Contents

1 Using CarbonData

1.1 CarbonData Data Types

Description

In CarbonData, data is stored in entities called tables. CarbonData tables are similar to RDBMS tables which organize data in rows and columns. CarbonData tables store structured data, and have fixed columns and data types.

Supported Data Types

CarbonData tables support the following data types:

- Int
- String
- BigInt
- Smallint
- Char
- Varchar
- Boolean
- Decimal
- Double
- TimeStamp
- Date
- Array
- Struct
- Map

The following table describes supported data types and their respective values ranges.

Table 1-1 CarbonData data types

Data Type	Value Range
Int	4-byte signed integer ranging from -2,147,483,648 to 2,147,483,647. **NOTE** **int** data in a non-dictionary column is internally stored as the **BigInt** type.
String	100,000 characters **NOTE** If the **CHAR** or **VARCHAR** data type is used in **CREATE TABLE**, the two data types are automatically converted to the String data type. If a column contains more than 32,000 characters, add the column to the **LONG_STRING_COLUMNS** attribute of the **tblproperties** table during table creation.
BigInt	64-bit value ranging from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807
SmallInt	–32,768 to 32,767
Char	A to Z and a to z
Varchar	A to Z, a to z, and 0 to 9
Boolean	**true** or **false**
Decimal	The default value is (10,0) and maximum value is (38,38). **NOTE** When query with filters, append **BD** to the number to achieve accurate results. For example, **select * from carbon_table where num = 1234567890123456.22BD**.
Double	64-bit value ranging from 4.9E-324 to 1.7976931348623157E308
TimeStamp	The default format is **yyyy-MM-dd HH:mm:ss**.
Date	The **DATE** data type is used to store calendar dates. The default format is **yyyy-MM-DD**.
Array<data_type>	N/A **NOTE** Currently, only two layers of complex types can be nested.
Struct<col_name: data_type COMMENT col_comment, ...>	
Map<primitive_type, data_type>	

Main Specifications of CarbonData

Table 1-2 Main specifications

Entity	Tested Value	Test Environment
Number of tables	10000	3 nodes. 4 vCPUs and 20 GB memory for each executor. Driver memory: 5 GB, 3 executors. Total columns: 107 String: 75 Int: 13 BigInt: 7 Timestamp: 6 Double: 6
Number of table columns	2000	3 nodes. 4 vCPUs and 20 GB memory for each executor. Driver memory: 5 GB, 3 executors.
Maximum size of a raw CSV file	200GB	17 cluster nodes. 150 GB memory and 25 vCPUs for each executor. Driver memory: 10 GB, 17 executors.
Number of CSV files in each folder	100 folders. Each folder has 10 files. The size of each file is 50 MB.	3 nodes. 4 vCPUs and 20 GB memory for each executor. Driver memory: 5 GB, 3 executors.
Number of load folders	10000	3 nodes. 4 vCPUs and 20 GB memory for each executor. Driver memory: 5 GB, 3 executors.

Table Specifications

Table 1-3 Table specifications

Entity	Tested Value
Number of secondary index tables	10
Number of composite columns in a secondary index table	5

Entity	Tested Value
Length of column name in a secondary index table (unit: character)	120
Length of a secondary index table name (unit: character)	120
Cumulative length of all secondary index table names + column names in an index table* (unit: character)	3800**

NOTE

- * Characters of column names in an index table refer to the upper limit allowed by Hive or the upper limit of available resources.
- ** Secondary index tables are registered using Hive and stored in HiveSERDEPROPERTIES in JSON format. The value of **SERDEPROPERTIES** supported by Hive can contain a maximum of 4,000 characters and cannot be changed.

1.2 CarbonData Table User Permissions

The following table provides details about Hive ACL permissions required for performing operations on CarbonData tables.

Prerequisites

Parameters listed in **Table 1-21** or **Table 1-22** have been configured.

Hive ACL permissions

Table 1-4 Hive ACL permissions required for CarbonData table-level operations

Scenario	Required Permission
DESCRIBE TABLE	SELECT (of table)
SELECT	SELECT (of table)
EXPLAIN	SELECT (of table)
CREATE TABLE	CREATE (of database)
CREATE TABLE As SELECT	CREATE (on database), INSERT (on table), RW on data file, and SELECT (on table)
LOAD	INSERT (of table) RW on data file
DROP TABLE	OWNER (of table)
DELETE SEGMENTS	DELETE (of table)
SHOW SEGMENTS	SELECT (of table)

Scenario	Required Permission
CLEAN FILES	DELETE (of table)
INSERT OVERWRITE / INSERT INTO	INSERT (of table) RW on data file and SELECT (of table)
CREATE INDEX	OWNER (of table)
DROP INDEX	OWNER (of table)
SHOW INDEXES	SELECT (of table)
ALTER TABLE ADD COLUMN	OWNER (of table)
ALTER TABLE DROP COLUMN	OWNER (of table)
ALTER TABLE CHANGE DATATYPE	OWNER (of table)
ALTER TABLE RENAME	OWNER (of table)
ALTER TABLE COMPACTION	INSERT (on table)
FINISH STREAMING	OWNER (of table)
ALTER TABLE SET STREAMING PROPERTIES	OWNER (of table)
ALTER TABLE SET TABLE PROPERTIES	OWNER (of table)
UPDATE CARBON TABLE	UPDATE (of table)
DELETE RECORDS	DELETE (of table)
REFRESH TABLE	OWNER (of main table)
REGISTER INDEX TABLE	OWNER (of table)
SHOW PARTITIONS	SELECT (on table)
ALTER TABLE ADD PARTITION	OWNER (of table)
ALTER TABLE DROP PARTITION	OWNER (of table)

NOTE

- If tables in the database are created by multiple users, the **Drop database** command fails to be executed even if the user who runs the command is the owner of the database.
- In a secondary index, when the parent table is triggered, **insert** and **compaction** are triggered on the index table. If you select a query that has a filter condition that matches index table columns, you should provide selection permissions for the parent table and index table.
- The LockFiles folder and lock files created in the LockFiles folder will have full permissions, as the LockFiles folder does not contain any sensitive data.
- If you are using ACL, ensure you do not configure any path for DDL or DML which is being used by other process. You are advised to create new paths.

  Configure the path for the following configuration items:

  1) carbon.badRecords.location

  2) Db_Path and other items during database creation
- For Carbon ACL in a non-security cluster, **hive.server2.enable.doAs** in the **hive-site.xml** file must be set to **false**. Then the query will run as the user who runs the hiveserver2 process.

1.3 Creating a CarbonData Table Using the Spark Client

This section describes how to create CarbonData tables, load data, and query data. This quick start provides operations based on the Spark Beeline client. If you want to use Spark shell, wrap the queries with **spark.sql()**.

The following describes how to load data from a CSV file to a CarbonData table.

Table 1-5 CarbonData Quick Start

Operation	Description
Preparing a CSV File	Prepare the CSV file to be loaded to the CarbonData Table.
Connecting to CarbonData	Connect to CarbonData before performing any operations on CarbonData.
Creating a CarbonData Table	Create a CarbonData table to load data and perform query operations.
Loading Data to a CarbonData Table	Load data from CSV to the created table.
Querying Data from a CarbonData Table	Perform query operations such as filters and groupby.

Preparing a CSV File

1. Prepare a CSV file named **test.csv** on the local PC. An example is as follows:

   13418592122,1001, *MAC address*, 2017-10-23 15:32:30,2017-10-24 15:32:30,62.50,74.56
   13418592123 1002, *MAC address*, 2017-10-23 16:32:30,2017-10-24 16:32:30,17.80,76.28
   13418592124,1003, *MAC address*, 2017-10-23 17:32:30,2017-10-24 17:32:30,20.40,92.94
   13418592125 1004, *MAC address*, 2017-10-23 18:32:30,2017-10-24 18:32:30,73.84,8.58
   13418592126,1005, *MAC address*, 2017-10-23 19:32:30,2017-10-24 19:32:30,80.50,88.02
   13418592127 1006, *MAC address*, 2017-10-23 20:32:30,2017-10-24 20:32:30,65.77,71.24
   13418592128,1007, *MAC address*, 2017-10-23 21:32:30,2017-10-24 21:32:30,75.21,76.04
   13418592129,1008, *MAC address*, 2017-10-23 22:32:30,2017-10-24 22:32:30,63.30,94.40
   13418592130, 1009, *MAC address*, 2017-10-23 23:32:30,2017-10-24 23:32:30,95.51,50.17
   13418592131,1010, *MAC address*, 2017-10-24 00:32:30,2017-10-25 00:32:30,39.62,99.13

2. Use WinSCP to import the CSV file to the directory of the node where the client is installed, for example, **/opt**.
3. Log in to FusionInsight Manager and choose **System**. In the navigation pane on the left, choose **Permission** > **User**, click **Create** to create human-machine user **sparkuser**, and add the user to user groups hadoop (primary group) and hive.
4. Run the following commands to go to the client installation directory, load environment variables, and authenticate the user.

   cd /*Client installation directory*

   source ./bigdata_env

   source ./Spark2x/component_env

   NOTE

   In MRS 3.3.0-LTS and later versions, the Spark2x component is renamed Spark, and the role names of this component are also changed. For example, JobHistory2x is changed to JobHistory. Refer to the descriptions and operations related to the component name and role names in the document based on your MRS version.

   kinit sparkuser
5. Run the following command to upload the CSV file to the **/data** directory of the HDFS.

   hdfs dfs -put /opt/test.csv /data/

Connecting to CarbonData

- Use Spark SQL or Spark shell to connect to Spark and run Spark SQL commands.
- Run the following commands to start the JDBCServer and use a JDBC client (for example, Spark Beeline) to connect to the JDBCServer.

  cd ./Spark2x/spark/bin

  ./spark-beeline

Creating a CarbonData Table

After connecting Spark Beeline with the JDBCServer, create a CarbonData table to load data and perform query operations. Run the following commands to create a simple table:

create table x1 (imei string, deviceInformationId int, mac string, productdate timestamp, updatetime timestamp, gamePointId double, contractNumber

double) STORED AS carbondata TBLPROPERTIES ('SORT_COLUMNS'='imei,mac');

The command output is as follows:

```
+---------+
| Result  |
+---------+
+---------+
No rows selected (1.093 seconds)
```

Loading Data to a CarbonData Table

After you have created a CarbonData table, you can load the data from CSV to the created table.

Run the following command with required parameters to load data from CSV. The column names of the CarbonData table must match the column names of the CSV file.

LOAD DATA inpath 'hdfs://hacluster/data/*test.csv***' into table** ***x1*** **options('DELIMITER'=',', 'QUOTECHAR'='"','FILEHEADER'='imei, deviceinformationid,mac, productdate,updatetime, gamepointid,contractnumber');**

test.csv is the CSV file prepared in **Preparing a CSV File** and **x1** is the table name.

The CSV example file is as follows:

```
13418592122,1001, MAC address, 2017-10-23 15:32:30,2017-10-24 15:32:30,62.50,74.56
13418592123 1002,  MAC address, 2017-10-23 16:32:30,2017-10-24 16:32:30,17.80,76.28
13418592124,1003, MAC address, 2017-10-23 17:32:30,2017-10-24 17:32:30,20.40,92.94
13418592125 1004,  MAC address, 2017-10-23 18:32:30,2017-10-24 18:32:30,73.84,8.58
13418592126,1005, MAC address, 2017-10-23 19:32:30,2017-10-24 19:32:30,80.50,88.02
13418592127 1006,  MAC address, 2017-10-23 20:32:30,2017-10-24 20:32:30,65.77,71.24
13418592128,1007, MAC address, 2017-10-23 21:32:30,2017-10-24 21:32:30,75.21,76.04
13418592129,1008, MAC address, 2017-10-23 22:32:30,2017-10-24 22:32:30,63.30,94.40
13418592130, 1009, MAC address, 2017-10-23 23:32:30,2017-10-24 23:32:30,95.51,50.17
13418592131,1010, MAC address, 2017-10-24 00:32:30,2017-10-25 00:32:30,39.62,99.13
```

The command output is as follows:

```
+------------+
|Segment ID  |
+------------+
|0           |
+------------+
No rows selected (3.039 seconds)
```

Querying Data from a CarbonData Table

After a CarbonData table is created and the data is loaded, you can perform query operations as required. Some query operations are provided as examples.

- **Obtaining the number of records**

  Run the following command to obtain the number of records in the CarbonData table:

  select count(*) from x1;

- **Querying with the groupby condition**

  Run the following command to obtain the **deviceinformationid** records without repetition in the CarbonData table:

select deviceinformationid,count (distinct deviceinformationid) from x1 group by deviceinformationid;

- **Querying with Filter**

  Run the following command to obtain specific **deviceinformationid** records:

  select * from x1 where deviceinformationid='1010';

  NOTE

  If the query result has Chinese or other non-English characters, the columns in the query result may not be aligned. This is because characters of different languages occupy different widths.

Using CarbonData on Spark-shell

If you need to use CarbonData on a Spark-shell, you need to create a CarbonData table, load data to that table, and query data as follows:

```
spark.sql("CREATE TABLE x2(imei string, deviceInformationId int, mac string, productdate timestamp, updatetime timestamp, gamePointId double, contractNumber double) STORED AS carbondata")
spark.sql("LOAD DATA inpath 'hdfs://hacluster/data/x1_without_header.csv' into table x2 options('DELIMITER'=',', 'QUOTECHAR'='\"','FILEHEADER'='imei, deviceinformationid,mac, productdate,updatetime, gamepointid,contractnumber')")
spark.sql("SELECT * FROM x2").show()
```

1.4 CarbonData Data Analytics

1.4.1 Creating a CarbonData Table

Scenario

A CarbonData table must be created to load and query data. You can run the **Create Table** command to create a table. This command is used to create a table using custom columns.

Creating a Table with Self-Defined Columns

Users can create a table by specifying its columns and data types.

Sample command:

CREATE TABLE *IF NOT EXISTS productdb.productSalesTable (*

productNumber Int,

productName String,

storeCity String,

storeProvince String,

productCategory String,

productBatch String,

saleQuantity Int,

revenue Int)

STORED AS *carbondata*

TBLPROPERTIES (

'table_blocksize'='128');

The following table describes parameters of preceding commands.

Table 1-6 Parameter description

Parameter	Description
productSalesTable	Table name. The table is used to load data for analysis. The table name consists of letters, digits, and underscores (_).
productdb	Database name. The database maintains logical connections with tables stored in it to identify and manage the tables. The database name consists of letters, digits, and underscores (_).
productName storeCity storeProvince procuctCategory productBatch saleQuantity revenue	Columns in the table. The columns are service entities for data analysis. The column name (field name) consists of letters, digits, and underscores (_).
table_blocksize	Indicates the block size of data files used by the CarbonData table, in MB. The value ranges from **1** to **2048**. The default value is **1024**. If **table_blocksize** is too small, a large number of small files will be generated when data is loaded. This may affect the performance of HDFS. If **table_blocksize** is too large, during data query, the amount of block data that matches the index is large, and some blocks contain a large number of blocklets, affecting read concurrency and lowering query performance. You are advised to set the block size based on the data volume. For example, set the block size to 256 MB for GB-level data, 512 MB for TB-level data, and 1024 MB for PB-level data.

NOTE

- Measurement of all Integer data is processed and displayed using the **BigInt** data type.
- CarbonData parses data strictly. Any data that cannot be parsed is saved as **null** in the table. For example, if the user loads the **double** value (3.14) to the BigInt column, the data is saved as **null**.
- The Short and Long data types used in the **Create Table** command are shown as Smallint and BigInt in the **DESCRIBE** command, respectively.
- You can run the **DESCRIBE** command to view the table data size and table index size.

