(-1,0),(1,0)]]  
(1 row)
  - lseg(point, point)**  
Description: Points to line segment  
Return type: lseg  
Example:  
gaussdb=# SELECT lseg(point '(-1,0)', point '(1,0)') AS RESULT;  
result  
-----  
[(-1,0),(1,0)]  
(1 row)
  - slope(point, point)**  
Description: Calculates the slope of a straight line formed by two points.  
Return type: double

Example:

```
gaussdb=# SELECT slope(point '(1,1)', point '(0,0)') AS RESULT;  
result  
-----  
1  
(1 row)
```

- **path(polygon)**

Description: Polygon to path

Return type: path

Example:

```
gaussdb=# SELECT path(polygon '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

- **point(double precision, double precision)**

Description: Points

Return type: point

Example:

```
gaussdb=# SELECT point(23.4, -44.5) AS RESULT;  
result  
-----  
(23.4,-44.5)  
(1 row)
```

- **point(box)**

Description: Center of box

Return type: point

Example:

```
gaussdb=# SELECT point(box '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(circle)**

Description: Center of circle

Return type: point

Example:

```
gaussdb=# SELECT point(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(lseg)**

Description: Center of a line segment

Return type: point

Example:

```
gaussdb=# SELECT point(lseg '((-1,0),(1,0))') AS RESULT;  
result  
-----  
(0,0)  
(1 row)
```

- **point(polygon)**  
Description: Center of a polygon  
Return type: point

Example:

```
gaussdb=# SELECT point(polygon '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
(1,0.3333333333333333)  
(1 row)
```

- **polygon(box)**  
Description: Box to 4-point polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(box '((0,0),(1,1)')) AS RESULT;  
result  
-----  
((0,0),(0,1),(1,1),(1,0))  
(1 row)
```

- **polygon(circle)**  
Description: Circle to 12-point polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- **polygon(npts, circle)**  
Description: Circle to npts-point polygon  
Return type: polygon

Example:

```
gaussdb=# SELECT polygon(12, circle '((0,0),2.0)') AS RESULT;  
result  
-----  
-----  
-----  
((-2,0),(-1.73205080756888,1),(-1,1.73205080756888),(-1.22464679914735e-16,2),  
(1,1.73205080756888),(1.73205080756888,1),(2,2.44929359829471e-16),  
(1.73205080756888,-0.999999999999999),(1,-1.73205080756888),(3.67394039744206e-16,-2),  
(-0.999999999999999,-1.73205080756888),(-1.73205080756888,-1))  
(1 row)
```

- **polygon(path)**  
Description: Path to polygon  
Return type: polygon  
Example:

```
gaussdb=# SELECT polygon(path '((0,0),(1,1),(2,0)')) AS RESULT;  
result  
-----  
((0,0),(1,1),(2,0))  
(1 row)
```

## 7.5.11 Network Address Functions and Operators

### cidr and inet Operators

The operators <<, <=, >>, and >= test for subnet inclusion. They consider only the network parts of the two addresses (ignoring any host part) and determine whether one network is identical to or a subnet of the other.

- <

Description: Is less than

Example:

```
gaussdb=# SELECT inet '192.168.1.5' < inet '192.168.1.6' AS RESULT;  
result  
-----  
t  
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' <= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- =

Description: Equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' = inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT inet '192.168.1.5' >= inet '192.168.1.5' AS RESULT;  
result  
-----  
t  
(1 row)
```

- >

Description: Is greater than

Example:

```
gaussdb=# SELECT inet '192.168.1.5' > inet '192.168.1.4' AS RESULT;  
result  
-----  
t  
(1 row)
```

- <>  
Description: Does not equal  
Example:

```
gaussdb=# SELECT inet '192.168.1.5' <> inet '192.168.1.4' AS RESULT;
result
-----
t
(1 row)
```
- <<  
Description: Is contained in  
Example:

```
gaussdb=# SELECT inet '192.168.1.5' << inet '192.168.1/24' AS RESULT;
result
-----
t
(1 row)
```
- <<=  
Description: Is contained in or equals  
Example:

```
gaussdb=# SELECT inet '192.168.1/24' <<= inet '192.168.1/24' AS RESULT;
result
-----
t
(1 row)
```
- >>  
Description: Contains  
Example:

```
gaussdb=# SELECT inet '192.168.1/24' >> inet '192.168.1.5' AS RESULT;
result
-----
t
(1 row)
```
- >>=  
Description: Contains or equals  
Example:

```
gaussdb=# SELECT inet '192.168.1/24' >>= inet '192.168.1/24' AS RESULT;
result
-----
t
(1 row)
```
- ~  
Description: Bitwise NOT  
Example:

```
gaussdb=# SELECT ~ inet '192.168.1.6' AS RESULT;
result
-----
63.87.254.249
(1 row)
```
- &  
Description: Performs an AND operation on each bit of the two network addresses.  
Example:

```
gaussdb=# SELECT inet '192.168.1.6' & inet '10.0.0.0' AS RESULT;
result
-----
0.0.0.0
(1 row)
```

- |  
Description: Performs an OR operation on each bit of the two network addresses.

Example:

```
gaussdb=# SELECT inet '192.168.1.6' | inet '10.0.0.0' AS RESULT;
result
-----
202.168.1.6
(1 row)
```

- +  
Description: Addition

Example:

```
gaussdb=# SELECT inet '192.168.1.6' + 25 AS RESULT;
result
-----
192.168.1.31
(1 row)
```

- -  
Description: Subtraction

Example:

```
gaussdb=# SELECT inet '192.168.1.43' - 36 AS RESULT;
result
-----
192.168.1.7
(1 row)
```

- -  
Description: Subtraction

Example:

```
gaussdb=# SELECT inet '192.168.1.43' - inet '192.168.1.19' AS RESULT;
result
-----
24
(1 row)
```

## cidr and inet Functions

The **abbrev**, **host**, and **text** functions are primarily intended to offer alternative display formats.

- abbrev(inet)  
Description: Abbreviated display format as text  
Return type: text

Example:

```
gaussdb=# SELECT abbrev(inet '10.1.0.0/16') AS RESULT;
result
-----
10.1.0.0/16
(1 row)
```

- abbrev(cidr)

Description: Abbreviated display format as text

Return type: text

Example:

```
gaussdb=# SELECT abbrev(cidr '10.1.0.0/16') AS RESULT;  
result  
-----  
10.1/16  
(1 row)
```

- broadcast(inet)

Description: Broadcast address for networks

Return type: inet

Example:

```
gaussdb=# SELECT broadcast('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.255/24  
(1 row)
```

- family(inet)

Description: Extracts family of addresses, 4 for IPv4.

Return type: int

Example:

```
gaussdb=# SELECT family('127.0.0.1') AS RESULT;  
result  
-----  
4  
(1 row)
```

- host(inet)

Description: Extracts IP addresses as text.

Return type: text

Example:

```
gaussdb=# SELECT host('192.168.1.5/24') AS RESULT;  
result  
-----  
192.168.1.5  
(1 row)
```

- hostmask(inet)

Description: Constructs the host mask for a network.

Return type: inet

Example:

```
gaussdb=# SELECT hostmask('192.168.23.20/30') AS RESULT;  
result  
-----  
0.0.0.3  
(1 row)
```

- masklen(inet)

Description: Extracts subnet mask length.

Return type: int

Example:

```
gaussdb=# SELECT masklen('192.168.1.5/24') AS RESULT;  
result  
-----
```

- ```
24
(1 row)
```
- **netmask(inet)**  
Description: Constructs the subnet mask for a network.  
Return type: inet  
Example:  

```
gaussdb=# SELECT netmask('192.168.1.5/24') AS RESULT;
result
-----
255.255.255.0
(1 row)
```
  - **network(inet)**  
Description: Extracts the network part of an address.  
Return type: cidr  
Example:  

```
gaussdb=# SELECT network('192.168.1.5/24') AS RESULT;
result
-----
192.168.1.0/24
(1 row)
```
  - **set\_masklen(inet, int)**  
Description: Sets subnet mask length for the **inet** value.  
Return type: inet  
Example:  

```
gaussdb=# SELECT set_masklen('192.168.1.5/24', 16) AS RESULT;
result
-----
192.168.1.5/16
(1 row)
```
  - **set\_masklen(cidr, int)**  
Description: Sets subnet mask length for the **cidr** value.  
Return type: cidr  
Example:  

```
gaussdb=# SELECT set_masklen('192.168.1.0/24::cidr', 16) AS RESULT;
result
-----
192.168.0.0/16
(1 row)
```
  - **text(inet)**  
Description: Extracts IP addresses and subnet mask length as text.  
Return type: text  
Example:  

```
gaussdb=# SELECT text(inet '192.168.1.5') AS RESULT;
result
-----
192.168.1.5/32
(1 row)
```

Any **cidr** value can be cast to **inet** implicitly or explicitly; therefore, the functions shown above as operating on **inet** also work on **cidr** values. An **inet** value can be cast to **cidr**. After the conversion, any bits to the right of the subnet mask are silently zeroed to create a valid **cidr** value. In addition, you can cast a text string to

**inet** or **cidr** using normal casting syntax. For example, **inet(expression)** or **colname::cidr**.

## macaddr Functions

The function **trunc(macaddr)** returns a MAC address with the last 3 bytes set to zero.

- **trunc(macaddr)**  
Description: Sets last 3 bytes to zero.  
Return type: macaddr

Example:

```
gaussdb=# SELECT trunc(macaddr '12:34:56:78:90:ab') AS RESULT;
result
-----
12:34:56:00:00:00
(1 row)
```

The **macaddr** type also supports the standard relational operators (such as > and <=) for lexicographical ordering, and the bitwise arithmetic operators (~, & and |) for NOT, AND and OR.

## 7.5.12 Text Search Functions and Operators

### Text Search Operators

- **@@**  
Description: Specifies whether the tsvector-typed words match the tsquery-typed words.  
Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```
- **@@@**  
Description: Synonym for @@  
Example:

```
gaussdb=# SELECT to_tsvector('fat cats ate rats') @@@ to_tsquery('cat & rat') AS RESULT;
result
-----
t
(1 row)
```
- **||**  
Description: Connects two tsvector-typed words.  
Example:

```
gaussdb=# SELECT 'a:1 b:2'::tsvector || 'c:1 d:2 b:3'::tsvector AS RESULT;
result
-----
'a':1 'b':2,5 'c':3 'd':4
(1 row)
```
- **&&**  
Description: Performs the AND operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery && 'cat'::tsquery AS RESULT;
result
-----
( 'fat' | 'rat' ) & 'cat'
(1 row)
```

- ||

Description: Performs the OR operation on two tsquery-typed words.

Example:

```
gaussdb=# SELECT 'fat | rat'::tsquery || 'cat'::tsquery AS RESULT;
result
-----
( 'fat' | 'rat' ) | 'cat'
(1 row)
```

- !!

Description: Not a tsquery-typed word.

Example:

```
gaussdb=# SELECT !! 'cat'::tsquery AS RESULT;
result
-----
!'cat'
(1 row)
```

- @>

Description: Specifies whether a tsquery-typed word contains another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery @> 'cat & rat'::tsquery AS RESULT;
result
-----
f
(1 row)
```

- <@

Description: Specifies whether a tsquery-typed word is contained in another tsquery-typed word.

Example:

```
gaussdb=# SELECT 'cat'::tsquery <@ 'cat & rat'::tsquery AS RESULT;
result
-----
t
(1 row)
```

In addition to the preceding operators, the ordinary B-tree comparison operators (including = and <) are defined for types **tsvector** and **tsquery**.

## Text Search Functions

- `get_current_ts_config()`

Description: Obtains default text search configurations.

Return type: `regconfig`

Example:

```
gaussdb=# SELECT get_current_ts_config();
get_current_ts_config
-----
english
(1 row)
```

- length(tsvector)**  
Description: Specifies the number of lexemes in a **tsvector**-typed word.  
Return type: integer  
Example:  

```
gaussdb=# SELECT length('fat:2,4 cat:3 rat:5A':tsvector);
length
-----
      3
(1 row)
```
- numnode(tsquery)**  
Description: Specifies the number of lexemes plus **tsquery** operators.  
Return type: integer  
Example:  

```
gaussdb=# SELECT numnode('(fat & rat) | cat':tsquery);
numnode
-----
      5
(1 row)
```
- plainto\_tsquery([ config regconfig , ] query text)**  
Description: Generates **tsquery** lexemes without punctuations.  
Return type: tsquery  
Example:  

```
gaussdb=# SELECT plainto_tsquery('english', 'The Fat Rats');
plainto_tsquery
-----
'fat' & 'rat'
(1 row)
```
- querytree(query tsquery)**  
Description: Obtains the indexable part of a **tsquery**.  
Return type: text  
Example:  

```
gaussdb=# SELECT querytree('foo & ! bar':tsquery);
querytree
-----
'foo'
(1 row)
```
- setweight(tsvector, "char")**  
Description: Assigns weight to each element of tsvector.  
Return type: tsvector  
Example:  

```
gaussdb=# SELECT setweight('fat:2,4 cat:3 rat:5B':tsvector, 'A');
setweight
-----
'cat':3A 'fat':2A,4A 'rat':5A
(1 row)
```
- strip(tsvector)**  
Description: Removes positions and weights from **tsvector**.  
Return type: tsvector  
Example:  

```
gaussdb=# SELECT strip('fat:2,4 cat:3 rat:5A':tsvector);
strip
```

- ```
-----
'cat' 'fat' 'rat'
(1 row)
```
- `to_tsquery([ config regconfig , ] query text)`  
 Description: Normalizes words and converts them to **tsquery**.  
 Return type: tsquery  
 Example:  

```
gaussdb=# SELECT to_tsquery('english', 'The & Fat & Rats');
to_tsquery
-----
'fat' & 'rat'
(1 row)
```
  - `to_tsvector([ config regconfig , ] document text)`  
 Description: Reduces document text to **tsvector**.  
 Return type: tsvector  
 Example:  

```
gaussdb=# SELECT to_tsvector('english', 'The Fat Rats');
to_tsvector
-----
'fat':2 'rat':3
(1 row)
```
  - `to_tsvector_for_batch([ config regconfig , ] document text)`  
 Description: Reduces document text to **tsvector**.  
 Return type: tsvector  
 Example:  

```
gaussdb=# SELECT to_tsvector_for_batch('english', 'The Fat Rats');
to_tsvector
-----
'fat':2 'rat':3
(1 row)
```
  - `ts_headline([ config regconfig, ] document text, query tsquery [, options text ])`  
 Description: Highlights a query match.  
 Return type: text  
 Example:  

```
gaussdb=# SELECT ts_headline('x y z', 'z!::tsquery');
ts_headline
-----
x y <b>z</b>
(1 row)
```
  - `ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])`  
 Description: Ranks document for query.  
 Return type: float4  
 Example:  

```
gaussdb=# SELECT ts_rank('hello world'::tsvector, 'world'::tsquery);
ts_rank
-----
.0607927
(1 row)
```
  - `ts_rank_cd([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])`

Description: Ranks document for query using cover density.

Return type: float4

Example:

```
gaussdb=# SELECT ts_rank_cd('hello world':tsvector, 'world':tsquery);
ts_rank_cd
-----
.0
(1 row)
```

- `ts_rewrite(query tsquery, target tsquery, substitute tsquery)`

Description: Replaces **tsquery**-typed word.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('a & b':tsquery, 'a':tsquery, 'foo|bar':tsquery);
ts_rewrite
-----
'b' & ( 'foo' | 'bar' )
(1 row)
```

- `ts_rewrite(query tsquery, select text)`

Description: Replaces **tsquery** data in the target with the result of a **SELECT** command.

Return type: tsquery

Example:

```
gaussdb=# SELECT ts_rewrite('world':tsquery, 'select "world":tsquery, "hello":tsquery');
ts_rewrite
-----
'hello'
(1 row)
```

## Text Search Debugging Functions

- `ts_debug([ config regconfig, ] document text, OUT alias text, OUT description text, OUT token text, OUT dictionaries regdictionary[], OUT dictionary regdictionary, OUT lexemes text[])`

Description: Tests a configuration.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_debug('english', 'The Brightest supernovaes');
ts_debug
-----
(asciiword,"Word, all ASCII",The,{english_stem},english_stem,{})
(blank,"Space symbols"," ",{},{,})
(asciiword,"Word, all ASCII",Brightest,{english_stem},english_stem,{brightest})
(blank,"Space symbols"," ",{},{,})
(asciiword,"Word, all ASCII",supernovaes,{english_stem},english_stem,{supernova})
(5 rows)
```

- `ts_lexize(dict regdictionary, token text)`

Description: Tests a data dictionary.

Return type: text[]

Example:

```
gaussdb=# SELECT ts_lexize('english_stem', 'stars');
ts_lexize
-----
{star}
(1 row)
```

- `ts_parse(parser_name text, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse('default', 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- `ts_parse(parser_oid oid, document text, OUT tokid integer, OUT token text)`

Description: Tests a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_parse(3722, 'foo - bar');
ts_parse
-----
(1,foo)
(12," ")
(12,"- ")
(1,bar)
(4 rows)
```

- `ts_token_type(parser_name text, OUT tokid integer, OUT alias text, OUT description text)`

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type('default');
ts_token_type
-----
(1,asciword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- `ts_token_type(parser_oid oid, OUT tokid integer, OUT alias text, OUT description text)`

Description: Obtains token types defined by a parser.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_token_type(3722);
          ts_token_type
-----
(1,asciiword,"Word, all ASCII")
(2,word,"Word, all letters")
(3,numword,"Word, letters and digits")
(4,email,"Email address")
(5,url,URL)
(6,host,Host)
(7,sfloat,"Scientific notation")
(8,version,"Version number")
(9,hword_numpart,"Hyphenated word part, letters and digits")
(10,hword_part,"Hyphenated word part, all letters")
(11,hword_asciipart,"Hyphenated word part, all ASCII")
(12,blank,"Space symbols")
(13,tag,"XML tag")
(14,protocol,"Protocol head")
(15,numhword,"Hyphenated word, letters and digits")
(16,asciihword,"Hyphenated word, all ASCII")
(17,hword,"Hyphenated word, all letters")
(18,url_path,"URL path")
(19,file,"File or path name")
(20,float,"Decimal notation")
(21,int,"Signed integer")
(22,uint,"Unsigned integer")
(23,entity,"XML entity")
(23 rows)
```

- `ts_stat(sqlquery text, [ weights text, ] OUT word text, OUT ndoc integer, OUT nentry integer)`

Description: Obtains statistics of a **tsvector** column.

Return type: SETOF record

Example:

```
gaussdb=# SELECT ts_stat('select "hello world"::tsvector');
          ts_stat
-----
(world,1,1)
(hello,1,1)
(2 rows)
```

## 7.5.13 JSON/JSONB Functions and Operators

For details about the JSON/JSONB data type, see [JSON/JSONB Types](#). For details about operators, see [Table 7-39](#) and [Table 7-40](#).

**Table 7-39** JSON/JSONB common operators

| Operator | Left Operand Type | Right Operand Type | Return Type | Description                                                                                         | Example                                                                                                  |
|----------|-------------------|--------------------|-------------|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| ->       | Array - json(b)   | int                | json(b)     | Obtains the <b>array-json</b> element. If the subscript does not exist, <b>NULL</b> is returned.    | <pre>SELECT '{"a":"foo"}, {"b":"bar"}, {"c":"baz"}::json-&gt;2; ?column? ----- {"c":"baz"} (1 row)</pre> |
| ->       | object-json(b)    | text               | json(b)     | Obtains the value by a key. If no record is found, <b>NULL</b> is returned.                         | <pre>SELECT '{"a": {"b":"foo"}}::json-&gt;'a'; ?column? ----- {"b":"foo"} (1 row)</pre>                  |
| ->>      | Array - json(b)   | int                | text        | Obtains the JSON array element. If the subscript does not exist, <b>NULL</b> is returned.           | <pre>SELECT '[1,2,3]::json-&gt;&gt;2; ?column? ----- 3 (1 row)</pre>                                     |
| ->>      | object-json(b)    | text               | text        | Obtains the value by a key. If no record is found, <b>NULL</b> is returned.                         | <pre>SELECT '{"a":1,"b":2}::json-&gt;&gt;'b'; ?column? ----- 2 (1 row)</pre>                             |
| #>       | container-json(b) | text[ ]            | json(b)     | Obtains the JSON object in the specified path. If the path does not exist, <b>NULL</b> is returned. | <pre>SELECT '{"a": {"b": {"c": "foo"}}}'::json #&gt;'a,b'; ?column? ----- {"c": "foo"} (1 row)</pre>     |
| #>>      | container-json(b) | text[ ]            | text        | Obtains the JSON object in the specified path. If the path does not exist, <b>NULL</b> is returned. | <pre>SELECT '{"a":[1,2,3],"b":[4,5,6]}'::json #&gt;&gt;'a,2'; ?column? ----- 3 (1 row)</pre>             |

 **CAUTION**

For the #> and #>> operators, if no data can be found in the specified path, no error is reported and a **NULL** value is returned.

**Table 7-40** Additional JSONB support for operators

| Operators | Right Operand Type | Description                                                                                                           | Example                                           |
|-----------|--------------------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| @>        | jsonb              | Specifies whether the top layer of the JSON on the left contains all items of the top layer of the JSON on the right. | '{"a":1, "b":2}'::jsonb @> '{"b":2}'::jsonb       |
| <@        | jsonb              | Specifies whether all items in the JSON file on the left exist at the top layer of the JSON file on the right.        | '{"b":2}'::jsonb <@ '{"a":1, "b":2}'::jsonb       |
| ?         | text               | Specifies whether the string of the key or element exists at the top layer of the JSON value.                         | '{"a":1, "b":2}'::jsonb ? 'b'                     |
| ?         | text[]             | Specifies whether any of these array strings exists as top-layer keys.                                                | '{"a":1, "b":2, "c":3}'::jsonb ?  array['b', 'c'] |
| ?&        | text[]             | Specifies whether all these array strings exist as top-layer keys.                                                    | '["a", "b"]'::jsonb ? & array['a', 'b']           |
| =         | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_eq function.                              | /                                                 |
| <>        | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_ne function.                              | /                                                 |
| <         | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_lt function.                              | /                                                 |

| Operators | Right Operand Type | Description                                                                              | Example |
|-----------|--------------------|------------------------------------------------------------------------------------------|---------|
| >         | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_gt function. | /       |
| <=        | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_le function. | /       |
| >=        | jsonb              | Determines the size between two JSONB files, which is the same as the jsonb_ge function. | /       |

## Functions Supported by JSON/JSONB

- array\_to\_json(anyarray [, pretty\_bool])**

Description: Returns the array as JSON. It combines a multi-dimensional array into a JSON array. Line feeds will be added between one-dimensional elements if **pretty\_bool** is **true**.

Return type: json

Example:

```
gaussdb=# SELECT array_to_json('{{1,5},{99,100}}::int[]);
array_to_json
-----
[[1,5],[99,100]]
(1 row)
```
- row\_to\_json(record [, pretty\_bool])**

Description: Returns the row as JSON. Line feeds will be added between level-1 elements if **pretty\_bool** is **true**.

Return type: json

Example:

```
gaussdb=# SELECT row_to_json(row(1,'foo'));
row_to_json
-----
{"f1":1,"f2":"foo"} (1 row)
```
- json\_array\_element(array-json, integer), jsonb\_array\_element(array-jsonb, integer)**

Description: Same as the operator `->`, which returns the element with the specified subscript in the array.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_element('[1,true,[1,[2,3]],null]',2);
```

```
json_array_element
```

```
-----  
[1,[2,3]]  
(1 row)
```

- `json_array_element_text(array-json, integer)`, `jsonb_array_element_text(array-jsonb, integer)`

Description: Same as the operator ``->>``, which returns the element with the specified subscript in the array.

Return type: text, text

Example:

```
gaussdb=# SELECT json_array_element_text('[1,true,[1,[2,3]],null]',2);  
json_array_element_text
```

```
-----  
[1,[2,3]]  
(1 row)
```

- `json_object_field(object-json, text)`, `jsonb_object_field(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: json, json

Example:

```
gaussdb=# SELECT json_object_field('{\"a\": {\"b\":\"foo\"}}', 'a');  
json_object_field
```

```
-----  
{\"b\":\"foo\"}  
(1 row)
```

- `json_object_field_text(object-json, text)`, `jsonb_object_field_text(object-jsonb, text)`

Description: Same as the operator ``->``, which returns the value of a specified key in an object.

Return type: text, text

Example:

```
gaussdb=# SELECT json_object_field_text('{\"a\": {\"b\":\"foo\"}}', 'a');  
json_object_field_text
```

```
-----  
{\"b\":\"foo\"}  
(1 row)
```

- `json_extract_path(json, VARIADIC text[])`, `jsonb_extract_path((jsonb, VARIADIC text[])`

Description: It is equivalent to the operator ``#>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path('{\"f2\":{\"f3\":1},\"f4\":{\"f5\":99,\"f6\":\"stringy\"}}', 'f4','f6');  
json_extract_path
```

```
-----  
\"stringy\"  
(1 row)
```

- `json_extract_path_op(json, text[])`, `jsonb_extract_path_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_extract_path_op('{ "f2": {"f3": 1}, "f4": {"f5": 99, "f6": "stringy"} }', ARRAY['f4', 'f6']);
json_extract_path_op
-----
"stringy"
(1 row)
```

- `json_extract_path_text(json, VARIADIC text[]), jsonb_extract_path_text((jsonb, VARIADIC text[])`

Description: It is equivalent to the operator ``#>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text('{ "f2": {"f3": 1}, "f4": {"f5": 99, "f6": "stringy"} }', 'f4', 'f6');
json_extract_path_text
-----
"stringy"
(1 row)
```

- `json_extract_path_text_op(json, text[]), jsonb_extract_path_text_op(jsonb, text[])`

Description: It is equivalent to the operator ``#>>`` and searches for JSON based on the path specified by `$2` and returns the result.

Return type: text, text

Example:

```
gaussdb=# SELECT json_extract_path_text_op('{ "f2": {"f3": 1}, "f4": {"f5": 99, "f6": "stringy"} }',
ARRAY['f4', 'f6']);
json_extract_path_text_op
-----
"stringy"
(1 row)
```

- `json_array_elements(array-json), jsonb_array_elements(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: json, jsonb

Example:

```
gaussdb=# SELECT json_array_elements('[1,true,[1,[2,3]],null]');
json_array_elements
-----
1
true
[1,[2,3]]
null
(4 rows)
```

- `json_array_elements_text(array-json), jsonb_array_elements_text(array-jsonb)`

Description: Splits an array. Each element returns a row.

Return type: text, text

Example:

```
gaussdb=# SELECT * FROM json_array_elements_text('[1,true,[1,[2,3]],null]');
value
-----
1
true
[1,[2,3]]
(4 rows)
```

- `json_array_length(array-json), jsonb_array_length(array-jsonb)`

Description: Returns the array length.

Return type: integer

Example:

```
gaussdb=# SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4,null]');
 json_array_length
-----
                6
(1 row)
```

- `json_each(object-json), jsonb_each(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value json), setof(key text, value jsonb)`

Example:

```
gaussdb=# SELECT * FROM json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  | null
(3 rows)
```

- `json_each_text(object-json), jsonb_each_text(object-jsonb)`

Description: Splits each key-value pair of an object into one row and two columns.

Return type: `setof(key text, value text), setof(key text, value text)`

Example:

```
gaussdb=# SELECT * FROM json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null}');
 key | value
-----+-----
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  |
(3 rows)
```

- `json_object_keys(object-json), jsonb_object_keys(object-jsonb)`

Description: Returns all keys at the top layer of the object.

Return type: `SETOF text`

Example:

```
gaussdb=# SELECT json_object_keys('{"f1":"abc","f2":{"f3":"a"}, "f4":"b"}, {"f1":"abcd"}');
 json_object_keys
-----
 f1
 f2
 f1
(3 rows)
```

- **JSONB deduplication operations:**

```
gaussdb=# SELECT jsonb_object_keys('{"f1":"abc","f2":{"f3":"a"}, "f4":"b"}, {"f1":"abcd"}');
 jsonb_object_keys
-----
 f1
 f2
(2 rows)
```

- `json_populate_record(anyelement, object-json [, bool]), jsonb_populate_record(anyelement, object-jsonb [, bool])`

Description: *\$1* must be a compound parameter. Each key-value in the **object-json** file is split. The key is used as the column name to match the column name in *\$1* and fill in the *\$1* format.

Return type: `anyelement, anyelement`

Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_record(null::jpop, '{"a": "blurfl", "x": 43.2}');
 a | b | c
-----+-----+----
blurfl | |
(1 row)

gaussdb=# SELECT * FROM json_populate_record((1,1,null)::jpop, '{"a": "blurfl", "x": 43.2}');
 a | b | c
-----+-----+----
blurfl | 1 |
(1 row)
```

- `json_populate_record_set(anelement, array-json [, bool])`,  
`jsonb_populate_record_set(anelement, array-jsonb [, bool])`

Description: Performs the preceding operations on each element in the \$2 array by referring to the `json_populate_record` and `jsonb_populate_record` functions. Therefore, each element in the \$2 array must be of the object-json type.

Return type: setof anelement, setof anelement

Example:

```
gaussdb=# CREATE TYPE jpop AS (a text, b int, c bool);
CREATE TYPE
gaussdb=# SELECT * FROM json_populate_recordset(null::jpop, '{"a":1,"b":2},{ "a":3,"b":4}');
 a | b | c
---+---+---
 1 | 2 |
 3 | 4 |
(2 rows)
```

- `json_typeof(json)`, `jsonb_typeof(jsonb)`

Description: Checks the JSON type.

Return type: text, text

Example:

```
gaussdb=# SELECT value, json_typeof(value) FROM (values (json '123.4'), (json '"foo"'), (json 'true'),
(json 'null'), (json '[1, 2, 3]'), (json '{"x": "foo", "y": 123}'), (NULL::json)) AS data(value);
 value | json_typeof
-----+-----
123.4 | number
"foo" | string
true | boolean
null | null
[1, 2, 3] | array
{"x": "foo", "y": 123} | object
(7 rows)
```

- `json_build_array( [VARIADIC "any"] )`

Description: Constructs a JSON array from a variable parameter list.

Return type: array-json

Example:

```
gaussdb=# SELECT json_build_array('a',1,'b',1.2,'c',true,'d',null,'e',json '{"x": 3, "y": [1,2,3]}');
 json_build_array
-----
["a", 1, "b", 1.2, "c", true, "d", null, "e", {"x": 3, "y": [1,2,3]}]
(1 row)
```

- `json_build_object( [VARIADIC "any"] )`

Description: Constructs a JSON object from a variable parameter list. The number of input parameters must be an even number. Every two input parameters form a key-value pair. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_build_object(1,2);
 json_build_object
-----
{"1" : 2}
(1 row)
```

- `json_to_record(object-json, bool)`

Description: Like all functions that return **record**, the caller must explicitly define the structure of the record with an AS clause. The object-json key-value pair is split and reassembled. The key is used as a column name to match and fill in the structure of the specified record displayed by the AS clause. The input parameter of the Boolean type specifies whether object nesting is supported, that is, whether the value of a JSON object member is also a JSON object. The value **true** indicates that the function is supported, and **false** indicates that the function is not supported.

Return type: record

Example:

```
gaussdb=# SELECT * FROM json_to_record('{"a":1,"b":"foo","c":"bar"}',true) AS x(a int, b text, d text);
 a | b | d
---+-----+---
 1 | foo |
(1 row)
```

- `json_to_recordset(array-json, bool)`

Description: Performs the preceding operations on each element in the array by referring to the `json_to_record` function. Therefore, each element in the array must be object-json. The input parameter of the Boolean type specifies whether object nesting is supported, that is, whether the value of a JSON object member is also a JSON object. The value **true** indicates that the function is supported, and **false** indicates that the function is not supported.

Return type: SETOF record

Example:

```
gaussdb=# SELECT * FROM json_to_recordset(
gaussdb(#  '{"a":1,"b":"foo","d":false},{"a":2,"b":"bar","c":true}'],
gaussdb(#  false
gaussdb(# ) AS x(a int, b text, c boolean);
 a | b | c
---+-----+---
 1 | foo |
 2 | bar | t
(2 rows)
```

- `json_object(text[], json_object(text[], text[]))`

Description: Constructs an object-json from a text array. This is an overloaded function. When the input parameter is a text array, the array length must be an even number, and members are considered as alternate key-value pairs. When two text arrays are used, the first array is considered as a key, and the second array a value. The lengths of the two arrays must be the same. Note that the value of a key cannot be null.

Return type: object-json

Example:

```
gaussdb=# SELECT json_object('{a,1,b,2,3,NULL,"d e f","a b c"}');
 json_object
-----
{"a" : "1", "b" : "2", "3" : null, "d e f" : "a b c"}
(1 row)
```

```
gaussdb=# SELECT json_object('{a,b,"a b c"}', '{a,1,1}');
          json_object
-----
{"a" : "a", "b" : "1", "a b c" : "1"}
(1 row)
```

- **json\_agg(any)**

Description: Aggregates values into a JSON array.

Return type: array-json

Example:

```
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A   |    2
 A   |    3
 D   |    5
 D   |
(4 rows)
gaussdb=# SELECT name, json_agg(score) score FROM classes GROUP BY name ORDER BY name;
 name | score
-----+-----
 A   | [2, 3]
 D   | [5, null]
      | [null]
(3 rows)
```

- **json\_object\_agg(any, any)**

Description: Aggregates values into a JSON object.

Return type: object-json

Example:

```
gaussdb=# SELECT * FROM classes;
 name | score
-----+-----
 A   |    2
 A   |    3
 D   |    5
 D   |
(4 rows)
gaussdb=# SELECT json_object_agg(name, score) FROM classes GROUP BY name ORDER BY name;
          json_object_agg
-----
{"A" : 2, "A" : 3 }
{"D" : 5, "D" : null }
(2 rows)
```

- **- jsonb\_contained(jsonb, jsonb)**

Description: Same as the operator `<@`, determines whether all elements in \$1 exist at the top layer of \$2.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_contained('[1,2,3]', '[1,2,3,4]');
          jsonb_contained
-----
 t
(1 row)
```

- **- jsonb\_contains(jsonb, jsonb)**

Description: Same as the operator `@>`, checks whether all top-layer elements in \$1 are contained in \$2.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_contains('[1,2,3,4]', '[1,2,3]');
 jsonb_contains
-----
t
(1 row)
```

- - jsonb\_exists(jsonb, text)

Description: Same as the operator `?`, determines whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists('["1",2,3]', '1');
 jsonb_exists
-----
t
(1 row)
```

- - jsonb\_exists\_all(jsonb, text[])

Description: Same as the operator `?&`, checks whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_all('["1","2",3]', '{1, 2}');
 jsonb_exists_all
-----
t
(1 row)
```

- - jsonb\_exists\_any(jsonb, text[])

Description: Same as the operator `?|`, checks whether all elements in the string array \$2 exist at the top layer of \$1 in the form of **key\elem\scalar**.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_exists_any('["1","2",3]', '{1, 2, 4}');
 jsonb_exists_any
-----
t
(1 row)
```

- - jsonb\_cmp(jsonb, jsonb)

Description: Compares values. A positive value indicates greater than, a negative value indicates less than, and **0** indicates equal.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_cmp('["a", "b"]', '{"a":1, "b":2}');
 jsonb_cmp
-----
-1
(1 row)
```

- - jsonb\_eq(jsonb, jsonb)

Description: Same as the operator `=`, compares two values.

Return type: Boolean

Example:

```
gaussdb=# SELECT jsonb_eq('["a", "b"]', '{"a":1, "b":2}');
 jsonb_eq
-----
f
(1 row)
```

- - jsonb\_ne(jsonb, jsonb)  
Description: Same as the operator ` $\neq$ `, compares two values.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_ne('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ne
-----
t
(1 row)
```
- - jsonb\_gt(jsonb, jsonb)  
Description: Same as the operator ` $>$ `, compares two values.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_gt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_gt
-----
f
(1 row)
```
- - jsonb\_ge(jsonb, jsonb)  
Description: Same as the operator ` $\geq$ `, compares two values.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_ge('["a", "b"]', '{"a":1, "b":2}');
 jsonb_ge
-----
f
(1 row)
```
- - jsonb\_lt(jsonb, jsonb)  
Description: Same as the operator ` $<$ `, compares two values.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_lt('["a", "b"]', '{"a":1, "b":2}');
 jsonb_lt
-----
t
(1 row)
```
- - jsonb\_le(jsonb, jsonb)  
Description: Same as the operator ` $\leq$ `, compares two values.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT jsonb_le('["a", "b"]', '{"a":1, "b":2}');
 jsonb_le
-----
t
(1 row)
```
- - to\_json(anyelement)  
Description: Converts parameters to **json**.  
Return type: json  
Example:

```
gaussdb=# SELECT to_json('{1,5}::text[]);
 to_json
-----
```

```
["1","5"]
(1 row)
```

- - jsonb\_hash(jsonb)

Description: Performs the hash operation on JSONB.

Return type: integer

Example:

```
gaussdb=# SELECT jsonb_hash('["1,2,3"]');
 jsonb_hash
-----
-559968547
(1 row)
```

- Other functions

Description: Internal functions used by JSON and JSONB aggregate functions.

```
json_agg_transfn
json_agg_finalfn
json_object_agg_transfn
json_object_agg_finalfn
```

## 7.5.14 HLL Functions and Operators

### Hash Functions

- hll\_hash\_boolean(bool)

Description: Hashes data of the bool type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE);
 hll_hash_boolean
-----
-5451962507482445012
(1 row)
```

- hll\_hash\_boolean(bool, int32)

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the bool type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_boolean(FALSE, 10);
 hll_hash_boolean
-----
-1169037589280886076
(1 row)
```

- hll\_hash\_smallint(smallint)

Description: Hashes data of the smallint type.

Return type: hll\_hashval

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint);
 hll_hash_smallint
-----
962727970174027904
(1 row)
```

 NOTE

If parameters with the same numeric value are hashed using different data types, the data will differ, because hash functions select different calculation policies for each type.

- `hll_hash_smallint(smallint, int32)`

Description: Configures a hash seed (that is, change the hash policy) and hashes data of the `smallint` type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_smallint(100::smallint, 10);
 hll_hash_smallint
-----
-9056177146160443041
(1 row)
```

- `hll_hash_integer(integer)`

Description: Hashes data of the `integer` type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_integer(0);
 hll_hash_integer
-----
5156626420896634997
(1 row)
```

- `hll_hash_integer(integer, int32)`

Description: Hashes data of the `integer` type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_integer(0, 10);
 hll_hash_integer
-----
-5035020264353794276
(1 row)
```

- `hll_hash_bigint(bigint)`

Description: Hashes data of the `bigint` type.

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint);
 hll_hash_bigint
-----
-2401963681423227794
(1 row)
```

- `hll_hash_bigint(bigint, int32)`

Description: Hashes data of the `bigint` type and configures a hash seed (that is, change the hash policy).

Return type: `hll_hashval`

Example:

```
gaussdb=# SELECT hll_hash_bigint(100::bigint, 10);
 hll_hash_bigint
-----
-2305749404374433531
(1 row)
```

- **hll\_hash\_bytea(bytea)**  
Description: Hashes data of the bytea type.  
Return type: hll\_hashval  
Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x');
hll_hash_bytea
-----
0
(1 row)
```
- **hll\_hash\_bytea(bytea, int32)**  
Description: Hashes data of the bytea type and configures a hash seed (that is, change the hash policy).  
Return type: hll\_hashval  
Example:

```
gaussdb=# SELECT hll_hash_bytea(E'\x', 10);
hll_hash_bytea
-----
7233188113542599437
(1 row)
```
- **hll\_hash\_text(text)**  
Description: Hashes data of the text type.  
Return type: hll\_hashval  
Example:

```
gaussdb=# SELECT hll_hash_text('AB');
hll_hash_text
-----
-5666002586880275174
(1 row)
```
- **hll\_hash\_text(text, int32)**  
Description: Hashes data of the text type and configures a hash seed (that is, change the hash policy).  
Return type: hll\_hashval  
Example:

```
gaussdb=# SELECT hll_hash_text('AB', 10);
hll_hash_text
-----
-2215507121143724132
(1 row)
```
- **hll\_hash\_any(anytype)**  
Description: Hashes data of any type.  
Return type: hll\_hashval  
Example:

```
gaussdb=# SELECT hll_hash_any(1);
hll_hash_any
-----
-1316670585935156930
(1 row)

gaussdb=# SELECT hll_hash_any('08:00:2b:01:02:03'::macaddr);
hll_hash_any
-----
-3719950434455589360
(1 row)
```

- `hll_hash_any(anytype, int32)`  
Description: Hashes data of any type and configures a hash seed (that is, change the hash policy).  
Return type: `hll_hashval`  
Example:

```
gaussdb=# SELECT hll_hash_any(1, 10);
 hll_hash_any
-----
7048553517657992351
(1 row)
```
- `hll_hashval_eq(hll_hashval, hll_hashval)`  
Description: Compares two pieces of data of the `hll_hashval` type to check whether they are the same.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT hll_hashval_eq(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_eq
-----
t
(1 row)
```
- `hll_hashval_ne(hll_hashval, hll_hashval)`  
Description: Compares two pieces of data of the `hll_hashval` type to check whether they are different.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT hll_hashval_ne(hll_hash_integer(1), hll_hash_integer(1));
 hll_hashval_ne
-----
f
(1 row)
```

## HLL Functions

There are three HLL modes: explicit, sparse, and full. When the data size is small, the explicit mode is used. In this mode, distinct values are calculated without errors. As the number of distinct values increases, the HLL mode is switched to the sparse and full modes in sequence. The two modes have no difference in the calculation result, but vary in the calculation efficiency of HLL functions and the storage space of HLL objects. The following functions can be used to view some HLL parameters:

- `hll_print(hll)`  
Description: Prints some debugging parameters of an HLL.  
Example:

```
gaussdb=# SELECT hll_print(hll_empty());
 hll_print
-----
type=1(HLL_EMPTY), log2m=14, log2explicit=10, log2sparse=12, duplicatecheck=0
(1 row)
```
- `hll_type(hll)`  
Description: Checks the type of the current HLL. The return values are described as follows: **0** indicates **HLL\_UNINIT**, an HLL object that is not

initialized. **1** indicates **HLL\_EMPTY**, an empty HLL object. **2** indicates **HLL\_EXPLICIT**, an HLL object in explicit mode. **3** indicates **HLL\_SPARSE**, an HLL object in sparse mode. **4** indicates **HLL\_FULL**, an HLL object in full mode. **5** indicates **HLL\_UNDEFINED**, an invalid HLL object.

Example:

```
gaussdb=# SELECT hll_type(hll_empty());
 hll_type
-----
      1
(1 row)
```

- **hll\_log2m(hll)**

Description: Checks the value of **log2m** in the current HLL data structure. **log2m** is the logarithm of the number of buckets. This value affects the error rate of calculating distinct values by HLL. The error rate =  $\pm 1.04/\sqrt{(2^{\log 2m})}$ . If the value of **log2m** ranges from 10 to 16, HLL sets the number of buckets to  $2^{\log 2m}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2m(hll_empty());
 hll_log2m
-----
      14
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(10));
 hll_log2m
-----
      10
(1 row)

gaussdb=# SELECT hll_log2m(hll_empty(-1));
 hll_log2m
-----
      14
(1 row)
```

- **hll\_log2explicit(hll)**

Description: Queries the value of **log2explicit** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can change the value of **log2explicit** to change the policy. For example, if the value of **log2explicit** is **0**, the HLL will skip the **explicit** mode and directly enter the **sparse** mode. When the value of **log2explicit** is explicitly set to a value ranging from 1 to 12, the HLL will switch to the sparse mode when the length of the data segment exceeds  $2^{\log 2explicit}$ . When the value of **log2explicit** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2explicit(hll_empty());
 hll_log2explicit
-----
      10
(1 row)

gaussdb=# SELECT hll_log2explicit(hll_empty(12, 8));
 hll_log2explicit
-----
      8
(1 row)
```

```
gaussdb=# SELECT hll_log2explicit(hll_empty(12, -1));
hll_log2explicit
-----
          10
(1 row)
```

- **hll\_log2sparse(hll)**

Description: Queries the value of **log2sparse** in the current HLL data structure. Generally, the HLL changes from the explicit mode to the sparse mode and then to the full mode. This process is called the promotion hierarchy policy. You can adjust the value of **log2sparse** to change the policy. For example, if the value of **log2sparse** is **0**, the system skips the sparse mode and directly enters the full mode. If the value of **log2sparse** is explicitly set to a value ranging from 1 to 14, the HLL will switch to the full mode when the length of the data segment exceeds  $2^{\text{log2sparse}}$ . When the value of **log2sparse** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_log2sparse(hll_empty());
hll_log2sparse
-----
          12
(1 row)

gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, 10));
hll_log2sparse
-----
          10
(1 row)

gaussdb=# SELECT hll_log2sparse(hll_empty(12, 8, -1));
hll_log2sparse
-----
          12
(1 row)
```

- **hll\_duplicatecheck(hll)**

Description: Specifies whether duplicate check is enabled. **0**: disable; **1**: enable. This function is disabled by default. If there are many duplicate values, you can enable this function to improve efficiency. When the value of **duplicatecheck** is explicitly set to **-1**, the built-in default value is used.

Example:

```
gaussdb=# SELECT hll_duplicatecheck(hll_empty());
hll_duplicatecheck
-----
          0
(1 row)

gaussdb=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, 1));
hll_duplicatecheck
-----
          1
(1 row)

gaussdb=# SELECT hll_duplicatecheck(hll_empty(12, 8, 10, -1));
hll_duplicatecheck
-----
          0
(1 row)
```

## Functional Functions

- `hll_empty()`

Description: Creates an empty HLL.

Return type: `hll`

Example:

```
gaussdb=# SELECT hll_empty();
           hll_empty
-----
\x484c4c00000000002b0500
(1 row)
```

- `hll_empty(int32 log2m)`

Description: Creates an empty HLL and sets the **log2m** parameter. The parameter value ranges from 10 to 16. If the input is **-1**, the built-in default value is used.

Return type: `HLL`

Example:

```
gaussdb=# SELECT hll_empty(10);
           hll_empty
-----
\x484c4c00000000002b0400
(1 row)

gaussdb=# SELECT hll_empty(-1);
           hll_empty
-----
\x484c4c00000000002b0500
(1 row)
```

- `hll_empty(int32 log2m, int32 log2explicit)`

Description: Creates an empty HLL and sets the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches  $2^{\text{log2explicit}}$ , the mode is switched to the sparse or full mode. If the input is **-1**, the built-in default value of **log2explicit** is used.

Return type: `HLL`

Example:

```
gaussdb=# SELECT hll_empty(10, 4);
           hll_empty
-----
\x484c4c0000000000130400
(1 row)

gaussdb=# SELECT hll_empty(10, -1);
           hll_empty
-----
\x484c4c00000000002b0400
(1 row)
```

- `hll_empty(int32 log2m, int32 log2explicit, int64 log2sparse)`

Description: Creates an empty HLL and sets the **log2m**, **log2explicit** and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches  $2^{\text{log2sparse}}$ , the mode is switched to the full mode. If the input is **-1**, the built-in default value of **log2sparse** is used.

Example:

```
gaussdb=# SELECT hll_eq(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_eq
-----
 f
(1 row)
```

- **hll\_ne(hll, hll)**

Description: Compares two HLLs to check whether they are different.

Return type: Boolean

Example:

```
gaussdb=# SELECT hll_ne(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
 hll_ne
-----
 t
(1 row)
```

- **hll\_cardinality(hll)**

Description: Calculates the number of distinct values of an HLL.

Return type: int

Example:

```
gaussdb=# SELECT hll_cardinality(hll_empty() || hll_hash_integer(1));
 hll_cardinality
-----
 1
(1 row)
```

- **hll\_union(hll, hll)**

Description: Performs the UNION operation on two HLL data structures to obtain one HLL.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_union(hll_add(hll_empty(), hll_hash_integer(1)), hll_add(hll_empty(),
hll_hash_integer(2)));
          hll_union
-----
\x484c4c10002000002b090000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

## Aggregate Functions

- **hll\_add\_agg(hll\_hashval)**

Description: Groups hashed data into HLL.

Return type: HLL

Example:

```
-- Prepare data:
gaussdb=# CREATE TABLE t_id(id int);
gaussdb=# INSERT INTO t_id VALUES(generate_series(1,500));
gaussdb=# CREATE TABLE t_data(a int, c text);
gaussdb=# INSERT INTO t_data SELECT mod(id,2), id FROM t_id;

-- Create a table and specify an HLL column:
gaussdb=# CREATE TABLE t_a_c_hll(a int, c hll);
```

```
-- Use GROUP BY on column a to group data, and insert the data to the HLL.
gaussdb=# INSERT INTO t_a_c_hll SELECT a, hll_add_agg(hll_hash_text(c)) FROM t_data GROUP BY a;

-- Calculate the number of distinct values for each group in the HLL:
gaussdb=# SELECT a, #c AS cardinality FROM t_a_c_hll ORDER BY a;
 a | cardinality
---+-----
 0 | 247.862354346299
 1 | 250.908710610377
(2 rows)
```

- `hll_add_agg(hll_hashval, int32 log2m)`

Description: Groups hashed data into HLL and specifies the **log2m** parameter. The value ranges from 10 to 16. If the input is **-1** or **NULL**, the built-in default value is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), 12)) FROM t_data;
 hll_cardinality
-----
497.965240179228
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit)`

Description: Groups hashed data into HLL and specifies the **log2m** and **log2explicit** parameters in sequence. The value of **log2explicit** ranges from 0 to 12. The value **0** indicates that the explicit mode is skipped. This parameter is used to set the threshold of the explicit mode. When the length of the data segment reaches  $2^{\text{log2explicit}}$ , the mode is switched to the sparse or full mode. If the input is **-1** or **NULL**, the built-in default value of **log2explicit** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 1)) FROM t_data;
 hll_cardinality
-----
498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, and **log2sparse** parameters in sequence. The value of **log2sparse** ranges from 0 to 14. The value **0** indicates that the sparse mode is skipped. This parameter is used to set the threshold of the sparse mode. When the length of the data segment reaches  $2^{\text{log2sparse}}$ , the mode is switched to the full mode. If the input is **-1** or **NULL**, the built-in default value of **log2sparse** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10)) FROM t_data;
 hll_cardinality
-----
498.496062953313
(1 row)
```

- `hll_add_agg(hll_hashval, int32 log2m, int32 log2explicit, int64 log2sparse, int32 duplicatecheck)`

Description: Groups hashed data into HLL and sets the **log2m**, **log2explicit**, **log2sparse**, and **duplicatecheck** parameters. The value of **duplicatecheck** can be **0** or **1**, indicating whether to enable this mode. By default, this mode

is disabled. If the input is **-1** or **NULL**, the built-in default value of **duplicatecheck** is used.

Return type: HLL

Example:

```
gaussdb=# SELECT hll_cardinality(hll_add_agg(hll_hash_text(c), NULL, 6, 10, -1)) FROM t_data;
hll_cardinality
-----
498.496062953313
(1 row)
```

- **hll\_union\_agg(hll)**

Description: Performs the UNION operation on multiple pieces of data of the HLL type to obtain one HLL.

Return type: HLL

Example:

```
-- Perform the UNION operation on data of the HLL type in each group to obtain one HLL, and
calculate the number of distinct values:
gaussdb=# SELECT #hll_union_agg(c) AS cardinality FROM t_a_c_hll;
cardinality
-----
498.496062953313
(1 row)
```

 **NOTE**

To perform the UNION operation on data in multiple HLLs, ensure that the HLLs have the same precision. Otherwise, **UNION** cannot be performed. This constraint also applies to the **hll\_union(hll, hll)** function.

## Obsolete Functions

Some old HLL functions are discarded due to version upgrade. You can replace them with similar functions.

- **hll\_schema\_version(hll)**

Description: Checks the schema version in the current HLL. In earlier versions, the schema version is fixed at **1**, which is used to verify the header of the HLL field. After refactoring, the HLL field is added to the header for verification. The schema version is no longer used.

- **hll\_regwidth(hll)**

Description: Queries the bucket size in the HLL data structure. In earlier versions, the value of **regwidth** ranges from 1 to 5, which has a large error and limits the upper limit of the cardinality estimation. After refactoring, the value of *regwidth* is fixed at **6** and the variable is not used.

- **hll\_expthresh(hll)**

Description: Obtains the value of **expthresh** in the current HLL. The **hll\_log2explicit(hll)** function is used to replace similar functions.

- **hll\_sparseon(hll)**

Description: Specifies whether the sparse mode is enabled. Use **hll\_log2sparse(hll)** to replace similar functions. The value **0** indicates that the sparse mode is disabled.

## Built-In Functions

HLL has a series of built-in functions for internal data processing. Generally, users do not need to know how to use these functions. For details, see [Table 7-41](#).

**Table 7-41** Built-in functions

| Function        | Description                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hll_in          | Receives hll data in string format.                                                                                                                                   |
| hll_out         | Sends hll data in string format.                                                                                                                                      |
| hll_recv        | Receives hll data in bytea format.                                                                                                                                    |
| hll_send        | Sends hll data in bytea format.                                                                                                                                       |
| hll_trans_in    | Receives hll_trans_type data in string format.                                                                                                                        |
| hll_trans_out   | Sends hll_trans_type data in string format.                                                                                                                           |
| hll_trans_recv  | Receives hll_trans_type data in bytea format.                                                                                                                         |
| hll_trans_send  | Sends hll_trans_type data in bytea format.                                                                                                                            |
| hll_typmod_in   | Receives typmod data.                                                                                                                                                 |
| hll_typmod_out  | Sends typmod data.                                                                                                                                                    |
| hll_hashval_in  | Receives hll_hashval data.                                                                                                                                            |
| hll_hashval_out | Sends hll_hashval data.                                                                                                                                               |
| hll_add_trans0  | It is similar to <b>hll_add</b> . No input parameter is specified during initialization. It is usually used in the first phase of DNs in aggregation operations.      |
| hll_add_trans1  | It is similar to <b>hll_add</b> . An input parameter is specified during initialization. It is usually used in the first phase of DNs in aggregation operations.      |
| hll_add_trans2  | It is similar to <b>hll_add</b> . Two input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations.   |
| hll_add_trans3  | It is similar to <b>hll_add</b> . Three input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations. |
| hll_add_trans4  | It is similar to <b>hll_add</b> . Four input parameters are specified during initialization. It is usually used in the first phase of DNs in aggregation operations.  |
| hll_union_trans | It is similar to <b>hll_union</b> and is used in the first phase of DNs in aggregation operations.                                                                    |

| Function          | Description                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| hll_union_collect | It is similar to <b>hll_union</b> and is used in the second phase of DNs in aggregation operations to summarize the results of each DN. |
| hll_pack          | It is used in the third phase of DNs in aggregation operations to convert a user-defined type hll_trans_type to the hll type.           |
| hll               | Converts a hll type to another hll type. Input parameters can be specified.                                                             |
| hll_hashval       | Converts the bigint type to the hll_hashval type.                                                                                       |
| hll_hashval_int4  | Converts the int4 type to the hll_hashval type.                                                                                         |

## Operators

- =  
Description: Compares the values of the hll or hll\_hashval type to check whether they are the same.

Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) = (hll_empty() || hll_hash_integer(1));
column
-----
t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) = hll_hash_integer(1);
?column?
-----
t
(1 row)
```

- <> or !=  
Description: Compares the values of the hll or hll\_hashval type to check whether they are different.

Return type: Boolean

Example:

```
--hll
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) <> (hll_empty() || hll_hash_integer(2));
?column?
-----
t
(1 row)

--hll_hashval
gaussdb=# SELECT hll_hash_integer(1) <> hll_hash_integer(2);
?column?
-----
t
(1 row)
```

- `||`  
Description: Represents the functions of `hll_add`, `hll_union`, and `hll_add_rev`.  
Return type: HLL

Example:

```
--hll_add
gaussdb=# SELECT hll_empty() || hll_hash_integer(1);
           ?column?
-----
\x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_add_rev
gaussdb=# SELECT hll_hash_integer(1) || hll_empty();
           ?column?
-----
\x484c4c08000002002b0900000000000000f03f3e2921ff133fbaed3e2921ff133fbaed00
(1 row)

--hll_union
gaussdb=# SELECT (hll_empty() || hll_hash_integer(1)) || (hll_empty() || hll_hash_integer(2));
           ?column?
-----
\x484c4c10002000002b09000000000000004000000000000000b3ccc49320cca1ae3e2921ff133fba
ed00
(1 row)
```

- `#`  
Description: Calculates the number of distinct values of an HLL. It works the same as the `hll_cardinality` function.

Return type: int

Example:

```
gaussdb=# SELECT #(hll_empty() || hll_hash_integer(1));
           ?column?
-----
           1
(1 row)
```

## 7.5.15 SEQUENCE Functions

The sequence functions provide a simple method to ensure security of multiple users for users to obtain sequence values from sequence objects.

- `nextval(regclass)`  
Description: Specifies an increasing sequence and returns a new value.

### NOTE

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, a `nextval` operation is never rolled back; that is, once a value is fetched, it is considered used, even if the transaction that did the `nextval` later aborts. This means that aborted transactions may leave unused "holes" in the sequence of assigned values. Therefore, sequences in GaussDB cannot be used to obtain sequence without gaps.

### NOTICE

The `nextval` function can be executed only on the primary node. It is not supported on standby nodes.

Return type: numeric

The `nextval` function can be called in either of the following ways: (In example 2, the sequence name cannot contain a dot.)

Example 1:

```
gaussdb=# SELECT nextval('seqDemo');
 nextval
-----
      2
(1 row)
```

Example 2:

```
gaussdb=# SELECT seqDemo.nextval;
 nextval
-----
      2
(1 row)
```

- `currval(regclass)`

Description: Returns the last value of **nextval** in the current session. If **nextval** has not been called for the specified sequence in the current session, an error is reported when **currval** is called.

Return type: numeric

The **currval** function can be called in either of the following ways: (In example 2, the sequence name cannot contain a dot.)

Example 1:

```
gaussdb=# SELECT currval('seq1');
 currval
-----
      2
(1 row)
```

Example 2:

```
gaussdb=# SELECT seq1.currval;
 currval
-----
      2
(1 row)
```

- `lastval()`

Description: Returns the last value of **nextval** in the current session. This function is equivalent to **currval**, but **lastval** does not have a parameter. If **nextval** has not been called in the current session, calling **lastval** will report an error.

Return type: numeric

Example:

```
gaussdb=# SELECT lastval();
 lastval
-----
      2
(1 row)
```

- `setval(regclass, numeric)`

Sets the current value of a sequence.

Return type: numeric

Example:

```
gaussdb=# SELECT setval('seqDemo',1);
 setval
-----
```

```
1
(1 row)
```

- **setval**(regclass, numeric, Boolean)

Sets the current value of a sequence and the is\_called sign.

Return type: numeric

Example:

```
gaussdb=# SELECT setval('seqDemo',1,true);
setval
-----
1
(1 row)
```

 **NOTE**

The current session will take effect immediately after **setval** is performed. If other sessions have buffered sequence values, **setval** will take effect only after the values are used up. Therefore, to prevent sequence value conflicts, you are advised to use **setval** with caution.

Because the sequence is non-transactional, changes made by **setval** will not be canceled when a transaction rolled back.

**NOTICE**

The **nextval** function can be executed only on the primary node. It is not supported on standby nodes.

- **pg\_sequence\_last\_value**(sequence\_oid oid, OUT cache\_value int16, OUT last\_value int16)

Description: Obtains the parameters of a specified sequence, including the cache value and current value.

Return type: int16, int16

- **last\_insert\_id**()

Description: Gets the first auto-generated value that was last successfully inserted for an auto-increment column.

Return type: int16

- **last\_insert\_id**(int16)

Description: Sets the return value of the next **last\_insert\_id**() function and returns the value. If the parameter is **NULL**, set the return value of the next **last\_insert\_id**() function to **0**. This function returns **NULL**.

Return type: int16

Example:

```
gaussdb=# SELECT last_insert_id(100);
last_insert_id
-----
100
(1 row)
gaussdb=# SELECT last_insert_id();
last_insert_id
-----
100
(1 row)
```

 NOTE

- last\_insert\_id() and last\_insert\_id(int16) are session-level functions. If no data is inserted into the auto-increment column in the current session, last\_insert\_id() returns 0.
- last\_insert\_id() and last\_insert\_id(int16) are available only when sql\_compatibility is set to 'B'.

## 7.5.16 Array Functions and Operators

### Array Operators

- =  
Description: Specifies whether two arrays are equal.  
Example:  

```
gaussdb=# SELECT ARRAY[1,1,2,1,3,1]::int[] = ARRAY[1,2,3] AS RESULT ;
result
-----
t
(1 row)
```
- <>  
Description: Specifies whether two arrays are not equal.  
Example:  

```
gaussdb=# SELECT ARRAY[1,2,3] <> ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```
- <  
Description: Specifies whether an array is less than another.  
Example:  

```
gaussdb=# SELECT ARRAY[1,2,3] < ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```
- >  
Description: Specifies whether an array is greater than another.  
Example:  

```
gaussdb=# SELECT ARRAY[1,4,3] > ARRAY[1,2,4] AS RESULT;
result
-----
t
(1 row)
```
- <=  
Description: Specifies whether an array is less than another.  
Example:  

```
gaussdb=# SELECT ARRAY[1,2,3] <= ARRAY[1,2,3] AS RESULT;
result
-----
t
(1 row)
```
- >=

Description: Specifies whether an array is greater than or equal to another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] >= ARRAY[1,4,3] AS RESULT;
result
-----
t
(1 row)
```

- @>

Description: Specifies whether an array contains another.

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] @> ARRAY[3,1] AS RESULT;
result
-----
t
(1 row)
```

- <@

Description: Specifies whether an array is contained in another.

Example:

```
gaussdb=# SELECT ARRAY[2,7] <@ ARRAY[1,7,4,2,6] AS RESULT;
result
-----
t
(1 row)
```

- &&

Description: Specifies whether an array overlaps another (have common elements).

Example:

```
gaussdb=# SELECT ARRAY[1,4,3] && ARRAY[2,1] AS RESULT;
result
-----
t
(1 row)
```

- ||

Description: Array-to-array concatenation

Example:

```
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[4,5,6] AS RESULT;
result
-----
{1,2,3,4,5,6}
(1 row)
gaussdb=# SELECT ARRAY[1,2,3] || ARRAY[[4,5,6],[7,8,9]] AS RESULT;
result
-----
{{1,2,3},{4,5,6},{7,8,9}}
(1 row)
```

- ||

Description: Element-to-array concatenation

Example:

```
gaussdb=# SELECT 3 || ARRAY[4,5,6] AS RESULT;
result
-----
{3,4,5,6}
(1 row)
```

- ||

Description: Array-to-element concatenation

Example:

```
gaussdb=# SELECT ARRAY[4,5,6] || 7 AS RESULT;
result
-----
{4,5,6,7}
(1 row)
```

Array comparisons compare the array contents element-by-element, using the default B-tree comparison function for the element data type. In multidimensional arrays, the elements are accessed in row-major order. If the contents of two arrays are equal but the dimensionality is different, the first difference in the dimensionality information determines the sort order.

## Array Functions

- `array_append(anyarray, anyelement)`

Description: Appends an element to the end of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_append(ARRAY[1,2], 3) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

- `array_prepend(anyelement, anyarray)`

Description: Appends an element to the beginning of an array, and only supports dimension-1 arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_prepend(1, ARRAY[2,3]) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

- `array_cat(anyarray, anyarray)`

Description: Concatenates two arrays, and supports multi-dimensional arrays.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_cat(ARRAY[1,2,3], ARRAY[4,5]) AS RESULT;
result
-----
{1,2,3,4,5}
(1 row)

gaussdb=# SELECT array_cat(ARRAY[[1,2],[4,5]], ARRAY[6,7]) AS RESULT;
result
-----
{{1,2},{4,5},{6,7}}
(1 row)
```

- `array_union(anyarray, anyarray)`

Description: Concatenates two arrays. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2,3,3,4,5}
(1 row)
```

```
gaussdb=# SELECT array_union(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

- `array_union_distinct(anyarray, anyarray)`

Description: Concatenates two arrays and deduplicates them. Only one-dimensional arrays are supported. If an input parameter is **NULL**, another input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2,3,4,5}
(1 row)
```

```
gaussdb=# SELECT array_union_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

- `array_intersect(anyarray, anyarray)`

Description: Intersects two arrays. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{3}
(1 row)
```

```
gaussdb=# SELECT array_intersect(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
(1 row)
```

- `array_intersect_distinct(anyarray, anyarray)`

Description: Intersects two arrays and deduplicates them. Only one-dimensional arrays are supported. If any input parameter is **NULL**, **NULL** is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,2], ARRAY[2,2,4,5]) AS RESULT;
result
-----
{2}
(1 row)
```

```
gaussdb=# SELECT array_intersect_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
(1 row)
```

- `array_except(anyarray, anyarray)`

Description: Calculates the difference between two arrays. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)
```

```
gaussdb=# SELECT array_except(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

```
gaussdb=# SELECT array_except(NULL, ARRAY[3,4,5]) AS RESULT;
result
-----
(1 row)
```

- `array_except_distinct(anyarray, anyarray)`

Description: Calculates the difference between two arrays and deduplicates them. Only one-dimensional arrays are supported. If the first input parameter is **NULL**, **NULL** is returned. If the second input parameter is **NULL**, the first input parameter is returned.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,2,3], ARRAY[3,4,5]) AS RESULT;
result
-----
{1,2}
(1 row)
```

```
gaussdb=# SELECT array_except_distinct(ARRAY[1,2,3], NULL) AS RESULT;
result
-----
{1,2,3}
(1 row)
```

```
gaussdb=# SELECT array_except_distinct(NULL, ARRAY[3,4,5]) AS RESULT;
result
-----
(1 row)
```

- `array_ndims(anyarray)`

Description: Returns the number of dimensions of an array.

Return type: int

Example:

```
gaussdb=# SELECT array_ndims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result
-----
      2
(1 row)
```

- **array\_dims(anyarray)**

Description: Returns the low-order flag bits and high-order flag bits of each dimension in an array.

Return type: text

Example:

```
gaussdb=# SELECT array_dims(ARRAY[[1,2,3], [4,5,6]]) AS RESULT;
result
-----
[1:2][1:3]
(1 row)
```

- **array\_length(anyarray, int)**

Description: Returns the length of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_length(array[1,2,3], 1) AS RESULT;
result
-----
      3
(1 row)

gaussdb=# SELECT array_length(array[[1,2,3],[4,5,6]], 2) AS RESULT;
result
-----
      3
(1 row)
```

- **array\_lower(anyarray, int)**

Description: Returns lower bound of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_lower('[0:2]={1,2,3}::int[]', 1) AS RESULT;
result
-----
      0
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **null** is returned.

- **array\_upper(anyarray, int)**

Description: Returns upper bound of the requested array dimension. **int** is the requested array dimension.

Return type: int

Example:

```
gaussdb=# SELECT array_upper(ARRAY[1,8,3,7], 1) AS RESULT;
result
-----
      4
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **null** is returned.

- `array_to_string(anyarray, text [, text])`

Description: Uses the first **text** as the new delimiter and the second **text** to replace **NULL** values.

Return type: text

Example:

```
gaussdb=# SELECT array_to_string(ARRAY[1, 2, 3, NULL, 5], ',', '**') AS RESULT;
result
-----
1,2,3,**5
(1 row)
```

- `array_delete(anyarray)`

Description: Clears elements in an array and returns an empty array of the same type.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_delete(ARRAY[1,8,3,7]) AS RESULT;
result
-----
{}
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **null** is returned.

- `array_deleteidx(anyarray, int)`

Description: Deletes specified subscript elements from an array and returns an array consisting of the remaining elements.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_deleteidx(ARRAY[1,2,3,4,5], 1) AS RESULT;
result
-----
{2,3,4,5}
(1 row)
```

 **NOTE**

- **array\_deleteidx(anyarray, int)**: This function is disabled when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.
- After the **varray\_compat** parameter is enabled, if the first parameter is null, error "Reference to uninitialized collection" is reported. If the second parameter is null, the original array is returned. If this parameter is disabled and one of the parameters is null, **null** is returned. If the value of the second parameter is less than or equal to **0**, the error "Subscript outside of limit" is reported after the parameter is enabled. Before the parameter is enabled, the original array is returned. If the value of the second parameter is greater than the number of elements in the array (including **0**, that is, an empty array), the error "Subscript outside of count" is reported after the parameter is enabled. Before the parameter is enabled, the original array is returned.
- `array_extendnull(anyarray, int)`

Description: Adds a specified number of null elements to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],1) AS RESULT;
 result
-----
{1,8,3,7,null}
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **null** is returned. If the second parameter is null, **null** is returned before **varray\_compat** is enabled. After **varray\_compat** is enabled, the original array is returned. If the second parameter is less than 0, error "numeric or value error" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, the original array is returned.

- `array_extendnull(anyarray, int, int)`

Description: Adds a specified number of elements with a specified index to the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_extendnull(ARRAY[1,8,3,7],2,2) AS RESULT;
 result
-----
{1,8,3,7,8,8}
(1 row)
```

 **NOTE**

- **array\_extendnull(anyarray, int, int)**: This function takes effect when the value of **a\_format\_version** is **10c** and the value of **a\_format\_dev\_version** is **s1**.
  - If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **null** is returned. If the second or third parameter is null, **null** is returned before **varray\_compat** is enabled. After **varray\_compat** is enabled, the original array is returned.
- `array_trim(anyarray, int)`

Description: Deletes a specified number of elements from the end of an array.