Operation Result

Run the command to create a table.

1.4.2 Deleting a CarbonData Table

Scenario

You can run the **DROP TABLE** command to delete a table. After a CarbonData table is deleted, its metadata and loaded data are deleted together.

Procedure

Run the following command to delete a CarbonData table:

Run the following command:

DROP TABLE *[IF EXISTS] [db_name.]table_name;*

Once this command is executed, the table is deleted from the system. In the command, **db_name** is an optional parameter. If **db_name** is not specified, the table named **table_name** in the current database is deleted.

Example:

DROP TABLE *productdb.productSalesTable;*

Run the preceding command to delete the **productSalesTable** table from the **productdb** database.

Operation Result

Deletes the table specified in the command from the system. After the table is deleted, you can run the **SHOW TABLES** command to check whether the table is successfully deleted. For details, see **SHOW TABLES**.

1.4.3 Modifying a CarbonData Table

SET and UNSET

When you run the SET command, all the attributes of the new SET overwrite the existing properties.

- SORT SCOPE

  An example of the SET SORT SCOPE command is as follows:

ALTER TABLE *tablename* **SET TBLPROPERTIES('SORT_SCOPE'**='*no_sort*')

After the UNSET SORT SCOPE command is executed, the default option NO_SORT is used.

Example for UNSET SORT SCOPE:

ALTER TABLE *tablename* **UNSET TBLPROPERTIES('SORT_SCOPE')**

- SORT COLUMNS

  Example for SET SORT COLUMNS:

  ALTER TABLE *tablename* **SET TBLPROPERTIES('SORT_COLUMNS'**='*column1*')

  This command applies new setting of SORT_COLUMNS to new imports. You can adjust SORT_COLUMNS to get optimal query result, but the old data will not be changed. Query performance of historical segments is not affected they are not queried based on the new SORT_COLUMNS.

  The UNSET command is not supported. Instead, you can set SORT_COLUMNS to an empty string.

  ALTER TABLE *tablename* **SET TBLPROPERTIES('SORT_COLUMNS'**='')

  NOTE

  - In later versions, custom merge will be enhanced to sort old segments again.
  - SORT_COLUMNS cannot be modified for streaming tables.
  - If an inverted index column is removed from SORT_COLUMNS, no inverted index will be created for the column. The old INVERTED_INDEX settings will not change.

1.4.4 Loading Data to a CarbonData Table

Scenario

After a CarbonData table is created, you can run the **LOAD DATA** command to load data to the table for query.

Once data loading is triggered, data is encoded in CarbonData format and files in multi-dimensional and column-based format are compressed and copied to the HDFS path of CarbonData files for quick analysis and queries.

The HDFS path can be configured in the **carbon.properties** file.

For details, see **Typical CarbonData Configuration Parameters**.

1.4.5 Deleting Segments of a CarbonData Table

Scenario

If you want to modify and reload the data because you have loaded wrong data into a table, or there are too many bad records, you can delete specific segments by segment ID or data loading time.

NOTE

The segment deletion operation only deletes segments that are not compacted. You can run the **CLEAN FILES** command to clear compacted segments.

Deleting a Segment by Segment ID

Each segment has a unique ID. This segment ID can be used to delete the segment.

Step 1 Obtain the segment ID.

Command:

SHOW SEGMENTS FOR Table *dbname.tablename LIMIT number_of_loads;*

Example:

SHOW SEGMENTS FOR TABLE *carbonTable;*

Run the preceding command to show all the segments of the table named **carbonTable**.

SHOW SEGMENTS FOR TABLE *carbonTable LIMIT 2;*

Run the preceding command to show segments specified by *number_of_loads*.

The command output is as follows:

```
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
| ID  | Status |     Load Start Time      | Load Time Taken  | Partition  | Data Size  | Index Size  | File Format  |
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
| 3   | Success  | 2020-09-28 22:53:26.336  | 3.726S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
| 2   | Success  | 2020-09-28 22:53:01.702  | 6.688S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
```

NOTE

The output of the **SHOW SEGMENTS** command includes ID, Status, Load Start Time, Load Time Taken, Partition, Data Size, Index Size, and File Format. The latest loading information is displayed in the first line of the command output.

Step 2 Run the following command to delete the segment after you have found the Segment ID:

Command:

DELETE FROM TABLE tableName WHERE SEGMENT.ID IN (load_sequence_id1, load_sequence_id2, ...);

Example:

DELETE FROM TABLE carbonTable WHERE SEGMENT.ID IN (1,2,3);

For details, see **DELETE SEGMENT by ID**.

----End

Deleting a Segment by Data Loading Time

You can delete a segment based on the loading time.

Command:

DELETE FROM TABLE db_name.table_name WHERE SEGMENT.STARTTIME BEFORE date_value;

Example:

DELETE FROM TABLE carbonTable WHERE SEGMENT.STARTTIME BEFORE '2017-07-01 12:07:20';

The preceding command can be used to delete all segments before 2017-07-01 12:07:20.

For details, see **DELETE SEGMENT by DATE**.

Result

Data of corresponding segments is deleted and is unavailable for query. You can run the **SHOW SEGMENTS** command to display the segment status and check whether the segment has been deleted.

NOTE

- Segments are not physically deleted after the execution of the **DELETE SEGMENT** command. Therefore, if you run the **SHOW SEGMENTS** command to check the status of a deleted segment, it will be marked as **Marked for Delete**. If you run the **SELECT * FROM tablename** command, the deleted segment will be excluded.
- The deleted segment will be deleted physically only when the next data loading reaches the maximum query execution duration, which is configured by the **max.query.execution.time** parameter. The default value of the parameter is 60 minutes.
- If you want to forcibly delete a physical segment file, run the **CLEAN FILES** command.

  Example:

  CLEAN FILES FOR TABLE table1;

  This command will physically delete the segment file in the **Marked for delete** state.

  If this command is executed before the time specified by **max.query.execution.time** arrives, the query may fail. **max.query.execution.time** indicates the maximum time allowed for a query, which is set in the **carbon.properties** file.

1.4.6 Compacting CarbonData Table Segments

Scenario

Frequent data access results in a large number of fragmented CarbonData files in the storage directory. In each data loading, data is sorted and indexing is performed. This means that an index is generated for each load. With the increase of data loading times, the number of indexes also increases. As each index works only on one loading, the performance of index is reduced. CarbonData provides loading and compression functions. In a compression process, data in each segment is combined and sorted, and multiple segments are combined into one large segment.

Prerequisites

Multiple data loadings have been performed.

Operation Description

There are three types of compaction: Minor, Major, and Custom.

- Minor compaction:

  In minor compaction, you can specify the number of loads to be merged. If **carbon.enable.auto.load.merge** is set, minor compaction is triggered for every data load. If any segments are available to be merged, then compaction will run parallel with data load.

  There are two levels in minor compaction:

  - Level 1: Merging of the segments which are not yet compacted
  - Level 2: Merging of the compacted segments again to form a larger segment

- Major compaction:

  Multiple segments can be merged into one large segment. You can specify the compaction size so that all segments below the size will be merged. Major compaction is usually done during the off-peak time.

- Custom compaction:

  In Custom compaction, you can specify the IDs of multiple segments to merge them into a large segment. The IDs of all the specified segments must exist and be valid. Otherwise, the compaction fails. Custom compaction is usually done during the off-peak time.

For details, see **ALTER TABLE COMPACTION**.

Table 1-7 Compaction parameters

Parameter	Default Value	Application Type	Description
carbon.enable.auto.load.merge	false	Minor	Whether to enable compaction along with data loading. **true**: Compaction is automatically triggered when data is loaded. **false**: Compaction is not triggered when data is loaded.

Parameter	Default Value	Application Type	Description
carbon.compaction.level.threshold	4,3	Minor	This configuration is for minor compaction which decides how many segments to be merged. For example, if this parameter is set to **2,3**, minor compaction is triggered every two segments and segments form a single level 1 compacted segment. When the number of compacted level 1 segments reach 3, compaction is triggered again to merge them to form a single level 2 segment. The compaction policy depends on the actual data size and available resources. The value ranges from 0 to 100.
carbon.major.compaction.size	1024 MB	Major	The major compaction size can be configured using this parameter. Sum of the segments which is below this threshold will be merged. For example, if this parameter is set to 1024 MB, and there are five segments whose sizes are 300 MB, 400 MB, 500 MB, 200 MB, and 100 MB used for major compaction, only segments whose total size is less than this threshold are compacted. In this example, only the segments whose sizes are 300 MB, 400 MB, 200 MB, and 100 MB are compacted.
carbon.numberof.preserve.segments	0	Minor/ Major	If you want to preserve some number of segments from being compacted, then you can set this configuration. For example, if **carbon.numberof.preserve.segments** is set to **2**, the latest two segments will always be excluded from the compaction. By default, no segments are reserved.

Parameter	Default Value	Application Type	Description
carbon.allowed.compaction.days	0	Minor/ Major	This configuration is used to control on the number of recent segments that needs to be compacted. For example, if this parameter is set to **2**, the segments which are loaded in the time frame of past 2 days only will get merged. Segments which are loaded earlier than 2 days will not be merged. This configuration is disabled by default.
carbon.number.of.cores.while.compacting	2	Minor/ Major	Number of cores to be used while compacting data. The greater the number of cores, the better the compaction performance. If the CPU resources are sufficient, you can increase the value of this parameter.
carbon.merge.index.in.segment	true	SEGMENT_INDEX	If this parameter is set to **true**, all the Carbon index (.carbonindex) files in a segment will be merged into a single Index (.carbonindexmerge) file. This enhances the first query performance.

Reference

You are advised not to perform minor compaction on historical data. For details, see **How to Avoid Minor Compaction for Historical Data?**.

1.5 CarbonData Performance Tuning

1.5.1 Tuning Approach

Query Performance Tuning

There are various parameters that can be tuned to improve the query performance in CarbonData. Most of the parameters focus on increasing the parallelism in processing and optimizing system resource usage.

- Spark executor count: Executors are basic entities of parallelism in Spark. Raising the number of executors can increase the amount of parallelism in the cluster. For details about how to configure the number of executors, see the Spark documentation.

- Executor core: The number of concurrent tasks that an executor can run are controlled in each executor. Increasing the number of executor cores will add more concurrent processing tasks to improve performance.
- HDFS block size: CarbonData assigns query tasks by allocating different blocks to different executors for processing. HDFS block is the partition unit. CarbonData maintains a global block level index in Spark driver, which helps to reduce the quantity of blocks that need to be scanned for a query. Higher block size means higher I/O efficiency and lower global index efficiency. Reversely, lower block size means lower I/O efficiency, higher global index efficiency, and greater memory consumption.
- Number of scanner threads: Scanner threads control the number of parallel data blocks that are processed by each task. By increasing the number of scanner threads, you can increase the number of data blocks that are processed in parallel to improve performance. The **carbon.number.of.cores** parameter in the **carbon.properties** file is used to configure the number of scanner threads. For example, **carbon.number.of.cores = 4**.
- B-Tree caching: The cache memory can be optimized using the B-Tree least recently used (LRU) caching. In the driver, the B-Tree LRU caching configuration helps free up the cache by releasing table segments which are not accessed or not used. Similarly, in the executor, the B-Tree LRU caching configuration will help release table blocks that are not accessed or used. For details, see the description of **carbon.max.driver.lru.cache.size** and **carbon.max.executor.lru.cache.size** in **Table 1-18**.

CarbonData Query Process

When CarbonData receives a table query task, for example query for table A, the index data of table A will be loaded to the memory for the query process. When CarbonData receives a query task for table A again, the system does not need to load the index data of table A.

When a query is performed in CarbonData, the query task is divided into several scan tasks, namely, task splitting based on HDFS blocks. Scan tasks are executed by executors on the cluster. Tasks can run in parallel, partially parallel, or in sequence, depending on the number of executors and configured number of executor cores.

Some parts of a query task can be processed at the individual task level, such as **select** and **filter.** Some parts of a query task can be processed at the individual task level, such as **group-by**, **count**, and **distinct count**.

Some operations cannot be performed at the task level, such as **Having Clause** (filter after grouping) and **sort**. Operations which cannot be performed at the task level or can be only performed partially at the task level require data (partial results) transmission across executors on the cluster. The transmission operation is called shuffle.

The more the tasks are, the more data needs to be shuffled. This affects query performance.

The number of tasks is depending on the number of HDFS blocks and the number of blocks is depending on the size of each block. You are advised to configure proper HDFS block size to achieve a balance among increased parallelism, the amount of data to be shuffled, and the size of aggregate tables.

Relationship Between Splits and Executors

If the number of splits is less than or equal to the executor count multiplied by the executor core count, the tasks are run in parallel. Otherwise, some tasks can start only after other tasks are complete. Therefore, ensure that the executor count multiplied by executor cores is greater than or equal to the number of splits. In addition, make sure that there are sufficient splits so that a query task can be divided into sufficient subtasks to ensure concurrency.

Configuring Scanner Threads

The scanner threads property decides the number of data blocks to be processed. If there are too many data blocks, a large number of small data blocks will be generated, affecting performance. If there are few data blocks, the parallelism is poor and the performance is affected. When determining the number of scanner threads, you need to consider the average data size within a partition and select a value that makes the data block not small. Based on experience, you are advised to divide a single block size (unit: MB) by 250 and use the result as the number of scanner threads.

The number of actual available vCPUs is an important factor to consider when you want to increase the parallelism. The number of vCPUs that conduct parallel computation must not exceed 75% to 80% of actual vCPUs.

The number of vCPUs is approximately equal to:

Number of parallel tasks x Number of scanner threads. Number of parallel tasks is the smaller value of number of splits or executor count x executor cores.

Data Loading Performance Tuning

Tuning of data loading performance is different from that of query performance. Similar to query performance, data loading performance depends on the amount of parallelism that can be achieved. In case of data loading, the number of worker threads decides the unit of parallelism. Therefore, more executors mean more executor cores and better data loading performance.

To achieve better performance, you can configure the following parameters in HDFS.

Table 1-8 HDFS configuration

Parameter	Recommended Value
dfs.datanode.drop.cache.behind.reads	false
dfs.datanode.drop.cache.behind.writes	false
dfs.datanode.sync.behind.writes	true

Compression Tuning

CarbonData uses a few lightweight compression and heavyweight compression algorithms to compress data. Although these algorithms can process any type of

data, the compression performance is better if the data is ordered with similar values being together.

During data loading, data is sorted based on the order of columns in the table to achieve good compression performance.

Since CarbonData sorts data in the order of columns defined in the table, the order of columns plays an important role in the effectiveness of compression. If the low cardinality dimension is on the left, the range of data partitions after sorting is small and the compression efficiency is high. If a high cardinality dimension is on the left, a range of data partitions obtained after sorting is relatively large, and compression efficiency is relatively low.

Memory Tuning

CarbonData provides a mechanism for memory tuning where data loading depends on the columns needed in the query. Whenever a query command is received, columns required by the query are fetched and data is loaded for those columns in memory. During this operation, if the memory threshold is reached, the least used loaded files are deleted to release memory space for columns required by the query.

1.5.2 Typical Performance Tuning Parameters

Scenario

This section describes the configurations that can improve CarbonData performance.

Procedure

Table 1-9 and **Table 1-10** describe the configurations about query of CarbonData.

Table 1-9 Number of tasks started for the shuffle process

Parameter	spark.sql.shuffle.partitions
Configuration File	spark-defaults.conf
Function	Data query
Scenario Description	Number of tasks started for the shuffle process in Spark
Tuning	You are advised to set this parameter to one to two times as much as the executor cores. In an aggregation scenario, reducing the number from 200 to 32 can reduce the query time by two folds.

Table 1-10 Number of executors and vCPUs, and memory size used for CarbonData data query

Parameter	spark.executor.cores spark.executor.instances spark.executor.memory
Configuration File	spark-defaults.conf
Function	Data query
Scenario Description	Number of executors and vCPUs, and memory size used for CarbonData data query
Tuning	In the bank scenario, configuring 4 vCPUs and 15 GB memory for each executor will achieve good performance. The two values do not mean the more the better. Configure the two values properly in case of limited resources. If each node has 32 vCPUs and 64 GB memory in the bank scenario, the memory is not sufficient. If each executor has 4 vCPUs and 12 GB memory, Garbage Collection may occur during query, time spent on query from increases from 3s to more than 15s. In this case, you need to increase the memory or reduce the number of vCPUs.

Table 1-11, **Table 1-12**, and **Table 1-13** describe the configurations for CarbonData data loading.

Table 1-11 Number of vCPUs used for data loading

Parameter	carbon.number.of.cores.while.loading
Configuration File	carbon.properties
Function	Data loading
Scenario Description	Number of vCPUs used for data processing during data loading in CarbonData
Tuning	If there are sufficient CPUs, you can increase the number of vCPUs to improve performance. For example, if the value of this parameter is changed from 2 to 4, the CSV reading performance can be doubled.

Table 1-12 Whether to use Yarn local directories for multi-disk data loading

Parameter	carbon.use.local.dir

Configuration File	carbon.properties
Function	Data loading
Scenario Description	Whether to use Yarn local directories for multi-disk data loading
Tuning	If this parameter is set to **true**, CarbonData uses local Yarn directories for multi-table load disk load balance, improving data loading performance.

Table 1-13 Whether to use multiple directories during loading

Parameter	carbon.use.multiple.temp.dir
Configuration File	carbon.properties
Function	Data loading
Scenario Description	Whether to use multiple temporary directories to store temporary sort files
Tuning	If this parameter is set to **true**, multiple temporary directories are used to store temporary sort files during data loading. This configuration improves data loading performance and prevents single points of failure (SPOFs) on disks.

Table 1-14 describes the configurations for CarbonData data loading and query.

Table 1-14 Number of vCPUs used for data loading and query

Parameter	carbon.compaction.level.threshold
Configuration File	carbon.properties
Function	Data loading and query
Scenario Description	For minor compaction, specifies the number of segments to be merged in stage 1 and number of compacted segments to be merged in stage 2.

Tuning	Each CarbonData load will create one segment, if every load is small in size, it will generate many small files over a period of time impacting the query performance. Configuring this parameter will merge the small segments to one big segment which will sort the data and improve the performance. The compaction policy depends on the actual data size and available resources. For example, a bank loads data once a day and at night when no query is performed. If resources are sufficient, the compaction policy can be 6 or 5.

Table 1-15 Whether to enable data pre-loading when the index cache server is used

Parameter	carbon.indexserver.enable.prepriming
Configuration File	carbon.properties
Function	Data loading
Scenario Description	Enabling data pre-loading during the use of the index cache server can improve the performance of the first query.
Tuning	You can set this parameter to **true** to enable the pre-loading function. The default value is **false**.

1.5.3 Creating a CarbonData Table with High Query Performance

Scenario

This section provides suggestions based on more than 50 test cases to help you create CarbonData tables with higher query performance.

Table 1-16 Columns in the CarbonData table

Column name	Data type	Cardinality	Attribution
msname	String	30 million	dimension
BEGIN_TIME	bigint	10,000	dimension
host	String	1 million	dimension
dime_1	String	1,000	dimension
dime_2	String	500	dimension
dime_3	String	800	dimension

Column name	Data type	Cardinality	Attribution
counter_1	numeric(20,0)	NA	measure
...	...	NA	measure
counter_100	numeric(20,0)	NA	measure

Procedure

- If the to-be-created table contains a column that is frequently used for filtering, for example, this column is used in more than 80% of filtering scenarios,

  implement optimization as follows:

  Place this column in the first column of **sort_columns**.

  For example, if **msname** is used most frequently as a filter criterion in a query, it is placed in the first column. Run the following command to create a table. The query performance is good if **msname** is used as the filter criterion.

  ```
  create table carbondata_table(
     msname String,
     ...
     )STORED AS carbondata TBLPROPERTIES ('SORT_COLUMS'='msname');
  ```

- If the to-be-created table has multiple columns which are frequently used to filter the results,

  implement optimization as follows:

  Create an index for the columns.

  For example, if **msname**, **host**, and **dime_1** are frequently used columns, the **sort_columns** column sequence is "dime_1-> host-> msname..." based on cardinality. Run the following command to create a table. The following command can improve the filtering performance of **dime_1**, **host**, and **msname**.

  ```
  create table carbondata_table(
     dime_1 String,
     host String,
     msname String,
     dime_2 String,
     dime_3 String,
     ...
     )STORED AS carbondata
  TBLPROPERTIES ('SORT_COLUMS'='dime_1,host,msname');
  ```

- If the frequency of each column used for filtering is similar,

  implement optimization as follows:

  sort_columns is sorted in ascending order of cardinality.

  Run the following command to create a table:

  ```
  create table carbondata_table(
     Dime_1 String,
     BEGIN_TIME bigint,
     HOST String,
     msname String,
     ...
     )STORED AS carbondata
  TBLPROPERTIES ('SORT_COLUMS'='dime_2,dime_3,dime_1, BEGIN_TIME,host,msname');
  ```

- Create tables in ascending order of cardinalities. Then create secondary indexes for columns with more cardinalities. The statement for creating an index is as follows:

```
create index carbondata_table_index_msidn on tablecarbondata_table (
msname String) as 'carbondata' PROPERTIES ('table_blocksize'='128');
create index carbondata_table_index_host on tablecarbondata_table (
host String) as 'carbondata' PROPERTIES ('table_blocksize'='128');
```

- For columns of measure type, not requiring high accuracy, the numeric (20,0) data type is not required. You are advised to use the double data type to replace the numeric (20,0) data type to enhance query performance.

  The result of performance analysis of test-case shows reduction in query execution time from 15 to 3 seconds, thereby improving performance by nearly 5 times. The command for creating a table is as follows:

```
create table carbondata_table(
    Dime_1 String,
    BEGIN_TIME bigint,
    HOST String,
    msname String,
    counter_1 double,
    counter_2 double,
    ...
    counter_100 double,
    )STORED AS carbondata
;
```

- If values (**start_time** for example) of a column are incremental:

  For example, if data is loaded to CarbonData every day, **start_time** is incremental for each load. In this case, it is recommended that the **start_time** column be put at the end of **sort_columns**, because incremental values are efficient in using min/max index. The command for creating a table is as follows:

```
create table carbondata_table(
    Dime_1 String,
    HOST String,
    msname String,
    counter_1 double,
    counter_2 double,
    BEGIN_TIME bigint,
    ...
    counter_100 double,
    )STORED AS carbondata
    TBLPROPERTIES ( 'SORT_COLUMS'='dime_2,dime_3,dime_1..BEGIN_TIME');
```

1.6 Typical CarbonData Configuration Parameters

This section provides the details of how to configure all common CarbonData parameters.

Parameters in the carbon.properties File

Configure CarbonData parameters on the server or client based on the actual application scenario.

- Server: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Spark**. Click **Configurations** then **All Configurations**, click **JDBCServer(Role)**, and select **Customization**. Then, add CarbonData parameters in **spark.carbon.customized.configs**.

- Client: Log in to the client node and configure related parameters in the *{Client installation directory}*/**Spark/spark/conf/carbon.properties** file.

Table 1-17 System configurations in **carbon.properties**

Parameter	Default Value	Description
carbon.ddl.base.hdfs.url	hdfs://hacluster/opt/data	HDFS relative path from the HDFS base path, which is configured in **fs.defaultFS**. The path configured in **carbon.ddl.base.hdfs.url** will be appended to the HDFS path configured in **fs.defaultFS**. If this path is configured, you do not need to pass the complete path while dataload. For example, if the absolute path of the CSV file is **hdfs://10.18.101.155:54310/data/cnbc/2016/xyz.csv**, the path **hdfs://10.18.101.155:54310** will come from property **fs.defaultFS** and you can configure **/data/cnbc/** as **carbon.ddl.base.hdfs.url**. During data loading, you can specify the CSV path as **/2016/xyz.csv**.
carbon.badRecords.location	-	Storage path of bad records. This path is an HDFS path. The default value is **Null**. If bad records logging or bad records operation redirection is enabled, the path must be configured by the user.
carbon.bad.records.action	fail	The following are four types of actions for bad records: **FORCE**: Data is automatically corrected by storing the bad records as NULL. **REDIRECT**: Bad records are written to the CSV file in **carbon.badRecords.location** instead of being loaded. **IGNORE**: Bad records are neither loaded nor written to the CSV file. **FAIL**: Data loading fails if any bad records are found.

Parameter	Default Value	Description
carbon.update.sync.folder	/tmp/carbondata	Specifies the **modifiedTime.mdt** file path. You can set it to an existing path or a new path. **NOTE** If you set this parameter to an existing path, ensure that all users can access the path and the path has the 777 permission.
carbon.enable.badrecord.action.redirect	false	Specifies whether to enable the REDIRECT mode to handle bad records during data loading. When it is enabled, bad records in source files will be recorded in a CSV file generated in a specified storage location each time data is loaded. CSV injection may occur when such CSV files are opened in Windows.
carbon.enable.partitiondata.trash	false	After this function is enabled, the **ALTER DROP PARTITION** operation moves the deleted partition data to the carbon trash. **NOTE** This function is supported only in MRS 3.2.0 or later.
carbon.enable.show.mv.for.showtables	false	If this parameter is set to **true**, materialized views are filtered out when the **show tables** command is executed. If this parameter is set to **true** when there are a large number of tables, the execution of the **show tables** command will take a long time. **NOTE** This function is supported only in MRS 3.2.0 or later.
carbon.enable.droptable.remove.staleentry	true	If this parameter is set to **true**, obsolete records of the table will be deleted from the cache when the **drop table** command is executed. If this parameter is set to **true** when there are a large number of databases, the execution of the **drop table** command will take a long time. **NOTE** This function is supported only in MRS 3.2.0 or later.

Parameter	Default Value	Description
carbon.enable.multi.version.table.status	false	Whether to enable versioning management of tablestatus files. If this parameter is set to **true**, a tablestatus file is generated each time a load, insert, or IUD operation is performed. **NOTE** If JDBCServer and the client are both used to load data to a table, ensure that this feature is enabled or disabled for both of them at the same time.
carbon.tablestatus.multi.version.file.coun	3	This parameter is available only when **carbon.enable.multi.version.table.status** is set to **true**. This parameter indicates the default number of the latest tablestatus files to be retained. Tablestatus files that exceed the value of this parameter will be deleted.

Table 1-18 Performance configurations in **carbon.properties**

Parameter	Default Value	Description
Data Loading Configuration		
carbon.sort.file.write.buffer.size	16384	CarbonData sorts data and writes it to a temporary file to limit memory usage. This parameter controls the size of the buffer used for reading and writing temporary files. The unit is bytes. The value ranges from 10240 to 10485760.
carbon.graph.rowset.size	100,000	Rowset size exchanged in data loading graph steps. The value ranges from 500 to 1,000,000.
carbon.number.of.cores.while.loading	6	Number of cores used during data loading. The greater the number of cores, the better the compaction performance. If the CPU resources are sufficient, you can increase the value of this parameter.
carbon.sort.size	500000	Number of records to be sorted

Parameter	Default Value	Description
carbon.enableXXHash	true	Hashmap algorithm used for hashkey calculation
carbon.number.of.cores.block.sort	7	Number of cores used for sorting blocks during data loading
carbon.max.driver.lru.cache.size	-1	Maximum size of LRU caching for data loading at the driver side. The unit is MB. The default value is **-1**, indicating that there is no memory limit for the caching. Only integer values greater than 0 are accepted.
carbon.max.executor.lru.cache.size	-1	Maximum size of LRU caching for data loading at the executor side. The unit is MB. The default value is **-1**, indicating that there is no memory limit for the caching. Only integer values greater than 0 are accepted. If this parameter is not configured, the value of **carbon.max.driver.lru.cache.size** is used.
carbon.merge.sort.prefetch	true	Whether to enable prefetch of data during merge sort while reading data from sorted temp files in the process of data loading
carbon.update.persist.enable	true	Configuration to enable the dataset of RDD/dataframe to persist data. Enabling this will reduce the execution time of UPDATE operation.
enable.unsafe.sort	true	Whether to use unsafe sort during data loading. Unsafe sort reduces the garbage collection during data load operation, resulting in better performance. The default value is **true**, indicating that unsafe sort is enabled.
enable.offheap.sort	true	Whether to use off-heap memory for sorting of data during data loading
offheap.sort.chunk.size.inmb	64	Size of data chunks to be sorted, in MB. The value ranges from 1 to 1024.

Parameter	Default Value	Description
carbon.unsafe.working.memory.in.mb	512	Size of the unsafe working memory. This will be used for sorting data and storing column pages. The unit is MB. Memory required for data loading: carbon.number.of.cores.while.loading [default value is 6] x Number of tables to load in parallel x offheap.sort.chunk.size.inmb [default value is 64 MB] + carbon.blockletgroup.size.in.mb [default value is 64 MB] + Current compaction ratio [64 MB/3.5] = Around 900 MB per table Memory required for data query: (SPARK_EXECUTOR_INSTANCES. [default value is 2] x (carbon.blockletgroup.size.in.mb [default value: 64 MB] + carbon.blockletgroup.size.in.mb [default value = 64 MB x 3.5) x Number of cores per executor [default value: 1]) = ~ 600 MB
carbon.sort.inmemory.storage.size.in.mb	512	Size of the intermediate sort data to be kept in the memory. Once the specified value is reached, the system writes data to the disk. The unit is MB.

Parameter	Default Value	Description
sort.inmemory.size.inmb	1024	Size of the intermediate sort data to be kept in the memory. Once the specified value is reached, the system writes data to the disk. The unit is MB. If **carbon.unsafe.working.memory.in.mb** and **carbon.sort.inmemory.storage.size.in.mb** are configured, you do not need to set this parameter. If this parameter has been configured, 20% of the memory is used for working memory **carbon.unsafe.working.memory.in.mb**, and 80% is used for sort storage memory **carbon.sort.inmemory.storage.size.in.mb**. **NOTE** The value of **spark.yarn.executor.memoryOverhead** configured for Spark must be greater than the value of **sort.inmemory.size.inmb** configured for CarbonData. Otherwise, Yarn might stop the executor if off-heap access exceeds the configured executor memory.
carbon.blockletgroup.size.in.mb	64	The data is read as a group of blocklets which are called blocklet groups. This parameter specifies the size of each blocklet group. Higher value results in better sequential I/O access. The minimum value is 16 MB. Any value less than 16 MB will be reset to the default value (64 MB). The unit is MB.
enable.inmemory.merge.sort	false	Whether to enable **inmemorymerge sort**.
use.offheap.in.query.processing	true	Whether to enable **offheap** in query processing.