Return type: anyarray

Example:

```
gaussdb=# SELECT array_trim(ARRAY[1,8,3,7],1) AS RESULT;
 result
-----
{1,8,3}
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled and **null** is returned before **varray\_compat** is enabled. If the second parameter is null, **null** is returned before **varray\_compat** is enabled and the original array is returned after **varray\_compat** is enabled. If the second parameter exceeds the number of array elements (including **0**, that is, an empty array), error "Subscript outside of count" is reported after **varray\_compat** is enabled, and before **varray\_compat** is enabled, an empty array is returned. If the value of the second parameter is less than **0**, an error message "numeric or value error" is displayed after **varray\_compat** is enabled. Before **varray\_compat** is enabled, the original array is returned.

- `array_exists(anyarray, int)`

Description: Checks whether the second parameter is a valid subscript of an array.

Return type: Boolean

Example:

```
gaussdb=# SELECT array_exists(ARRAY[1,8,3,7],1) AS RESULT;  
result  
-----  
t  
(1 row)
```

- `array_next(anyarray, int)`

Description: Returns the subscript of the element following a specified subscript in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_next(ARRAY[1,8,3,7],1) AS RESULT;  
result  
-----  
2  
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **NULL** is returned.

- `array_prior(anyarray, int)`

Description: Returns the subscript of the element followed by a specified subscript in an array based on the second input parameter.

Return type: int

Example:

```
gaussdb=# SELECT array_prior(ARRAY[1,8,3,7],2) AS RESULT;  
result  
-----  
1  
(1 row)
```

 **NOTE**

If the first parameter is null, error "Reference to uninitialized collection" is reported after **varray\_compat** is enabled. Before **varray\_compat** is enabled, **NULL** is returned.

- `string_to_array(text, text, [text])`

Description: Uses the second **text** as the new delimiter and the third **text** as the substring to be replaced by **NULL** values. A substring can be replaced by **NULL** values only when it is the same as the third **text**.

Return type: text[]

Example:

```
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'yy') AS RESULT;
 result
-----
{xx,NULL,zz}
(1 row)
gaussdb=# SELECT string_to_array('xx~^~yy~^~zz', '~^~', 'y') AS RESULT;
 result
-----
{xx,yy,zz}
(1 row)
```

- **unnest(anyarray)**

Description: Expands an array to a set of rows.

Return type: setof anyelement

Example:

```
gaussdb=# SELECT unnest(ARRAY[1,2]) AS RESULT;
 result
-----
 1
 2
(2 rows)
```

- **unnest(annesttable)**

Description: Returns a collection of elements in a nest-table.

Return type: setof anyelement

Restriction: The tableof type cannot be nested with the tableof type, or the tableof type cannot be nested with other types and then the tableof type.

Example:

```
CREATE OR REPLACE PROCEDURE f1()
AS
  TYPE t1 IS TABLE of INT;
  v2 t1 := t1(null, 2, 3, 4, null);
  tmp INT;
  CURSOR c1 IS SELECT * FROM unnest(v2);
BEGIN
OPEN c1;
FOR i IN 1 .. v2.count LOOP
  FETCH c1 INTO tmp;
  IF tmp IS null THEN
    dbe_output.print_line(i || ': is null');
  ELSE
    dbe_output.print_line(i || ':' || tmp);
  END IF;
END LOOP;
CLOSE c1;
END;
/

gaussdb=# CALL f1();
1: is null
2: 2
3: 3
4: 4
5: is null
f1
----
```

(1 row)

- `unnest(anyindexbytable)`

Description: Returns the collection of elements in an index-by table sorted by index.

Return type: setof anyelement

Restriction: The tableof type cannot be nested with the tableof type, or the tableof type cannot be nested with other types and then the tableof type. Only the index by int type is supported. The index by varchar type is not supported.

Example:

```
CREATE OR REPLACE PROCEDURE f1 ()
AS
  TYPE t1 IS TABLE of INT INDEX BY INT;
  v2 t1 := t1(1=>1, -10=>(-10), 6=>6, 4=>null);
  tmp INT;
  CURSOR c1 IS SELECT * FROM unnest(v2);
BEGIN
  OPEN c1;
  FOR i IN 1 .. v2.count LOOP
    FETCH c1 INTO tmp;
    IF tmp IS null THEN
      dbe_output.print_line(i || ': is null');
    ELSE
      dbe_output.print_line(i || ': ' || tmp);
    END IF;
  END LOOP;
  CLOSE c1;
END;
/

gaussdb=# CALL f1();
1: -10
2: 1
3: is null
4: 6
f1
----
(1 row)
```

In **string\_to\_array**, if the delimiter parameter is **NULL**, each character in the input string will become a separate element in the resulting array. If the delimiter is an empty string, then the entire input string is returned as a one-element array. Otherwise the input string is split at each occurrence of the delimiter string.

In **string\_to\_array**, if the null-string parameter is omitted or **NULL**, none of the substrings of the input will be replaced by **NULL**.

In **array\_to\_string**, if the null-string parameter is omitted or **NULL**, any null elements in the array are simply skipped and not represented in the output string.

- `_pg_keysequal`

Description: Checks whether two smallint arrays are the same.

Parameter: smallint[], smallint[]

Return type: Boolean

#### NOTE

This function exists in the `information_schema` namespace.

## 7.5.17 Range Functions and Operators

### Range Operators

- =

Description: Equals

Example:

```
gaussdb=# SELECT int4range(1,5) = '[1,4]::int4range AS RESULT;  
result  
-----  
t  
(1 row)
```

- <>

Description: Does not equal

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <> numrange(1.1,2.3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <

Description: Is less than

Example:

```
gaussdb=# SELECT int4range(1,10) < int4range(2,3) AS RESULT;  
result  
-----  
t  
(1 row)
```

- >

Description: Is greater than

Example:

```
gaussdb=# SELECT int4range(1,10) > int4range(1,5) AS RESULT;  
result  
-----  
t  
(1 row)
```

- <=

Description: Is less than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) <= numrange(1.1,2.2) AS RESULT;  
result  
-----  
t  
(1 row)
```

- >=

Description: Is greater than or equals

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) >= numrange(1.1,2.0) AS RESULT;  
result  
-----  
t  
(1 row)
```

- @>  
Description: Contains range  
Example:  

```
gaussdb=# SELECT int4range(2,4) @> int4range(2,3) AS RESULT;  
result  
-----  
t  
(1 row)
```
- @>  
Description: Contains element  
Example:  

```
gaussdb=# SELECT '[2011-01-01,2011-03-01]':tsrange @> '2011-01-10':timestamp AS RESULT;  
result  
-----  
t  
(1 row)
```
- <@  
Description: Range is contained by  
Example:  

```
gaussdb=# SELECT int4range(2,4) <@ int4range(1,7) AS RESULT;  
result  
-----  
t  
(1 row)
```
- <@  
Description: Element is contained by  
Example:  

```
gaussdb=# SELECT 42 <@ int4range(1,7) AS RESULT;  
result  
-----  
f  
(1 row)
```
- &&  
Description: Overlap (have points in common)  
Example:  

```
gaussdb=# SELECT int8range(3,7) && int8range(4,12) AS RESULT;  
result  
-----  
t  
(1 row)
```
- <<  
Description: Strictly left of  
Example:  

```
gaussdb=# SELECT int8range(1,10) << int8range(100,110) AS RESULT;  
result  
-----  
t  
(1 row)
```
- >>  
Description: Strictly right of  
Example:  

```
gaussdb=# SELECT int8range(50,60) >> int8range(20,30) AS RESULT;  
result
```

- ```
-----
t
(1 row)
```
- **&<**  
Description: Does not extend to the right of  
Example:  
gaussdb=# SELECT int8range(1,20) &< int8range(18,20) AS RESULT;  
result  
-----  
t  
(1 row)
- **&>**  
Description: Does not extend to the left of  
Example:  
gaussdb=# SELECT int8range(7,20) &> int8range(5,10) AS RESULT;  
result  
-----  
t  
(1 row)
- **-|-**  
Description: Is adjacent to  
Example:  
gaussdb=# SELECT numrange(1.1,2.2) -|- numrange(2.2,3.3) AS RESULT;  
result  
-----  
t  
(1 row)
- **+**  
Description: Union  
Example:  
gaussdb=# SELECT numrange(5,15) + numrange(10,20) AS RESULT;  
result  
-----  
[5,20)  
(1 row)
- **\***  
Description: Intersection  
Example:  
gaussdb=# SELECT int8range(5,15) \* int8range(10,20) AS RESULT;  
result  
-----  
[10,15)  
(1 row)
- **-**  
Description: Difference  
Example:  
gaussdb=# SELECT int8range(5,15) - int8range(10,20) AS RESULT;  
result  
-----  
[5,10)  
(1 row)

The simple comparison operators **<**, **>**, **<=**, and **>=** compare the lower bounds first, and only if those are equal, compare the upper bounds.

The <<, >>, and -|- operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges.

## Range Functions

The lower and upper functions return null if the range is empty or the requested bound is infinite. The lower\_inc, upper\_inc, lower\_inf, and upper\_inf functions all return false for an empty range.

- numrange(numeric, numeric, [text])

Description: Specifies a range.

Return type: Range's element type

Example:

```
gaussdb=# SELECT numrange(1.1,2.2) AS RESULT;
result
-----
[1.1,2.2)
(1 row)
gaussdb=# SELECT numrange(1.1,2.2, '(') AS RESULT;
result
-----
(1.1,2.2)
(1 row)
```

- lower(anyrange)

Description: Lower bound of range

Return type: Range's element type

Example:

```
gaussdb=# SELECT lower(numrange(1.1,2.2)) AS RESULT;
result
-----
1.1
(1 row)
```

- upper(anyrange)

Description: Upper bound of range

Return type: Range's element type

Example:

```
gaussdb=# SELECT upper(numrange(1.1,2.2)) AS RESULT;
result
-----
2.2
(1 row)
```

- isempty(anyrange)

Description: Is the range empty?

Return type: Boolean

Example:

```
gaussdb=# SELECT isempty(numrange(1.1,2.2)) AS RESULT;
result
-----
f
(1 row)
```

- **lower\_inc(anyrange)**  
Description: Is the lower bound inclusive?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT lower_inc(numrange(1.1,2.2)) AS RESULT;
result
-----
t
(1 row)
```
- **upper\_inc(anyrange)**  
Description: Is the upper bound inclusive?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT upper_inc(numrange(1.1,2.2)) AS RESULT;
result
-----
f
(1 row)
```
- **lower\_inf(anyrange)**  
Description: Is the lower bound infinite?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT lower_inf('()::daterange) AS RESULT;
result
-----
t
(1 row)
```
- **upper\_inf(anyrange)**  
Description: Is the upper bound infinite?  
Return type: Boolean  
Example:

```
gaussdb=# SELECT upper_inf('()::daterange) AS RESULT;
result
-----
t
(1 row)
```
- **elem\_contained\_by\_range(anyelement, anyrange)**  
Description: Determines whether an element is within the range.  
Return type: Boolean  
Example:

```
gaussdb=# SELECT elem_contained_by_range('2', numrange(1.1,2.2));
elem_contained_by_range
-----
t
(1 row)
```

## 7.5.18 Aggregate Functions

### Aggregate Functions

- **sum(expression)**

Description: Specifies the sum of expressions across all input values.

Return type:

Generally, same as the argument data type. In the following cases, type conversion occurs:

- **BIGINT** for **SMALLINT** or **INT** arguments
- **NUMBER** for **BIGINT** arguments
- **DOUBLE PRECISION** for floating-point arguments

Example:

```
gaussdb=# CREATE TABLE tab(a int);
CREATE TABLE
gaussdb=# INSERT INTO tab values(1);
INSERT 0 1
gaussdb=# INSERT INTO tab values(2);
INSERT 0 1
gaussdb=# SELECT sum(a) FROM tab;
 sum
-----
   3
(1 row)
```

- **max(expression)**

Description: Specifies the maximum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE max_t1(a int, b int);
gaussdb=# INSERT INTO max_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MAX(a) FROM max_t1;
 max
-----
   4
(1 row)
gaussdb=# DROP TABLE max_t1;
```

- **min(expression)**

Description: Specifies the minimum value of expression across all input values.

Parameter type: any array, numeric, string, or date/time type

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE min_t1(a int, b int);
gaussdb=# INSERT INTO min_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT MIN(a) FROM min_t1;
 min
-----
   1
(1 row)
gaussdb=# DROP TABLE min_t1;
```

- **avg(expression)**

Description: Specifies the average (arithmetic mean) of all input values.

Return type:

NUMBER for any integer-type argument.

DOUBLE PRECISION for floating-point parameters.

Otherwise, it is the same as the argument data type.

Example:

```
gaussdb=# CREATE TABLE avg_t1(a int, b int);
gaussdb=# INSERT INTO avg_t1 VALUES(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT AVG(a) FROM avg_t1;
      avg
-----
2.5000000000000000
(1 row)
gaussdb=# DROP TABLE avg_t1;
```

- **count(expression)**

Description: Specifies the number of input rows for which the value of the expression is not null.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(a) FROM count_t1;
      count
-----
4
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **count(\*)**

Description: Returns the number of input rows.

Return type: bigint

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE count_t1(a int, b int);
gaussdb=# INSERT INTO count_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT COUNT(*) FROM count_t1;
      count
-----
5
(1 row)
gaussdb=# DROP TABLE count_t1;
```

- **median(expression) [over (query partition clause)]**

Description: Returns the median of an expression. **NULL** will be ignored by the median function during calculation. The **DISTINCT** keyword can be used to exclude duplicate records in an expression. The data type of the input expression can be numeric (including integer, double, and bigint) or interval. For other data types, the median cannot be calculated.

Return type: double or interval

Example:

```
SELECT median(id) FROM (values(1), (2), (3), (4), (null)) test(id);
median
-----
2.5
(1 row)
```

- **array\_agg(expression)**

Description: Concatenates input values, including nulls, into an array.

Return type: array of the argument type

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE array_agg_t1(a int, b int);
gaussdb=# INSERT INTO array_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT ARRAY_AGG(a) FROM array_agg_t1;
array_agg
-----
{NULL,1,2,3,4}
(1 row)
gaussdb=# DROP TABLE array_agg_t1;
```

- **string\_agg(expression, delimiter)**

Description: Concatenates input values into a string, separated by delimiter.

Return type: same as the argument type

Operations on XML data that is explicitly converted to the character type are supported.

Example:

```
gaussdb=# CREATE TABLE string_agg_t1(a int, b int);
gaussdb=# INSERT INTO string_agg_t1 VALUES (NULL,1),(1,2),(2,3),(3,4),(4,5);
gaussdb=# SELECT STRING_AGG(a,',' ) FROM string_agg_t1;
string_agg
-----
1;2;3;4
(1 row)
gaussdb=# DROP TABLE string_agg_t1;
```

- **listagg(expression [, delimiter]) WITHIN GROUP(ORDER BY order-list)**

Description: Sorts aggregation column data according to the mode specified by **WITHIN GROUP** and concatenates the data to a string using the specified delimiter.

- **expression:** Mandatory. It specifies an aggregation column name or a column-based valid expression. It does not support the **DISTINCT** keyword and the **VARIADIC** parameter.
- **delimiter:** Optional. It specifies a delimiter, which can be a string constant or a deterministic expression based on a group of columns. The default value is empty.
- **order-list:** Mandatory. It specifies the sorting mode in a group.

Return type: text

Example:

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b text);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'a1'),(1,'b2'),(1,'c3'),(2,'d4'),(2,'e5'),(3,'f6');
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | b2;c3
2 | d4;e5
3 | f6
  | a1
(4 rows)
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b int);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b float);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,1.111),(1,2.222),(1,3.333),(2,4.444),(2,5.555),
(3,6.666);
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2.222000;3.333000
2 | 4.444000;5.555000
3 | 6.666000
  | 1.111000
(4 rows)
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b timestamp);
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),(1,'2000-03-03'),
(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
gaussdb=# SELECT a,LISTAGG(b,') WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2000-02-02 00:00:00;2000-03-03 00:00:00
2 | 2000-04-04 00:00:00;2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
  | 2000-01-01 00:00:00
(4 rows)
gaussdb=# DROP TABLE listagg_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b,;) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2 days;3 days
2 | 4 days;5 days
3 | 6 days
  | 1 day
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

By default, the delimiter is empty.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) FROM listagg_t1 group by a;
a | listagg
---+-----
1 | 2 days3 days
2 | 4 days5 days
3 | 6 days
  | 1 day
(4 rows)

gaussdb=# DROP TABLE listagg_t1;
```

When listagg is used as a window function, the OVER clause does not support the window sorting of ORDER BY, and the listagg column is an ordered aggregation of the corresponding groups.

```
gaussdb=# CREATE TABLE listagg_t1(a int, b interval);

gaussdb=# INSERT INTO listagg_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),(2,'5
days'),(3,'6 days');

gaussdb=# SELECT a,LISTAGG(b) WITHIN GROUP(ORDER BY b) OVER(PARTITION BY a) FROM
listagg_t1;
a | listagg
---+-----
1 | 2 days3 days
1 | 2 days3 days
2 | 4 days5 days
2 | 4 days5 days
3 | 6 days
  | 1 day
(6 rows)

gaussdb=# DROP TABLE listagg_t1;
```

- `group_concat([DISTINCT | ALL] expression [,expression ...] [ORDER BY { expression [ [ ASC | DESC | USING operator ] | nlssort_expression_clause ] [ NULLS { FIRST | LAST } ] } [,...]] [SEPARATOR str_val])`

Description: The number of parameters is not fixed. Multiple columns can be concatenated. Aggregation columns are sorted based on the value of **ORDER BY** and concatenated into a character string using the specified separator. This function cannot be used as a window function.

- **DISTINCT**: Optional. It deduplicates the results after each row is concatenated.
- **expression**: Mandatory. It specifies the aggregation column name or a valid column-based expression.

- **ORDER BY:** Optional. It is followed by a variable number of expressions and sorting rule. The group\_concat function does not support the (ORDER BY + number) format.
- **SEPARATOR:** Optional. It is followed by a character or string. This separator is used to concatenate the expression results of two adjacent lines in a group. If this parameter is not specified, ',' is used by default.
- When both DISTINCT and ORDER BY are specified, all ORDER BY expressions must be in DISTINCT expressions. Otherwise, an error is reported.

Return type: text

Example:

Set **separator** to ';':

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT a,group_concat(b separator ';') FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
---+-----
1 | 2;3
2 | 4;5
3 | 6
  | 1
(4 rows)

gaussdb=# DROP TABLE group_concat_t1;
```

By default, the separator is a comma (,).

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
---+-----
1 | 12,13
2 | 24,25
3 | 36
  | 1
(4 rows)

gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the text character set type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b text);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'a1'),('1','b2'),('1','c3'),('2','d4'),('2','e5'),('3','f6');
gaussdb=# SELECT a,group_concat(a,b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
---+-----
1 | 1b2,1c3
2 | 2d4,2e5
3 | 3f6
  | a1
(4 rows)

gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the integer type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b int);
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2,3
2 | 4,5
3 | 6
  | 1
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the floating point type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b float);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,1.11),(1,2.22),(1,3.33),(2,4.44),(2,5.55),
(3,6.66);
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2.22,3.33
2 | 4.44,5.55
3 | 6.66
  | 1.11
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b timestamp);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'2000-01-01'),(1,'2000-02-02'),
(1,'2000-03-03'),(2,'2000-04-04'),(2,'2000-05-05'),(3,'2000-06-06');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | 2000-02-02 00:00:00,2000-03-03 00:00:00
2 | 2000-04-04 00:00:00,2000-05-05 00:00:00
3 | 2000-06-06 00:00:00
  | 2000-01-01 00:00:00
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the binary type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b bytea);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1'),(1,'2'),(1,'3'),(2,'4'),(2,'5'),(3,'6');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
a | group_concat
-----+-----
1 | \x32,\x33
2 | \x34,\x35
3 | \x36
  | \x31
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

The aggregation column is of the time interval type.

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

**Set `distinct` to deduplicate data.**

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'2 days'),(1,'3 days'),
(1,'3 days'),(2,'4 days'),(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(distinct b) FROM group_concat_t1 GROUP BY a ORDER BY a;
```

```
a | group_concat
-----+-----
1 | 2 days,3 days
2 | 4 days,5 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

**Set `ORDER BY` to sort data.**

```
gaussdb=# CREATE TABLE group_concat_t1(a int, b interval);
```

```
gaussdb=# INSERT INTO group_concat_t1 VALUES (NULL,'1 days'),(1,'2 days'),(1,'3 days'),(2,'4 days'),
(2,'5 days'),(3,'6 days');
```

```
gaussdb=# SELECT a,group_concat(b ORDER BY b desc) FROM group_concat_t1 GROUP BY a ORDER
BY a;
```

```
a | group_concat
-----+-----
1 | 3 days,2 days
2 | 5 days,4 days
3 | 6 days
  | 1 day
(4 rows)
```

```
gaussdb=# DROP TABLE group_concat_t1;
```

- `wm_concat(expression)`

Description: Concatenates column data into a string separated by commas (,).

Return type: same as the argument type

 **NOTE**

`wm_concat` is developed for compatibility with database A. Currently, this function has been canceled and replaced by the `listagg` function in the latest version of database A. You can also use the `string_agg` function. For details, see the description of the two functions.

- `covar_pop(Y, X)`

Description: Specifies the overall covariance.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_pop_t1(a int, b int);
```

```
gaussdb=# INSERT INTO covar_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
```

```
gaussdb=# SELECT COVAR_POP(a,b) FROM covar_pop_t1;
covar_pop
```

```
-----
      100
(1 row)

gaussdb=# DROP TABLE covar_pop_t1;
```

- **covar\_samp(Y, X)**  
Description: Specifies the sample covariance.  
Return type: double precision

Example:

```
gaussdb=# CREATE TABLE covar_samp_t1(a int, b int);
gaussdb=# INSERT INTO covar_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT COVAR_SAMP(a,b) FROM covar_samp_t1;
 covar_samp
```

```
-----
      125
(1 row)

gaussdb=# DROP TABLE covar_samp_t1;
```

- **stddev\_pop(expression)**  
Description: Specifies the overall standard deviation.  
Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_pop_t1(a int, b int);
gaussdb=# INSERT INTO stddev_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_POP(a) FROM stddev_pop_t1;
 stddev_pop
```

```
-----
7.4833147735478828
(1 row)
```

```
gaussdb=# DROP TABLE stddev_pop_t1;
```

- **stddev\_samp(expression)**  
Description: Specifies the sample standard deviation of the input values.  
Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_samp_t1(a int, b int);
gaussdb=# INSERT INTO stddev_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT STDDEV_SAMP(a) FROM stddev_samp_t1;
 stddev_samp
```

```
-----
8.3666002653407555
(1 row)
```

```
gaussdb=# DROP TABLE stddev_samp_t1;
```

- **var\_pop(expression)**  
Description: Specifies the population variance of the input values (square of the population standard deviation).  
Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_pop_t1(a int, b int);
gaussdb=# INSERT INTO var_pop_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_POP(a) FROM var_pop_t1;
var_pop
-----
56.000000000000000000
(1 row)
gaussdb=# DROP TABLE var_pop_t1;
```

- **var\_samp(expression)**

Description: Specifies the sample variance of the input values (square of the sample standard deviation).

Return type: DOUBLE PRECISION for floating-point arguments, otherwise NUMERIC

Example:

```
gaussdb=# CREATE TABLE var_samp_t1(a int, b int);
gaussdb=# INSERT INTO var_samp_t1 VALUES (NULL,11),(11,21),(11,31),(21,41),(21,51),(31,61);
gaussdb=# SELECT VAR_SAMP(a) FROM var_samp_t1;
var_samp
-----
70.000000000000000000
(1 row)
gaussdb=# DROP TABLE var_samp_t1;
```

- **bit\_and(expression)**

Description: bitwise AND of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE bit_and_t1(a int, b int);
gaussdb=# INSERT INTO bit_and_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT BIT_AND(a) FROM bit_and_t1;
bit_and
-----
0
(1 row)
gaussdb=# DROP TABLE bit_and_t1;
```

- **bit\_or(expression)**

Description: bitwise OR of all non-null input values, or null if none

Return type: same as the argument type

Example:

```
gaussdb=# CREATE TABLE bit_or_t1(a int, b int);
gaussdb=# INSERT INTO bit_or_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT BIT_OR(a) FROM bit_or_t1;
bit_or
-----
3
(1 row)
gaussdb=# DROP TABLE bit_or_t1;
```

- bool\_and(expression)**

Description: Its value is **true** if all input values are **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_and(100 <2500);
bool_and
-----
t
(1 row)
```
- bool\_or(expression)**

Description: Its value is **true** if at least one input value is **true**, otherwise **false**.

Return type: Boolean

Example:

```
gaussdb=# SELECT bool_or(100 <2500);
bool_or
-----
t
(1 row)
```
- corr(Y, X)**

Description: Specifies the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE corr_t1(a int, b int);
gaussdb=# INSERT INTO corr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CORR(a,b) FROM corr_t1;
corr
-----
.944911182523068
(1 row)
gaussdb=# DROP TABLE corr_t1;
```
- every(expression)**

Description: Equivalent to **bool\_and**

Return type: Boolean

Example:

```
gaussdb=# SELECT every(100 <2500);
every
-----
t
(1 row)
```
- regr\_avgx(Y, X)**

Description: Specifies the average of the independent variable (**sum(X)/N**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_t1(a int, b int);
gaussdb=# INSERT INTO regr_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_AVGX(a,b) FROM regr_t1;
regr_avgx
```

```
-----
      4
(1 row)

gaussdb=# DROP TABLE regr_t1;
```

- **regr\_avgy(Y, X)**

Description: Specifies the average of the dependent variable (**sum(Y)/N**).

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_avgy_t1(a int, b int);

gaussdb=# INSERT INTO regr_avgy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_AVGY(a,b) FROM regr_avgy_t1;
regr_avgy
-----
      1.8
(1 row)

gaussdb=# DROP TABLE regr_avgy_t1;
```

- **regr\_count(Y, X)**

Description: Specifies the number of input rows in which both expressions are non-null.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE regr_count_t1(a int, b int);

gaussdb=# INSERT INTO regr_count_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_COUNT(a,b) FROM regr_count_t1;
regr_count
-----
      5
(1 row)

gaussdb=# DROP TABLE regr_count_t1;
```

- **regr\_intercept(Y, X)**

Description: Specifies the y-intercept of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_intercept_t1(a int, b int);

gaussdb=# INSERT INTO regr_intercept_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);

gaussdb=# SELECT REGR_INTERCEPT(b,a) FROM regr_intercept_t1;
regr_intercept
-----
.785714285714286
(1 row)

gaussdb=# DROP TABLE regr_intercept_t1;
```

- **regr\_r2(Y, X)**

Description: Specifies the square of the correlation coefficient.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_r2_t1(a int, b int);
gaussdb=# INSERT INTO regr_r2_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_R2(b,a) FROM regr_r2_t1;
   regr_r2
-----
.892857142857143
(1 row)
gaussdb=# DROP TABLE regr_r2_t1;
```

- **regr\_slope(Y, X)**

Description: Specifies the slope of the least-squares-fit linear equation determined by the (X, Y) pairs.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_slope_t1(a int, b int);
gaussdb=# INSERT INTO regr_slope_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SLOPE(b,a) FROM regr_slope_t1;
   regr_slope
-----
1.78571428571429
(1 row)
gaussdb=# DROP TABLE regr_slope_t1;
```

- **regr\_sxx(Y, X)**

Description:  $\sum(X^2) - \sum(X)^2/N$  (sum of squares of the independent variables)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxx_t1(a int, b int);
gaussdb=# INSERT INTO regr_sxx_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SXX(b,a) FROM regr_sxx_t1;
   regr_sxx
-----
2.8
(1 row)
gaussdb=# DROP TABLE regr_sxx_t1;
```

- **regr\_sxy(Y, X)**

Description:  $\sum(X*Y) - \sum(X) * \sum(Y)/N$  (sum of products of independent times dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_sxy_t1(a int, b int);
gaussdb=# INSERT INTO regr_sxy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SXY(b,a) FROM regr_sxy_t1;
   regr_sxy
-----
5
(1 row)
gaussdb=# DROP TABLE regr_sxy_t1;
```

- `regr_syy(Y, X)`

Description:  **$\text{sum}(Y^2) - \text{sum}(Y)^2/N$**  (sum of squares of the dependent variable)

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE regr_syy_t1(a int, b int);
gaussdb=# INSERT INTO regr_syy_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT REGR_SYY(b,a) FROM regr_syy_t1;
regr_syy
-----
      10
(1 row)
gaussdb=# DROP TABLE regr_syy_t1;
```

- `stddev(expression)`

Description: Specifies the alias of **`stddev_samp`**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE stddev_t1(a int, b int);
gaussdb=# INSERT INTO stddev_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT STDDEV(a) FROM stddev_t1;
stddev
-----
.83666002653407554798
(1 row)
gaussdb=# DROP TABLE stddev_t1;
```

- `variance(expression,ression)`

Description: Specifies the alias of **`var_samp`**.

Return type: **double precision** for floating-point arguments, otherwise **numeric**

Example:

```
gaussdb=# CREATE TABLE variance_t1(a int, b int);
gaussdb=# INSERT INTO variance_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT VARIANCE(a) FROM variance_t1;
variance
-----
.70000000000000000000
(1 row)
gaussdb=# DROP TABLE variance_t1;
```

- `delta`

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- `checksum(expression)`

Description: Returns the **CHECKSUM** value of all input values. This function can be used to check whether the data in the tables is the same before and

after the backup, restoration, or migration of the GaussDB database (databases other than GaussDB are not supported). Before and after database backup, database restoration, or data migration, you need to manually run SQL commands to obtain the execution results. Compare the obtained execution results to check whether the data in the tables before and after the backup or migration is the same.

**NOTE**

- For large tables, the execution of the **CHECKSUM** function may take a long time.
  - If the **CHECKSUM** values of two tables are different, it indicates that the contents of the two tables are different. Using the hash function in the **CHECKSUM** function may incur conflicts. There is low possibility that two tables with different contents may have the same **CHECKSUM** value. The same problem may occur when **CHECKSUM** is used for columns.
  - If the time type is timestamp, timestamptz, or smalldatetime, ensure that the time zone settings are the same when calculating the **CHECKSUM** value.
- If the **CHECKSUM** value of a column is calculated and the column type can be changed to TEXT by default, set *expression* to the column name.
  - If the **CHECKSUM** value of a column is calculated and the column type cannot be converted to TEXT by default, set *expression* to *Column name::TEXT*.
  - If the **CHECKSUM** value of all columns is calculated, set *expression* to *Table name::TEXT*.

The following types of data can be converted into the TEXT type by default: char, name, int8, int2, int1, int4, raw, pg\_node\_tree, float4, float8, bpchar, varchar, nvarchar, nvarchar2, date, timestamp, timestamptz, numeric, and smalldatetime. Other types need to be forcibly converted to TEXT.

Return type: numeric

Example:

The following shows the CHECKSUM value of a column that can be converted to the TEXT type by default:

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of a column that cannot be converted to the TEXT type by default. Note that the CHECKSUM parameter is set to *Column name::TEXT*.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(a::TEXT) FROM checksum_t1;
checksum
-----
18126842830
(1 row)

gaussdb=# DROP TABLE checksum_t1;
```

The following shows the CHECKSUM value of all columns in a table. Note that the CHECKSUM parameter is set to *Table name::TEXT*. The table name is not modified by its schema.

```
gaussdb=# CREATE TABLE checksum_t1(a int, b int);
gaussdb=# INSERT INTO checksum_t1 VALUES (NULL,11),(1,2),(1,3),(2,4),(2,5),(3,6);
gaussdb=# SELECT CHECKSUM(checksum_t1::TEXT) FROM checksum_t1;
checksum
-----
1116052226
(1 row)
gaussdb=# DROP TABLE checksum_t1;
```

- percentile\_cont(percentile float)

Description: Sorts a given column by time series and returns a percentile value.

Return type: float

 NOTE

- **percentile** is a decimal from 0 to 1. The value is of the floating point type and does not support the percent sign (%), for example, 95%.
- This parameter must be used together with WITHIN GROUP (ORDER BY) to specify the column to be calculated. The column must be of the numeric type.

Example:

```
gaussdb=# SELECT percentile_cont(0) WITHIN GROUP (ORDER BY value) FROM (VALUES (1),(2))
v(value);
percentile_cont
-----
1
(1 row)
```

- mode() WITHIN GROUP (ORDER BY value anyelement)

Description: Returns the value with the highest occurrence frequency in a column. If multiple values have the same frequency, the smallest value is returned. The sorting mode is the same as the default sorting mode of the column type. **value** is an input parameter and can be of any type.

Return type: same as the input parameter type

Example:

```
gaussdb=# SELECT mode() WITHIN GROUP (ORDER BY value) FROM (values(1, 'a'), (2, 'b'), (2, 'c'))
v(value, tag);
mode
-----
2
(1 row)
gaussdb=# SELECT mode() WITHIN GROUP (ORDER BY tag) FROM (values(1, 'a'), (2, 'b'), (2, 'c'))
v(value, tag);
mode
-----
a
(1 row)
```

- pivot\_func(anyelement)

Description: Returns the only non-null value in a column. If there are two or more non-null values, an error is reported. **value** is an input parameter and can be of any type.

Return type: same as the input parameter type

 **NOTE**

This aggregate function is mainly used inside the pivot syntax.

Example:

```
gaussdb=# CREATE TABLE pivot_func_t1(a int, b int);
gaussdb=# INSERT INTO pivot_func_t1 VALUES (NULL,11),(1,2);
gaussdb=# SELECT PIVOT_FUNC(a) FROM pivot_func_t1;
pivot_func
-----
          1
(1 row)
gaussdb=# DROP TABLE pivot_func_t1;
```

## 7.5.19 Window Functions

### Window Functions

This statement is used together with the window function. The OVER clause is used for grouping data and sorting the elements in a group. Window functions are used for generating sequence numbers for the values in the group.

 **NOTE**

ORDER BY in a window function must be followed by a column name. If it is followed by a number, the number is processed as a constant value and the target column is not ranked.

- **RANK()**

Description: The RANK function is used for generating non-consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE rank_t1(a int, b int);
gaussdb=# INSERT INTO rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,RANK() OVER(PARTITION BY a ORDER BY b) FROM rank_t1;
a | b | rank
-----+-----+-----
1 | 1 | 1
1 | 1 | 1
1 | 2 | 3
1 | 3 | 4
2 | 4 | 1
2 | 5 | 2
3 | 6 | 1
(7 rows)
gaussdb=# DROP TABLE rank_t1;
```

- **ROW\_NUMBER()**

Description: The ROW\_NUMBER function is used for generating consecutive sequence numbers for the values in each group. The same values have different sequence numbers.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE row_number_t1(a int, b int);

gaussdb=# INSERT INTO row_number_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,ROW_NUMBER() OVER(PARTITION BY a ORDER BY b) FROM row_number_t1;
a | b | row_number
-----+-----
1 | 1 |          1
1 | 1 |          2
1 | 2 |          3
1 | 3 |          4
2 | 4 |          1
2 | 5 |          2
3 | 6 |          1
(7 rows)

gaussdb=# DROP TABLE row_number_t1;
```

- **DENSE\_RANK()**

Description: The DENSE\_RANK function is used for generating consecutive sequence numbers for the values in each group. The same values have the same sequence number.

Return type: bigint

Example:

```
gaussdb=# CREATE TABLE dense_rank_t1(a int, b int);

gaussdb=# INSERT INTO dense_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,DENSE_RANK() OVER(PARTITION BY a ORDER BY b) FROM dense_rank_t1;
a | b | dense_rank
-----+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          2
1 | 3 |          3
2 | 4 |          1
2 | 5 |          2
3 | 6 |          1
(7 rows)

gaussdb=# DROP TABLE dense_rank_t1;
```

- **PERCENT\_RANK()**

Description: The PERCENT\_RANK function is used for generating corresponding sequence numbers for the values in each group. That is, the function calculates the value according to the formula: Sequence number = **(rank - 1) / (totalrows - 1)**. **rank** is the corresponding sequence number generated based on the **RANK** function for the value and **totalrows** is the total number of elements in a group.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE percent_rank_t1(a int, b int);

gaussdb=# INSERT INTO percent_rank_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);

gaussdb=# SELECT a,b,PERCENT_RANK() OVER(PARTITION BY a ORDER BY b) FROM percent_rank_t1;
a | b | percent_rank
-----+-----
1 | 1 |          0
1 | 1 |          0
1 | 2 | .6666666666666667
1 | 3 |          1
2 | 4 |          0
```

```
2 | 5 |      1
3 | 6 |      0
(7 rows)
```

```
gaussdb=# DROP TABLE percent_rank_t1;
```

- **CUME\_DIST()**

Description: The CUME\_DIST function is used for generating accumulative distribution sequence numbers for the values in each group. That is, the function calculates the value according to the following formula: Sequence number = Number of rows preceding or peer with current row/Total rows.

Return type: double precision

Example:

```
gaussdb=# CREATE TABLE cume_dist_t1(a int, b int);
```

```
gaussdb=# INSERT INTO cume_dist_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,CUME_DIST() OVER(PARTITION BY a ORDER BY b) FROM cume_dist_t1;
```

```
a | b | cume_dist
```

```
-----
```

```
1 | 1 |      .5
1 | 1 |      .5
1 | 2 |     .75
1 | 3 |      1
2 | 4 |      .5
2 | 5 |      1
3 | 6 |      1
(7 rows)
```

```
gaussdb=# DROP TABLE cume_dist_t1;
```

- **NTILE(num\_buckets integer)**

Description: The NTILE function is used for equally allocating sequential data sets to the buckets whose quantity is specified by **num\_buckets** according to **num\_buckets integer** and allocating the bucket number to each row. Divide the partition as evenly as possible.

Return type: integer

Example:

```
gaussdb=# CREATE TABLE ntile_t1(a int, b int);
```

```
gaussdb=# INSERT INTO ntile_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,NTILE(2) OVER(PARTITION BY a ORDER BY b) FROM ntile_t1;
```

```
a | b | ntile
```

```
-----
```

```
1 | 1 |      1
1 | 1 |      1
1 | 2 |      2
1 | 3 |      2
2 | 4 |      1
2 | 5 |      2
3 | 6 |      1
(7 rows)
```

```
gaussdb=# DROP TABLE ntile_t1;
```

- **LAG(value any [, offset integer [, default any ]])**

Description: The LAG function is used for generating lag values for the corresponding values in each group. That is, the value of the row obtained by moving forward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row does not exist after the moving, the result value is the default value. If omitted, **offset** defaults to **1** and

**default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 VALUES('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 VALUES('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(' ', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LAG and set offset to 3 and default to null.
gaussdb=# SELECT hire_date, last_name, department_id, lag(hire_date, 3, null) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
 hire_date | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq | 11 |
2008-05-10 00:00:00 | zi | 11 |
| | 11 | 2007-05-10 00:00:00
2005-12-24 00:00:00 | Baida | 30 |
2007-08-10 00:00:00 | Colmenares | 30 |
2006-11-15 00:00:00 | Himuro | 30 |
2003-05-18 00:00:00 | Khoo | 30 | 2005-12-24 00:00:00
2002-12-07 00:00:00 | Raphaely | 30 | 2007-08-10 00:00:00
2005-07-24 00:00:00 | Tobias | 30 | 2006-11-15 00:00:00
| yq1 | 30 | 2003-05-18 00:00:00
| yq2 | 30 | 2002-12-07 00:00:00
2007-12-10 00:00:00 | yq3 | 30 | 2005-07-24 00:00:00
(13 rows)
```

- LEAD(value any [, offset integer [, default any ]])

Description: The LEAD function is used for generating leading values for the corresponding values in each group. That is, the value of the row obtained by moving backward the row corresponding to the current value by **offset** (integer) is the sequence number. If the row after the moving exceeds the total number of rows for the current group, the result value is the default value. If omitted, **offset** defaults to **1** and **default** to **NULL**. The type of the **default** value must be the same as that of the **value** value.

Return type: same as the parameter type

Example:

```
-- Create a table and insert data into the table.
gaussdb=# CREATE TABLE ta1 (hire_date date, last_name varchar(20), department_id int);
CREATE TABLE
gaussdb=# INSERT INTO ta1 values('07-DEC-02', 'Raphaely', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-JUL-05', 'Tobias', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('24-DEC-05', 'Baida', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('18-MAY-03', 'Khoo', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('15-NOV-06', 'Himuro', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-AUG-07', 'Colmenares', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-07', 'yq', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-MAY-08', 'zi', 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('', 'yq1', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, 'yq2', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values('10-DEC-07', 'yq3', 30);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1
gaussdb=# INSERT INTO ta1 values(null, null, 11);
INSERT 0 1

-- Call LEAD and set offset to 2.
gaussdb=# SELECT hire_date, last_name, department_id, lead(hire_date, 2) OVER (PARTITION BY
department_id ORDER BY last_name) AS "NextHired" FROM ta1 ORDER BY department_id;
  hire_date   | last_name | department_id | NextHired
-----+-----+-----+-----
2007-05-10 00:00:00 | yq       |          11 |
2008-05-10 00:00:00 | zi       |          11 |
                |          |          11 |
                |          |          11 |
2005-12-24 00:00:00 | Baida    |          30 | 2006-11-15 00:00:00
2007-08-10 00:00:00 | Colmenares |          30 | 2003-05-18 00:00:00
2006-11-15 00:00:00 | Himuro   |          30 | 2002-12-07 00:00:00
2003-05-18 00:00:00 | Khoo     |          30 | 2005-07-24 00:00:00
2002-12-07 00:00:00 | Raphaely |          30 |
2005-07-24 00:00:00 | Tobias    |          30 |
                | yq1      |          30 | 2007-12-10 00:00:00
                | yq2      |          30 |
2007-12-10 00:00:00 | yq3      |          30 |
(13 rows)
```

- **FIRST\_VALUE(value any)**

Description: Returns the first value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE first_value_t1(a int, b int);
gaussdb=# INSERT INTO first_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
gaussdb=# SELECT a,b,FIRST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM first_value_t1;
 a | b | first_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
1 | 3 |          1
2 | 4 |          4
2 | 5 |          4
3 | 6 |          6
```

(7 rows)

```
gaussdb=# DROP TABLE first_value_t1;
```

- **LAST\_VALUE**(value any)

Description: Returns the last value of each group.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE last_value_t1(a int, b int);
```

```
gaussdb=# INSERT INTO last_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,LAST_VALUE(b) OVER(PARTITION BY a ORDER BY b) FROM last_value_t1;
```

```
a | b | last_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          2
1 | 3 |          3
2 | 4 |          4
2 | 5 |          5
3 | 6 |          6
(7 rows)
```

```
gaussdb=# DROP TABLE last_value_t1;
```

- **DELTA**

Description: Returns the difference between the current row and the previous row.

Parameter: numeric

Return type: numeric

- **NTH\_VALUE**(value any, nth integer)

Description: The *n*th row for a group is the returned value. If the row does not exist, **NULL** is returned by default.

Return type: same as the parameter type

Example:

```
gaussdb=# CREATE TABLE nth_value_t1(a int, b int);
```

```
gaussdb=# INSERT INTO nth_value_t1 VALUES(1,1),(1,1),(1, 2),(1, 3),(2, 4),(2, 5),(3,6);
```

```
gaussdb=# SELECT a,b,NTH_VALUE(b, 2) OVER(PARTITION BY a order by b) FROM nth_value_t1;
```

```
a | b | nth_value
---+---+-----
1 | 1 |          1
1 | 1 |          1
1 | 2 |          1
1 | 3 |          1
2 | 4 |          5
2 | 5 |          5
3 | 6 |          6
(7 rows)
```

```
gaussdb=# DROP TABLE nth_value_t1;
```

## 7.5.20 Security Functions

### Security Functions

- **gs\_encrypt\_aes128**(encryptstr,keyststr)

Description: Encrypts **encryptstr** strings using **keyst** as the encryption password and returns encrypted strings. The value of **keyst** ranges from 8 to 16 bytes and contains at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters.

Return type: text

Length of the return value: At least 92 bytes and no more than  $(4 * [Len / 3] + 68)$  bytes, where *Len* indicates the length of the data before encryption (unit: byte).

Example:

```
gaussdb=# SELECT gs_encrypt_aes128('MPPDB','Asdf1234');
          gs_encrypt_aes128
-----
jRLOH2cqywwbAeiQQ9KuuJGhJVGfp317wsdKbUC+AcWX7NLZAUPmITDJhuu/
6164qOrLA8uvCRA60QNX6MF3yOPViWc=
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the **gsq** tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsq** by paging up and down.

- **gs\_encrypt(encryptstr,keyst, encrypttype)**

Description: Encrypts **encryptstr** strings using **keyst** as the encryption password and returns encrypted strings based on **encrypttype**. The value of **keyst** contains 8 to 16 bytes and at least three types of the following characters: uppercase letters, lowercase letters, digits, and special characters. The value of **encrypttype** can be **aes128** or **sm4**.

Return type: text

Example:

```
gaussdb=# SELECT gs_encrypt('MPPDB','Asdf1234','sm4');
          gs_encrypt
-----
ZBzOmaGA4Bb+coyucJ0B8AkIShq
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the **gsq** tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in **gsq** by paging up and down.

- **gs\_decrypt\_aes128(decryptstr,keyst)**

Description: Decrypts **decrypt** strings using **keyst** as the decryption password and returns decrypted strings. The **keyst** used for decryption must be consistent with that used for encryption. **keyst** cannot be empty.

 **NOTE**

This parameter needs to be used with the **gs\_encrypt\_aes128** encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt_aes128('jRLOH2cqywwbAeiQQ9KuuJGhJVGfp317wsdKbUC
+AcWX7NLZAUPmITDJhuu/6164qOrLA8uvCRA60QNX6MF3yOPViWc=','Asdf1234');
          gs_decrypt_aes128
```

```
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- `gs_decrypt(decryptstr,keystr,decrypttype)`

Description: Decrypts **decrypt** strings using **keystr** as the decryption password and returns decrypted strings based on **decrypttype**. The **decrypttype** and **keystr** used for decryption must be consistent with **encrypttype** and **keystr** used for encryption. **keystr** cannot be empty. The value of **decrypttype** can be **aes128** or **sm4**.

This function needs to be used with the `gs_encrypt` encryption function.

Return type: text

Example:

```
gaussdb=# SELECT gs_decrypt('ZBzOmaGA4Bb+coyucJ0B8AklShqc','Asdf1234','sm4');
gs_decrypt
-----
MPPDB
(1 row)
```

 **NOTE**

A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.

- `aes_encrypt(str, key_str, init_vector)`

Description: Encrypts the string **str** using the key string **key\_str** and initialization vector **init\_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **str**: character string to be encrypted. If **str** is set to **NULL**, the function returns **NULL**.
- **key\_str**: key character string. If **key\_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block\_encryption\_mode**).
- **init\_vector**: An initialization variable is provided for the required block encryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **str** nor **key\_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456');
aes_encrypt
```

```
-----  
u*8\x05c?0  
(1 row)
```

**NOTE**

- This function is valid only when GaussDB is compatible with the MY type (that is, **sql\_compatibility** is set to 'B').
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug\_print\_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug\_print\_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- The SQL\_ASCII setting performs quite differently from other settings. If the character set of the server is SQL\_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL\_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL\_ASCII, the encoding of the client must also be set to SQL\_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- **aes\_decrypt**(pass\_str, key\_str, init\_vector)

Description: Decrypts the string **str** using the key string **key\_str** and initialization vector **init\_vector** based on the AES algorithm.

Parameters in the command above are as follows:

- **pass\_str**: character string to be decrypted. If **pass\_str** is set to **NULL**, the function returns **NULL**.
- **key\_str**: key character string. If **key\_str** is set to **NULL**, the function returns **NULL**. For security purposes, you are advised to use a 128-bit, 192-bit, or 256-bit secure random number as the key character string if the key length is 128 bits, 192 bits, or 256 bits (determined by the value of **block\_encryption\_mode**).
- **init\_vector**: An initialization variable is provided for the required block decryption mode. The length is greater than or equal to 16 bytes. Bytes greater than 16 bytes are automatically ignored. If neither **pass\_str** nor **key\_str** is **NULL**, this parameter cannot be **NULL**. Otherwise, an error is reported. For security purposes, you are advised to ensure that the IV value for each encryption is unique in OFB mode and that the IV value for each encryption is unpredictable in CBC or CFB mode.

Return type: text

Example:

```
gaussdb=# SELECT  
aes_decrypt(aes_encrypt('huwei123','123456vfhex4dyu,vdaladhjsadad','1234567890123456'),'123456vf  
hex4dyu,vdaladhjsadad','1234567890123456');  
aes_decrypt
```

```
-----  
huwei123  
(1 row)
```

 **NOTE**

- This function is valid only when GaussDB is compatible with the MY type (that is, **sql\_compatibility** is set to 'B').
- A decryption password is required during the execution of this function. For security purposes, the gsql tool does not record the SQL statements containing the function name in the execution history. That is, the execution history of this function cannot be found in gsql by paging up and down.
- Do not call this function during operations related to stored procedures, preventing the risk of sensitive information disclosure. In addition, when using the stored procedure that contains the function, you are advised to filter the parameter information of the function before providing the information for external maintenance personnel to locate the fault. Delete the logs after using them.
- Do not call the function when **debug\_print\_plan** is set to **on**, preventing the risk of sensitive information disclosure. You are advised to filter parameter information of the function in the log files generated when **debug\_print\_plan** is set to **on** before providing the log files to external maintenance engineers for fault locating. After you finish using the logs, delete them as soon as possible.
- To ensure successful decryption, ensure that the values of **block\_encryption\_mode**, **key\_str** and IV are the same as those during encryption.
- Due to encoding differences, encrypted data cannot be directly copied from the gsql client for decryption. In this scenario, the decryption result may not be the character string before encryption.
- The SQL\_ASCII setting performs quite differently from other settings. If the character set of the server is SQL\_ASCII, the server interprets the byte values 0 to 127 according to the ASCII standard. The byte values 128 to 255 are regarded as the characters that cannot be parsed. If this parameter is set to SQL\_ASCII, no code conversion occurs. When this function calls the third-party OpenSSL library, the returned data is non-ASCII data. Therefore, when the character set of the database server is set to SQL\_ASCII, the encoding of the client must also be set to SQL\_ASCII. Otherwise, an error is reported. The database does not convert or verify non-ASCII characters.

- **gs\_digest(input\_string, hash\_algorithm)**

Description: Hashes the input string using the specified hash algorithm and returns a hexadecimal number.

Parameters in the command above are as follows:

- **input\_string**: character string to be hashed. The value cannot be **NULL**.
- **hash\_algorithm**: specifies the hash algorithm. Currently, SHA-256, SHA-384, SHA-512, and SM3 are supported. Both uppercase and lowercase letters are supported. If an unsupported hash algorithm is used, an error is reported.

Return type: text

Example:

```
gaussdb=# SELECT pg_catalog.gs_digest('gaussdb', 'sha256');  
          gs_digest  
-----  
4dc50d746f4e04f9b446986b34a0050e358fbfb8bc1fba314c54b52a417b0b8e  
(1 row)
```

- **gs\_password\_deadline**

Description: Indicates the number of remaining days before the password of the current user expires.

Return type: interval

Example:

```
gaussdb=# SELECT gs_password_deadline();
gs_password_deadline
-----
83 days 17:44:32.196094
(1 row)
```

- `gs_password_notifytime()`

Description: Specifies the number of days prior to password expiration that a user will receive a reminder.

Return type: int32

- `login_audit_messages(BOOLEAN)`

Description: Queries login information about a login user.

Return type: tuple

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(true);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | testdb  | 2020-06-29 21:56:40+08 | login_success | ok    | gsql@[local]
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages(false);
username | database | logintime      | mytype | result | client_conninfo
-----+-----+-----+-----+-----+-----
omm      | testdb  | 2020-06-29 21:57:55+08 | login_failed | failed | [unknown]@[local]
omm      | testdb  | 2020-06-29 21:57:53+08 | login_failed | failed | [unknown]@[local]
(2 rows)
```

- `login_audit_messages_pid`

Description: Queries login information about a login user. Different from **login\_audit\_messages**, this function queries login information based on **backendid**. Information about subsequent logins of the same user does not alter the query result of previous logins and cannot be found using this function.

Return type: tuple

 **NOTE**

When the thread pool is enabled, the **backendid** obtained in the same session may change due to thread switchover. As a result, the return values are different when the function is called for multiple times. You are advised not to call this function when the thread pool is enabled.

Example:

- Check the date, time, and IP address of the last successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(true);
username | database | logintime      | mytype | result | client_conninfo | backendid
-----+-----+-----+-----+-----+-----+-----
omm      | testdb  | 2020-06-29 21:56:40+08 | login_success | ok    | gsql@[local]   | 139823109633792
(1 row)
```

- Check the number, date, and time of failed attempts since the previous successful login.

```
gaussdb=> SELECT * FROM login_audit_messages_pid(false);
username | database | logintime      | mytype | result | client_conninfo | backendid
```

Name	Type	Description
database	text	Database name
client_conninfo	text	Client connection information
object_name	text	Object name
detail_info	text	Operation details
node_name	text	Node name
thread_id	text	Thread ID
local_port	text	Local port
remote_port	text	Remote port

- pg\_delete\_audit**  
Description: Deletes audit logs in a specified period.  
Return type: void
- alldigitsmasking**  
Description: Specifies the internal function of the masking policy, which is used to anonymize all characters.  
Parameter: col text, letter character default '0'  
Return type: text
- creditcardmasking**  
Description: Specifies the internal function of the masking policy, which is used to anonymize all credit card information.  
Parameter: col text, letter character default 'x'  
Return type: text
- randommasking**  
Description: Specifies the internal function of the masking policy. The random policy is used.  
Parameter: col text  
Return type: text
- fullemailmasking**  
Description: Specifies the internal function of the masking policy, which is used to anonymize the text (except @) before the last period (.).  
Parameter: col text, letter character default 'x'  
Return type: text
- basicemailmasking**  
Description: Specifies the internal function of the masking policy, which is used to anonymize the text before the first at sign (@).  
Parameter: col text, letter character default 'x'  
Return type: text

- shufflemasking  
Description: Specifies the internal function of the masking policy, which is used to sort characters out of order.  
Parameter: col text  
Return type: text

## 7.5.21 Encrypted Functions and Operators

- byteawithoutorderwithequalcolin(cstring)  
Description: Converts input data to the internal byteawithoutorderwithequalcol format.  
Parameter type: cstring  
Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcolout(byteawithoutorderwithequalcol)  
Description: Converts internal data of the byteawithoutorderwithequalcol type to data of the cstring type.  
Parameter type: byteawithoutorderwithequalcol  
Return type: cstring
- byteawithoutorderwithequalcolsend(byteawithoutorderwithequalcol)  
Description: Converts data of the byteawithoutorderwithequalcol type to data of the bytea type.  
Parameter type: byteawithoutorderwithequalcol  
Return type: bytea
- byteawithoutorderwithequalcolrecv(internal)  
Description: Converts data of the internal type to data of the byteawithoutorderwithequalcol type.  
Parameter type: internal  
Return type: byteawithoutorderwithequalcol
- byteawithoutorderwithequalcoltypmodin(cstring[])  
Description: Converts data of the cstring[] type to data of the byteawithoutorderwithequalcol type.  
Parameter type: cstring[]  
Return type: int4
- byteawithoutorderwithequalcoltypmodout(int4)  
Description: Converts data of the int4 type into data of the cstring type.  
Parameter type: int4  
Return type: cstring
- byteawithoutordercolin(cstring)  
Description: Converts input data to the internal byteawithoutordercolin format.  
Parameter type: cstring  
Return type: byteawithoutordercol
- byteawithoutordercolout(byteawithoutordercol)

Description: Converts internal data of the `byteawithoutordercol` type to data of the `cstring` type.

Parameter type: `byteawithoutordercol`

Return type: `cstring`

- `byteawithoutordercolsend(byteawithoutordercol)`

Description: Converts data of the `byteawithoutordercol` type to data of the `bytea` type.

Parameter type: `byteawithoutordercol`

Return type: `bytea`

- `byteawithoutordercolrecv(internal)`

Description: Converts data of the internal type to data of the `byteawithoutordercol` type.

Parameter type: `internal`

Return type: `byteawithoutordercol`

- `byteawithoutorderwithequalcolcmp(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `byteawithoutorderwithequalcol` or `bytea`

Return type: `int4`

- `byteawithoutorderwithequalcolcmpbyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data sizes. If the first data size is smaller than the second one, **-1** is returned. If the first data size is equal to the second one, **0** is returned. If the first data size is larger than the second one, **1** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: `int4`

- `byteawithoutorderwithequalcoleq(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`

- Return type: Boolean

  - `byteawithoutorderwithequalcoleqbyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: Boolean
  - `byteawithoutorderwithequalcoleqbytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `bytea`

Return type: Boolean
  - `byteawithoutorderwithequalcolne(byteawithoutorderwithequalcol, byteawithoutorderwithequalcol)`

Description: Compares two `byteawithoutorderwithequalcol` data records. If they are different, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `byteawithoutorderwithequalcol`

Return type: Boolean
  - `byteawithoutorderwithequalcolnebyteal(bytea, byteawithoutorderwithequalcol)`

Description: Compares the `bytea` and `byteawithoutorderwithequalcol` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `bytea`, `byteawithoutorderwithequalcol`

Return type: Boolean
  - `byteawithoutorderwithequalcolnebytear(byteawithoutorderwithequalcol, bytea)`

Description: Compares the `byteawithoutorderwithequalcol` and `bytea` data records. If they are the same, **true** is returned. Otherwise, **false** is returned.

Parameter type: `byteawithoutorderwithequalcol`, `bytea`

Return type: Boolean
  - `hll_hash_byteawithoutorderwithequalcol(byteawithoutorderwithequalcol)`

Description: Returns the hll hash value of `byteawithoutorderwithequalcol`.

Parameter type: `byteawithoutorderwithequalcol`

Return type: `hll_hashval`

## Examples

Encrypted equality functions such as `byteawithoutorderwithequalcolin` and `byteawithoutorderwithequalcolout` are read/write format conversion functions such as `in`, `out`, `send`, and `recv` specified by the data type `byteawithoutorderwithequalcol` in the database kernel. For details, see the `byteain` and `byteaout` functions of the `bytea` type. However, the local CEK is verified, and the function can be successfully executed only when the encrypted column contains `cekoid` that exists on the local host.

```
-- For example, if the int_type encrypted table exists, int_col2 is the encrypted column.

-- Use a non-encrypted client to connect to the database and query the ciphertext of the encrypted column.
gaussdb=# SELECT int_col2 FROM int_type;
           int_col2
-----
\01c35301bf421c8edf38c34704bcc82838742917778ccb402a1b7452ad4a6ac7371acc0ac33100000035fe3424
919854c86194f1aa5bb4e1ca656e8fc6d05324a1419b69f488bdc3c6
(1 row)

-- The ciphertext of the encrypted column is used as the input parameter of
byteawithoutorderwithequalcolin. The format is converted from cstring to byteawithoutorderwithequalcol.
gaussdb=# SELECT
byteawithoutorderwithequalcolin('\01c35301bf421c8edf38c34704bcc82838742917778ccb402a1b7452ad4a
6ac7371acc0ac33100000035fe3424919854c86194f1aa5bb4e1ca656e8fc6d05324a1419b69f488bdc3c6');
           byteawithoutorderwithequalcolin
-----
\01c35301bf421c8edf38c34704bcc82838742917778ccb402a1b7452ad4a6ac7371acc0ac33100000035fe3424
919854c86194f1aa5bb4e1ca656e8fc6d05324a1419b69f488bdc3c6
(1 row)
```

Implementations such as `byteawithoutorderwithequalcolin` search for CEK and determine whether it is a normal encrypted data type.

Therefore, if the format of the data entered by the user is not the encrypted data format and the corresponding CEK does not exist on the local host, an error is returned.

```
gaussdb=# SELECT * FROM
byteawithoutorderwithequalcolsend('\x907219912381298461289346129':byteawithoutorderwithequalcol);
ERROR: cek with OID 596711794 not found

## 7.5.22 Set Returning Functions

### Series Generating Functions

- `generate_series(start, stop)`

Description: Generates a series of values, from **start** to **stop** with a step size of one.

Parameter type: int, bigint, numeric

Return type: setof int, setof bigint, setof numeric (same as the parameter type)

- `generate_series(start, stop, step)`  
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.  
Parameter type: int, bigint, numeric  
Return type: setof int, setof bigint, setof numeric (same as the parameter type)
- `generate_series(start, stop, step interval)`  
Description: Generates a series of values, from **start** to **stop** with a step size of **step**.  
Parameter type: timestamp or timestamp with time zone  
Return type: setof timestamp or setof timestamp with time zone (same as parameter type)

When **step** is positive, zero rows are returned if **start** is greater than **stop**. Conversely, when **step** is negative, zero rows are returned if **start** is less than **stop**. Zero rows are also returned for **NULL** inputs. It is an error for **step** to be zero.

Example:

```
gaussdb=# SELECT * FROM generate_series(2,4);
generate_series
-----
         2
         3
         4
(3 rows)

gaussdb=# SELECT * FROM generate_series(5,1,-2);
generate_series
-----
         5
         3
         1
(3 rows)

gaussdb=# SELECT * FROM generate_series(4,3);
generate_series
-----
(0 rows)

-- This example applies to the date-plus-integer operator.
gaussdb=# SELECT current_date + s.a AS dates FROM generate_series(0,14,7) AS s(a);
dates
-----
2017-06-02
2017-06-09
2017-06-16
(3 rows)

gaussdb=# SELECT * FROM generate_series('2008-03-01 00:00'::timestamp, '2008-03-04 12:00', '10 hours');
generate_series
-----
2008-03-01 00:00:00
2008-03-01 10:00:00
2008-03-01 20:00:00
2008-03-02 06:00:00
2008-03-02 16:00:00
2008-03-03 02:00:00
2008-03-03 12:00:00
2008-03-03 22:00:00
2008-03-04 08:00:00
(9 rows)
```

## Subscript Generating Functions

- `generate_subscripts(array anyarray, dim int)`  
Description: Generates a series comprising the given array's subscripts.  
Return type: setof int
- `generate_subscripts(array anyarray, dim int, reverse boolean)`  
Description: Generates a series comprising the given array's subscripts. When **reverse** is true, the series is returned in reverse order.  
Return type: setof int

**generate\_subscripts** is a function that generates the set of valid subscripts for the specified dimension of the given array. Zero rows are returned for arrays that do not have the requested dimension, or for NULL arrays (but valid subscripts are returned for NULL array elements). Example:

```
-- Basic usage
gaussdb=# SELECT generate_subscripts('{NULL,1,NULL,2}'::int[], 1) AS s;
s
-----
1
2
3
4
(4 rows)
-- Unnest a 2D array:
gaussdb=# CREATE OR REPLACE FUNCTION unnest2(anyarray)
RETURNS SETOF anyelement AS $$
SELECT $1[i][j]
FROM generate_subscripts($1,1) g1(i),
generate_subscripts($1,2) g2(j);
$$ LANGUAGE sql IMMUTABLE;

gaussdb=# SELECT * FROM unnest2(ARRAY[[1,2],[3,4]]);
unnest2
-----
1
2
3
4
(4 rows)

-- Delete the function.
gaussdb=# DROP FUNCTION unnest2;
```

## 7.5.23 Conditional Expression Functions

### Conditional Expression Functions

- `coalesce(expr1, expr2, ..., exprn)`  
Description:  
Returns the first of its arguments that are not null.  
**COALESCE(expr1, expr2)** is equivalent to **CASE WHEN expr1 IS NOT NULL THEN expr1 ELSE expr2 END**.  
Example:

```
gaussdb=# SELECT coalesce(NULL,'hello');
coalesce
-----
hello
(1 row)
```

Note:

- Null is returned only if all parameters are null.
- This value is replaced by the default value when data is displayed.
- Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-**NULL** parameter are not evaluated.

- decode(base\_expr, compare1, value1, Compare2,value2, ... default)

Description: Compares **base\_expr** with each **compare(n)** and **returns value(n)** if they are matched. If **base\_expr** does not match each **compare(n)**, the default value is returned.

Example:

```
gaussdb=# SELECT decode('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

Note:

- Operations on the XML data are not supported.

- nullif(expr1, expr2)

Description: Returns **NULL** only when **expr1** is equal to **expr2**. Otherwise, **expr1** is returned.

**nullif(expr1, expr2)** is equivalent to **CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END**.

Example:

```
gaussdb=# SELECT nullif('hello','world');
nullif
-----
hello
(1 row)
```

Note:

- Operations on the XML data are not supported.
- Assume the two parameter data types are different:
  - If implicit conversion exists between the two data types, implicitly convert the parameter of lower priority to this data type using the data type of higher priority. If the conversion succeeds, computation is performed. Otherwise, an error is reported. Example:
 

```
gaussdb=# SELECT nullif('1234'::VARCHAR,123::INT4);
nullif
-----
1234
(1 row)
gaussdb=# SELECT nullif('1234'::VARCHAR,'2012-12-24'::DATE);
ERROR: invalid input syntax for type timestamp: "1234"
```
  - If implicit conversion is not applied between two data types, an error is displayed. Example:
 

```
gaussdb=# SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE);
ERROR: operator does not exist: boolean = timestamp without time zone
LINE 1: SELECT nullif(TRUE::BOOLEAN,'2012-12-24'::DATE) FROM sys_dummy;
^
HINT: No operator matches the given name and argument type(s). You might need to add explicit type casts.
```

- `nvl( expr1 , expr2 )`

Description:

- If the value of **expr1** is **NULL**, the value of **expr2** is returned.
- If the value of **expr1** is not **NULL**, the value of **expr1** is returned.

Example:

```
gaussdb=# SELECT nvl('hello','world');
nvl
-----
hello
(1 row)
```

Note: Parameters **expr1** and **expr2** can be of any data type. If **expr1** and **expr2** are of different data types, NVL checks whether **expr2** can be implicitly converted to **expr1**. If it can, the data type of **expr1** is returned. Otherwise, an error is returned.

- `nvl2(expr1, expr2, expr3)`

Description:

- If *expr1* is **NULL**, *expr3* is returned.
- If *expr1* is not **NULL**, *expr2* is returned.

 **NOTE**

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

Example:

```
gaussdb=# SELECT nvl2('hello','world','other');
case
-----
world
(1 row)
```

Note: The *expr2* and *expr3* parameters can be of any type. If the last two parameters of NVL2 are of different types, check whether *expr3* can be implicitly converted to *expr2*. If *expr3* cannot be implicitly converted to *expr2*, an error is returned. If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- `greatest(expr1 [, ...])`

Description: Selects the largest value from a list of any number of expressions.

Return type:

Example:

```
gaussdb=# SELECT greatest(1*2,2-3,4-1);
greatest
-----
3
(1 row)
gaussdb=# SELECT greatest('HARRY', 'HARRIOT', 'HAROLD');
greatest
-----
HARRY
(1 row)
```

Note:

Operations on the XML data are not supported.

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**:

- If the value of any parameter is null, the function returns null.
  - If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.
- **least(expr1 [, ...])**

Description: Selects the smallest value from a list of any number of expressions.

Example:

```
gaussdb=# SELECT least(1*2,2-3,4-1);
least
-----
-1
(1 row)
gaussdb=# SELECT least('HARRY','HARRIOT','HAROLD');
least
-----
HAROLD
(1 row)
```

Note:

Operations on the XML data are not supported.

 **NOTE**

When **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**:

- If the value of any parameter is null, the function returns null.
- If the first parameter is of the numeric type, the function converts this parameter and other parameters to the numeric type, and then compares them. If the parameters cannot be converted, an error message is displayed. If the first parameter is of another type, the function converts other parameters to the type of the first parameter for comparison. If the parameters cannot be converted, an error message is displayed.

- **EMPTY\_BLOB()**

Description: Initiates a BLOB variable in an **INSERT** or an **UPDATE** statement to a **NULL** value.

Return type: BLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE blob_tb(b blob,id int);
-- Insert data.
gaussdb=# INSERT INTO blob_tb VALUES (empty_blob(),1);
-- Drop the table.
gaussdb=# DROP TABLE blob_tb;
```

Note: The length is 0 obtained using **DBE\_LOB.GET\_LENGTH**.

- **EMPTY\_CLOB()**

Description: Initiates a CLOB variable in an **INSERT** or **UPDATE** statement to a null value.

 NOTE

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s1**.

Return type: CLOB

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE clob_tb(c clob,id int);
-- Insert data.
gaussdb=# INSERT INTO clob_tb VALUES (empty_clob(),1);
-- Drop the table.
gaussdb=# DROP TABLE clob_tb;
```

Note: The length is 0 obtained using **DBE\_LOB.GET\_LENGTH**.

- **lnvl(condition)**

Description: Checks the condition in the WHERE clause of a query statement. If the condition is true, **false** is returned. If the condition is unknown or false, **true** is returned.

**condition:** The value must be a logical expression but cannot be used in composite conditions with keywords such as AND, OR, and BETWEEN.

Return type: Boolean

Example:

```
-- Create a table.
gaussdb=# CREATE TABLE student_demo (name VARCHAR2(20), grade NUMBER(10,2));
CREATE TABLE

-- Insert data.
gaussdb=# INSERT INTO student_demo VALUES ('name0',0);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name1',1);
INSERT 0 1
gaussdb=# INSERT INTO student_demo VALUES ('name2',2);
INSERT 0 1

-- Invoke lnvl.
gaussdb=# SELECT * FROM student_demo WHERE LNNVL(name = 'name1');
 name | grade
-----+-----
name0 |  0.00
name2 |  2.00
(2 rows)
```

 NOTE

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

## 7.5.24 System Information Functions

### Session Information Functions

- **SYS\_CONTEXT()**

Description: Returns the value of the parameter associated with the context namespace at the current time.

Return type: text

Example:

```
select SYS_CONTEXT('userenv','NLS_CURRENCY');
sys_context
```

```
-----  
$  
(1 row)  
  
select SYS_CONTEXT('userenv','NLS_DATE_FORMAT');  
sys_context  
-----  
ISO, MDY  
(1 row)  
  
select SYS_CONTEXT('userenv','NLS_DATE_LANGUAGE');  
sys_context  
-----  
en_US.UTF-8  
(1 row)
```

- **current\_catalog**

Description: Name of the current database (called "catalog" in the SQL standard)

Return type: name

Example:

```
testdb=# SELECT current_catalog;  
current_database  
-----  
testdb  
(1 row)
```

- **current\_database()**

Description: Name of the current database

Return type: name

Example:

```
testdb=# SELECT current_database();  
current_database  
-----  
testdb  
(1 row)
```

- **current\_query()**

Description: Text of the currently executing query committed by the client (which might contain more than one statement)

Return type: text

Example:

```
gaussdb=# SELECT current_query();  
current_query  
-----  
SELECT current_query();  
(1 row)
```

- **current\_schema[()]**

Description: Name of the current schema

Return type: name

Example:

```
gaussdb=# SELECT current_schema();  
current_schema  
-----  
public  
(1 row)
```

Note: **current\_schema** returns the first valid schema name in the search path. (If the search path is empty or contains no valid schema name, **NULL** is

returned.) This is the schema that will be used for any tables or other named objects that are created without specifying a target schema.

- `current_schemas(Boolean)`

Description: Name of a schema in the search path

Return type: `name[]`

Example:

```
gaussdb=# SELECT current_schemas(true);
current_schemas
-----
{pg_catalog,public}
(1 row)
```

Note:

**`current_schemas(Boolean)`** returns an array of the names of all schemas presently in the search path. The Boolean option specifies whether implicitly included system schemas such as **`pg_catalog`** are included in the returned search path.

#### NOTE

The search path can be altered at the run time. The command is as follows:

```
SET search_path TO schema [, schema, ...]
```

- `current_user`

Description: Username of current execution context

Return type: `name`

Example:

```
gaussdb=# SELECT current_user;
current_user
-----
omm
(1 row)
```

Note: **`current_user`** is the user identifier used for permission check. Normally it is equal to the session user, but it can be changed by using **`SET ROLE`**. It also changes during the execution of functions with the **`SECURITY DEFINER`** attribute.

- `definer_current_user`

Description: Username in the current execution environment

Return type: `name`

Example:

```
gaussdb=# SELECT definer_current_user();
definer_current_user
-----
omm
(1 row)
```

- `pg_current_sessionid()`

Description: Session ID of the current execution context

Return type: `text`

Example:

```
gaussdb=# SELECT pg_current_sessionid();
pg_current_sessionid
-----
1579228402.140190434944768
(1 row)
```

Note: **pg\_current\_sessionid()** is used to obtain the session ID in the current execution environment. The structure of the value is *Timestamp. Session ID*. When **enable\_thread\_pool** is set to **off**, the actual session ID is the thread ID.

- **pg\_current\_sessid**

Description: Session ID in the current execution environment

Return type: text

Example:

```
gaussdb=# select pg_current_sessid();
pg_current_sessid
-----
140308875015936
(1 row)
```

Note: In thread pool mode, the session ID of the current session is obtained. In non-thread pool mode, the backend thread ID of the current session is obtained.

- **pg\_current\_userid**

Description: Current user ID

Return type: text

```
gaussdb=# SELECT pg_current_userid();
pg_current_userid
-----
10
(1 row)
```

- **working\_version\_num()**

Description: version number. It returns a version number related to system compatibility.

Return type: int

Example:

```
gaussdb=# SELECT working_version_num();
working_version_num
-----
92231
(1 row)
```

- **tablespace\_oid\_name()**

Description: Queries the tablespace name based on the tablespace OID.

Return type: text

Example:

```
gaussdb=# select tablespace_oid_name(1663);
tablespace_oid_name
-----
pg_default
(1 row)
```

- **inet\_client\_addr()**

Description: Remote connection address. **inet\_client\_addr** returns the IP address of the current client.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_client_addr();
inet_client_addr
-----
10.10.0.50
(1 row)
```

- `inet_client_port()`

Description: Remote connection port. **inet\_client\_port** returns the port number of the current client.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_client_port();
inet_client_port
-----
33143
(1 row)
```

- `inet_server_addr()`

Description: Local connection address. **inet\_server\_addr** returns the IP address on which the server accepts the current connection.

 **NOTE**

It is available only in remote connection mode.

Return type: inet

Example:

```
gaussdb=# SELECT inet_server_addr();
inet_server_addr
-----
10.10.0.13
(1 row)
```

- `inet_server_port()`

Description: Local connection port. **inet\_server\_port** returns the number of the port receiving the current connection. All these functions return **NULL** if the current connection is via a Unix-domain socket.

 **NOTE**

This function is valid only in remote connection mode.

Return type: int

Example:

```
gaussdb=# SELECT inet_server_port();
inet_server_port
-----
8000
(1 row)
```

- `pg_backend_pid()`

Description: Process ID of the service process attached to the current session.

Return type: int

Example:

```
gaussdb=# SELECT pg_backend_pid();
pg_backend_pid
-----
```

```
140229352617744
(1 row)
```

- `pg_conf_load_time()`

Description: Configures load time. **pg\_conf\_load\_time** returns the timestamp when the server configuration files were last loaded.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_conf_load_time();
 pg_conf_load_time
-----
2017-09-01 16:05:23.89868+08
(1 row)
```

- `pg_my_temp_schema()`

Description: OID of the temporary schema of a session. The value is **0** if the OID does not exist.

Return type: oid

Example:

```
gaussdb=# SELECT pg_my_temp_schema();
 pg_my_temp_schema
-----
0
(1 row)
```

Note: **pg\_my\_temp\_schema** returns the OID of the current session's temporary schema, or **0** if it has no temporary schemas (because no temporary tables are created). **pg\_is\_other\_temp\_schema** returns **true** if the given OID is the OID of another session's temporary schema.

- `pg_is_other_temp_schema(oid)`

Description: Specifies whether the schema is the temporary schema of another session.

Return type: Boolean

Example:

```
gaussdb=# SELECT pg_is_other_temp_schema(25356);
 pg_is_other_temp_schema
-----
f
(1 row)
```

- `pg_listening_channels()`

Description: Name of the channel that the session is currently listening to.

Return type: setof text

Example:

```
gaussdb=# SELECT pg_listening_channels();
 pg_listening_channels
-----
(0 rows)
```

Note: **pg\_listening\_channels** returns a set of names of channels that the current session is currently listening to.

- `pg_postmaster_start_time()`

Description: Server start time. **pg\_postmaster\_start\_time** returns the **timestamp with time zone** when the server is started.

Return type: timestamp with time zone

Example:

```
gaussdb=# SELECT pg_postmaster_start_time();
 pg_postmaster_start_time
-----
2017-08-30 16:02:54.99854+08
(1 row)
```

- `pg_get_ruledef(rule_oid)`

Description: Obtains the **CREATE RULE** command for a rule.

Return type: text

Example:

```
gaussdb=# select * from pg_get_ruledef(24828);
 pg_get_ruledef
-----
CREATE RULE t1_ins AS ON INSERT TO t1 DO INSTEAD INSERT INTO t2 (id) VALUES (new.id);
(1 row)
```

- `sessionid2pid()`

Description: Obtains PID information from a session ID (for example, the **sessid** column in **gs\_session\_stat**).

Return type: int8

Example:

```
gaussdb=# select sessionid2pid(sessid::cstring) from gs_session_stat limit 2;
 sessionid2pid
-----
139973107902208
139973107902208
(2 rows)
```

- `session_context('namespace', 'parameter')`

Description: Obtains and returns the parameter values of a specified namespace.

Return type: VARCHAR

Example:

```
gaussdb=# SELECT session_context('USERENV', 'CURRENT_SCHEMA');
 session_context
-----
public
(1 row)
```

Note: Currently, the **current\_user**, **current\_schema**, **client\_info**, **ip\_address**, **sessionid**, and **sid** parameters are supported.

- `pg_trigger_depth()`

Description: Nesting level of triggers.

Return type: int

Example:

```
gaussdb=# SELECT pg_trigger_depth();
 pg_trigger_depth
-----
0
(1 row)
```

- `session_user`

Description: Session username.

Return type: name

Example:

```
gaussdb=# SELECT session_user;
 session_user
-----
 omm
(1 row)
```

Note: **session\_user** usually specifies the initial user connected to the current database, but the system administrator can change this setting by using [SET SESSION AUTHORIZATION](#).

- user

Description: Equivalent to current\_user.

Return type: name

Example:

```
gaussdb=# SELECT user;
 current_user
-----
 omm
(1 row)
```

- getpgusername()

Description: Obtains the database username.

Return type: name

Example:

```
gaussdb=# select getpgusername();
 getpgusername
-----
 GaussDB_userna
(1 row)
```

- getdatabaseencoding()

Description: Obtains the database encoding mode.

Return type: name

Example:

```
gaussdb=# select getdatabaseencoding();
 getdatabaseencoding
-----
 SQL_ASCII
(1 row)
```

- version()

Description: version information. **version** returns a string describing a server's version.

Return type: text

Example:

```
gaussdb=# select version();
 version
-----
 gaussdb (GaussDB Kernel 503.1.XXX build fab4f5ea) compiled at 2021-10-24 11:58:22 commit 3086
last mr 6592 release
(1 row)
```

- .opengauss\_version()

Description: openGauss version information

Return type: text

The following is an example. Replace *x.x.x* in the query result with the actual value.

```
gaussdb=# select opengauss_version();
opengauss_version
-----
x.x.x
(1 row)
```

- `gs_deployment()`

Description: Information about the deployment mode of the current system

Return type: text

Example:

```
gaussdb=# select gs_deployment();
gs_deployment
-----
BusinessCentralized
(1 row)
```

- `get_hostname()`

Description: Returns the host name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_hostname();
get_hostname
-----
linux-user
(1 row)
```

- `get_nodename()`

Description: Returns the name of the current node.

Return type: text

Example:

```
gaussdb=# SELECT get_nodename();
get_nodename
-----
datanode1
(1 row)
```

- `get_schema_oid(cstring)`

Description: Returns the OID of the queried schema.

Return type: oid

Example:

```
gaussdb=# SELECT get_schema_oid('public');
get_schema_oid
-----
2200
(1 row)
```

- `get_client_info()`

Description: Returns client information.

Return type: record

## Access Permission Query Functions

The DDL permissions, including ALTER, DROP, COMMENT, INDEX, and VACUUM, are inherent permissions implicitly owned by the owner.

The following access permission query functions only specify whether a user has a certain permission on an object (that is, a permission on an object recorded in the **acl** column of a system catalog is returned):

- `has_any_column_privilege(user, table, privilege)`  
Description: Queries whether a specified user has permissions on any column of a table.

**Table 7-42** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
table	text, oid
privilege	text

Return type: Boolean

- `has_any_column_privilege(table, privilege)`  
Description: Queries whether the current user has the permission to access any column of a table. For details about the valid parameter types, see [Table 7-42](#).

Return type: Boolean

Note: **has\_any\_column\_privilege** checks whether a user can access any column of a table in a particular way. Its parameter possibilities are analogous to **has\_table\_privilege**, except that the desired access permission must be some combination of SELECT, INSERT, UPDATE, COMMENT or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table. Therefore, **has\_any\_column\_privilege** always returns **true** if **has\_table\_privilege** has the same parameters. A success message is also returned if a column-level permission is granted for at least one column.

- `has_column_privilege(user, table, column, privilege)`  
Description: Specifies whether a specified user has the permission to access columns.

**Table 7-43** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
table	text, oid
column	text, smallint
privilege	text

Return type: Boolean

- `has_column_privilege(table, column, privilege)`

Description: Specifies whether the current user has the permission to access columns. For details about the valid parameter types, see [Table 7-43](#).

Return type: Boolean

**has\_column\_privilege** checks whether a user can access a column in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. Columns can be added either by name or by attribute number. The desired access permission must be some combination of SELECT, INSERT, UPDATE, COMMENT or REFERENCES.

 **NOTE**

Note that having any of these permissions at the table level indicates that the permission is implicitly granted for each column of the table.

- `has_cek_privilege(user, cek, privilege)`

Description: Specifies whether a specified user has permissions on CEKs. The parameters are described as follows:

**Table 7-44** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cek	text, oid	CEK	Name or ID of a CEK
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: allows users to use the specified CEK.</li> <li>• <b>DROP</b>: allows users to delete the specified CEK.</li> </ul>

Return type: Boolean

- `has_cmk_privilege(user, cmk, privilege)`

Description: Specifies whether a specified user has permissions on CMKs. The parameters are described as follows:

**Table 7-45** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name, oid	Users	Username or ID
cmk	text, oid	CMK	Name or ID of the CMK

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	Permission	<ul style="list-style-type: none"> <li>• <b>USAGE</b>: allows users to use the specified CMK.</li> <li>• <b>DROP</b>: allows users to delete the specified CMK.</li> </ul>

Return type: Boolean

- `has_database_privilege(user, database, privilege)`

Description: Specifies whether a specified user has permissions on databases. The parameters are described as follows:

**Table 7-46** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
database	text, oid
privilege	text

Return type: Boolean

- `has_database_privilege(database, privilege)`

Description: Specifies whether the current user has permission to access a database. For details about the valid parameter types, see [Table 7-46](#).

Return type: Boolean

Note: **has\_database\_privilege** checks whether a user can access a database in a particular way. Its argument possibilities are analogous to **has\_table\_privilege**. The desired access permission must be some combination of CREATE, CONNECT, TEMPORARY, ALTER, DROP, COMMENT or TEMP (which is equivalent to TEMPORARY).

- `has_directory_privilege(user, directory, privilege)`

Description: Specifies whether a specified user has permissions on directories.

**Table 7-47** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
directory	text, oid
privilege	text

- Return type: Boolean
- `has_directory_privilege(directory, privilege)`  
Description: Specifies whether the current user has permission to access a directory. For details about the valid parameter types, see [Table 7-47](#).  
Return type: Boolean
  - `has_foreign_data_wrapper_privilege(user, fdw, privilege)`  
Description: Specifies whether a specified user has permissions on foreign data wrappers.

**Table 7-48** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
fdw	text, oid
privilege	text

- Return type: Boolean
- `has_foreign_data_wrapper_privilege(fdw, privilege)`  
Description: Specifies whether the current user has permission for accessing foreign-data wrappers. For details about the valid parameter types, see [Table 7-48](#).  
Return type: Boolean  
Note: **has\_foreign\_data\_wrapper\_privilege** checks whether a user can access a foreign data wrapper in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must evaluate to **USAGE**.
  - `has_function_privilege(user, function, privilege)`  
Description: Specifies whether a specified user has permissions on functions.

**Table 7-49** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
function	text, oid
privilege	text

- Return type: Boolean
- `has_function_privilege(function, privilege)`  
Description: Specifies whether the current user has permissions on functions. For details about the valid parameter types, see [Table 7-49](#).  
Return type: Boolean

Note: **has\_function\_privilege** checks whether a user can access a function in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. When a function is specified by a text string rather than by an OID, the allowed input is the same as that for the **regprocedure** data type (see [Object Identifier Types](#)). The access permission must be EXECUTE, ALTER, DROP, or COMMENT.

- **has\_language\_privilege**(user, language, privilege)  
Description: Specifies whether a specified user has permissions on languages.

**Table 7-50** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
language	text, oid
privilege	text

Return type: Boolean

- **has\_language\_privilege**(language, privilege)  
Description: Specifies whether the current user has permissions on languages. For details about the valid parameter types, see [Table 7-50](#).

Return type: Boolean

Note: **has\_language\_privilege** checks whether a user can access a procedural language in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be **USAGE**.

- **has\_nodegroup\_privilege**(user, nodegroup, privilege)  
Description: Checks whether a user has permission to access a database node.  
Return type: Boolean

**Table 7-51** Parameter type description

Parameter	Valid Input Parameter Type
user	name, oid
nodegroup	text, oid
privilege	text

- **has\_nodegroup\_privilege**(nodegroup, privilege)  
Description: Checks whether a user has permission to access a database node. The parameter is similar to **has\_table\_privilege**. The access permission must be USAGE, CREATE, COMPUTE, ALTER, or DROP.  
Return type: Boolean
- **has\_schema\_privilege**(user, schema, privilege)

Description: Specifies whether a specified user has permissions on schemas.

Return type: Boolean

- `has_schema_privilege(schema, privilege)`

Description: Specifies whether the current user has permissions on schemas.

Return type: Boolean

Note: **has\_schema\_privilege** checks whether a user can access a schema in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The desired access permission type must be **CREATE**, **USAGE**, **ALTER**, **DROP**, or **COMMENT**.

- `has_server_privilege(user, server, privilege)`

Description: Specifies whether a specified user has permissions on foreign servers.

Return type: Boolean

- `has_server_privilege(server, privilege)`

Description: Specifies whether the current user has permissions on foreign servers.

Return type: Boolean

Note: **has\_server\_privilege** checks whether a user can access a foreign server in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be **USAGE**, **ALTER**, **DROP**, or **COMMENT**.

- `has_table_privilege(user, table, privilege)`

Description: Specifies whether a specified user has permissions on tables.

Return type: Boolean

- `has_table_privilege(table, privilege)`

Description: Specifies whether the current user has permissions on tables.

Return type: Boolean

Note: **has\_table\_privilege** checks whether a user can access a table in a particular way. The user can be specified by name or by OID (**pg\_authid.oid**), or be set to **public** which indicates public pseudo roles. If this parameter is omitted, **current\_user** is used. The table can be specified by name or by OID. When it is specified by name, the name can be schema-qualified if necessary. The desired access permission is specified by a text string, which must be **SELECT**, **INSERT**, **UPDATE**, **DELETE**, **TRUNCATE**, **REFERENCES**, **TRIGGER**, **ALTER**, **DROP**, **COMMENT**, **INDEX** or **VACUUM**. Optionally, **WITH GRANT OPTION** can be added to a permission type to test whether the permission is held with the grant option. Also, multiple permission types can be listed separated by commas, in which case the result will be **true** if any of the listed permissions is held.

Example:

```
gaussdb=# SELECT has_table_privilege('tpcds.web_site', 'select');
has_table_privilege
-----
t
(1 row)

gaussdb=# SELECT has_table_privilege('omm', 'tpcds.web_site', 'select,INSERT WITH GRANT OPTION ');
has_table_privilege
-----
```

t

(1 row)

- `has_tablespace_privilege(user, tablespace, privilege)`  
Description: Specifies whether a specified user has permissions on tablespaces.  
Return type: Boolean
- `has_tablespace_privilege(tablespace, privilege)`  
Description: Specifies whether the current user has permissions on tablespaces.  
Return type: Boolean  
Note: **has\_tablespace\_privilege** checks whether a user can access a tablespace in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**. The access permission type must be **CREATE**, **ALTER**, **DROP**, or **COMMENT**.
- `pg_has_role(user, role, privilege)`  
Description: Specifies whether a specified user has permissions on roles.  
Return type: Boolean
- `pg_has_role(role, privilege)`  
Description: Specifies whether the current user has permissions on roles.  
Return type: Boolean  
Note: **pg\_has\_role** checks whether a user can access a role in a particular way. Its parameter possibilities are analogous to those of **has\_table\_privilege**, except that **public** cannot be used as a username. The desired access permission type must be some combination of **MEMBER** or **USAGE**. **MEMBER** denotes direct or indirect membership in the role (that is, permission **SET ROLE**), while **USAGE** denotes the usage permission on the role that is available without the **SET ROLE** permission.
- `has_any_privilege(user, privilege)`  
Description: Queries whether a specified user has certain ANY permission. If multiple permissions are queried at the same time, **true** is returned as long as one permission is obtained.  
Return type: Boolean

**Table 7-52** Parameter type description

Parameter	Valid Input Parameter Type	Description	Value Range
user	name	Users	Existing username

Parameter	Valid Input Parameter Type	Description	Value Range
privilege	text	ANY permission	Available values: <ul style="list-style-type: none"> <li>• CREATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• ALTER ANY TABLE [WITH ADMIN OPTION]</li> <li>• DROP ANY TABLE [WITH ADMIN OPTION]</li> <li>• SELECT ANY TABLE [WITH ADMIN OPTION]</li> <li>• INSERT ANY TABLE [WITH ADMIN OPTION]</li> <li>• UPDATE ANY TABLE [WITH ADMIN OPTION]</li> <li>• DELETE ANY TABLE [WITH ADMIN OPTION]</li> <li>• CREATE ANY SEQUENCE [WITH ADMIN OPTION]</li> <li>• CREATE ANY INDEX [WITH ADMIN OPTION]</li> <li>• CREATE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• EXECUTE ANY FUNCTION [WITH ADMIN OPTION]</li> <li>• CREATE ANY PACKAGE [WITH ADMIN OPTION]</li> <li>• EXECUTE ANY PACKAGE [WITH ADMIN OPTION]</li> <li>• CREATE ANY TYPE [WITH ADMIN OPTION]</li> </ul>

## Schema Visibility Query Functions

Each function performs the visibility check on one type of database objects. For functions and operators, an object in the search path is visible if there is no object of the same name and parameter data type earlier in the path. For operator classes, both name and associated index access methods are considered.

All these functions require OIDs to identify the objects to be checked. If you want to test an object by name, it is convenient to use the OID alias type (**regclass**, **regtype**, **regprocedure**, **regoperator**, **regconfig**, or **regdictionary**).

For example, a table is said to be visible if the schema where the table is located is in the search path and no table of the same name appears earlier in the search

path. This is equivalent to the statement that the table can be referenced by name without explicit schema qualification. To list the names of all visible tables, run the following command:

```
gaussdb=# SELECT relname FROM pg_class WHERE pg_table_is_visible(oid);
```

- `pg_collation_is_visible(collation_oid)`  
Description: Specifies whether the collation is visible in the search path.  
Return type: Boolean
- `pg_conversion_is_visible(conversion_oid)`  
Description: Specifies whether the conversion is visible in the search path.  
Return type: Boolean
- `pg_function_is_visible(function_oid)`  
Description: Specifies whether the function is visible in the search path.  
Return type: Boolean
- `pg_opclass_is_visible(opclass_oid)`  
Description: Specifies whether the operator class is visible in the search path.  
Return type: Boolean
- `pg_operator_is_visible(operator_oid)`  
Description: Specifies whether the operator is visible in the search path.  
Return type: Boolean
- `pg_opfamily_is_visible(opclass_oid)`  
Description: Specifies whether the operator family is visible in the search path.  
Return type: Boolean
- `pg_table_is_visible(table_oid)`  
Description: Specifies whether the table is visible in the search path.  
Return type: Boolean
- `pg_ts_config_is_visible(config_oid)`  
Description: Specifies whether the text search configuration is visible in the search path.  
Return type: Boolean
- `pg_ts_dict_is_visible(dict_oid)`  
Description: Specifies whether the text search dictionary is visible in the search path.  
Return type: Boolean
- `pg_ts_parser_is_visible(parser_oid)`  
Description: Specifies whether the text search parser is visible in the search path.  
Return type: Boolean
- `pg_ts_template_is_visible(template_oid)`  
Description: Specifies whether the text search template is visible in the search path.  
Return type: Boolean
- `pg_type_is_visible(type_oid)`

Description: Specifies whether the type (or domain) is visible in the search path.

Return type: Boolean

## System Catalog Information Functions

- `format_type(type_oid, typemod)`

Description: Obtains the SQL name of a data type.

Return type: text

Note: **format\_type** returns the SQL name of a data type based on the OID of the data type and possible modifiers. If the specific modifier is unknown, pass **NULL** at the position of the modifier. Modifiers are generally meaningful only for data types with length restrictions. The SQL name returned by **format\_type** contains the length of the data type, which can be calculated by taking `sizeof(int32)` from actual storage length [actual storage len - `sizeof(int32)`] in the unit of bytes. 32-bit space is required to store the customized length set by users. Therefore, the actual storage length contains 4 bytes more than the customized length. In the following example, the SQL name returned by **format\_type** is `character varying(6)`, indicating the length of the `varchar` type is 6 bytes. Therefore, the actual storage length of the `varchar` type is 10 bytes.

```
gaussdb=# SELECT format_type((SELECT oid FROM pg_type WHERE typename='varchar'), 10);
format_type
-----
character varying(6)
(1 row)
```

- `getdistributekey(table_name)`

Description: Gets a distribution key for a hash table. Distribution is not supported in a standalone system and the return value of this function is empty.

- `pg_check_authid(role_oid)`

Description: Checks whether a role name with given OID exists.

Return type: Boolean

Example:

```
gaussdb=# select pg_check_authid(1);
pg_check_authid
-----
f
(1 row)
```

- `pg_describe_object(catalog_id, object_id, object_sub_id)`

Description: Obtains the description of a database object.

Return type: text

Note: **pg\_describe\_object** returns the description of a database object specified by a catalog OID, an object OID, and a (possibly zero) sub-object ID. This is useful to determine the identity of an object stored in the **pg\_depend** catalog.

- `pg_get_constraintdef(constraint_oid)`

Description: Obtains definition of a constraint.

Return type: text

- `pg_get_constraintdef(constraint_oid, pretty_bool)`  
 Description: Obtains definition of a constraint.  
 Return type: text  
 Note: **pg\_get\_constraintdef** and **pg\_get\_indexdef** respectively reconstruct the creation command for a constraint and an index.
- `pg_get_expr(pg_node_tree, relation_oid)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text
- `pg_get_expr(pg_node_tree, relation_oid, pretty_bool)`  
 Description: Decompiles the internal form of an expression, assuming that any Vars in it refer to the relationship indicated by the second parameter.  
 Return type: text  
 Note: **pg\_get\_expr** decompiles the internal form of an individual expression, such as the default value of a column, which helps to check the contents of system catalogs. If the expression might contain keywords, specify the OID of the relationship they refer to as the second parameter; if no keywords are expected, zero is sufficient.
- `pg_get_functiondef(func_oid)`  
 Description: Obtains the definition of a function.  
 Return type: text  
 Example:  

```
gaussdb=# SELECT * FROM pg_get_functiondef(598);
headerlines |          definition
-----+-----
4 | CREATE OR REPLACE FUNCTION pg_catalog.abbrev(inet)+
  | RETURNS text +
  | LANGUAGE internal +
  | IMMUTABLE STRICT NOT FENCED NOT SHIPPABLE +
  | AS $function$inet_abbrev$function$ +
  |
(1 row)
```
- `pg_get_function_arguments(func_oid)`  
 Description: Obtains the parameter list of the function's definition (with default values).  
 Return type: text  
 Note: **pg\_get\_function\_arguments** returns the parameter list of a function, in the form it would need to appear in CREATE FUNCTION.
- `pg_get_function_identity_arguments(func_oid)`  
 Description: Obtains the parameter list to identify a function (without default values).  
 Return type: text  
 Note: **pg\_get\_function\_identity\_arguments** returns the parameter list necessary to identify a function, in the form it would need to appear in within ALTER FUNCTION. This form omits default values.
- `pg_get_function_result(func_oid)`  
 Description: Obtains the RETURNS clause for a function.  
 Return type: text

Note: **pg\_get\_function\_result** returns the appropriate RETURNS clause for the function.

- **pg\_get\_indexdef(index\_oid)**

Description: Obtains the **CREATE INDEX** command for an index.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416);
           pg_get_indexdef
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
```

- **pg\_get\_indexdef(index\_oid, dump\_schema\_only)**

Description: Obtains the **CREATE INDEX** command for indexes in dump scenarios. For an interval partitioned table that contains a local index, if **dump\_schema\_only** is set to **true**, the returned index creation statement does not contain the local index information of the automatically created partition. If **dump\_schema\_only** is set to **false**, the returned index creation statement contains the local index information of the automatically created partition. For a non-interval partitioned table or an interval partitioned table that does not contain a local index, the value of **dump\_schema\_only** does not affect the returned result of the function.

Return type: text

Example:

```
gaussdb=# CREATE TABLE sales
gaussdb=# (prod_id NUMBER(6),
gaussdb=# cust_id NUMBER,
gaussdb=# time_id DATE,
gaussdb=# channel_id CHAR(1),
gaussdb=# promo_id NUMBER(6),
gaussdb=# quantity_sold NUMBER(3),
gaussdb=# amount_sold NUMBER(10,2)
gaussdb=# )
PARTITION BY RANGE( time_id) INTERVAL('1 day')
gaussdb=# (
gaussdb=# partition p1 VALUES LESS THAN ('2019-02-01 00:00:00'),
gaussdb=# partition p2 VALUES LESS THAN ('2019-02-02 00:00:00')
gaussdb=# );
CREATE TABLE
gaussdb=# create index index_sales on sales(prod_id) local (PARTITION idx_p1 ,PARTITION idx_p2);
CREATE INDEX
gaussdb=# #-- If the data to be inserted does not match any partition, create a partition and insert
the data into the new partition.
gaussdb=# INSERT INTO sales VALUES(1, 12, '2019-02-05 00:00:00', 'a', 1, 1, 1);
INSERT 0 1
gaussdb=# SELECT oid FROM pg_class WHERE relname = 'index_sales';
   oid
-----
24632
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(24632, true);
           pg_get_indexdef
-----
---
CREATE INDEX index_sales ON sales USING btree (prod_id) LOCAL(PARTITION idx_p1, PARTITION
idx_p2) TABLESPACE pg_default
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(24632, false);
           pg_get_indexdef
-----
-----
```

```
-----
CREATE INDEX index_sales ON sales USING btree (prod_id) LOCAL(PARTITION idx_p1, PARTITION
idx_p2, PARTITION sys_p1_prod_id_idx) TA
BLESFACE pg_default
(1 row)
```

- `pg_get_indexdef(index_oid, column_no, pretty_bool)`

Description: Obtains the **CREATE INDEX** command for an index, or definition of just one index column when the value of **column\_no** is not zero.

Example:

```
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 0, false);
pg_get_indexdef
```

```
-----
CREATE INDEX test3_b_idx ON test3 USING btree (b) TABLESPACE pg_default
(1 row)
gaussdb=# SELECT * FROM pg_get_indexdef(16416, 1, false);
pg_get_indexdef
-----
b
(1 row)
```

Return type: text

Note: **pg\_get\_functiondef** returns a complete **CREATE OR REPLACE FUNCTION** statement for a function.

- `pg_get_keywords()`

Description: Obtains the list of SQL keywords and their categories.

Return type: SETOF record

Note: **pg\_get\_keywords** returns a set of records describing the SQL keywords recognized by the server. The **word** column contains the keywords. The **catcode** column contains a category code: **U** for unreserved, **C** for column name, **T** for type or function name, or **R** for reserved. The **catdesc** column contains a possibly-localized string describing the category.

- `pg_get_userbyid(role_oid)`

Description: Obtains the role name with a given OID.

Return type: name

Note: **pg\_get\_userbyid** extracts a role's name given its OID.

- `pg_check_authid(role_id)`

Description: Checks whether a user exists based on **role\_id**.

Return type: text

Example:

```
gaussdb=# SELECT pg_check_authid(20);
pg_check_authid
-----
f
(1 row)
```

- `pg_get_viewdef(view_name)`

Description: Obtains the underlying **SELECT** command for a view.

Return type: text

- `pg_get_viewdef(view_name, pretty_bool)`

Description: Obtains the underlying **SELECT** command for a view, lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.

Return type: text

Note: **pg\_get\_viewdef** reconstructs the **SELECT** query that defines a view. Most of these functions come in two forms. When the function has the **pretty\_bool** parameter and the value is **true**, it can optionally "pretty-print" the result. The pretty-printed format is more readable. The other one is the default format which is more likely to be interpreted in the same way by future versions. Avoid using pretty-printed output for dump purposes. Passing **false** to the pretty-print parameter generates the same result as a variant without this parameter.

- **pg\_get\_viewdef(view\_oid)**  
Description: Obtains the underlying **SELECT** command for a view.  
Return type: text
- **pg\_get\_viewdef(view\_oid, pretty\_bool)**  
Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to 80 columns if **pretty\_bool** is set to **true**.  
Return type: text
- **pg\_get\_viewdef(view\_oid, wrap\_column\_int)**  
Description: Obtains the underlying **SELECT** command for a view. Lines with columns are wrapped to the specified number of columns and printing is implicit.  
Return type: text
- **pg\_get\_tabledef(table\_oid)**  
Description: Obtains the definition of a table based on **table\_oid**.

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef(16384);
pg_get_tabledef
-----
SET search_path = public;          +
CREATE TABLE t1 (                  +
  c1 bigint DEFAULT nextval('serial'::regclass)+
)                                     +
WITH (orientation=row, compression=no) +
TO GROUP group1;
(1 row)
```

Return type: text

- **pg\_get\_tabledef(table\_name)**  
Description: Obtains the definition of a table based on **table\_name**.

Example:

```
gaussdb=# SELECT * FROM pg_get_tabledef('t1');
pg_get_tabledef
-----
SET search_path = public;          +
CREATE TABLE t1 (                  +
  c1 bigint DEFAULT nextval('serial'::regclass)+
)                                     +
WITH (orientation=row, compression=no) +
TO GROUP group1;
(1 row)
```

Return type: text

Note: **pg\_get\_tabledef** reconstructs the **CREATE** statement of the definition of the table, including the table definition, index information, and comments. Users need to create the dependent objects of the table, such as groups, schemas, tablespaces, and servers. The table definition does not include the statements for creating these dependent objects.

- `pg_options_to_table(reloptions)`  
Description: Obtains the set of storage option name/value pairs.  
Return type: SETOF record  
Note: **pg\_options\_to\_table** returns the set of storage option name/value pairs (**option\_name/option\_value**) when **pg\_class.reloptions** or **pg\_attribute.attoptions** is passed.
- `pg_tablespace_databases(tablespace_oid)`  
Description: Obtains the set of database OIDs that have objects in the specified tablespace.  
Return type: setof oid  
Note: **pg\_tablespace\_databases** allows a tablespace to be checked. It returns the set of OIDs of databases that have objects stored in the tablespace. If this function returns any rows of data, the tablespace is not empty and cannot be dropped. To display the specific objects in the tablespace, you need to connect to the databases identified by **pg\_tablespace\_databases** and query the `pg_class` system catalogs.
- `pg_tablespace_location(tablespace_oid)`  
Description: Obtains the path in the file system that this tablespace is located in.  
Return type: text
- `pg_typeof(any)`  
Description: Obtains the data type of any value.  
Return type: regtype  
Note: **pg\_typeof** returns the OID of the data type of the value that is passed to it. This can be helpful for troubleshooting or dynamically constructing SQL queries. It is declared that the function returns **regtype**, which is an OID alias type (see [Object Identifier Types](#)). This means that it is the same as an OID for comparison purposes but displays as a type name.  
Example:

```
gaussdb=# SELECT pg_typeof(33);
pg_typeof
-----
integer
(1 row)

gaussdb=# SELECT typen FROM pg_type WHERE oid = pg_typeof(33);
typen
-----
4
(1 row)
```
- `collation for (any)`  
Description: Obtains the collation of the parameter.  
Return type: text  
Note: The expression **collation for** returns the collation of the value that is passed to it.  
Example:

```
gaussdb=# SELECT collation for (description) FROM pg_description LIMIT 1;
pg_collation_for
-----
```

```
"default"
(1 row)
```

The value might be quoted and schema-qualified. If no collation is derived for the parameter expression, then a null value is returned. If the argument is not of a collatable data type, then an error is raised.

- `pg_extension_update_paths(name)`

Description: Returns the version update path of the specified extension.

Return type: text(source text), text(path text), text(target text)

- `pg_get_serial_sequence(tablename, colname)`

Description: Obtains the sequence of the corresponding table name and column name.

Return type: text

Example:

```
gaussdb=# SELECT * FROM pg_get_serial_sequence('t1', 'c1');
pg_get_serial_sequence
-----
public.serial
(1 row)
```

- `pg_sequence_parameters(sequence_oid)`

Description: Obtains the parameters of a specified sequence, including the start value, minimum value, maximum value, and incremental value.

Return type: int16, int16, int16, int16, Boolean

Example:

```
gaussdb=# SELECT * FROM pg_sequence_parameters(16420);
start_value | minimum_value | maximum_value | increment | cycle_option
-----+-----+-----+-----+-----
101 | 1 | 9223372036854775807 | 1 | f
(1 row)
```

## Comment Information Functions

- `col_description(table_oid, column_number)`

Description: Obtains the comment for a table column.

Return type: text

Note: **col\_description** returns the comment for a table column, which is specified by the OID of its table and its column number.

- `obj_description(object_oid, catalog_name)`

Description: Obtains the comment for a database object.

Return type: text

Note: The two-parameter form of **obj\_description** returns the comment for a database object specified by its OID and the name of the system catalog to which it belongs. For example, **obj\_description(123456,'pg\_class')** would retrieve the comment for the table with OID 123456. The one-parameter form of **obj\_description** requires only the OID.

**obj\_description** cannot be used for table columns since columns do not have OIDs of their own.

- `obj_description(object_oid)`

Description: Obtains the comment for a database object.

Return type: text

- shobj\_description(object\_oid, catalog\_name)**  
 Description: Obtains the comment for a shared database object.  
 Return type: text  
 Note: **shobj\_description** is used just like **obj\_description**, except that the former is used for shared objects. Some system catalogs are global to all databases in the GaussDB, and the comments for objects in them are stored globally as well.

## XIDs and Snapshots

Internal XIDs are 64 bits. **txid\_snapshot**, data type used by these functions, stores information about XID visibility at a particular moment in time. [Table 7-53](#) describes its components.

**Table 7-53** Snapshot components

Name	Description
xmin	Earliest XID ( <b>txid</b> ) that is still active. All earlier transactions will either be committed and visible, or rolled back.
xmax	First as-yet-unassigned <b>txid</b> . All txids greater than or equal to this are not yet started as of the time of the snapshot, so they are invisible.
xip_list	Active <b>txids</b> at the time of the snapshot. The list includes only those active <b>txids</b> between <b>xmin</b> and <b>xmax</b> ; there might be active <b>txids</b> higher than <b>xmax</b> . A <b>txid</b> that is greater than or equal to <b>xmin</b> and less than <b>xmax</b> and that is not in this list was already completed at the time of the snapshot, and is either visible or rolled back according to its commit status. The list does not include <b>txids</b> of subtransactions.

The textual representation of **txid\_snapshot** is **xmin:xmax:xip\_list**.

For example, **10:20:10,14,15** means **xmin=10, xmax=20, xip\_list=10, 14, 15**.

The following functions provide server transaction information in an exportable form. These functions are mainly used to determine which transactions were committed between two snapshots.

- txid\_current()**  
 Description: Obtains the current XID.  
 Return type: bigint
- gs\_txid\_oldestxmin()**  
 Description: Obtains the minimum XID (specified by **oldesxmin**).  
 Return type: bigint
- txid\_current\_snapshot()**  
 Description: Obtains the current snapshot.  
 Return type: txid\_snapshot

- `txid_snapshot_xip(txid_snapshot)`  
Description: Obtains in-progress XIDs in a snapshot.  
Return type: setof bigint
- `txid_snapshot_xmax(txid_snapshot)`  
Description: Obtains **xmax** of snapshots.  
Return type: bigint
- `txid_snapshot_xmin(txid_snapshot)`  
Description: Obtains **xmin** of snapshots.  
Return type: bigint
- `txid_visible_in_snapshot(bigint, txid_snapshot)`  
Description: Specifies whether the XID is visible in a snapshot (do not use subtransaction IDs).  
Return type: Boolean
- `get_local_prepared_xact()`  
Description: Obtains the two-phase residual transaction information of the current node, including the XID, GID of the two-phase transaction, prepared time, owner OID, database OID, and node name of the current node.  
Return type: xid, text, timestamptz, oid, oid, text
- `get_remote_prepared_xacts()`  
Description: Obtains the two-phase residual transaction information of all remote nodes, including the XID, GID of the two-phase transaction, prepared time, owner name, database name, and node name.  
Return type: xid, text, timestamptz, name, name, text
- `global_clean_prepared_xacts(text, text)`  
Description: Concurrently cleans two-phase residual transactions. Only the **gs\_clean** tool can call this function for the cleaning in the distributed environment. If other users call this function, **false** is returned.  
Return type: Boolean
- `gs_get_next_xid_csn()`  
Description: Returns the values of **next\_xid** and **next\_csn** on all nodes globally.  
The return values are as follows:

**Table 7-54** `gs_get_next_xid_csn` parameter description

Field	Description
<code>nodename</code>	Node name
<code>next_xid</code>	ID of the next transaction on the current node.
<code>next_csn</code>	Next CSN of the current node.

- `pg_control_system()`  
Description: Returns the status of the system control file.

- Return type: SETOF record
- `pg_control_checkpoint()`  
Description: Returns the system checkpoint status.  
Return type: SETOF record
- `pv_builtin_functions`  
Description: Displays information about all built-in system functions.  
Parameter: nan  
Return type: proname name, pronamespace oid, proowner oid, prolang oid, procost real, prorows real, provariadic oid, protransform regproc, proisagg boolean, proiswindow boolean, prosecedef boolean, proleakproof boolean, proisstrict boolean, proretset boolean, provolatile "char", pronargs smallint, pronargdefaults smallint, prorettype oid, proargtypes oidvector, proallargtypes integer[], proargmodes "char"[], proargnames text[], proargdefaults `pg_node_tree`, prosrc text, probin text, proconfig text[], proacl aclitem[], prodefaultargpos int2vector, fencedmode boolean, proshippable boolean, propackage boolean, oid oid
- `pv_thread_memory_detail`  
Description: Returns the memory information of each thread.  
Parameter: nan  
Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `pg_relation_compression_ratio`  
Description: Queries the compression rate of a table. By default, **1.0** is returned.  
Parameter: text  
Return type: real
- `pg_relation_with_compression`  
Description: Specifies whether a table is compressed.  
Parameter: text  
Return type: Boolean
- `pg_stat_file_recursive`  
Description: Lists all files in a path.  
Parameter: location text
- `pg_shared_memory_detail`  
Description: Returns usage information about all generated shared memory contexts. For details about each column, see [GS\\_SHARED\\_MEMORY\\_DETAIL](#).  
Parameter: nan  
Return type: contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint
- `get_gtm_lite_status`  
Description: Returns the backup XID and CSN on the GTM for fault locating. This system function is not supported in GTM-FREE mode.
- `gs_stat_get_wlm_plan_operator_info`  
Description: Obtains operator plan information from the internal hash table.

Parameter: oid

Return type: datname text, queryid int8, plan\_node\_id int4, startup\_time int8, total\_time int8, actual\_rows int8, max\_peak\_memory int4, query\_dop int4, parent\_node\_id int4, left\_child\_id int4, right\_child\_id int4, operation text, orientation text, strategy text, options text, condition text, projection text

- pg\_stat\_get\_partition\_tuples\_hot\_updated

Description: Returns statistics on the number of hot-updated tuples in a partition with a specified partition ID.

Parameter: oid

Return type: bigint

- gs\_session\_memory\_detail\_tp

Description: Returns the memory usage of the session. For details, see **gs\_session\_memory\_detail**.

Parameter: nan

Return type: sessid text, sesstype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- gs\_thread\_memory\_detail

Description: Returns the memory information of each thread.

Parameter: nan

Return type: threadid text, tid bigint, thrdtype text, contextname text, level smallint, parent text, totalsize bigint, freesize bigint, usedsize bigint

- pg\_stat\_get\_wlm\_realtime\_operator\_info

Description: Obtains the operator information of the real-time execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, status text, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_operator\_info

Description: Obtains the operator information of the execution plan from the internal hash table.

Parameter: nan

Return type: queryid bigint, pid bigint, plan\_node\_id integer, plan\_node\_name text, start\_time timestamp with time zone, duration bigint, query\_dop integer, estimated\_rows bigint, tuple\_processed bigint, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, warning text

- pg\_stat\_get\_wlm\_node\_resource\_info

This function is unavailable in the current version.

- `pg_stat_get_session_wlmstat`  
Description: Returns the load information of the current session.  
Parameter: pid integer  
Return type: datid oid, threadid bigint, sessionid bigint, threadpid integer, usesysid oid, appname text, query text, priority bigint, block\_time bigint, elapsed\_time bigint, total\_cpu\_time bigint, skew\_percent integer, statement\_mem integer, active\_points integer, dop\_value integer, current\_cgroup text, current\_status text, enqueue\_state text, attribute text, is\_plana boolean, node\_group text, srespool name
- `pg_stat_get_wlm_instance_info`  
Description: Returns the load information of the current instance.  
Parameter: nan  
Return type: instancename text, timestamp, timestamp with time zone, used\_cpu integer, free\_memory integer, used\_memory integer, io\_await double precision, io\_util double precision, disk\_read double precision, disk\_write double precision, process\_read bigint, process\_write bigint, logical\_read bigint, logical\_write bigint, read\_counts bigint, write\_counts bigint
- `pg_stat_get_wlm_instance_info_with_cleanup`  
Description: Returns the load information of the current instance and saves the information to the system catalog.  
Parameter: nan  
Return type: instancename text, timestamp, timestamp with time zone, used\_cpu integer, free\_memory integer, used\_memory integer, io\_await double precision, io\_util double precision, disk\_read double precision, disk\_write double precision, process\_read bigint, process\_write bigint, logical\_read bigint, logical\_write bigint, read\_counts bigint, write\_counts bigint
- `pg_stat_get_wlm_realtime_session_info`  
Description: Returns the load information of the real-time session.  
Parameter: nan  
Return type: nodename text, threadid bigint, block\_time bigint, duration bigint, estimate\_total\_time bigint, estimate\_left\_time bigint, schemaname text, query\_band text, spill\_info text, control\_group text, estimate\_memory integer, min\_peak\_memory integer, max\_peak\_memory integer, average\_peak\_memory integer, memory\_skew\_percent integer, min\_spill\_size integer, max\_spill\_size integer, average\_spill\_size integer, spill\_skew\_percent integer, min\_dn\_time bigint, max\_dn\_time bigint, average\_dn\_time bigint, dntime\_skew\_percent integer, min\_cpu\_time bigint, max\_cpu\_time bigint, total\_cpu\_time bigint, cpu\_skew\_percent integer, min\_peak\_iops integer, max\_peak\_iops integer, average\_peak\_iops integer, iops\_skew\_percent integer, warning text, query text, query\_plan text, cpu\_top1\_node\_name text, cpu\_top2\_node\_name text, cpu\_top3\_node\_name text, cpu\_top4\_node\_name text, cpu\_top5\_node\_name text, mem\_top1\_node\_name text, mem\_top2\_node\_name text, mem\_top3\_node\_name text, mem\_top4\_node\_name text, mem\_top5\_node\_name text, cpu\_top1\_value bigint, cpu\_top2\_value bigint, cpu\_top3\_value bigint, cpu\_top4\_value bigint, cpu\_top5\_value bigint, mem\_top1\_value bigint, mem\_top2\_value bigint, mem\_top3\_value bigint, mem\_top4\_value bigint, mem\_top5\_value bigint, top\_mem\_dn text, top\_cpu\_dn text

- pg\_stat\_get\_wlm\_session\_iostat\_info**  
 Description: Returns the session load I/O information.  
 Parameter: nan  
 Return type: threadid bigint, maxcurr\_iops integer, mincurr\_iops integer, maxpeak\_iops integer, minpeak\_iops integer, iops\_limits integer, io\_priority integerw, and curr\_io\_limits integer
- pg\_stat\_get\_wlm\_statistics**  
 Description: Returns session load statistics.  
 Parameter: nan  
 Return type: statement text, block\_time bigint, elapsed\_time bigint, total\_cpu\_time bigint, qualification\_time bigint, skew\_percent integer, control\_group text, status text, action text
- adm\_hist\_snapshot\_func()**  
 Description: Returns information about the snapshot execution time. To access this function, set the **enable\_wdr\_snapshot** parameter to **on** and obtain the permission to access the **snapshot schema**, **snapshot table**, and **tables\_snap\_timestamp** tables.  
 Parameter: nan  
 Return type: snap\_id bigint, dbid oid, begin\_interval\_time timestamp(3), end\_interval\_time timestamp(3), flush\_elapsed interval day(5) to second(1), begin\_interval\_time\_tz timestamp(3) with time zone, end\_interval\_time\_tz timestamp(3) with time zone
- gs\_get\_current\_version()**  
 Description: Returns the current compilation mode based on the current compilation macro. 'P' is returned.  
 Parameter: nan  
 Return type: char
- gs\_get\_kernel\_info()**  
 Description: Transaction information on DNs.  
 The return values are as follows:

**Table 7-55** gs\_get\_kernel\_info parameter description

Name	Type	Description
node_name	text	Node name.
module	text	Module name, including: <ul style="list-style-type: none"> <li>● <b>XACT</b> (transaction module)</li> <li>● <b>STANDBY</b> (standby module)</li> <li>● <b>UNDO</b> (undo module)</li> <li>● <b>HOTPATH</b> (hot patch module)</li> </ul>

Name	Type	Description
name	text	<p>Name of the key data in the memory state, including:</p> <ul style="list-style-type: none"> <li>• <b>startup_max_xid</b> (maximum XID when a process is started)</li> <li>• <b>recent_local_xmin</b> (minimum XID of a local active transaction)</li> <li>• <b>recent_global_xmin</b> (minimum XID of a global active transaction)</li> <li>• <b>standby_xmin</b> (minimum XID of an active transaction on the standby node)</li> <li>• <b>standby_redo_cleanup_xmin</b> (minimum XID of cleanup logs during redo on the standby node)</li> <li>• <b>standby_redo_cleanup_xmin_lsn</b> (LSN of the minimum XID of cleanup logs during redo on the standby node)</li> <li>• <b>local_csn_min</b> (minimum CSN of a local active transaction)</li> <li>• <b>replication_slot_xmin</b> (minimum XID of a replication slot)</li> <li>• <b>replication_slot_catalog_xmin</b> (minimum XID of a catalog replication slot)</li> <li>• <b>global_recycle_xid</b> (minimum XID of a global undo recycling transaction)</li> <li>• <b>global_frozen_xid</b> (minimum XID of a globally frozen transaction)</li> <li>• <b>hotpatch_additional_info</b> (reserved column for hot patches)</li> </ul>
value	text	Value of the key data in the memory state.

Example:

```
gaussdb=# select * from gs_get_kernel_info();
node_name | module | name | value
-----+-----+-----+-----
datanode1 | XACT | startup_max_xid | 16488
datanode1 | XACT | recent_local_xmin | 15805
datanode1 | XACT | recent_global_xmin | 15805
datanode1 | STANDBY | standby_xmin | 0
datanode1 | STANDBY | standby_redo_cleanup_xmin | 0
datanode1 | STANDBY | standby_redo_cleanup_xmin_lsn | 0/0
datanode1 | XACT | local_csn_min | 6014225
datanode1 | XACT | replication_slot_xmin | 0
datanode1 | XACT | replication_slot_catalog_xmin | 0
datanode1 | UNDO | global_recycle_xid | 15805
datanode1 | XACT | global_frozen_xid | 0
datanode1 | HOTPATH | hotpatch_additional_info |
(12 row)
```

## 7.5.25 System Administration Functions

### 7.5.25.1 Configuration Settings Functions

Configuration setting functions are used for querying and modifying configuration parameters during running.

- `current_setting(setting_name)`

Description: Specifies the current setting.

Return type: text

Note: **current\_setting** obtains the current setting of **setting\_name** by query. It is equivalent to the **SHOW** statement. For example:

```
gaussdb=# SELECT current_setting('datestyle');
```

```
current_setting  
-----  
ISO, MDY  
(1 row)
```

- `set_working_grand_version_num_manually(tmp_version)`

Description: Upgrades new features of the database by switching the authorization version.

Return type: void

- `shell_in(type)`

Description: Inputs a route for the shell type that has not yet been filled.

Return type: void

- `shell_out(type)`

Description: Outputs a route for the shell type that has not yet been filled.

Return type: void

- `set_config(setting_name, new_value, is_local)`

Description: Sets the parameter and returns a new value.

Return type: text

Note: The **set\_config** parameter sets the value of **setting\_name** to **new\_value**. If **is\_local** is **true**, the new value applies only to the current transaction. If you want the new value to apply to the current session, use **false** instead. This function is equivalent to the SET statement. Example:

```
gaussdb=# SELECT set_config('log_statement_stats', 'off', false);
```

```
set_config  
-----  
off  
(1 row)
```

### 7.5.25.2 Universal File Access Functions

Universal file access functions provide local access interfaces for files on a database server. Only files in the database directory and the **log\_directory** directory can be accessed. A relative path is used for files in the database directory, and a path matching the **log\_directory** configuration setting is used for log files. Only database initialization users can use these functions.

- `pg_ls_dir(dirname text)`

Description: Lists files in a directory.

Return type: setof text

Note: `pg_ls_dir` returns all the names in the specified directory, except the special entries "." and "..".

Example:

```
gaussdb=# SELECT pg_ls_dir('./');
 pg_ls_dir
-----
.postgresql.conf.swp
postgresql.conf
pg_tblspc
PG_VERSION
pg_ident.conf
core
server.crt
pg_serial
pg_twophase
postgresql.conf.lock
pg_stat_tmp
pg_notify
pg_subtrans
pg_ctl.lock
pg_xlog
pg_clog
base
pg_snapshots
postmaster.opts
postmaster.pid
server.key.rand
server.key.cipher
pg_multixact
pg_errorinfo
server.key
pg_hba.conf
pg_replslot
.pg_hba.conf.swp
cacert.pem
pg_hba.conf.lock
global
gaussdb.state
(32 rows)
```

- `pg_read_file(filename text, offset bigint, length bigint)`

Description: Returns the content of a text file.

Return type: text

Note: `pg_read_file` returns part of a text file. It can return a maximum of *length* bytes from *offset*. The actual size of fetched data is less than *length* if the end of the file is reached first. If *offset* is negative, it is the length rolled back from the file end. If *offset* and *length* are omitted, the entire file is returned.

Example:

```
gaussdb=# SELECT pg_read_file('postmaster.pid',0,100);
 pg_read_file
-----
53078          +
/srv/BigData/hadoop/data1/dbnode+
1500022474     +
8000           +
/var/run/FusionInsight    +
localhost      +
```

```

2
(1 row)

```

- pg\_read\_binary\_file(filename text [, offset bigint, length bigint,missing\_ok boolean])**

Description: Returns the content of a binary file.

Return type: bytea

Note: pg\_read\_binary\_file is similar to pg\_read\_file, except that the result is a **bytea** value; accordingly, no encoding checks are performed. In combination with the convert\_from function, this function can be used to read a file in a specified encoding.

```
gaussdb=# SELECT convert_from(pg_read_binary_file('filename'), 'UTF8');
```
- pg\_stat\_file(filename text)**

Description: Returns status information about a file.

Return type: record

Note: pg\_stat\_file returns a record containing the file size, last access timestamp, last modification timestamp, last file status change timestamp, and a Boolean value indicating if it is a directory. Typical usages are as follows:

```
gaussdb=# SELECT * FROM pg_stat_file('filename');
gaussdb=# SELECT (pg_stat_file('filename')).modification;
```

Example:

```
gaussdb=# SELECT convert_from(pg_read_binary_file('postmaster.pid'), 'UTF8');
convert_from
-----
4881          +
/srv/BigData/gaussdb/data1/dbnode+
1496308688    +
25108         +
/opt/user/Bigdata/gaussdb/gaussdb_tmp +
*            +
25108001 43352069      +
(1 row)
gaussdb=# SELECT * FROM pg_stat_file('postmaster.pid');
```

size	access creation	modification	change
117	2017-06-05 11:06:34+08	2017-06-01 17:18:08+08	2017-06-01 17:18:08+08

```

(1 row)
gaussdb=# SELECT (pg_stat_file('postmaster.pid')).modification;
modification
-----
2017-06-01 17:18:08+08
(1 row)

```

### 7.5.25.3 Server Signal Functions

Server signal functions send control signals to other server processes. Only a system administrator has the permission to execute the following functions:

- pg\_cancel\_backend(pid int)**

Description: Cancels a statement that is being executed by a backend thread.

Return type: Boolean

Note: **pg\_cancel\_backend** sends a query cancellation (SIGINT) signal to the backend process identified by **pid**. The PID of an active backend process can be found in the **pid** column of the **pg\_stat\_activity** view, or can be found by listing the database process using **ps** on the server. A user with the **SYSADMIN** permission, the owner of the database connected to the backend process, the owner of the backend process, or a user who inherits the built-in role permission **gs\_role\_signal\_backend** has the permission to use this function.

- **pg\_cancel\_session**(pid bigint, sessionid bigint)

Description: Cancels the statement that is being executed by an active session in thread pool mode.

Return type: Boolean

Note: The input parameters of **pg\_cancel\_session** can be queried using the **pid** and **sessionid** columns in **pg\_stat\_activity**. The input parameters can be used to clear the statements that are being executed by active sessions in thread pool mode. When the input parameters **pid** and **sessionid** are the same and both are thread IDs, the function of **pg\_cancel\_backend** is the same as that of **pg\_cancel\_backend**.

- **pg\_reload\_conf**()

Description: Causes all server processes to reload their configuration files.

Return type: Boolean

Note: **pg\_reload\_conf** sends a SIGHUP signal to the server. As a result, all server processes reload their configuration files.

- **pg\_rotate\_logfile**()

Description: Rotates the log files of the server.

Return type: Boolean

Note: **pg\_rotate\_logfile** sends a signal to the log file manager, instructing the manager to immediately switch to a new output file. This function works only when **redirect\_stderr** is used for log output. Otherwise, no log file manager subprocess is generated.

- **pg\_terminate\_backend**(pid int)

Description: Terminates a backend thread.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the **SYSADMIN** permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission **gs\_role\_signal\_backend** can use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

---

#### NOTICE

This function can terminate non-thread pool threads and active thread pool threads, but cannot terminate inactive thread pool threads.

---

Example:

```
gaussdb=# SELECT pid from pg_stat_activity;
 pid
-----
 140657876268816
(1 rows)

gaussdb=# SELECT pg_terminate_backend(140657876268816);
 pg_terminate_backend
-----
 t
(1 row)
```

- `pg_terminate_session(pid int64, sessionid int64)`

Description: Terminates a backend session in thread pool mode.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the session, the owner of the session, or a user who inherits the built-in role permission `gs_role_signal_backend` has the permission to use this function. If the target session fails to be terminated after this function is executed, the socket connection between the session and the client is forcibly closed.

---

**NOTICE**

When the input parameters **pid** and **sessionid** are the same and both are thread IDs, this function can terminate non-thread pool threads and active thread pool threads.

When the input parameters **pid** and **sessionid** are different, this function can terminate active sessions or close inactive sessions and the socket connection of the client.

- 
- `pg_terminate_active_session_socket(pid int64, sessionid int64)`

Description: Closes the socket connection between an active session and the client.

Return type: Boolean

Note: Each of these functions returns **true** if they are successful and **false** otherwise. A user with the SYSADMIN permission, the owner of the database connected to the backend thread, the owner of the backend thread, or a user who inherits the built-in role permission `gs_role_signal_backend` has the permission to use this function.

## 7.5.25.4 Backup and Restoration Control Functions

### Backup Control Functions

Backup control functions help with online backup.

- `pg_create_restore_point(name text)`

Description: Creates a named point for performing a restore (requires an administrator role).

Return type: text

Note: **pg\_create\_restore\_point** creates a named transaction log record that can be used as a restoration target, and returns the corresponding transaction log location. The given name can then be used with **recovery\_target\_name** to specify the point up to which restoration will proceed. Avoid creating multiple restoration points with the same name, since restoration will stop at the first one whose name matches the restoration target.

- **pg\_current\_xlog\_location()**

Description: Obtains the write position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_location** displays the write position of the current transaction log in the same format as those of the previous functions. Read-only operations do not require permissions of the system administrator.

- **pg\_current\_xlog\_insert\_location()**

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **pg\_current\_xlog\_insert\_location** displays the insert position of the current transaction log. The insertion point is the logical end of the transaction log at any instant, while the write location is the end of what has been written out from the server's internal buffers. The write position is the end that can be detected externally from the server. This operation can be performed to archive only some of completed transaction log files. The insert position is mainly used for commissioning the server. Read-only operations do not require permissions of the system administrator.

- **gs\_current\_xlog\_insert\_end\_location()**

Description: Obtains the insert position of the current transaction log.

Return type: text

Note: **gs\_current\_xlog\_insert\_end\_location** displays the insert position of the current transaction log.

- **pg\_start\_backup(label text [, fast boolean ])**

Description: Starts executing online backup An administrator, replication role, or O&M administrator must enable **operation\_mode**.

Return type: text

Note: **pg\_start\_backup** receives a user-defined backup label (usually the name of the position where the backup dump file is stored). This function writes a backup label file to the data directory of the database and then returns the starting position of backed up transaction logs in text mode.

```
gaussdb=# SELECT pg_start_backup('label_goes_here');
pg_start_backup
-----
0/3000020
(1 row)
```

- **pg\_stop\_backup()**

Description: Completes online backup An administrator, replication role, or O&M administrator must enable **operation\_mode**.

Return type: text

Note: **pg\_stop\_backup** deletes the label file created by **pg\_start\_backup** and creates a backup history file in the transaction log archive area. The history file includes the label given to **pg\_start\_backup**, the start and end transaction

log locations for the backup, and the start and end time of the backup. The return value is the backup's ending transaction log location. After the end position is calculated, the insert position of the current transaction log automatically goes ahead to the next transaction log file. The ended transaction log file can be immediately archived so that backup is complete.

- `pg_switch_xlog()`

Description: Switches to a new transaction log file. An administrator or O&M administrator must enable **operation\_mode**.

Return type: text

Note: **pg\_switch\_xlog** moves to the next transaction log file so that the current log file can be archived (if continuous archive is used). The return value is the ending transaction log location + 1 within the just-completed transaction log file. If there has been no transaction log activity since the last transaction log switchover, `pg_switch_xlog` does not move but returns the start location of the transaction log file currently in use.

- `pg_xlogfile_name(location text)`

Description: Converts the position string in a transaction log to a file name.

Return type: text

Note: **pg\_xlogfile\_name** extracts only the transaction log file name. If the given transaction log position is the transaction log file border, a transaction log file name will be returned for both the two functions. This is usually the desired behavior for managing transaction log archiving, since the preceding file is the last one that currently needs to be archived.

- `pg_xlogfile_name_offset(location text)`

Description: Converts the position string in a transaction log to a file name and returns the byte offset in the file.

Return type: text, integer

Note: **pg\_xlogfile\_name\_offset** can extract transaction log file names and byte offsets from the returned results of the preceding functions. Example:

```
gaussdb=# SELECT * FROM pg_xlogfile_name_offset(pg_stop_backup());
NOTICE: pg_stop_backup cleanup done, waiting for required WAL segments to be archived
NOTICE: pg_stop_backup complete, all required WAL segments have been archived
  file_name          | file_offset
-----+-----
000000010000000000000003 |      272
(1 row)
```

- `pg_xlog_location_diff(location text, location text)`

Description: Calculates the difference in bytes between two transaction log locations.

Return type: numeric

- `pg_cbm_start_tracked_location()`

Description: Queries the start LSN parsed by CBM.

Return type: text

- `pg_cbm_tracked_location()`

Description: Queries the LSN location parsed by CBM.

Return type: text

- `pg_cbm_get_merged_file(startLSNArg text, endLSNArg text)`

Description: Combines CBM files within the specified LSN range into one and returns the name of the combined file.

Return type: text

Note: Only the system administrator or O&M administrator can obtain the CBM combination file.

- `pg_cbm_get_changed_block(startLSNArg text, endLSNArg text)`

Description: Combines CBM files within the specified LSN range into a table and return records of this table.

Return type: record

Note: The table columns returned by `pg_cbm_get_changed_block` include the start LSN, end LSN, tablespace OID, database OID, table relfilenode, table fork number, whether the table is a system catalog, whether the table is deleted, whether the table is created, whether the table is truncated, number of pages in the truncated table, number of modified pages, and list of modified page numbers.

- `pg_cbm_recycle_file(targetLSNArg text)`

Description: Deletes the CBM files that are no longer used and returns the first LSN after the deletion.

Return type: text

- `pg_cbm_force_track(targetLSNArg text,timeOut int)`

Description: Forcibly executes the CBM trace to the specified Xlog position and returns the Xlog position of the actual trace end point.

Return type: text

- `pg_enable_delay_ddl_recycle()`

Description: Enables DDL delay and returns the Xlog position of the enabling point. An administrator or O&M administrator must enable **operation\_mode**.

Return type: text

- `pg_disable_delay_ddl_recycle(barrierLSNArg text, isForce bool)`

Description: Disables DDL delay and returns the Xlog range where DDL delay takes effect. An administrator or O&M administrator must enable **operation\_mode**.

Return type: record

- `pg_enable_delay_xlog_recycle()`

Description: Enables Xlog recycle delay. This function is used in primary database node restoration. An administrator or O&M administrator must enable **operation\_mode**.

Return type: void

- `pg_disable_delay_xlog_recycle()`

Description: Disables Xlog recycle delay. This function is used in primary database node restoration. An administrator or O&M administrator must enable **operation\_mode**.

Return type: void

- `pg_cbm_rotate_file(rotate_lsn text)`

Description: Forcibly switches the file after the CBM parses **rotate\_lsn**. This function is called during the build process.

Return type: void

- `gs_roach_stop_backup(backupid text)`

Description: Stops a backup started by the internal backup tool GaussRoach. It is similar to the **pg\_stop\_backup\_system** function but is more lightweight.

Return type: text. The content is the insertion position of the current log.

- `gs_roach_enable_delay_ddl_recycle(backupid name)`

Description: Enables DDL delay and returns the log location of the enabling point. It is similar to the **pg\_enable\_delay\_ddl\_recycle** system function but is more lightweight. In addition, different **backupid** values can be used to concurrently open DDL statements with delay.

Return type: text. The content is the log location of the start point.

- `gs_roach_disable_delay_ddl_recycle(backupid text)`

Description: Disables DDL delay, returns the range of logs on which DDL delay takes effect. It is similar to the `pg_enable_delay_ddl_recycle` system function but is more lightweight. In addition, the DDL delay function can be disabled concurrently by specifying different backupid values.

Return type: record. The content is the range of logs for which DDL is delayed to take effect.

- `gs_roach_switch_xlog(request_ckpt bool)`

Description: Switches the currently used log segment file and triggers a full checkpoint if **request\_ckpt** is set to **true**.

Return type: text. The content is the location of the segment log.

- `gs_block_dw_io(timeout int, identifier text)`

Description: Blocks doublewrite page flushing.

Parameter description:

- `timeout`

Block duration.

Value range: [0,3600], in seconds. The value **0** indicates that the block duration is 0s.

- `identifier`

ID of the operation.

Value range: a string, supporting only uppercase letters, lowercase letters, digits, and underscores (\_).

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_is_dw_io_blocked()`

Description: Checks whether disk flushing on the current doublewrite page is blocked. If disk flushing is blocked, **true** is returned.

Return type: Boolean

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_pitr_advance_last_updated_barrier()`

Description: In PITR mode, forcibly pushes the global maximum archived recovery point uploaded to OBS/NAS last time to the current point. No input parameter is required.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. This parameter is valid only on the primary DN in a centralized system. The return value is the latest local maximum archived recovery point.

- `gs_pitr_clean_local_barrier_files('delete_timestamp')`

Description: Clears locally cached barrier record files.

Value range: The **delete\_timestamp** parameter is of the text type. It is a Linux timestamp and contains 10 characters.

Return type: text

Note: To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**. The returned result is the start timestamp of the earliest barrier file on the local host after the deletion.

- `gs_get_barrier_lsn(barrier_name text)`

Description: Obtains the LSN corresponding to the barrier created using a backup.

Return type: text

Note: Currently, this function is not supported. Currently, only **gs\_roach\_full** and **gs\_roach\_inc** are supported. To call this function, the user must have the SYSADMIN or OPRADMIN permission. An O&M administrator must enable **operation\_mode**.

- `gs_gbr_relation_associated_filinode(schemaName name, tableName name)`

Description: Returns the relfilenode of all indexes, sequences, partitions, TOASTs, and TOAST indexes related to the input table.

Return type: record

Note: The table columns returned by `gs_gbr_relation_associated_filinode` include the file type relkind, namespace where the file is located, relation name corresponding to the file, OID of the database where the file is located, OID of the tablespace where the file is located, and relfilenode of the file.

- `pg_create_physical_replication_slot_extern(slotname text, dummy_standby bool, extra_content text, need_recycle_xlog bool)`

---

#### NOTICE

Value range of **slotname**: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name. You are advised to use an alphabetic character string as the archive slot name, and the length cannot exceed 64 characters.

---

Description: Creates an OBS or a NAS archive slot. **slotname** indicates the name of the archive slot or recovery slot. The primary and standby slots must use the same slot name. **dummy\_standby** is a reserved parameter.

**extra\_content** contains some information about the archive slot. For an OBS archive slot, the format is **OBS;obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**, in which **OBS** indicates the archive media of the archive slot, **obs\_server\_ip** indicates the IP address of OBS, **obs\_bucket\_name** indicates the bucket name, **obs\_ak** indicates the AK of OBS, **obs\_sk** indicates the SK of OBS, **archive\_path** indicates the archive path, and **is\_recovery** specifies whether the slot is an archive slot or a recovery slot (**0**: archive slot; **1**: recovery slot). **is\_vote\_replicate** specifies whether the voting copy is archived first. The value **0** indicates that the synchronous standby server is archived first, and the value **1** indicates that the voting copy is archived first. This field is reserved in the current version and is not adapted yet. For a NAS archive slot, the format is **NAS;archive\_path;is\_recovery;is\_vote\_replicate**. Compared with the OBS archive slot, the NAS archive slot does not have the OBS configuration information, while the meanings of other fields are the same.

If the media is not OBS or NAS, the OBS archive slot is used by default. The **extra\_content** format is **obs\_server\_ip;obs\_bucket\_name;obs\_ak;obs\_sk;archive\_path;is\_recovery;is\_vote\_replicate**.

**need\_recycle\_xlog** specifies whether to recycle old archived logs when creating an archive slot. The value **true** indicates that old archived logs are recycled, and the value **false** indicates that old archive logs are not recycled.

Return type: record contains slotname and xlog\_position

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, multiple archive slots cannot be created.

Examples:

Create an OBS archive slot.

```
gaussdb=# select * from pg_create_physical_replication_slot_extern('uuid', false, 'OBS;obs.cn-north-7.ulanqab.huawei.com;dyk;19D772JBCACXX3KWS51D;*****;gaussdb_uuid/dn1;0;0', false);
slotname | xlog_position
-----+-----
uuid |
(1 row)
```

Create a NAS archive slot.

```
gaussdb=# select * from pg_create_physical_replication_slot_extern('uuid', false, 'NAS;/data/nas/media/gaussdb_uuid/dn1;0;0', false);
slotname | xlog_position
-----+-----
uuid |
```

- **gs\_set\_obs\_delete\_location(delete\_location text)**

Description: Sets the location where OBS archive logs can be deleted. The value of **delete\_location** is an LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS.

Return type: xlog\_file\_name text, indicating the file name of the logs that can be deleted. The value is returned regardless of whether OBS is deleted successfully.