Parameter	Default Value	Description
carbon.load.sort.scope	local_sort	Sort scope for the load operation. There are two types of sort: **batch_sort** and **local_sort**. If **batch_sort** is selected, the loading performance is improved but the query performance is reduced. **NOTE** **local_sort** conflicts with DDL operations on partitioned tables and they cannot be used at the same time. In addition, **local_sort** does not significantly improve the performance of partitioned tables. You are advised not to enable this feature on partitioned tables.
carbon.batch.sort.size.inmb	-	Size of data to be considered for batch sorting during data loading. The recommended value is less than 45% of the total sort data. The unit is MB. **NOTE** If this parameter is not set, its value is about 45% of the value of **sort.inmemory.size.inmb** by default.
enable.unsafe.columnpage	true	Whether to keep page data in heap memory during data loading or query to prevent garbage collection bottleneck.
carbon.use.local.dir	false	Whether to use Yarn local directories for multi-disk data loading. If this parameter is set to **true**, Yarn local directories are used to load multi-disk data to improve data loading performance.
carbon.use.multiple.temp.dir	false	Whether to use multiple temporary directories for storing temporary files to improve data loading performance.
carbon.load.datamaps.parallel.db_name.table_name	N/A	The value can be **true** or **false**. You can set the database name and table name to improve the first query performance of the table.
Compaction Configuration		
carbon.number.of.cores.while.compacting	2	Number of cores to be used while compacting data. The greater the number of cores, the better the compaction performance. If the CPU resources are sufficient, you can increase the value of this parameter.

Parameter	Default Value	Description
carbon.compaction.level.threshold	4,3	This configuration is for minor compaction which decides how many segments to be merged. For example, if this parameter is set to **2,3**, minor compaction is triggered every two segments. **3** is the number of level 1 compacted segments which is further compacted to new segment. The value ranges from 0 to 100.
carbon.major.compaction.size	1024	Major compaction size. Sum of the segments which is below this threshold will be merged. The unit is MB.
carbon.horizontal.compaction.enable	true	Whether to enable/disable horizontal compaction. After every DELETE and UPDATE statement, horizontal compaction may occur in case the incremental (DELETE/ UPDATE) files becomes more than specified threshold. By default, this parameter is set to **true**. You can set this parameter to **false** to disable horizontal compaction.
carbon.horizontal.update.compaction.threshold	1	Threshold limit on number of UPDATE delta files within a segment. In case the number of delta files goes beyond the threshold, the UPDATE delta files within the segment becomes eligible for horizontal compaction and are compacted into single UPDATE delta file. By default, this parameter is set to **1**. The value ranges from **1** to **10000**.
carbon.horizontal.delete.compaction.threshold	1	Threshold limit on number of DELETE incremental files within a block of a segment. In case the number of incremental files goes beyond the threshold, the DELETE incremental files for the particular block of the segment becomes eligible for horizontal compaction and are compacted into single DELETE incremental file. By default, this parameter is set to **1**. The value ranges from **1** to **10000**.
Query Configuration		

Parameter	Default Value	Description
carbon.number.of.cores	4	Number of cores to be used during query
carbon.limit.block.distribution.enable	false	Whether to enable the CarbonData distribution for limit query. The default value is **false**, indicating that block distribution is disabled for query statements that contain the keyword limit. For details about how to optimize this parameter, see **Typical Performance Tuning Parameters**.
carbon.custom.block.distribution	false	Whether to enable Spark or CarbonData block distribution. By default, the value is **false**, indicating that Spark block distribution is enabled. To enable CarbonData block distribution, change the value to **true**.
carbon.infilter.subquery.pushdown.enable	false	If this is set to **true** and a Select query is triggered in the filter with subquery, the subquery is executed and the output is broadcast as IN filter to the left table. Otherwise, SortMergeSemiJoin is executed. You are advised to set this to **true** when IN filter subquery does not return too many records. For example, when the IN clause subquery returns 10,000 or fewer records, enabling this parameter will display query results faster. Example: ***select * from flow_carbon_256b where cus_no in (select cus_no from flow_carbon_256b where dt>='20260101' and dt<='20260701' and txn_bk='tk_1' and txn_br='tr_1') limit 1000;***
carbon.scheduler.minRegisteredResourcesRatio	0.8	Minimum resource (executor) ratio needed for starting the block distribution. The default value is **0.8**, indicating that 80% of the requested resources are allocated for starting block distribution.
carbon.dynamicAllocation.schedulerTimeout	5	Maximum time that the scheduler waits for executors to be active. The default value is **5** seconds, and the maximum value is **15** seconds.

Parameter	Default Value	Description
enable.unsafe.in.query.processing	true	Whether to use unsafe sort during query. Unsafe sort reduces the garbage collection during query, resulting in better performance. The default value is **true**, indicating that unsafe sort is enabled.
carbon.enable.vector.reader	true	Whether to enable vector processing for result collection to improve query performance
carbon.query.show.datamaps	true	**SHOW TABLES** lists all tables, including the primary table and datamaps. To filter out the datamaps, set this parameter to **false**.
Secondary Index Configuration		
carbon.secondary.index.creation.threads	1	Number of threads to concurrently process segments during secondary index creation. This property helps fine-tuning the system when there are a lot of segments in a table. The value ranges from 1 to 50.
carbon.si.lookup.partialstring	true	• When the parameter value is **true**, it includes indexes started with, ended with, and contained. • When the parameter value is **false**, it includes only secondary indexes started with.
carbon.si.segment.merge	true	Enabling this property merges **.carbondata** files inside the secondary index segment. The merging will happen after the load operation. That is, at the end of the secondary index table load, small files are checked and merged. **NOTE** Table Block Size is used as the size threshold for merging small files.

Table 1-19 Other configurations in **carbon.properties**

Parameter	Default Value	Description
Data Loading Configuration		

Parameter	Default Value	Description
carbon.lock.type	HDFSLOCK	Type of lock to be acquired during concurrent operations on a table. There are following types of lock implementation: • **LOCALLOCK**: Lock is created on local file system as a file. This lock is useful when only one Spark driver (or JDBCServer) runs on a machine. • **HDFSLOCK**: Lock is created on HDFS file system as a file. This lock is useful when multiple Spark applications are running and no ZooKeeper is running on a cluster.
carbon.sort.intermediate.files.limit	20	Minimum number of intermediate files. After intermediate files are generated, sort and merge the files. For details about how to optimize this parameter, see **Typical Performance Tuning Parameters**.
carbon.csv.read.buffersize.byte	1048576	Size of CSV reading buffer
carbon.merge.sort.reader.thread	3	Maximum number of threads used for reading intermediate files for final merging.
carbon.concurrent.lock.retries	100	Maximum number of retries used to obtain the concurrent operation lock. This parameter is used for concurrent loading.
carbon.concurrent.lock.retry.timeout.sec	1	Interval between the retries to obtain the lock for concurrent operations.
carbon.lock.retries	3	Maximum number of retries to obtain the lock for any operations other than import.
carbon.lock.retry.timeout.sec	5	Interval between the retries to obtain the lock for any operation other than import.

Parameter	Default Value	Description
carbon.tempstore.location	/opt/Carbon/TempStoreLoc	Temporary storage location. By default, the **System.getProperty("java.io.tmpdir")** method is used to obtain the value. For details about how to optimize this parameter, see the description of **carbon.use.local.dir** in **Typical Performance Tuning Parameters**.
carbon.load.log.counter	500000	Data loading records count in logs
SERIALIZATION_NULL_FORMAT	\N	Value to be replaced with NULL
carbon.skip.empty.line	false	Setting this property will ignore the empty lines in the CSV file during data loading.
carbon.load.datamaps.parallel	false	Whether to enable parallel datamap loading for all tables in all sessions. This property will improve the time to load datamaps into memory by distributing the job among executors, thus improving query performance.
Merging Configuration		
carbon.numberof.preserve.segments	0	If you want to preserve some number of segments from being compacted, then you can set this configuration. For example, if **carbon.numberof.preserve.segments** is set to **2**, the latest two segments will always be excluded from the compaction. No segments will be preserved by default.
carbon.allowed.compaction.days	0	This configuration is used to control on the number of recent segments that needs to be merged. For example, if this parameter is set to **2**, the segments which are loaded in the time frame of past 2 days only will get merged. Segments which are loaded earlier than 2 days will not be merged. This configuration is disabled by default.

Parameter	Default Value	Description
carbon.enable.auto.load.merge	false	Whether to enable compaction along with data loading.
carbon.merge.index.in.segment	true	This configuration merges all the CarbonIndex files (**.carbonindex**) in a segment into a single MergeIndex file (**.carbonindexmerge**) upon data loading completion. This significantly reduces the delay in serving the first query.
carbon.enable.compact.autoclean	false	If this parameter is set to **true**, the **clean files** command is invoked to delete obsolete files after segments are compacted. **NOTE** This function is supported only in MRS 3.2.0 or later.
Query Configuration		
max.query.execution.time	60	Maximum time allowed for one query to be executed. The unit is minute.
carbon.enableMinMax	true	MinMax is used to improve query performance. You can set this to **false** to disable this function.
carbon.lease.recovery.retry.count	5	Maximum number of attempts that need to be made for recovering a lease on a file. Minimum value: **1** Maximum value: **50**
carbon.lease.recovery.retry.interval	1000 (ms)	Interval or pause time after a lease recovery attempt is made on a file. Minimum value: **1000** (ms) Maximum value: **10000** (ms)

Parameters in the spark-defaults.conf File

- Log in to the client node and configure the parameters listed in **Table 1-20** in the *{Client installation directory}*/**Spark/spark/conf/spark-defaults.conf** file.

Table 1-20 Spark configuration reference in **spark-defaults.conf**

Parameter	Default Value	Description
spark.driver.memory	4G	Memory to be used for the driver process. SparkContext has been initialized. **NOTE** In client mode, do not use SparkConf to set this parameter in the application because the driver JVM has been started. To configure this parameter, configure it in the **--driver-memory** command-line option or in the default property file.
spark.executor.memory	4 GB	Memory to be used for each executor process.
spark.sql.crossJoin.enabled	true	If the query contains a cross join, enable this property so that no error occurs. In this case, you can use a cross join instead of a join for better performance.

- Configure the following parameters in the **spark-defaults.conf** file on the Spark driver.
  - In spark-sql mode: Log in to the Spark client node and configure the parameters listed in **Table 1-21** in the *{Client installation directory}*/**Spark/spark/conf/spark-defaults.conf** file.

Table 1-21 Parameter description

Parameter	Value	Description
spark.driver.extraJavaOptions	-Dlog4j.configuration=file:/opt/client/Spark/spark/conf/log4j.properties -Djetty.version=x.y.z -Dzookeeper.server.principal=zookeeper/hadoop.*<System domain name>* -Djava.security.krb5.conf=/opt/client/KrbClient/kerberos/var/krb5kdc/krb5.conf -Djava.security.auth.login.config=/opt/client/Spark/spark/conf/jaas.conf -Dorg.xerial.snappy.tempdir=/opt/client/Spark/tmp -Dcarbon.properties.filepath=/opt/client/Spark/spark/conf/carbon.properties -Djava.io.tmpdir=/opt/client/Spark/tmp	The default value **/opt/client/Spark/spark** indicates **CLIENT_HOME** of the client and is added to the end of the value of **spark.driver.extraJavaOptions**. This parameter is used to specify the path of the **carbon.properties**file in Driver. **NOTE** Spaces next to equal marks (=) are not allowed.
spark.sql.session.state.builder	org.apache.spark.sql.hive.FIHiveACLSessionStateBuilder	Session state constructor.
spark.carbon.sqlastbuilder.classname	org.apache.spark.sql.hive.CarbonInternalSqlAst-Builder	AST constructor.

Parameter	Value	Description
spark.sql.catalog.class	org.apache.spark.sql.hive.HiveACLExternalCatalog	Hive External catalog to be used. This parameter is mandatory if Spark ACL is enabled.
spark.sql.hive.implementation	org.apache.spark.sql.hive.HiveACLClientImpl	How to call the Hive client. This parameter is mandatory if Spark ACL is enabled.
spark.sql.hiveClient.isolation.enabled	false	This parameter is mandatory if Spark ACL is enabled.

- In JDBCServer: Log in to the node where JDBCServer is installed and configure the parameters listed in **Table 1-22** in the **{BIGDATA_HOME}/FusionInsight_Spark_*/*_JDBCServer/etc/spark-defaults.conf** file.

Table 1-22 Parameter description

Parameter	Value	Description
spark.driver.extraJavaOptions	-Xloggc:${SPARK_LOG_DIR}/indexserver-omm-%p-gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:MaxDirectMemorySize=512M -XX:MaxMetaspaceSize=512M -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=10M -XX:OnOutOfMemoryError='kill -9 %p' -Djetty.version=x.y.z -Dorg.xerial.snappy.tempdir=${BIGDATA_HOME}/tmp/spark/JDBCServer/snappy_tmp -Djava.io.tmpdir=${BIGDATA_HOME}/tmp/spark/JDBCServer/io_tmp -Dcarbon.properties.filepath=${SPARK_CONF_DIR}/carbon.properties -Djdk.tls.ephemeralDHKeySize=2	The default value **${SPARK_CONF_DIR}** depends on a specific cluster and is added to the end of the value of the **spark.driver.extraJavaOptions** parameter. This parameter is used to specify the path of the **carbon.properties** file in Driver. **NOTE** Spaces next to equal marks (=) are not allowed.

Parameter	Value	Description
	048 -Dspark.ssl.keyStore=${SPARK_CONF_DIR}/child.keystore #{java_stack_prefer}	
spark.sql.session.state.builder	org.apache.spark.sql.hive.FIHiveACLSessionStateBuilder	Session state constructor.
spark.carbon.sqlastbuilder.classname	org.apache.spark.sql.hive.CarbonInternalSqlAst-Builder	AST constructor.
spark.sql.catalog.class	org.apache.spark.sql.hive.HiveACLExternalCatalog	Hive External catalog to be used. This parameter is mandatory if Spark ACL is enabled.
spark.sql.hive.implementation	org.apache.spark.sql.hive.HiveACLClientImpl	How to call the Hive client. This parameter is mandatory if Spark ACL is enabled.
spark.sql.hiveClient.isolation.enabled	false	This parameter is mandatory if Spark ACL is enabled.

1.7 CarbonData Syntax Reference

1.7.1 CREATE TABLE

Function

This command is used to create a CarbonData table by specifying the list of fields along with the table properties.

Syntax

CREATE TABLE *[IF NOT EXISTS] [db_name.]table_name*

[(col_name data_type, ...)]

STORED AS *carbondata*

[TBLPROPERTIES (property_name=property_value, ...)];

Additional attributes of all tables are defined in **TBLPROPERTIES**.

Parameter Description

Table 1-23 CREATE TABLE parameters

Parameter	Description
db_name	Database name that contains letters, digits, and underscores (_).
col_name data_type	List with data types separated by commas (,). The column name contains letters, digits, and underscores (_). **NOTE** When creating a CarbonData table, do not use tupleId, PositionId, and PositionReference as column names because columns with these names are internally used by secondary index commands.
table_name	Table name of a database that contains letters, digits, and underscores (_).
STORED AS	The **carbondata** parameter defines and creates a CarbonData table.
TBLPROPERTIES	List of CarbonData table properties.

Precautions

Table attributes are used as follows:

- Block size

  The block size of a data file can be defined for a single table using **TBLPROPERTIES**. The larger one between the actual size of the data file and the defined block size is selected as the actual block size of the data file in HDFS. The unit is MB. The default value is 1024 MB. The value ranges from 1 MB to 2048 MB. If the value is beyond the range, the system reports an error.

  Once the block size reaches the configured value, the write program starts a new block of CarbonData data. Data is written in multiples of the page size (32,000 records). Therefore, the boundary is not strict at the byte level. If the new page crosses the boundary of the configured block, the page is written to the new block instead of the current block.

  TBLPROPERTIES('table_blocksize'='128')

NOTE

- If a small block size is configured in the CarbonData table while the size of the data file generated by the loaded data is large, the block size displayed in HDFS is different from the configured value. This is because when data is written to a local block file for the first time, even though the size of the to-be-written data is larger than the configured value of the block size, data will still be written into the block. Therefore, the actual value of block size in HDFS is the larger value between the size of the data to be written and the configured block size.
- If **block.num** is less than the parallelism, the blocks are split into new blocks so that new blocks.num is greater than parallelism and all cores can be used. This optimization is called block distribution.

- **SORT_SCOPE** specifies the sort scope during table creation. There are four types of sort scopes:
  - **GLOBAL_SORT**: It improves query performance, especially for point queries. *TBLPROPERTIES('SORT_SCOPE'='GLOBAL_SORT'*)
  - **LOCAL_SORT**: Data is sorted locally (task-level sorting).
  - **NO_SORT**: The default sorting mode is used. Data is loaded in unsorted manner, which greatly improves loading performance.
- SORT_COLUMNS

  This table property specifies the order of sort columns.

  TBLPROPERTIES('SORT_COLUMNS'='column1, column3')

  NOTE

  - If this attribute is not specified, no columns are sorted by default.
  - If this property is specified but with empty argument, then the table will be loaded without sort. For example, *('SORT_COLUMNS'='')*.
  - **SORT_COLUMNS** supports the string, date, timestamp, short, int, long, byte, and boolean data types.
- RANGE_COLUMN

  This property is used to specify a column to partition the input data by range. Only one column can be configured. During data import, you can use **global_sort_partitions** or **scale_factor** to avoid generating small files.

  TBLPROPERTIES('RANGE_COLUMN'='column1')
- LONG_STRING_COLUMNS

  The length of a common string cannot exceed 32,000 characters. To store a string of more than 32,000 characters, set **LONG_STRING_COLUMNS** to the target column.

  TBLPROPERTIES('LONG_STRING_COLUMNS'='column1, column3')

  NOTE

  LONG_STRING_COLUMNS can be set only for columns of the STRING, CHAR, or VARCHAR type.

Scenarios

Creating a Table by Specifying Columns

The **CREATE TABLE** command is the same as that of Hive DDL. The additional configurations of CarbonData are provided as table properties.

CREATE TABLE *[IF NOT EXISTS] [db_name.]table_name*

[(col_name data_type , ...)]

STORED AS *carbondata*

[TBLPROPERTIES (property_name=property_value, ...)];

Examples

CREATE TABLE *IF NOT EXISTS productdb.productSalesTable (*

productNumber Int,

productName String,

storeCity String,

storeProvince String,

productCategory String,

productBatch String,

saleQuantity Int,

revenue Int)

STORED AS carbondata

TBLPROPERTIES (

'table_blocksize'='128',

'SORT_COLUMNS'='productBatch, productName')

System Response

A table will be created and the success message will be logged in system logs.

1.7.2 CREATE TABLE As SELECT

Function

This command is used to create a CarbonData table by specifying the list of fields along with the table properties.

Syntax

CREATE TABLE *[IF NOT EXISTS] [db_name.]table_name* ***STORED AS carbondata*** *[TBLPROPERTIES (key1=val1, key2=val2, ...)] AS select_statement;*

Parameter Description

Table 1-24 CREATE TABLE parameters

Parameter	Description
db_name	Database name that contains letters, digits, and underscores (_).
table_name	Table name of a database that contains letters, digits, and underscores (_).
STORED AS	Used to store data in CarbonData format.
TBLPROPERTIES	List of CarbonData table properties. For details, see **Precautions**.

Precautions

N/A

Examples

CREATE TABLE ctas_select_parquet ***STORED AS*** carbondata as select * from parquet_ctas_test;

System Response

This example will create a Carbon table from any Parquet table and load all the records from the Parquet table.

1.7.3 DROP TABLE

Function

This command is used to delete an existing table.

Syntax

DROP TABLE *[IF EXISTS] [db_name.]table_name;*

Parameter Description

Table 1-25 DROP TABLE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Name of the table to be deleted

Precautions

In this command, **IF EXISTS** and **db_name** are optional.

Example

DROP TABLE IF EXISTS productDatabase.productSalesTable;

System Response

The table will be deleted.

1.7.4 SHOW TABLES

Function

SHOW TABLES command is used to list all tables in the current or a specific database.

Syntax

SHOW TABLES *[IN db_name];*

Parameter Description

Table 1-26 SHOW TABLE parameters

Parameter	Description
IN db_name	Name of the database. This parameter is required only when tables of this specific database are to be listed.

Usage Guidelines

IN db_Name is optional.

Examples

SHOW TABLES IN ProductDatabase;

System Response

All tables are listed.

1.7.5 ALTER TABLE COMPACTION

Function

The **ALTER TABLE COMPACTION** command is used to merge a specified number of segments into a single segment. This improves the query performance of a table.

Syntax

ALTER TABLE*[db_name.]table_name COMPACT 'MINOR/MAJOR/SEGMENT_INDEX';*

ALTER TABLE*[db_name.]table_name COMPACT 'CUSTOM' WHERE SEGMENT.ID IN (id1, id2, ...);*

Parameter Description

Table 1-27 ALTER TABLE COMPACTION parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Table name.
MINOR	Minor compaction. For details, see **Compacting CarbonData Table Segments**.
MAJOR	Major compaction. For details, see **Compacting CarbonData Table Segments**.
SEGMENT_INDEX	This configuration enables you to merge all the CarbonData index files (**.carbonindex**) inside a segment to a single CarbonData index merge file (**.carbonindexmerge**). This enhances the first query performance. For more information, see **Table 1-7**.
CUSTOM	Custom compaction. For details, see **Combining Segments**.

Precautions

N/A

Examples

ALTER TABLE ProductDatabase COMPACT 'MINOR';

ALTER TABLE ProductDatabase COMPACT 'MAJOR';

ALTER TABLE ProductDatabase COMPACT 'SEGMENT_INDEX';

ALTER TABLE ProductDatabase COMPACT 'CUSTOM' WHERE SEGMENT.ID IN (0, 1);

System Response

ALTER TABLE COMPACTION does not show the response of the compaction because it is run in the background.

If you want to view the response of minor and major compactions, you can check the logs or run the ***SHOW SEGMENTS*** command.

Example:

```
+------+------------+--------------------------+-----------------+------------+------------+-------------+--------------
+--+
|  ID  |   Status   |     Load Start Time      | Load Time Taken  | Partition  | Data Size  | Index Size  | File
Format  |
+------+------------+--------------------------+-----------------+------------+------------+-------------+--------------
+--+
| 3    | Success    | 2020-09-28 22:53:26.336  | 3.726S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
| 2    | Success    | 2020-09-28 22:53:01.702  | 6.688S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
| 1    | Compacted  | 2020-09-28 22:51:15.242  | 5.82S            | {}         | 6.50KB     | 3.43KB      |
columnar_v3  |
| 0.1  | Success    | 2020-10-30 20:49:24.561  | 16.66S           | {}         | 12.87KB    | 6.91KB      | columnar_v3
|
| 0    | Compacted  | 2020-09-28 22:51:02.6    | 6.819S           | {}         | 6.50KB     | 3.43KB      | columnar_v3
|
+------+------------+--------------------------+-----------------+------------+------------+-------------+--------------
+--+
```

In the preceding information:

- **Compacted** indicates that data has been compacted.
- **0.1** indicates the compacting result of segment 0 and segment 1.

The compact operation does not incur any change to other operations.

Compacted segments, such as segment 0 and segment 1, become useless. To save space, before you perform other operations, run the ***CLEAN FILES*** command to delete compacted segments. For more information about the **CLEAN FILES** command, see **CLEAN FILES**.

1.7.6 TABLE RENAME

Function

This command is used to rename an existing table.

Syntax

ALTER TABLE *[db_name.]table_name* **RENAME TO** *new_table_name*;

Parameter Description

Table 1-28 RENAME parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Current name of the existing table
new_table_name	New name of the existing table

Precautions

- Parallel queries (using table names to obtain paths for reading CarbonData storage files) may fail during this operation.
- The secondary index table cannot be renamed.

Example

ALTER TABLE *carbon* **RENAME TO** *carbondata*;

ALTER TABLE *test_db.carbon* **RENAME TO** *test_db.carbondata*;

System Response

The new table name will be displayed in the CarbonData folder. You can run **SHOW TABLES** to view the new table name.

1.7.7 ADD COLUMNS

Function

This command is used to add a column to an existing table.

Syntax

ALTER TABLE *[db_name.]table_name* **ADD COLUMNS** *(col_name data_type,...)* **TBLPROPERTIES***(''COLUMNPROPERTIES.columnName.shared_column'='sharedFolder.sharedColumnName,...', 'DEFAULT.VALUE.COLUMN_NAME'='default_value')*;

Parameter Description

Table 1-29 ADD COLUMNS parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Table name.
col_name data_type	Name of a comma-separated column with a data type. It consists of letters, digits, and underscores (_). **NOTE** When creating a CarbonData table, do not name columns as tupleId, PositionId, and PositionReference because they will be used in UPDATE, DELETE, and secondary index commands.

Precautions

- Only **shared_column** and **default_value** are read. If any other property name is specified, no error will occur and the property will be ignored.

- If no default value is specified, the default value of the new column is considered null.
- If filter is applied to the column, new columns will not be added during sort. New columns may affect query performance.

Examples

- **ALTER TABLE** *carbon* **ADD COLUMNS** *(a1 INT, b1 STRING)*;
- **ALTER TABLE** *carbon* **ADD COLUMNS** *(a1 INT, b1 STRING)* **TBLPROPERTIES***('COLUMNPROPERTIES.b1.shared_column'='sharedFolder.b1')*;
- ALTER TABLE *carbon* **ADD COLUMNS** *(a1 INT, b1 STRING)* **TBLPROPERTIES***('DEFAULT.VALUE.a1'='10')*;

System Response

The newly added column can be displayed by running the **DESCRIBE** command.

1.7.8 DROP COLUMNS

Function

This command is used to delete one or more columns from a table.

Syntax

ALTER TABLE *[db_name.]table_name* **DROP COLUMNS** *(col_name, ...)*;

Parameter Description

Table 1-30 DROP COLUMNS parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Table name.
col_name	Name of a column in a table. Multiple columns are supported. It consists of letters, digits, and underscores (_).

Precautions

After a column is deleted, at least one key column must exist in the schema. Otherwise, an error message is displayed, and the column fails to be deleted.

Examples

Assume that the table contains four columns named a1, b1, c1, and d1.

- Delete a column:
  ALTER TABLE *carbon* **DROP COLUMNS** *(b1)*;
  ALTER TABLE *test_db.carbon* **DROP COLUMNS** *(b1)*;
- Delete multiple columns:
  ALTER TABLE *carbon* **DROP COLUMNS** *(b1,c1)*;
  ALTER TABLE *test_db.carbon* **DROP COLUMNS** *(b1,c1)*;

System Response

If you run the **DESCRIBE** command, the deleted columns will not be displayed.

1.7.9 CHANGE DATA TYPE

Function

This command is used to convert INT to BIGINT or increase decimal precision.

Syntax

ALTER TABLE *[db_name.]table_name* **CHANGE** *col_name col_name changed_column_type*;

Parameter Description

Table 1-31 CHANGE DATA TYPE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Table name.
col_name	Name of a column in a table. A column name consists of letters, digits, and underscores (_).
changed_column_type	Target data type.

Precautions

- The decimal precision conversion is available only when no data is lost. The decimal precision is represented in the (precision, scale) format.
  - Unavailable: Decimal precision cannot be changed from (10,2) to (10,5) because only the scale increases, but the total number of digits remains unchanged.
  - Available: Decimal precision can be changed from (10,2) to (12,3). The total number of digits increases by 2 but the scale increases only by 1, which does not cause any data loss.
- The maximum precision allowed is (38,38).

Example

- Convert the data type of column **a1** from INT to BIGINT.
  ALTER TABLE *test_db.carbon* **CHANGE** *a1 a1 BIGINT*;
- Change the precision of column **a1** from 10 to 18.
  ALTER TABLE *test_db.carbon* **CHANGE** *a1 a1 DECIMAL(18,2)*;

Response

You can run the **DESCRIBE** command to check the changed data type of the modified column.

1.7.10 REFRESH TABLE

Function

This command is used to register Carbon table data with the Hive metabase.

Syntax

REFRESH TABLE *db_name.table_name*;

Parameter Description

Table 1-32 REFRESH TABLE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
table_name	Table name.

Precautions

- Before you run this command, copy the schema and data of the source table to the destination database.
- For the repository of an earlier version, the time zones of the source and destination clusters must be the same.
- The names of the destination database and the source database must be the same.
- If you are using aggregate tables, all of them should be copied to the destination database.
- If the source cluster uses Hive metabase to store the table structure, the refresh does not take effect because the schema file does not exist in the file system.

Example

REFRESH TABLE *dbcarbon.productSalesTable*;

Response

The source Carbon table data is registered with the Hive metabase.

1.7.11 REGISTER INDEX TABLE

Function

This command is used to register an index table with the primary table.

Syntax

REGISTER INDEX TABLE *indextable_name* ON *db_name.maintable_name*;

Parameter Description

Table 1-33 REFRESH INDEX TABLE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is selected.
indextable_name	Index table name.
maintable_name	Primary table name.

Precautions

Before running this command, run **REFRESH TABLE** to register the primary table and secondary index table with the Hive metastore.

Examples

create database productdb;

use productdb;

CREATE TABLE productSalesTable(a int,b string,c string) stored as carbondata;

create index productNameIndexTable on table productSalesTable(c) as 'carbondata';

insert into table productSalesTable select 1,'a','aaa';

create database productdb2;

Run the **hdfs** command to copy **productSalesTable** and **productNameIndexTable** in the **productdb** database to the **productdb2** database.

refresh table productdb2.productSalesTable ;

refresh table productdb2.productNameIndexTable ;

explain select * from productdb2.productSalesTable where c = 'aaa'; / The query command does not use an index table.

REGISTER INDEX TABLE productNameIndexTable ON productdb2.productSalesTable;

explain select * from productdb2.productSalesTable where c = 'aaa'; // The query command uses an index table.

System Response

By running this command, the index table will be registered to the primary table.

1.7.12 LOAD DATA

Function

This command is used to load user data of a particular type, so that CarbonData can provide good query performance.

NOTE

Only the raw data on HDFS can be loaded.

Syntax

LOAD DATA *INPATH 'folder_path' INTO TABLE [db_name.]table_name OPTIONS(property_name=property_value, ...);*

Parameter Description

Table 1-34 LOAD DATA parameters

Parameter	Description
folder_path	Path of the file or folder used for storing the raw CSV data.
db_name	Database name. If this parameter is not specified, the current database is used.
table_name	Name of a table in a database.

Precautions

The following configuration items are involved during data loading:

- **DELIMITER**: Delimiters and quote characters provided in the load command. The default value is a comma (**,**).

  OPTIONS('DELIMITER'=',' , 'QUOTECHAR'='"')

  You can use **'DELIMITER'='\t'** to separate CSV data using tabs.

  OPTIONS('DELIMITER'='\t')

  CarbonData also supports **\001** and **\017** as delimiters.

NOTE

When the delimiter of CSV data is a single quotation mark ('), the single quotation mark must be enclosed in double quotation marks (" "). For example, 'DELIMITER'= "'".