```
gaussdb=# select gs_set_obs_delete_location('0/54000000');
gs_set_obs_delete_location
-----
0000000100000000000000054_00
(1 row)
```

- `gs_set_obs_delete_location_with_slotname(cstring, cstring )`  
Description: Sets the location where OBS archive logs in a specified archive slot can be deleted. The first parameter indicates the LSN. The logs before this location have been replayed and flushed to disks and can be deleted on OBS. The second parameter indicates the name of the archive slot.  
Return type: `xlog_file_name` text, indicating the file name of the logs that can be deleted. The value is returned regardless of whether OBS is deleted successfully.
- `gs_get_global_barrier_status()`  
Description: `gs_get_global_barrier_status` is used to query the latest global barrier that has been archived in OBS for the primary database instance.  
Return type: text  
**global\_barrier\_id**: globally latest barrier ID.  
**global\_achive\_barrier\_id**: globally latest archived barrier ID.
- `gs_get_global_barriers_status()`  
Description: `gs_get_global_barriers_status` is used to query the latest global barrier that has been archived in OBS for the primary database instance.  
Return type: text  
**slot\_name**: slot name.  
**global\_barrier\_id**: globally latest barrier ID.  
**global\_achive\_barrier\_id**: globally latest archived barrier ID.

## Restoration Control Functions

Restoration control functions provide information about the status of standby nodes. These functions may be executed both during restoration and in normal running.

- `pg_is_in_recovery()`  
Description: Returns **true** if restoration is still in progress.  
Return type: Boolean
- `pg_last_xlog_receive_location()`  
Description: Obtains the last transaction log location received and synchronized to disk by streaming replication. While streaming replication is in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received and synchronized to disk during restoration. If streaming replication is disabled or if it has not yet started, the function returns a null value.  
Return type: text
- `pg_last_xlog_replay_location()`  
Description: Obtains last transaction log location replayed during restoration. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. When the server has been started normally without restoration, the function returns a null value.  
Return type: text

- `pg_last_xact_replay_timestamp()`  
Description: Obtains the timestamp of last transaction replayed during restoration. This is the time to commit a transaction or abort a WAL record on the primary node. If no transactions have been replayed during restoration, this function will return a null value. If restoration is still in progress, this will increase monotonically. If restoration has been completed, then this value will remain static at the value of the last WAL record received during that restoration. If the server normally starts without manual intervention, this function will return a null value.  
Return type: timestamp with time zone

Restoration control functions control restoration processes. These functions may be executed only during restoration.

- `pg_is_xlog_replay_paused()`  
Description: Returns **true** if restoration is paused.  
Return type: Boolean
- `pg_xlog_replay_pause()`  
Description: Pauses restoration immediately.  
Return type: void
- `pg_xlog_replay_resume()`  
Description: Restarts restoration if it was paused.  
Return type: void
- `gs_get_active_archiving_standby()`  
Description: Queries information about archive standby nodes in the same shard. The standby node name, archive location, and number of archived logs are returned.  
Return type: text, int
- `gs_pitr_get_warning_for_xlog_force_recycle()`  
Description: Checks whether logs are recycled because a large number of logs are stacked in the archive slot after archiving is enabled.  
Return type: Boolean
- `gs_pitr_clean_history_global_barriers(stop_barrier_timestamp cstring)`  
Description: Clears all barrier records generated before the specified time. The earliest barrier record is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.  
Return type: text
- `gs_pitr_archive_slot_force_advance(stop_barrier_timestamp cstring)`  
Description: Forcibly pushes the archive slot and clears unnecessary barrier records. The new archive slot location is returned. The input parameter is of the cstring type and is a Linux timestamp. You need to perform this operation as an administrator or O&M administrator.  
Return type: text

While restoration is paused, no further database changes are applied. In hot standby mode, all new queries will see the same consistent snapshot of the

database, and no further query conflicts will be generated until restoration is resumed.

If streaming replication is disabled, the paused state may continue indefinitely without problem. While streaming replication is in progress, WAL records will continue to be received, which will eventually fill available disk space. This progress depends on the duration of the pause, the rate of WAL generation, and available disk space.

- `gs_recent_barrier_buffer_info(start_time text, end_time text)`

Description: Queries barrier information based on the time range entered by the user to obtain `time_stamp`, `CSN`, `LSN`, and `standard_time`.

Return type: record

Note: To call this function, you must have the `SYSADMIN` or `OPRADMIN` permission. The input parameters **start\_time** and **end\_time** are in the format of year-month-day time, where the time is in the clock format. The maximum query time span is one day. If the time span exceeds the limit, the end time is automatically converted to the limit boundary based on the query start time.

Example:

```
gaussdb=# SELECT * FROM gs_recent_barrier_buffer_info('2024-01-15 23:27:50', '2024-01-15 23:28:00');
```

timestamp	lsn	csn	standard_time
1705332470	00000000/15FFBBA0	41020421	2024-01-15 23:27:50
1705332471	00000000/15FFBDF0	41020422	2024-01-15 23:27:51
1705332472	00000000/15FFC058	41020423	2024-01-15 23:27:52
1705332472	00000000/15FFC0F8	41020424	2024-01-15 23:27:52
1705332473	00000000/15FFC348	41020425	2024-01-15 23:27:53
1705332474	00000000/15FFC598	41020426	2024-01-15 23:27:54
1705332475	00000000/15FFC638	41020427	2024-01-15 23:27:55
1705332476	00000000/15FFC888	41020428	2024-01-15 23:27:56
1705332476	00000000/15FFDC80	41020433	2024-01-15 23:27:56
1705332477	00000000/15FFDD20	41020434	2024-01-15 23:27:57
1705332478	00000000/15FFDF70	41020435	2024-01-15 23:27:58
1705332479	00000000/15FFE1D8	41020436	2024-01-15 23:27:59
1705332480	00000000/15FFE278	41020437	2024-01-15 23:28:00
1705332480	00000000/15FFE4C8	41020438	2024-01-15 23:28:00

(14 rows)

- `gs_show_obs_media_files(slot_name cstring, src cstring, offset int32, limit int32)`

Description: Queries the OBS file list based on the archive slot (**slot\_name**) and OBS directory address (**src**) entered by the user.

Return type: record

Note: To call this function, you must have the `SYSADMIN` or `OPRADMIN` permission. **offset** indicates the query result offset, and **limit** indicates the maximum number of output lines. All files in **src** are queried. Example:

```
gaussdb=# SELECT gs_show_obs_archive_files('ssh','dn1/pg_xlog',0, 5);
gs_show_obs_archive_files
```

(wstdist_ssh/archive/dn1/pg_xlog/
00000001000000000000000007_00_01_00000004_00000002_00000000)
(wstdist_ssh/archive/dn1/pg_xlog/
00000001000000000000000007_00_01_00000103_00000003_00000000)
(wstdist_ssh/archive/dn1/pg_xlog/
00000001000000000000000007_01_01_00000004_00000002_00000000)
(wstdist_ssh/archive/dn1/pg_xlog/
00000001000000000000000007_01_01_00000103_00000003_00000000)
(wstdist_ssh/archive/dn1/pg_xlog/
00000001000000000000000007_02_01_00000004_00000002_00000000)

(5 rows)

- `gs_upload_obs_media_file(slot_name cstring, src cstring, dest cstring, is_forced bool)`

Description: Uploads OBS files based on the archive slot (**slot\_name**), source address (**src**), OBS address (**dest**), and whether to forcibly upload files (**is\_forced**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The original file directory must be the directory specified by *\$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_upload_obs_archive_file('ssh', '/data/gauss/log/stwang/test/000000010000000000000007_02_01_00000004_00000002_00000000', 'dn1/pg_xlog/000000010000000000000019_02_01_00000000_00000000_00000003', true);
gs_upload_obs_archive_file
-----
```

(1 row)

- `gs_download_obs_media_file(slot_name cstring, src cstring, dest cstring)`

Description: Downloads OBS files based on the archive slot (**slot\_name**), download source address (**src**), and local destination address (**dest**).

Return type: void

Note: To call this function, you must have the SYSADMIN or OPRADMIN permission. The download directory must be the directory specified by *\$GAUSSLOG*. Example:

```
gaussdb=# SELECT * FROM gs_download_obs_archive_file('ssh','dn1/pg_xlog/000000010000000000000019_02_01_00000000_00000000_00000003','/data/gauss/log/stwang/test');
gs_download_obs_archive_file

### 7.5.25.5 DR Control Functions for Dual-Database Instances

- `gs_streaming_dr_in_switchover()`

Description: Truncates services during a planned switchover in the primary database instance in streaming replication-based remote DR solutions.

Return type: Boolean, indicating whether the service truncation is successful and whether the switchover process can be performed normally.

### 7.5.25.6 DR Query Functions for Dual-Database Instances

- `gs_get_local_barrier_status()`

Description: If two-city 3DC DR is enabled, logs of the primary database instance and DR database instance are synchronized. The progress of the primary database instance's archived logs and the standby database instance's log replay is determined by flushing barrier logs to the primary database instance and replaying them on the standby database instance. `gs_get_local_barrier_status` is used to query the current log replay status of each node of the DR database instance.

Return type: text

**barrier\_id**: latest barrier ID of a node of the DR database instance.

**barrier\_lsn**: LSN of the latest barrier ID returned by a node in the DR database instance.

**archive\_lsn**: location of archived logs obtained by a node in the DR database instance. This parameter does not take effect currently.

**flush\_lsn**: location of logs that have been flushed to disks on a node in the DR database instance.

- `gs_hadr_has_barrier_creator()`

Description: Checks whether the **barrier\_creator** thread exists on the current node if two-city 3DC DR is enabled. If yes, **true** is returned (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the DR database instance.

- `gs_hadr_in_recovery()`

Description: Checks whether the current node is in barrier-based log restoration if two-city 3DC DR is enabled. If yes, **true** is returned. The DR database instance can be promoted to the production database instance through the switchover process only after the log restoration is complete (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the DR database instance.

- `gs_streaming_dr_get_switchover_barrier()`

Description: Checks whether the DN instance of the DR database instance has received the switchover barrier logs and replayed the logs in two-city 3DC DR solutions based on streaming replication. If it has, **true** is returned. In the DR database instance, the procedure for promoting the DR database instance to the production database instance in the switchover process can be started only after the switchover barrier logs of all DN instances are replayed (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the DR database instance in streaming DR solutions.

- `gs_streaming_dr_service_truncation_check()`

Description: Checks whether the DN instance of the primary database instance has sent the switchover barrier logs in two-city 3DC DR solutions based on streaming replication. If it has, **true** is returned. The procedure for demoting the production database instance to the DR database instance in the switchover process can be started only after the logs are sent (restricted to the system administrator).

Return type: Boolean

Note: This function is used only when a planned switchover is performed on the DR database instance.

- `gs_hadr_local_rto_and_rpo_stat()`

Description: Displays the log flow control information about the primary and standby database instances in the streaming DR scenario. (This view can be used only on the primary DN of the primary database instance. Statistics cannot be obtained from the standby DN or the standby database instance.)

The return value type is record. The types and meanings of the columns are as described in [Table 7-56](#).

**Table 7-56** Parameters of `gs_hadr_local_rto_and_rpo_stat`

Parameter	Type	Description
<code>hadr_sender_node_name</code>	text	Node name, including the primary database instance and the first standby node of the standby database instance.
<code>hadr_receiver_node_name</code>	text	Name of the first standby node of the standby database instance.
<code>source_ip</code>	text	IP address of the primary DN of the primary database instance.
<code>source_port</code>	int	Communication port of the primary DN of the primary database instance.
<code>dest_ip</code>	text	IP address of the first standby DN of the standby database instance.
<code>dest_port</code>	int	Communication port of the first standby DN of the standby database instance.
<code>current_rto</code>	int	Flow control information, that is, log RTO time of the current primary and standby database instances (unit: second).
<code>target_rto</code>	int	Flow control information, that is, the RTO time between the target primary and standby database instances (unit: second).
<code>current_rpo</code>	int	Flow control information, that is, log RPO time of the current primary and standby database instances (unit: second).
<code>target_rpo</code>	int	Flow control information, that is, the RPO time between the target primary and standby database instances (unit: second).
<code>rto_sleep_time</code>	int	RTO flow control information, that is, the expected sleep time (unit: $\mu$ s) required by walsender on the host to reach the specified RTO.
<code>rpo_sleep_time</code>	int	RPO flow control information, that is, the expected sleep time (unit: $\mu$ s) required by xlogInsert on the host to reach the specified RPO.

- `gs_hadr_remote_rto_and_rpo_stat()`

Description: Displays the log flow control information of the primary and standby database instances of other non-local data shards in streaming DR mode. This function is not supported in centralized deployment scenarios.

### 7.5.25.7 Snapshot Synchronization Functions

Snapshot synchronization functions save the current snapshot and return its identifier.

- `pg_export_snapshot()`

Description: Saves the current snapshot and returns its identifier.

Return type: text

Note: **pg\_export\_snapshot** saves the current snapshot and returns a text string identifying the snapshot. This string must be passed to clients that want to import the snapshot. A snapshot can be imported when the **set transaction snapshot snapshot\_id;** command is executed. Doing so is possible only when the transaction is set to the **SERIALIZABLE** or **REPEATABLE READ** isolation level. GaussDB does not support these two isolation levels currently. The output of the function cannot be used as the input of **set transaction snapshot**.

- `pg_export_snapshot_and_csn()`

Description: Saves the current snapshot and returns its identifier. Compared with **pg\_export\_snapshot()**, **pg\_export\_snapshot()** returns a CSN, indicating the CSN of the current snapshot.

Return type: text

### 7.5.25.8 Database Object Functions

#### Database Object Size Functions

Database object size functions calculate the actual disk space used by database objects.

- `pg_column_size(any)`

Description: Specifies the number of bytes used to store a particular value (possibly compressed)

Return type: int

Note: **pg\_column\_size** displays the space for storing an independent data value.

```
gaussdb=# SELECT pg_column_size(1);
pg_column_size
```

```
-----
         4
(1 row)
```

- `pg_database_size(oid)`

Description: Specifies the disk space used by the database with the specified OID.

Return type: bigint

- `pg_database_size(name)`

Description: Specifies the disk space used by the database with the specified name.

Return type: bigint

Note: **pg\_database\_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

Example:

```
gaussdb=# SELECT pg_database_size('testdb');
pg_database_size
-----
      51590112
(1 row)
```

- `pg_relation_size(oid)`

Description: Specifies the disk space used by the table with a specified OID or index.

Return type: `bigint`

- `get_db_source_datasize()`

Description: Estimates the total size of non-compressed data in the current database.

Return type: `bigint`

Note: Perform an analysis before this function is called.

Example:

```
gaussdb=# analyze;
ANALYZE
gaussdb=# SELECT get_db_source_datasize();
get_db_source_datasize
-----
      35384925667
(1 row)
```

- `pg_relation_size(text)`

Description: Specifies the disk space used by the table with a specified name or index. The table name can be schema-qualified.

Return type: `bigint`

- `pg_relation_size(relation regclass, fork text)`

Description: Specifies the disk space used by the specified bifurcating tree ('main', 'fsm', or 'vm') of a certain table or index.

Return type: `bigint`

- `pg_relation_size(relation regclass)`

Description: Is an abbreviation of **`pg_relation_size(..., 'main')`**.

Return type: `bigint`

Note: **`pg_relation_size`** receives the OID or name of a table, an index, or a compressed table, and returns the size.

- `pg_partition_size(oid, oid)`

Description: Specifies the disk space used by the partition with a specified OID. The first **`oid`** is the OID of the table and the second **`oid`** is the OID of the partition.

Return type: `bigint`

- `pg_partition_size(text, text)`

Description: Specifies the disk space used by the partition with a specified name. The first **`text`** is the table name and the second **`text`** is the partition name.

Return type: `bigint`

- `pg_partition_indexes_size(oid, oid)`

Description: Specifies the disk space used by the index of the partition with a specified OID. The first **oid** is the OID of the table and the second **oid** is the OID of the partition.

Return type: bigint

- `pg_partition_indexes_size(text, text)`

Description: Specifies the disk space used by the index of the partition with a specified name. The first **text** is the table name and the second **text** is the partition name.

Return type: bigint

- `pg_indexes_size(regclass)`

Description: Specifies the total disk space used by the index appended to the specified table.

Return type: bigint

- `pg_size_pretty(bigint)`

Description: Converts a size in bytes expressed as a 64-bit integer into a human-readable format with size units.

Return type: text

- `pg_size_pretty(numeric)`

Description: Converts a size in bytes expressed as a numeric value into a human-readable format with size units.

Return type: text

Note: **pg\_size\_pretty** formats the results of other functions into a human-readable format. KB, MB, GB, and TB can be used.

- `pg_table_size(regclass)`

Description: Specifies the disk space used by the specified table, excluding indexes (but including TOAST, free space mapping, and visibility mapping).

Return type: bigint

- `pg_tablespace_size(oid)`

Description: Specifies the disk space used by the tablespace with a specified OID.

Return type: bigint

- `pg_tablespace_size(name)`

Description: Specifies the disk space used by the tablespace with a specified name.

Return type: bigint

Note:

**pg\_tablespace\_size** receives the OID or name of a database and returns the disk space used by the corresponding object.

- `pg_total_relation_size(oid)`

Description: Specifies the disk space used by the table with a specified OID, including the index and the compressed data.

Return type: bigint

- `pg_total_relation_size(regclass)`

Description: Specifies the total disk space used by the specified table, including all indexes and TOAST data.

Return type: bigint

- `pg_total_relation_size(text)`

Description: Specifies the disk space used by the table with a specified name, including the index and the compressed data. The table name can be schema-qualified.

Return type: bigint

Note: **pg\_total\_relation\_size** receives the OID or name of a table or a compressed table, and returns the sizes of the data, related indexes, and the compressed table in bytes.

- `datalength(any)`

Description: Specifies the number of bytes used by an expression of a specified data type (data management space, data compression, or data type conversion is not considered).

Return type: int

Note: **datalength** is used to calculate the space of an independent data value.

Example:

```
gaussdb=# SELECT datalength(1);
datalength
-----
4
(1 row)
```

The following table lists the supported data types and calculation methods.

Data Type		Storage Space	
Numeric data types	Integer types	TINYINT	1
		SMALLINT	2
		INTEGER	4
		BINARY_INTEGER	4
		BIGINT	8
	Arbitrary precision types	DECIMAL	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		NUMERIC	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.

Data Type		Storage Space	
		NUMBER	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
	Sequence integer	SMALLSERIAL	2
		SERIAL	4
		BIGSERIAL	8
		LARGESERIAL	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
	Floating point types	FLOAT4	4
		DOUBLE PRECISION	8
		FLOAT8	8
		BINARY_DOUBLE	8
		FLOAT[(p)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		DEC[(p,s)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
		INTEGER[(p,s)]	Every four decimal digits occupy two bytes. The digits before and after the decimal point are calculated separately.
Boolean data types	Boolean type	BOOLEAN	1
Character data types	Character types	CHAR	n
		CHAR(n)	n
		CHARACTER(n)	n
		NCHAR(n)	n

Data Type		Storage Space	
		VARCHAR(n)	n
		CHARACTER	Actual number of bytes of a character.
		VARYING(n)	Actual number of bytes of a character.
		VARCHAR2(n)	Actual number of bytes of a character.
		NVARCHAR(n)	Actual number of bytes of a character.
		NVARCHAR2(n)	Actual number of bytes of a character.
		TEXT	Actual number of bytes of a character.
		CLOB	Actual number of bytes of a character.
Time data types	Time types	DATE	8
		TIME	8
		TIMEZ	12
		TIMESTAMP	8
		TIMESTAMPZ	8
		SMALLDATETIME	8
		INTERVAL DAY TO SECOND	16
		INTERVAL	16
		RELTIME	4
		ABSTIME	4
		TINTERVAL	12

## Database Object Position Functions

- `pg_relation_filenode(relation regclass)`

Description: Specifies the ID of a filenode with the specified relationship.

Return type: oid

Description: **pg\_relation\_filenode** receives the OID or name of a table, an index, a sequence, or a compressed table, and returns the number of **filenode** allocated to it. **filenode** is the basic component of the file name used by the

relationship. For most tables, the result is the same as that of **pg\_class.relfilenode**. For a specified system directory, **relfilenode** is set to 0 and this function must be used to obtain the correct value. If a relationship that is not stored is transmitted, such as a view, this function returns a null value.

- **pg\_relation\_filepath**(relation regclass)  
Description: Specifies the name of a file path with the specified relationship.  
Return type: text  
Description: **pg\_relation\_filepath** is similar to **pg\_relation\_filenode**, except that **pg\_relation\_filepath** returns the whole file path name (relative to the data directory **PGDATA** of the database) for the relationship.
- **pg\_filenode\_relation**(tablespace oid, filenode oid)  
Description: Obtains the table names corresponding to the tablespace and relfilenode.  
Return type: regclass
- **pg\_partition\_filenode**(partition\_oid)  
Description: Obtains **filenode** corresponding to the OID lock of a specified partitioned table.  
Return type: oid
- **pg\_partition\_filepath**(partition\_oid)  
Description: Specifies the file path name of a partition.  
Return type: text

## Recycle Bin Object Functions

- **gs\_is\_recycle\_object**(classid, objid, objname)  
Description: Determines whether an object is in the recycle bin.  
Return type: Boolean

## 7.5.25.9 Advisory Lock Functions

Advisory lock functions manage advisory locks.

- **pg\_advisory\_lock**(key bigint)  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void  
Note: **pg\_advisory\_lock** locks resources defined by an application. The resources can be identified using a 64-bit or two nonoverlapped 32-bit key values. If another session locks the resources, the function blocks the resources until they can be used. The lock is exclusive. Multiple locking requests are pushed into the stack. Therefore, if the same resource is locked three times, it must be unlocked three times so that it is released to another session.
- **pg\_advisory\_lock**(key1 int, key2 int)  
Description: Obtains an exclusive session-level advisory lock.  
Return type: void

Note: Only users with the sysadmin permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- `pg_advisory_lock(lock_id int4, lock_id int4, database_name Name)`

Description: Obtains the exclusive advisory lock of a specified database by inputting the lock ID and database name.

Return type: void

- `pg_advisory_lock_shared(key bigint)`

Description: Obtains a shared session-level advisory lock.

Return type: void

- `pg_advisory_lock_shared(key1 int, key2 int)`

Description: Obtains a shared session-level advisory lock.

Return type: void

Note: `pg_advisory_lock_shared` works in the same way as `pg_advisory_lock`, except that `pg_advisory_lock_shared` obtains an advisory lock shared with other sessions requesting the lock, while `pg_advisory_lock` obtains an exclusive advisory lock.

- `pg_advisory_unlock(key bigint)`

Description: Releases an exclusive session-level advisory lock.

Return type: Boolean

- `pg_advisory_unlock(key1 int, key2 int)`

Description: Releases an exclusive session-level advisory lock.

Return type: Boolean

Note: `pg_advisory_unlock` releases the obtained exclusive advisory lock. If the release is successful, the function returns **true**. If the lock was not held, it will return **false**. In addition, an SQL warning will be reported by the server.

- `pg_advisory_unlock(lock_id int4, lock_id int4, database_name Name)`

Description: Releases an exclusive advisory lock of a specified database by inputting the lock ID and database name.

Return type: Boolean

Note: If the release is successful, **true** is returned. If no lock is held, **false** is returned.

- `pg_advisory_unlock_shared(key bigint)`

Description: Releases a shared session-level advisory lock.

Return type: Boolean

- `pg_advisory_unlock_shared(key1 int, key2 int)`

Description: Releases a shared session-level advisory lock.

Return type: Boolean

Note: `pg_advisory_unlock_shared` works in the same way as `pg_advisory_unlock`, except it releases a shared session-level advisory lock.

- `pg_advisory_unlock_all()`

Description: Releases all advisory locks owned by the current session.

Return type: void

Note: `pg_advisory_unlock_all` releases all advisory locks owned by the current session. The function is implicitly invoked when the session ends even if the client is abnormally disconnected.

- `pg_advisory_xact_lock(key bigint)`

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

- `pg_advisory_xact_lock(key1 int, key2 int)`

Description: Obtains an exclusive transaction-level advisory lock.

Return type: void

Note: `pg_advisory_xact_lock` works in the same way as `pg_advisory_lock`, except that the lock is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the `sysadmin` permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).

- `pg_advisory_xact_lock_shared(key bigint)`

Description: Obtains a shared transaction-level advisory lock.

Return type: void

- `pg_advisory_xact_lock_shared(key1 int, key2 int)`

Description: Obtains a shared transaction-level advisory lock.

Return type: void

Note: `pg_advisory_xact_lock_shared` works in the same way as `pg_advisory_lock_shared`, except the lock is automatically released at the end of the current transaction and cannot be released explicitly.

- `pg_try_advisory_lock(key bigint)`

Description: Obtains an exclusive session-level advisory lock if available.

Return type: Boolean

Note: `pg_try_advisory_lock` is similar to `pg_advisory_lock`, except `pg_try_advisory_lock` does not block the resource until the resource is released. It either immediately obtains the lock and returns **true** or returns **false**, which indicates the lock cannot be performed currently.

- `pg_try_advisory_lock(key1 int, key2 int)`

Description: Obtains an exclusive session-level advisory lock if available.

Return type: Boolean

Note: Only users with the `sysadmin` permission can add session-level exclusive advisory locks to the key-value pair (65535, 65535).

- `pg_try_advisory_lock_shared(key bigint)`

Description: Obtains a shared session-level advisory lock if available.

Return type: Boolean

- `pg_try_advisory_lock_shared(key1 int, key2 int)`

Description: Obtains a shared session-level advisory lock if available.

Return type: Boolean

Note: `pg_try_advisory_lock_shared` works in the same way as `pg_try_advisory_lock`, except that `pg_try_advisory_lock_shared` attempts to obtain a shared lock instead of an exclusive lock.

- `pg_try_advisory_xact_lock(key bigint)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock(key1 int, key2 int)`  
Description: Obtains an exclusive transaction-level advisory lock if available.  
Return type: Boolean  
Note: `pg_try_advisory_xact_lock` works in the same way as `pg_try_advisory_lock`, except that the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly. Only users with the `sysadmin` permission can add transaction-level exclusive advisory locks to the key-value pair (65535, 65535).
- `pg_try_advisory_xact_lock_shared(key bigint)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean
- `pg_try_advisory_xact_lock_shared(key1 int, key2 int)`  
Description: Obtains a shared transaction-level advisory lock if available.  
Return type: Boolean  
Note: `pg_try_advisory_xact_lock_shared` works in the same way as `pg_try_advisory_lock_shared`, except the lock, if acquired, is automatically released at the end of the current transaction and cannot be released explicitly.
- `lock_cluster_ddl()`  
Description: Attempts to obtain a session-level exclusive advisory lock for all active primary database nodes in the database.  
Return type: Boolean  
Note: Only users with the `sysadmin` permission can call this function.
- `unlock_cluster_ddl()`  
Description: Attempts to add a session-level exclusive advisory lock on the primary database node.  
Return type: Boolean

### 7.5.25.10 Logical Replication Functions

#### NOTE

When using the logical replication functions, set the GUC parameter `wal_level` to **logical**. For details about the configuration, see "Logical Replication > Logical Decoding > Logical Decoding by SQL Function Interfaces" in *Feature Guide*.

- `pg_create_logical_replication_slot('slot_name', 'plugin_name', 'output_order')`  
Description: Creates a logical replication slot.  
Parameter description:
  - `slot_name`  
Indicates the name of the streaming replication slot.  
Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- plugin\_name  
Indicates the name of the plugin.  
Value range: a string, supporting **mppdb\_decoding**
- output\_order  
Indicates the output sequence of the replication slot decoding results.  
This parameter is optional.  
Value range: **0** and **1**. The default value is **0**.
  - **0**: The replication slot decoding results are sorted by transaction COMMIT LSN. In this case, the value of **confirmed\_csn** of the replication slot is **0**. This replication slot is called an LSN-based replication slot.
  - **1**: The replication slot decoding results are sorted by transaction CSN. In this case, the value of **confirmed\_csn** of the replication slot is a non-zero value. This replication slot is called a CSN-based replication slot.

Return type: name, text

Example:

```
gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_lsn','mppdb_decoding',0);
 slotname | xlog_position
-----+-----
 slot_lsn | 0/6D08B58
(1 row)

gaussdb=# SELECT * FROM pg_create_logical_replication_slot('slot_csn','mppdb_decoding',1);
 slotname | xlog_position
-----+-----
 slot_csn | 0/59AD800
(1 row)
```

Note: The first return value is the slot name, and the second one has different meanings in LSN-based replication slots and CSN-based replication slots. For an LSN-based replication slot, the value is **confirmed\_flush** of the replication slot, indicating that transactions whose commit LSN is less than or equal to the value will not be decoded and output. For a CSN-based replication slot, the value is **confirmed\_csn** of the replication slot, indicating that transactions whose CSN is less than or equal to the value will not be decoded and output. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, this function can be called only on the primary node.

- pg\_create\_physical\_replication\_slot('slot\_name', 'isDummyStandby')

Description: Creates a physical replication slot.

Parameter description:

- slot\_name  
Indicates the name of the streaming replication slot.  
Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.
- isDummyStandby  
Reserved parameter.  
Type: bool

Return type: name, text

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. The physical replication slot created by this function does not have restart\_lsn. Therefore, the slot is considered invalid and will be automatically deleted when the checkpoint is performed.

- `pg_drop_replication_slot('slot_name')`

Description: Deletes a streaming replication slot.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

Return type: void

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, this function can be called only on the primary node.

- `pg_logical_slot_peek_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding but does not go to the next streaming replication slot. (The decoded result will be returned again during the next decoding.)

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

- `upto_nchanges`

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically,

decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 NOTE

If any of the **upto\_lsn** and **upto\_nchanges** values is reached, decoding ends.

– **options**: specifies optional parameters, consisting of **options\_name** and **options\_value**.

▪ **include-xids**

Specifies whether the decoded **data** column contains XID information.

Valid value: **0** and **1**. The default value is **1**.

- **0**: The decoded **data** column does not contain XID information.
- **1**: The decoded **data** column contains XID information.

▪ **skip-empty-xacts**

Specifies whether to ignore empty transaction information during decoding.

Value range: **0** and **1**. The default value is **0**.

- **0**: The empty transaction information is not ignored during decoding.
- **1**: The empty transaction information is ignored during decoding.

▪ **include-timestamp**

Specifies whether decoded information contains the **commit** timestamp.

Value range: **0** and **1**. The default value is **0**.

- **0**: The decoded information does not contain the **commit** timestamp.
- **1**: The decoded information contains the **commit** timestamp.

▪ **only-local**

Specifies whether to decode only local logs.

Value range: **0** and **1**. The default value is **1**.

- **0**: Non-local logs and local logs are decoded.
- **1**: Only local logs are decoded.

▪ **force-binary**

Specifies whether to output the decoding result in binary format.

Value range: **0**

- **0**: The decoding result is output in text format.

▪ **white-table-list**

Whitelist parameter, including the schema and table name to be decoded.

Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. The following is an example:

```
SELECT * FROM pg_logical_slot_peek_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');
```

- **max-txn-in-memory**  
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **max-reorderbuffer-in-memory**  
Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **include-user**  
Specifies whether the BEGIN logical log of a transaction records the username of the transaction.  
Value range: **0** and **1**. The default value is **0**.
  - **0**: The BEGIN logical log of a transaction does not contain the username of the transaction.
  - **1**: The BEGIN logical log of a transaction records the username of the transaction.
- **exclude-userids**  
Specifies the OID of a blacklisted user.  
Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.
- **exclude-users**  
Specifies the name of a blacklisted user.  
Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.
- **dynamic-resolution**  
Specifies whether to dynamically parse the names of blacklisted users.

Value range: **0** and **1**. The default value is **1**.

- **0**: If the parameter is set to **0**, an error is reported and the logic decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**.
- **1**: If the parameter is set to **1**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

 **NOTE**

For details about other configuration options, see "Logical Replication > Logical Decoding > Logical Decoding Options" in the *Feature Guide*.

Return type: text, xid, text

Example:

```
gaussdb=# SELECT * FROM pg_logical_slot_peek_changes('slot_lsn',NULL,4096,'skip-empty-xacts','on');
location | xid | data
-----+-----+-----
0/6D0B500 | 46914 | BEGIN 46914
0/6D0B530 | 46914 | {"table_name":"public.t1","op_type":"INSERT","columns_name":

(9 rows)
```

Note: The decoding result returned by the function contains three columns, corresponding to the preceding return value types, which are the LSN (for an LSN-based replication slot) or CSN (for a CSN-based replication slot), XID, and decoded content, respectively. If the **location** column indicates the CSN, the value of the **location** column is updated only when the commit logs are decoded.

Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

- `pg_logical_slot_get_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding and goes to the next streaming replication slot.

Parameter: This function has the same parameters as [pg\\_logical\\_slot\\_peek\\_changes](#). For details, see [pg\\_logical\\_slot\\_peek\\_ch...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. This function can be called on the primary or standby node. If this function is called on the standby node, the corresponding logical replication slot number on the primary node is updated.

#### NOTE

If this function is executed on the standby node, a WAL sender of the primary node is occupied when the replication slot number on the primary node is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary node is updated normally. If this function is executed continuously in a short period of time, the primary node fails to update the slot number and no error is reported.

- `pg_logical_slot_peek_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary mode and does not go to the next streaming replication slot. (The decoded data can be obtained again during the next decoding.)

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, the decoding is complete until the transaction whose CSN is less than or equal to the value is decoded (a transaction whose CSN is greater than the specified CSN may be decoded). For the LSN-based replication slot, the decoding is complete until the first transaction whose COMMIT LSN is greater than or equal to the value is decoded.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

- `upto_nchanges`

Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which

involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to **4**, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 NOTE

If any of the **upto\_lsn** and **upto\_nchanges** values is reached, decoding ends.

– **options**: specifies optional parameters, consisting of **options\_name** and **options\_value**.

▪ **include-xids**

Specifies whether the decoded **data** column contains XID information.

Value range: **0** and **1**. The default value is **1**.

- **0**: The decoded **data** column does not contain XID information.
- **1**: The decoded **data** column contains XID information.

▪ **skip-empty-xacts**

Specifies whether to ignore empty transaction information during decoding.

Value range: **0** and **1**. The default value is **0**.

- **0**: The empty transaction information is not ignored during decoding.
- **1**: The empty transaction information is ignored during decoding.

▪ **include-timestamp**

Specifies whether decoded information contains the **commit** timestamp.

Value range: **0** and **1**. The default value is **0**.

- **0**: The decoded information does not contain the **commit** timestamp.
- **1**: The decoded information contains the **commit** timestamp.

▪ **only-local**

Specifies whether to decode only local logs.

Value range: **0** and **1**. The default value is **1**.

- **0**: Non-local logs and local logs are decoded.
- **1**: Only local logs are decoded.

▪ **force-binary**

Specifies whether to output the decoding result in binary format.

Value range: **0** or **1**. The default value is **0**. The result is output in binary format.

- **white-table-list**  
Whitelist parameter, including the schema and table name to be decoded.  
Value range: a string that contains table names in the whitelist. Different tables are separated by commas (,). An asterisk (\*) is used to fuzzily match all tables. Schema names and table names are separated by periods (.). No space character is allowed. Example:  
**select \* from pg\_logical\_slot\_peek\_binary\_changes('slot1', NULL, 4096, 'white-table-list', 'public.t1,public.t2');**
- **max-txn-in-memory**  
Memory control parameter. The unit is MB. If the memory occupied by a single transaction is greater than the value of this parameter, data is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **max-reorderbuffer-in-memory**  
Memory control parameter. The unit is GB. If the total memory (including the cache) of transactions being concatenated in the sender thread is greater than the value of this parameter, the current decoding transaction is flushed to disks.  
Value range: an integer ranging from 0 to 100. The default value is **0**, indicating that memory control is disabled.
- **include-user**  
Specifies whether the BEGIN logical log of a transaction records the username of the transaction.  
Value range: **0** and **1**. The default value is **0**.
  - **0**: The BEGIN logical log of a transaction does not contain the username of the transaction.
  - **1**: The BEGIN logical log of a transaction records the username of the transaction.
- **exclude-userids**  
Specifies the OID of a blacklisted user.  
Value range: OIDs of blacklisted users. Multiple OIDs are separated by commas (,). The system does not check whether the OIDs exist.
- **exclude-users**  
Specifies the name of a blacklisted user.  
Value range: names of blacklisted users. Multiple names are separated by commas (,). **dynamic-resolution** specifies whether to dynamically parse and identify usernames. If the decoding is interrupted because the user does not exist and the corresponding blacklisted user does not exist at the time when logs are generated, you can set **dynamic-resolution** to **true** or delete the username from the blacklist to start decoding and continue to obtain logical logs.

- **dynamic-resolution**  
Specifies whether to dynamically parse the names of blacklisted users.  
Value range: **0** and **1**. The default value is **1**.
  - **0**: If the parameter is set to **0**, an error is reported and the logic decoding exits when the decoding detects that the user does not exist in blacklist **exclude-users**.
  - **1**: If the parameter is set to **1**, decoding continues when it detects that the user does not exist in blacklist **exclude-users**.

 **NOTE**

Some configuration options do not take effect even if they are configured in functions. For details, see "Logical Replication > Logical Decoding > Logical Decoding Options" in the *Feature Guide*.

Return type: text, xid, bytea

Note: The function returns the decoding result. Each decoding result contains three columns, corresponding to the above return types and indicating the LSN position, XID, and decoded content in binary format, respectively. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.

- `pg_logical_slot_get_binary_changes('slot_name', 'upto_lsn', upto_nchanges, 'options_name', 'options_value')`

Description: Performs decoding in binary mode and does not go to the next streaming replication slot.

Parameter: This function has the same parameters as **pg\_logical\_slot\_peek\_binary\_changes**. For details, see [pg\\_logical\\_slot\\_peek\\_bi...](#)

Note: Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role. Currently, this function can be called only on the primary node.

- `pg_replication_slot_advance ('slot_name', 'upto_lsn')`

Description: Directly goes to the streaming replication slot for a specified **upto\_lsn**, without outputting any decoded result.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- `upto_lsn`

For the CSN-based logical replication slot, it indicates the target CSN before which logs are decoded. During the next decoding, only the transaction results whose CSN is greater than this value will be output. If the input CSN is smaller than the value of **confirmed\_csn** recorded in the current stream replication slot, the function directly returns the decoded result. If the input CSN is greater than the latest CSN that can be obtained or no CSN is input, the latest CSN will be used for decoding.

For the LSN-based logical replication slot, it indicates the target LSN before which logs are decoded. During the next decoding, only the transaction results whose LSN is greater than this value will be output. If the input LSN is smaller than the position recorded in the current streaming replication slot, the function directly returns the decoded result. If the input LSN is greater than the LSN of the current physical log or no LSN is input, the latest LSN will be directly used for decoding.

Value range: a string, for example, '1/2AAFC60', '0/A060', or '3A/0' (a hexadecimal uint64 value containing two uint32 values separated by a slash (/); if any uint32 value is **0**, **0** is displayed.) (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)

Return type: name, text

Note: A return result contains the slot name and LSN or CSN that is actually used for decoding. Users who call this function must have the SYSADMIN permission or the REPLICATION permission, or inherit the `gs_role_replication` permission of the built-in role. This function can be called on the primary or standby node. When this function is called on the standby node, the corresponding logical replication slot number on the primary node is updated.

#### NOTE

This function can be executed on the standby node to synchronously update the corresponding logical replication slot number on the primary node. If this function is executed on the standby node, a WAL sender of the primary node is occupied when the replication slot number on the primary node is updated. The logical decoding function reserves a WAL sender for each logical replication slot. Therefore, if this function is executed in normal scenarios, the logical replication slot number on the primary node is updated normally. If this function is executed continuously in a short period of time, the primary node fails to update the slot number and no error is reported.

- `pg_logical_get_area_changes('LSN_start', 'LSN_end', upto_nchanges, 'decoding_plugin', 'xlog_path', 'options_name', 'options_value')`

Description: Specifies an LSN range or an Xlog file for decoding when no DDL operation is performed.

 NOTE

The constraints are as follows:

- The current network and hardware environment are normal.
- It is recommended that the size of a single tuple be less than or equal to 500 MB. If the size ranges from 500 MB to 1 GB, an error is reported.
- Data page replication is not supported for data retrieval that does not fall into Xlogs.
- When the API is called, only when **wal\_level** is set to **logical**, the generated log files can be parsed. If the used Xlog file is not of the logical level, the decoded content does not have the corresponding value and type, and there is no other impact. If **wal\_level** is not set to **logical**, an error is reported and decoding is not performed.
- The Xlog file can be parsed only by a copy of a completely homogeneous DN, and no DDL operation or VACUUM FULL occurs in the database to ensure that the metadata corresponding to the data can be found.
- Do not read too many Xlog files at a time. If no file is specified for decoding within a specified range, you are advised to read one Xlog file each time. Generally, the memory occupied by an Xlog file during decoding is about two to three times the size of the Xlog file.
- Data before VACUUM FULL cannot be retrieved.
- The Xlog file before scale-out cannot be decoded.
- To decode the UPDATE statement, the table must have a primary key. Otherwise, the WHERE clause in the UPDATE statement is empty.
- In this decoding mode, the content that can be decoded is decoded based on the Xlog text record data, and the decoding is not performed based on transactions. Therefore, data that is not in the Xlog cannot be decoded.
- If no decoding file is specified from the decoding point, the system checks whether DDL occurs between the decoding start point and the latest redo value. If DDL occurs, the system does not decode all data. If a decoding file is specified, the system checks whether DDL occurs between the start point of the decoding file and the last readable content of the file and between the start point of the Xlog in the data directory and the latest redo value. If a DDL operation is detected, the system does not decode all tables.

Note: When separation-of-duty is enabled, only the initial database user can call the function. When separation-of-duty is disabled, the system administrator permission is required.

Parameter description:

- LSN\_start  
Specifies the LSN at the start of decoding.  
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)
- LSN\_end  
Specifies the LSN at the end of decoding.  
Value range: a string, in the format of *xlogid/xrecoff*, for example, '1/2AAFC60'. (If this parameter is set to a null value, the target LSN indicating the end position of decoding is not specified.)
- upto\_nchanges  
Indicates the number of decoded records (including the **begin** and **commit** timestamps). Assume that there are three transactions, which

involve 3, 5, and 7 records, respectively. If **upto\_nchanges** is set to 4, 8 records of the first two transactions will be decoded. Specifically, decoding is stopped when the number of decoded records exceeds the value of **upto\_nchanges** after decoding in the first two transactions is finished.

Value range: a non-negative integer

 **NOTE**

If any of the **LSN** and **upto\_nchanges** values are reached, decoding ends.

- decoding\_plugin

Decoding plug-in, which is a .so plug-in that specifies the output format of the decoded content.

Value range: **mppdb\_decoding** and **sql\_decoding**.

- xlog\_path

Decoding plug-in, which specifies the Xlog absolute path and file level of the decoding file.

Value range: **NULL** or a character string of the absolute path of the Xlog file.

- **options**: This parameter is optional and consists of multiple pairs of **options\_name** and **options\_value**. You can retain the default values. For details, see [pg\\_logical\\_slot\\_peek\\_changes](#).

Example:

```
gaussdb=# CREATE TABLE t1(a int, b int);
CREATE TABLE
gaussdb=# SELECT pg_current_xlog_location();
pg_current_xlog_location
-----
0/5ECBCD48
(1 row)

gaussdb=# INSERT INTO t1 VALUES(1,1);
INSERT 0 1
gaussdb=# UPDATE t1 SET b = 2 WHERE a = 1;
UPDATE 1
gaussdb=# DELETE FROM t1;
DELETE 1
gaussdb=# SELECT * FROM pg_logical_get_area_changes('0/5ECBCD48', NULL, NULL, 'sql_decoding',
NULL);
 location | xid | data
-----+-----+-----
0/5ECBCD78 | 70718 | insert into public.t1 values (1, 1);
0/5ECBCEA0 | 70718 | COMMIT 70718 (at 2023-11-01 10:58:51.448885+08) 39319
0/5ECBCED0 | 70719 | delete from public.t1 where a = 1 and b = 1;insert into public.t1 values (1, 2);
0/5ECBD028 | 70719 | COMMIT 70719 (at 2023-11-01 10:58:56.487796+08) 39320
0/5ECBD210 | 70720 | delete from public.t1 where a = 1 and b = 2;
0/5ECBD338 | 70720 | COMMIT 70720 (at 2023-11-01 10:58:58.856661+08) 39321
(6 rows)

-- For a table with generated columns:
gaussdb=# CREATE TABLE t2(a int, b int generated always as (a + 1) stored);
CREATE TABLE
gaussdb=# SELECT pg_current_xlog_location();
pg_current_xlog_location
-----
0/5F62CFE8
(1 row)

gaussdb=# INSERT INTO t2(a) VALUES(1);
INSERT 0 1
gaussdb=# UPDATE t2 SET a = 2 WHERE a = 1;
```

Return type: text, int, text, text, text, int64, int64, TimestampTz

Example:

```
gaussdb=# SELECT * FROM gs_get_parallel_decode_status();
 slot_name | parallel_decode_num | read_change_queue_length | decode_change_queue_length |
 reader_lsn | working_txn_cnt | working_txn_memory | decoded_time
-----+-----+-----+-----+-----+-----+-----+-----
 slot1 | 2 | queue0: 1005, queue1: 320 | queue0: 63, queue1: 748 | 0/1DCE2578
 | 42 | 192927504 | 2023-01-10 11:18:22+08
(1 row)
```

Note: In the return values, **slot\_name** indicates the replication slot name, **parallel\_decode\_num** indicates the number of parallel decoder threads in the replication slot, **read\_change\_queue\_length** indicates the current length of the log queue read by each decoder thread, **decode\_change\_queue\_length** indicates the current length of the decoding result queue of each decoder thread, **reader\_lsn** indicates the log location read by the reader thread, **working\_txn\_cnt** indicates the number of transactions being concatenated in the current sender thread, **working\_txn\_memory** indicates the total memory (in bytes) occupied by the concatenation transactions in the sender thread, and **decoded\_time** indicates the time of the latest WAL decoded by the replication slot.

#### NOTICE

The value of **decoded\_time** comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed.

- `gs_get_slot_decoded_wal_time(slot_name)`

Description: Queries the latest decoded WAL time of an active replication slot that performs parallel decoding.

Parameter:

- `slot_name`

Specifies the name of the replication slot to be queried.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

Example:

```
gaussdb=# SELECT * FROM gs_get_slot_decoded_wal_time('replication_slot');
 gs_get_slot_decoded_wal_time
-----
 2023-01-10 11:25:22+08
(1 row)
```

Note: The returned values indicate the time of the latest WAL decoded by the replication slot.

**NOTICE**

The returned time comes from checkpoint logs and transaction commit logs, which has a certain error. If no log containing the time is decoded, "2000-01-01 08:00:00+08" (depending on the time zone set in the database) is displayed. When you query the latest decoded WAL log time of a logical replication slot that does not exist, **NULL** is returned. In `gsql`, the display of **NULL** is related to the setting, which can be set using `\pset null'null'`.

- `gs_logical_parallel_decode_status('slot_name')`

Description: Obtains the decoding statistics of an active replication slot that performs parallel logical decoding, including 26 rows of statistical items.

The descriptions of the statistical items are listed in the following table.

Record - (stat\_id int, stat\_name TEXT, value TEXT)

**Table 7-57** Description

Statistical Item	Description
slot_name	Name of the logical replication slot.
reader_lsn	Location of the logic logs to be decoded.
wal_read_total_time	Time required for loading the log module.
wal_wait_total_time	Time required for waiting for log decoding.
parser_total_time	Processing duration of the reader thread.
decoder_total_time	Processing duration of all decoder threads.
sender_total_time	Processing duration of the sender thread.
net_send_total_time	Time required for the network to send logical logs.
net_wait_total_time	Time required for the network to wait for sending logical logs.
net_send_total_bytes	Number of logical log bytes sent by the network.
transaction_count	Number of transactions.
big_transaction_count	Number of large transactions.
max_transaction_tuples	Maximum number of transaction operation tuples.
sent_transaction_count	Number of transactions sent (by the local database).
spill_disk_transaction_count	Number of flushed transactions.
spill_disk_bytes	Total number of bytes flushed to disks.

Statistical Item	Description
spill_disk_count	Number of disk flushing times.
input_queue_full_count	Total number of times that the input queues of all decoder threads are full.
output_queue_full_count	Total number of times that the output queues of all decoder threads are full.
dml_count	Total number of DML statements in WALs decoded by each decoder thread in the local database.
dml_filtered_count	Total number of DML statements in WALs decoded and filtered by each decoder thread in the local database.
toast_count	Number of modified TOAST table rows.
candidate_catalog_xmin	Indicates the <b>catalog_xmin</b> candidate point of the current logical replication slot.
candidate_xmin_lsn	Updates the log confirmation receiving point required by <b>catalog_xmin</b> .
candidate_restart_valid	Updates the log confirmation receiving point required by <b>restart_lsn</b> .
candidate_restart_lsn	Indicates the <b>restart_lsn</b> candidate point of the current logical replication slot.

Parameter description:

- slot\_name

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

Return type: int, text, text

Example:

```
gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
stat_id | stat_name | value
```

```
-----+-----+-----
 1 | slot_name | replication_slot
 2 | reader_lsn | 0/357E180
 3 | wal_read_total_time | 266694599
 4 | wal_wait_total_time | 266691307
 5 | parser_total_time | 39971
 6 | decoder_total_time | 81216
 7 | sender_total_time | 48193
 8 | net_send_total_time | 19388
 9 | net_wait_total_time | 0
10 | net_send_total_bytes | 266897
11 | transaction_count | 7
12 | big_transaction_count | 1
13 | max_transaction_tuples | 4096
```

```

14 | sent_transaction_count      | 7
15 | spill_disk_transaction_count | 1
16 | spill_disk_bytes           | 244653
17 | spill_disk_count           | 4096
18 | input_queue_full_count     | 0
19 | output_queue_full_count    | 0
20 | dml_count                   | 4097
21 | dml_filtered_count         | 0
22 | toast_count                 | 0

24 | candidate_xmin_lsn         | 0/420A598
25 | candidate_restart_valid    | 0/420A598
26 | candidate_restart_lsn      | 0/420A598
(26 rows)

```

Note: According to the definitions of statistical items, they must meet the following requirements:

`wal_read_total_time >= wal_wait_total_time;`

`transaction_count >= big_transaction_count;`

`transaction_count >= sent_transaction_count;`

`transaction_count >= spill_disk_transaction_count;`

`dml_count >= dml_filtered_count;`

`dml_count >= toast_count;`

If `spill_transaction_count == 0`, then `spill_disk_bytes == 0`;

However, frequent locking and unlocking are required, which greatly affects the performance. As a result, the preceding constraints may not be met in extreme cases.

**transaction\_count** indicates the number of transactions in all databases.

**sent\_transaction\_count** indicates the number of transactions sent by the local database because transactions that are not in the local database will not be sent.

If the value of **slot\_name** does not exist, the function does not report an error and the return value is empty.

- `gs_logical_parallel_decode_reset_status('slot_name')`

Description: Resets indicators in

**`gs_logical_parallel_decode_status('slot_name')`**.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

Return type: text

Example:

```

gaussdb=# SELECT * FROM gs_logical_parallel_decode_reset_status('replication_slot');
gs_logical_parallel_decode_reset_status
-----
OK
(1 row)

gaussdb=# SELECT * FROM gs_logical_parallel_decode_status('replication_slot');
stat_id | stat_name | value
-----+-----+-----

```

```
1 | slot_name          | replication_slot
2 | reader_lsn         | 0/357E420
3 | wal_read_total_time | 0
4 | wal_wait_total_time | 0
5 | parser_total_time  | 0
6 | decoder_total_time | 0
7 | sender_total_time  | 0
8 | net_send_total_time | 0
9 | net_wait_total_time | 0
10 | net_send_total_bytes | 0
11 | transaction_count   | 0
12 | big_transaction_count | 0
13 | max_transaction_tuples | 0
14 | sent_transaction_count | 0
15 | spill_disk_transaction_count | 0
16 | spill_disk_bytes    | 0
17 | spill_disk_count    | 0
18 | input_queue_full_count | 0
19 | output_queue_full_count | 0
20 | dml_count           | 0
21 | dml_filtered_count  | 0
22 | toast_count         | 0
23 | candidate_catalog_xmin | 0
24 | candidate_xmin_lsn  | 0/0
25 | candidate_restart_valid | 0/420A598
26 | candidate_restart_lsn | 0/420A598
(26 rows)
```

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

Do not reset a replication slot that is being observed. The error information is as follows:

- a. If **slot\_name** is empty, the following error is reported: "ERROR: inputString should not be NULL is displayed".
  - b. If **slot\_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.
  - c. If **slot\_name** is not empty but the replication slot corresponding to **slot\_name** is being observed, no error is reported but "can't reset during observing! use gs\_logical\_decode\_stop\_observe to stop." is displayed.
- `gs_logical_decode_start_observe('slot_name', window, interval)`

Description: Enables performance sampling for an active logical replication slot that performs parallel decoding.

Parameter:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`). One or two periods cannot be used alone as the replication slot name.

- `window`

Specifies the sampling window.

Value range: an integer ranging from 2 to 1024. Sampling data in the latest *interval*  $\times$  *window* period is collected.

- `interval`

Specifies the performance monitoring interval, in seconds.

Value range: interval type. The minimum value is 1s and the maximum value is 1 minute. Sampling data in the latest *interval* x *window* period is collected.

Return type: text

Example:

```
gaussdb=# SELECT * FROM gs_logical_decode_start_observe('replication_slot',20,5);
gs_logical_decode_start_observe
```

```
-----
OK
(1 row)
```

```
gaussdb=# SELECT * FROM gs_logical_decode_start_observe('replication_slot',20,5);
gs_logical_decode_start_observe
```

```
-----
observe has started!
(1 row)
```

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

Do not enable the observe function for a replication slot that is being observed. The error information is as follows:

1. If **slot\_name** is empty, the following error is reported: "ERROR: inputString should not be NULL is displayed".
2. If **slot\_name** is not empty but does not exist, no error is reported but "invalid slot name" is displayed.
3. If the value of **window** is less than 2, "window has to be >= 2" is displayed.
4. If the value of **window** is greater than 1024, "window has to be <= 1024" is displayed.
5. If the value of **interval** is less than 1s, "sample interval has to be >= 1s" is displayed.
6. If the value of **interval** is greater than 60s, "sample interval has to be <= 60s" is displayed.
7. If **slot\_name** is not empty but the observe function has been enabled for the replication slot corresponding to **slot\_name**, no error is reported and the message "observe has started!" is displayed.

- `gs_logical_decode_stop_observe('slot_name')`

Description: Stops logical replication performance sampling.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- Return type: text

Example:

```
gaussdb=# select * from gs_logical_decode_stop_observe('replication_slot');
gs_logical_decode_stop_observe
```

```
-----
OK
(1 row)
```

```
gaussdb=# select * from gs_logical_decode_stop_observe('replication_slot');
```

(14 rows)

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is an empty record.

- `gs_logical_decode_observe('slot_name')`

Description: Displays logical replication performance data.

Parameter description:

- **slot\_name**

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- Return type: SETOF record

Example:

```
gaussdb=# select * from gs_logical_decode_observe('replication_slot');
 slot_name | sample_time | logical_decode_rate | wal_read_rate | parser_rate |
decoder_rate | sender_rate | net_send_rate
-----+-----+-----+-----+-----+-----+-----+-----

1152000000.000 | 144000000.000 | 0.000
```

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is an empty record. If the denominator is 0, the

latest collected valid data is returned. If the denominator is not 0 and the numerator is 0, 0 is returned.

Formula:

$$\text{logical\_decode\_rate} = (\text{reader\_lsn1} - \text{reader\_lsn2}) / (\text{sample\_time1} - \text{sample\_time2})$$

$$\text{wal\_read\_rate} = (\text{reader\_lsn1} - \text{reader\_lsn2}) / (\text{wal\_read\_total\_time1} - \text{wal\_read\_total\_time2}) - (\text{wal\_wait\_total\_time1} - \text{wal\_wait\_total\_time2})$$

$$\text{parser\_rate} = (\text{reader\_lsn1} - \text{reader\_lsn2}) / (\text{parser\_total\_time1} - \text{parser\_total\_time2})$$

$$\text{decoder\_rate} = (\text{reader\_lsn1} - \text{reader\_lsn2}) / \text{avg}(\text{decoder\_total\_time1}[i] - \text{decoder\_total\_time2}[i])$$

$$\text{sender\_rate} = (\text{reader\_lsn1} - \text{reader\_lsn2}) / (\text{sender\_total\_time1} - \text{sender\_total\_time2}) - (\text{net\_send\_total\_time1} - \text{net\_send\_total\_time2})$$

$$\text{sender\_rate} = (\text{net\_sent\_bytes1} - \text{net\_sent\_bytes2}) / (\text{net\_send\_total\_time1} - \text{net\_send\_total\_time2}) - (\text{net\_wait\_total\_time1} - \text{net\_wait\_total\_time2})$$

- `gs_logical_decode_observe_status('slot_name')`

Description: Queries the monitoring status of a specified logical decoding task.

Parameter description:

- `slot_name`

Indicates the name of the streaming replication slot.

Value range: a string, supporting only lowercase letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.). One or two periods cannot be used alone as the replication slot name.

- Return type: text

Example:

```
gaussdb=# select * from gs_logical_decode_observe_status('replication_slot');
gs_logical_decode_observe_status
-----
START
(1 row)

gaussdb=# select * from gs_logical_decode_observe_status('replication_slot');
gs_logical_decode_observe_status
-----
invalid slot name
(1 row)

gaussdb=# select * from gs_logical_decode_stop_observe('replication_slot');
gs_logical_decode_stop_observe
-----
OK
(1 row)

gaussdb=# select * from gs_logical_decode_observe_status('replication_slot');
gs_logical_decode_observe_status
-----
STOP
(1 row)
```

Note: If the value of **slot\_name** does not exist, the function does not report an error and the return value is **invalid slot name**.

- `gs_get_parallel_decode_thread_info()`

Description: Returns the thread information for parallel decoding.

Return type: int64, text, text, int

Example:

```
gaussdb=# select * from gs_get_parallel_decode_thread_info();
 thread_id | slot_name | thread_type | seq_number
-----+-----+-----+-----
140335364699904 | slot1 | sender | 1
140335214098176 | slot1 | reader | 1
140335325312768 | slot1 | decoder | 1
140335291750144 | slot1 | decoder | 2
140335274968832 | slot1 | decoder | 3
140335258187520 | slot1 | decoder | 4
140335165404928 | slot2 | sender | 1
140335022864128 | slot2 | reader | 1
140335129818880 | slot2 | decoder | 1
140335113037568 | slot2 | decoder | 2
(10 rows)
```

Note: In the return values, **thread\_id** indicates the thread ID, **slot\_name** indicates the replication slot name, and **thread\_type** indicates the thread type (including the sender, reader and decoder), **seq\_number** indicates the sequence number of each thread with same type in the current replication slot. Each parallel decoding connection only has one sender and reader. Therefore, the sequence numbers of the sender and reader are both 1. The sequence numbers of the decoders are arranged from 1 to the decoding degree of parallelism (DOP) of the current replication slot.

- `pg_replication_origin_create (node_name)`

Description: Creates a replication source with a given external name and returns the internal ID assigned to it.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `node_name`  
Name of the replication source to be created.  
Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- `pg_replication_origin_drop (node_name)`

Description: Deletes a previously created replication source, including any associated replay progress.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `node_name`  
Name of the replication source to be deleted.  
Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- `pg_replication_origin_oid (node_name)`

Description: Searches for a replication source by name and returns the internal ID. If no such replication source is found, an error is thrown.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `node_name`

Specifies the name of the replication source to be queried.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

Return type: oid

- `pg_replication_origin_session_setup (node_name)`

Description: Marks the current session for replaying from a given origin, allowing you to track replay progress. This parameter can be used only when no origin is selected. Run the **pg\_replication\_origin\_session\_reset** command to cancel the configuration.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `node_name`

Name of the replication source.

Value range: a string, supporting only letters, digits, underscores (\_), question marks (?), hyphens (-), and periods (.).

- `pg_replication_origin_session_reset ()`

Description: Cancels the **pg\_replication\_origin\_session\_setup()** effect.

Note: The user who calls this function must have the SYSADMIN permission.

- `pg_replication_origin_session_is_setup ()`

Description: Returns a true value if a replication source is selected in the current session.

Note: The user who calls this function must have the SYSADMIN permission.

Return type: Boolean

- `pg_replication_origin_session_progress (flush)`

Description: Returns the replay position of the replication source selected in the current session.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `flush`

Determines whether the corresponding local transaction has been flushed to disk.

Value range: Boolean

Return type: LSN

- `pg_replication_origin_xact_setup (origin_lsn, origin_timestamp)`

Description: Marks the current transaction as recommitted at a given LSN and timestamp. This function can be called only when **pg\_replication\_origin\_session\_setup** is used to select a replication source.

Note: The user who calls this function must have the SYSADMIN permission.

Parameter description:

- `origin_lsn`

Position for replaying the replication source.

Value range: LSN

- `origin_timestamp`

Time point when a transaction is committed

Value range: timestamp with time zone

- `pg_replication_origin_xact_reset ()`  
Description: Cancels the **`pg_replication_origin_xact_setup()`** effect.  
Note: The user who calls this function must have the SYSADMIN permission.
- `pg_replication_origin_advance (node_name, lsn)`  
Description:  
Sets the replication progress of a given node to a given position. This is primarily used to set the initial position, or to set a new position after a configuration change or similar change.  
Note: Improper use of this function may cause inconsistent replication data.  
Note: The user who calls this function must have the SYSADMIN permission.  
Parameter description:
  - `node_name`  
Name of an existing replication source.  
Value range: a string, supporting only letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`).
  - `lsn`  
Position for replaying the replication source.  
Value range: LSN
- `pg_replication_origin_progress (node_name, flush)`  
Description: Returns the position for replaying the given replication source.  
Note: The user who calls this function must have the SYSADMIN permission.  
Parameter description:
  - `node_name`  
Name of the replication source.  
Value range: a string, supporting only letters, digits, underscores (`_`), question marks (`?`), hyphens (`-`), and periods (`.`).
  - `flush`  
Determines whether the corresponding local transaction has been flushed to disk.  
Value range: Boolean
- `pg_show_replication_origin_status()`  
Description: Displays the replication status of the replication source.  
Note: The user who calls this function must have the SYSADMIN permission.  
Return type:
  - **`local_id`**: OID, which specifies the ID of the replication source.
  - **`external_id`**: text, which specifies the name of the replication source.
  - **`remote_lsn`**: LSN of the replication source.
  - **`local_lsn`**: local LSN.

### 7.5.25.11 Other Functions

- `plan_seed()`  
Description: Obtains the seed value of the previous query statement (internal use).  
Return type: int
- `pg_stat_get_env()`  
Description: Obtains the environment variable information of the current node. Only users with the `sysadmin` or `monitor admin` permission can access the environment variable information.  
Return type: record  
Example:

```
gaussdb=# select pg_stat_get_env();
```

pg_stat_get_env
(sgnode,"localhost,XXX.XXX.XXX.XXX",28589,26000,/home/omm,/home/omm/data/single_node,pg_log)

(1 row)
- `pg_catalog.plancache_clean()`  
Description: Clears the global plan cache that is not used on nodes.  
Return type: Boolean
- `pg_catalog.plancache_status()`  
Description: Displays information about the global plan cache on nodes. The information returned by the function is the same as that in [GLOBAL\\_PLANCACHE\\_STATUS](#).  
Return type: record
- `textlen(text)`  
Description: Provides the method of querying the logical length of text.  
Return type: int
- `threadpool_status()`  
Description: Displays the status of worker threads and sessions in the thread pool.  
Return type: record
- `get_local_active_session()`  
Description: Provides sampling records of the historical active sessions stored in the memory of the current node.  
Return type: record
- `pg_stat_get_thread()`  
Description: Provides status information about all threads on the current node. Users with the `sysadmin` or `monitor admin` permission can view information about all threads, and common users can view only their own thread information.  
Return type: record
- `pg_stat_get_sql_count()`  
Description: Provides the counts of the `SELECT`, `UPDATE`, `INSERT`, `DELETE`, and `MERGE INTO` statements executed on the current node. Users with the

sysadmin or monitor admin permission can view information about all users, and common users can view only their own statistics.

Return type: record

- `pg_stat_get_data_senders()`

Description: Provides detailed information about the data-copy sender thread active at the moment.

Return type: record

- `get_wait_event_info()`

Description: Provides detailed information about the wait event.

Return type: record

- `generate_wdr_report(begin_snap_id bigint, end_snap_id bigint, report_type cstring, report_scope cstring, node_name cstring)`

Description: Generates system diagnosis reports based on two snapshots. You need to run the command in the system database. By default, the initial user or users with the monadmin role permission can access the database. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

**Table 7-58** generate\_wdr\_report parameter description

Parameter	Description	Range
<code>begin_snap_id</code>	Snapshot ID that starts the diagnosis report period.	N/A
<code>end_snap_id</code>	Snapshot ID that ends the diagnosis report period. By default, the value of <b>end_snap_id</b> is greater than that of <b>begin_snap_id</b> .	N/A
<code>report_type</code>	Specifies the type of the generated report.	<ul style="list-style-type: none"> <li>• <b>summary</b></li> <li>• <b>detail</b></li> <li>• <b>all</b>: Both <b>summary</b> and <b>detail</b> types are included.</li> </ul>
<code>report_scope</code>	Specifies the scope for a report to be generated.	<ul style="list-style-type: none"> <li>• <b>cluster</b>: database-level information</li> <li>• <b>node</b>: node-level information</li> </ul>

node_name	<p>When <b>report_scope</b> is set to <b>node</b>, set this parameter to the name of the corresponding node. (You can run the <b>select * from pg_node_env;</b> command to query the node name.)</p> <p>If <b>report_scope</b> is set to <b>cluster</b>, this parameter can be omitted, left blank, or set to <b>NULL</b>.</p>	<ul style="list-style-type: none"> <li>• <b>cluster</b>: omitted, empty, or <b>NULL</b>.</li> <li>• <b>node</b>: node name in GaussDB.</li> </ul>
-----------	--	---

- **create\_wdr\_snapshot()**  
Description: Manually generates system diagnosis snapshots. This function requires the **sysadmin** permission.  
Return type: text
- **kill\_snapshot()**  
Description: Kills the WDR snapshot backend thread. Users who call this function must have the SYSADMIN permission, the REPLICATION permission, or inherit the gs\_role\_replication permission of the built-in role.  
Return type: void
- **capture\_view\_to\_json(text, integer)**  
Description: Saves the view result to the directory specified by GUC: **perf\_directory**. If **is\_crossdb** is set to **1**, the view is accessed once for all databases. If the value of **is\_crossdb** is **0**, the current database is accessed only once. Only users with the sysadmin or monitor admin permission can execute this function.  
Return type: int
- **reset\_unique\_sql(text, text, bigint)**  
Description: Clears the unique SQL statements in the memory of the database node. (The sysadmin or monitor admin permission is required.)  
Return type: Boolean

**Table 7-59** reset\_unique\_sql parameter description

Parameter	Type	Description
scope	text	<p>Clearance scope type. The options are as follows:</p> <ul style="list-style-type: none"> <li>• <b>GLOBAL</b>: Clears all nodes. If the value is <b>GLOBAL</b>, this function can be executed only on the primary node.</li> <li>• <b>LOCAL</b>: Clears the current node.</li> </ul>

Parameter	Type	Description
clean_type	text	<ul style="list-style-type: none"> <li>• <b>BY_USERID</b>: Unique SQL statements are cleared based on user IDs.</li> <li>• <b>BY_CNID</b>: Unique SQL statements are cleared based on primary node IDs.</li> <li>• <b>ALL</b>: All data is cleared.</li> </ul>
clean_value	int8	Clearance value corresponding to the clearance type.

- `wdr_xdb_query(db_name_str text, query text)`  
Description: Provides the capability of executing local cross-database queries. For example, when connecting to the **testdb** database, only the initial user has the permission to access the table in the **test** database.  