- **QUOTECHAR**: Delimiters and quote characters provided in the load command. The default value is double quotation marks (**"**).

  OPTIONS('DELIMITER'=',' , 'QUOTECHAR'='"')

- **COMMENTCHAR**: Comment characters provided in the load command. During data loading, if there is a comment character at the beginning of a line, the line is regarded as a comment line and data in the line will not be loaded. The default value is a pound key (#).

  OPTIONS('COMMENTCHAR'='#')

- **FILEHEADER**: If the source file does not contain any header, add a header to the **LOAD DATA** command.

  OPTIONS('FILEHEADER'='column1,column2')

- **ESCAPECHAR**: Is used to perform strict verification of the escape character on CSV files. The default value is backslash (****).

  OPTIONS('ESCAPECHAR'='\')

  NOTE

  Enter **ESCAPECHAR** in the CSV data. **ESCAPECHAR** must be enclosed in double quotation marks (" "). For example, "a\b".

- Bad records handling:

  In order for the data processing application to provide benefits, certain data integration is required. In most cases, data quality problems are caused by data sources.

  Methods of handling bad records are as follows:

  – Load all of the data before dealing with the errors.

  – Clean or delete bad records before loading data or stop the loading when bad records are found.

  There are many options for clearing source data during CarbonData data loading, as listed in **Table 1-35**.

Table 1-35 Bad Records Logger

Configuration Item	Default Value	Description
BAD_RECORDS_LOGGER_ENABLE	false	Whether to log details about bad records.

Configuration Item	Default Value	Description
BAD_RECORDS_ACTION	FAIL	The four types of actions for bad records are as follows: • **FORCE**: Auto-corrects the data by storing the bad records as NULL. • **REDIRECT**: Bad records cannot be loaded and written to the CSV file in **BAD_RECORD_PATH**. This mode is disabled by default. To enable it, set **carbon.enable.badrecord.action.redirect** to **true**. • **IGNORE**: Bad records are neither loaded nor written to the CSV file. • **FAIL**: Data loading fails if any bad records are found. **NOTE** In loaded data, if all records are bad records, **BAD_RECORDS_ACTION** is invalid and the load operation fails.
IS_EMPTY_DATA_BAD_RECORD	false	Whether empty data of a column to be considered as bad record or not. If this parameter is set to **false**, empty data (""','', or,) is not considered as bad records. If this parameter is set to **true**, empty data is considered as bad records.
BAD_RECORD_PATH	-	HDFS path where bad records are stored. The default value is **Null**. If bad records logging or bad records operation redirection is enabled, the path must be configured by the user.

Example:

LOAD DATA INPATH *'filepath.csv'* **INTO TABLE** *tablename*
OPTIONS('BAD_RECORDS_LOGGER_ENABLE'='true',
'BAD_RECORD_PATH'='hdfs://hacluster/tmp/carbon',
'BAD_RECORDS_ACTION'='REDIRECT',
'IS_EMPTY_DATA_BAD_RECORD'='false');

NOTE

If **REDIRECT** is used, CarbonData will add all bad records into a separate CSV file. However, this file must not be used for subsequent data loading because the content may not exactly match the source record. You must clean up the source record for further data ingestion. This option is used to remind you which records are bad.

- **MAXCOLUMNS**: (Optional) Specifies the maximum number of columns parsed by a CSV parser in a line.

  OPTIONS('MAXCOLUMNS'='400')

Table 1-36 MAXCOLUMNS

Name of the Optional Parameter	Default Value	Maximum Value
MAXCOLUMNS	2000	20000

Table 1-37 Behavior chart of MAXCOLUMNS

MAXCOLUMNS Value	Number of Columns in the File Header	Final Value Considered
Not specified in Load options	5	2000
Not specified in Load options	6000	6000
40	7	Max (column count of file header, MAXCOLUMNS value)
22000	40	20000
60	Not specified in Load options	Max (Number of columns in the first line of the CSV file, MAXCOLUMNS value)

NOTE

There must be sufficient executor memory for setting the maximum value of **MAXCOLUMNS Option**. Otherwise, data loading will fail.

- If **SORT_SCOPE** is set to **GLOBAL_SORT** during table creation, you can specify the number of partitions to be used when sorting data. If this parameter is not set or is set to a value less than **1**, the number of map tasks is used as the number of reduce tasks. It is recommended that each reduce task process 512 MB to 1 GB data.

  OPTIONS('GLOBAL_SORT_PARTITIONS'='2')

NOTE

To increase the number of partitions, you may need to increase the value of **spark.driver.maxResultSize**, as the sampling data collected in the driver increases with the number of partitions.

- **DATEFORMAT**: Specifies the date format of the table.

  OPTIONS('DATEFORMAT'='dateFormat')

  NOTE

  Date formats are specified by date pattern strings. The date pattern letters in Carbon are same as in JAVA.

- **TIMESTAMPFORMAT**: Specifies the timestamp of a table.
- *OPTIONS('TIMESTAMPFORMAT'='timestampFormat')*
- **SKIP_EMPTY_LINE**: Ignores empty rows in the CSV file during data loading.

  OPTIONS('SKIP_EMPTY_LINE'='TRUE/FALSE')

- **Optional: SCALE_FACTOR**: Used to control the number of partitions for **RANGE_COLUMN**, **SCALE_FACTOR**. The formula is as follows:

```
splitSize = max(blocklet_size, (block_size - blocklet_size)) * scale_factor
numPartitions = total size of input data / splitSize
```

  The default value is **3**. The value ranges from **1** to **300**.

  OPTIONS('SCALE_FACTOR'='10')

  NOTE

  - If **GLOBAL_SORT_PARTITIONS** and **SCALE_FACTOR** are used at the same time, only **GLOBAL_SORT_PARTITIONS** is valid.
  - The compaction on **RANGE_COLUMN** will use **LOCAL_SORT** by default.

Scenarios

To load a CSV file to a CarbonData table, run the following statement:

LOAD DATA *INPATH 'folder path' INTO TABLE tablename OPTIONS(property_name=property_value, ...);*

Examples

The data in the **data.csv** file is as follows:

```
ID,date,country,name,phonetype,serialname,salary
4,2014-01-21 00:00:00,xxx,aaa4,phone2435,ASD66902,15003
5,2014-01-22 00:00:00,xxx,aaa5,phone2441,ASD90633,15004
6,2014-03-07 00:00:00,xxx,aaa6,phone294,ASD59961,15005
```

CREATE TABLE carbontable(ID int, date Timestamp, country String, name String, phonetype String, serialname String,salary int) STORED AS carbondata;

LOAD DATA *inpath 'hdfs://hacluster/tmp/data.csv' INTO table carbontable*

options('DELIMITER'=',');

System Response

Success or failure will be recorded in the driver logs.

1.7.13 UPDATE CARBON TABLE

Function

This command is used to update the CarbonData table based on the column expression and optional filtering conditions.

Syntax

- Syntax 1:

  UPDATE <CARBON TABLE> SET (column_name1, column_name2, ... column_name n) = (column1_expression , column2_expression , column3_expression ... column n_expression) [WHERE { <filter_condition> }];

- Syntax 2:

  UPDATE <CARBON TABLE> SET (column_name1, column_name2,) = (select sourceColumn1, sourceColumn2 from sourceTable [WHERE { <filter_condition> }]) [WHERE { <filter_condition> }];

Parameter Description

Table 1-38 UPDATE parameters

Parameter	Description
CARBON TABLE	Name of the CarbonData table to be updated
column_name	Target column to be updated
sourceColumn	Column value of the source table that needs to be updated in the target table
sourceTable	Table from which the records are updated to the target table

Precautions

Note the following before running this command:

- The UPDATE command fails if multiple input rows in the source table are matched with a single row in the target table.
- If the source table generates empty records, the UPDATE operation completes without updating the table.
- If rows in the source table do not match any existing rows in the target table, the UPDATE operation completes without updating the table.
- UPDATE is not allowed in the table with secondary index.
- In a subquery, if the source table and target table are the same, the UPDATE operation fails.
- The UPDATE operation fails if the subquery used in the UPDATE command contains an aggregate function or a GROUP BY clause.

For example, **update t_carbn01 a set (a.item_type_code, a.profit) = (select b.item_type_cd, sum(b.profit) from t_carbn01b b where item_type_cd =2 group by item_type_code);**.

In the preceding example, aggregate function **sum(b.profit)** and GROUP BY clause are used in the subquery. As a result, the UPDATE operation will fail.

- If the **carbon.input.segments** property has been set for the queried table, the UPDATE operation fails. To solve this problem, run the following statement before the query:

  Syntax:

  SET carbon.input.segments. <database_name>. <table_name>=*;

Examples

- Example 1:

  update carbonTable1 d set (d.column3,d.column5) = (select s.c33 ,s.c55 from sourceTable1 s where d.column1 = s.c11) where d.column1 = 'country' exists(select * from table3 o where o.c2 > 1);

- Example 2:

  update carbonTable1 d set (c3) = (select s.c33 from sourceTable1 s where d.column1 = s.c11) where exists(select * from iud.other o where o.c2 > 1);

- Example 3:

  update carbonTable1 set (c2, c5) = (c2 + 1, concat(c5 , "y"));

- Example 4:

  update carbonTable1 d set (c2, c5) = (c2 + 1, "xyx") where d.column1 = 'india';

- Example 5:

  update carbonTable1 d set (c2, c5) = (c2 + 1, "xyx") where d.column1 = 'india' and exists(select * from table3 o where o.column2 > 1);

System Response

Success or failure will be recorded in the driver log and on the client.

1.7.14 DELETE RECORDS from CARBON TABLE

Function

This command is used to delete records from a CarbonData table.

Syntax

DELETE FROM CARBON_TABLE [WHERE expression];

Parameter Description

Table 1-39 DELETE RECORDS parameters

Parameter	Description
CARBON TABLE	Name of the CarbonData table in which the DELETE operation is performed

Precautions

- If a segment is deleted, all secondary indexes associated with the segment are deleted as well.
- If the **carbon.input.segments** property has been set for the queried table, the DELETE operation fails. To solve this problem, run the following statement before the query:

  Syntax:

  SET carbon.input.segments. <database_name>.<table_name>=*;

Examples

- Example 1:

  delete from columncarbonTable1 d where d.column1 = 'country';
- Example 2:

  delete from dest where column1 IN ('country1', 'country2');
- Example 3:

  delete from columncarbonTable1 where column1 IN (select column11 from sourceTable2);
- Example 4:

  delete from columncarbonTable1 where column1 IN (select column11 from sourceTable2 where column1 = 'xxx');
- Example 5:

  delete from columncarbonTable1 where column2 >= 4;

System Response

Success or failure will be recorded in the driver log and on the client.

1.7.15 INSERT INTO CARBON TABLE

Function

This command is used to insert the output of the SELECT command to a Carbon table.

Syntax

INSERT INTO [CARBON TABLE] [select query];

Parameter Description

Table 1-40 INSERT INTO parameters

Parameter	Description
CARBON TABLE	Name of the CarbonData table where data is to be inserted
select query	SELECT query on the source table (CarbonData, Hive, and Parquet tables are supported)

Precautions

- A table has been created.
- You must belong to the data loading group in order to perform data loading operations. By default, the data loading group is named **ficommon**.
- CarbonData tables cannot be overwritten.
- The data type of the source table and the target table must be the same. Otherwise, data in the source table will be regarded as bad records.
- The **INSERT INTO** command does not support partial success. If bad records exist, the command fails.
- When you insert data of the source table to the target table, you cannot upload or update data of the source table.

  To enable data loading or updating during the INSERT operation, set the following parameter to **true**.

  carbon.insert.persist.enable=**true**

  By default, the preceding parameters are set to **false**.

  NOTE

  Enabling this property will reduce the performance of the INSERT operation.

Example

create table carbon01(a int,b string,c string) stored as carbondata;

insert into table carbon01 values(1,'a','aa'),(2,'b','bb'),(3,'c','cc');

create table carbon02(a int,b string,c string) stored as carbondata;

INSERT INTO carbon02 select * from carbon01 where a > 1;

System Response

Success or failure will be recorded in the driver logs.

1.7.16 DELETE SEGMENT by ID

Function

This command is used to delete a segment based on the segment ID.

Syntax

DELETE FROM TABLE db_name.table_name WHERE SEGMENT.ID IN (segment_id1,segment_id2);

Parameters Description

Table 1-41 DELETE LOAD parameters

Parameter	Description
segment_id	ID of the segment to be deleted.
db_name	Database name. If this parameter is not specified, the current database is used.
table_name	Name of a table in the specified database.

Precautions

Segments cannot be deleted from stream tables.

Example

DELETE FROM TABLE CarbonDatabase.CarbonTable WHERE SEGMENT.ID IN (0);

DELETE FROM TABLE CarbonDatabase.CarbonTable WHERE SEGMENT.ID IN (0,5,8);

Response

Success or failure will be recorded in CarbonData logs.

1.7.17 DELETE SEGMENT by DATE

Function

This command is used to delete segments by loading date. Segments created before a specific date will be deleted.

Syntax

DELETE FROM TABLE db_name.table_name WHERE SEGMENT.STARTTIME BEFORE date_value;

Parameter Description

Table 1-42 DELETE SEGMENT by DATE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is used.
table_name	Name of a table in the specified database
date_value	Valid date when segments are started to be loaded. Segments before the date will be deleted.

Precautions

Segments cannot be deleted from the stream table.

Example

DELETE FROM TABLE db_name.table_name WHERE SEGMENT.STARTTIME BEFORE '2017-07-01 12:07:20';

STARTTIME indicates the loading start time of different loads.

System Response

Success or failure will be recorded in CarbonData logs.

1.7.18 SHOW SEGMENTS

Function

This command is used to list the segments of a CarbonData table.

Syntax

SHOW SEGMENTS FOR TABLE *[db_name.]table_name* **LIMIT** *number_of_loads;*

Parameter Description

Table 1-43 SHOW SEGMENTS FOR TABLE parameters

Parameter	Description
db_name	Database name. If this parameter is not specified, the current database is used.
table_name	Name of a table in the specified database
number_of_loads	Threshold of records to be listed

Precautions

None

Examples

create table carbon01(a int,b string,c string) stored as carbondata;

insert into table carbon01 select 1,'a','aa';

insert into table carbon01 select 2,'b','bb';

insert into table carbon01 select 3,'c','cc';

SHOW SEGMENTS FOR TABLE carbon01 LIMIT 2;

System Response

```
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
| ID  |  Status  |     Load Start Time      | Load Time Taken  | Partition  | Data Size  | Index Size  | File Format  |
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
| 3   | Success  | 2020-09-28 22:53:26.336  | 3.726S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
| 2   | Success  | 2020-09-28 22:53:01.702  | 6.688S           | {}         | 6.47KB     | 3.30KB      | columnar_v3  |
+-----+----------+--------------------------+------------------+------------+------------+-------------+--------------+--
+
```

1.7.19 CREATE SECONDARY INDEX

Function

This command is used to create secondary indexes in the CarbonData tables.

Syntax

CREATE INDEX *index_name*

ON TABLE *[db_name.]table_name (col_name1, col_name2)*

AS *'carbondata'*

PROPERTIES *('table_blocksize'='256')*;

Parameter Description

Table 1-44 CREATE SECONDARY INDEX parameters

Parameter	Description
index_name	Index table name. It consists of letters, digits, and special characters (_).
db_name	Database name. It consists of letters, digits, and special characters (_).
table_name	Name of the database table. It consists of letters, digits, and special characters (_).

Parameter	Description
col_name	Name of a column in a table. Multiple columns are supported. It consists of letters, digits, and special characters (_).
table_blocksize	Block size of a data file. For details, see •**Block Size**.

Precautions

db_name is optional.

Examples

create table productdb.productSalesTable(id int,price int,productName string,city string) stored as carbondata;

CREATE INDEX productNameIndexTable on table productdb.productSalesTable (productName,city) as 'carbondata' ;

In this example, a secondary table named **productdb.productNameIndexTable** is created and index information of the provided column is loaded.

System Response

A secondary index table will be created. Index information related to the provided column will be loaded into the secondary index table. The success message will be recorded in system logs.

1.7.20 SHOW SECONDARY INDEXES

Function

This command is used to list all secondary index tables in the CarbonData table.

Syntax

SHOW INDEXES ON db_name.table_name;

Parameter Description

Table 1-45 SHOW SECONDARY INDEXES parameters

Parameter	Description
db_name	Database name. It consists of letters, digits, and special characters (_).
table_name	Name of the database table. It consists of letters, digits, and special characters (_).

Precautions

db_name is optional.

Examples

create table productdb.productSalesTable(id int,price int,productName string,city string) stored as carbondata;

CREATE INDEX productNameIndexTable on table productdb.productSalesTable (productName,city) as 'carbondata' ;

SHOW INDEXES ON productdb.productSalesTable;

System Response

All index tables and corresponding index columns in a given CarbonData table will be listed.

1.7.21 DROP SECONDARY INDEX

Function

This command is used to delete a secondary index table from a specified table.

Syntax

DROP INDEX [IF EXISTS] index_name ON [db_name.]table_name;

Parameter Description

Table 1-46 Parameter parameters

Parameter	Description
index_name	Index table name. It consists of letters, digits, and special characters (_).
db_name	Database name. If this parameter is not specified, the current default database is selected.
table_name	Name of the table to be deleted.

Precautions

IF EXISTS and db_name are optional.

Example

DROP INDEX if exists productNameIndexTable ON productdb.productSalesTable;

Response

The secondary index table is deleted, and the index information is deleted from the CarbonData table. The deletion success message is recorded in the system log.

1.7.22 CLEAN FILES

Function

After the **DELETE SEGMENT** command is executed, the deleted segments are marked as the **delete** state. After the segments are merged, the status of the original segments changes to **compacted**. The data files of these segments are not physically deleted. If you want to forcibly delete these files, run the **CLEAN FILES** command.

However, running this command may result in a query command execution failure.

Syntax

CLEAN FILES FOR TABLE *[db_name.]table_name* ;

Parameter Description

Table 1-47 CLEAN FILES FOR TABLE parameters

Parameter	Description
db_name	Database name. It consists of letters, digits, and underscores (_).
table_name	Name of the database table. It consists of letters, digits, and underscores (_).

Precautions

None

Examples

Add Carbon configuration parameters.

```
carbon.clean.file.force.allowed = true
```

create table carbon01(a int,b string,c string) stored as carbondata;

insert into table carbon01 select 1,'a','aa';

insert into table carbon01 select 2,'b','bb';

delete from table carbon01 where segment.id in (0);

show segments for table carbon01;

CLEAN FILES FOR TABLE carbon01 options('force'='true');

show segments for table carbon01;

In this example, all the segments marked as **deleted** and **compacted** are physically deleted.

System Response

Success or failure will be recorded in the driver logs.

1.7.23 SET/RESET

Function

This command is used to dynamically add, update, display, or reset the CarbonData properties without restarting the driver.

Syntax

- Add or Update parameter value:

  SET *parameter_name=parameter_value*

  This command is used to add or update the value of **parameter_name**.
- Display property value:

  SET *parameter_name*

  This command is used to display the value of **parameter_name**.
- Display session parameter:

  SET

  This command is used to display all supported session parameters.
- Display session parameters along with usage details:

  SET -v

  This command is used to display all supported session parameters and their usage details.
- Reset parameter value:

  RESET

  This command is used to clear all session parameters.

Parameter Description

Table 1-48 SET parameters

Parameter	Description
parameter_name	Name of the parameter whose value needs to be dynamically added, updated, or displayed
parameter_value	New value of **parameter_name** to be set

Precautions

The following table lists the properties which you can set or clear using the SET or RESET command.

Table 1-49 Properties

Property	Description
carbon.options.bad.records.logger.enable	Whether to enable bad record logger.
carbon.options.bad.records.action	Operations on bad records, for example, force, redirect, fail, or ignore. For more information, see **•Bad record handling**.
carbon.options.is.empty.data.bad.record	Whether the empty data is considered as a bad record. For more information, see **Bad record handling**.
carbon.options.sort.scope	Scope of the sort during data loading.
carbon.options.bad.record.path	HDFS path where bad records are stored.
carbon.custom.block.distribution	Whether to enable Spark or CarbonData block distribution.
enable.unsafe.sort	Whether to use unsafe sort during data loading. Unsafe sort reduces the garbage collection during data loading, thereby achieving better performance.
carbon.si.lookup.partialstring	If this is set to **TRUE**, the secondary index uses the starts-with, ends-with, contains, and LIKE partition condition strings. If this is set to **FALSE**, the secondary index uses only the starts-with partition condition string.

Property	Description
carbon.input.segments	Segment ID to be queried. This property allows you to query a specified segment of a specified table. CarbonScan reads data only from the specified segment ID. Syntax: **carbon.input.segments.<database_name>.<table_name> = <list of segment ids >** If you want to query a specified segment in multi-thread mode, you can use **CarbonSession.threadSet** instead of the **SET** statement. Syntax: **CarbonSession.threadSet ("carbon.input.segments.<database_name>.<table_name>","<list of segment ids >");** **NOTE** You are advised not to set this property in the **carbon.properties** file because all sessions contain the segment list unless session-level or thread-level overwriting occurs.

Examples

- Add or Update:

  SET *enable.unsafe.sort=true*

- Display property value:

  SET *enable.unsafe.sort*

- Show the segment ID list, segment status, and other required details, and specify the segment list to be read:

  SHOW SEGMENTS FOR *TABLE carbontable1;*

  SET *carbon.input.segments.db.carbontable1 = 1, 3, 9;*

- Query a specified segment in multi-thread mode:

  CarbonSession.threadSet (*"carbon.input.segments.default.carbon_table_MulTI_THread", "1,3"*);

- Use **CarbonSession.threadSet** to query segments in a multi-thread environment (Scala code is used as an example):

```
def main(args: Array[String]) {
 Future
{             CarbonSession.threadSet("carbon.input.segments.default.carbon_table_MulTI_THread", "1")
     spark.sql("select count(empno) from carbon_table_MulTI_THread").show()
   }
}
```

- Reset:
  RESET

System Response

- You can view the success result in driver logs.
- You can view the failure result on the UI.

1.7.24 Concurrent CarbonData Table Operations

Before performing DDL and DML operations, you need to obtain the corresponding locks. See **Table 1-50** for details about the locks that need to be obtained for each operation. The check mark (√) indicates that the lock is required. An operation can be performed only after all required locks are obtained.

You can check whether any two operations can be executed concurrently by using the following method: The first two lines in **Table 1-50** indicate two operations. If no column in the two lines is marked with the check mark (√), the two operations can be executed concurrently. That is, if the columns with check marks (√) in the two lines do not exist, the two operations can be executed concurrently.

Table 1-50 List of obtaining locks for operations

Operation	METADATA_LOCK	COMPACTION_LOCK	DROP_TABLE_LOCK	DELETE_SEGMENT_LOCK	CLEAN_FILES_LOCK	ALTER_PARTITION_LOCK	UPDATE_LOCK	STREAMING_LOCK	CONCURRENT_LOAD_LOCK	SEGMENT_LOCK

1.7.25 CarbonData Segment API

This topic describes the Segment APIs and their usage. All methods are in the **org.apache.spark.util.CarbonSegmentUtil** class.

The following method has been discarded:

```
/**
* Returns the valid segments for the query based on the filter condition
* present in carbonScanRdd.
*
* @param carbonScanRdd
* @return Array of valid segments
*/
@deprecated def getFilteredSegments(carbonScanRdd: CarbonScanRDD[InternalRow]): Array[String];
```

How to Use

Use the following method to obtain CarbonScanRDD from the query statement:

```
val df=carbon.sql("select * from table where age='12'")
val myscan=df.queryExecution.sparkPlan.collect {
case scan: CarbonDataSourceScan if scan.rdd.isInstanceOf[CarbonScanRDD[InternalRow]] => scan.rdd
case scan: RowDataSourceScanExec if scan.rdd.isInstanceOf[CarbonScanRDD[InternalRow]] => scan.rdd
}.head
val carbonrdd=myscan.asInstanceOf[CarbonScanRDD[InternalRow]]
```

The following is an example:

```
CarbonSegmentUtil.getFilteredSegments(carbonrdd)
```

You can pass the following SQL statement to obtain the filtered segment:

```
/**
* Returns an array of valid segment numbers based on the filter condition provided in the sql
* NOTE: This API is supported only for SELECT Sql (insert into,ctas,.., is not supported)
*
* @param sql
* @param sparkSession
* @return Array of valid segments
* @throws UnsupportedOperationException because Get Filter Segments API supports if and only
* if only one carbon main table is present in query.
*/
def getFilteredSegments(sql: String, sparkSession: SparkSession): Array[String];
```

The following is an example:

```
CarbonSegmentUtil.getFilteredSegments("select * from table where age='12'", sparkSession)
```

Pass the database name and table name to obtain the list of segments to be merged. The obtained segment list can be used as the parameter of the **getMergedLoadName** function.

```
/**
* Identifies all segments which can be merged with MAJOR compaction type.
* NOTE: This result can be passed to getMergedLoadName API to get the merged load name.
*
* @param sparkSession
* @param tableName
* @param dbName
* @return list of LoadMetadataDetails
*/
def identifySegmentsToBeMerged(sparkSession: SparkSession,
tableName: String,
dbName: String) : util.List[LoadMetadataDetails];
```

The following is an example:

```
CarbonSegmentUtil.identifySegmentsToBeMerged(sparkSession, "table_test","default")
```

Pass the database name, table name, and custom segment list to obtain the list of segments that will be merged on demand. The obtained segment list can be used as the parameter of the **getMergedLoadName** function.

```
/**
* Identifies all segments which can be merged with CUSTOM compaction type.
*  NOTE: This result can be passed to getMergedLoadName API to get the merged load name.
*
* @param sparkSession
* @param tableName
* @param dbName
* @param customSegments
* @return list of LoadMetadataDetails
* @throws UnsupportedOperationException if customSegments is null or empty.
* @throws MalformedCarbonCommandException if segment does not exist or is not valid
*/
def identifySegmentsToBeMergedCustom(sparkSession: SparkSession,
tableName: String,
dbName: String,
customSegments: util.List[String]): util.List[LoadMetadataDetails];
```

The following is an example:

```
val customSegments = new util.ArrayList[String]()
customSegments.add("1")
customSegments.add("2")
CarbonSegmentUtil.identifySegmentsToBeMergedCustom(sparkSession, "table_test","default",
customSegments)
```

Pass a specified segment list, and return the new Merged Load Name.

```
/**
* Returns the Merged Load Name for given list of segments
*
* @param list of segments
* @return Merged Load Name
* @throws UnsupportedOperationException if list of segments is less than 1
*/
def getMergedLoadName(list: util.List[LoadMetadataDetails]): String;
```

The following is an example:

```
val carbonTable = CarbonEnv.getCarbonTable(Option(databaseName), tableName)(sparkSession)
val loadMetadataDetails = SegmentStatusManager.readLoadMetadata(carbonTable.getMetadataPath)
CarbonSegmentUtil.getMergedLoadName(loadMetadataDetails.toList.asJava)
```

1.7.26 CarbonData Tablespace Index

Quick Example

```
create table IF NOT EXISTS carbonTable
(
COLUMN1    BIGINT,
LONGITUDE    BIGINT,
LATITUDE    BIGINT,
COLUMN2    BIGINT,
COLUMN3    BIGINT
)
STORED AS carbondata
TBLPROPERTIES
('SPATIAL_INDEX.mygeohash.type'='geohash','SPATIAL_INDEX.mygeohash.sourcecolumns'='longitude,
latitude','SPATIAL_INDEX.mygeohash.originLatitude'='39.850713','SPATIAL_INDEX.mygeohash.gridSize'='50','S
PATIAL_INDEX.mygeohash.minLongitude'='115.828503','SPATIAL_INDEX.mygeohash.maxLongitude'='720.000
000','SPATIAL_INDEX.mygeohash.minLatitude'='39.850713','SPATIAL_INDEX.mygeohash.maxLatitude'='720.0
00000','SPATIAL_INDEX'='mygeohash','SPATIAL_INDEX.mygeohash.conversionRatio'='1000000','SORT_COLU
MNS'='column1,column2,column3,latitude,longitude');
```

Introduction to Spatial Indexes

Spatial data includes multidimensional points, lines, rectangles, cubes, polygons, and other geometric objects. A spatial data object occupies a certain region of

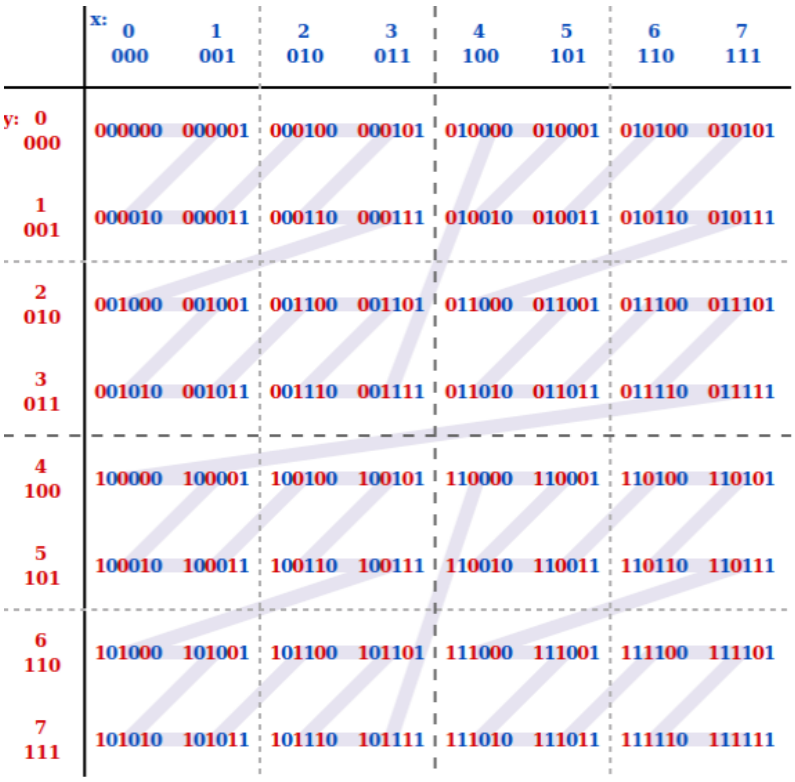
space, called spatial scope, characterized by its location and boundary. The spatial data can be either point data or region data.

- Point data: A point has a spatial extent characterized completely by its location. It does not occupy space and has no associated boundary. Point data consists of a collection of points in a two-dimensional space. Points can be stored as a pair of longitude and latitude.
- Region data: A region has a spatial extent with a location, and boundary. The location can be considered as the position of a fixed point in the region, such as its centroid. In two dimensions, the boundary can be visualized as a line (for finite regions, a closed loop). Region data contains a collection of regions.