```
select col1 from wdr_xdb_query('dbname=test','select col1 from t1') as dd(col1 int);
```

  
Return type: record
- `pg_wlm_jump_queue(pid int)`  
Description: Moves a task to the top of the queue of primary database node.  
Return type: Boolean
  - **true**: success
  - **false**: failure
- `gs_wlm_switch_cgroup(pid int, cgroup text)`  
Description: Moves a job to another Cgroup to change the job priority.  
Return type: Boolean
  - **true**: success
  - **false**: failure
- `pv_session_memctx_detail(threadid tid, MemoryContextName text)`  
Description: Records information about the memory context **MemoryContextName** of the thread **tid** into the `threadid_timestamp.log` file in the `$GAUSSLOG/pg_log/${node_name}/dumpmem` directory. `threadid` can be obtained from `sessid` in the **GS\_SESSION\_MEMORY\_DETAIL** view. In the officially released version, only the **MemoryContextName** that is an empty string (two single quotation marks indicate that the input is an empty string) is accepted. In this case, all memory context information is recorded. Otherwise, no operation is performed. This function can be executed only by the administrator.  
Return type: Boolean
  - **true**: success
  - **false**: failure

- `pg_shared_memctx_detail(MemoryContextName text)`  
Description: Records information about the memory context **MemoryContextName** into the `threadid_timestamp.log` file in the `$GAUSSLOG/pg_log/${node_name}/dumpmem` directory. This function is provided only for internal development and test personnel to debug in the DEBUG version. Calling this function in the officially released version does not involve any operation. Only the administrator can execute this function.  
Return type: Boolean
  - **true**: success
  - **false**: failure
- `local_bgwriter_stat()`  
Description: Displays the information about pages flushed by the bgwriter thread of this instance, number of pages in the candidate buffer chain, and buffer elimination information.  
Return type: record
- `local_candidate_stat()`  
Description: Displays the number of pages in the candidate buffer chain of this instance and buffer elimination information, including the normal buffer pool and segment buffer pool.  
Return type: record
- `local_ckpt_stat()`  
Description: Displays the information about checkpoints and flushing pages of the current instance.  
Return type: record
- `local_double_write_stat()`  
Description: Displays the doublewrite file status of the current instance.  
Return type: record

**Table 7-60** local\_double\_write\_stat parameters

Parameter	Type	Description
node_name	text	Instance name
curr_dwn	int8	Sequence number of the doublewrite file
curr_start_page	int8	Start page for restoring the doublewrite file
file_trunc_num	int8	Number of times that the doublewrite file is reused
file_reset_num	int8	Number of reset times after the doublewrite file is full
total_writes	int8	Total number of I/Os of the doublewrite file
low_threshold_writes	int8	Number of I/Os for writing doublewrite files with low efficiency (the number of I/O flushing pages at a time is less than 16)

Parameter	Type	Description
high_threshold_writes	int8	Number of I/Os for writing doublewrite files with high efficiency (the number of I/O flushing pages at a time is more than 421)
total_pages	int8	Total number of pages that are flushed to the doublewrite file area
low_threshold_pages	int8	Number of pages that are flushed with low efficiency
high_threshold_pages	int8	Number of pages that are flushed with high efficiency
file_id	int8	ID of the current doublewrite file

- local\_single\_flush\_dw\_stat()**  
 Description: Displays the elimination of dual-write files on a single page in the instance.  
 Return type: record
- local\_pagewriter\_stat()**  
 Description: Displays the page flushing information and checkpoint information of the current instance.  
 Return type: record
- local\_redo\_stat()**  
 Description: Displays the replay status of the current standby instance.  
 Return type: record  
 Note: The returned replay status includes the current replay position and the replay position of the minimum restoration point.
- local\_recovery\_status()**  
 Description: Displays log flow control information about the primary and standby nodes.  
 Return type: record
- gs\_wlm\_node\_recover(boolean isForce)**  
 Description: Obtains top SQL query statement-level statistics recorded in the current memory. If the input parameter is not **0**, the information is cleared from the memory.  
 Return type: record
- gs\_cgroup\_map\_ng\_conf(group name)**  
 Description: Reads the Cgroup configuration file of a specified logical database.  
 Return type: record
- gs\_wlm\_switch\_cgroup(sess\_id int8, cgroup name)**  
 Description: Switches the Cgroup of a specified session.  
 Return type: record

- `comm_client_info()`  
Description: Queries information about active client connections of a single node.  
Return type: SETOF record
- `pg_get_flush_lsn()`  
Description: Returns the position of the Xlog flushed from the current node.  
Return type: text
- `pg_get_sync_flush_lsn()`  
Description: Returns the position of the Xlog flushed by the majority on the current node.  
Return type: text
- `db_perf.get_global_full_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`  
Description: Obtains full SQL information at the database level. The result can be queried only in the system database but cannot be queried in the user database.  
Return type: record

**Table 7-61** `db_perf.get_global_full_sql_by_timestamp` parameter description

Parameter	Type	Description
<code>start_timestamp</code>	timestamp with time zone	Start point of the SQL start time range.
<code>end_timestamp</code>	timestamp with time zone	End point of the SQL start time range.

- `db_perf.get_global_slow_sql_by_timestamp(start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`  
Description: Obtains slow SQL information at the database level. The result can be queried only in the system database but cannot be queried in the user database.  
Return type: record

**Table 7-62** `db_perf.get_global_slow_sql_by_timestamp` parameter description

Parameter	Type	Description
<code>start_timestamp</code>	timestamp with time zone	Start point of the SQL start time range.
<code>end_timestamp</code>	timestamp with time zone	End point of the SQL start time range.

- `statement_detail_decode(detail text, format text, pretty boolean)`  
Description: Parses the **details** column in a full or slow SQL statement. The result can be queried only in the system database but cannot be queried in the user database.

Return type: text

**Table 7-63** statement\_detail\_decode parameter description

Parameter	Type	Description
<b>detail</b>	text	Set of events generated by the SQL statement (unreadable).
format	text	Parsing output format. The value is <b>plaintext</b> .
pretty	Boolean	Specifies whether to display the text in pretty format when <b>format</b> is set to <b>plaintext</b> . The options are as follows: <ul style="list-style-type: none"> <li>The value <b>true</b> indicates that events are separated by \n.</li> <li>The value <b>false</b> indicates that events are separated by commas (,).</li> </ul>

- pg\_control\_system()  
Description: Returns the status of the system control file.  
Return type: SETOF record
- pg\_control\_checkpoint()  
Description: Returns the system checkpoint status.  
Return type: SETOF record
- get\_prepared\_pending\_xid()  
Description: Returns nextxid when restoration is complete.  
Parameter: nan  
Return type: text
- pg\_clean\_region\_info()  
Description: Clears the regionmap.  
Parameter: nan  
Return type: character varying
- pg\_get\_replication\_slot\_name()  
Description: Obtains the slot name.  
Parameter: nan  
Return type: text
- pg\_get\_running\_xacts()  
Description: Obtains running xact.  
Parameter: nan  
Return type: handle integer, gxid xid, state tinyint, node text, xmin xid, vacuum boolean, timeline bigint, prepare\_xid xid, pid bigint, and next\_xid xid
- pg\_get\_variable\_info()  
Description: Obtains the shared memory variable *cache*.

Parameter: nan

Return type: node\_name text, nextOid oid, nextXid xid, oldestXid xid, xidVacLimit xid, oldestXidDB oid, lastExtendCSNLogpage xid, startExtendCSNLogpage xid, nextCommitSeqNo xid, latestCompletedXid xid, and startupMaxXid xid

- pg\_get\_xidlimit()

Description: Obtains transaction ID information from the shared memory.

Parameter: nan

Return type: nextXid xid, oldestXid xid, xidVacLimit xid, xidWarnLimit xid, xidStopLimit xid, xidWrapLimit xid, and oldestXidDB oid

- pg\_relation\_compression\_ratio()

Description: Queries the compression rate of a table. By default, **1.0** is returned.

Parameter: text

Return type: real

- pg\_relation\_with\_compression()

Description: Queries whether a table is compressed.

Parameter: text

Return type: Boolean

- pg\_stat\_file\_recursive()

Description: Lists all files in the path.

Parameter: location text

Return type: path text, filename text, size bigint, and isdir boolean

- pg\_stat\_get\_activity\_for temptable()

Description: Returns records of backend processes related to the temporary table.

Parameter: nan

Return type: datid oid, timelineid integer, tempid integer, and sessionid bigint

- pg\_stat\_get\_activity\_ng()

Description: Returns records of backend processes related to nodegroup.

Parameter: pid bigint

Return type: datid oid, pid bigint, sessionid bigint, and node\_group text

- pg\_stat\_get\_cgroup\_info()

Description: Returns Cgroup information.

Parameter: nan

Return type: cgroup\_name text, percent integer, usage\_percent integer, shares bigint, usage bigint, cpuset text, relpath text, valid text, and node\_group text

- pg\_stat\_get\_realtime\_info\_internal()

Description: Returns real-time information. Currently, this API is unavailable. **FailedToGetSessionInfo** is returned.

Parameter: oid, oid, bigint, cstring, oid

Return type: text

- pg\_test\_err\_contain\_err()**  
Description: Tests the error type and return information.  
Parameter: integer  
Return type: void
- get\_global\_user\_transaction()**  
Description: Returns transaction information about each user on all nodes.  
Return type: node\_name name, username name, commit\_counter bigint, rollback\_counter bigint, resp\_min bigint, resp\_max bigint, resp\_avg bigint, resp\_total bigint, bg\_commit\_counter bigint, bg\_rollback\_counter bigint, bg\_resp\_min bigint, bg\_resp\_max bigint, bg\_resp\_avg bigint, and bg\_resp\_total bigint
- pg\_collation\_for()**  
Description: Returns the sorting rule corresponding to the input parameter string.  
Parameter: any (Explicit type conversion is required for constants.)  
Return type: text
- pgxc\_unlock\_for\_sp\_database(name Name)**  
This function is unavailable in the current version.
- pgxc\_lock\_for\_sp\_database(name Name)**  
This function is unavailable in the current version.
- copy\_error\_log\_create()**  
Description: Creates the error table (**public.pgxc\_copy\_error\_log**) required for creating the **COPY FROM** error tolerance mechanism.  
Return type: Boolean

 **NOTE**

- This function attempts to create the **public.pgxc\_copy\_error\_log** table. For details about the table, see [Table 7-64](#).
- In addition, it creates a B-tree index on the **relname** column and executes **REVOKE ALL on public.pgxc\_copy\_error\_log FROM public** to manage permissions on the error table (the permissions are the same as those of the COPY statement).
- public.pgxc\_copy\_error\_log** is a row-store table. Therefore, this function can be executed and COPY error tolerance is available only when row-store tables can be created in the database instance. Note that after the GUC parameter **enable\_hadoop\_env** is enabled, row-store tables cannot be created in the database instance (the default value is **off** for GaussDB).
- Same as the error table and the COPY statement, the function requires sysadmin or higher permissions.
- If the **public.pgxc\_copy\_error\_log** table or the **copy\_error\_log\_relname\_idx** index exists before the function creates it, the function will report an error and roll back.

**Table 7-64** Error table public.pgxc\_copy\_error\_log

Column	Type	Description
relname	character varying	Table name in the form of <i>Schema name.Table name</i>

Column	Type	Description
begintime	timestamp with time zone	Time when a data format error was reported
filename	character varying	Name of the source data file where a data format error occurs
lineno	bigint	Number of the row where a data format error occurs in a source data file
rawrecord	text	Raw record of a data format error in the source data file
<b>detail</b>	text	Error details

- `dynamic_func_control(scope text, function_name text, action text, "{params}" text[])`  
 Description: Dynamically enables built-in functions. Currently, only full SQL statements can be dynamically enabled.  
 Return type: record

**Table 7-65** Parameter description of `dynamic_func_control`

Parameter	Type	Description
scope	text	Scope where the function is to be dynamically enabled. Currently, only <b>LOCAL</b> is supported.
function_name	text	Function name. Currently, only <b>STMT</b> is supported.
action	text	When <b>function_name</b> is set to <b>STMT</b> , the value of <b>action</b> can only be <b>TRACK</b> , <b>UNTRACK</b> , <b>LIST</b> , or <b>CLEAN</b> . <ul style="list-style-type: none"> <li>• <b>TRACK</b>: records the full SQL information of normalized SQL statements.</li> <li>• <b>UNTRACK</b>: cancels the recording of full SQL information of normalized SQL statements.</li> <li>• <b>LIST</b>: lists normalized SQL information that is recorded in the current track.</li> <li>• <b>CLEAN</b>: cleans normalized SQL information that is recorded in the current track.</li> </ul>

Parameter	Type	Description
params	text[]	<p>When <b>function_name</b> is set to <b>STMT</b>, the parameters corresponding to different actions are set as follows:</p> <ul style="list-style-type: none"> <li>• <b>TRACK:</b> '{"Normalized SQLID", "L0/L1/L2"}'</li> <li>• <b>UNTRACK:</b> '{"Normalized SQLID"}'</li> <li>• <b>LIST:</b> '{}'</li> <li>• <b>CLEAN:</b> '{}'</li> </ul>

- `gs_parse_page_bypath(path text, blocknum bigint, relation_type text, read_memory boolean)`

Description: Parses a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

**Table 7-66** gs\_parse\_page\_bypath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> <li>For an ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (Physical file name)</i>. For example, <b>base/16603/16394</b>.</li> <li>For the visibility map of an ordinary table, the relative path is <i>Tablespace name/Database OID/Visibility map of the ordinary table</i>. For example, <b>base/16603/16394_vm</b>.</li> <li>For clog files, the parsed content is stored in the <b>pg_clog</b> directory. For example: 000000000000.</li> <li>For csnlog files, the parsed content is stored in the <b>pg_csnlog</b> directory. For example: 000000000000.</li> <li>For undo record files, the relative path is <b>undo/UNDOPERSISTENCE/zondid.segno</b> in the <b>undo</b> directory. Example: <b>undo/permanent/00000.0000009</b>.</li> <li>For undo meta files, the relative path is <b>undo/UNDOPERSISTENCE/zondid.meta.segno</b> in the <b>undo</b> directory. Example: <b>undo/permanent/00000.meta.0000004</b>.</li> <li>You can run the <b>pg_relation_filepath(table_name text)</b> command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call <b>pg_partition_filepath(partition_oid)</b>.</li> <li>Valid path formats are as follows: <ul style="list-style-type: none"> <li>global/relNode</li> <li>base/dbNode/relNode</li> <li>pg_tblspc/spcNode/version_dir/dbNode/relNode</li> </ul> </li> </ul>

Parameter	Type	Description
blocknum	bigint	<ul style="list-style-type: none"> <li>• <b>-1</b>: Information about all blocks (forcibly parsed from disks)</li> <li>• <b>0-MaxBlockNumber</b>: Information about the corresponding block</li> <li>• For B-tree/UB-tree indexes, <b>0</b> indicates the index meta-page.</li> <li>• For undo record files, the logical block number is used. The block number of the corresponding file is greater than or equal to <b>segno</b> x 128 and less than <b>(segno + 1) x 128</b>.</li> <li>• For undo meta files, the logical block number is used. The block number of the corresponding file is greater than or equal to <b>segno</b> x 4 and less than <b>(segno + 1) x 4</b>.</li> </ul>
relation_type	text	<ul style="list-style-type: none"> <li>• <b>heap</b>: Astore table</li> <li>• <b>uheap</b>: Ustore table</li> <li>• <b>btree</b>: B-tree index</li> <li>• <b>ubtree</b>: UB-tree index</li> <li>• <b>segment</b>: segment-page. This parameter is reserved and is not supported currently.</li> <li>• <b>vm</b>: visibility map of the Astore ordinary table</li> <li>• <b>clog</b> (commit log): transaction status log</li> <li>• <b>csnlog</b> (commit sequence number log): snapshot timestamp log</li> <li>• <b>undo_slot</b>: transaction slot information</li> <li>• <b>undo_record</b>: undo record information</li> </ul>
read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>false</b>: The system parses the page from the disk file.</li> <li>• <b>true</b>: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.</li> </ul>

Example:

```
# Parse the information of all pages in the B-tree index file.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# select gs_parse_page_bypath('base/16603/16394', -1, 'btree', false);
           gs_parse_page_bypath
-----
/data_dir/1663_16603_16394_-1.page
(1 row)

# Parse the visibility result of all blocks in the visibility map file.
```

```
gaussdb=# select gs_parse_page_bypath('base/12828/16771_vm', -1, 'vm', false);
gs_parse_page_bypath
-----
/data_dir/1663_12828_16771_-1_vm.page
(1 row)

# Parse the commit log of block 0 in the Clog file.
gaussdb=# select gs_parse_page_bypath('000000000000', 0, 'clog', false);
gs_parse_page_bypath
-----
/data_dir/000000000000.clog
(1 row)
```

The following is an example of an exception error:

```
# An error is reported when the value of the block number exceeds the value range.
gaussdb=# select gs_parse_page_bypath('base/12828/16777', -10, 'heap', false);
ERROR: Blocknum should be between -1 and 4294967294.
CONTEXT: referenced column: gs_parse_page_bypath
```

- gs\_xlogdump\_lsn(start\_lsn text, end\_lsn text)**

Description: Parses Xlogs within the specified LSN range and returns the path for storing the parsed content. You can use **pg\_current\_xlog\_location()** to obtain the current Xlog position.

Return type: text

Parameters: LSN start position and LSN end position

Note: Only the system administrator or O&M administrator can execute this function.
- gs\_xlogdump\_xid(c\_xid xid)**

Description: Parses Xlogs of a specified XID and returns the path for storing the parsed content. You can use **txid\_current()** to obtain the current XID.

Parameter: XID

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.
- gs\_xlogdump\_tablepath(path text, blocknum bigint, relation\_type text)**

Description: Parses logs corresponding to a specified table page and returns the path for storing the parsed content.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

**Table 7-67** gs\_xlogdump\_tablepath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> <li>For an ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (Physical file name)</i>. For example, <b>base/16603/16394</b>.</li> <li>You can run the <b>pg_relation_filepath(table_name text)</b> command to query the relative path of the table file. To obtain the path of the partitioned table, view the <b>pg_partition</b> system catalog and call <b>pg_partition_filepath(partition_oid)</b>.</li> <li>Valid path formats are as follows: <ul style="list-style-type: none"> <li>global/relNode</li> <li>base/dbNode/relNode</li> <li>pg_tblspc/spcNode/version_dir/dbNode/relNode</li> </ul> </li> </ul>
blocknum	bigint	<ul style="list-style-type: none"> <li><b>-1</b>: Information about all blocks (forcibly parsed from disks)</li> <li><b>0–MaxBlockNumber</b>: Information about the corresponding block</li> </ul>
relation_type	text	<ul style="list-style-type: none"> <li><b>heap</b>: Astore table</li> <li><b>uheap</b>: Ustore table</li> <li><b>btree</b>: B-tree index</li> <li><b>ubtree</b>: UB-tree index</li> <li><b>segment</b>: segment-page. This parameter is reserved and is not supported currently.</li> </ul>

- gs\_xlogdump\_parsepage\_tablepath(path text, blocknum bigint, relation\_type text, read\_memory boolean)

Description: Parses the specified table page and logs corresponding to the table page and returns the path for storing the parsed content. It can be regarded as one execution of gs\_parse\_page\_bypath and gs\_xlogdump\_tablepath. The prerequisite for executing this function is that the table file exists. To view logs of deleted tables, call gs\_xlogdump\_tablepath.

Return type: text

Note: Only the system administrator or O&M administrator can execute this function.

**Table 7-68** gs\_xlogdump\_parsepage\_tablepath parameters

Parameter	Type	Description
path	text	<ul style="list-style-type: none"> <li>For an ordinary table, the relative path is <i>Tablespace name/Database OID/Relfilenode of the table (physical file name)</i>, for example, <b>base/16603/16394</b>.</li> <li>You can run the <b>pg_relation_filepath(table_name text)</b> command to query the relative path of the table file. To obtain the path of the partitioned table, view the pg_partition system catalog and call pg_partition_filepath(partition_oid).</li> <li>Valid path formats are as follows: <ul style="list-style-type: none"> <li>global/relNode</li> <li>base/dbNode/relNode</li> <li>pg_tblspc/spcNode/version_dir/dbNode/relNode</li> </ul> </li> </ul>
blocknum	bigint	<ul style="list-style-type: none"> <li><b>-1</b>: Information about all blocks (forcibly parsed from disks)</li> <li><b>0–MaxBlockNumber</b>: Information about the corresponding block</li> </ul>
relation_type	text	<ul style="list-style-type: none"> <li><b>heap</b>: Astore table</li> <li><b>uheap</b>: Ustore table</li> <li><b>btree</b>: B-tree index</li> <li><b>ubtree</b>: UB-tree index</li> <li><b>segment</b>: segment-page. This parameter is reserved and is not supported currently.</li> </ul>
read_memory	Boolean	<ul style="list-style-type: none"> <li><b>false</b>: The system parses the page from the disk file.</li> <li><b>true</b>: The system attempts to parse the page from the shared buffer. If the page does not exist in the shared buffer, the system parses the page from the disk file.</li> </ul>

- gs\_index\_verify(Oid oid, uint32 blkno)  
Description: Checks whether the sequence of keys on the UB-tree index page or index tree is correct.  
Return type: record

**Table 7-69** gs\_index\_verify parameters

Parameter	Type	Description
oid	Oid	<ul style="list-style-type: none"> <li>Index file relfilenode, which can be queried using <b>select relfilenode from pg_class where relname='Index file name'</b>.</li> </ul>
blkno	uint32	<ul style="list-style-type: none"> <li><b>0</b>: indicates that all pages in the index tree are checked.</li> <li>If the value is greater than 0, the index page whose page code is equal to the value of <b>blkno</b> is checked.</li> </ul>

- gs\_index\_recycle\_queue(Oid oid, int type, uint32 blkno)  
Description: Parses the UB-tree index recycling queue information.  
Return type: record

**Table 7-70** gs\_index\_recycle\_queue parameters

Parameter	Type	Description
oid	Oid	<ul style="list-style-type: none"> <li>Index file relfilenode, which can be queried using <b>select relfilenode from pg_class where relname='Index file name'</b>.</li> </ul>
type	int	<ul style="list-style-type: none"> <li><b>0</b>: The entire queue to be recycled is parsed.</li> <li><b>1</b>: The entire empty page queue is parsed.</li> <li><b>2</b>: A single page is parsed.</li> </ul>
blkno	uint32	<ul style="list-style-type: none"> <li>ID of the recycling queue page. This parameter is valid only when <b>type</b> is set to <b>2</b>. The value of <b>blkno</b> ranges from 1 to 4294967294.</li> </ul>

- gs\_stat\_wal\_entrytable(int64 idx)  
Description: Exports the content of the write-ahead log insertion status table in the Xlog.  
Return type: record

**Table 7-71** gs\_stat\_wal\_entrytable parameters

Category	Parameter	Type	Description
Input parameter	idx	int64	<ul style="list-style-type: none"> <li><b>-1</b>: queries all elements in an array.</li> <li><b>0–Maximum value</b>: content of a specific array element.</li> </ul>

Category	Parameter	Type	Description
Output parameter	idx	uint64	Records the subscripts in the corresponding array.
Output parameter	endlsn	uint64	Records the LSN label.
Output parameter	lrc	int32	Records the corresponding LRC.
Output parameter	status	uint32	Determines whether the Xlog corresponding to the current entry has been completely copied to the WAL buffer: <ul style="list-style-type: none"> <li>• <b>0</b>: Not copied.</li> <li>• <b>1</b>: Copied</li> </ul>

- `gs_walwriter_flush_position()`  
Description: Outputs the refresh position of write-ahead logs.  
Return type: record

**Table 7-72** `gs_walwriter_flush_position` parameters

Category	Parameter	Type	Description
Output parameter	last_flush_status_entry	int32	Subscript index obtained after the Xlog flushes the tblEntry of the last flushed disk.
Output parameter	last_scanned_lrc	int32	LRC obtained after the Xlog flushes the last tblEntry scanned last time.
Output parameter	curr_lrc	int32	Latest LRC usage in the WALInsertStatusEntry status table. The LRC indicates the LRC value corresponding to the WALInsertStatusEntry when the next Xlog record is written.

Category	Parameter	Type	Description
Output parameter	curr_byte_pos	uint64	The latest Xlog position after the Xlog is written to the WAL file, which is also the next Xlog insertion point.
Output parameter	prev_byte_size	uint32	Length of the previous Xlog record.
Output parameter	flush_result	uint64	Position of the current global Xlog flush.
Output parameter	send_result	uint64	Xlog sending position on the current host.
Output parameter	shm_rqst_write_pos	uint64	The write position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_rqst_flush_pos	uint64	The flush position of the LogwrtRqst request in the XLogCtl recorded in the shared memory.
Output parameter	shm_result_write_pos	uint64	The write position of the LogwrtResult request in the XLogCtl recorded in the shared memory.
Output parameter	shm_result_flush_pos	uint64	The flush position of the LogwrtResult request in the XLogCtl recorded in the shared memory.
Output parameter	curr_time	text	Current time.

- gs\_walwriter\_flush\_stat(int operation)**  
 Description: Collects statistics on the frequency of writing and synchronizing write-ahead logs, data volume, and Xlog file information.  
 Return type: record

**Table 7-73** gs\_walwriter\_flush\_stat parameters

Category	Parameter	Type	Description
Input parameter	operation	int	<ul style="list-style-type: none"> <li>• <b>-1</b>: Disables the statistics function. (Default value)</li> <li>• <b>0</b>: Enable the statistics function.</li> <li>• <b>1</b>: Query statistics.</li> <li>• <b>2</b>: Reset statistics.</li> </ul>
Output parameter	write_times	uint 64	Number of times that the Xlog calls the write API.
Output parameter	sync_times	uint 64	Number of times that the Xlog calls the sync API.
Output parameter	total_xlog_sync_bytes	uint 64	Total number of backend thread requests for writing data to Xlogs.
Output parameter	total_actual_xlog_sync_bytes	uint 64	Total number of Xlogs that call the sync API for disk flushing.
Output parameter	avg_write_bytes	uint 32	Number of Xlogs written each time the XLogWrite API is called.
Output parameter	avg_actual_write_bytes	uint 32	Number of Xlogs written each time the write API is called.
Output parameter	avg_sync_bytes	uint 32	Average number of Xlogs for each synchronization request.
Output parameter	avg_actual_sync_bytes	uint 32	Actual Xlog amount of disk flushing by calling sync each time.
Output parameter	total_write_time	uint 64	Total time of calling the write operation (unit: $\mu$ s).

Category	Parameter	Type	Description
Output parameter	total_sync_time	uint 64	Total time for calling the sync API (unit: $\mu$ s).
Output parameter	avg_write_time	uint 32	Average time for calling the write API each time (unit: $\mu$ s).
Output parameter	avg_sync_time	uint 32	Average time for calling the sync API each time (unit: $\mu$ s).
Output parameter	curr_init_xlog_segno	uint 64	ID of the latest Xlog segment file.
Output parameter	curr_open_xlog_segno	uint 64	ID of the Xlog segment file that is being written.
Output parameter	last_reset_time	text	Time when statistics were last collected.
Output parameter	curr_time	text	Current time.

- `gs_catalog_attribute_records()`

Description: Returns the definition of each field in a specified system catalog. Only common system catalogs whose OIDs are less than 10000 are supported. Indexes and TOAST tables are not supported.

Parameter: OID of the system catalog

Return type: record
- `gs_comm_proxy_thread_status()`

Description: Collects statistics on data packets sent and received by the proxy communications library **comm\_proxy** when a user-mode network is configured for the database instance.

Parameter: nan

Return type: record

 **NOTE**

The query result of this function is displayed only when the user-mode network is deployed in a centralized environment and **enable\_dfx\_in\_comm\_proxy\_attr** is set to **true**. In other scenarios, an error message is displayed, indicating that queries are not supported.

- **pg\_ls\_tmpdir()**

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql\_tmp**) of the default tablespace.

Parameter: nan

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestamptz	Last file modification time.

- **pg\_ls\_tmpdir(oid)**

Description: Returns the name, size, and last modification time of each file in the temporary directory (**pgsql\_tmp**) of the specified tablespace.

Parameter: oid

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Input parameter	oid	oid	Tablespace ID.
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestamptz	Last file modification time.

- **pg\_ls\_waldir()**

Description: Returns the name, size, and last modification time of each file in the WAL directory.

Parameter: nan

Return type: record

Note: Only the system administrator or monitor administrator can execute this function.

Category	Parameter	Type	Description
Output parameter	name	text	File name.
Output parameter	size	int8	File size (unit: byte).
Output parameter	modification	timestampz	Last file modification time.

- `gs_write_term_log(void)`

Description: Writes a log to record the current **term** value of a DN. The standby DN returns **false**. After the data is successfully written to the primary DN, **true** is returned.

Return type: Boolean

- `gs_stat_space(bool init)`

Description: Queries the status of extended pages when the INSERT operation is performed on a Ustore table.

Return type: record

Category	Parameter	Type	Description
Input parameter	init	bool	Specifies whether to reset the statistics.
Output parameter	access_func	int8	Total number of access times of the <code>relation_get_buffer_for_utuple</code> API.
Output parameter	cache_blk	int8	Number of times that the <code>relation_get_buffer_for_utuple</code> API obtains buffers.
Output parameter	cache_succ	int8	Number of times that the <code>relation_get_buffer_for_utuple</code> API successfully obtains buffers.
Output parameter	nblk_first	int8	Number of times that <code>relation_get_buffer_for_utuple</code> obtains <b>nblocks-1</b> for the first time.

Category	Parameter	Type	Description
Output parameter	nblk_first_suc c	int8	Number of times that relation_get_buffer_for_utuple obtains <b>nblocks-1</b> successfully for the first time.
Output parameter	nblk_second	int8	Number of times that relation_get_buffer_for_utuple obtains <b>nblocks-1</b> for the second time.
Output parameter	nblk_second_ succ	int8	Number of times that relation_get_buffer_for_utuple obtains <b>nblocks-1</b> successfully for the second time.
Output parameter	fsm_first	int8	Number of times that FSM is accessed for the first time.
Output parameter	fsm_first_suc cess	int8	Number of times that FSM is accessed successfully for the first time.
Output parameter	fsm_rewrite	int8	Number of FSM writeback times.
Output parameter	fsm_second	int8	Number of times that FSM is accessed for the second time.
Output parameter	fsm_second_s uccess	int8	Number of times that FSM is accessed successfully for the second time.
Output parameter	prune_count	int8	Number of prune times in relation_get_buffer_for_utuple.
Output parameter	prune_space	int8	Total prune space in relation_get_buffer_for_utuple.
Output parameter	coprune_cou nt	int8	Number of times that joint prune is performed.
Output parameter	coprune_scan _blocks	int8	Total number of pages scanned for joint prune.
Output parameter	coprune_prun e_count	int8	Number of joint prune times.

Category	Parameter	Type	Description
Input parameter	reset	int8	<ul style="list-style-type: none"> <li><b>0</b>: The statistics are reset to the initial value 0 and the statistics are collected again.</li> <li><b>1</b>: The current statistics are displayed.</li> </ul>
Input parameter	out_type	text	<ul style="list-style-type: none"> <li><b>urq</b>: outputs statistics about cyclic queues.</li> <li><b>ubtree</b>: outputs statistics on index pages.</li> <li><b>all</b>: All statistics about cyclic queues and index pages are output.</li> </ul>
Output parameter	relfilenode	oid	Index relfilenode corresponding to the maximum buffer read value.
Output parameter	max_count	int8	Maximum buffer read value.
Output parameter	ave_count	int8	Average buffer read value.

 **NOTE**

- Currently, this API supports only Ustore index tables.
- When this API is executed, the reset operation is performed to clear all records and set all records to 0. If you query the information again, the query result is always 0 until the information is collected next time. The following are query examples:

```
gaussdb=# select * from gs_index_dump_read(0, 'all');
relfilenode | max_count | ave_count
-----+-----+-----
|          |          |
(1 row)
gaussdb=# select * from gs_index_dump_read(1, 'all');
relfilenode | max_count | ave_count
-----+-----+-----
0 |          |          0
0 |          |          0
(2 rows)
```

- `gs_redo_upage(directory_path text, backup_path text, blocknum bigint, relation_type text, xlog_path text, lsn text)`

Description:Redoes a specific Ustore data page that is backed up to a specified LSN and verifies the page in this process. If a damaged page is detected, the page is flushed to the disk and the disk flushing path, page LSN, and damage information is returned; otherwise, the page is redone to the specified LSN and flushed to the disk, and the result is returned. Only system administrators or O&M administrators can execute this function.

Return type: record

Category	Parameter	Type	Description
Input parameter	directory_path	text	Specifies the directory for storing the backup file.
Input parameter	backup_path	text	Relative path of the backup table file, which is combined with the directory where the backup file is located to form the complete path of the table file, for example, <b>base/15635/12488</b> . If the backup file does not exist, set this parameter to null.
Input parameter	blocknum	bigint	<b>0</b> to <i>MaxBlockNumber</i> : block number of the corresponding page.
Input parameter	relation_type	text	<ul style="list-style-type: none"> <li>• <b>uheap</b>: Ustore data page</li> <li>• <b>ubtree</b>: Ustore index page</li> <li>• <b>indexurq</b>: Urq page</li> <li>• <b>undo_record</b>: Undo record page</li> <li>• <b>undo_slot</b>: Transaction slot page</li> </ul>
Input parameter	xlog_path	text	Absolute path of the archive log directory.
Input parameter	lsn	text	The LSN consists of two hexadecimal numbers (32 bits each), which are separated by a slash (/), for example, 2/962D1DF8. If the value is <b>0</b> , the latest version is used.
Output parameter	output_filename	text	Path and name of the file to be flushed to the disk.
Output parameter	output_lsn	text	LSN of the last page redo.
Output parameter	corruption_desc	text	Page damage description.

- `dbe_perf.get_full_sql_by_parent_id_and_timestamp(parent_id bigint, start_timestamp timestamp with time zone, end_timestamp timestamp with time zone)`

Description: Obtains the records of database-level full SQL statements and their substatements that execute a stored procedure in a specified period based on **parent\_id**. The result can be queried only in the system database but cannot be queried in the user database.

Return type: record

Parameter	Type	Description
parent_id	bigint	Specifies the unique_sql_id of the statement calling a stored procedure.
start_timestamp	timestamp with time zone	Start point of the SQL start time range.
end_timestamp	timestamp with time zone	End point of the SQL start time range.

Example:

```

gaussdb=# CREATE TABLE test(a int,b int);
CREATE TABLE
gaussdb=# INSERT INTO test values(1,1);
INSERT 0 1
gaussdb=# CREATE PROCEDURE mypro1() as num int;
gaussdb$# begin
gaussdb$# INSERT INTO test values(2,2);
gaussdb$# DELETE FROM test where a = 2;
gaussdb$# end;
gaussdb$# /
CREATE PROCEDURE

# Enable the parameter to trace the substatements of the stored procedure.
gaussdb=# SET instr_unique_sql_track_type = 'all';
SET

# Enable the parameter. Full statement records are generated in the db_perf.statement_history table.
gaussdb=# SET track_stmt_stat_level = 'L0,L0';
SET

gaussdb=# CALL mypro1();
mypro1
-----

(1 row)

gaussdb=# SET track_stmt_stat_level = 'off,L0';
SET

gaussdb=# SET instr_unique_sql_track_type = 'top';
SET

# Query key information, which is used as a function parameter.
gaussdb=# SELECT query,unique_query_id,start_time,finish_time FROM db_perf.statement_history;
          query          | unique_query_id |      start_time      |      finish_time
-----+-----+-----+-----
set track_stmt_stat_level = 'L0,L0'; | 636388010 | 2023-06-02 17:40:49.176155+08 | 2023-06-02
17:40:49.176543+08
call mypro1();          | 536458473 | 2023-06-02 17:40:59.028144+08 | 2023-06-02

call mypro1();
delete from test where a = ?
insert into test values(?,?)
(3 rows)

```

- gs\_xlogdump\_bylastlsn(last\_lsn text, blocknum bigint, relation\_type text)**  
 Description: Inputs a page LSN and block number, parses the WAL corresponding to the LSN, obtains the last LSN of the corresponding block number, continues parsing until the last LSN is 0 or the WAL of an earlier version has been reused and recycled, and flushes the parsed log to a specified path. Only system administrators or O&M administrators can execute this function. This system function cannot be called by the standby node.

Return type: text

Category	Parameter	Type	Description
Input parameter	last_lsn	text	Parses the LSN of a specified page in hexadecimal notation, for example, 12BA/32CDEDDD. The LSN can be obtained using a page parsing tool (such as gs_parse_page_bypath).
Input parameter	blocknum	bigint	Specifies the logical block number of a page. Value range: <b>-1</b> to <i>MaxBlockNumber</i> . If the block number is set to <b>-1</b> , the default block number is obtained from the WAL.
Input parameter	relation_type	text	Specifies the type of the page to be parsed. Valid value: <b>uheap</b> , <b>ubtree</b> , <b>heap</b> , <b>btree</b> , <b>undo_record</b> , and <b>undo_slot</b> .
Output parameter	output_filepath	text	Specifies the path for flushing WAL parsing results to disks.

**Example:**

```

# Obtain the page LSN.
# Before calling the function, ensure that the file path exists based on the parameter description.
gaussdb=# select * from gs_parse_page_bypath('base/15833/16768', 0, 'uheap', false);
output_filepath
-----
/data1/database/cluster/primary/data/1663_15833_16768_0.page
(1 row)
gaussdb=# select * from gs_xlogdump_bylastlsn('0/4593570', -1, 'uheap');
output_filepath
-----
/data1/database/cluster/primary/data/pg_log/dump/4593570_-1.xlog
(1 row)

```

```
gaussdb=# select * from gs_xlogdump_bylastlsn('0/4593570', 0, 'ubtree');
ERROR: The input lsn 0/4593570 related xlog is not ubtree.
```

### 7.5.25.12 Undo System Functions

- `gs_undo_meta(type, zoneld, location)`

Description: Specifies metadata of a module in the undo system.

Parameter description:

- **type** (metadata type)
  - **0**: indicates metadata corresponding to an undo zone (record).
  - **1**: indicates metadata corresponding to an undo zone(transaction slot).
  - **2**: indicates metadata corresponding to an undo space (record).
  - **3**: indicates metadata corresponding to an undo space(transaction slot).
- **zoneld** (undo zone ID)
  - **-1**: indicates metadata of all undo zones.
  - **0 to 1024 x 1024 - 1**: indicates the metadata of the corresponding zone ID.
- **location** (read location)
  - **0**: indicates that data is read from the current memory.
  - **1**: indicates that data is read from a physical file.

Return type: record

**Table 7-74** `gs_undo_meta` parameters

Category	Parameter	Type	Description
Output parameter	zoneld	oid	Undo zone ID.
Output parameter	persistType	oid	Persistence level.
Output parameter	insert	text	Position of the next undo record to be inserted
Output parameter	discard	text	Position of the undo record that is recycled in common mode

Category	Parameter	Type	Description
Output parameter	end	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.
Output parameter	used	text	Undo space that has been used.
Output parameter	lsn	text	Modifies the LSN of an undo zone.
Output parameter	pid	oid	ID of a process bound to an undo zone.

- `gs_undo_translot(location, zoneId)`

Description: Specifies transaction slot information of the undo system.

Parameter description:

- **location** (read location)
  - **0**: indicates that data is read from the current memory.
  - **1**: indicates that data is read from a physical file.
- **zoneId** (undo zone ID)
  - **-1**: indicates metadata of all undo zones.
  - **0 to 1024 x 1024 - 1**: indicates the metadata of the corresponding zone ID.

Return type: record

**Table 7-75** `gs_undo_translot` parameters

Category	Parameter	Type	Description
Output parameter	groupId	oid	Undo zone ID that is used.
Output parameter	xactId	text	Transaction ID.
Output parameter	startUndoPtr	text	Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.

Category	Parameter	Type	Description
Output parameter	endUndoPtr	text	Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.
Output parameter	lsn	text	Transaction slot pointer.
Output parameter	slot_states	oid	Transaction status. <ul style="list-style-type: none"> <li>• <b>0</b>: committed.</li> <li>• <b>1</b>: being executed.</li> <li>• <b>2</b>: being rolled back.</li> <li>• <b>3</b>: rolled back.</li> </ul>

- `gs_stat_undo([bool init])`  
Description: Collects undo statistics.  
Return type: record

**Table 7-76** `gs_stat_undo` parameters

Category	Parameter	Type	Description
Input parameter	init	bool	(Optional) Specifies whether to clear statistics and restart statistics collection.
Output parameter	curr_used_zone_count	uint32	Number of used undo zones.
Output parameter	top_used_zones	text	Information about the first three undo zones with the maximum usage. The output format is as follows: <ul style="list-style-type: none"> <li>• <b>zoneId1</b>: used size of zone 1.</li> <li>• <b>zoneId2</b>: used size of zone 2.</li> <li>• <b>zoneId3</b>: used size of zone 3.</li> </ul>
Output parameter	curr_used_undo_size	uint32	Total size of the undo tablespace that is being used. The unit is MB.

Category	Parameter	Type	Description
Output parameter	undo_threshold	uint32	Calculation result of the value of the GUC parameter <b>undo_space_limit_size</b> x 80%. The unit is MB.
Output parameter	global_recycle_xid	uint64	XID of the transaction recycled to the undo space. The undo records generated by the transaction whose XID is smaller than the value of XID are recycled.
Output parameter	oldest_xmin	uint64	Oldest active transaction.
Output parameter	total_undo_chain_len	int64	Total length of all accessed undo chains.
Output parameter	max_undo_chain_len	int64	Maximum length of the accessed undo chain.
Output parameter	create_undo_file_count	uint32	Number of created undo files.
Output parameter	discard_undo_file_count	uint32	Number of deleted undo files.
Output parameter	info	text	If the input parameter is <b>false</b> , suggestions on the <b>undo_space_limit_size</b> , <b>undo_limit_size_per_transaction</b> , and <b>undo_retention_time</b> parameters are provided. If the input parameter is <b>true</b> , init (clearing statistics) is required, and only 'The statistics have been initialized.' is displayed.

Example 1: Clear undo statistics.

```
gaussdb=# select * from gs_stat_undo(true);
curr_used_zone_count | top_used_zones | curr_used_undo_size | undo_threshold |
global_recycle_xid | oldest_xmin | total_undo_chain_len | max_undo_chain_len | create_undo_file_coun
```

```
t | discard_undo_file_count | info
-----+-----+-----+-----+-----
| 3 | 0 : 0, 0 : 0, 0 : 0 | 1 | 209715 | 15741 | 15741
| 0 | 0 |
2 | 0 | The statistics have been initialized.
(1 row)
```

**Example 2: Output undo statistics.**

```
gaussdb=# select * from gs_stat_undo(false);
curr_used_zone_count | top_used_zones | curr_used_undo_size | undo_threshold |
global_recycle_xid | oldest_xmin | total_undo_chain_len | max_undo_chain_len | create_undo_file_coun
t | discard_undo_file_count |
info
-----+-----+-----+-----+-----
| 3 | 0 : 0, 0 : 0, 0 : 0 | 1 | 209715 | 16253 | 16253
| 0 | 0 |
2 | 0 | Based on the statistic info from last initialization, undo_space_limit_size is
recommended to set >= 120953 blocks, undo_limit_size_per_transaction is
recommended to set <= 327150 blocks, undo_retention_time is recommended to set <= 259200
seconds. Since last initialization, max undo space used by a single transaction is 32715 blocks.
(1 row)
```

- **gs\_undo\_record(undoptr)**  
Description: Parses undo records.  
Parameter description:  
– **undoptr** (undo record pointer)  
Return type: record
- **gs\_undo\_dump\_parsepage\_mv(relpath text, blkno bigint, reltype text, rmem boolean)**  
Description: Parses the page header information of the disk page in the Ustore table, header information of each tuple, flag bit information, and all historical undo version information that can be queried.  
Return type: text  
Note: Only the system administrator or O&M administrator can execute this function.

 **NOTE**

Currently, this API supports only Ustore tables.

**Table 7-77** gs\_undo\_dump\_parsepage\_mv parameters

Category	Parameter	Type	Description
Input parameter	relpath	text	Relative path of the Ustore table data file, in the format of <i>Tablespace name/Database OID/relfilenode</i> . For example, <b>base/16603/16384</b> . You can run the <b>pg_relation_filepath('tablename')</b> command to query the relative path.
Input parameter	blkno	bigint	<ul style="list-style-type: none"> <li>• <b>-1</b>: All block pages are parsed.</li> <li>• <b>0–MaxBlocNumber</b>: A specified block page is parsed.</li> </ul>
Input parameter	reltype	text	Table type. Currently, only the Ustore table is supported. The value is <b>uheap</b> .
Input parameter	rmem	Boolean	<ul style="list-style-type: none"> <li>• <b>false</b></li> <li>• <b>true</b> Currently, the value can only be <b>false</b>, indicating that the corresponding page is parsed from the disk file.</li> </ul>
Output parameter	output	text	Absolute path of the parsing result file.

- **gs\_undo\_meta\_dump\_zone(zone\_id int, read\_memory boolean)**  
Description: Parses undo zone metadata in an undo module.  
Return type: record

**Table 7-78** gs\_undo\_meta\_dump\_zone parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. <ul style="list-style-type: none"> <li>• <b>-1</b>: All undo zones are queried.</li> <li>• <b>0–1048575</b>: The undo zone metadata is queried based on the zone ID.</li> </ul>
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>

Category	Parameter	Type	Description
Output parameter	zone_id	int	Undo zone ID.
Output parameter	persist_type	int	Persistence level <ul style="list-style-type: none"> <li>• 0: ordinary table</li> <li>• 1: unlogged table</li> <li>• 2: temporary table</li> </ul>
Output parameter	insert	text	Position of the next undo record to be inserted
Output parameter	discard	text	Position of the undo record that is recycled in common mode
Output parameter	forcediscard	text	Position of the undo record that is forcibly recycled. Values smaller than the value of this parameter indicate that the record has been recycled.
Output parameter	lsn	text	Modifies the LSN of a zone.

- `gs_undo_meta_dump_spaces(zone_id int, read_memory boolean)`  
Description: Parses metadata of an undo record space and a transaction slot space in an undo module.  
Return type: record

**Table 7-79** `gs_undo_meta_dump_spaces` parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID. <ul style="list-style-type: none"> <li>• -1: All undo zones are queried.</li> <li>• 0-1048575: The undo zone metadata is queried based on the zone ID.</li> </ul>

Category	Parameter	Type	Description
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>
Output parameter	zone_id	int	Undo zone ID.
Output parameter	undorecord_space_tail	text	End position of the undo record space
Output parameter	undorecord_space_head	text	Start position of the undo record space
Output parameter	undorecord_space_lsn	text	Modifies the LSN of an undo record space.
Output parameter	undoslot_space_tail	text	End position of a transaction slot space
Output parameter	undoslot_space_head	text	Start position of a transaction slot space
Output parameter	undoreslot_space_lsn	text	Modifies the LSN of a transaction slot space.

- `gs_undo_meta_dump_slot(zone_id int, read_memory boolean)`  
Description: Parses transaction slot metadata in an undo module.  
Return type: record

**Table 7-80** gs\_undo\_meta\_dump\_slot parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID <ul style="list-style-type: none"> <li>• <b>-1</b>: All undo zones are queried.</li> <li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li> </ul>
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>
Output parameter	zone_id	int	Undo zone ID.
Output parameter	allocate	text	Allocation position of the undo transaction slot.
Output parameter	recycle	text	Recycling position of the undo transaction slot.
Output parameter	frozen_xid	text	Frozen XID, which is used to determine the visibility.
Output parameter	global_frozen_xid	text	Minimum frozen XID in the system. Transactions whose XID is smaller than the value of this parameter are visible.
Output parameter	recycle_xid	text	Recycled XID. Transactions whose XID is smaller than the value of this parameter are recycled.
Output parameter	global_recycle_xid	text	Minimum recycled XID in the system. Transactions whose XID is smaller than the value of this parameter are recycled.

- gs\_undo\_translot\_dump\_slot(zone\_id int, read\_memory boolean)  
Description: Parses a transaction slot in an undo zone.  
Return type: record

**Table 7-81** gs\_undo\_translot\_dump\_slot parameters

Category	Parameter	Type	Description
Input parameter	zone_id	oid	Undo zone ID. <ul style="list-style-type: none"> <li>• <b>-1</b>: All undo zones are queried.</li> <li>• <b>0-1048575</b>: The undo zone metadata is queried based on the zone ID.</li> </ul>
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>
Output parameter	zone_id	text	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undo_ptr	text	Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.
Output parameter	end_undo_ptr	text	Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.
Output parameter	slot_ptr	text	Position of a transaction slot.
Output parameter	slot_states	oid	Transaction state. <ul style="list-style-type: none"> <li>• <b>0</b>: committed</li> <li>• <b>1</b>: being executed</li> <li>• <b>2</b>: being rolled back</li> <li>• <b>3</b>: rolled back</li> </ul>

- gs\_undo\_translot\_dump\_xid(slot\_xid xid, read\_memory boolean)  
Description: Parses a transaction slot in an undo zone based on the XID.  
Return type: record

**Table 7-82** gs\_undo\_translot\_dump\_xid parameters

Category	Parameter	Type	Description
Input parameter	slot_xid	xid	Transaction ID to be queried.
Input parameter	read_memory	Boolean	<ul style="list-style-type: none"> <li>• <b>true</b>: Data is read from the current memory.</li> <li>• <b>false</b>: Data is read from the physical file.</li> </ul>
Output parameter	zone_id	text	Undo zone ID.
Output parameter	slot_xid	text	Transaction ID.
Output parameter	start_undo_ptr	text	Position where an undo record is inserted at the start of a transaction corresponding to a transaction slot.
Output parameter	end_undoptr	text	Position where an undo record is inserted at the end of a transaction corresponding to a transaction slot.
Output parameter	slot_ptr	text	Position of a transaction slot.
Output parameter	slot_states	oid	Transaction state <ul style="list-style-type: none"> <li>• <b>0</b>: committed</li> <li>• <b>1</b>: being executed</li> <li>• <b>2</b>: being rolled back</li> <li>• <b>3</b>: rolled back</li> </ul>

- gs\_undo\_dump\_record(undoptr bigint)  
Description: Parses undo records.  
Return type: record

**Table 7-83** gs\_undo\_dump\_record parameters

Category	Parameter	Type	Description
Input parameter	undoptr	bigint	Start position of the undo record to be parsed.

Category	Parameter	Type	Description
Output parameter	undoptr	bigint	Start position of the undo record to be parsed.
Output parameter	xactid	text	Transaction ID.
Output parameter	cid	text	Command ID.
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.
Output parameter	partitionoid	text	Partition OID.

**Table 7-84** gs\_undo\_dump\_xid parameters

Category	Parameter	Type	Description
Input parameter	undo_xid	xid	Transaction XID.
Output parameter	undoptr	xid	Start position of the undo record to be parsed.
Output parameter	xactid	text	Transaction ID.
Output parameter	cid	text	Command ID.
Output parameter	reloid	text	Relation OID.
Output parameter	relfilenode	text	Relfinode of the file.
Output parameter	utype	text	Undo record type.
Output parameter	blkprev	text	Position of the previous undo record in the same block.
Output parameter	blockno	text	Block number.
Output parameter	uoffset	text	Undo record offset.
Output parameter	prevurp	text	Position of the previous undo record.
Output parameter	payloadlen	text	Length of the undo record data.
Output parameter	oldxactid	text	Previous transaction ID.

Category	Parameter	Type	Description
Output parameter	partitionoid	text	Partition OID.
Output parameter	tablespace	text	Tablespace.
Output parameter	alreadyread_bytes	text	Length of the read undo record.
Output parameter	prev_undo_rec_len	text	Length of the previous undo record.
Output parameter	td_id	text	ID of the transaction directory.
Output parameter	reserved	text	Reserved flag of the old version tuple stored in an undo record.
Output parameter	flag	text	Status flag of the old version tuple stored in an undo record.
Output parameter	flag2	text	Number of old version tuple columns stored in an undo record.
Output parameter	t_hoff	text	Length of the undo record data header

- `gs_verify_undo_record(type, start_idx, end_idx, location)`

Description: Verifies undo records. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.

Return type: record

**Table 7-85** gs\_verify\_undo\_record parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. <ul style="list-style-type: none"> <li>'urp': verifies all undo records in a specified URP range.</li> <li>'zone': verifies all undo records of all zones in a specified zone range.</li> </ul>
Input parameter	start_idx	int64	Start position. <ul style="list-style-type: none"> <li>When <b>type</b> is set to 'urp', this parameter indicates the start position of undo records.</li> <li>When type is set to 'zone', this parameter indicates the start undo zone ID.</li> </ul>
Input parameter	end_idx	int64	End position. <ul style="list-style-type: none"> <li>When <b>type</b> is set to 'urp', this parameter indicates the end position of undo records.</li> <li>When <b>type</b> is set to 'zone', this parameter indicates the end undo zone ID.</li> </ul>
Input parameter	location	bool	<ul style="list-style-type: none"> <li>0: memory verification</li> <li>1: disk verification</li> </ul> Currently, this parameter can only be set to 1.
Output parameter	zone_id	int64	Undo zone ID.
Output parameter	detail	text	Verification error information.

Example 1: Verify the undo record whose URP is 24.

```
gaussdb=# select * from gs_verify_undo_record('urp', 24, 24, 1);
zone_id | detail
-----+-----
(0 rows)
```

Example 2: If the entered value of **urp** is incorrect, that is, the value is not the start position of the undo record, the system may return a message indicating that the verification result is empty or the verification fails.

```
gaussdb=# select * from gs_verify_undo_record('urp', 35184372173095, 35184372173095, 1);
zone_id | detail
-----+-----
```

```
2 | verification failed: xid is invalid, urp:35184372173095.
(1 row)
```

Example 3: Verify all undo records from zone 0 to zone 2 on the disk.

```
gaussdb=# select * from gs_verify_undo_record('zone', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_verify_undo_slot(type, start_idx, end_idx, location)`  
Description: Verifies undo transaction slots. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.  
Return type: record

**Table 7-86** `gs_verify_undo_slot` parameters

Category	Parameter	Type	Description
Input parameter	type	text	Verification type. <ul style="list-style-type: none"> <li>• <b>'zone'</b>: verifies all transaction slots of all zones in a specified zone range.</li> </ul>
Input parameter	start_idx	int64	Start undo zone ID.
Input parameter	end_idx	int64	End undo zone ID.
Input parameter	location	bool	<ul style="list-style-type: none"> <li>• <b>0</b>: memory verification</li> <li>• <b>1</b>: disk verification</li> </ul> Currently, this parameter can only be set to <b>1</b> .
Output parameter	zone_id	int64	Undo zone ID.
Output parameter	detail	text	Verification error information.

Example: Verify all transaction slot records from zone 0 to zone 2 on the disk.

```
gaussdb=# select * from gs_verify_undo_slot('zone', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_verify_undo_meta(type, start_idx, end_idx, location)`  
Description: Verifies undo metadata. Currently, only the disk verification mode is supported. Offline verification can be performed only when services are not running. Before the verification, you need to manually perform checkpoint flushing.  
Return type: record

**Table 7-87** `gs_verify_undo_meta` parameters

Category	Parameter	Type	Description
Input parameter	<code>type</code>	text	Verification type. The value of <b>type</b> can only be set to 'all'. <ul style="list-style-type: none"> <li>• 'all': verifies all meta information of all zones in a specified zone range.</li> </ul>
Input parameter	<code>start_idx</code>	int64	Start undo zone ID.
Input parameter	<code>end_idx</code>	int64	End undo zone ID.
Input parameter	<code>location</code>	bool	<ul style="list-style-type: none"> <li>• 0: memory verification</li> <li>• 1: disk verification</li> </ul> Currently, this parameter can only be set to 1.
Output parameter	<code>zone_id</code>	int64	Undo zone ID.
Output parameter	<code>detail</code>	text	Verification error information.

Example: Verify all meta information records from zone 0 to zone 2 on the disk.

```
gaussdb=# select * from gs_verify_undo_meta('all', 0, 2, 1);
zone_id | detail
-----+-----
(0 rows)
```

 **NOTE**

If an error is reported when this view is called, contact Huawei technical support.

- `gs_async_rollback_worker_status()`  
Description: Monitors the status of active asynchronous rollback threads.  
Return type: record

**Table 7-88** gs\_async\_rollback\_worker\_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int64	Process ID.
Output parameter	sessionid	int64	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int32	Thread status. <b>0</b> : undefined <b>1</b> : idle <b>2</b> : running
Output parameter	rollback_start_time	timestampz	Timestamp when a thread is started.
Output parameter	idx	uint32	Index of an asynchronous rollback thread in the array.
Output parameter	xid	uint64	XID of the transaction that is being rolled back.
Output parameter	progress	text	Rollback progress of the transaction (number of undo records that have been rolled back/total number of undo records, in percentage).

- `gs_async_rollback_xact_status()`  
Description: Monitors the hash table of asynchronous rollback tasks.  
Return type: record

**Table 7-89** gs\_async\_rollback\_xact\_status parameters

Category	Parameter	Type	Description
Output parameter	xid	xid	XID of the transaction that requires asynchronous rollback.
Output parameter	start_undoptr	uint64	Pointer to the start undo record of the transaction.
Output parameter	end_undoptr	uint64	Pointer to the end undo record of the transaction.
Output parameter	dbid	uint32	ID of the database where the transaction is located.
Output parameter	slot_ptr	uint64	Pointer to the transaction slot corresponding to the transaction.
Output parameter	launched	bool	Checks whether there is an active asynchronous rollback thread.

- gs\_undo\_recycler\_status()  
Description: Monitors the status of asynchronous recycling threads.  
Return type: record

**Table 7-90** gs\_undo\_recycler\_status parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int64	Process ID.
Output parameter	sessionid	int64	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int32	Thread status. <b>0</b> : undefined <b>1</b> : idle <b>2</b> : running
Output parameter	backend_start	timestampz	Timestamp when a thread is started.

Category	Parameter	Type	Description
Output parameter	total_recycle_time	uint64	Total recycling time.
Output parameter	max_recycle_time	uint64	Maximum recycling time.
Output parameter	total_recycle_size	uint64	Total recycled space.
Output parameter	total_recycle_count	uint64	Total number of recycling times.
Output parameter	recycle_sleep_count	uint64	Number of sleep times.
Output parameter	recycle_sleep_time	uint64	Total sleep time.
Output parameter	max_recycle_sleep_time	uint64	Maximum sleep time.
Output parameter	last_recycle_timestamp	uint64	Timestamp of the last successful recycling.
Output parameter	last_update_global_recycle_xid_timestamp	uint64	Timestamp of the last global recycling transaction.

- `gs_undo_launcher_status()`  
Description: Monitors the status of asynchronous rollback launcher threads.  
Return type: record

**Table 7-91** `gs_undo_launcher_status` parameters

Category	Parameter	Type	Description
Output parameter	datid	oid	Database ID.
Output parameter	pid	int64	Process ID.
Output parameter	sessionid	int64	Session ID.
Output parameter	usesysid	oid	ID of the user who initiates the thread.
Output parameter	state	int32	Thread status. <b>0</b> : undefined <b>1</b> : idle <b>2</b> : running

Category	Parameter	Type	Description
Output parameter	backend_start	timestamptz	Timestamp when a thread is started.
Output parameter	total_async_rollback_task_count	uint64	Total number of asynchronous rollback tasks initiated after the database on the local node is started.
Output parameter	average_async_rollback_time	uint64	Average duration of an asynchronous rollback task.
Output parameter	max_async_rollback_time	uint64	Maximum duration of an asynchronous rollback task.
Output parameter	min_async_rollback_time	uint64	Minimum duration of an asynchronous rollback task.

### 7.5.25.13 SQL Statement Concurrency Control Function

- `gs_add_workload_rule(rule_type, rule_name, databases, start_time, end_time, max_workload, option_val)`

Description: Only users with the sysadmin permission can create an SQL statement concurrency control rule.

Parameters: For details, see [Table 7-92](#).

Return type: int8

**Table 7-92** `gs_add_workload_rule` parameters

Parameter	Type	Description	Value Range
rule_type	text	Type of the concurrency control rule, which is case insensitive.	<p><b>"sqlid"</b>: Concurrency control is based on the unique SQL ID.</p> <p><b>"select", "insert", "update", "delete", and "merge"</b>: Concurrency control is based on the query type and keyword.</p> <p><b>"resource"</b>: Instance-level concurrency control is based on the system resource usage.</p>

Parameter	Type	Description	Value Range
rule_name	name	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or <b>NULL</b> .
databases	name[]	Array of database names for which the concurrency control rule takes effect. The value is case-sensitive.	List of names of created databases. The value can be <b>NULL</b> , indicating that the configuration takes effect in all databases.  Currently, the database list takes effect only when <b>rule_type</b> is set to a query type because a unique SQL ID is bound to a database and belongs to only one database. The concurrency control rules based on resource usage take effect for instances, that is, all databases.
start_time	timestampz	Start time of a concurrency control rule.	The value can be <b>NULL</b> , indicating that it takes effect from now on.
end_time	timestampz	End time of a concurrency control rule.	The value can be <b>NULL</b> , indicating that the rule is always effective.
max_workload	int8	Maximum number of concurrent requests set in a concurrency control rule.	-

Parameter	Type	Description	Value Range
option_val	text[]	Supplementary information about the concurrency control rule.	<p>It matches <b>rule_type</b>. The matching relationship is as follows:</p> <ul style="list-style-type: none"> <li>• <b>"sqlid"</b>: specifies the unique ID of the SQL statement whose concurrency is to be controlled and slow SQL control rule. The format is '{id=1234, time_limit=100, max_execute_time=500, max_iops=1}', in which <b>id</b> indicates the unique SQL ID and is mandatory. You can obtain it from the <code>dbe_perf.statement</code> or <code>pg_stat_activity</code> view. Others are optional. For details about their meanings, see section "Hint for Setting Slow SQL Control Rules."</li> <li>• <b>"select", "insert", "update", "delete", and "merge"</b>: specifies the keyword sequence for concurrency control, which is case insensitive and can be <b>NULL</b>.</li> <li>• <b>"resource"</b>: specifies the resource threshold for triggering instance-level concurrency control. The value is in the format of '{cpu-80, memory-70}', indicating the OS resource threshold for triggering instance-level concurrency control. The value can be <b>NULL</b>, indicating that concurrency control is performed regardless of the resource usage.</li> </ul>

Example:

```
gaussdb=# select gs_add_workload_rule('sqlid', 'rule for one query', '', now(), '', 20, '{id=32413214}');
gs_add_workload_rule
```

```

1
(1 row)
gaussdb=# create database db1;
gaussdb=# create database db2;
gaussdb=# select gs_add_workload_rule('select', 'rule for select', '{db1, db2}', '', '', 100, '{tb1, tb2}');
gs_add_workload_rule
-----
2
(1 row)
gaussdb=# select gs_add_workload_rule('resource', 'rule for resource', '{}', '', '', 20, '{cpu-80}');
gs_add_workload_rule
-----
3
(1 row)

```

- `gs_update_workload_rule(rule_id, rule_name, databases, start_time, end_time, max_workload, option_val)`

Description: To update an SQL statement concurrency control rule, users need to reset all parameters instead of only some parameters. Users must have the sysadmin permission.

Parameters: For details, see [Table 7-93](#).

Return type: Boolean

**Table 7-93** `gs_update_workload_rule` parameters

Parameter	Type	Description	Value Range
<code>rule_id</code>	<code>int8</code>	ID of the concurrency control rule to be updated.	-
<code>rule_name</code>	<code>name</code>	Name of a concurrency control rule, which is used to search for the concurrency control rule.	Any character string or <b>NULL</b> .
<code>databases</code>	<code>name[]</code>	Array of database names for which the concurrency control rule takes effect. The value is case-sensitive.	List of names of created databases. The value can be <b>NULL</b> , indicating that the configuration takes effect in all databases. Currently, the database list takes effect only when <b>rule_type</b> is set to a query type because a unique SQL ID is bound to a database and belongs to only one database. The concurrency control rules based on resource usage take effect for instances, that is, all databases.

Parameter	Type	Description	Value Range
start_time	timestampz	Start time of a concurrency control rule.	The value can be <b>NULL</b> , indicating that it takes effect from now on.
end_time	timestampz	End time of a concurrency control rule.	The value can be <b>NULL</b> , indicating that the rule is always effective.
max_workload	int8	Maximum number of concurrent requests set in a concurrency control rule.	-

Parameter	Type	Description	Value Range
option_val	text[]	Supplementary information about the concurrency control rule.	<p>It matches <b>rule_type</b>. The matching relationship is as follows:</p> <ul style="list-style-type: none"> <li>• <b>"sqlid"</b>: specifies the unique ID of the SQL statement whose concurrency is to be controlled and slow SQL control rule. The format is '{id=1234, time_limit=100, max_execute_time=500, max_iops=1}', in which <b>id</b> indicates the unique SQL ID and is mandatory. You can obtain it from the <code>dbe_perf.statement</code> or <code>pg_stat_activity</code> view. Others are optional. For details about their meanings, see section "Hint for Setting Slow SQL Control Rules."</li> <li>• <b>"select", "insert", "update", "delete", and "merge"</b>: specifies the keyword sequence for concurrency control, which is case insensitive and can be <b>NULL</b>.</li> <li>• <b>"resource"</b>: specifies the resource threshold for triggering instance-level concurrency control. The value is in the format of '{cpu-80, memory-70}', indicating the OS resource threshold for triggering instance-level concurrency control. The value can be <b>NULL</b>, indicating that concurrency control is performed regardless of the resource usage.</li> </ul>

Example:

```
gaussdb=# create database db1;
gaussdb=# select gs_update_workload_rule(2, 'rule for select 2', '{db1}', now(), '', 50, '{tb1}');
gs_update_workload_rule
-----
t
(1 row)
```

- `gs_delete_workload_rule(rule_id int8)`

Description: Only users with the sysadmin permission can delete an SQL statement concurrency control rule.

Parameter: **rule\_id** indicates the ID of the concurrency control rule to be updated. The type is int8.

Return type: Boolean

Example:

```
gaussdb=# select gs_delete_workload_rule(3);
gs_delete_workload_rule
-----
t
(1 row)
```

- `gs_get_workload_rule_stat(rule_id)`

Description: Only users with the sysadmin permission can query the number of SQL statements blocked by an SQL statement concurrency control rule.

Parameter: **rule\_id** indicates the ID of the concurrency control rule to be queried. The type is int8. You can set **rule\_id** to **-1**, indicating that all SQL statement concurrency control rules are queried.

Return type:

Name	Type	Description
rule_id	int8	ID of the SQL statement concurrency control rule.
validate_count	int8	Number of SQL statements intercepted by the SQL statement concurrency control rule.

Example:

```
gaussdb=# select * from gs_get_workload_rule_stat(1);
rule_id | validate_count
-----+-----
1 | 0
(1 row)
gaussdb=# select * from gs_get_workload_rule_stat(-1);
rule_id | validate_count
-----+-----
1 | 0
2 | 0
(2 rows)
```

## 7.5.26 Statistics Information Functions

Statistics information functions are divided into the following two categories: functions that access databases, using the OID of each table or index in a database to mark the database for which statistics are generated; functions that

access servers, identified by the server process ID, whose value ranges from 1 to the number of currently active servers.

- `pg_stat_get_db_conflict_tablespace(oid)`  
Description: Specifies the number of queries canceled due to a conflict between the restored tablespace and the deleted tablespace in the database.  
Return type: bigint
- `pg_control_group_config()`  
Description: Prints Cgroup configurations on the current node. Only users with the SYSADMIN permission can execute this function.  
Return type: record
- `pg_stat_get_db_stat_reset_time(oid)`  
Description: Specifies the most recent time when database statistics were reset. It is initialized to the system time during the first connection to each database. The reset time is updated when you call `pg_stat_reset` on the database and execute `pg_stat_reset_single_table_counters` against any table or index in it.  
Return type: timestamptz
- `pg_stat_get_function_total_time(oid)`  
Description: Specifies the total wall clock time spent in the function, in microseconds. The time spent on this function calling other functions is included.  
Return type: bigint
- `pg_stat_get_xact_tuples_returned(oid)`  
Description: Specifies the number of rows read through sequential scans when the parameter is a table in the current transaction or the number of index entries returned when the parameter is an index.  
Return type: bigint
- `pg_lock_status()`  
Description: Queries information about locks held by open transactions. All users can execute this function.  
Return type: For details, see the return result of [PG\\_LOCKS](#), which is obtained by querying this function.
- `gs_lwlock_status()`  
Description: Queries information about all lightweight locks in the database system, including lock waiting and lock holding information. All users can execute this function.  
Return type: setofrecord
- `pg_stat_get_xact_numscans(oid)`  
Description: Specifies the number of sequential scans performed when the parameter is a table in the current transaction or the number of index scans performed when the parameter is an index.  
Return type: bigint
- `pg_stat_get_xact_blocks_fetched(oid)`  
Description: Specifies the number of disk block fetch requests for a table or an index in the current transaction.

- Return type: bigint
- `pg_stat_get_xact_blocks_hit(oid)`  
Description: Specifies the number of disk block fetch requests for tables or indexes found in cache in the current transaction.  
Return type: bigint
  - `pg_stat_get_xact_function_calls(oid)`  
Description: Specifies the number of times the function is called in the current transaction.  
Return type: bigint
  - `pg_stat_get_xact_function_self_time(oid)`  
Description: Specifies the time spent on this function in the current transaction, excluding the time spent on this function internally calling other functions.  
Return type: bigint
  - `pg_stat_get_xact_function_total_time(oid)`  
Description: Specifies the total wall clock time (in microseconds) spent on the function in the current transaction, including the time spent on this function internally calling other functions.  
Return type: bigint
  - `pg_stat_get_wal_senders()`  
Description: Queries walsender information on the primary node.  
Return type: setofrecord  
The following table describes return columns.

**Table 7-94** Return column description

Column	Type	Description
pid	bigint	Thread ID of the WAL sender
sender_pid	integer	Lightweight thread ID of the WAL sender
local_role	text	Type of the primary node
peer_role	text	Type of the standby node
peer_state	text	Status of the standby node
state	text	Status of the WAL sender
catchup_start	timestamp with time zone	Startup time of a catchup task

Column	Type	Description
catchup_end	timestamp with time zone	End time of a catchup task
sender_sent_location	text	Sending position of the primary node
sender_write_location	text	Writing position of the primary node
sender_flush_location	text	Flushing position of the primary node
sender_replay_location	text	Redo position of the primary node
receiver_received_location	text	Receiving position of the standby node
receiver_write_location	text	Writing position of the standby node
receiver_flush_location	text	Flushing position of the standby node
receiver_replay_location	text	Redo position of the standby node
sync_percent	text	Synchronization percentage
sync_state	text	Synchronization status
sync_group	text	Group to which the synchronous replication belongs
sync_priority	text	Priority of synchronous replication
sync_most_available	text	Maximum availability mode
channel	text	Channel information of the WAL sender

- get\_paxos\_replication\_info()**  
 Description: Queries the primary/standby replication status in Paxos mode.  
 Return type: setofrecord  
 The following table describes return columns.

**Table 7-95** Return column description

Column	Type	Description
paxos_write_location	text	Location of the Xlog that has been written to the Distribute Consensus Framework (DCF)
paxos_commit_location	text	Location of the Xlog agreed in the DCF
local_write_location	text	Writing position of a node
local_flush_location	text	Flushing position of a node
local_replay_location	text	Redo position of a node
dcf_replication_info	text	DCF module information of a node

- `pg_stat_get_stream_replications()`  
Description: Queries the primary/standby replication status.  
Return type: setofrecord  
The following table describes return values.

**Table 7-96** Return value description

Return Parameter	Type	Description
local_role	text	Local role
static_connections	integer	Connection statistics
db_state	text	Database status
detail_information	text	Detailed information

- `pg_stat_get_db_numbackends(oid)`  
Description: Specifies the number of active server processes for a database.  
Return type: integer
- `pg_stat_get_db_xact_commit(oid)`  
Description: Specifies the number of transactions committed in a database.  
Return type: bigint
- `pg_stat_get_db_xact_rollback(oid)`  
Description: Specifies the number of transactions rolled back in a database.  
Return type: bigint
- `pg_stat_get_db_blocks_fetched(oid)`  
Description: Specifies the number of disk blocks fetch requests for a database.

- Return type: bigint
- `pg_stat_get_db_blocks_hit(oid)`  
Description: Specifies the number of disk block fetch requests found in cache for a database.  
Return type: bigint
  - `pg_stat_get_db_tuples_returned(oid)`  
Description: Specifies the number of tuples returned for a database.  
Return type: bigint
  - `pg_stat_get_db_tuples_fetched(oid)`  
Description: Specifies the number of tuples fetched for a database.  
Return type: bigint
  - `pg_stat_get_db_tuples_inserted(oid)`  
Description: Specifies the number of tuples inserted in a database.  
Return type: bigint
  - `pg_stat_get_db_tuples_updated(oid)`  
Description: Specifies the number of tuples updated in a database.  
Return type: bigint
  - `pg_stat_get_db_tuples_deleted(oid)`  
Description: Specifies the number of tuples deleted in a database.  
Return type: bigint
  - `pg_stat_get_db_conflict_lock(oid)`  
Description: Specifies the number of lock conflicts in a database.  
Return type: bigint
  - `pg_stat_get_db_deadlocks(oid)`  
Description: Specifies the number of deadlocks in a database.  
Return type: bigint
  - `pg_stat_get_numscans(oid)`  
Description: Number of sequential row scans done if parameters are in a table, or the number of index rows if parameters are in an index.  
Return type: bigint
  - `pg_stat_get_role_name(oid)`  
Description: Obtains the username based on the user OID. Only users with the SYSADMIN and MONADMIN permissions can access the information.  
Return type: text  
Example:

```
gaussdb=# select pg_stat_get_role_name(10);
 pg_stat_get_role_name
-----
 aabbcc
(1 row)
```
  - `pg_stat_get_tuples_returned(oid)`  
Description: Specifies the number of sequential rows read by sequential scans if parameters are in a table, or the number of index rows if parameters are in an index.

- Return type: bigint

  - `pg_stat_get_tuples_fetched(oid)`  
Description: Specifies the number of table rows fetched by bitmap scans if parameters are in a table, or the number of table rows fetched by simple index scans if parameters are in an index.  
Return type: bigint
  - `pg_stat_get_tuples_inserted(oid)`  
Description: Specifies the number of rows inserted into a table.  
Return type: bigint
  - `pg_stat_get_tuples_updated(oid)`  
Description: Specifies the number of rows updated in a table.  
Return type: bigint
  - `pg_stat_get_tuples_deleted(oid)`  
Description: Specifies the number of rows deleted from a table.  
Return type: bigint
  - `pg_stat_get_tuples_changed(oid)`  
Description: Specifies the total number of inserted, updated, and deleted rows after a table was last analyzed or autoanalyzed.  
Return type: bigint
  - `pg_stat_get_tuples_hot_updated(oid)`  
Description: Specifies the number of rows hot updated in a table.  
Return type: bigint
  - `pg_stat_get_live_tuples(oid)`  
Description: Specifies the number of live rows in a table.  
Return type: bigint
  - `pg_stat_get_dead_tuples(oid)`  
Description: Specifies the number of dead rows in a table.  
Return type: bigint
  - `pg_stat_get_blocks_fetched(oid)`  
Description: Specifies the number of disk block fetch requests for a table or an index.  
Return type: bigint
  - `pg_stat_get_blocks_hit(oid)`  
Description: Specifies the number of disk block requests found in cache for a table or an index.  
Return type: bigint
  - `pg_stat_get_xact_tuples_fetched(oid)`  
Description: Specifies the number of tuple rows scanned in a transaction.  
Return type: bigint
  - `pg_stat_get_xact_tuples_inserted(oid)`  
Description: Specifies the number of tuple inserted into the active subtransactions related to a table.

- Return type: bigint
- `pg_stat_get_xact_tuples_deleted(oid)`  
Description: Specifies the number of deleted tuples in the active subtransactions related to a table.  
Return type: bigint
  - `pg_stat_get_xact_tuples_hot_updated(oid)`  
Description: Specifies the number of hot updated tuples in the active subtransactions related to a table.  
Return type: bigint
  - `pg_stat_get_xact_tuples_updated(oid)`  
Description: Specifies the number of updated tuples in the active subtransactions related to a table.  
Return type: bigint
  - `pg_stat_get_last_vacuum_time(oid)`  
Description: Specifies the most recent time when the autovacuum thread is manually started to clear a table.  
Return type: timestampz
  - `pg_stat_get_last_autovacuum_time(oid)`  
Description: Specifies the time of the last vacuum initiated by the autovacuum daemon on a table.  
Return type: timestampz
  - `pg_stat_get_vacuum_count(oid)`  
Description: Specifies the number of times a table is manually cleared.  
Return type: bigint
  - `pg_stat_get_autovacuum_count(oid)`  
Description: Specifies the number of times the autovacuum daemon is started to clear a table.  
Return type: bigint
  - `pg_stat_get_last_analyze_time(oid)`  
Description: Specifies the last time when a table starts to be analyzed manually or by the autovacuum thread.  
Return type: timestampz
  - `pg_stat_get_last_autoanalyze_time(oid)`  
Description: Specifies the time when the last analysis initiated by the autovacuum daemon on a table.  
Return type: timestampz
  - `pg_stat_get_analyze_count(oid)`  
Description: Specifies the number of times a table is manually analyzed.  
Return type: bigint
  - `pg_stat_get_autoanalyze_count(oid)`  
Description: Specifies the number of times the autovacuum daemon analyzes a table.  
Return type: bigint

- `pg_total_autovac_tuples(bool)`  
 Description: Returns tuple records related to the total autovac, such as **nodename**, **nspname**, **relname**, and tuple IUDs. The input parameter specifies whether to query the **relation** information.  
 Return type: setofrecord  
 The following table describes return parameters.

**Table 7-97** Return parameter description

Return Parameter	Type	Description
nodename	name	Node name
nspname	name	Name of a namespace
relname	name	Name of an object, such as a table, an index, or a view
partname	name	Partition name
n_dead_tuples	bigint	Number of dead rows in a table partition
n_live_tuples	bigint	Number of live rows in a table partition
changes_since_analyze	bigint	Number of changes generated by ANALYZE

- `pg_total_gsi_autovac_tuples(bool)`  
 Description: The function is not supported in centralized mode.  
 Return type: setofrecord
- `pg_autovac_status(oid)`  
 Description: Returns autovac information, such as **nodename**, **nspname**, **relname**, **analyze**, **vacuum**, thresholds for the ANALYZE and VACUUM operations, and the number of analyzed or vacuumed tuples. Only users with the SYSADMIN permission can use this function.  
 Return type: SETOF record  
 The following table describes return parameters.

**Table 7-98** Return parameter description

Return Parameter	Type	Description
nspname	text	Name of a namespace
relname	text	Name of an object, such as a table, an index, or a view
nodename	text	Node name

Return Parameter	Type	Description
doanalyze	Boolean	Specifies whether to execute ANALYZE.
anltuples	bigint	Number of ANALYZE tuples
anlthresh	bigint	ANALYZE threshold
dovacuum	Boolean	Specifies whether to execute VACUUM.
vactuples	bigint	Number of VACUUM tuples
vacthresh	bigint	VACUUM threshold

- pg\_autovac\_timeout(oid)**  
 Description: Returns the number of consecutive timeouts during the autovac operation on a table. If the table information is invalid or the node information is abnormal, **NULL** will be returned.  
 Return type: bigint
- pg\_stat\_get\_last\_data\_changed\_time(oid)**  
 Description: Returns the time when **INSERT**, **UPDATE**, **DELETE**, or **TRUNCATE** was last performed on a table, or the time when **EXCHANGE**, **TRUNCATE**, or **DROP** was last performed on a partition or subpartition. The data in the **last\_data\_changed** column of the **PG\_STAT\_ALL\_TABLES** view is calculated by using this function. The performance of obtaining the last modification time by using the view is poor when the table has a large amount of data. In this case, you are advised to use functions. The input parameter is a table OID.  
 Return type: timestamptz
- pg\_stat\_set\_last\_data\_changed\_time(oid)**  
 Description: Manually changes the time when **INSERT**, **UPDATE**, **DELETE**, or **EXCHANGE/TRUNCATE/DROP PARTITION** was last performed.  
 Return type: void
- pg\_backend\_pid()**  
 Description: Specifies the thread ID of the server thread attached to the current session.  
 Return type: integer
- pg\_stat\_get\_activity(integer)**  
 Description: Returns a record about the backend with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The returned result does not contain the **connection\_info** column. The initial user, system administrators and users with the MONADMIN permission can view all data. Common users can only query their own results.

Example:

```
gaussdb=# select * from pg_stat_get_activity(139881386280704);
 datid | pid | sessionid | usesysid | application_name | state |
```

```

query          | waiting |      xact_start      |      query_start      |
 backend_start | state_change | client_addr | client_hostname | client_port | enqueue
 | query_id    | srespool | global_sessionid | unique_sql_id | trace_id
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
16545 | 139881386280704 | 69 | 10 | gsql          | active | select * from

72620543991624410 | default_pool | 1938253334#69#0 | 3751941862 |
(1 row)

```

Return type: SETOF record

The following table describes return parameters.

**Table 7-99** Return parameter description

Return Parameter	Type	Description
datid	oid	OID of the database that the user session connects to in the backend
pid	bigint	Backend thread ID
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend
application_name	text	Name of the application connected to the backend
state	text	Overall status of the backend
query	text	Latest query at the backend. If <b>state</b> is <b>active</b> , this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting on a lock. If yes, the value is <b>true</b> .

Return Parameter	Type	Description
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the <b>query_start</b> column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if <b>state</b> is not <b>active</b> . For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server
state_change	timestamp with time zone	Time when <b>state</b> was last modified
client_addr	inet	IP address of the client connected to the backend. If this column is <b>NULL</b> , it indicates either the client is connected via a Unix socket on the server or this is an internal process, such as <b>AUTOVACUUM</b> .

Return Parameter	Type	Description
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of <b>client_addr</b> . This column will be non-null only for IP connections and only when <b>log_hostname</b> is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (-1 if a Unix socket is used)
enqueue	text	Unsupported currently
query_id	bigint	ID of a query
srespool	name	Name of the resource pool
global_sessionid	text	Global session ID
unique_sql_id	bigint	Unique SQL statement ID
trace_id	text	Driver-specific trace ID, which is associated with an application request

- pg\_stat\_get\_activity\_with\_conninfo(integer)**

Description: Returns a record about the backend with the specified PID. A record for each active backend in the system is returned if **NULL** is specified. The initial user, system administrators and users with the MONADMIN permission can view all data. Common users can only query their own results.

Return type: SETOF record

The following table describes return values.

**Table 7-100** Return value description

Return Value	Return Type	Return value description
datid	oid	OID of the database that the user session connects to in the backend

Return Value	Return Type	Return value description
pid	bigint	Backend thread ID
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend
application_name	text	Name of the application connected to the backend
state	text	Overall status of the backend.
query	text	Latest query at the backend. If <b>state</b> is <b>active</b> , this column shows the ongoing query. In all other states, it shows the last query that was executed.
waiting	Boolean	Specifies whether the backend is currently waiting on a lock. If yes, the value is <b>true</b> .
xact_start	timestamp with time zone	Time when current transaction was started (null if no transaction is active). If the current query is the first of its transaction, the value of this column is the same as that of the <b>query_start</b> column.
query_start	timestamp with time zone	Time when the currently active query was started, or time when the last query was started if <b>state</b> is not <b>active</b> . For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.

Return Value	Return Type	Return value description
backend_start	timestamp with time zone	Time when this process was started, that is, when the client connected to the server
state_change	timestamp with time zone	Time when <b>state</b> was last modified
client_addr	inet	IP address of the client connected to the backend. If this column is <b>NULL</b> , it indicates either the client is connected via a Unix socket on the server or this is an internal process, such as <b>AUTOVACUUM</b> .
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of <b>client_addr</b> . This column will be non-null only for IP connections and only when <b>log_hostname</b> is enabled.
client_port	integer	TCP port number that the client uses for communication with this backend (-1 if a Unix socket is used)
enqueue	text	Unsupported currently
query_id	bigint	ID of a query
connection_info	text	A string in JSON format recording the driver type, driver version, driver deployment path, and process owner of the connected database
srespool	name	Name of the resource pool
global_sessionid	text	Global session ID

Return Value	Return Type	Return value description
unique_sql_id	bigint	Unique SQL statement ID
trace_id	text	Driver-specific trace ID, which is associated with an application request

- `gs_get_explain(integer)`

Description: Returns a running plan for the background thread with the specified PID. The PID cannot be empty. This function takes effect only when the GUC parameter **track\_activities** is set to **on**. Only explainable SQL statements whose plans do not contain stream operators are supported. The details are as follows:

- If the GUC parameter **plan\_collect\_thresh** is set to **-1**, the return result of the function is always empty.
- If **plan\_collect\_thresh** is set to **0**, the current SQL execution time is greater than or equal to the value of **log\_min\_duration\_statement**, and the total number of tuples processed by all operators in the plan is greater than or equal to 10000, the system starts to collect plans in running state. Each time the total number of tuples processed by all operators exceeds 10000, a collection is performed.
- If **plan\_collect\_thresh** is set to a value greater than 0, running plans are collected incrementally based on the threshold specified by this parameter.

The return value type is text. The types and meanings of the fields are as follows:

Parameter	Type	Description
Character string of the plans in the running state	text	<b>A-rows</b> in the plan string indicates the number of rows returned by the operator in real time.

- `pg_stat_get_function_calls(oid)`

Description: Specifies the number of times the function has been called.

Return type: bigint

- `pg_stat_get_function_self_time(oid)`

Description: Specifies the time spent in only this function. The time spent on this function calling other functions is excluded.

Return type: bigint

- `pg_stat_get_backend_idset()`

Description: Sets the number of currently active server processes (from 1 to the number of active server processes).

Return type: setofinteger

- `pg_stat_get_backend_pid(integer)`

Description: Specifies the ID of the given server thread.

Return type: bigint

- `pg_stat_get_backend_dbid(integer)`

Description: Specifies the ID of the database connected to the given server process.

Return type: oid

- `pg_stat_get_backend_userid(integer)`

Description: Specifies the user ID of the given server process. This function can be called only by the system administrator.

Return type: oid

- `pg_stat_get_backend_activity(integer)`

Description: Active command of the given server process, but only if the current user is a system administrator or the same user as that of the session being queried and **track\_activities** is on

Return type: text

- `pg_stat_get_backend_waiting(integer)`

Description: True if the given server process is waiting for a lock, but only if the current user is a system administrator or the same user as that of the session being queried and **track\_activities** is on

Return type: Boolean

- `pg_stat_get_backend_activity_start(integer)`

Description: Specifies the time when the given server process's currently executing query is started only if the current user is the system administrator or the user of the session being queried and **track\_activities** is enabled.

Return type: timestamp with time zone

- `pg_stat_get_backend_xact_start(integer)`

Description: Specifies the time when the given server process's currently executing transaction is started only if the current user is the system administrator or the user of the session being queried and **track\_activities** is enabled.

Return type: timestamp with time zone

- `pg_stat_get_backend_start(integer)`

Description: Specifies the time when the given server process is started. If the current user is neither the system administrator nor the user of the session being queried, **NULL** is returned.

Return type: timestamp with time zone

- `pg_stat_get_backend_client_addr(integer)`

Description: Specifies the IP address of the client connected to the given server process. If the connection is over a Unix domain socket, or if the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.

Return type: inet

- `pg_stat_get_backend_client_port(integer)`  
Description: Specifies the TCP port number of the client connected to the given server process. If the connection is over a Unix domain socket, **-1** will be returned. If the current user is neither a system administrator nor the same user as that of the session being queried, **NULL** will be returned.  
Return type: integer
- `pg_stat_get_bgwriter_timed_checkpoints()`  
Description: Specifies the time when the background writer starts scheduled checkpoints (because the **checkpoint\_timeout** time has expired).  
Return type: bigint
- `pg_stat_get_bgwriter_requested_checkpoints()`  
Description: Specifies the time when the background writer starts checkpoints based on requests from the backend because **checkpoint\_segments** has been exceeded or the **CHECKPOINT** command has been executed.  
Return type: bigint
- `pg_stat_get_bgwriter_buf_written_checkpoints()`  
Description: Specifies the number of buffers written by the background writer during checkpoints.  
Return type: bigint
- `pg_stat_get_bgwriter_buf_written_clean()`  
Description: Specifies the number of buffers written by the background writer for routine cleaning of dirty pages.  
Return type: bigint
- `pg_stat_get_bgwriter_maxwritten_clean()`  
Description: Specifies the time when the background writer stops its cleaning scan because it has written more buffers than specified in the **bgwriter\_lru\_maxpages** parameter.  
Return type: bigint
- `pg_stat_get_buf_written_backend()`  
Description: Specifies the number of buffers written by the backend because they need to allocate a new buffer.  
Return type: bigint
- `pg_stat_get_buf_alloc()`  
Description: Specifies the total number of the allocated buffers.  
Return type: bigint
- `pg_stat_clear_snapshot()`  
Description: Clears the current statistics snapshot. This function can be executed only by SYSADMIN and MONADMIN.  
Return type: void
- `pg_stat_reset()`  
Description: Resets all statistics counters for the current database to zero (requires system administrator permissions).  
Return type: void

- `pg_stat_reset_shared(text)`  
Description: Resets all statistics counters for the current database in each node in a shared cluster to zero (requires system administrator permissions).  
Return type: void
- `pg_stat_reset_single_table_counters(oid)`  
Description: Resets statistics for a single table or index in the current database to zero (requires system administrator permissions).  
Return type: void
- `pg_stat_reset_single_function_counters(oid)`  
Description: Resets statistics for a single function in the current database to zero (requires system administrator permissions).  
Return type: void
- `fenced_udf_process(integer)`  
Description: Shows the number of local UDF Master and Work processes. If the input parameter is set to **1**, the number of Master processes is queried. If the input parameter is set to **2**, the number of Worker processes is queried. If the input parameter is set to **3**, all Worker processes are killed.  
Return type: text
- `total_cpu()`  
Description: Obtains the CPU time used by the current node, in jiffies.  
Return type: bigint
- `total_memory()`  
Description: Obtains the size of the virtual memory used by the current node, in KB.  
Return type: bigint
- `pg_stat_bad_block(text, int, int, int, int, int, timestamp with time zone, timestamp with time zone)`  
Description: Obtains damage information about pages after the current node is started.  
Example: `select * from pg_stat_bad_block();`  
Return type: record
- `pg_stat_bad_block_clear()`  
Description: Deletes the page damage information that is read and recorded on the node (requires system administrator permissions).  
Return type: void
- `gs_respool_exception_info(pool text)`  
Description: Queries the query rule of a specified resource pool.  
Return type: record
- `gs_control_group_info(pool text)`  
Description: Queries information about Cgroups associated with a resource pool. Only users with the SYSADMIN permission can execute this function.  
Return type: record  
The command output is as follows:

Attribute	Value	Description
name	class_a:workload_a1	Class name and workload name.
class	class_a	Class Cgroup name.
workload	workload_a1	Workload Cgroup name.
type	DEFWD	Cgroup type ( <b>Top</b> , <b>CLASS</b> , <b>BAKWD</b> , <b>DEFWD</b> , or <b>TSWD</b> ).
gid	87	Cgroup ID.
shares	30	Percentage of CPU resources to those on the parent node.
limits	0	Percentage of CPU cores to those on the parent node.
rate	0	Allocation ratio in Timeshare.
cpucores	0-3	Number of CPU cores.

- `gs_prepared_statements()`

Description: Displays all available prepared statements of all sessions. Only users with the SYSADMIN permission can execute this function. The columns returned by this function are the same as those in [GS\\_ALL\\_PREPARED\\_STATEMENTS](#).

Return type: record
- `gs_all_control_group_info()`

Description: Collects information about all Cgroups in the database.

Return type: record
- `gs_get_control_group_info()`

Description: Collects information about all Cgroups. For details about the columns returned by the function, see [GS\\_GET\\_CONTROL\\_GROUP\\_INFO](#). Only users with the SYSADMIN permission can execute this function.

Return type: record
- `gs_plan_trace_delete(TIMESTAMPTZ)`

Description: Deletes all plan traces earlier than or equal to **max\_time** for the current user. All users can use this function, and as long as no exception occurs during the execution of this function, this function returns **t**.

Return type: Boolean
- `gs_plan_trace_watch_sqlid(bigint)`

Description: Listens to a unique SQL ID for which plan traces are to be generated. The ID is obtained from the **unique\_sql\_id** column in the `db_perf.statement` system catalog. In addition, this function can be called only by the initial user and users with the SYSADMIN, opradmin, or MONADMIN permission. If no exception occurs during the execution of this function, **t** is returned.

Return type: Boolean

**NOTICE**

1. In the database system, the unique SQL ID that is listened to is stored in a cyclic array whose length is 128. If the function is called too frequently, the unique SQL ID that is listened to but does not generate a plan trace may be overwritten.
2. If a unique SQL ID is listened only once, only one plan trace can be generated for the unique SQL ID. If the same unique SQL ID is listened for multiple times, multiple plan traces are generated for the unique SQL ID.

- `gs_plan_trace_show_sqlids()`

Description: Queries the list of unique SQL IDs for which plan traces are to be generated in the current system. This function can be called only by the initial user and users with the SYSADMIN, opradmin, or MONADMIN permission.

Return type: text

**NOTICE**

1. If there are two unique SQ IDs 730834934 and 730834935 for which plan traces are to be generated in the system, the result of using this function is a character string text "730834934,730834935,".
2. When this function is used, the unique SQL ID that is generating the plan trace cannot be viewed.

- `get_instr_workload_info(integer)`

Description: Obtains the transaction volume and time information on the primary database node.

Return type: record

Attribute	Value	Description
resourcepool_oid	10	OID of the resource pool (the logic is equivalent to the load).
commit_counter	4	Number of frontend transactions that were committed.
rollback_counter	1	Number of frontend transactions that were rolled back.
resp_min	949	Minimum response time of frontend transactions (unit: $\mu$ s).
resp_max	201891	Maximum response time of frontend transactions (unit: $\mu$ s).
resp_avg	43564	Average response time of frontend transactions (unit: $\mu$ s).

Attribute	Value	Description
resp_total	217822	Total response time of frontend transactions (unit: $\mu$ s).
bg_commit_counter	910	Number of backend transactions that were committed.
bg_rollback_counter	0	Number of backend transactions that were rolled back.
bg_resp_min	97	Minimum response time of backend transactions (unit: $\mu$ s).
bg_resp_max	678080687	Maximum response time of backend transactions (unit: $\mu$ s).
bg_resp_avg	327847884	Average response time of backend transactions (unit: $\mu$ s).
bg_resp_total	298341575300	Total response time of backend transactions (unit: $\mu$ s).

- pv\_instance\_time()

Description: Obtains the time consumed in each execution phase on the current node.

Return type: record

Stat_name Attribute	Value	Description
DB_TIME	1062385	Total end-to-end wall time consumed by all threads (unit: $\mu$ s).
CPU_TIME	311777	Total CPU time consumed by all threads (unit: $\mu$ s).
EXECUTION_TIME	380037	Total time consumed on the executor (unit: $\mu$ s).
PARSE_TIME	6033	Total time consumed for parsing SQL statements (unit: $\mu$ s).
PLAN_TIME	173356	Total time consumed for generating an execution plan (unit: $\mu$ s).
REWRITE_TIME	2274	Total time consumed on query rewriting (unit: $\mu$ s).
PL_EXECUTION_TIME	0	Total time consumed for executing PL/SQL statements (unit: $\mu$ s).
PL_COMPILATION_TIME	557	Total time consumed for compiling SQL statements (unit: $\mu$ s).

Stat_name Attribute	Value	Description
NET_SEND_TIME	1673	Total time consumed for sending data over network (unit: μs).
DATA_IO_TIME	426622	Total time consumed for data read and write (unit: μs).

- `DBE_PERF.get_global_instance_time()`  
 Description: Provides the time consumed in each key phase in the entire database. To query this function, you must have the MONADMIN permission.  
 Return type: record
- `get_instr_unique_sql()`  
 Description: Obtains information about execution statements (normalized SQL statements) on the current node. Only users with the SYSADMIN or MONADMIN permission can query this function.  
 Return type: record
- `reset_unique_sql(text, text, bigint)`  
 Description: Clears the Unique SQL statements in the memory of CN/DN. (The SYSADMIN or MONADMIN permission is required.)  
 Return type: Boolean

**Table 7-101** reset\_unique\_sql parameters

Parameter	Type	Description
scope	text	Clearance scope type. The options are as follows: 'GLOBAL': Clears all CNs/DNs. If the value is 'GLOBAL', this function can be executed only on the CN. 'LOCAL': Clears the current node.
clean_type	text	'BY_USERID': Clears unique SQL statements based on user IDs. 'BY_CNID': Clears unique SQL statements based on CN IDs. 'ALL': Clears all data.
clean_value	int8	Clearance value corresponding to the clearance type. If the second parameter is set to <b>ALL</b> , the third parameter does not take effect and can be set to any value.

 **NOTE**

This function involves distributed nodes. Currently, GaussDB is a centralized database, for which the function of the value **global** is the same as that of the value **local** and the second parameter cannot set to be **BY\_CNID**.

- `get_instr_wait_event(NULL)`  
Description: Obtains the statistics on wait events of the current node.  
Return type: record
- `get_instr_user_login()`  
Description: Obtains the number of user login and logout times on the current node. Only users with the SYSADMIN or MONADMIN permission can execute this function.  
Return type: record
- `get_instr_rt_percentile(integer)`  
Description: Obtains the SQL response time P80 and P95 distribution information of the database.  
Return type: record
- `get_node_stat_reset_time()`  
Description: Obtains statistics about reset (restart, primary/standby switchover, and database deletion) time of the current node.  
Return type: record
- `DBE_PERF.get_global_os_runtime()`  
Description: Displays the running status of the current OS. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_os_threads()`  
Description: Provides information about the threads under all normal nodes of the entire database. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_summary_workload_sql_count()`  
Description: Provides statistics about the number of SELECT, UPDATE, INSERT, DELETE, DDL, DML, and DCL statements of different service loads in the entire database. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_summary_workload_sql_elapse_time()`  
Description: Provides statistics about the number of SELECT, UPDATE, INSERT, and DELETE statements and response time information (TOTAL, AVG, MIN, and MAX) for different loads in the entire database. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_workload_transaction()`  
Description: Obtains the transaction volume and time information on all nodes of the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_stat()

Description: Obtains the session status information on all nodes of the database. To query this function, you must have the MONADMIN permission.

Return type: record

 NOTE

There are 14 status information items: **commit**, **rollback**, **sql**, **table\_scan**, **blocks\_fetched**, **physical\_read\_operation**, **shared\_blocks\_dirtied**, **local\_blocks\_dirtied**, **shared\_blocks\_read**, **local\_blocks\_read**, **blocks\_read\_time**, **blocks\_write\_time**, **sort\_imemory**, and **sort\_idisk**.

- DBE\_PERF.get\_global\_session\_time()

Description: Provides the time consumed in each key phase of each node in the entire database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_memory()

Description: Displays statistics about memory usage at the session level on each node in the unit of MB, including all the memory allocated to GaussDB and stream threads on DN for jobs currently executed by users. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_session\_memory\_detail()

Description: Displays statistics about thread memory usage on each node by MemoryContext node. To query this function, you must have the MONADMIN permission.

Return type: record

- create\_wlm\_session\_info(int flag)

Description: Clears top SQL query statement-level statistics recorded in the current memory. Only the administrator can execute this function.

Return type: int

- pg\_stat\_get\_wlm\_session\_info(int flag)

Description: Obtains top SQL query statement-level statistics recorded in the current memory. If the input parameter is not 0, the information is cleared from the memory. Only users with the SYSADMIN and MONADMIN permission can execute this function.

Return type: record

- gs\_paxos\_stat\_replication()

Description: Queries the standby node information on the primary node.

Return type: SETOF record

The following table describes return columns.

Column	Type	Description
local_role	text	Role of the node that sends logs
peer_role	text	Role of the node that receives logs

local_dcf_role	text	DCF role of the node that sends logs
peer_dcf_role	text	DCF role of the node that receives logs
peer_state	text	Status of the node that receives logs
sender_write_location	text	Location in the Xlog buffer where the node that sends logs is written
sender_commit_location	text	Consistency point reached for the DCF logs of the node that sends logs
sender_flush_location	text	Location in the Xlog disk where the node that sends logs is written
sender_replay_location	text	Location where the node that sends logs replays logs
receiver_write_location	text	Location in the Xlog buffer where the node that receives logs is written
receiver_commit_location	text	Consistency point reached for the DCF logs of the node that receives logs
receiver_flush_location	text	Location in the Xlog disk where the node that receives logs is written
receiver_replay_location	text	Location where the node that receives logs replays Xlogs
sync_percent	text	Synchronization percentage
dcf_run_mode	int4	DCF synchronization mode
channel	text	Channel information

- gs\_wlm\_get\_resource\_pool\_info(int)**  
 Description: Obtains resource usage statistics of all users. The input parameter can be any value of the INT type or be null.  
 Return type: record
- gs\_wlm\_get\_all\_user\_resource\_info()**  
 Description: Obtains resource usage statistics of all users.  
 Return type: record
- gs\_wlm\_get\_user\_info(int)**  
 Description: Obtains information about all users. The input parameter is of the int type and can be any int value or **NULL**. Only users with the SYSADMIN permission can execute this function.  
 Return type: record
- gs\_wlm\_readjust\_user\_space(oid)**  
 Description: Corrects the storage space usage of all users. Only the administrator can execute this function.  
 Return type: record

- `gs_wlm_readjust_user_space_through_username(text name)`  
Description: Corrects the storage space usage of a specified user. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.  
Return type: record
- `gs_wlm_readjust_user_space_with_reset_flag(text name, boolean isfirst)`  
Description: Corrects the storage space usage of a specified user. If the input parameter **isfirst** is set to **true**, statistics are collected from 0. Otherwise, statistics are collected from the previous result. Common users can use this function to modify only their own usage. Only the administrator can modify the usage of all users. If the value of **name** is **0000**, the usage of all users needs to be modified.  
Return type: record
- `gs_wlm_session_respool(bigint)`  
Description: Obtains the session resource pool information about all backend threads. The input parameter can be any value of the bigint type or can be null.  
Return type: record
- `gs_wlm_get_session_info()`  
Description: This API has been discarded and is unavailable currently.
- `gs_wlm_get_user_session_info()`  
Description: This API has been discarded and is unavailable currently.
- `gs_io_wait_status()`  
Description: This API does not support single-node systems or centralized systems and is unavailable currently.
- `global_stat_get_hotkeys_info()`  
Description: Obtains the statistics on hot keys in the entire database instance. This API does not support single-node systems or centralized systems and is unavailable currently.
- `global_stat_clean_hotkeys()`  
Description: Clears statistics on hot keys in the entire database instance. This API does not support single-node systems or centralized systems and is unavailable currently.
- `DBE_PERF.get_global_session_stat_activity()`  
Description: Displays information about threads that are running on each node in the database. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_thread_wait_status()`  
Description: Displays the block waiting status of backend threads and auxiliary threads on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.get_global_operator_history_table()`

Description: Displays the operator-related records (persistent) generated after jobs are executed on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_operator\_history()

Description: Displays the operator-related records generated after jobs are executed on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_operator\_runtime()

Description: Displays real-time operator-related records of jobs executed on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statement\_complex\_history()

Description: Displays the historical records of complex queries on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statement\_complex\_history\_table()

Description: Displays the historical records (persistent) of complex queries on the primary database node of the current user. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statement\_complex\_runtime()

Description: Displays the real-time information of complex queries on the primary database node of the current user. To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_memory\_node\_detail()

Description: Displays the memory usage of a certain database on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_shared\_memory\_detail()

Description: Displays the usage information about all the shared memory contexts of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_all\_indexes()

Description: Displays statistics about each index displayed in a row in the current database, showing I/O statistics about accesses to that specific index. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_all\_tables()

Description: Displays statistics about a row in each table (including the TOAST table) in the aggregated data of each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_all\_tables()

Description: Displays statistics about a row in each table (including the TOAST table) of data on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_local\_toastname\_and\_toastindexname()

Description: Provides the mapping between the name and index of the local TOAST table and its associated table. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_all\_indexes()

Description: Collects statistics about each index displayed in a row in the current databases of all nodes and displays the I/O statistics of a specific index. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_all\_sequences()

Description: Provides I/O status information about all sequences in the namespace. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_all\_tables()

Description: Displays the I/O statistics about each table in databases on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_all\_tables()

Description: Collects I/O statistics about each table in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_local\_toast\_relation()

Description: Provides the mapping between the name of the local TOAST table and its associated table. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_sys\_indexes()

Description: Displays the I/O status information about all system catalog indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_sys\_indexes()

Description: Collects the I/O status information about all system catalog indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_sys\_sequences()

Description: Provides the I/O status information about all the system sequences in the namespace. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_sys\_tables()

Description: Provides I/O status information about all system catalogs in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_sys\_tables()

Description: Displays the I/O status information of all system catalogs in the namespace in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_user\_indexes()

Description: Displays the I/O status information about all user relationship table indexes in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_user\_indexes()

Description: Displays the I/O status information about all user relationship table indexes in namespaces in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_user\_sequences()

Description: Displays the I/O status information about all user sequences in the namespace of each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_statio\_user\_tables()

Description: Displays the I/O status information about all user relationship tables in namespaces on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_statio\_user\_tables()

Description: Displays the I/O status information about all user relationship tables in namespaces in the database. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_all\_indexes()

Description: Displays statistics of each index in databases on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_all\_indexes()

Description: Collects statistics of each index in all databases on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_sys\_tables()

Description: Displays statistics about the system catalogs of all the namespaces in **pg\_catalog** and **information\_schema** schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_sys\_tables()

Description: Collects statistics about the system catalogs of all the namespaces in pg\_catalog and information\_schema schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_sys\_indexes()

Description: Displays index status information about all the system catalogs in the pg\_catalog and information\_schema schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_sys\_indexes()

Description: Collects statistics about index status information about all the system catalogs in the pg\_catalog and information\_schema schemas on each node. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_user\_tables()

Description: Displays the status information about customized ordinary tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_user\_tables()

Description: Collects statistics about the status information about customized ordinary tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_user\_indexes()

Description: Displays the status information about the index of customized ordinary tables in all databases. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_user\_indexes()

Description: Collects statistics about the status information about the index of customized ordinary tables in all databases. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_database()

Description: Displays database statistics of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_database\_conflicts()

Description: Collects statistics on the database of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_all\_tables()

Description: Displays transaction status information about all ordinary tables and TOAST tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_xact\_all\_tables()

Description: Collects statistics about transaction status information about all ordinary tables and TOAST tables in all namespaces. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_sys\_tables()

Description: Displays transaction status information about all system catalogs in namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_xact\_sys\_tables()

Description: Collects statistics about transaction status information about all system catalogs in namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_user\_tables()

Description: Displays the transaction status information of the user tables in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_summary\_stat\_xact\_user\_tables()

Description: Collects statistics about the transaction status information of the user tables in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_user\_functions()

Description: Displays the transaction status information of customized functions in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_xact\_user\_functions()

Description: Collects statistics about the transaction status information of customized functions in the namespaces on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_stat\_bad\_block()

Description: Displays information about table and index read failures on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_file\_redo\_iostat()

Description: Collects statistics on information about table and index read failures on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_file\_iostat()

Description: Displays statistics about data file I/Os on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_locks()

Description: Displays lock information of all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.get\_global\_replication\_slots()

Description: Displays logical replication information on all nodes. To query this function, you must have the MONADMIN permission.

Return type: record

- DBE\_PERF.GET\_GLOBAL\_PARALLEL\_DECODE\_STATUS()

Description: Displays parallel decoding information of replication slots on the current node. To query this function, you must have the MONADMIN permission. The return value is the same as that of the view [DBE\\_PERF.GLOBAL\\_PARALLEL\\_DECODE\\_STATUS](#).

Return type: record

- DBE\_PERF.GET\_GLOBAL\_PARALLEL\_DECODE\_THREAD\_INFO()

Description: Displays parallel decoding thread information of replication slots on the current node. To query this function, you must have the MONADMIN permission. The return value is the same as that of the view [DBE\\_PREF.GLOBAL\\_PARALLEL\\_DECODE\\_THREAD\\_INFO](#).

Return type: record

- DBE\_PERF.get\_global\_bgwriter\_stat()

Description: Displays statistics about the backend writer process's activities on all nodes. To query this function, you must have the MONADMIN permission.

- Return type: record
- DBE\_PERF.get\_global\_replication\_stat()  
Description: Displays information about log synchronization status on each node, such as the locations where the sender sends logs and where the receiver receives logs. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_global\_transactions\_running\_xacts()  
Description: Displays information about running transactions on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_summary\_transactions\_running\_xacts()  
Description: Collects statistics of information about running transactions on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_global\_transactions\_prepared\_xacts()  
Description: Displays information about transactions that are currently prepared for two-phase commit on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_summary\_transactions\_prepared\_xacts()  
Description: Collects statistics information about transactions that are currently prepared for two-phase commit on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_summary\_statement()  
Description: Displays the status information of the historically executed statements on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_global\_statement\_count()  
Description: Displays the number of SELECT, UPDATE, INSERT, and DELETE statements and response time information (**TOTAL**, **AVG**, **MIN**, and **MAX**) on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_global\_config\_settings()  
Description: Displays the wait event status information on each node. To query this function, you must have the MONADMIN permission.  
Return type: record
  - DBE\_PERF.get\_global\_wait\_events()  
Description: Displays the wait event status information on each node. To query this function, you must have the MONADMIN permission.  
Return type: record

- DBE\_PERF.get\_statement\_responsetime\_percentile()  
 Description: Obtains the response time distribution for 80% and 95% SQL statements of the database. To query this function, you must have the MONADMIN permission.  
 Return type: record
- DBE\_PERF.get\_summary\_user\_login()  
 Description: Collects statistics about number of user login and logout times on each node in the database. To query this function, you must have the MONADMIN permission.  
 Return type: record
- DBE\_PERF.get\_global\_record\_reset\_time()  
 Description: Displays the statistics about reset (restart, primary/standby switchover, and database deletion) time of the database. To query this function, you must have the MONADMIN permission.  
 Return type: record
- DBE\_PERF.standby\_statement\_history(only\_slow[, time1, time2])  
 Description: Queries full SQL statements on the standby node. The primary node queries full SQL statements using the statement\_history table, while the standby node queries using this function. To query this function, you must have the MONADMIN permission.  
 For details, see [Table 7-102](#).  
 Return type: record, which is the same as that in the statement\_history table.

**Table 7-102** standby\_statement\_history parameters

Parameter	Type	Description
only_slow	bool	Specifies whether to query only slow SQL statements. <b>true</b> : yes, which is equivalent to <b>select .. where is_slow_sql = true</b> ; <b>false</b> or <b>NULL</b> indicates that all SQL statements are queried, that is, <b>is_slow_sql</b> is not used as a filtering condition.
time1	timestamptz	Minimum time specified by <b>finish_time</b> for querying SQL statements. This parameter is optional.
time2	timestamptz	Maximum time specified by <b>finish_time</b> for querying SQL statements. This parameter is optional.

 NOTE

- The two time parameters **time1** and **time2** indicate the time segment to which **finish\_time** of the queried SQL statement belongs. They indicate the start time and end time respectively. If **NULL** or no value is entered, there is no limit. The function of **time1** and **time2** is the same as that of **select .. where finish\_time between time1 and time2**.
- The data generated from this function on the standby node is not stored in a table, and there is no index on the **start\_time** column. You are advised to use the parameter to search for **finish\_time**.
- Full/Slow SQL statements on the standby node are written to disks asynchronously. Therefore, the storage of user SQL information may be delayed. You are advised to query this API to expand the query time range.

- `DBE_PERF.track_memory_context(context_list text)`

Description: Sets the memory context whose memory application details need to be collected. The input parameter is the memory context names, which are separated by commas (,), for example, **ThreadTopMemoryContext**, **SessionCacheMemoryContext**. Note that the memory context names are context-sensitive. In addition, the length of a single memory context is 63, and the excess part is truncated. The maximum number of memory contexts that can be collected at a time is 16. If the number of memory contexts exceeds 16, the setting fails. Each time this function is called, the previous statistics result is cleared. When the input parameter is set to "", the statistics function is disabled. To query this function, you must have the MONADMIN permission.

Return type: Boolean

- `DBE_PERF.track_memory_context_detail()`

Description: Obtains the memory application details of the memory context specified by the **DBE\_PERF.track\_memory\_context** function. For details, see the `DBE_PERF.track_memory_context_detail` view. To query this function, you must have the MONADMIN permission.

Return type: record

- `pg_stat_get_mem_mbytes_reserved(tid)`

Description: Collects statistics on variables related to resource management, which is used only for fault locating.

Parameter: thread ID

Return type: text

- `gs_wlm_user_resource_info(name text)`

Description: Queries a user's resource quota and resource usage.

Return type: record

- `pg_stat_get_file_stat()`

Description: Records statistics about data file I/Os to indicate I/O performance and detect performance problems such as abnormal I/O operations.

Return type: record

- `pg_stat_get_redo_stat()`

Description: Displays statistics on the replay of session thread logs.

Return type: record

- `pg_stat_get_status(int8)`  
Description: Tests the block waiting status about the backend thread and auxiliary thread of the current instance.  
Return type: record
- `get_local_rel_iostat()`  
Description: Queries the accumulated I/O status of data files on the current node.  
Return type: record
- `DBE_PERF.get_global_rel_iostat()`  
Description: Displays statistics about data file I/Os on all nodes. To query this function, you must have the MONADMIN permission.  
Return type: record
- `DBE_PERF.global_threadpool_status()`  
Description: Displays the status of worker threads and sessions in thread pools on all nodes. The [GLOBAL\\_THREADPOOL\\_STATUS](#) column is returned by the function. To query the function, you must have the MONADMIN permission.  
Return type: record
- `pv_os_run_info()`  
Description: Displays the running status of the current OS. For details about the columns, see [GS\\_OS\\_RUN\\_INFO](#).  
Parameter: nan  
Return type: SETOF record
- `pv_session_stat()`  
Description: Collects session status information by session thread or AutoVacuum thread. For details about the columns, see [GS\\_SESSION\\_STAT](#).  
Parameter: **nan**  
Return type: SETOF record
- `pv_session_time()`  
Description: Collects statistics on the running time of session threads and the time consumed in each execution phase. For details about the columns, see [GS\\_SESSION\\_TIME](#).  
Parameter: **nan**  
Return type: SETOF record
- `pg_stat_get_db_temp_bytes()`  
Description: Collects statistics on the total amount of data written to temporary files through database query. All temporary files are counted, regardless of why the temporary file was created, and regardless of the **log\_temp\_files** setting.  
Parameter: **oid**  
Return type: bigint
- `pg_stat_get_db_temp_files()`  
Description: Queries the number of temporary files created in the database. All temporary files are counted, regardless of why the temporary file was created (for example, sorting or hashing), and regardless of the **log\_temp\_files** setting.

Parameter: **oid**

Return type: bigint

- create\_wlm\_instance\_statistics\_info()

Description: Saves the historical monitoring data of the current instance persistently.

Parameter: **nan**

Return type: integer

- remote\_candidate\_stat()

Description: Displays the checkpoint information and log flushing information about all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- remote\_ckpt\_stat()

Description: Displays the checkpoint information and log flushing information about all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- remote\_single\_flush\_dw\_stat()

Description: Displays the single-page doublewrite file status of all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- remote\_double\_write\_stat()

Description: Displays doublewrite file status of all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- remote\_pagewriter\_stat()

Description: Displays the page flushing information and checkpoint information about all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- remote\_recovery\_status()

Description: Displays log flow control information about the primary and standby nodes (except the current node). Centralized systems are not supported.

Return type: record

- remote\_redo\_stat()

Description: Displays the log replay status of all instances in the database (except the current node). Centralized systems are not supported.

Return type: record

- DBE\_PERF.gs\_stat\_activity\_timeout(int)

Description: Obtains information about query jobs whose execution time exceeds the timeout threshold on the current node. The correct result can be returned only when the GUC parameter **track\_activities** is set to **on**. The

timeout threshold ranges from 0 to 2147483. To query this function, you must have the MONADMIN permission.

Return type: SETOF record

Name	Type	Description
database	name	Name of the database to which a user session is connected
pid	bigint	Backend thread ID
sessionid	bigint	Session ID
usesysid	oid	OID of the user logged in to the backend
application_name	text	Name of the application connected to the backend
query	text	Query that is being executed on the backend
xact_start	timestampz	Time when the current transaction is started
query_start	timestampz	Time when the current query starts For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
query_id	bigint	Query statement ID

- `gs_wlm_user_resource_info(name text)`

Description: Queries a user's resource quota and resource usage. Common users can query only their own information. Administrators can query information about all users.

Return type: record

- `create_wlm_instance_statistics_info`

Description: Saves the historical monitoring data of the current instance persistently.

Parameter: **nan**

Return type: integer

- `create_wlm_operator_info(int flag)`

Description: Clears top SQL operator-level statistics recorded in the current memory. If the input parameter is greater than 0, the information is archived to `gs_wlm_operator_info`. Otherwise, the information is not archived. Only users with the SYSADMIN permission can execute this function.

Return type: int

- `GS_ALL_NODEGROUP_CONTROL_GROUP_INFO(text)`

Description: Provides Cgroup information for all logical database instances. Before calling this function, you need to specify the name of the logical database instance to be queried. For example, to query the Cgroup

information of the installation logical database instance, run the following command:

```
SELECT * FROM GS_ALL_NODEGROUP_CONTROL_GROUP_INFO('installation')
```

Return type: record

The following table describes return columns.

Name	Type	Description
name	text	Cgroup name.
type	text	Cgroup type.
gid	bigint	Cgroup ID.
classgid	bigint	ID of the class Cgroup where a workload Cgroup belongs.
class	text	Class Cgroup.
workload	text	Workload Cgroup.
shares	bigint	CPU quota allocated to the Cgroup.
limits	bigint	Limit of CPU resources allocated to a Cgroup.
wdlevel	bigint	Workload Cgroup level.
cpucores	text	Information about the CPU cores used by a Cgroup.

- `gs_total_nodegroup_memory_detail`

Description: Returns information about the memory used by the current logical database, in MB.

Return type: SETOF record

- `local_redo_time_count()`

Description: Returns the time consumption statistics on each process of each replayer thread on the current node (valid data exists only on the standby node).

The return values are as follows:

`local_redo_time_count` parameters

Column	Description
thread_name	Thread name.

Column	Description
step1_total	<p>Total duration of step 1. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <ul style="list-style-type: none"> <li><b>redo batch</b>: obtains a log from a queue.</li> <li><b>redo manager</b>: obtains a log from a queue.</li> <li><b>redo worker</b>: obtains a log from a queue.</li> <li><b>txn manager</b>: reads a log from a queue.</li> <li><b>txn worker</b>: reads a log from a queue.</li> <li><b>read worker</b>: reads an Xlog page (overall) from a file.</li> <li><b>read page worker</b>: obtains a log from a queue.</li> <li><b>startup</b>: obtains a log from a queue.</li> </ul> </li> <li>• Parallel replay: <ul style="list-style-type: none"> <li><b>page redo</b>: obtains a log from a queue.</li> <li><b>startup</b>: reads a log.</li> </ul> </li> </ul>
step1_count	Number of accumulated execution times of step 1.

Column	Description
step2_total	<p>Total duration of step 2. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <ul style="list-style-type: none"> <li><b>redo batch</b>: processes logs (overall).</li> <li><b>redo manager</b>: processes logs (overall).</li> <li><b>redo worker</b>: processes logs (overall).</li> <li><b>txn manager</b>: processes logs (overall).</li> <li><b>txn worker</b>: processes logs (overall).</li> <li><b>read worker</b>: specifies the time required for reading the Xlog page.</li> <li><b>read page worker</b>: generates and sends LSN forwarders.</li> <li><b>startup</b>: checks whether to replay to the specified position.</li> </ul> </li> <li>• Parallel replay: <ul style="list-style-type: none"> <li><b>page redo</b>: processes logs (overall).</li> <li><b>startup</b>: checks whether to replay to the specified position.</li> </ul> </li> </ul>
step2_count	Number of accumulated execution times of step 2.

Column	Description
step3_total	<p>Total duration of step 3. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <ul style="list-style-type: none"> <li><b>redo batch</b>: updates the standby state.</li> <li><b>redo manager</b>: processes data logs.</li> <li><b>redo worker</b>: replays page logs (overall).</li> <li><b>txn manager</b>: updates the flushing LSN.</li> <li><b>txn worker</b>: replays logs.</li> <li><b>read worker</b>: pushes the Xlog segment.</li> <li><b>read page worker</b>: obtains a new item.</li> <li><b>startup</b>: collects statistics on the wait time of delayed replay feature.</li> </ul> </li> <li>• Parallel replay: <ul style="list-style-type: none"> <li><b>page redo</b>: updates the standby state.</li> <li><b>startup</b>: collects statistics on the wait time of delayed replay feature.</li> </ul> </li> </ul>
step3_count	Number of accumulated execution times of step 3.

Column	Description
step4_total	<p>Total duration of step 4. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <ul style="list-style-type: none"> <li><b>redo batch</b>: parses Xlogs.</li> <li><b>redo manager</b>: processes DDL operations.</li> <li><b>redo worker</b>: reads data pages.</li> <li><b>txn manager</b>: synchronizes the wait time.</li> <li><b>txn worker</b>: updates the LSN of the current thread.</li> <li><b>read page worker</b>: stores logs in the distribution thread.</li> <li><b>startup</b>: distributes logs (overall).</li> </ul> </li> <li>• Parallel replay: <ul style="list-style-type: none"> <li><b>page redo</b>: replays undo logs.</li> <li><b>startup</b>: distributes logs (overall).</li> </ul> </li> </ul>
step4_count	Number of accumulated execution times of step 4.
step5_total	<p>Total duration of step 5. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <ul style="list-style-type: none"> <li><b>redo batch</b>: distributes to the redo manager.</li> <li><b>redo manager</b>: distributes logs to redo workers.</li> <li><b>redo worker</b>: replays data page logs.</li> <li><b>txn manager</b>: distributes data to the txn worker.</li> <li><b>txn worker</b>: forcibly synchronizes the wait time.</li> <li><b>read page worker</b>: updates the LSN of the current thread.</li> <li><b>startup</b>: decodes logs.</li> </ul> </li> <li>• Parallel replay: <ul style="list-style-type: none"> <li><b>page redo</b>: replays shared transaction logs.</li> <li><b>startup</b>: replays logs.</li> </ul> </li> </ul>
step5_count	Number of accumulated execution times of step 5.

Column	Description
step6_total	<p>Total duration of step 6. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <b>redo worker</b>: replays non-data page logs. <b>txn manager</b>: updates global LSNs. <b>redo manager</b>: performs CRC verification for data page logs stored in hash tables.</li> <li>• Parallel replay: <b>page redo</b>: replays synctxn logs. <b>startup</b>: forcibly synchronizes the wait time.</li> </ul>
step6_count	Number of accumulated execution times of step 6.
step7_total	<p>Total duration of step 7. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <b>redo manager</b>: creates tablespaces. <b>redo worker</b>: updates FSM.</li> <li>• Parallel replay: <b>page redo</b>: replays a single log.</li> </ul>
step7_count	Number of accumulated execution times of step 7.
step8_total	<p>Total duration of step 8. The process of each thread is as follows:</p> <ul style="list-style-type: none"> <li>• Ultimate RTO: <b>redo worker</b>: forcibly synchronizes the wait time.</li> <li>• Parallel replay: <b>page redo</b>: replays all workers do logs.</li> </ul>
step8_count	Number of accumulated execution times of step 8.

Column	Description
step9_total	Total duration of step 9. The process of each thread is as follows: <ul style="list-style-type: none"> <li>Ultimate RTO: <b>redo manager</b>: distributes logs to the page redo thread.</li> <li>Parallel replay: <b>page redo</b>: replays multi-worker do logs.</li> </ul>
step9_count	Number of accumulated execution times of step 9.

- local\_xlog\_redo\_statics()

Description: Returns the statistics on each type of logs that have been replayed on the current node (valid data exists only on the standby node).

The return values are as follows:

**Table 7-103** local\_xlog\_redo\_statics parameters

Column	Description
xlog_type	Log types.
rmid	Resource manager ID.
info	Xlog operation.
num	Number of logs.
extra	Valid values are available for page replay logs and xact logs. <ul style="list-style-type: none"> <li>Number of pages read from the disk if the log is of the page type.</li> <li>Number of deleted files if the log is of the xact type.</li> </ul>

- gs\_get\_shared\_memctx\_detail(text)

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). Only the memory context queried through the pg\_shared\_memory\_detail view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the pg\_shared\_memory\_detail view). To query this function, you must have the SYSADMIN or MONADMIN permission.  
Return type: SETOF record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the applied memory. The value is accumulated if the memory is applied for multiple times in the same line of the same file.

 **NOTE**

This view is not supported in the Lite release version.

- `gs_get_session_memctx_detail(text)`

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). This parameter is valid only in thread pool mode. Only the memory context queried through the `gs_session_memory_context` view can be queried. The input parameter is the memory context name (that is, the **contextname** column in the result returned by the `gs_session_memory_context` view). To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

 **NOTE**

This view takes effect only in thread pool mode and is not supported in the Lite release version.

- `gs_get_history_memory_detail(cstring)`

Description: Queries historical memory snapshot information. The input parameter type is `cstring`. The value can be **NULL** or the name of the memory snapshot log file.

- If the value of the input parameter is **NULL**, the list of all memory snapshot log files on the current node is displayed.

- b. If the value of the input parameter is the name of the memory snapshot log file in the list queried in [a](#), the detailed information about the memory snapshot recorded in the log file is displayed.
- c. If you enter any other input parameter, the system displays a message indicating that the input parameter is incorrect or the file fails to be opened.

To query this function, you must have the SYSADMIN or MONADMIN permission.

Return type: text

Name	Type	Description
memory_info	text	Memory information. If the input parameter of the function is set to <b>NULL</b> , the memory snapshot file list is displayed. If the input parameter is set to the name of the memory snapshot file, the content of the file is displayed.

- **gs\_stack()**

Description: Displays the call stack of a thread. To query this function, you must have the SYSADMIN or MONADMIN permission.

Parameter: tid, which indicates the thread ID. **tid** is an optional parameter. If it is specified, the function returns the call stack of the thread corresponding to **tid**. If it is not specified, the function returns the call stacks of all threads.

Return value: If **tid** is specified, the return value is of the TEXT type. If **tid** is not specified, the return value is a SETOF record.

Example:

Run **select \* from gs\_stack(pid)** to obtain the call stack of a specified thread.

```
gaussdb=# select * from gs_stack(139663481165568);
gs_stack
-----
__poll + 0x2d
WaitLatchOrSocket(Latch volatile*, int, int, long) + 0x29f
WaitLatch(Latch volatile*, int, long) + 0x2e
JobScheduleMain() + 0x90f
int GaussDbThreadMain<(knl_thread_role)9>(knl_thread_arg*) + 0x456+
InternalThreadFunc(void*) + 0x2d
ThreadStarterFunc(void*) + 0xa4
start_thread + 0xc5
clone + 0x6d
(1 row)
```

Run **select \* from gs\_stack()** to obtain the call stacks of all threads.

```
gaussdb=# select * from gs_stack();
-[ RECORD
1 ]-----
tid | 139670364324352
lwtid | 308
stack | __poll + 0x2d
      | CommWaitPollParam::caller(int (*)(pollfd*, unsigned long, int), unsigned long) + 0x34
      | int comm_socket_call<CommWaitPollParam, int (*)(pollfd*, unsigned long,
int)>(CommWaitPollParam*, int (*)(pollfd*, unsigned long
, int)) + 0x28
      | comm_poll(pollfd*, unsigned long, int) + 0xb1
      | ServerLoop() + 0x72b
      | PostmasterMain(int, char**) + 0x314e
      | main + 0x617
      | __libc_start_main + 0xf5
```

```

      | SysLoggerMain(int) + 0xc86
      | int GaussDbThreadMain<(knl_thread_role)17>(knl_thread_arg*) + 0x45d
      | InternalThreadFunc(void*) + 0x2d
      | ThreadStarterFunc(void*) + 0xa4
      | start_thread + 0xc5
      | clone + 0x6d

```

- `gs_get_thread_memctx_detail(tid,text)`

Description: Returns the memory application details of the specified memory context, including the file, line number, and size of each memory application (the size of the same line in the same file is accumulated). Only the memory context queried through the `gs_thread_memory_context` view is supported. The first input parameter is the thread ID (the `tid` column of the data returned by the `gs_thread_memory_context`), and the second parameter is the memory context name (the `contextname` column of the data returned by `gs_thread_memory_context`). To query this function, you must have the `SYSADMIN` or `MONADMIN` permission.

Return type: SETOF record

Name	Type	Description
file	text	Name of the file where the memory is applied for.
line	int8	Line number of the code in the file where the requested memory is located.
size	int8	Size of the allocated memory, in bytes. The value is accumulated if the memory is allocated for multiple times to the same line of the same file.

 **NOTE**

This view is not supported in the Lite release version.

- `gs_tpworker_execstmt_stat()`

Description: Displays the runtime information of a statement. If the `SYSADMIN` or `MONADMIN` user runs the statement, the information about all the statements that are being executed is displayed. Common users can query only the information about the SQL statements executed by themselves.

Return type: SETOF record

Name	Type	Description
db_oid	oid	OID of the database that the user session connects to in the backend.
db_name	name	Name of the database that the user session connects to in the backend

Name	Type	Description
threadpool_worker	varchar	NUMA group to which a thread belongs and thread ID. The format is <i>numagroup_threadid</i> .
thread_id	bigint	Thread ID.
session_id	bigint	Session ID
query_id	bigint	ID of the SQL statement that is being executed
query_text	text	Content of the SQL statement that is being executed
unique_sql_id	bigint	Unique ID generated by the SQL statement
client_hostname	text	Host name of the connected client, as reported by a reverse DNS lookup of <b>client_addr</b> . This column will be non-null only for IP connections and only when <b>log_hostname</b> is enabled.
client_app_name	text	Name of the client app
stmt_slow_time_threshold	int	Preset timeout interval for marking an SQL statement as a slow SQL statement, in milliseconds
stmt_start_time	timestamp with time zone	Time when the statement starts to be executed For a stored procedure, function, or package, the first query time is queried and does not change with the running of statements in the stored procedure.
stmt_elapsed_time	int	Time elapsed since the query starts
stmt_control_status	varchar	Current statement state. <ul style="list-style-type: none"> <li>● <b>Waiting</b>: The session access is successful but it is not executed by the thread.</li> <li>● <b>Running</b>: The current statement is executed properly.</li> <li>● <b>Control</b>: The current statement enters the resource control phase.</li> </ul>
stmt_control_rule	text	Slow SQL control rule corresponding to the current language

Name	Type	Description
stmt_control_io stat	text	IOPS value and maximum IOPS of the current statement The format is as follows: curVal/maxVal
stmt_control_m emstat	text	This field is reserved and is not supported currently.
stmt_control_c pustat	text	This field is reserved and is not supported currently.
stmt_control_n etstat	text	This field is reserved and is not supported currently.

- `gs_tpworker_execslot_stat()`

Description: Displays the thread running information. If the SYSADMIN or MONADMIN user runs the command, information about all threads is displayed. Common users can query only information about the threads where the SQL statements executed by themselves are located.

Return type: SETOF record

Name	Type	Description
numagroup	int	NUMA group to which the current thread belongs
worker_id	int	Thread ID of the current thread
worker_bind_t ype	text	Thread binding mode. The value can be <b>numabind</b> , <b>cpubind</b> , <b>allbind</b> , or <b>nobind</b> .
worker_cpu_aff inity	text	Affinity between threads and CPU cores, that is, the range of CPU cores that can be scheduled by threads.
worker_status	varchar	Current thread status: <ul style="list-style-type: none"> <li>• <b>Waiting</b>: The session access is successful but it is not executed by the thread.</li> <li>• <b>Running</b>: The current statement is executed properly.</li> <li>• <b>Control</b>: The current statement enters the resource control phase.</li> </ul>
served_query_i d	bigint	ID of the SQL statement that is being executed
served_query_t ext	text	Content of the SQL statement that is being executed

- `gs_session_all_settings(sessionid bigint)`

Description: Queries the full GUC parameter settings of the session corresponding to the session ID on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

Input parameter description: **sessionid** indicates the session ID.

Return type: SETOF record

The following table describes return fields.

Name	Type	Description
name	text	Parameter name
setting	text	Current parameter value
unit	text	Implicit unit of a parameter

Example:

```
gaussdb=# select sessionid from pg_stat_activity where username = 'testuser';
sessionid
-----
 788861
(1 row)
```

```
gaussdb=# select * from gs_session_all_settings(788861) where name = 'work_mem';
 name | setting | unit
-----+-----+-----
work_mem | 131072 | kB
(1 row)
```

- **gs\_session\_all\_settings()**

Description: Queries full GUC parameter settings of all sessions on the local node. To execute this function, you must have the SYSADMIN or MONADMIN permission.

Return type: SETOF record

Name	Type	Description
sessionid	bigint	Session ID
pid	bigint	Backend thread ID
name	text	Parameter name
setting	text	Current parameter value
unit	text	Implicit unit of a parameter

Example:

```
gaussdb=# select * from gs_session_all_settings() where name = 'work_mem';
 sessionid | pid | name | setting | unit
-----+-----+-----+-----+-----
140550214145792 | 96974 | work_mem | 65536 | kB
140550214145792 | 96971 | work_mem | 65536 | kB
140549731735296 | 140549731735296 | work_mem | 65536 | kB
140549764413184 | 140549764413184 | work_mem | 65536 | kB
(4 rows)
```

- `gs_local_wal_preparse_statistics()`  
Description: Queries the latest startup of the log pre-parsing thread on the local node as well as the pre-parsing logs. Only the user with the SYSADMIN permission can execute this function.

Return type: SETOF record

Name	Type	Description
preparser_term	text	Maximum term value obtained from the latest pre-parsing log.
preparser_start_time	timestampz	Time when the latest pre-parsing is started.
preparser_end_time	timestampz	End time of the latest pre-parsing.
preparser_start_location	text	Start position of the latest pre-parsing log.
preparser_end_location	text	End position of the latest pre-parsing log.
preparser_total_bytes	int8	Number of latest pre-parsed logs, in bytes.
preparser_speed	int8	Latest pre-parsing speed, in bytes/ms.
is_valid	bool	Specifies whether the latest pre-parsing result can be used for leader selection.

Example:

```
gaussdb=# select * from gs_local_wal_preparse_statistics();
preparser_term | preparser_start_time | preparser_end_time | preparser_start_location |
preparser_end_location | preparser_total_bytes | preparser_speed | is_valid
-----+-----+-----+-----+-----+-----+-----+-----
3107          | 2023-02-01 17:04:23.367946+08 | 2023-02-01 17:04:25.354434+08 | 00000003/
C3EEA660     | 00000004/0BE60738 | 1207394520 | 1207394520 | f
(1 row)
```

- `gs_hot_standby_space_info()`  
Description: Queries the total number and total size of files in the **standby\_read/base\_page**, **standby\_read/block\_info\_meta** and **standby\_read/lsn\_info\_meta** folders.

Return type: SETOF record

Name	Type	Description
base_page_file_num	xid	Total number of bage_page_files.
base_page_total_size	xid	Total size of bage_page_files.

Name	Type	Description
lsn_info_meta_file_num	xid	Total number of lsn_info_meta_files.
lsn_info_meta_total_size	xid	Total size of the lsn_info_meta_files.
block_info_meta_file_num	xid	Total number of block_info_meta_files.
block_info_meta_total_size	xid	Total size of the block_info_meta_files.

Example:

```
gaussdb=# select * from gs_hot_standby_space_info();
 base_page_file_num | base_page_total_size | lsn_info_meta_file_num | lsn_info_meta_total_size |
block_info_meta_file_num | block_info_meta_total_size
-----+-----+-----+-----+-----+-----
          6 |      163840 |          6 |          3136 |          16
|
|          147456
(1 row)
```

- `exrto_file_read_stat()`

Description: Queries the number of disk access times and total access latency of new **base page files**, **lsn info meta files**, and **block info meta files** read by the standby node. Connect to the standby DN for query. In other cases, the query result is 0.

Return type: SETOF record

Name	Type	Description
lsn_info_page_disk_read_counter	int8	Number of disk access times of <b>lsn info meta files</b>
lsn_info_page_disk_read_dur	int8	Total latency of <b>lsn info meta file</b> access to disks.
blk_info_meta_disk_read_counter	int8	Number of disk access times of <b>block info meta files</b>
blk_info_meta_disk_read_dur	int8	Total latency of <b>block info meta file</b> access to disks.
base_page_read_disk_counter	int8	Number of disk access times of <b>base page files</b>
base_page_read_disk_dur	int8	Total latency of <b>base page file</b> access to disks.

Example:

```
gaussdb=# SELECT * FROM exrto_file_read_stat();
lsn_info_page_disk_read_counter | lsn_info_page_disk_read_dur | blk_info_meta_disk_read_counter |
blk_info_meta_disk_read_dur | base_page_read_disk_counter | base_page_read_disk_dur
-----+-----+-----+-----+-----+-----
|          14987 |          92313 |          23879 |          129811
|              0 |              0
(1 row)
```

- **gs\_exrto\_recycle\_info()**  
Description: Queries the resource reclamation location, including the reclamation LSN of each thread, global reclamation LSN, and the earliest snapshot LSN of a query thread. Connect to the standby DN for query. In other cases, the query result is 0.

Return type: SETOF record

Name	Type	Description
page_redo_worker_thread_id	text	Reclamation LSN location of redo thread. <b>thread_id</b> indicates the redo thread ID.
global_recycle_lsn	text	LSN of global reclamation location
exrto_snapshot_oldest_lsn	text	The earliest snapshot LSN of a query thread

Example:

```
gaussdb=# SELECT * FROM gs_exrto_recycle_info();
thread_id | recycle_lsn
-----+-----
page_redo_worker_140148895381248 | 0/7B4552E0
page_redo_worker_140148872312576 | 0/7B4535B8
global_recycle_lsn | 0/7B4535B8
exrto_snapshot_oldest_lsn | 0/8488E6D0
(4 rows)
```

- **gs\_stat\_get\_db\_conflict\_all(oid)**  
Input parameter: **dbid(oid)** indicates the database OID.  
Description: Queries the number of sent replay conflict signals of different types.

Return type: SETOF record

Name	Type	Description
conflict_all	int8	Number of sent replay conflict signals
conflict_tablespace	int8	Number of sent replay conflict signals of the <b>tablespace</b> type
conflict_lock	int8	Number of sent replay conflict signals of the <b>lock</b> type

Name	Type	Description
conflict_snapshot	int8	Number of sent replay conflict signals of the <b>snapshot</b> type
conflict_bufferpin	int8	Number of sent replay conflict signals of the <b>bufferpin</b> type
conflict_startup_deadlock	int8	Number of sent replay conflict signals of the <b>startup_deadlock</b> type
conflict_truncate	int8	Number of sent replay conflict signals of the <b>truncate</b> type
conflict_standby_query_timeout	int8	Number of sent replay conflict signals of the <b>standby_query_timeout</b> type
conflict_force_recycle	int8	Number of sent replay conflict signals of the <b>force_recycle</b> type

Example:

```
gaussdb=# SELECT * FROM gs_stat_get_db_conflict_all(12738);
 conflict_all | conflict_tablespace | conflict_lock | conflict_snapshot | conflict_bufferpin |
 conflict_startup_deadlock | conflict_truncate | conflict_standby_query_timeout | conflict_force_recycle
-----+-----+-----+-----+-----+-----+-----+-----+-----
|          0 |          0 |          0 |          0 |          0 |          0 |          0 |          0
(1 row)
```

- **gs\_redo\_stat\_info()**

Description: Queries redo information, including the buffer hit ratio of the redo thread, number of unlink\_rels files executed, wait event information of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario, and wait event information of **wal\_read\_from\_write\_buffer**. The query must be executed by connecting to the standby DN.

Return type: SETOF record

Name	Type	Description
buffer_hit_rate	float8	Buffer hit ratio of the redo thread.
ddl_unlink_nrels_count	int8	Number of unlink rel files executed during the redo process of DDL statements.
read_buffer_io_counter	int8	Number of wait events of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_total_dur	int8	Total wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.

Name	Type	Description
read_buffer_io_avg_dur	int8	Average wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_min_dur	int8	Minimum wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_buffer_io_max_dur	int8	Maximum wait event duration of I/O operations generated when the redo thread reads the buffer in the ultimate RTO scenario.
read_wal_buf_counter	int8	Number of wait events triggered by <b>wal_read_from_write_buffer</b> in the ultimate RTO scenario.
read_wal_buf_total_dur	int8	Total wait event duration of <b>wal_read_from_write_buffer</b> in the ultimate RTO scenario.
read_wal_buf_avg_dur	int8	Average wait event duration of <b>wal_read_from_write_buffer</b> in the ultimate RTO scenario.
read_wal_buf_min_dur	int8	Minimum wait event duration of <b>wal_read_from_write_buffer</b> in the ultimate RTO scenario.
read_wal_buf_max_dur	int8	Maximum wait event duration of <b>wal_read_from_write_buffer</b> in the ultimate RTO scenario.

Example:

```
gaussdb=# SELECT * FROM gs_redo_stat_info();
-[ RECORD 1 ]-----+-----
buffer_hit_rate      | 70.5707
ddl_unlink_nrels_count | 3
read_buffer_io_counter | 1732
read_buffer_io_total_dur | 2850806
read_buffer_io_avg_dur | 1645
read_buffer_io_min_dur | 3
read_buffer_io_max_dur | 981639
read_wal_buf_counter | 9779
read_wal_buf_total_dur | 193612470
read_wal_buf_avg_dur | 19798
read_wal_buf_min_dur | 3
read_wal_buf_max_dur | 1914777
```

- `gs_recovery_conflict_waitevent_info()`  
Description: Queries wait event information about the function that processes redo conflicts. The query must be executed by connecting to the standby DN.  
Return type: SETOF record

Name	Type	Description
conflict_lock_counter	int8	Number of times that LOCK redo conflicts are triggered.
conflict_lock_total_dur	int8	Total duration for processing LOCK redo conflicts.
conflict_lock_avg_dur	int8	Average duration for processing LOCK redo conflicts.
conflict_lock_min_dur	int8	Minimum duration for processing LOCK redo conflicts.
conflict_lock_max_dur	int8	Maximum duration for processing LOCK redo conflicts.
conflict_snapshot_counter	int8	Number of times that SNAPSHOT redo conflicts are triggered.
conflict_snapshot_total_dur	int8	Total duration for processing SNAPSHOT redo conflicts.
conflict_snapshot_avg_dur	int8	Average duration for processing SNAPSHOT redo conflicts.
conflict_snapshot_min_dur	int8	Minimum duration for processing SNAPSHOT redo conflicts.
conflict_snapshot_max_dur	int8	Maximum duration for processing SNAPSHOT redo conflicts.
conflict_tablespace_counter	int8	Number of times that TABLESPACE redo conflicts are triggered.
conflict_tablespace_total_dur	int8	Total duration for processing TABLESPACE redo conflicts.
conflict_tablespace_avg_dur	int8	Average duration for processing TABLESPACE redo conflicts.
conflict_tablespace_min_dur	int8	Minimum duration for processing TABLESPACE redo conflicts.
conflict_tablespace_max_dur	int8	Maximum duration for processing TABLESPACE redo conflicts.
conflict_database_counter	int8	Number of times that DATABASE redo conflicts are triggered.
conflict_database_total_dur	int8	Total duration for processing DATABASE redo conflicts.
conflict_database_avg_dur	int8	Average duration for processing DATABASE redo conflicts.
conflict_database_min_dur	int8	Minimum duration for processing DATABASE redo conflicts.

Name	Type	Description
conflict_database_max_dur	int8	Maximum duration for processing DATABASE redo conflicts.
conflict_truncate_counter	int8	Number of times that TRUNCATE redo conflicts are triggered.
conflict_truncate_total_dur	int8	Total duration for processing TRUNCATE redo conflicts.
conflict_truncate_avg_dur	int8	Average duration for processing TRUNCATE redo conflicts.
conflict_truncate_min_dur	int8	Minimum duration for processing TRUNCATE redo conflicts.
conflict_truncate_max_dur	int8	Maximum duration for processing TRUNCATE redo conflicts.
conflict_standby_query_time_out_counter	int8	Number of times that STANDBY_QUERY_TIMEOUT redo conflicts are triggered.
conflict_standby_query_time_out_total_dur	int8	Total duration for processing STANDBY_QUERY_TIMEOUT redo conflicts.
conflict_standby_query_time_out_avg_dur	int8	Average duration for processing STANDBY_QUERY_TIMEOUT redo conflicts.
conflict_standby_query_time_out_min_dur	int8	Minimum duration for processing STANDBY_QUERY_TIMEOUT redo conflicts.
conflict_standby_query_time_out_max_dur	int8	Maximum duration for processing STANDBY_QUERY_TIMEOUT redo conflicts.
conflict_force_recycle_counter	int8	Number of times that FORCE_RECYCLE redo conflicts are triggered.
conflict_force_recycle_total_dur	int8	Total duration for processing FORCE_RECYCLE redo conflicts.
conflict_force_recycle_avg_dur	int8	Average duration for processing FORCE_RECYCLE redo conflicts.
conflict_force_recycle_min_dur	int8	Minimum duration for processing FORCE_RECYCLE redo conflicts.
conflict_force_recycle_max_dur	int8	Maximum duration for processing FORCE_RECYCLE redo conflicts.

Example:

```
gaussdb=# SELECT * FROM gs_recovery_conflict_waitevent_info();
-[ RECORD 1 ]-----+-----
conflict_lock_counter          | 0
conflict_lock_total_dur        | 0
conflict_lock_avg_dur          | 0
conflict_lock_min_dur          | 0
conflict_lock_max_dur          | 0
conflict_snapshot_counter      | 0
conflict_snapshot_total_dur    | 0
conflict_snapshot_avg_dur      | 0
conflict_snapshot_min_dur      | 0
conflict_snapshot_max_dur      | 0
conflict_tablespace_counter    | 0
conflict_tablespace_total_dur  | 0
conflict_tablespace_avg_dur    | 0
conflict_tablespace_min_dur    | 0
conflict_tablespace_max_dur    | 0
conflict_database_counter      | 0
conflict_database_total_dur    | 0
conflict_database_avg_dur      | 0
conflict_database_min_dur      | 0
conflict_database_max_dur      | 0
conflict_truncate_counter      | 6
conflict_truncate_total_dur    | 35872
conflict_truncate_avg_dur      | 5978
conflict_truncate_min_dur      | 5130
conflict_truncate_max_dur      | 7459
conflict_standby_query_timeout_counter | 0
conflict_standby_query_timeout_total_dur | 0
conflict_standby_query_timeout_avg_dur | 0
conflict_standby_query_timeout_min_dur | 0
conflict_standby_query_timeoutmax_dur | 0
conflict_force_recycle_counter | 0
conflict_force_recycle_total_dur | 0
conflict_force_recycle_avg_dur | 0
conflict_force_recycle_min_dur | 0
conflict_force_recycle_max_dur | 0
```

- `gs_display_delay_ddl_info()`

Description: Views information about files that are delayed for deletion on the standby node.

Return type: SETOF record

Name	Type	Description
type	INT4	Indicates that the deleted object is a table or database.
lsn	TEXT	Marks the location of a particular log file.
tablespace	INT4	Indicates the physical space for storing tables and indexes in a database.
database	INT4	Indicates the physical storage location of a database.
relation	INT4	Indicates the object in a database, which can be the physical location of a table, view, or index.

Name	Type	Description
bucketid	INT4	Specifies the bucket to which the relationship object belongs.
opt	INT4	Indicates the attribute of a compressed table.
forknum	INT4	Specifies a suffix name for a subject name. You can find a unique physical file based on the subject name and suffix name.

Example:

```
gaussdb=# SELECT * FROM gs_display_delay_ddl_info();
 type | lsn | tablespace | database | relation | bucketid | opt | forknum
-----+-----+-----+-----+-----+-----+-----+-----
(0 rows)
```

## Functions for Collecting Statistics in Partitioned Tables

- gs\_stat\_get\_partition\_stats(oid)**  
 Description: Obtains the statistics of a specific partition.  
 Return type: record
- gs\_stat\_get\_xact\_partition\_stats(oid)**  
 Description: Obtains transaction statistics of a specific partition.  
 Return type: record
- gs\_stat\_get\_all\_partitions\_stats()**  
 Description: Obtains the statistics of all partitions.  
 Return type: SETOF record
- gs\_stat\_get\_xact\_all\_partitions\_stats()**  
 Description: Obtains transaction statistics of all partitions.  
 Return type: SETOF record
- gs\_statio\_get\_all\_partitions\_stats()**  
 Description: Obtains the I/O statistics of all partitions.  
 Return type: SETOF record  
 Examples of the preceding five functions

### CAUTION

Statistics are reported asynchronously during execution. Based on UDP, delay and packet loss may occur during background thread processing. The following example is for reference only.

#### Querying out-of-transaction statistics

```
gaussdb=# CREATE TABLE part_tab1
gaussdb=# (
```

```
gaussdb=# a int, b int
gaussdb=#
gaussdb=# PARTITION BY RANGE(b)

```

- gs\_stat\_get\_partition\_analyze\_count(oid)**  
 Description: Specifies the number of times that a user starts analysis on a partition.  
 Return type: bigint
- gs\_stat\_get\_partition\_autoanalyze\_count(oid)**  
 Description: Specifies the number of times that the autovacuum daemon starts analysis in a partition.  
 Return type: bigint
- gs\_stat\_get\_partition\_autovacuum\_count(oid)**  
 Description: Specifies the number of times that the autovacuum daemon starts vacuum in a partition.  
 Return type: bigint
- gs\_stat\_get\_partition\_last\_analyze\_time(oid)**  
 Description: Specifies the last time when a partition starts to be analyzed manually or by the autovacuum thread.  
 Return type: timestamptz
- gs\_stat\_get\_partition\_last\_autoanalyze\_time(oid)**  
 Description: Specifies the time when the last analysis initiated by the autovacuum daemon in a partition.  
 Return type: timestamptz
- gs\_stat\_get\_partition\_last\_autovacuum\_time(oid)**  
 Description: Specifies the time of the last vacuum initiated by the autovacuum daemon in a partition.  
 Return type: timestamptz
- gs\_stat\_get\_partition\_last\_data\_changed\_time(oid)**  
 Description: Specifies the last time of a modification in a partition, such as insert, update, delete, and truncate. Currently, this parameter is not supported.

- Return type: timestampz
- `gs_stat_get_partition_last_vacuum_time(oid)`  
Description: Specifies the most recent time when the user manually cleared a table or when the autovacuum thread was started to clear a partition.  
Return type: timestampz
  - `gs_stat_get_partition_numscans(oid)`  
Description: Specifies the number of rows scanned and read in partition order.  
Return type: bigint
  - `gs_stat_get_partition_tuples_returned(oid)`  
Description: Specifies the number of sequential row scans in a partition.  
Return type: bigint
  - `gs_stat_get_partition_tuples_fetched(oid)`  
Description: Specifies the number of rows fetched by bitmap scans in a partition.  
Return type: bigint
  - `gs_stat_get_partition_vacuum_count(oid)`  
Description: Specifies the number of times that a user starts vacuum in a partition.  
Return type: bigint
  - `gs_stat_get_xact_partition_tuples_fetched(oid)`  
Description: Specifies the number of tuple rows scanned in a transaction.  
Return type: bigint
  - `gs_stat_get_xact_partition_numscans(oid)`  
Description: Specifies the number of sequential scans performed on a partition in the current transaction.  
Return type: bigint
  - `gs_stat_get_xact_partition_tuples_returned(oid)`  
Description: Specifies the number of rows read through sequential scans in a partition in the current transaction.  
Return type: bigint
  - `gs_stat_get_partition_blocks_fetched(oid)`  
Description: Specifies the number of disk block fetch requests for a partition.  
Return type: bigint
  - `gs_stat_get_partition_blocks_hit(oid)`  
Description: Specifies the number of disk block requests found in cache for a partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_inserted(oid)`  
Description: Specifies the number of rows in the corresponding table partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_updated(oid)`  
Description: Specifies the number of rows that have been updated in the corresponding table partition.

- Return type: bigint
- `pg_stat_get_partition_tuples_deleted(oid)`  
Description: Specifies the number of rows deleted from the corresponding table partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_changed(oid)`  
Description: Specifies the total number of inserted, updated, and deleted rows after a table partition was last analyzed or autoanalyzed.  
Return type: bigint
  - `pg_stat_get_partition_live_tuples(oid)`  
Description: Specifies the number of live rows in a partitioned table.  
Return type: bigint
  - `pg_stat_get_partition_dead_tuples(oid)`  
Description: Specifies the number of dead rows in a partitioned table.  
Return type: bigint
  - `pg_stat_get_xact_partition_tuples_inserted(oid)`  
Description: Specifies the number of inserted tuples in the active sub-transactions related to a table partition.  
Return type: bigint
  - `pg_stat_get_xact_partition_tuples_deleted(oid)`  
Description: Specifies the number of deleted tuples in the active sub-transactions related to a table partition.  
Return type: bigint
  - `pg_stat_get_xact_partition_tuples_hot_updated(oid)`  
Description: Specifies the number of hot updated tuples in the active sub-transactions related to a table partition.  
Return type: bigint
  - `pg_stat_get_xact_partition_tuples_updated(oid)`  
Description: Specifies the number of updated tuples in the active sub-transactions related to a table partition.  
Return type: bigint
  - `pg_stat_get_partition_tuples_hot_updated(oid)`  
Description: Returns statistics on the number of hot updated tuples in a partition with a specified partition ID.  
Parameter: oid  
Return type: bigint

## 7.5.27 Trigger Functions

- `pg_get_triggerdef(oid)`  
Description: Obtains the definition information of a trigger.  
Parameter: OID of the trigger to be queried  
Return type: text

## Example:

```
-- Create the tri_insert table.
gaussdb=# CREATE TABLE tri_insert (a int, b int);
CREATE TABLE
-- Create the trigger_func function.
gaussdb=# CREATE FUNCTION trigger_func() RETURNS trigger LANGUAGE plpgsql AS '
gaussdb'# BEGIN
gaussdb'# RAISE NOTICE "trigger_func(%) called: action = %, when = %, level = %", TG_ARGV[0],
TG_OP, TG_WHEN, TG_LEVEL;
gaussdb'# RETURN NULL;
gaussdb'# END;';
CREATE FUNCTION
-- Create the before_ins_stmt_trig trigger.
gaussdb=# CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert
gaussdb-# FOR EACH STATEMENT EXECUTE PROCEDURE trigger_func('before_ins_stmt');
CREATE TRIGGER
-- Create the after_ins_when_trig trigger.
gaussdb=# CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert
gaussdb-# FOR EACH ROW WHEN (new.a IS NOT NULL) EXECUTE PROCEDURE
trigger_func('after_ins_when');
CREATE TRIGGER
-- View the trigger definition information of the tri_insert table.
gaussdb=# SELECT pg_get_triggerdef(oid) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH STATEMENT
EXECUTE PROCEDURE trigger_func('before_ins_stmt')
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS
NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
(2 rows)
```

- `pg_get_triggerdef(oid, boolean)`

Description: Obtains the definition information of a trigger.

Parameter: OID of the trigger to be queried and whether it is displayed in pretty mode

 NOTE

Boolean parameters take effect only when the WHEN condition is specified during trigger creation.

Return type: text

## Example:

```
-- View the trigger definition information of the tri_insert table in non-pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, false) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH STATEMENT
EXECUTE PROCEDURE trigger_func('before_ins_stmt')
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN ((new.a IS
NOT NULL)) EXECUTE PROCEDURE trigger_func('after_ins_when')
(2 rows)

-- View the trigger definition information of the tri_insert table in pretty mode.
gaussdb=# SELECT pg_get_triggerdef(oid, true) FROM pg_trigger WHERE tgrelid = 'tri_insert'::regclass;

pg_get_triggerdef
-----
CREATE TRIGGER before_ins_stmt_trig BEFORE INSERT ON tri_insert FOR EACH STATEMENT
EXECUTE PROCEDURE trigger_func('before_ins_stmt')
CREATE TRIGGER after_ins_when_trig AFTER INSERT ON tri_insert FOR EACH ROW WHEN (new.a IS
NOT NULL) EXECUTE PROCEDURE trigger_func('after_ins_when')
```

```
(2 rows)
-- Clear the tri_insert table.
gaussdb=# DROP TABLE tri_insert CASCADE;
DROP TABLE
-- Clear the trigger_func function.
gaussdb=# DROP FUNCTION trigger_func;
DROP FUNCTION
```

## 7.5.28 Hash Function

- ora\_hash(expression,[seed])

Description: Calculates the hash value of a given expression. **expression**: The value can be a character string, time, or number. The hash value is calculated based on the expression. **seed**: an int8 value that can return different results for the same input value. This parameter is optional and is used to calculate the hash value with a random number.

Return type: hash value of the int8 type.

Example:

```
gaussdb=# select ora_hash(123);
ora_hash
-----
4089882933
(1 row)
gaussdb=# select ora_hash('123');
ora_hash
-----
2034089965
(1 row)
gaussdb=# select ora_hash('sample');
ora_hash
-----
1573005290
(1 row)
gaussdb=# select ora_hash(to_date('2012-1-2','yyyy-mm-dd'));
ora_hash
-----
1171473495
(1 row)
gaussdb=# select ora_hash(123,234);
ora_hash
-----
-9089505052966355682
(1 row)
gaussdb=# select ora_hash('123',234);
ora_hash
-----
5742589019960764616
(1 row)
gaussdb=# select ora_hash('sample',234);
ora_hash
-----
-1747984408055821656
(1 row)
gaussdb=# select ora_hash(to_date('2012-1-2','yyyy-mm-dd'),234);
ora_hash
-----
-3306025179710572679
(1 row)
```

### NOTE

This function is valid only when **a\_format\_version** is set to **10c** and **a\_format\_dev\_version** is set to **s2**.

- **hash\_array(anyarray)**  
Description: Hashes an array, obtains the result of an array element using the hash function, and returns the combination result.  
Parameter: data of the anyarray type.  
Return type: integer  
Example:

```
gaussdb=# select hash_array(ARRAY[[1,2,3],[1,2,3]]);
 hash_array
-----
-382888479
(1 row)
```
- **hash\_numeric(numeric)**  
Description: Calculates the hash value of numeric data.  
Parameter: data of the numeric type.  
Return type: integer  
Example:

```
gaussdb=# select hash_numeric(30);
 hash_numeric
-----
-282860963
(1 row)
```
- **hash\_range(anyrange)**  
Description: Calculates the hash value of a range.  
Parameter: data of the anyrange type.  
Return type: integer  
Example:

```
gaussdb=# select hash_range(numrange(1.1,2.2));
 hash_range
-----
683508754
(1 row)
```
- **hashbpchar(character)**  
Description: Calculates the hash value of bpchar.  
Parameter: data of the character type.  
Return type: integer  
Example:

```
gaussdb=# select hashbpchar('hello');
 hashbpchar
-----
-1870292951
(1 row)
```
- **hashchar(char)**  
Description: Converts char and Boolean data into hash values.  
Parameter: data of the char or Boolean type.  
Return type: integer  
Example:

```
gaussdb=# select hashbpchar('hello');
 hashbpchar
-----
-1870292951
```

```
(1 row)
gaussdb=# select hashchar('true');
 hashchar
-----
1686226652
(1 row)
```

- **hashenum(anyenum)**

Description: Converts enumerated values to hash values.

Parameter: data of the anyenum type.

Return type: integer

Example:

```
gaussdb=# CREATE TYPE b1 AS ENUM('good', 'bad', 'ugly');
CREATE TYPE
gaussdb=# call hashenum('good'::b1);
 hashenum
-----
1821213359
(1 row)
```

- **hashfloat4(real)**

Description: Converts float4 values to hash values.

Parameter: data of the real type.

Return type: integer

Example:

```
gaussdb=# select hashfloat4(12.1234);
 hashfloat4
-----
1398514061
(1 row)
```

- **hashfloat8(double precision)**

Description: Converts float8 values to hash values.

Parameter: data of the double precision type.

Return type: integer

Example:

```
gaussdb=# select hashfloat8(123456.1234);
 hashfloat8
-----
1673665593
(1 row)
```

- **hashinet(inet)**

Description: Converts inet or cidr values to hash values.

Parameter: data of the inet type.

Return type: integer

Example:

```
gaussdb=# select hashinet('127.0.0.1'::inet);
 hashinet
-----
-1435793109
(1 row)
```

- **hashint1(tinyint)**

Description: Converts INT1 values to hash values.

Parameter: data of the tinyint type.

Return type: uint32

Example:

```
gaussdb=# select hashint1(20);
 hashint1
-----
-2014641093
(1 row)
```

- hashint2(smallint)

Description: Converts INT2 values to hash values.

Parameter: data of the smallint type.

Return type: uint32

Example:

```
gaussdb=# select hashint2(20000);
 hashint2
-----
-863179081
(1 row)
```

## 7.5.29 Prompt Message Function

- report\_application\_error()

Description: This function can be used to throw errors during PL execution.

Return type: void

**Table 7-104** report\_application\_error parameter description

Parameter	Type	Description	Mandatory or Not
log	text	Content of an error message.	Yes
code	int4	Error code corresponding to an error message. The value ranges from -20999 to -20000.	No

## 7.5.30 Global Temporary Table Functions

- pg\_get\_gtt\_relstats(relOid)

Description: Displays basic information about a global temporary table specified by the current session.

Parameter: OID of the global temporary table

Return type: record

Example:

```
gaussdb=# select * from pg_get_gtt_relstats(74069);
 relfilenode | relpages | reltuples | relallvisible | relfrozenxid | relminmxid
-----+-----+-----+-----+-----+-----
      74069 |      58 |    13000 |              0 |      11151 |           0
(1 row)
```

- pg\_get\_gtt\_statistics(relOid, attnum, '::text)

Description: Displays statistics about a single column in a global temporary table specified by the current session.

**Table 7-105** db\_perf.get\_global\_full\_sql\_by\_timestamp parameter description

Parameter	Type	Description
start_timestamp	timestamp	Start point of the SQL start time range.
end_timestamp	timestamp	End point of the SQL start time range.

- db\_perf.get\_global\_slow\_sql\_by\_timestamp(start\_timestamp timestamp, end\_timestamp timestamp)

Description: Obtains slow SQL information at the instance level.

Return type: record

**Table 7-106** db\_perf.get\_global\_slow\_sql\_by\_timestamp parameter description

Parameter	Type	Description
start_timestamp	timestamp	Start point of the SQL start time range.
end_timestamp	timestamp	End point of the SQL start time range.

- statement\_detail\_decode(detail text, format text, pretty bool)

Parses the details column in a full or slow SQL statement.

**Table 7-107** statement\_detail\_decode parameter description

Parameter	Type	Description
detail	text	Set of events generated by the SQL statement (unreadable).
format	text	Parsing output format. The value is <b>plaintext</b> or <b>json</b> .
pretty	bool	Whether to display the text in pretty format when <b>format</b> is set to <b>plaintext</b> . The options are as follows: <ul style="list-style-type: none"> <li>• The value <b>true</b> indicates that events are separated by <b>\n</b>.</li> <li>• The value <b>false</b> indicates that events are separated by commas (,).</li> </ul>

- pg\_list\_gtt\_relfrozenxids()

Description: Displays the frozen XID of each session.

If the value of **pid** is **0**, the earliest frozen XID of all sessions is displayed.

Parameter: none

Return type: record

Example:

```
gaussdb=# select * from pg_list_gtt_relfrozenxids();
 pid      | relfrozenxid
-----+-----
139648123270912 | 11151
139648170456832 | 11155
          0 | 11151
(3 rows)
```

## 7.5.31 Fault Injection System Function

- `gs_fault_inject(int64, text, text, text, text, text)`

Description: This function cannot be called. WARNING information "unsupported fault injection" is reported when this function is called, which does not affect or change the database.

Parameter: fault injection of the int64 type (**0**: CLOG extended page; **1**: CLOG page reading; **2**: forcible deadlock)

- If the first input parameter of text is set to **2** and the second input parameter of text is set to **1**, the second input parameter deadlock occurs. Other input parameters are not deadlocked. When the first input parameter is **0** or **1**, the second input parameter indicates the number of the start page from which the CLOG starts to be extended or read.
- The third input parameter of text indicates the number of extended or read pages when the first input parameter is **0** or **1**.
- The fourth to sixth input parameters of text are reserved.

Return type: int64

## 7.5.32 AI Feature Functions

- `gs_index_advise(text)`

Description: Recommends an index for a single query statement.

Parameter: SQL statement string

Return type: record

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Single-Query Index Recommendation" in *Feature Guide*.

- `hypopg_create_index(text, [text])`

Description: Creates a virtual index.

Parameter: character string of the statement for creating an index, level of the created virtual index (optional)

Return type: record

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_display_index([text])`

Description: Displays information about all created virtual indexes.

Parameter: level of the virtual index to be displayed (optional)

Return type: record

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_drop_index(oid)`

Description: Deletes a specified virtual index.

Parameter: OID of the index

Return type: Boolean

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_reset_index([text])`

Description: Clears all virtual indexes.

Parameter: level of the virtual index to be cleared (optional)

Return type: none

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `hypopg_estimate_size(oid)`

Description: Estimates the space required for creating a specified index.

Parameter: OID of the index

Return type: int8

For details, see section "DBMind: Autonomous Database O&M > AI Sub-functions of DBMind > Index-advisor: Index Recommendation > Virtual Index" in *Feature Guide*.

- `check_engine_status(ip text, port text)`

Description: Tests whether a predictor engine provides services on a specified IP address and port.

Parameter: IP address and port number of the predictor engine.

Return type: text

 **NOTE**

This function is unavailable in the current version.

- `encode_plan_node(optname text, orientation text, strategy text, options text, dop int8, quals text, projection text)`

Description: Encodes the plan operator information in the input parameters.

Parameter: plan operator information

Return type: text

 **NOTE**

This function is an internal function. You are advised not to use it directly.

- `model_train_opt(template text, model text)`

Description: Trains a given query performance prediction model.

Parameters: template name and model name of the performance prediction model

Return type: `tartup_time_accuracy` FLOAT8, `total_time_accuracy` FLOAT8, `rows_accuracy` FLOAT8, `peak_memory_accuracy` FLOAT8

 **NOTE**

This function is unavailable in the current version.

- `track_model_train_opt(ip text, port text)`

Description: Returns the training log address of the specified IP address and port predictor engine.

Parameter: IP address and port number of the predictor engine

Return type: text

 **NOTE**

This function is unavailable in the current version.

- `encode_feature_perf_hist(datname text)`

Description: Encodes historical plan operators collected in the target database.

Parameter: database name

Return type: `queryid` bigint, `plan_node_id` int, `parent_node_id` int, `left_child_id` int, `right_child_id` int, `encode` text, `startup_time` bigint, `total_time` bigint, `rows` bigint, and `peak_memory` int

- `gather_encoding_info(datname text)`

Description: Invokes **`encode_feature_perf_hist`** to save the encoded data persistently.

Parameter: database name

Return type: int

- `db4ai_predict_by_bool (text, VARIADIC "any")`

Description: Obtains a model whose return value is of the Boolean type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: Boolean

- `db4ai_predict_by_float4(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the float4 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: float

- `db4ai_predict_by_float8(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the float8 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: float

- `db4ai_predict_by_int32(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the int32 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: int

- `db4ai_predict_by_int64(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the int64 type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: int

- `db4ai_predict_by_numeric(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the numeric type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: numeric

- `db4ai_predict_by_text(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: text

- `db4ai_predict_by_float8_array(text, VARIADIC "any")`

Description: Obtains a model whose return value is of the character type for model inference. This function is an internal function. You are advised to use the **PREDICT BY** syntax for inference.

Parameter: model name and input column name of the inference task

Return type: text

- `gs_explain_model(text)`

Description: Obtains the model whose return value is of the character type for text-based model parsing.

Parameter: model name

Return type: text

- `gs_ai_stats_explain(text, text[])`

Description: Prints the intelligent statistics of multiple columns in the corresponding table and columns.

Parameters: table name and column name collection.

Return type: text

- `ai_watchdog_detection_warnings()`

Description: Obtains the risk alarm information of the AI watchdog.

Parameter: none

Return type: record

- `ai_watchdog_monitor_status(int)`  
Description: Obtains the monitoring information of the AI watchdog.  
Parameter: Returns the upper limit of the length of the monitored sequence.  
Return type: record
- `ai_watchdog_parameters()`  
Description: Obtains the internal parameters or status information of the AI watchdog.  
Parameter: none  
Return type: record

## 7.5.33 Dynamic Data Masking Functions

### NOTE

This function is an internal function.

- `creditcardmasking(col text, letter char default 'x')`  
Description: Replaces the digits before the last four bits following the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `basicmailmasking(col text, letter char default 'x')`  
Description: Replaces the characters before the first at sign (@) in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `fullmailmasking(col text, letter char default 'x')`  
Description: Replaces the characters (except @) before the last period (.) in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `alldigitsmasking(col text, letter char default '0')`  
Description: Replaces the digits in the col string with letters.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `shufflemasking(col text)`  
Description: Sorts the characters in the col string out of order.  
Parameter: Character string to be replaced or character string used for replacement  
Return type: text
- `randommasking(col text)`

Description: Randomizes the characters in the col string.

Parameter: Character string to be replaced or character string used for replacement

Return type: text

- `regexprmasking(col text, reg text, replace_text text, pos INTEGER default 0, reg_len INTEGER default -1)`

Description: Replaces the col string with a regular expression.

Parameters: Character string to be replaced, regular expression, replacement start position, and replacement length.

Return type: text

## 7.5.34 Hierarchical Recursion Query Functions

The following functions can be used in a hierarchical recursion query statement to return information about the connection path.

- `sys_connect_by_path(col, separator)`

Description: Returns the connection path from the root node to the current row. This function applies only to hierarchical recursion queries.

The **col** parameter indicates the name of the column displayed in the path. Only columns of the CHAR, VARCHAR, NVARCHAR2, or TEXT type are supported. The **separator** parameter indicates the separator between path nodes.

Return type: text

Example:

```
gaussdb=# select *, sys_connect_by_path(name, '-') from connect_table start with id = 1 connect by
prior id = pid;
 id | pid | name | sys_connect_by_path
-----+-----+-----+-----
  1 |  0 | a   | -a
  2 |  1 | b   | -a-b
  4 |  1 | d   | -a-d
  3 |  2 | c   | -a-b-c
(4 rows)
```

- `connect_by_root(col)`

Description: Returns the value of a column in the top-most parent row of the current row. This function applies only to hierarchical recursion queries.

The **col** parameter indicates the name of an output column.

Return type: data type of the specified column **col**.

Example:

```
gaussdb=# select *, connect_by_root(name) from connect_table start with id = 1 connect by prior id =
pid;
 id | pid | name | connect_by_root
-----+-----+-----+-----
  1 |  0 | a   | a
  2 |  1 | b   | a
  4 |  1 | d   | a
  3 |  2 | c   | a
(4 rows)
```

## 7.5.35 Other System Functions

Built-in functions and operators of GaussDB are compatible with PostgreSQL.

The following lists the functions used by GaussDB to implement internal system functions. You are advised not to use these functions. If you need to use them, contact Huawei technical support.

- locktag\_decode(locktag text)  
Description: Parses lock details from **locktag**.  
Return type: text
- smgreq(a smgr, b smgr)  
Description: Compares two smgrs to check whether they are the same.  
Parameter: smgr, smgr  
Return type: Boolean
- smgrne(a smgr, b smgr)  
Description: Checks whether the two smgrs are different.  
Parameter: smgr, smgr  
Return type: Boolean
- xidin4  
Description: Inputs a 4-byte xid.  
Parameter: cstring  
Return type: xid32
- set\_hashbucket\_info  
Description: Sets hash bucket information.  
Parameter: text  
Return type: Boolean
- int1send  
Description: Packs unsigned 1-byte integers into the internal data buffer stream.  
Parameter: tinyint  
Return type: bytea
- listagg  
Description: Specifies aggregate functions of the list type.  
Parameter: smallint, text

Return type: text

- `log_fdw_validator`  
Description: Specifies validation functions.  
Parameter: text[], oid  
Return type: void
- `nvarchar2typmodin`  
Description: Obtains the typmod information of the varchar type.  
Parameter:cstring[]  
Return type: integer
- `nvarchar2typmodout`  
Description: Obtains the typmod information of the varchar type, constructs a character string, and returns the character string.  
Parameter: integer  
Return type:cstring
- `read_disable_conn_file`  
Description: Reads forbidden connection files.  
Parameter: nan  
Return type: disconn\_mode text, disconn\_host text, disconn\_port text, local\_host text, local\_port text, redo\_finished text
- `regex_like_m`  
Description: Specifies the regular expression match, which is used to determine whether a character string complies with a specified regular expression.  
Parameter: text, text  
Return type: Boolean
- `update_pgjob`  
Description: Updates a job.  
Parameters: bigint, "char", bigint, timestamp without time zone, smallint, text  
Return type: void
- `enum_cmp`  
Description: Specifies the enumeration comparison function, which is used to determine whether two enumeration classes are equal and determine their relative sizes.  
Parameters: anyenum, anyenum  
Return type: integer
- `enum_eq`  
Description: Specifies the enumeration comparison function, which is used to implement the equal sign (=).  
Parameters: anyenum, anyenum

Return type: Boolean

- `enum_first`

Description: Returns the first element in the enumeration class.

Parameter: `anyenum`

Return type: `anyenum`

- `enum_ge`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>) and equal sign (=).

Parameters: `anyenum`, `anyenum`

Return type: Boolean

- `enum_gt`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameters: `anyenum`, `anyenum`

Return type: Boolean

- `enum_in`

Description: Specifies the enumeration comparison function, which is used to determine whether an element is in an enumeration class.

Parameter: `cstring`, `oid`

Return type: `anyenum`

- `enum_larger`

Description: Specifies the enumeration comparison function, which is used to implement the greater-than sign (>).

Parameters: `anyenum`, `anyenum`

Return type: `anyenum`

- `enum_last`

Description: Returns the last element in the enumeration class.

Parameter: `anyenum`

Return type: `anyenum`

- `enum_le`

Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<) and equal sign (=).

Parameters: `anyenum`, `anyenum`

Return type: Boolean

- `enum_lt`

Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).

Parameters: `anyenum`, `anyenum`

Return type: Boolean

- enum\_smaller**  
Description: Specifies the enumeration comparison function, which is used to implement the less-than sign (<).  
Parameters: anyenum, anyenum  
Return type: Boolean
- node\_oid\_name**  
Description: Not supported.  
Parameter: oid  
Return type:cstring
- pg\_buffercache\_pages**  
Description: Reads data from the shared buffer.  
Parameter: nan  
Return type: bufferid integer, refilenode oid, bucketid smallint, reltablespace oid, reldatabase oid, relforknumber smallint, relblocknumber bigint, isdirty boolean, usage\_count smallint
- pg\_check\_xidlimit**  
Description: Checks whether nextxid is greater than or equal to xidwarnlimit.  
Parameter: nan  
Return type: Boolean
- gs\_validate\_ext\_listen\_ip**  
Description: Clears services connected to invalid IP addresses on DNs.  
Parameter: For details, see [Table 7-108](#).  
Return value: bigint pid, text node\_name  
Note: When this function is queried in the current environment, the first input parameter can only be set to '**normal**' and no value is returned.

**Table 7-108** GS\_VALIDATE\_EXT\_LISTEN\_IP columns

Name	Type	Description
clear	IN cstring	Specifies whether to clear services. <b>normal</b> indicates that services connected to invalid IP addresses on DNs are cleared.
validate_node_name	IN cstring	Specifies the name of the DN where the IP address connections to be cleared are located.
validate_ip	IN cstring	Specifies the IP address to be cleared.
pid	OUT bigint	ID of the service thread where the IP address connections to be cleared are located.
node_name	OUT text	Name of the instance where the IP connections to be cleared are located.

- `gs_comm_listen_address_ext_info`

Description: Displays the DFX information about the extended IP address configured for **listen\_address\_ext** connected to the current node.

Parameter: nan

Return type: text node\_name, text app, bigint tid, integer lwtid, bigint query\_id, integer socket, text remote\_ip, text remote\_port, text local\_ip or text local\_port

Note: Currently, this function is not supported.

**Table 7-109** GS\_COMM\_LISTEN\_ADDRESS\_EXT\_INFO columns

Name	Type	Description
node_name	OUT text	Name of the current instance.
app	OUT text	Client connected to the DN.
tid	OUT bigint	Thread ID of the current thread.
lwtid	OUT integer	Lightweight thread ID of the current thread.
query_id	OUT bigint	Query ID of the current thread.
socket	OUT integer	Socket FD of the current physical connection.
remote_ip	OUT text	Peer IP address of the current connection.
remote_port	OUT text	Peer port of the current connection.
local_ip	OUT text	Local IP address of the current connection.
local_port	OUT text	Local port of the current connection.

- `gs_get_global_listen_address_ext_info()`

Description: Queries the global extended IP address configuration information.

Parameter: For details, see [Table 7-110](#).

Return type: text node\_name, text host, text port, text ext\_listen\_ip

Note: Currently, this function is not supported.

**Table 7-110** GS\_GET\_GLOBAL\_LISTEN\_ADDRESS\_EXT\_INFO columns

Name	Type	Description
dn_mode	IN cstring	Specifies the range of DNs to be displayed. If this parameter is set to <b>null</b> , all DNs are queried by default.

Name	Type	Description
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT text	Listening port of the DN.
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- gs\_get\_listen\_address\_ext\_info()**  
 Description: Queries the extended IP address configuration of the current instance.  
 Parameter: nan  
 Return type: text node\_name, text host, bigint port, text ext\_listen\_ip  
 Note: Currently, this function is not supported.

**Table 7-111** GS\_GET\_LISTEN\_ADDRESS\_EXT\_INFO

Name	Type	Description
node_name	OUT text	DN name.
host	OUT text	Listening IP address of the DN.
port	OUT bigint	Listening port of the DN.
ext_listen_ip	OUT text	Extended listening IP address of the DN.

- pg\_comm\_delay**  
 Description: Displays the delay status of the communications library of a single DN.  
 Parameter: nan  
 Return type: text, text, integer, integer, integer, integer
- pg\_comm\_rcv\_stream**  
 Description: Displays the receiving stream status of all communication libraries on a single DN.  
 Parameter: nan  
 Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint
- pg\_comm\_send\_stream**  
 Description: Displays the sending stream status of all communication libraries on a single DN.  
 Parameter: nan  
 Return type: text, bigint, text, bigint, integer, integer, integer, text, bigint, integer, integer, integer, bigint, bigint, bigint, bigint, bigint

- `pg_comm_status`  
Description: Displays the communication status of a single DN.  
Parameter: nan  
Return type: text, integer, integer, bigint, bigint, bigint, bigint, bigint, integer, integer, integer, integer, integer
- `pg_log_comm_status`  
Description: Prints some logs on the DN.  
Parameter: nan  
Return type: Boolean
- `pg_parse_clog`  
Description: Parses clog to obtain the status of xid.  
Parameter: nan  
Return type: xid xid, status text
- `pg_pool_ping`  
Description: Sets PoolerPing.  
Parameter: Boolean  
Return type: SETOF boolean
- `pg_resume_bkp_flag`  
Description: Obtains the delay xlong flag for backup and restoration.  
Parameter: slot\_name name  
Return type: start\_backup\_flag boolean, to\_delay boolean, ddl\_delay\_recycle\_ptr text, rewind\_time text
- `psortoptions`  
Description: Returns the psort attribute.  
Parameter: text[], boolean  
Return type: bytea
- `xideq4`  
Description: Compares two values of the xid type to check whether they are the same.  
Parameter: xid32, xid32  
Return type: Boolean
- `xideqint8`  
Description: Compares values of the xid type and int8 type to check whether they are the same.  
Parameter: xid, bigint  
Return type: Boolean
- `xidlt`  
Description: Returns whether `xid1 < xid2` is true.  
Parameter: xid, xid  
Return type: Boolean

- `xidlt4`  
Description: Returns whether `xid1 < xid2` is true.  
Parameter: `xid32`, `xid32`  
Return type: Boolean
- `gs_shutdown_cross_region_walsenders`  
Description: Interrupts cross-cluster streaming replication.  
Parameter: `nan`  
Return type: `void`  
Note: To call this function, the user must have the `SYSADMIN` or `OPRADMIN` permission, and **`operate_mode`** must be enabled for the O&M administrator role.
- `is_dblink_in_transaction`  
Description: Checks whether a database link corresponding to an OID is used in the current transaction.  
Parameter: `oid`  
Return type: Boolean
- `dblink_has_updatasent`  
Description: Checks whether DML statements are sent using a database link corresponding to an OID in the current transaction and are not committed.  
Parameter: `oid`  
Return type: Boolean
- `get_last_xmin_by_oid`  
Description: Obtains the maximum **`xmin`** value of all columns in a table based on the table OID.  
Parameter: `oid`  
Return type: `xid`
- `get_relid_by_relname`  
Description: Obtains the OID of a table based on the table name and `relnamespace`.  
Parameter: `cstring`, `oid`  
Return type: `oid`
- `copy_summary_create`  
Description: Creates a `gs_copy_summary` table.  
Parameter: `none`  
Return type: `text`

## 7.5.36 Internal Functions

The following functions of GaussDB use internal data types, which cannot be directly called by users.

- Selectivity calculation functions

areajoin sel	areasel	arraycon tjoin sel	arraycon tsel	contjoin sel	contsel	eqjoin sel
eqsel	iclikejoin sel	iclikesel	icnlikejoin sel	icnlkese l	icregexe qjoin sel	icregexe qsel
icregexn ejoin sel	icregexn esel	likejoin sel	likesel	neqjoin sel	neqsel	nlikejoin sel
nlikesel	positionj oin sel	position sel	regexej oin sel	regexeq sel	regexnej oin sel	regexn sel
scalargtj oin sel	scalargt sel	scalartj oin sel	scalart sel	tmatchj oin sel	tmatch sel	-

- Statistics collection functions

array_tyanalyze	range_tyanalyze	ts_tyanalyze
local_rto_stat	-	-

- Internal functions for sorting

bpchar_sorts upport	bytea_sorts upport	date_sorts upport	numeric_sort support	timestamp_s ortsupport
------------------------	-----------------------	----------------------	-------------------------	---------------------------

dblink_f dw_han dler	dblink_f dw_valid ator	-	-	-	-	-

- Auxiliary functions for the primary DN to remotely read data pages from the standby DN.  

`gs_read_block_from_remote` is used to read the pages of a table file. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.
- Auxiliary functions for the primary DN to remotely read data files from the standby DN.  

`gs_read_file_from_remote` is used to read a specified file. After obtaining the file size using the **`gs_read_file_size_from_remote`** function, **`gs_repair_file`** reads the remote file segment by segment using this function. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.

`gs_read_file_size_from_remote` is used to read the size of a specified file. Before using the `gs_repair_file` function to repair a file, you need to obtain the size of the file from the remote end to verify the missing file information and repair the missing files one by one. By default, only the initial user can view the data. Other users can use the data only after being granted with permissions.
- Auxiliary functions for incrementally rebuilding other standby or cascaded standby DNs using the standby DN.  

`gs_standby_incremental_filemap_create` is used to create a temporary filemap file for incremental rebuilding on the standby DN. The filemap file is used to store the path and size of the data to be transferred during the incremental rebuilding. This API can be called only when the initial user is used and **application** is **`gs_rewind`**.

`gs_standby_incremental_filemap_insert` is used to insert file information into a specified temporary filemap file. The file information includes the file path, transfer start point, length of data to be transferred at a time, and rebuild flag bit. This API can be called only when the initial user is used and **application** is **`gs_rewind`**.

`gs_standby_incremental_filemap_execute` is used to obtain file information stored in a specified temporary filemap file and delete the specified filemap file for data transmission during incremental standby DN rebuilding. This API can be called only when the initial user is used and **application** is **`gs_rewind`**.
- AI feature functions

create_s napshot	create_s napshot _internal	prepare_ snapshot _internal	prepare_ snapshot	manage_ snapsh ot_inter nal	archive_ snapshot	publish_ snapshot
purge_sn apshot_i nternal	purge_sn apshot	sample_ snapshot	-	-	-	-

• View-related reference functions

adm\_hist\_sqlstat\_func  
adm\_hist\_sqlstat\_idlog\_func  
adm\_hist\_sqltext\_func

• gs\_txn\_snapshot system catalog maintenance function

gs\_insert\_delete\_txn\_snapshot is used to maintain the gs\_txn\_snapshot system catalog of each node in distributed GTM-Lite mode. Only the system administrator can call gs\_insert\_delete\_txn\_snapshot. In the current version, if this function is called, **f** is returned.

```

### 7.5.38 Data Damage Detection and Repair Functions

The restrictions for repairing file or page of the primary node are as follows.

File Type	File/ Page	Primary/ Standby	Detection and Repair
Common row-store tables (including Astore, Ustore and compressed tables) (excluding index)	File and page	Primary	Manual detection and repair.
Undo files (excluding undo meta)	Page	Primary	Manual detection and repair (excluding analyse verify).
<b>init fork</b> file for unlogged tables	File	Primary	Manual detection and repair.

- gs\_verify\_data\_file**(verify\_segment bool)
 

Description: Checks whether files in the current database of the current instance are lost. The verification only checks whether intermediate segments are lost in the main file of the data table. The default value is **false**. If this parameter is set to **true**, it is a reserved parameter and not supported currently. By default, only initial users, users with the sysadmin permission, and users with the O&M administrator attribute in the O&M mode can view the information. Other users can view the information only after being granted with permissions.

The returned result is as follows:

- rel\_oid** and **rel\_name** indicate the table OID and table name of the corresponding file, and **miss\_file\_path** indicates the relative path of the lost file.

Parameter description:

- verify\_segment**

Specifies the range of files to be checked.

The value can be **true** or **false** (default value). **true** is a reserved parameter and not supported currently.

Return type: record

Example (The abnormal line is displayed only when an exception is detected. Otherwise, no line is displayed.):

```
gaussdb=# select * from gs_verify_data_file();
node_name      | rel_oid | rel_name  | miss_file_path
-----+-----+-----+-----
dn_6001_6002_6003 | 16554 | test     | base/16552/24745
```

- `gs_repair_file(tableoid Oid, path text, timeout int)`

Description: Repairs the file based on the input parameters. Only the primary DN with normal primary/standby connection is supported. The parameter is set based on the OID and path returned by the `gs_verify_data_file` function. If the repair is successful, **true** is returned. If the repair fails, the failure cause is displayed. By default, only initial users, users with the `sysadmin` permission, and users with the O&M administrator permission in the O&M mode on the primary DN can view the information. Other users can view the information only after being granted with permissions.

---

**CAUTION**

1. If a file on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal.
2. If a file exists but its size is 0, the file will not be repaired. To repair the file, you need to delete the file whose size is 0 and then repair it.
3. You can delete a file only after the file descriptor is automatically closed. You can manually restart the process or perform a primary/standby switchover.

---

Parameter description:

- `tableoid`

OID of the table corresponding to the file to be repaired. Set this parameter based on the **rel\_oid** column in the list returned by the **gs\_verify\_data\_file** function.

Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.

- `path`

Path of the file to be repaired. Set this parameter based on the **miss\_file\_path** column in the list returned by the **gs\_verify\_data\_file** function.

Value range: a string

- `timeout`

Specifies the duration for waiting for the standby DN to replay. The repair file needs to wait for the standby DN to be put back to the corresponding location on the current primary DN. Set this parameter based on the replay duration of the standby DN.

Value range: 60s to 3600s.

Return type: Boolean

Example (Set **tablespace** and **path** based on the output of `gs_verify_data_file`):

```
gaussdb=# select * from gs_repair_file(16554,'base/16552/24745',360);
gs_repair_file
```

t

- `local_bad_block_info()`

Description: Displays the page damage of the instance. You can read the page from the disk and record the page CRC failure. By default, only initial users, users with the sysadmin permission, users with the monitoring administrator attribute, users with the O&M administrator attribute in the O&M mode, and monitoring users can view the information. Other users can view the information only after being granted with permissions.

In the displayed information, **file\_path** indicates the relative path of the damaged file. **block\_num** indicates the number of the page where the file is damaged. The page number starts from 0. **check\_time** indicates the time when the page damage is detected. **repair\_time** indicates the time when the page is repaired.

Return type: record

Example (Related entries are displayed only when there are damaged records. Otherwise, no log is displayed.):

```
gaussdb=# select * from local_bad_block_info();
node_name | spc_node | db_node | rel_node | bucket_node | fork_num | block_num | file_path |
check_time | repair_time
-----+-----+-----+-----+-----+-----+-----+-----+
dn_6001_6002_6003 | 1663 | 16552 | 24745 | -1 | 0 | 0 | base/16552/24745 |
2022-01-13 20:19:08.385004+08 | 2022-01-13 20:19:08.407314+08
```

- `local_clear_bad_block_info()`

Description: Deletes data of repaired pages from **local\_bad\_block\_info**, that is, information whose **repair\_time** is not empty. By default, only initial users, users with the sysadmin permission, users with the O&M administrator attribute in the O&M mode, and monitoring users can view the information. Other users can view the information only after being granted with permissions.

Return type: Boolean

Example:

```
gaussdb=# select * from local_clear_bad_block_info();
result
-----
t
```

- `gs_verify_and_tryrepair_page (path text, blocknum oid, verify_mem bool, is_segment bool)`

Description: Verifies the page specified by the instance. By default, only the initial user, users with the sysadmin permission, and users with the O&M administrator attribute in O&M mode on the primary DN can view the table. Other users can view the table only after being granted with permissions.

In the command output, **disk\_page\_res** indicates the verification result of the page on the disk, **mem\_page\_res** indicates the verification result of the page in the memory, and **is\_repair** specifies whether the repair function is triggered during the verification. **t** indicates that the page is repaired, and **f** indicates that the page is not repaired.

Note:

- If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be

promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.

- b. The repair triggered by this function can only repair pages in the memory. The repair takes effect only after the memory pages are flushed to disks.

Parameter description:

- path  
Path of the damaged file. Set this parameter based on the **file\_path** column in the **local\_bad\_block\_info** file. To verify the undo pages of a Ustore table, enter the path of the undo pages to be verified.  
Value range: a string
- blocknum  
Page number of the damaged file. Set this parameter based on the **block\_num** column in the **local\_bad\_block\_info** file. If you want to verify the undo pages of a Ustore table, enter the block number of the undo pages to be verified.  
Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.
- verify\_mem  
Specifies whether to verify a specified page in the memory. If this parameter is set to **false**, only pages on the disk are verified. If this parameter is set to **true**, pages in the memory and on the disk are verified. If a page on the disk is damaged, the system verifies the basic information of the page in the memory and flushes the page to the disk to restore the page. If a page is not found in the memory during memory page verification, the page on the disk is read through the memory API. During this process, if the disk page is faulty, the remote read automatic repair function is triggered.  
Value range: The value is of a Boolean type and can be **true** or **false**.
- is\_segment  
Determines whether the table is a segment-page table. **false** indicates that the table is not a segment-page table. **true** indicates a reserved parameter value, which is not supported currently.  
Value range: The value is of a Boolean type and can be **true** or **false**.

Return type: record

Examples (Transfer parameters based on the output of local\_bad\_block\_info. Otherwise, an error is reported.):

```
gaussdb=# select * from gs_verify_and_tryrepair_page('base/16552/24745',0,false,false);
node_name | path | blocknum | disk_page_res | mem_page_res | is_repair
-----+-----+-----+-----+-----+-----
dn_6001_6002_6003 | base/16552/24745 | 0 | page verification succeeded. | | f
```

- **gs\_repair\_page**(path text, blocknum oid, is\_segment bool, timeout int)  
Description: Restores the specified page of the instance. This function can be used only by the primary DN that is properly connected to the primary and standby DNs. If the page is successfully restored, **true** is returned. If an error occurs during the restoration, an error message is displayed. By default, only the initial user, users with the sysadmin permission, and users with the O&M administrator attribute in O&M mode on the primary DN can view the table. Other users can view the table only after being granted with permissions.

Note: If a page on a DN is damaged, a verification error at the PANIC level is reported when the DN is promoted to primary. The DN cannot be promoted to primary, which is normal. Damaged pages of hash bucket tables cannot be repaired.

Parameter description:

- path  
Path of the damaged page. Set this parameter based on the **file\_path** column in **local\_bad\_block\_info** or the **path** column in the **gs\_verify\_and\_tryrepair\_page** function.  
Value range: a string
- blocknum  
Number of the damaged page. Set this parameter based on the **block\_num** column in **local\_bad\_block\_info** or the **blocknum** column in the **gs\_verify\_and\_tryrepair\_page** function.  
Value range: OID ranging from 0 to 4294967295. Note: A negative value will be forcibly converted to a non-negative integer.
- is\_segment  
Determines whether the table is a segment-page table. **false** indicates that the table is not a segment-page table. **true** indicates a reserved parameter value, which is not supported currently.  
Value range: The value is of a Boolean type and can be **true** or **false**.
- timeout  
Duration of waiting for standby DN replay. The page to be repaired needs to wait for the standby DN to be played back to the location of the current primary DN. Set this parameter based on the replay duration of the standby DN.  
Value range: 60s to 3600s.

Return type: Boolean

Examples (Transfer parameters based on the output of `local_bad_block_info`. Otherwise, an error is reported.):

```
gaussdb=# select * from gs_repair_page('base/16552/24745',0,false,60);
result
-----
t
```

- `gs_edit_page_bypath(path text, blocknum int64, offset int, data text, data_size int, read_backup bool, storage_type text)`

Description: Transfers the path, block number, offset, target data to be modified, and length of the target table file, and modifies the target data to the corresponding fields on the page. The **read\_backup** column determines the file reading mode, and the **storage\_type** column indicates the file storage mode (for example, page storage). To prevent incorrect modification, this function does not directly modify the original page but modifies the copied page and flushes the modified page to the specified path. Only the system administrator or O&M administrator in O&M mode can execute this function.

Return type: text

**Table 7-112** gs\_edit\_page\_bypath parameters

Category	Parameter	Type	Description
Input parameter	path	text	<p>Physical file path of the file to be modified, which is related to the <b>read_backup</b> column. The value can be the relative path of the file in the database directory or the absolute path of files such as the backup file. If the target file does not exist or fails to be read, an error message is displayed.</p> <ul style="list-style-type: none"> <li>If <b>read_backup</b> is <b>false</b>, the path format is <i>tablespace name/database oid/table relfilenode (physical file name)</i>. For example, <b>base/16603/16394</b>.</li> <li>If <b>read_backup</b> is <b>true</b>, <b>path</b> is a valid path. In this case, because other information about the input file cannot be obtained, you need to ensure that the input data is correct.</li> </ul> <p>Note: Only U-page and UB-tree data pages can be edited and modified. Tables with tablespaces are not supported. Other information about the input file cannot be obtained. Therefore, you need to ensure that the input data type is correct.</p>
Input parameter	blocknum	bigint	<p>Block number of the page to be repaired. Value range: 0 to <i>MaxBlockNumber</i>.</p> <p>Reads the page corresponding to the specified physical or logical block number based on the <b>read_backup</b> column. If the specified block number is out of range, an error message is returned.</p>
Input parameter	offset	int	<p>In-page offset of the column to be modified. Value range: 0 to <i>BLCKSZ</i>.</p> <p>If the specified value is less than <b>0</b> or greater than that of <b>BLCKSZ</b>, the system view is used to return the corresponding error information.</p>
Input parameter	data	text	<p>Type of the target value to be modified. Type:</p> <ul style="list-style-type: none"> <li>'0x': hexadecimal.</li> <li>'0b': binary.</li> <li>'0s': character string.</li> </ul> <p>Others: If the value of the data parameter is not one of the preceding types, the data is a decimal character string.</p>

Category	Parameter	Type	Description
Input parameter	data_size	int	Length of the written data, in bytes. Value range: 1 to 8. If the specified write length is less than 1 byte or greater than 8 bytes, or the sum of offset and data_size is greater than the value of <b>BLCKSZ</b> , the system view is used to return the corresponding error information.
Input parameter	read_backup	bool	Specifies whether to read pages from the backup directory. If this parameter is set to <b>false</b> , the target page is read based on the logical block number. Otherwise, the page is read based on the physical block number.
Input parameter	storage_type	text	File storage mode. Currently, only the page storage mode is supported. This parameter is optional. <ul style="list-style-type: none"> <li><b>'page'</b>: page mode.</li> <li><b>'segment'</b>: segment-page mode. This parameter is reserved and is not supported currently.</li> </ul>
Output parameter	output_msg	text	If the modification is successful, the absolute path of the modified file is returned. The modified file is stored in the <b>pg_log/dump</b> directory. If the modification fails, a failure message is returned.

Note: In the example, transfer parameters based on the parameter description and use the actual physical path.

Example 1: Overwrite the data whose value is **0X1FFF** at the offset of 16 bytes on page 0 in the **base/15808/25075** table.

```
gaussdb=# select gs_edit_page_bypath('base/15808/25075',0,16,'0x1FFF', 2, false, 'page');
gs_edit_page_bypath
-----
/pg_log_dir/dump/1663_15808_25075_0.editpage
(1 rows)
```

Example 2: If the input parameter does not comply with the specifications, an error message is returned.

```
gaussdb=# select gs_edit_page_bypath('base/15808/25075', 0,16,'@1231!', 8, false, 'page');
gs_edit_page_bypath
-----
Error: the parameter 'data' decode failed.
(1 row)
```

Example 3: When the data to be written is the same as the original value, an alarm is returned.

```
gaussdb=# select gs_edit_page_bypath('/pg_log_dir/dump/1663_15808_25075_0.editpage',
0,16,'0x1FFF', 2, true, 'page');
gs_edit_page_bypath
```

---

Warning: source buffer is consistent with target buffer.  
(1 row)

- `gs_repair_page_bypath(src_path text, src_blkno int64, dest_path text, dest_blkno int64, storage_type text)`

Description: Transfers the path and page number of the source file, and writes the page to the specified page number of the target file. You can repair the pages of the primary node through the standby node. In addition, you can initialize bad blocks in this view.

- a. The target page is overwritten and synchronized to the standby node. The page-based modification object supports the U-heap and UB-tree pages. The Undo Record page, Undo Slot page, compressed table, and Astore page will be supported later. System catalog files and data sections cannot be modified.
- b. With this function, you can overwrite target pages during the write operation. Before overwriting, the target page is backed up and flushed to a specified directory. The backup page can be rewritten back to the target page. If an ordinary table is modified on the primary node, a new WAL is generated and synchronized to the standby node. If an ordinary table is modified on the standby node, no WAL is recorded.
- c. The repair view applies only to the primary node in a centralized or distributed system or the standby node when the read function is enabled on the standby node. Only the system administrator or O&M administrator in O&M mode can use this function. All modifications will be recorded in database logs. In addition, you are advised to enable the audit logging function of system functions before using this function to record audit information.
- d. The LSNs of the source and target pages must be the same. Otherwise, the repair fails.

Return type: text

---

 **CAUTION**

Calling this system function is a high-risk operation. Exercise caution when performing this operation.

---

Category	Parameter	Type	Description
Input parameter	src_path	text	Path of the source file. The following types of paths are supported: <ul style="list-style-type: none"> <li>• Data files and index files: <b>pg_log/dump/1663_15808_25075_0.editpage</b>.</li> <li>• <b>src_path</b> is set to <b>'standby'</b> on the primary node. That is, pages are read from the standby node to repair the primary node.</li> <li>• <b>src_path</b> is set to <b>init_block</b> on the primary node to allow skipping bad blocks in extreme scenarios.</li> </ul>
Input parameter	src_blkno	bigint	Physical block number of the source page. Value range: 0 to <i>MaxBlockNumber</i> .
Input parameter	dest_path	text	Relative path of the target file. For example, <b>base/15808/25075</b> .
Input parameter	dest_blkno	bigint	Logical block number of the target page. Value range: 0 to <i>MaxBlockNumber</i> .
Input parameter	storage_type	text	Storage mode of the target file. Currently, only the page storage mode is supported. This parameter is optional. <ul style="list-style-type: none"> <li>• <b>'page'</b>: page mode.</li> <li>• <b>'segment'</b>: segment-page. This parameter is reserved and is not supported currently.</li> </ul>
Output parameter	output_msg	text	If the write overwrite operation is successful, the backup path of the target page is returned. If the write overwrite operation fails, an error message is returned. The format of the flushed file name is <i>relfilepath_blocknum_timestamp.repairpage</i> .

Note: Transfer parameters based on the preceding table and ensure that the physical file exists. If the input parameter is abnormal or the restoration fails, an error is reported.

Example 1: Enter a file in a specified path to overwrite the target file.

```
gaussdb=# select * from gs_repair_page_bypath('pg_log/dump/1663_15991_16767_0.editpage', 0,
'base/15991/16767', 0, 'page');
          output_msg
-----
/pg_log_dir/dump/1663_15991_16767_0_738039702421788.repairpage
(1 row)
```

Example 2: Read pages from the standby node to repair the primary node.

```
gaussdb=# select * from gs_repair_page_bypath('standby', 0, 'base/15990/16768', 0, 'page');
          output_msg
-----
/pg_log_dir/dump/1663_15990_16768_0_738040397197907.repairpage
(1 row)
```

Example 3: Initialize the target page and skip bad blocks.

```
gaussdb=# select * from gs_repair_page_bypath('init_block', 0, 'base/15990/16768', 0, 'page');
          output_msg
-----
/pg_log_dir/dump/1663_15990_16768_0_738040768010281.repairpage
(1 row)
```

- `gs_repair_undo_byzone(zone_id int)`

Description: Transfers the ID of the undo zone to be repaired, repairs the metadata of the target undo zone, and returns the repair result details. If the undo zone is not repaired, no information is output.

Return type: record

Note: Currently, the function can be called only on the primary node. After the repair is successful, the repair will be synchronized to the standby node by recording Xlogs. The caller must be a system administrator or an O&M administrator in O&M mode. You are advised to enable the audit logging function before using the function to record audit information.

Calling this system function is a high-risk operation. Exercise caution when performing this operation.

**Table 7-113** `gs_repair_undo_byzone` parameters

Category	Parameter	Type	Description
Input parameter	zone_id	int	Undo zone ID: <ul style="list-style-type: none"> <li>• <b>-1</b>: repairs the metadata of all undo zones.</li> <li>• <b>0 to 1048575</b>: repairs the metadata of the undo zone corresponding to the zone ID.</li> </ul>
Output parameter	zone_id	int	Undo zone ID.

Category	Parameter	Type	Description
Output parameter	repair_detail	text	Repair result of the undo zone metadata corresponding to the zone ID. If the repair is successful, "rebuild undo meta succeed." is displayed. If the repair fails, "rebuild undo meta failed." as well as the failure cause is displayed.

Note: The output is one of the three cases based on the repair result.

Example 1: If the undo zone meta information corresponding to the entered **zone\_id** is not damaged, no output is expected.

```
gaussdb=# select * from gs_repair_undo_byzone(4);
zone_id | repair_detail
-----+-----
(0 rows)
```

Example 2: If the undo zone metadata corresponding to the entered **zone\_id** is successfully restored, the system displays a message indicating that the restoration is successful.

```
gaussdb=# select * from gs_repair_undo_byzone(78);
zone_id | repair_detail
-----+-----
78 | rebuild undo meta succeed.
(1 row)
```

Example 3: If the undo zone metadata corresponding to the entered zone ID fails to be repaired, the detailed information about the repair failure is displayed.

```
gaussdb=# select * from gs_repair_undo_byzone(0);
zone_id | repair_detail
-----+-----
0 | rebuild undo meta failed. try lock undo zone_id failed.
(1 row)
```

#### NOTE

If the undo zone to be repaired is damaged and the zone ID is occupied by another active thread, the active thread that occupies the zone ID automatically ends when the repair function is called to forcibly repair the damaged undo zone metadata.

- `gs_verify_urq(index_oid oid, partindex_oid oid, blocknum bigint, queue_type text)`

Description: Verifies the correctness of the index recycling queue (potential queue/available queue/single page).

Parameter description: See [Table 7-114](#).

Return type: record

**Table 7-114** gs\_verify\_urq parameters

Category	Parameter	Type	Description
Input parameter	index_oid	oid	UB-tree index OID. <ul style="list-style-type: none"> <li>• Common index: index OID.</li> <li>• Global index: GPI OID.</li> <li>• Local index: OID of the primary index.</li> </ul>
Input parameter	partindex_oid	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> <li>• Common index: 0.</li> <li>• Global index: 0.</li> <li>• Local index: OID of the partitioned index (primary or secondary).</li> </ul>
Input parameter	blocknum	bigint	Specifies the page number: <ul style="list-style-type: none"> <li>• If the queue type is single page, the correctness of all tuples of <b>blocknum</b> on a single page is verified. The value range is [0, <i>Queue file size</i>/8192).</li> <li>• If the queue is empty or free, <b>blocknum</b> is an invalid value.</li> </ul>
Input parameter	queue_type	text	Specifies the queue type: <ul style="list-style-type: none"> <li>• <b>empty queue</b>: potential queue</li> <li>• <b>free queue</b>: available queue</li> <li>• <b>single page</b>: single-page queue</li> </ul>
Output parameter	error_code	text	Error code
Output parameter	detail	text	Detailed error information and other key information.

Example 1: When using the example, transfer parameters based on the parameter description and use the actual OID and **blocknum**. Otherwise, an error is reported.

```
gaussdb=# select * from gs_verify_urq(16387, 0, 1, 'free queue');
error_code | detail
-----+-----
(0 rows)
```

Example 2: When using the example, transfer parameters based on the parameter description and use the actual OID and **blocknum**. Otherwise, an error is reported.

```
gaussdb=# select * from gs_verify_urq(16387, 0, 1, 'empty queue');
   error_code |
-----+-----
detail
-----+-----
+-----+-----
VERIFY_URQ_PAGE_ERROR | invalid urq meta: oid 16387, blkno 1, head_blkno = 1, tail_blkno = 3,
nblocks_upper = 4294967295, nblocks_lower = 1; urq_blocks = 6, index_blocks = 12
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables. If the verification of the index recycling queue is normal, the view does not display the error code and error details. Otherwise, the view displays the error code and error details. The error codes include "VERIFY\_URQ\_PAGE\_ERROR", "VERIFY\_URQ\_LINK\_ERROR", "VERIFY\_URQ\_HEAD\_MISSED\_ERROR", and "VERIFY\_URQ\_TAIL\_MISSED\_ERROR". If any of the preceding error codes is displayed, contact Huawei engineers to locate the fault.

- `gs_urq_dump_stat(index_oid oid, partindex_oid oid)`

Description: Queries information about a specified index recycling queue.

In the return result, **recentGlobalDataXmin** and **globalFrozenXid** are two oldestxmins used by the recycling queue to determine whether the index page can be recycled, **next\_xid** is the XID of the next latest transaction, **urq\_blocks** indicates the total number of pages in the recycling queue and information about valid pages in the free queue (available queue) and empty queue (potential queue).

Parameter description: See [Table 7-115](#).

**Table 7-115** `gs_urq_dump_stat` parameters

Category	Parameter	Type	Description
Input parameter	<code>index_oid</code>	oid	UB-tree index OID. <ul style="list-style-type: none"> <li>• Common index: index OID.</li> <li>• Global index: GPI OID.</li> <li>• Local index: OID of the primary index.</li> </ul>
Input parameter	<code>partindex_oid</code>	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> <li>• Common index: 0.</li> <li>• Global index: 0.</li> <li>• Local index: OID of the partitioned index (primary or secondary).</li> </ul>
Output parameter	<code>result</code>	text	Detailed statistics about the index recycling queue.

Example: When using the example, transfer parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

```
gaussdb=# select * from gs_urq_dump_stat(16387, 0);
      result
```

```
-----
urq stat info: recentGlobalDataXmin = 213156, globalFrozenXid = 213156, next_xid = 214157,
urq_blocks = 6, +
free queue: head page blkno = 0 min_xid = 211187 max_xid = 214157, tail page blkno = 0
min_xid = 211187 max_xid = 214157,+
middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 1, valid_items =
6, can_use_item = 3 +
empty queue: head page blkno = 1 min_xid = 212160 max_xid = 213160, tail page blkno = 3
min_xid = 213162 max_xid = 214156,+
middle page min_xid = 1152921504606846975 max_xid = 0, valid_pages = 2, valid_items =
999, can_use_item = 498 +
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables.

- `gs_repair_urq(index_oid oid, partindex_oid oid)`  
Description: Repairs (with loss) index recycling queues (potential and available queues). The recycling queue file of the current index is deleted and an empty recycling queue file is created. If the repair is successful, **reinitial the recycle queue of index relation successfully** is displayed.

Parameter description: See [Table 7-116](#).

Note: The current function can be called only on the primary node.

**Table 7-116** `gs_repair_urq` parameters

Category	Parameter	Type	Description
Input parameter	<code>index_oid</code>	oid	UB-tree index OID. <ul style="list-style-type: none"> <li>• Common index: index OID.</li> <li>• Global index: GPI OID.</li> <li>• Local index: OID of the primary index.</li> </ul>
Input parameter	<code>partindex_oid</code>	oid	UB-Tree partitioned index OID: <ul style="list-style-type: none"> <li>• Common index: 0.</li> <li>• Global index: 0.</li> <li>• Local index: OID of the partitioned index (primary or secondary).</li> </ul>
Output parameter	<code>result</code>	text	If the repair is successful, <b>reinitial the recycle queue of index relation successfully</b> is displayed.

Example: When using the example, transfer parameters based on the parameter description and use the actual OID. Otherwise, an error is reported.

```
gaussdb=# select * from gs_repair_urq(16387, 0);
result
-----
reinitial the recycle queue of index relation successfully.
(1 row)
```

 **NOTE**

Currently, this API supports only Ustore index tables.

- `gs_get_standby_bad_block_info()`

Description: Displays the pages that have been detected on the standby node but have not been repaired. By default, only initial users, users with the `sysadmin` permission, users with the O&M administrator permission in the O&M mode, and users with the monitor administrator permission on the standby DN can view the information. Other users can view the information only after being granted with permissions. There are four return values in the **invalid\_type** column: **NOT\_PRESENT** (the page does not exist), **NOT\_INITIALIZED** (the page initialization fails), **LSN\_CHECK\_ERROR** (the LSN check fails), and **CRC\_CHECK\_ERROR** (the CRC check fails).

Return type: record

Example: If no page is detected but not repaired, no line is displayed.

```
gaussdb=# select * from gs_get_standby_bad_block_info();
 spc_node | db_node | rel_node | bucket_node | fork_num | block_num | invalid_type | master_page_lsn
-----+-----+-----+-----+-----+-----+-----+-----
 1663 | 16552 | 24745 | -1 | 0 | 0 | CRC_CHECK_ERROR | 0/B2009E8
(1 rows)
```

## 7.5.39 Functions of the XML Type

The following functions are inherited from open source PostgreSQL 9.2:

- `xmlparse ( { DOCUMENT | CONTENT } value [wellformed])`

Description: Generates XML values from character data.

Parameter: data of the TEXT type.

Return type: XML

Example:

```
gaussdb=# SELECT XMLPARSE (DOCUMENT '<?xml version="1.0"?><book><title>Manual</title><chapter>...</chapter></book>');
 xmlparse
-----
<book><title>Manual</title><chapter>...</chapter></book>
(1 row)
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo><bar>foo</bar>');
 xmlparse
-----
abc<foo>bar</foo><bar>foo</bar>
(1 row)
gaussdb=# SELECT XMLPARSE (CONTENT 'abc<foo>bar</foo>' wellformed);
 xmlparse
-----
abc<foo>bar</foo>
(1 row)
```

- `xmlserialize( { DOCUMENT | CONTENT } value AS type )`

Description: Generates a string from an XML file.

Parameter: The type can be character, character varying, text, or any variant of them.

Return type: XML

Example:

```
gaussdb=# SELECT XMLSERIALIZE(CONTENT 'good' AS CHAR(10));
 xmlserialize
```

```

-----
good
(1 row)
gaussdb=# SELECT xmlserialize(DOCUMENT '<head>bad</head>' as text);
xmlserialize
-----
<head>bad</head>
(1 row)

```

 **NOTE**

If a string value is converted to XML without using the XMLPARSE or XMLSERIALIZE function, the **XML OPTION** session parameter determines the value: **DOCUMENT** or **CONTENT**. The **XML OPTION** session parameter can be set by the standard command.

```
SET XML OPTION { DOCUMENT | CONTENT };
```

Or use similar syntax to set this parameter.

```
SET xmloption TO { DOCUMENT | CONTENT };
```

- **xmlcomment(text)**

Description: Creates an XML value that contains an XML comment with the specified text as the content. The text does not contain the "--" character and does not end with a "-" character. Besides, the text should meet the format requirements of XML comments. If the parameter is empty, the result is also empty.

Parameter: data of the TEXT type

Return type: XML

Example:

```

gaussdb=# SELECT xmlcomment('hello');
xmlcomment
-----
<!--hello-->

```

- **xmlconcat(xml[, ...])**

Description: Concatenates a list of single XML values into a single value that contains an XML content fragment. Null values are ignored, and the result is null only when all parameters are null. In database A-compatible mode, you can set **a\_format\_version** to **10c** and **a\_format\_dev\_version** to **s2** to check whether the input segment is well-formed XML text.

Parameter: data of the XML type

Return type: XML

Example 1:

```

gaussdb=# set xmloption=content;
SET
gaussdb=# select XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>'));
xmlconcat
-----
<?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)
gaussdb=# select XMLCONCAT('abc');
xmlconcat
-----
abc>
(1 row)

```

Example 2: Syntax of the A-compatible database

```

gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version=s2;

```

```

SET
gaussdb=# set xmloption=content;
SET
gaussdb=# select XMLCONCAT(('<?xml version="1.0" encoding="GB2312" standalone="no"?
><bar>foo</bar>'),('<?xml version="1.0" encoding="GB2312" standalone="no" ?><bar>foo</bar>'));
          xmlconcat
-----
<?xml version="1.0" standalone="no"?><bar>foo</bar><bar>foo</bar>
(1 row)
gaussdb=# select XMLCONCAT('abc');
ERROR:  invalid XML document
DETAIL:  line 1: Start tag expected, '<' not found
abc>
^
CONTEXT:  referenced column: xmlconcat

```

- xmlelement**( [ ENTITYESCAPING | NOENTITYESCAPING ] { [ NAME ] element\_name | EVALNAME element\_name } [ , xmlattributes( [ ENTITYESCAPING | NOENTITYESCAPING ] value [ [ AS ] attname | AS EVALNAME attname ] [ , ... ] ) ] [ , content [ [ AS ] alias ] [ , ... ] ] )

Description: Generates an XML element with the given name, attribute, and content.

Return type: XML

Example:

```

gaussdb=# SELECT xmlelement(name foo);
xmlelement
-----
<foo/>

```

In A-compatible mode:

```

gaussdb=# set a_format_version='10c';
SET
gaussdb=# set a_format_dev_version=s2;
SET

```

1. If the keyword ENTITYESCAPING is not set in XMLElement by default or is set, the reserved characters in the content of XMLElement are escaped.

```

gaussdb=# SELECT xmlelement("entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$&gt;&lt;&amp;quot;b</entityescaping<>>
(1 row)

```

```

gaussdb=# SELECT xmlelement(entityescaping "entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$&gt;&lt;&amp;quot;b</entityescaping<>>
(1 row)

```

2. When the keyword NOENTITYESCAPING is set in XMLElement, the reserved characters in the content of XMLElement will not be escaped.

```

gaussdb=# SELECT xmlelement(noentityescaping "entityescaping<>", 'a$<&"b');
          xmlelement
-----
<entityescaping<>>a$<&"b</entityescaping<>>
(1 row)

```

3. When [AS] alias is used to declare an alias for the content in XMLElement, the content value type must be XML.

```

gaussdb=# SELECT xmlelement("entityescaping<>", '<abc/>' b);
ERROR:  argument of XMLELEMENT must be type xml, not type unknown
LINE 1: SELECT xmlelement("entityescaping<>", '<abc/>' b);
          ^

```

CONTEXT: referenced column: xmlelement

```

gaussdb=# SELECT xmlelement("entityescaping<>", '<abc/>' as b);

```

```
ERROR: argument of XMLEMENT must be type xml, not type unknown
LINE 1: SELECT xmlement("entityescaping<>", '<abc/>' as b);
                ^
```

CONTEXT: referenced column: xmlement

```
gaussdb=# SELECT xmlement("entityescaping<>", xml('<abc/>') b);
xmlement
```

```
-----
<entityescaping<>><abc/></entityescaping<>>
(1 row)
```

```
gaussdb=# SELECT xmlement("entityescaping<>", xml('<abc/>') as b);
xmlement
```

```
-----
<entityescaping<>><abc/></entityescaping<>>
(1 row)
```

4. If the keyword ENTITYESCAPING is not set in XMLAttributes by default or is set, the reserved characters in XMLAttributes are escaped.

```
gaussdb=# SELECT xmlement("entityescaping<>", xmlattributes('entityescaping<>'
"entityescaping<>"));
xmlement
```

```
-----
<entityescaping<> entityescaping<>="entityescaping&lt;&gt;"/>
(1 row)
```

```
gaussdb=# SELECT xmlement(name "entityescaping<>", xmlattributes(entityescaping
'entityescaping<>' "entityescaping<>"));
xmlement
```

```
-----
<entityescaping<> entityescaping<>="entityescaping&lt;&gt;"/>
(1 row)
```

5. When the NOENTITYESCAPING keyword is set in XMLAttributes, the reserved characters in XMLAttributes will not be escaped.

```
gaussdb=# SELECT xmlement("entityescaping<>", xmlattributes(noentityescaping 'entityescaping<>'
"entityescaping<>"));
xmlement
```

```
-----
<entityescaping<> entityescaping<>="entityescaping<>"/>
(1 row)
```

#### NOTE

1. For **xmlement** and **xmlattributes**, when the value of **name** is **NULL**, the database behavior is different from that of the A database. When the **name** column of **xmlement** is set to **NULL**, the name information is empty and the attribute information is not displayed. When the **name** column of **xmlattributes** is set to **NULL**, the attribute information is not displayed.
2. After the following two parameters are set, the content escape rule of **xmlement** is A-compatible. If the two parameters are not set, the content escape rule of **xmlement** is PG-compatible.

```
set a_format_version='10c';
set a_format_dev_version=s2;
```

- **xmlforest**(content [AS name] [, ...])

Description: Generates an XML sequence of elements using the given name and content.

Return type: XML

Example:

```
gaussdb=# SELECT xmlforest('abc' AS foo, 123 AS bar);
xmlforest
```

```
-----
<foo>abc</foo><bar>123</bar>
```

- **xmlpi**(name target [, content])

Description: Creates an XML processing instruction. If the content is not empty, the content cannot contain collations.

Return type: XML

Example:

```
gaussdb=# SELECT xmlpi(name php, 'echo "hello world";');
          xmlpi
-----
<?php echo "hello world";?>
```

- `xmlroot(xml, version text | no value [, standalone yes|no|no value])`

Description: Modifies the attributes of the root node of an XML value. If a version is specified, it replaces the value in the version declaration of the root node. If a standalone property is specified, it replaces the value of standalone declaration in the root node.

Example:

```
gaussdb=# SELECT xmlroot('<?xml version="1.1"?><content>abc</content>',version '1.0', standalone yes);
          xmlroot
-----
<?xml version="1.0" standalone="yes"?><content>abc</content>
(1 row)
```

- `xmlagg(xml [order_by_clause])`

Description: Concatenates the input values called by the aggregate function. Cross-line concatenation is supported. For details about **order\_by\_clause**, see [SELECT](#). In A-compatible database mode, you can set **a\_format\_version** to **10c** and **a\_format\_dev\_version** to **s2**. The **xmloption** parameter of the database is set to **content** by default. When **xmloption** is set to **document**, newline characters are used to concatenate multiple XML lines. If the encoding attribute value in the XML declaration is not the default UTF-8, the aggregation result contains the XML declaration.

Parameter: XML

Return type: XML

Example 1:

```
gaussdb=# CREATE TABLE xmltest (
          id int,
          data xml
        );
gaussdb=# INSERT INTO xmltest VALUES (1, '<value>one</value>');
INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<value>two</value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<value>one</value><value>two</value>
(1 row)
```

Example 2: Syntax of the A-compatible database

```
gaussdb=# set xmloption=document;
SET
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<value>one</value>+
<value>two</value>
(1 row)
gaussdb=# DELETE FROM XMLTEST;
DELETE 2
gaussdb=# INSERT INTO xmltest VALUES (1, '<?xml version="1.0" encoding="GBK"?><value>one</value>');
```

```

INSERT 0 1
gaussdb=# INSERT INTO xmltest VALUES (2, '<?xml version="1.0" encoding="GBK"?><value>two</value>');
INSERT 0 1
gaussdb=# SELECT xmlagg(data) FROM xmltest;
          xmlagg
-----
<?xml version="1.0" encoding="GBK"?><value>one</value>+
<value>two</value>
(1 row)
gaussdb=# SELECT xmlagg(data order by id desc) FROM xmltest;
          xmlagg
-----
<?xml version="1.0" encoding="GBK"?><value>two</value>+
<value>one</value>
(1 row)

gaussdb=# DROP TABLE xmltest;

```

- `xmlexists(text passing [BY REF] xml [BY REF])`

Description: Evaluates an XPath 1.0 expression (the first parameter) with the passed XML value as its context item. If the evaluation result generates an empty set of nodes, the function returns **false**. If any other value is generated, the function returns **true**. If the value of any parameter is null, the function returns **Null**. The non-null value passed as a context item must be an XML document, not a content fragment or any non-XML value.

Parameter: XML

Return type: Boolean

Example:

```

gaussdb=# SELECT xmlexists('/town[text() = "Toronto"]' PASSING BY REF '<towns><town>Toronto</town><town>Ottawa</town></towns>');
xmlexists
-----
t
(1 row)

```

- `xml_is_well_formed(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```

gaussdb=# SELECT xml_is_well_formed('<>');
xml_is_well_formed
-----
f
(1 row)

```

- `xml_is_well_formed_document(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```

gaussdb=# SELECT xml_is_well_formed_document('<pg:foo xmlns:pg="http://postgresql.org/stuff">bar</pg:foo>');
xml_is_well_formed_document
-----
t
(1 row)

```

- `xml_is_well_formed_content(text)`

Description: Checks whether the text is in the correct XML format and returns a Boolean value.

Parameter: text

Return type: Boolean

Example:

```
gaussdb=# select xml_is_well_formed_content('k');
xml_is_well_formed_content
-----
t
(1 row)
```

- `xpath(xpath, xml [, nsarray])`

Description: Calculates an XPath 1.0 expression, for example, `xpath` (a text value), on XML data. It returns an array of XML values corresponding to the node set generated by the XPath expression. If the XPath expression returns a scalar value rather than a node set, a single-element array is returned.

The second parameter must be a well formed XML document. Note that it must have a single root node element.

The optional third parameter of the function is an array of namespace mappings. This array should be a two-dimensional text array with the length of the second axis being equal to 2 (that is, it should be an array of arrays, each of which consists of exactly 2 elements). The first element of each array entry is the namespace name (alias), and the second the namespace URI. It is not required that aliases provided in this array be the same as those being used in the XML document itself (in other words, both in the XML document and in the XPath function context, aliases are local).

Return type: XML

Example:

```
gaussdb=# SELECT xpath('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>',ARRAY[ARRAY['my', 'http://example.com']]);
xpath
-----
{test}
(1 row)
```

- `xpath_exists(xpath, xml [, nsarray])`

Description: This function is a special form of the `xpath` function. It returns a Boolean indicating whether the query is satisfied or not (specifically, whether it produces any value other than an empty node set), instead of returning the individual XML values that satisfy the XPath 1.0 expression. This function is equivalent to the standard `XMLEXISTS` predicate, but it also provides support for a namespace mapping parameter.

Return type: Boolean

Example:

```
gaussdb=# SELECT xpath_exists('/my:a/text()', '<my:a xmlns:my="http://example.com">test</my:a>',ARRAY[ARRAY['my', 'http://example.com']]);
xpath_exists
-----
t
(1 row)
```

```

+
</xsd:schema>
(1 row)

```

- query\_to\_xml\_and\_xmlschema(query text, nulls boolean, tableforest boolean, targetns text)

Description: This function maps the contents of a query to an XML document and an XML schema document, and joins the two documents together.

Return type: XML

Example:

```

gaussdb=# SELECT query_to_xml_and_xmlschema('SELECT * FROM testxmlschema.test1', true, true, '');
query_to_xml_and_xmlschema

```

```

-----

                +
(1 row)
    
```

- `cursor_to_xml(cursor refcursor, count int, nulls boolean,tableforest boolean, targetns text)`

Description: This function maps the contents of a cursor to an XML document.

Return type: XML

Example:

```

gaussdb=#CURSOR xc WITH HOLD FOR SELECT * FROM testxmlschema.test1 ORDER BY 1, 2;
DECLARE CURSOR
gaussdb=# SELECT cursor_to_xml('xc':refcursor, 5, false, true, '');
           cursor_to_xml
    
```

(1 row)

```

- `table_to_xml_and_xmlschema`(tbl regclass, nulls boolean, tableforest boolean, targetns text)

Description: This function maps the contents of a relational table to an XML document and an XML schema document, and joins the two documents together.

Return type: XML

Example:

```

gaussdb=# SELECT table_to_xml_and_xmlschema('testxmlschema.test1', false, false, '');
          table_to_xml_and_xmlschema

```

```

-----
<test1 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="#">

<row>                                     +
  <a>2</a>                                 +
  <b>two</b>                                +
</row>                                     +
<row>                                     +
  <a>-1</a>                                 +
</row>                                     +
</test1>                                  +
(1 row)

```

 **NOTE**

- For XPath-related functions, only XPath() and XPath\_exists() are supported. These functions use the XPath language to query XML files and depend on the Libxml2 library, which is provided only in XPath1.0. Therefore, only XPath 1.0 is supported.
- The XQuery, XML extension, and XSLT functions are not supported.

## 7.5.40 Functions of the XMLType Type

- createxml(varchar2 [,varchar2 ,numeric ,numeric])

Description: Statically creates the XMLType type. The input parameters are of the varchar2 type.

Parameters: The first parameter is the character string to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is 0 by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is 0 by default and does not take effect currently).

Return type: XMLType

Example:

```

gaussdb=# SELECT createxml('<a>123</a>');
 createxml
-----
<a>123</a>
(1 row)

```

 NOTE

- Different from that in database A, in PL/SQL, createxml allows input parameters to be empty strings and returns **NULL**.
- For character encoding, only UTF-8, GBK, and LATIN1 to LATIN10 are supported, and the **version** field can only be set to **1.x**.
- The createxml function can be called using the xmltype.createxml() syntax.

Example:

```
gaussdb=# SELECT xmltype.createxml('<a>123</a>');
createxml
-----
<a>123</a>
(1 row)
```

- In this chapter, the function whose input parameter is xmltype() can be called in xmltype().func() mode. The XMLType type returned by a function is transferred to the next function as the input parameter. This syntax supports multi-layer nesting. (If the input parameter is defined as XMLType by a user, this syntax is not supported.)

Example:

```
gaussdb=# select xmltype('<a>123<b>456</b></a>').extract('/a/b').getstringval();
xmltypefunc
-----
<b>456</b>
(1 row)
```

The actual effect of the preceding example is the same as that of the following function nesting:

```
gaussdb=# select getstringval(extractxml(xmltype('<a>123<b>456</b></a>'), '/a/b'));
getstringval
-----
<b>456</b>
(1 row)
```

- In a stored procedure, variables of the XMLType type can call functions in a.func() mode. This syntax supports one-layer nesting.

Example:

```
gaussdb=# declare
          a xmltype;
          b varchar2;
begin
  a:=xmltype('<a>123<b>456</b></a>');
  b:=a.getstringval();
  RAISE NOTICE 'xmltype_str is : %',b;
end;
/
NOTICE: xmltype_str is : <a>123<b>456</b></a>
```

- createxml(clob [,varchar2 ,numeric ,numeric])

Description: Statically creates the XMLType type. The input parameters are of the CLOB type.

Parameters: The first parameter is the CLOB to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

**Example:**

```
gaussdb=# declare
xmltype_clob clob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_clob := '<a>123</a>';
xmltype_obj := createxml(xmltype_clob);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <a>123</a>
```

 **NOTE**

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- `createxml(blob, numeric [,varchar2 ,numeric ,numeric])`

Description: Statically creates the XMLType type. The input parameters are of the BLOB type.

Parameters: The first parameter is the BLOB to be converted to XMLType (mandatory column). The second parameter is the character set ID of the input XML data (mandatory column). The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

**Example:**

```
gaussdb=# declare
xmltype_blob blob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_blob := xmltype('<a>123</a>').getblobval(7);
xmltype_obj := createxml(xmltype_blob,7);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

 **NOTE**

- The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
- The character set ID ranges from 1 to 41.
- `getblobval(xmltype, numeric)`

Description: Converts the XMLType type to the BLOB type. The `xmltype().func()` method can be called.

Parameters: The first parameter is of the XMLType type, and the second parameter is the ID of the target character set to be converted.

Return type: BLOB

Example:

```
gaussdb=# SELECT getblobval(xmltype('<asd/>'),7);
           getblobval
-----
3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

**xmltype ().func ():**

```
gaussdb=# select xmltype('<asd/>').getblobVal(7);
           xmltypefunc
-----
3C3F786D6C2076657273696F6E3D22312E302220656E636F64696E673D2255544638223F3E0A3C6173
642F3E
(1 row)
```

 **NOTE**

The maximum length of the input parameter of the XMLType type is 256 MB minus 1 byte.

- **getclobval(xmltype)**

Description: Converts the XMLType type to the CLOB type. The xmltype().func() method can be called.

Parameter: The input parameter is of the XMLType type.

Return type: CLOB

Example:

```
gaussdb=# SELECT getclobval(xmltype('<a>123</a>'));
           getclobval
-----
<a>123</a>
(1 row)
```

**xmltype ().func ():**

```
gaussdb=# SELECT xmltype('<a>123</a>').getclobval();
           xmltypefunc
-----
<a>123</a>
(1 row)
```

- **getnumberval(xmltype)**

Description: Converts the XMLType type to the numeric type. The xmltype().func() method can be called.

Parameter: The input parameter is of the XMLType type.

Return type: numeric

Example:

```
gaussdb=# SELECT getnumberval(xmltype('<a>123</a>').extract('/a/text()'));
           getnumberval
-----
           123
(1 row)
```

**xmltype ().func ():**

```
gaussdb=# SELECT xmltype('<a>123</a>').extract('/a/text()').getnumberval();
           xmltypefunc
-----
           123
(1 row)
```

- **isfragment(xmltype)**

Description: Returns a result indicating whether the XMLType type is fragment (1) or document (0). The xmltype().func() method can be called.

Parameter: The input parameter is of the XMLType type.

Return type: numeric

Example:

```
gaussdb=# SELECT isfragment(xmltype('<a>123</a>'));
isfragment
-----
0
(1 row)
```

xmltype ().func ():

```
gaussdb=# SELECT xmltype('<a>123</a>').isfragment();
xmltypefunc
-----
0
(1 row)
```

- xmltype(varchar2 [,varchar2 ,numeric ,numeric])

Description: Creates the XMLType type from the varchar2 type.

Parameters: The first parameter is the character string to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# SELECT xmltype('<a>123</a>');
xmltype
-----
<a>123</a>
(1 row)
```

#### NOTE

- Different from that in database A, in PL/SQL, XMType allows input parameters to be empty strings and returns **NULL**.
- For character encoding, only UTF-8, GBK, and LATIN1 to LATIN10 are supported, and the **version** field can only be set to **1.x**.
- xmltype(clob [,varchar2 ,numeric ,numeric])

Description: Creates the XMLType type from the CLOB type.

Parameters: The first parameter is the CLOB to be converted to XMLType (mandatory column). The second parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The third parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_clob clob;
```

```
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_clob := '<a>123</a>';
xmltype_obj := xmltype(xmltype_clob);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <a>123</a>
```

 **NOTE**

The maximum size of the input parameter of the CLOB type is 1 GB minus 1 byte.

- `xmltype(blob, numeric [,varchar2 ,numeric ,numeric])`

Description: Creates the XMLType type from the BLOB type.

Parameters: The first parameter is the BLOB to be converted to XMLType (mandatory column). The second parameter is the character set ID of the input XML data. The third parameter is the optional schema URL used to make the input comply with the specified schema (optional column, which is empty by default and does not take effect currently). The fourth parameter is the flag indicating whether the instance is valid according to the given XML schema (optional column, which is **0** by default and does not take effect currently). The fifth parameter is the flag indicating whether the instance is well-formed (optional column, which is **0** by default and does not take effect currently).

Return type: XMLType

Example:

```
gaussdb=# declare
xmltype_blob blob;
xmltype_obj xmltype;
xmltype_str varchar2(1000);
begin
xmltype_blob := getblobval(createxml('<a>123</a>',7));
xmltype_obj := xmltype(xmltype_blob,7);
xmltype_str := xmltype_obj.getstringval();
RAISE NOTICE 'xmltype_str is : %',xmltype_str;
end;
/
NOTICE: xmltype_str is : <?xml version="1.0" encoding="UTF8"?>
<a>123</a>
```

 **NOTE**

- The maximum size of input parameters of the BLOB type is 256 MB minus 1 byte.
- The character set ID ranges from 1 to 41.
- `getstringval(xmltype)`

Description: Converts `xmltype` into a string.

Parameter: XMLType to be converted.

Return type: varchar2

The `getstringval` function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT getstringval('<a>123<b>456</b></a>');
getstringval
-----
<a>123<b>456</b></a>
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getstringval();
xmltypefunc
-----
<a>123<b>456</b></a>
(1 row)
```

- `getrootelement(xmltype)`

Description: Gets the root element of the XMLType type.

Parameter: XMLType whose root element is to be obtained.

Return type: `varchar2`

The `getrootelement` function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT getrootelement('<a>123<b>456</b></a>');
getrootelement
-----
a
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').getrootelement();
xmltypefunc
-----
a
(1 row)
```

- `getnamespace(xmltype)`

Description: Gets the namespace of the XMLType top-level element.

Parameter: XMLType whose namespace is to be obtained.

Return type: `varchar2`

The `getnamespace` function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT getnamespace('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></c:a>');
getnamespace
-----
asd
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<c:a xmlns:c="asd">123<d:b xmlns:d="qwe">456</d:b></c:a>').getnamespace();
xmltypefunc
-----
asd
(1 row)
```

- `existsnode(xmltype, varchar2[, varchar2])`

Description: Determines whether the XML node exists in XMLType based on the XPath expression. If the XML node exists, **1** is returned. Otherwise, **0** is returned.

Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

Return type: `numeric`

The `existsnode` function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT existsnode('<a>123<b>456</b></a>', '/a/b');
existsnode
-----
1
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').existsnode('/a/b');
xmltypefunc
-----
1
(1 row)
```

Example 3

```
gaussdb=# SELECT existsnode('<a:b xmlns:a="asd">123<c>456</c></a:b>', '/a:b/c', 'xmlns:a="asd"');
existsnode
-----
1
(1 row)
```

Example 4: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').existsnode('/a:b/c', 'xmlns:a="asd"');
xmltypefunc
-----
1
(1 row)
```

- `extractxml(xmltype, varchar2[, varchar2])`

Description: Checks whether an XML node exists in the given XMLType based on the XPath expression. If yes, the XMLType containing the node is returned. If no, **NULL** is returned. The return value can be inserted into a table of the XMLType type.

Parameters: XMLType to be queried, path of the XPath node to be queried, and namespace of the XPath path (If the input parameter has a namespace, aliases must be defined for both the XPath and namespace, as shown in example 3.)

Return type: XMLType

The `extractxml` function can be called in either of the following ways:

Example 1:

```
gaussdb=# SELECT extractxml('<a>123<b>456</b></a>', '/a/b');
extractxml
-----
<b>456</b>
(1 row)
```

Example 2: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extract('/a/b');
xmltypefunc
-----
<b>456</b>
(1 row)
```

```
gaussdb=# SELECT xmltype('<a>123<b>456</b></a>').extractxml('/a/b');
xmltypefunc
-----
<b>456</b>
(1 row)
```

Example 3

```
gaussdb=# SELECT extractxml('<a:b xmlns:a="asd">123<c>456</c></a:b>', '/a:b', 'xmlns:a="asd"');
extractxml
```

```
-----
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

Example 4: The calling mode is compatible with the ORA syntax.

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extract('/a:b','xmlns:a="asd"');
xmltypefunc
```

```
-----
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

```
gaussdb=# SELECT xmltype('<a:b xmlns:a="asd">123<c>456</c></a:b>').extractxml('/
a:b','xmlns:a="asd"');
xmltypefunc
```

```
-----
<a:b xmlns:a="asd">123<c>456</c></a:b>
(1 row)
```

## 7.5.41 Global PL/SQL Cache Functions

- `invalidate_plsql_object()`, `invalidate_plsql_object(schema, objname, objtype)`;

Description: Invalidates objects in the global PL/SQL cache. This parameter is available only when **enable\_global\_plsqlcache** is set to **on**. The user who calls this function must have the SYSADMIN permission.

Parameter: This function is an overloaded function. If there is no input parameter, all global cache objects in all databases are invalidated.

If **schema**, **objname**, and **objtype** are specified, the specified global cache object in the current database is invalidated. **schema** indicates the name of the schema to which the object belongs, **objname** indicates the object name, and **objtype** indicates the object type. If the object is a package, the value of **objtype** is **package**. If the object is a function or stored procedure, the value of **objtype** is **function**.

Example:

This function does not return the invalidation result. You can query the invalidation result in the `gs_glc_memory_detail` view. If the object is not invalidated, you can find it in valid state in the view. If the object is invalidated, there is no such state.

**invalidate\_plsql\_object** belongs to the `pg_catalog` schema. It can be called even if no schema is specified.

-- If the cache information of function f3 is displayed in the view, the function is valid.

```
gaussdb=# SELECT * FROM gs_glc_memory_detail WHERE type='func' or type='pkg';
contextname | database | schema | type | status | location | env | usedsize
```

```
-----+-----+-----+-----+-----+-----+-----+-----
pkg1      | testdb | public | pkg | valid | in_global_hash_table | 0 | 184176
f3        | testdb | public | func | valid | in_global_hash_table | 0 | 47584
```

-- To invalidate function f3, specify the schema, function name, and type. Then, query the view again, the status of f3 is not valid.

```
gaussdb=# SELECT invalidate_plsql_object('public','f3','function');
invalidate_plsql_object
```

```
-----
(1 row)
```

-- To invalidate a package, set the parameters as follows:

```
gaussdb=# call pg_catalog.invalidate_plsql_object('public','pkg1','package');
invalidate_plsql_object
```

```
-----
(1 row)
```

-- If there is no input parameter, all cache objects will be invalidated.

```
gaussdb=# SELECT invalidate_plsql_object();
invalidate_plsql_object
```

-----  
(1 row)

## 7.5.42 Obsolete Functions

The following functions in GaussDB have been discarded in the latest version:

- `gs_wlm_get_session_info`
- `gs_wlm_get_user_session_info`
- `pgxc_get_csn`
- `pgxc_get_stat_dirty_tables`
- `pgxc_get_thread_wait_status`
- `pgxc_gtm_snapshot_status`
- `pgxc_is_committed`
- `pgxc_lock_for_backup`
- `pgxc_lock_for_sp_database`
- `pgxc_lock_for_transfer`
- `pgxc_log_comm_status`
- `pgxc_max_datanode_size`
- `pgxc_node_str`
- `pgxc_pool_check`
- `pgxc_pool_connection_status`
- `pgxc_pool_reload`
- `pgxc_prepared_xact`
- `pgxc_snapshot_status`
- `pgxc_stat_dirty_tables`
- `pgxc_unlock_for_sp_database`
- `pgxc_unlock_for_transfer`
- `pgxc_version`
- `array_extend`
- `prepare_statement_status`
- `remote_rto_stat`
- `dbe_perf.global_slow_query_info`
- `dbe_perf.global_slow_query_info_bytime`
- `dbe_perf.global_slow_query_history`
- `pg_stat_get_pooler_status`
- `pg_stat_get_wlm_node_resource_info`
- `pg_stat_get_wlm_session_info_internal`
- `DBE_PERF.get_wlm_controlgroup_ng_config()`
- `DBE_PERF.get_wlm_user_resource_runtime()`
- `global_space_shrink`
- `pg_pool_validate`
- `gs_stat_ustore`

- `table_skewness(text)`
- `table_skewness(text, text, text)`
- `pv_compute_pool_workload()`

## 7.6 Expressions

### 7.6.1 Simple Expressions

#### Logical Expressions

[Logical Operators](#) lists the operators and calculation rules of logical expressions.

#### Comparative Expressions

[Comparison Operators](#) lists the common comparative operators.

In addition to comparative operators, you can also use the following sentence structure:

- BETWEEN operator  
**a BETWEEN x AND y** is equivalent to **a >= x AND a <= y**.  
**a NOT BETWEEN x AND y** is equivalent to **a < x OR a > y**.
- To check whether a value is null, use:  
expression IS NULL  
expression IS NOT NULL  
or an equivalent (non-standard) sentence structure:  
expression ISNULL  
expression NOTNULL

---

#### NOTICE

- Do not write **expression=NULL** or **expression<>(=)NULL**, because **NULL** represents an unknown value and these expressions cannot determine whether two unknown values are equal.
  - Only the comparative expressions IS NULL and IS NOT NULL support data of XML type.
- 
- is distinct from/is not distinct from
    - is distinct from  
If the data types and values of A and B are different, the value is **true**.  
If the data types and values of A and B are the same, the value is **false**.  
Empty values are considered the same.
    - is not distinct from  
If the data types and values of A and B are different, the value is **false**.  
If the data types and values of A and B are the same, the value is **true**.

Empty values are considered the same.

- `<=>` NULL-safe equal operator

The comparison of NULL values is added on the basis of the comparison of '='. If neither the left nor right value of the operator is NULL, the result is the same as that of '='.

If the data types and values of A and B are different, the value is **false**.

If the data types and values of A and B are the same, the value is **true**.

Empty values are considered the same.

 **NOTE**

- The usage of the `<=>` operator is the same as that of IS NOT DISTINCT FROM.
- This operator is valid only when the database is compatible with the MY type (that is, `sql_compatibility` is set to 'B'). Other types do not support this operator.

## Examples

```
gaussdb=# SELECT 2 BETWEEN 1 AND 3 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2 >= 1 AND 2 <= 3 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2 NOT BETWEEN 1 AND 3 AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2 < 1 OR 2 > 3 AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2+2 IS NULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2+2 IS NOT NULL AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2+2 ISNULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 2+2 NOTNULL AS RESULT;
result
-----
t
(1 row)
```

```
gaussdb=# SELECT 2+2 IS DISTINCT FROM NULL AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT 2+2 IS NOT DISTINCT FROM NULL AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT 1 <=> 1 AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT NULL <=> 1 AS RESULT;
result
-----
f
(1 row)

gaussdb=# SELECT NULL <=> NULL AS RESULT;
result
-----
t
(1 row)
```

## 7.6.2 Condition Expressions

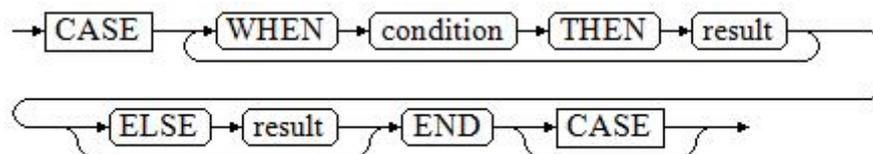

Data that meets the requirements specified by conditional expressions are filtered during SQL statement execution.

Conditional expressions include the following types:

- **CASE**  
**CASE** expressions are similar to the **CASE** statements in other coding languages.

**Figure 7-1** shows the syntax of a **CASE** expression.

**Figure 7-1** case::=

A **CASE** clause can be used in a valid expression. **condition** is an expression that returns a value of Boolean type.

- If the result is true, the result of the **CASE** expression is the required result.
- If the result is false, the following **WHEN** or **ELSE** clauses are processed in the same way.

- If every **WHEN condition** is false, the result of the expression is the result of the **ELSE** clause. If the **ELSE** clause is omitted and has no match condition, the result is NULL.
- Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE case_when_t1(CW_COL1 INT);
gaussdb=# INSERT INTO case_when_t1 VALUES (1), (2), (3);
gaussdb=# SELECT * FROM case_when_t1;
cw_col1
-----
1
2
3
(3 rows)

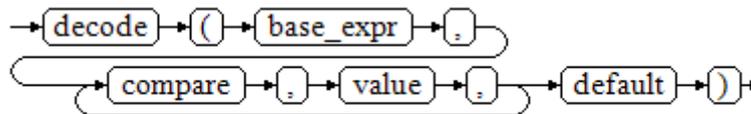

gaussdb=# SELECT CW_COL1, CASE WHEN CW_COL1=1 THEN 'one' WHEN CW_COL1=2 THEN 'two'
ELSE 'other' END FROM case_when_t1 ORDER BY 1;
cw_col1 | case
-----+-----
1 | one
2 | two
3 | other
(3 rows)

gaussdb=# DROP TABLE case_when_t1;
```

- DECODE

**Figure 7-2** shows the syntax of a **DECODE** expression.

**Figure 7-2** decode::=

Compare each following **compare(n)** with **base\_expr**. **value(n)** is returned if a **compare(n)** matches the **base\_expr** expression. If **base\_expr** does not match each **compare(n)**, the default value is returned.

Operations on XML data are supported.

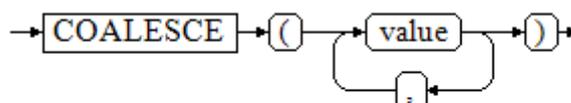

**Conditional Expression Functions** describes the examples.

```
gaussdb=# SELECT DECODE('A','A',1,'B',2,0);
case
-----
1
(1 row)
```

- COALESCE

**Figure 7-3** shows the syntax of a **COALESCE** expression.

**Figure 7-3** coalesce::=

**COALESCE** returns its first not-**NULL** value. If all the parameters are **NULL**, **NULL** is returned. This value is replaced by the default value when data is displayed. Like a **CASE** expression, **COALESCE** only evaluates the parameters that are needed to determine the result. That is, parameters to the right of the first non-null parameter are not evaluated.

Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE c_tabl(description varchar(10), short_description varchar(10), last_value
varchar(10)) ;

gaussdb=# INSERT INTO c_tabl VALUES('abc', 'efg', '123');
gaussdb=# INSERT INTO c_tabl VALUES(NULL, 'efg', '123');

gaussdb=# INSERT INTO c_tabl VALUES(NULL, NULL, '123');

gaussdb=# SELECT description, short_description, last_value, COALESCE(description, short_description,
last_value) FROM c_tabl ORDER BY 1, 2, 3, 4;
description | short_description | last_value | coalesce
-----+-----+-----+-----
abc         | efg              | 123       | abc
           | efg              | 123       | efg
           |                  | 123       | 123
(3 rows)

gaussdb=# DROP TABLE c_tabl;
```

If **description** is not **NULL**, the value of **description** is returned. Otherwise, parameter **short\_description** is calculated. If **short\_description** is not **NULL**, the value of **short\_description** is returned. Otherwise, parameter **last\_value** is calculated. If **last\_value** is not **NULL**, the value of **last\_value** is returned. Otherwise, **none** is returned.

```
gaussdb=# SELECT COALESCE(NULL,'Hello World');
coalesce
-----
Hello World
(1 row)
```

- **NULLIF**

**Figure 7-4** shows the syntax of a **NULLIF** expression.

**Figure 7-4** nullif::=

Only if **value1** is equal to **value2** can **NULLIF** return the **NULL** value. Otherwise, **value1** is returned. Operations on XML data are supported.

Example:

```
gaussdb=# CREATE TABLE null_if_t1 (
NI_VALUE1 VARCHAR(10),
NI_VALUE2 VARCHAR(10)
);

gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'abc');
gaussdb=# INSERT INTO null_if_t1 VALUES('abc', 'efg');

gaussdb=# SELECT NI_VALUE1, NI_VALUE2, NULLIF(NI_VALUE1, NI_VALUE2) FROM null_if_t1 ORDER
BY 1, 2, 3;
```

```

ni_value1 | ni_value2 | nullif
-----+-----+-----
abc      | abc      |
abc      | efg      | abc
(2 rows)
gaussdb=# DROP TABLE null_if_t1;
    
```

If the value of **value1** is equal to that of **value2**, **NULL** is returned. Otherwise, the value of **value1** is returned.

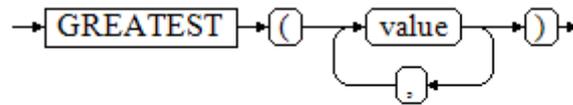

```

gaussdb=# SELECT NULLIF('Hello','Hello World');
nullif
-----
Hello
(1 row)
    
```

- GREATEST (maximum value) and LEAST (minimum value)

**Figure 7-5** shows the syntax of a **GREATEST** expression.

**Figure 7-5** greatest::=

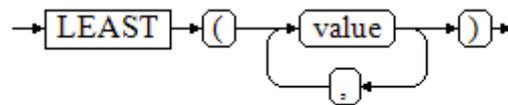

You can select the maximum value from any numerical expression list. Operations on XML data are supported.

```

gaussdb=# SELECT greatest(9000,15555,2.01);
greatest
-----
15555
(1 row)
    
```

**Figure 7-6** shows the syntax of a **LEAST** expression.

**Figure 7-6** least::=

You can select the minimum value from any numerical expression list.

Each of the preceding numeric expressions can be converted into a common data type, which will be the data type of the result.

The **NULL** values in the list will be ignored. The result is **NULL** only if the results of all expressions are **NULL**.

Operations on XML data are supported.

```

gaussdb=# SELECT least(9000,2);
least
-----
2
(1 row)
    
```

**Conditional Expression Functions** describes the examples.

- NVL

**Figure 7-7** shows the syntax of an **NVL** expression.

**Figure 7-7** nvl::=

If the value of **value1** is **NULL**, the value of **value2** is returned. Otherwise, the value of **value1** is returned. Operations on XML data are supported.

Example:

```
gaussdb=# SELECT nvl(null,1);
nvl
-----
1
(1 row)
gaussdb=# SELECT nvl ('Hello World',1);
nvl
-----
Hello World
(1 row)
```

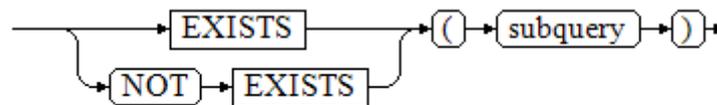

## 7.6.3 Subquery Expressions

Subquery expressions include the following types:

- EXISTS/NOT EXISTS

**Figure 7-8** shows the syntax of an **EXISTS/NOT EXISTS** expression.

**Figure 7-8** EXISTS/NOT EXISTS::=

The parameter of an **EXISTS** expression is an arbitrary **SELECT** statement, that is, subquery. The subquery is evaluated to determine whether it returns any rows. If it returns at least one row, the result of **EXISTS** is true. If the subquery returns no rows, the result of **EXISTS** is false.

The subquery will generally only be executed long enough to determine whether at least one row is returned, not all the way to completion.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE exists_t1(a int, b int);
gaussdb=# INSERT INTO exists_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE exists_t2(a int, c int);
gaussdb=# INSERT INTO exists_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM exists_t1 t1 WHERE EXISTS (SELECT * FROM exists_t2 t2 WHERE t2.a =
t1.a);
a | b
---+---
3 | 4
```

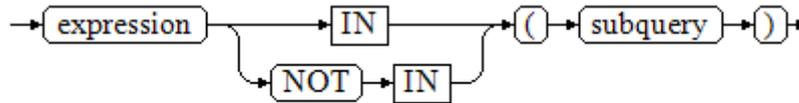

```
4 | 5
(2 rows)

gaussdb=# DROP TABLE exists_t1, exists_t2;
```

- IN/NOT IN

**Figure 7-9** shows the syntax of an **IN/NOT IN** expression.

**Figure 7-9** IN/NOT IN::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result. The result of **IN** is true if any equal subquery row is found. The result is false if no equal row is found (including the case where the subquery returns no rows).

This is in accordance with SQL normal rules for Boolean combinations of null values. If the columns corresponding to two rows equal and are not empty, the two rows are equal to each other. If any columns corresponding to the two rows do not equal and are not empty, the two rows are not equal to each other. Otherwise, the result is **NULL**. If there are no equal right-hand values and at least one right-hand row yields null, the result of **IN** will be null, not false.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE in_t1(a int, b int);
gaussdb=# INSERT INTO in_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE in_t2(a int, c int);
gaussdb=# INSERT INTO in_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

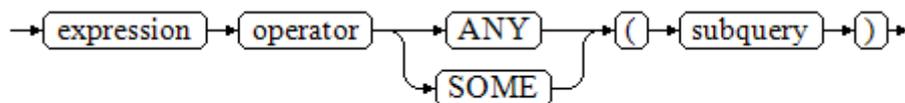

gaussdb=# SELECT * FROM in_t1 t1 WHERE t1.a IN (SELECT t2.a FROM in_t2 t2);
a | b
---+---
3 | 4
4 | 5
(2 rows)

gaussdb=# DROP TABLE in_t1, in_t2;
```

- ANY/SOME

**Figure 7-10** shows the syntax of an **ANY/SOME** expression.

**Figure 7-10** any/some::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row

of the subquery result using the given operator, which must yield a Boolean result. The result of **ANY** is "true" if any true result is obtained. The result is "false" if no true result is found (including the case where the subquery returns no rows). **SOME** is a synonym of **ANY**. **IN** can be equivalently replaced by **ANY**.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE any_t1(a int, b int);
gaussdb=# INSERT INTO any_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE any_t2(a int, c int);
gaussdb=# INSERT INTO any_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM any_t1 t1 WHERE t1.a < ANY(SELECT t2.a FROM any_t2 t2 where t2.a = 3
or t2.a = 4);
 a | b
---+---
 1 | 2
 2 | 3
 3 | 4
(3 rows)

gaussdb=# DROP TABLE any_t1, any_t2;
```

- ALL

**Figure 7-11** shows the syntax of an **ALL** expression.

**Figure 7-11** all::=

The right-hand side is a parenthesized subquery, which must return exactly one column. The left-hand expression is evaluated and compared to each row of the subquery result using the given operator, which must yield a Boolean result. The result of **ALL** is true if all values are true (including the case where the subquery returns no rows). The result is false if any false result is found.

Operations on XML data are not supported.

Example:

```
gaussdb=# CREATE TABLE all_t1(a int, b int);
gaussdb=# INSERT INTO all_t1 VALUES(1, 2),(2, 3),(3, 4),(4, 5);

gaussdb=# CREATE TABLE all_t2(a int, c int);
gaussdb=# INSERT INTO all_t2 VALUES(3, 4),(4, 5),(5, 6),(6, 7);

gaussdb=# SELECT * FROM all_t1 t1 WHERE t1.a < ALL(SELECT t2.a FROM all_t2 t2 where t2.a = 3 or
t2.a = 4);
 a | b
---+---
 1 | 2
 2 | 3
(2 rows)

gaussdb=# DROP TABLE all_t1, all_t2;
```

## 7.6.4 Array Expressions

### IN

*expression* **IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list meets the expression result on the left, the result of **IN** is **true**. If no result meets the requirements, the result of **IN** is **false**.

Example:

```
gaussdb=# SELECT 8000+500 IN (10000, 9000) AS RESULT;
result
-----
f
(1 row)
```

#### NOTE

- If the expression result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **IN** is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- Operations on XML data are not supported.

### NOT IN

*expression* **NOT IN** (*value* [, ...])

The parentheses on the right contain an expression list. The expression result on the left is compared with the content in the expression list. If the content in the list does not meet the expression result on the left, the result of **NOT IN** is **true**. If any content meets the expression result, the result of **NOT IN** is **false**.

Example:

```
gaussdb=# SELECT 8000+500 NOT IN (10000, 9000) AS RESULT;
result
-----
t
(1 row)
```

#### NOTE

- If the query statement result is null or the expression list does not meet the expression conditions and at least one empty value is returned for the expression list on the right, the result of **NOT IN** is null rather than false. This method is consistent with the Boolean rules used when SQL statements return empty values.
- In all situations, **X NOT IN Y** equals to **NOT(X IN Y)**.
- Operations on XML data are not supported.

### ANY/SOME (array)

*expression operator* **ANY** (*array expression*)

*expression operator* **SOME** (*array expression*)

The right side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the

results in each row of the array expression. The comparison result must be a Boolean value.

Example:

```
gaussdb=# SELECT 8000+500 < SOME (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)  
gaussdb=# SELECT 8000+500 < ANY (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)
```

#### NOTE

- If at least one comparison result is true, the result of ANY is true.
- If no comparison result is true, the result of ANY is false.
- If no comparison result is true and the array expression generates at least one null value, the value of **ANY** is **NULL** rather than **false**. This method is consistent with the Boolean rules used when SQL statements return empty values.
- SOME is a synonym of ANY.
- Operations on XML data are not supported.

## ALL (array)

*expression operator ALL (array expression)*

The right-hand side is a parenthesized expression, which must yield an array value. The result of the expression on the left uses operators to compute and compare the results in each row of the array expression. The comparison result must be a Boolean value.

- The result of **ALL** is **true** if all comparisons yield **true** (including the case where the array has zero elements).
- The result of **ALL** is **false** if one or multiple comparisons yield **false**.
- If the array expression yields a null array, the result of **ALL** will be null. If the expression on the left yields NULL, the result of ALL is generally NULL (though a non-strict comparison operator could possibly yield a different result). If the array on the right contains any null elements and no false comparison result is found, the result of ALL is NULL, not true (again, assuming a strict comparison operator). This method is consistent with the Boolean rules used when SQL statements return empty values.
- Operations on XML data are not supported.

```
gaussdb=# SELECT 8000+500 < ALL (array[10000,9000]) AS RESULT;  
result  
-----  
t  
(1 row)
```

## 7.6.5 Row Expressions

The syntax is as follows:

```
row_constructor operator row_constructor
```

Both sides of the row expression are row constructors. The values of both rows must have the same number of fields and they are compared with each other. The row comparison allows operators including =, <>, <, <=, and >= or a similar operator.

For operators <, <=, >, and >=, the columns in rows are compared from left to right until a pair of columns that are not equal or are empty are detected. If the pair of columns contains at least one null value, the comparison result is null. Otherwise, the comparison result of this pair of columns is the final result. If no unequal or empty column is found, the values in the two rows are equal. The final result is determined based on the operator meaning.

Operations on XML data are not supported.

Example:

```
gaussdb=# SELECT ROW(1,2,NULL) < ROW(1,3,0) AS RESULT;
result
-----
t
(1 row)

gaussdb=# SELECT (4,5,6) > (3,2,1) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,1) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT ('test','data') > ('data','data') AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (4,1,1) > (3,2,null) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (null,1,1) > (3,2,1) AS result;
result
-----
(1 row)

gaussdb=# SELECT (null,5,6) > (null,5,6) AS result;
result
-----
(1 row)

gaussdb=# SELECT (4,5,6) > (4,5,6) AS result;
result
-----
f
(1 row)

gaussdb=# SELECT (2,2,5) >= (2,2,3) AS result;
result
-----
```

```
t
(1 row)

gaussdb=# SELECT (2,2,1) <= (2,2,3) AS result;
result
-----
t
(1 row)
```

The use of operators = and <> is slightly different from other operators. If all columns in the two rows are not empty and meet the operator condition, the two rows meet the operator condition. If any column in the two rows is not empty and does not meet the operator condition, the two rows do not meet the operator condition. If any column in the two rows is empty, the comparison result is null.

Example:

```
gaussdb=# SELECT (1,2,3) = (1,2,3) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (1,2,3) <> (2,2,3) AS result;
result
-----
t
(1 row)

gaussdb=# SELECT (2,2,3) <> (2,2,null) AS result;
result
-----
(1 row)

gaussdb=# SELECT (null,5,6) <> (null,5,6) AS result;
result
-----
(1 row)
```

## 7.7 Pseudocolumn

**ROWNUM** is a pseudocolumn that returns a number indicating the row number of the obtained query result. The value of **ROWNUM** in the first row is **1**, the value of **ROWNUM** in the second row is **2**, and so on.

**ROWNUM** can be used to limit the number of rows returned by a query, as shown in the following example:

```
gaussdb=# CREATE TABLE Students (name varchar(20), id int) with (STORAGE_TYPE = USTORE);
gaussdb=# INSERT INTO Students VALUES ('Jack', 35);
gaussdb=# INSERT INTO Students VALUES ('Leon', 15);
gaussdb=# INSERT INTO Students VALUES ('James', 24);
gaussdb=# INSERT INTO Students VALUES ('Taker', 81);
gaussdb=# INSERT INTO Students VALUES ('Mary', 25);
gaussdb=# INSERT INTO Students VALUES ('Rose', 64);
gaussdb=# INSERT INTO Students VALUES ('Perl', 18);
gaussdb=# INSERT INTO Students VALUES ('Under', 57);
gaussdb=# INSERT INTO Students VALUES ('Angel', 101);
gaussdb=# INSERT INTO Students VALUES ('Frank', 20);
gaussdb=# INSERT INTO Students VALUES ('Charlie', 40);

-- Output the first 10 rows of data records in the Students table.
gaussdb=# SELECT * FROM Students WHERE rownum <= 10;
name | id
```

```
-----+-----
Jack | 35
Leon | 15
James | 24
Taker | 81
Mary | 25
Rose | 64
Perl | 18
Under | 57
Angel | 101
Frank | 20
(10 rows)
```

If the statement has a clause, the output rows are reordered according to the clause.

```
gaussdb=# SELECT * FROM Students WHERE rownum < 5 order by 1;
name | id
-----+-----
Jack | 35
James | 24
Leon | 15
Taker | 81
(4 rows)
```

If a subquery has a clause but the condition is placed in the top-level query, you can use the **ROWNUM** condition after sorting.

```
gaussdb=# SELECT rownum, * FROM (SELECT * FROM Students order by 1) WHERE rownum <= 2;
rownum | name | id
-----+-----+-----
1 | Angel | 101
2 | Charlie | 40
(2 rows)
```

As long as **ROWNUM** is greater than a specific positive integer, the condition is always false. As shown in the following example, the statement does not return any result in the table.

```
gaussdb=# SELECT * FROM Students WHERE rownum > 1;
name | id
-----+-----
(0 rows)
```

Use **ROWNUM** to assign a value to each row within a certain range of the table.

```
gaussdb=# SELECT * FROM Students;
name | id
-----+-----
Jack | 35
Leon | 15
James | 24
Taker | 81
Mary | 25
Rose | 64
Perl | 18
Under | 57
Angel | 101
Frank | 20
Charlie | 40
(11 rows)
```

```
gaussdb=# update Students set id = id + 5 WHERE rownum < 4;
UPDATE 3
gaussdb=# SELECT * FROM Students;
name | id
-----+-----
Jack | 40
Leon | 20
James | 29
Taker | 81
Mary | 25
```

```
Rose | 64
Perl | 18
Under | 57
Angel | 101
Frank | 20
Charlie | 40
(11 rows)
```

```
gaussdb=# DROP TABLE Students;
DROP TABLE
```

The restrictions on using **ROWNUM** are as follows:

- Do not use ROWNUM as an alias to avoid ambiguity in SQL statements.
- Do not use ROWNUM when creating an index.
- Do not use ROWNUM as the default value when creating a table.
- Do not use ROWNUM as an alias in the WHERE clause.
- Do not use ROWNUM when inserting data.
- Do not use ROWNUM in a tableless query.
- Do not use ROWNUM in the LIMIT clause.
- **ROWNUM** cannot be used as a parameter of the EXECUTE statement.
- Do not use ROWNUM to update a clause in the UPSERT statement.
- If the HAVING clause contains ROWNUM (not in an aggregate function), the GROUP BY clause must also contain ROWNUM (not in an aggregate function), unless the GROUP BY clause contains an expression, for example, **SELECT a + a FROM t group by a + a having rownum < 5**.
- If the ROWNUM condition exists in the HAVING clause, the HAVING clause cannot be pushed down to any scan node.

```
gaussdb=# CREATE TABLE test (a int, b int);
CREATE TABLE
gaussdb=# INSERT INTO test SELECT generate_series, generate_series from generate_series(1, 10);
INSERT 0 10
```

-- The rownum condition cannot be pushed down to **seqscan**.

```
gaussdb=# EXPLAIN SELECT a,rownum FROM test group by a,rownum having rownum < 5;
QUERY PLAN
```

```
-----
HashAggregate (cost=42.23..69.10 rows=2149 width=4)
  Group By Key: a, ROWNUM
  Filter: ((ROWNUM) < 5)
   -> Rownum (cost=0.00..31.49 rows=2149 width=4)
     -> Seq Scan on test (cost=0.00..31.49 rows=2149 width=4)
(5 rows)
```

- If a subquery contains the ROWNUM condition, the predicate cannot be pushed down to any scan node.

-- b<5 cannot be pushed down to **seqscan**.

```
gaussdb=# EXPLAIN SELECT * FROM (SELECT * FROM test WHERE rownum < 5) WHERE b < 5;
QUERY PLAN
```

```
-----
Subquery Scan on __unnamed_subquery__ (cost=0.00..0.01 rows=1 width=8)
  Filter: (__unnamed_subquery__.b < 5)
   -> Rownum (cost=0.00..0.00 rows=1 width=8)
     StopKey: (ROWNUM < 5)
     -> Seq Scan on test (cost=0.00..31.49 rows=2149 width=8)
(5 rows)
```

```
gaussdb=# DROP TABLE test;
DROP TABLE
```

 CAUTION

It is not recommended that the ROWNUM condition be used in the JOIN ON clause. In GaussDB, when the ROWNUM condition is used in the JOIN ON clause, the behavior in the LEFT JOIN, RIGHT JOIN, FULL JOIN, and MERGE INTO scenarios is different from that in other databases, causing risks in service migration.

## 7.8 Type Conversion

### 7.8.1 Overview

#### Background

SQL is a typed language. That is, every data item has an associated data type which determines its behavior and allowed usage. GaussDB has an extensible type system that is more general and flexible than other SQL implementations. Hence, most type conversion behaviors in GaussDB are governed by general rules. This allows the use of mixed-type expressions.

The GaussDB scanner/parser divides lexical elements into five fundamental categories: integers, floating-point numbers, strings, identifiers, and keywords. Constants of most non-numeric types are first classified as strings. The SQL language definition allows specifying type names with constant strings. Example:

```
gaussdb=# SELECT text 'Origin' AS "label", point '(0,0)' AS "value";
label | value
-----+-----
Origin | (0,0)
(1 row)
```

has two literal constants, of type **text** and **point**. If a type is not specified for a string literal, then the placeholder type **unknown** is assigned initially.

There are four fundamental SQL constructs requiring distinct type conversion rules in GaussDB parser:

- **Function calls**  
Much of the SQL type system is built around a rich set of functions. Functions can have one or more arguments. Since SQL permits function overloading, the function name alone does not uniquely identify the function to be called. The parser must select the right function based on the data types of the supplied arguments.
- **Operators**  
SQL allows expressions with prefix and postfix unary (one-argument) operators, as well as binary (two-argument) operators. Like functions, operators can be overloaded, so the same problem of selecting the right operator exists.
- **Value storage**  
SQL **INSERT** and **UPDATE** statements place the results of expressions into a table. The expressions in the statement must be matched up with, and perhaps converted to, the types of the target columns.

- UNION, CASE, and Related Constructs

Since all query results from a unionized **SELECT** statement must appear in a single set of columns, the types of the results of each **SELECT** clause must be matched up and converted to a uniform set. Similarly, the result expressions of a **CASE** construct must be converted to a common type so that the **CASE** expression as a whole has a known output type. The same holds for **ARRAY** constructs, and for the **GREATEST** and **LEAST** functions.

The system catalog `pg_cast` stores information about which conversions, or casts, exist between which data types, and how to perform those conversions. For details, see [PG\\_CAST](#).

The return type and conversion behavior of an expression are determined during semantic analysis. Data types are divided into several basic type categories, including Boolean, **numeric**, **string**, **bitstring**, **datetime**, **timespan**, **geometric**, and **network**. Within each category there can be one or more preferred types, which are preferred when there is a choice of possible types. With careful selection of preferred types and available implicit casts, it is possible to ensure that ambiguous expressions (those with multiple candidate parsing solutions) can be resolved in a useful way.

All type conversion rules are designed based on the following principles:

- Implicit conversions should never have surprising or unpredictable outcomes.
- There should be no extra overhead in the parser or executor if a query does not need implicit type conversion. That is, if a query is well-formed and the types already match, then the query should execute without spending extra time in the parser and without introducing unnecessary implicit conversion calls in the query.
- Additionally, if a query usually requires an implicit conversion for a function, and if then the user defines a new function with the correct argument types, the parser should use this new function.
- XML data does not support implicit type conversion, including implicit conversion between strings and XML types.

## 7.8.2 Operators

### Operator Type Resolution

1. Select the operators to be considered from the **pg\_operator** system catalog. Considered operators are those with the matching name and argument count. If the search path finds multiple available operators, only the most suitable one is considered.
2. Look for the best match.
  - a. Discard candidate operators for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown** literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.

- c. Run through all candidates and keep those that accept preferred types (of the input data type's type category) at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
- d. If any input arguments are of **unknown** types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
- e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the unknown-argument positions. If exactly one candidate passes this test, use it. Otherwise, fail.

## Examples

Example 1: Use factorial operator type resolution. There is only one factorial operator (postfix !) defined in the system catalog, and it takes an argument of type **bigint**. The scanner assigns an initial type of **bigint** to the argument in this query expression:

```
gaussdb=# SELECT 40 ! AS "40 factorial";
      40 factorial
-----
815915283247897734345611269596115894272000000000
(1 row)
```

So the parser does a type conversion on the operand and the query is equivalent to:

```
gaussdb=# SELECT CAST(40 AS bigint) ! AS "40 factorial";
```

Example 2: String concatenation operator type resolution. A string-like syntax is used for working with string types and for working with complex extension types. Strings with unspecified type are matched with likely operator candidates. An example with one unspecified argument:

```
gaussdb=# SELECT text 'abc' || 'def' AS "text and unknown";
text and unknown
-----
abcdef
(1 row)
```

In this example, the parser looks for an operator whose parameters are of the text type. Such an operator is found.

Here is a concatenation of two values of unspecified types:

```
gaussdb=# SELECT 'abc' || 'def' AS "unspecified";
unspecified
```

```
-----  
abcdef  
(1 row)
```

**NOTE**

In this case there is no initial hint for which type to use, since no types are specified in the query. So, the parser looks for all candidate operators and finds that there are candidates accepting both string-category and bit-string-category inputs. Since string category is preferred when available, that category is selected, and then the preferred type for strings, **text**, is used as the specific type to resolve the unknown-type literals as.

Example 3: Absolute-value and negation operator type resolution. The GaussDB operator catalog has several entries for the prefix operator @. All the entries implement absolute-value operations for various numeric data types. One of these entries is for type **float8**, which is the preferred type in the numeric category. Therefore, GaussDB will use that entry when faced with an unknown input:

```
gaussdb=# SELECT @ '-4.5' AS "abs";  
abs  
-----  
4.5  
(1 row)
```

Here the system has implicitly resolved the unknown-type literal as type **float8** before applying the chosen operator.

Example 4: Use the array inclusion operator type resolution as an example. Here is another example of resolving an operator with one known and one unknown input:

```
gaussdb=# SELECT array[1,2] <@ '{1,2,3}' as "is subset";  
is subset  
-----  
t  
(1 row)
```

**NOTE**

The GaussDB operator catalog has several entries for the infix operator <@, but the only two that could possibly accept an integer array on the left side are array inclusion (anyarray <@ anyarray) and range inclusion (anyelement <@ anyrange). Since none of these polymorphic pseudo-types (see [Pseudo-Types](#)) is considered preferred, the parser cannot resolve the ambiguity on that basis. However, the last resolution rule tells it to assume that the unknown-type literal is of the same type as the other input, that is, integer array. Now only one of the two operators can match, so array inclusion is selected. (Had range inclusion been selected, we would have gotten an error, because the string does not have the right format to be a range literal.)

## 7.8.3 Functions

### Function Type Resolution

1. Select the functions to be considered from the **pg\_proc** system catalog. If a non-schema-qualified function name was used, the functions in the current search path are considered. If a qualified function name was given, only functions in the specified schema are considered.

If the search path finds multiple functions of different argument types, a proper function in the path is considered.

2. Check for a function accepting exactly the input argument types. If the function exists, use it. Cases involving **unknown** will never find a match at this step.
3. If no exact match is found, see if the function call appears to be a special type conversion request.
4. Look for the best match.
  - a. Discard candidate functions for which the input types do not match and cannot be converted (using an implicit conversion) to match. **unknown** literals are assumed to be convertible to anything for this purpose. If only one candidate remains, use it; else continue to the next step.
  - b. Run through all candidates and keep those with the most exact matches on input types. Domains are considered the same as their base type for this purpose. Keep all candidates if none has exact matches. If only one candidate remains, use it; else continue to the next step.
  - c. Run through all candidates and keep those that accept preferred types at the most positions where type conversion will be required. Keep all candidates if none accepts preferred types. If only one candidate remains, use it; else continue to the next step.
  - d. If any input arguments are of **unknown** types, check the type categories accepted at those argument positions by the remaining candidates. At each position, select the string category if any candidate accepts that category. (This bias towards string is appropriate since an unknown-type literal looks like a string.) Otherwise, if all the remaining candidates accept the same type category, select that category; otherwise fail because the correct choice cannot be deduced without more clues. Now discard candidates that do not accept the selected type category. Furthermore, if any candidate accepts a preferred type in that category, discard candidates that accept non-preferred types for that argument. Keep all candidates if none survives these tests. If only one candidate remains, use it; else continue to the next step.
  - e. If there are both **unknown** and known-type arguments, and all the known-type arguments have the same type, assume that the **unknown** arguments are also of that type, and check which candidates can accept that type at the **unknown**-argument positions. If exactly one candidate passes this test, use it. Otherwise, fail.

## Examples

Example 1: Use the rounding function argument type resolution as the first example. There is only one **round** function that takes two arguments; it takes a first argument of type **numeric** and a second argument of type **integer**. So the following query automatically converts the first argument of type **integer** to **numeric**:

```
gaussdb=# SELECT round(4, 4);
round
-----
4.0000
(1 row)
```

That query is actually transformed by the parser to:

```
gaussdb=# SELECT round(CAST (4 AS numeric), 4);
```

Since numeric constants with decimal points are initially assigned the type **numeric**, the following query will require no type conversion and therefore might be slightly more efficient:

```
gaussdb=# SELECT round(4.0, 4);
```

Example 2: Use the substring function type resolution as the second example. There are several **substr** functions, one of which takes types **text** and **integer**. If the function is called with a string constant of unspecified type, the system chooses the candidate function that accepts an argument of the preferred category **string** (namely of type **text**).

```
gaussdb=# SELECT substr('1234', 3);
substr
-----
    34
(1 row)
```

If the string is declared to be of type **varchar**, as might be the case if it comes from a table, then the parser will try to convert it to become **text**:

```
gaussdb=# SELECT substr(varchar '1234', 3);
substr
-----
    34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (varchar '1234' AS text), 3);
```

#### NOTE

The parser learns from the **pg\_cast** catalog that **text** and **varchar** are binary-compatible, meaning that one can be passed to a function that accepts the other without doing any physical conversion. Therefore, no type conversion is really inserted in this case.

And, if the function is called with an argument of type **integer**, the parser will try to convert that to **text**:

```
gaussdb=# SELECT substr(1234, 3);
substr
-----
    34
(1 row)
```

This is transformed by the parser to effectively become:

```
gaussdb=# SELECT substr(CAST (1234 AS text), 3);
substr
-----
    34
(1 row)
```

## 7.8.4 Value Storage

### Value Storage Type Resolution

1. Search for an exact match with the target column.
2. Try to convert the expression to the target type. This will succeed if there is a registered cast between the two types. If the expression is an unknown-type literal, the content of the literal string will be fed to the input conversion routine for the target type.

3. Check to see if there is a sizing cast for the target type. A sizing cast is a cast from that type to itself. If one is found in the **pg\_cast** catalog, apply it to the expression before storing into the destination column. The implementation function for such a cast always takes an extra parameter of type **integer**. The parameter receives the destination column's **atttypmod** value (typically its declared length, although the interpretation of **atttypmod** varies for different data types), and may take a third Boolean parameter that says whether the cast is explicit or implicit. The cast function is responsible for applying any length-dependent semantics such as size checking or truncation.

## Examples

Use the **character** storage type conversion as an example. For a target column declared as **character(20)**, the following statement shows that the stored value is sized correctly:

```
gaussdb=# CREATE TABLE tpcds.value_storage_t1 (
VS_COL1 CHARACTER(20)
);
gaussdb=# INSERT INTO tpcds.value_storage_t1 VALUES('abcdef');
gaussdb=# SELECT VS_COL1, octet_length(VS_COL1) FROM tpcds.value_storage_t1;
   vs_col1   | octet_length
-----+-----
abcdef      |          20
(1 row)
)
```

```
gaussdb=# DROP TABLE tpcds.value_storage_t1;
```

### NOTE

What has happened here is that the two unknown literals are resolved to **text** by default, allowing the || operator to be resolved as **text** concatenation. Then the **text** result of the operator is converted to **bpchar** ("blank-padded char", the internal name of the **character** data type) to match the target column type. Since the conversion from **text** to **bpchar** is binary-coercible, this conversion does not insert any real function call. Finally, the sizing function **bpchar(bpchar, integer, Boolean)** is found in the system catalog and used for the operator's result and the stored column length. This type-specific function performs the required length check and addition of padding spaces.

## 7.8.5 UNION, CASE, and Related Constructs

SQL UNION constructs must match up possibly dissimilar types to become a single result set. The resolution algorithm is applied separately to each output column of a union query. INTERSECT and EXCEPT constructs resolve dissimilar types in the same way as UNION. The CASE, ARRAY, VALUES, GREATEST and LEAST constructs use the identical algorithm to match up their component expressions and select a result data type.

### Type Resolution for UNION, CASE, and Related Constructs

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.
- If all inputs are of the unknown type, resolve them as the text type (the preferred type of the string category). Otherwise, unknown inputs are ignored. (Exception: The UNION operation resolves a group of two unknown types into the text type, and then continues to match the type with other groups.)

- If the inputs are not all of the same type category, a failure will be resulted. (The unknown type is not included in this case.)
- If the inputs are all of the same type category, choose the top preferred type in that category. (Exception: The UNION operation regards the type of the first branch as the selected type.)

 NOTE

**typcategory** in the `pg_type` system catalog indicates the data type category.  
**typispreferred** indicates whether a type is preferred in **typcategory**.

- Convert all inputs to the selected type. (Retain the original lengths of strings). Fail if there is not an implicit conversion from a given input to the selected type.
- If the input contains the `json`, `txid_snapshot`, `sys_refcursor`, or geometry type, UNION cannot be performed.

## Type Resolution for CASE and COALESCE in TD Compatibility Type

- If all inputs are of the same type and are not unknown, resolve them as the unknown type.
- If all inputs are of the unknown type, resolve them as the text type.
- If inputs are of the string type (including unknown which is resolved as text) and digit type, resolve them as the string type. If the inputs are not of the two types, an error will be reported.
- If the inputs are all of the same type category, choose the top preferred type in that category.
- Convert all inputs to the selected type. Fail if there is not an implicit conversion from a given input to the selected type.

## Type Resolution for CASE in A Compatibility Mode

**decode(expr, search1, result1, search2, result2, ..., defresult)**: When **sql\_beta\_feature** is set to **a\_style\_coerce**, the final return value type of the expression is set to the data type of result1 or a higher-precision data type in the same type as result1. (For example, numeric and int are both numeric data types, but numeric has higher precision and priority than int.) For CASE WHEN, the behavior is the same as the default behavior in A-compatible mode.

- If all inputs are of the same type and are not unknown, resolve them as the unknown type. Otherwise, proceed to the next step.
- Set the data type of result1 to the final return value type `preferType`, which belongs to `preferCategory`.
- Consider the data types of result2, result3, and defresult in sequence. If the type category is also `preferCategory`, which is the same as that of result1, check whether the precision (priority) is higher than that of `preferType`. If it is, update `preferType` to a data type with higher precision. If the type category is not `preferCategory`, check whether the category can be implicitly converted to `preferType`. If it cannot, an error is reported.
- Uses the data type recorded by `preferType` as the return value type of the expression. The expression result is implicitly converted to this data type.

Note 1:

There is a special case where the character type of a super-large number is converted to the numeric type, for example, `select decode(1, 2, 2, '53465465676465454657567678676')`, in which the large number exceeds the range of the bigint and double types. If result1 is of the numeric type and does not meet the condition that all inputs are of the same type, the type of the return value is set to numeric to be compatible with this special case.

Note 2:

Priority of the numeric types: numeric > float8 > float4 > int8 > int4 > int2 > int1

Priority of the character types: text > varchar (nvarchar2) > bpchar > char

Priority of date types: timestamptz > timestamp > smalldatetime > date > abstime > timetz > time

Priority of date span types: interval > tinterval > reltime

Note 3:

The following figure shows the supported implicit type conversion when `set sql_beta_feature` is set to 'a\_style\_coerce' in ORA-compatible mode. \ indicates that conversion is not required, **yes** indicates that conversion is supported, and the blank value indicates that conversion is not supported.

	bool	int1	int2	int4	int8	float4	float8	numeric	money	char	bpchar	varchar2	nvarchar2	text/clob	raw	blob	date	time	timetz	timestamp	timestamptz	smalldatetime	interval	reltime	abstime	
bool	\																									
int1		\	yes	yes	yes	yes	yes	yes		yes	yes	yes	yes	yes												
int2		yes	\	yes	yes	yes	yes	yes		yes	yes	yes	yes	yes												
int4		yes	yes	\	yes	yes	yes	yes		yes	yes	yes	yes	yes												
int8		yes	yes	yes	\	yes	yes	yes		yes	yes	yes	yes	yes												
float4		yes	yes	yes	yes	\	yes	yes		yes	yes	yes	yes	yes												
float8		yes	yes	yes	yes	yes	\	yes		yes	yes	yes	yes	yes												
numeric		yes	yes	yes	yes	yes	yes	\		yes	yes	yes	yes	yes												
money									\																	
char		yes	yes	yes	yes	yes	yes	yes		\	yes	yes	yes	yes												
bpchar		yes	yes	yes	yes	yes	yes	yes		yes	\	yes	yes	yes												
varchar2		yes	yes	yes	yes	yes	yes	yes		yes	yes	\	yes	yes	yes											
nvarchar2		yes	yes	yes	yes	yes	yes	yes		yes	yes	yes	\	yes												
text/clob		yes	yes	yes	yes	yes	yes	yes		yes	yes	yes	yes	\												
raw												yes		yes	\	yes										
blob															yes	\										
date												yes	yes	yes			\			yes	yes	yes			yes	
time														yes				\	yes							
timetz														yes				yes	\							
timestamp												yes	yes	yes						\	yes	yes			yes	
timestamptz												yes	yes	yes						yes	\	yes			yes	
smalldatetime												yes	yes	yes						yes	yes	\			yes	
interval												yes	yes	yes										\	yes	
reltime														yes									yes	\		
abstime														yes						yes	yes	yes			\	

## Examples

Example 1: Use type resolution with underspecified types in a union as the first example. Here, the unknown-type literal 'b' will be resolved to the text type.

```
gaussdb=# SELECT text 'a' AS "text" UNION SELECT 'b';
text
-----
a
b
(2 rows)
```

Example 2: Use type resolution in a simple union as the second example. The literal **1.2** is of numeric type, and the integer value **1** can be cast implicitly to numeric type, so that type is used.

```
gaussdb=# SELECT 1.2 AS "numeric" UNION SELECT 1;
numeric
-----
      1
      1.2
(2 rows)
```

Example 3: Use type resolution in a transposed union as the third example. Since the real type cannot be implicitly cast to integer, but integer can be implicitly cast to real, the union result type is resolved as real.

```
gaussdb=# SELECT 1 AS "real" UNION SELECT CAST('2.2' AS REAL);
real
-----
      1
      2.2
(2 rows)
```

Example 4: In the TD-compatible mode, if input parameters for **COALESCE** are of int and varchar types, resolve them as the varchar type. In the A-compatible mode, an error is reported.

```
-- In the A-compatible mode, create the a_1 database compatible with A.
gaussdb=# CREATE DATABASE a_1 dbcompatibility = 'A';

-- Switch to the a_1 database.
gaussdb=# \c a_1

-- Create the t1 table.
a_1=# CREATE TABLE t1(a int, b varchar(10));

-- View the execution plan of the query statement whose coalesce parameter is of the int or varchar type.
a_1=# EXPLAIN SELECT coalesce(a, b) FROM t1;
ERROR: COALESCE types integer and character varying cannot be matched
LINE 1: EXPLAIN SELECT coalesce(a, b) FROM t1;
                        ^
CONTEXT: referenced column: coalesce

-- Delete the table.
a_1=# DROP TABLE t1;

-- Switch to the testdb database.
a_1=# \c testdb

-- In TD-compatible mode, create the td_1 database compatible with Teradata.
gaussdb=# CREATE DATABASE td_1 dbcompatibility = 'C';

-- Switch to the td_1 database.
gaussdb=# \c td_1

-- Create the t2 table.
td_1=# CREATE TABLE t2(a int, b varchar(10));

-- View the execution plan of the query statement whose coalesce parameter is of the int or varchar type.
td_1=# EXPLAIN VERBOSE select coalesce(a, b) from t2;
          QUERY PLAN
-----
Data Node Scan (cost=0.00..0.00 rows=0 width=0)
Output: (COALESCE((t2.a)::character varying, t2.b))
Node/s: All dbnodes
Remote query: SELECT COALESCE(a::character varying, b) AS "coalesce" FROM public.t2
(4 rows)

-- Delete the table.
```

```
td_1=# DROP TABLE t2;

-- Switch to the testdb database.
td_1=# \c testdb

-- Delete the A- and TD-compatible databases.
gaussdb=# DROP DATABASE a_1;
gaussdb=# DROP DATABASE td_1;
```

Example 5: In ORA mode, set the final return value type of the expression to the data type of result1 or a higher-precision data type whose category is the same as that of the data type of result1.

```
-- In ORA-compatible mode, create the ora_1 database compatible with ORA.
gaussdb=# CREATE DATABASE ora_1 dbcompatibility = 'A';

-- Switch to the ora_1 database.
gaussdb=# \c ora_1

-- Enable the decode compatibility parameters.
set sql_beta_feature='a_style_coerce';

-- Create the t1 table.
ora_1=# CREATE TABLE t1(c_int int, c_float8 float8, c_char char(10), c_text text, c_date date);

-- Insert data.
ora_1=# INSERT INTO t1 VALUES(1, 2, '3', '4', date '12-10-2010');

-- The data type of result1 is char and that of defresult is text. The precision of text is higher, and the type
of the return value is changed to text from char.
ora_1=# SELECT decode(1, 2, c_char, c_text) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
-----+-----
 4      | text
(1 row)

-- The data type of result1 is int, which is a numeric type. The type of the return value is set to numeric.
ora_1=# SELECT decode(1, 2, c_int, c_float8) AS result, pg_typeof(result) FROM t1;
 result | pg_typeof
-----+-----
 2      | numeric
(1 row)

-- The implicit conversion from the data type of defresult to that of result1 does not exist. If it is performed,
an error is reported.
ora_1=# SELECT decode(1, 2, c_int, c_date) FROM t1;
ERROR: CASE types integer and timestamp without time zone cannot be matched
LINE 1: SELECT decode(1, 2, c_int, c_date) FROM t1;
                        ^
CONTEXT: referenced column: c_date

-- Disable the decode compatibility parameters.
set sql_beta_feature='none';

-- Delete the table.
ora_1=# DROP TABLE t1;
DROP TABLE

-- Switch to the testdb database.
ora_1=# \c testdb

-- Delete the database in ORA-compatible mode.
gaussdb=# DROP DATABASE ora_1;
DROP DATABASE
```

Example 6: The UNION operation resolves a group of two unknown types into the text type, and then continues to match the type with other groups.

```
-- Resolve the first two NULL values of the unknown type as the text type. Then, match the text type with
the third element of the varchar2 type, and select the text type.
gaussdb=# SELECT "text", pg_typeof("text") as type from (SELECT NULL AS "text" UNION ALL SELECT
NULL AS "text" UNION ALL SELECT 'a'::varchar2 as "text");
 text | type
-----+-----
      | text
      | text
 a    | text
(3 rows)
```

## 7.9 System Operation

GaussDB text runs SQL statements to perform different system operations, such as setting variables, displaying the execution plan, and collecting garbage data.

### Setting Variables

For details about how to set various parameters for a session or transaction, see [SET](#).

### Displaying the Execution Plan

For details about how to display the execution plan that GaussDB makes for SQL statements, see [EXPLAIN](#).

### Specifying a Checkpoint in Transaction Logs

By default, WALs periodically specify checkpoints in a transaction log. **CHECKPOINT** forces an immediate checkpoint when the related command is issued, without waiting for a regular checkpoint scheduled by the system. For details, see [CHECKPOINT](#).

### Collecting Unnecessary Data

For details about how to collect garbage data and analyze a database as required, For details, see [VACUUM](#).

### Collecting Statistics

For details about how to collect statistics on tables in databases, see [ANALYZE | ANALYZE](#).

### Setting the Constraint Check Mode for the Current Transaction

For details about how to set the constraint check mode for the current transaction, For details, see [SET CONSTRAINTS](#).

### Shutting Down The Current Database Node

For details about shutting down the current database node, see [SHUTDOWN](#).

## 7.10 Controlling Transactions

A transaction is a user-defined sequence of database operations, which form an integral unit of work.

### Starting a Transaction