Currently, only point data is supported, and it can be stored.

Longitude and latitude can be encoded as a unique GeoID. Geohash is a public-domain geocoding system invented by Gustavo Niemeyer. It encodes geographical locations into a short string of letters and digits. It is a hierarchical spatial data structure which subdivides the space into buckets of grid shape, which is one of the many applications of what is known as the Z-order curve, and generally the space-filling curve.

The Z value of a point in multiple dimensions is calculated by interleaving the binary representation of its coordinate value, as shown in the following figure. When Geohash is used to create a GeoID, data is sorted by GeoID instead of longitude and latitude. Data is stored by spatial proximity.



Creating a Table

GeoHash encoding:

```
create table IF NOT EXISTS carbonTable
(
```

```
...
`LONGITUDE`     BIGINT,
`LATITUDE`      BIGINT,
...
)
STORED AS carbondata
TBLPROPERTIES
('SPATIAL_INDEX.mygeohash.type'='geohash','SPATIAL_INDEX.mygeohash.sourcecolumns'='longitude,
latitude','SPATIAL_INDEX.mygeohash.originLatitude'='xx.xxxxxx','SPATIAL_INDEX.mygeohash.gridSize'='xx','SP
ATIAL_INDEX.mygeohash.minLongitude'='xxx.xxxxxx','SPATIAL_INDEX.mygeohash.maxLongitude'='xxx.xxxxxx'
,'SPATIAL_INDEX.mygeohash.minLatitude'='xx.xxxxxx','SPATIAL_INDEX.mygeohash.maxLatitude'='xxx.xxxxxx','
SPATIAL_INDEX'='mygeohash','SPATIAL_INDEX.mygeohash.conversionRatio'='1000000','SORT_COLUMNS'='co
lumn1,column2,column3,latitude,longitude');
```

SPATIAL_INDEX is a user-defined index handler. This handler allows users to create new columns from the table-structure column set. The new column name is the same as that of the handler name. The **type** and **sourcecolumns** properties of the handler are mandatory. Currently, the value of **type** supports only **geohash**. Carbon provides a default implementation class that can be easily used. You can extend the default implementation class to mount the customized implementation class of **geohash**. The default handler also needs to provide the following table properties:

- **SPATIAL_INDEX.*xxx*.originLatitude**: specifies the origin latitude. (**Double** type.)
- **SPATIAL_INDEX.*xxx*.gridSize**: specifies the grid length in meters. (**Int** type.)
- **SPATIAL_INDEX.*xxx*.minLongitude**: specifies the minimum longitude. (**Double** type.)
- **SPATIAL_INDEX.*xxx*.maxLongitude**: specifies the maximum longitude. (**Double** type.)
- **SPATIAL_INDEX.*xxx*.minLatitude**: specifies the minimum latitude. (**Double** type.)
- **SPATIAL_INDEX.*xxx*.maxLatitude**: specifies the maximum latitude. (**Double** type.)
- **SPATIAL_INDEX.*xxx*.conversionRatio**: used to convert the small value of the longitude and latitude to an integer. (**Int** type.)

You can add your own table properties to the handlers in the above format and access them in your custom implementation class. **originLatitude**, **gridSize**, and **conversionRatio** are mandatory. Other parameters are optional in Carbon. You can use the **SPATIAL_INDEX.*xxx*.class** property to specify their implementation classes.

The default implementation class can generate handler column values for **sourcecolumns** in each row and support query based on the **sourcecolumns** filter criteria. The generated handler column is invisible to users. Except the **SORT_COLUMNS** table properties, no DDL commands or properties are allowed to contain the handler column.

NOTE

- By default, the generated handler column is regarded as the sorting column. If **SORT_COLUMNS** does not contain any **sourcecolumns**, add the handler column to the end of the existing **SORT_COLUMNS**. If the handler column has been specified in **SORT_COLUMNS**, its order in **SORT_COLUMNS** remains unchanged.
- If **SORT_COLUMNS** contains any **sourcecolumns** but does not contain the handler column, the handler column is automatically inserted before **sourcecolumns** in **SORT_COLUMNS**.
- If **SORT_COLUMNS** needs to contain any **sourcecolumns**, ensure that the handler column is listed before the **sourcecolumns** so that the handler column can take effect during sorting.

GeoSOT encoding:

```
CREATE TABLE carbontable(
...
longitude DOUBLE,
latitude DOUBLE,
...)
STORED AS carbondata
TBLPROPERTIES ('SPATIAL_INDEX'='xxx',
'SPATIAL_INDEX.xxx.type'='geosot',
'SPATIAL_INDEX.xxx.sourcecolumns'='longitude, latitude',
'SPATIAL_INDEX.xxx.level'='21',
'SPATIAL_INDEX.xxx.class'='org.apache.carbondata.geo.GeoSOTIndex')
```

Table 1-51 Parameter description

Parameter	Description
SPATIAL_INDEX	Specifies the spatial index. Its value is the same as the column name.
SPATIAL_INDEX.xxx.type	(Mandatory) The value is **geosot**.
SPATIAL_INDEX.xxx.source columns	(Mandatory) Specifies the source columns for calculating the spatial index. The value must be two existing columns of the double type.
SPATIAL_INDEX.xxx.level	(Optional) Specifies the columns for calculating the spatial index. The default value is **17**, through which you can obtain an accurate result and improve the computing performance.
SPATIAL_INDEX.xxx.class	(Optional) Specifies the implementation class of GeoSOT. The default value is **org.apache.carbondata.geo.GeoSOTIndex**.

Example:

```
create table geosot(
timevalue bigint,
longitude double,
latitude double)
stored as carbondata
TBLPROPERTIES ('SPATIAL_INDEX'='mygeosot',
'SPATIAL_INDEX.mygeosot.type'='geosot',
'SPATIAL_INDEX.mygeosot.level'='21', 'SPATIAL_INDEX.mygeosot.sourcecolumns'='longitude, latitude');
```

Preparing Data

- Data file 1: **geosotdata.csv**

```
timevalue,longitude,latitude

```

Importing Data

The GeoHash default implementation class extends the customized index abstract class. If the handler property is not set to a customized implementation class, the default implementation class is used. You can extend the default implementation class to mount the customized implementation class of **geohash**. The methods of the customized index abstract class are as follows:

- **Init** method: Used to extract, verify, and store the handler property. If the operation fails, the system throws an exception and displays the error information.

- **Generate** method: Used to generate indexes. It generates an index for each row of data.
- **Query** method: Used to generate an index value range list for given input.

The commands for importing data are the same as those for importing common Carbon tables.

LOAD DATA inpath '/tmp/*geosotdata.csv*' INTO TABLE geosot OPTIONS ('DELIMITER'= ',');

LOAD DATA inpath '/tmp/*geosotdata2.csv*' INTO TABLE geosot OPTIONS ('DELIMITER'= ',');

NOTE

For details about **geosotdata.csv** and **geosotdata2.csv**, see **Preparing Data**.

Aggregate Query of Irregular Spatial Sets

Query statements and filter UDFs

- Filtering data based on polygon

  IN_POLYGON(pointList)

  UDF input parameter

Parameter	Type	Description
pointList	String	Enter multiple points as a string. Each point is presented as **longitude latitude**. Longitude and latitude are separated by a space. Each pair of longitude and latitude is separated by a comma (,). The longitude and latitude values at the start and end of the string must be the same.

  UDF output parameter

Parameter	Type	Description
inOrNot	Boolean	Checks whether data is in the specified **polygon_list**.

  Example:

```
select longitude, latitude from geosot where IN_POLYGON('116.321011 40.123503, 116.137676 39.947911, 116.560993 39.935276, 116.321011 40.123503');
```

- Filtering data based on the polygon list

  IN_POLYGON_LIST(polygonList, opType)

  UDF input parameters

Parameter	Type	Description
polygonList	String	Inputs multiple polygons as a string. Each polygon is presented as **POLYGON ((longitude1 latitude1, longitude2 latitude2, ...))**. Note that there is a space after **POLYGON**. Longitudes and latitudes are separated by spaces. Each pair of longitude and latitude is separated by a comma (,). The longitudes and latitudes at the start and end of a polygon must be the same. **IN_POLYGON_LIST** requires at least two polygons. Example: POLYGON ((116.137676 40.163503, 116.137676 39.935276, 116.560993 39.935276, 116.137676 40.163503))
opType	String	Performs union, intersection, and subtraction on multiple polygons. Currently, the following operation types are supported: ● OR: A U B U C (Assume that three polygons A, B, and C are input.) ● AND: A ∩ B ∩ C

UDF output parameter

Parameter	Type	Description
inOrNot	Boolean	Checks whether data is in the specified **polygon_list**.

Example:

```
select longitude, latitude from geosot where IN_POLYGON_LIST('POLYGON ((120.176433 30.327431,120.171283 30.322245,120.181411 30.314540, 120.190509 30.321653,120.185188 30.329358,120.176433 30.327431)), POLYGON ((120.191603 30.328946,120.184179 30.327465,120.181819 30.321464, 120.190359 30.315388,120.199242 30.324464,120.191603 30.328946))', 'OR');
```

- Filtering data based on the polyline list

  IN_POLYLINE_LIST(polylineList, bufferInMeter)

  UDF input parameters

Parameter	Type	Description
polylineList	String	Inputs multiple polylines as a string. Each polyline is presented as **LINESTRING (longitude1 latitude1, longitude2 latitude2, ...)**. Note that there is a space after **LINESTRING**. Longitudes and latitudes are separated by spaces. Each pair of longitude and latitude is separated by a comma (,). A union will be output based on the data in multiple polylines. Example: `LINESTRING (116.137676 40.163503, 116.137676 39.935276, 116.260993 39.935276)`
bufferInMeter	Float	Polyline buffer distance, in meters. Right angles are used at the end to create a buffer.

UDF output parameter

Parameter	Type	Description
inOrNot	Boolean	Checks whether data is in the specified **polyline_list**.

Example:

```
select longitude, latitude from geosot where IN_POLYLINE_LIST('LINESTRING (120.184179 30.327465, 120.191603 30.328946, 120.199242 30.324464, 120.190359 30.315388)', 65);
```

- Filtering data based on the GeoID range list

  IN_POLYGON_RANGE_LIST(polygonRangeList, opType)

  UDF input parameters

Parameter	Type	Description
polygonRangeList	String	Inputs multiple rangeLists as a string. Each rangeList is presented as **RANGELIST (startGeoId1 endGeoId1, startGeoId2 endGeoId2, ...)**. Note that there is a space after **RANGELIST**. Start GeoIDs and end GeoIDs are separated by spaces. Each group of GeoID ranges is separated by a comma (,). Example: RANGELIST (855279368848 855279368850, 855280799610 855280799612, 855282156300 855282157400)
opType	String	Performs union, intersection, and subtraction on multiple rangeLists. Currently, the following operation types are supported: ● OR: A U B U C (Assume that three rangeLists A, B, and C are input.) ● AND: A ∩ B ∩ C

UDF output parameter

Parameter	Type	Description
inOrNot	Boolean	Checks whether data is in the specified **polyRange_list**.

Example:

```
select mygeosot, longitude, latitude from geosot where IN_POLYGON_RANGE_LIST('RANGELIST (526549722865860608 526549722865860618, 532555655580483584 532555655580483594)', 'OR');
```

- Performing polygon query

  IN_POLYGON_JOIN(GEO_HASH_INDEX_COLUMN, POLYGON_COLUMN)

  Perform join query on two tables. One is a spatial data table containing the longitude, latitude, and GeoHashIndex columns, and the other is a dimension table that saves polygon data.

  During query, **IN_POLYGON_JOIN UDF**, **GEO_HASH_INDEX_COLUMN**, and **POLYGON_COLUMN** of the polygon table are used. **Polygon_column** specifies the column containing multiple points (longitude and latitude pairs). The first and last points in each row of the Polygon table must be the same. All points in each row form a closed geometric shape.

  UDF input parameters

Parameter	Type	Description
GEO_HASH_INDEX_COLUMN	Long	GeoHashIndex column of the spatial data table.
POLYGON_COLUMN	String	Polygon column of the polygon table, the value of which is represented by the string of polygon, for example, **POLYGON ((longitude1 latitude1, longitude2 latitude2, ...))**.

Example:

```
CREATE TABLE polygonTable(
polygon string,
poiType string,
poiId String)
STORED AS carbondata;

insert into polygonTable select 'POLYGON ((120.176433 30.327431,120.171283 30.322245,
120.181411 30.314540,120.190509 30.321653,120.185188 30.329358,120.176433 30.327431))','abc','1';

insert into polygonTable select 'POLYGON ((120.191603 30.328946,120.184179 30.327465,
120.181819 30.321464,120.190359 30.315388,120.199242 30.324464,120.191603 30.328946))','abc','2';

select t1.longitude,t1.latitude from geosot t1
inner join
(select polygon,poiId from polygonTable where poitype='abc') t2
on in_polygon_join(t1.mygeosot,t2.polygon) group by t1.longitude,t1.latitude;
```

- Performing range_list query

  IN_POLYGON_JOIN_RANGE_LIST(GEO_HASH_INDEX_COLUMN, POLYGON_COLUMN)

  Use the **IN_POLYGON_JOIN_RANGE_LIST** UDF to associate the spatial data table with the polygon dimension table based on **Polygon_RangeList**. By using a range list, you can skip the conversion between a polygon and a range list.

  UDF input parameters

Parameter	Type	Description
GEO_HASH_INDEX_COLUMN	Long	GeoHashIndex column of the spatial data table.
POLYGON_COLUMN	String	Rangelist column of the Polygon table, the value of which is represented by the string of rangeList, for example, **RANGELIST (startGeoId1 endGeoId1, startGeoId2 endGeoId2, ...)**.

Example:

```
CREATE TABLE polygonTable(
polygon string,
```

```
poiType string,
poiId String)
STORED AS carbondata;

insert into polygonTable select 'RANGELIST (526546455897309184 526546455897309284,
526549831217315840 526549831217315850, 532555655580483534 532555655580483584)','xyz','2';

select t1.*
from geosot t1
inner join
(select polygon,poiId from polygonTable where poitype='xyz') t2
on in_polygon_join_range_list(t1.mygeosot,t2.polygon);
```

UDFs of spacial index tools

- Obtaining row number and column number of a grid converted from GeoID

  GeoIdToGridXy(geoId)

  UDF input parameter

Parameter	Type	Description
geoId	Long	Calculates the row number and column number of the grid based on GeoID.

  UDF output parameter

Parameter	Type	Description
gridArray	Array[Int]	Returns the grid row and column numbers contained in GeoID in array. The first digit indicates the row number, and the second digit indicates the column number.

  Example:

```
select longitude, latitude, mygeohash, GeoIdToGridXy(mygeohash) as GridXY from geoTable;
```

- Converting longitude and latitude to GeoID

  LatLngToGeoId(latitude, longitude oriLatitude, gridSize)

  UDF input parameters

Parameter	Type	Description
longitude	Long	Longitude. Note: The value is an integer after conversion.
latitude	Long	Latitude. Note: The value is an integer after conversion.
oriLatitude	Double	Origin latitude, required for calculating GeoID.

Parameter	Type	Description
gridSize	Int	Grid size, required for calculating GeoID.

UDF output parameter

Parameter	Type	Description
geoId	Long	Returns a number that indicates the longitude and latitude after coding.

Example:

```
select longitude, latitude, mygeohash, LatLngToGeoId(latitude, longitude, 39.832277, 50) as geoId
from geoTable;
```

- Converting GeoID to longitude and latitude

  GeoIdToLatLng(geoId, oriLatitude, gridSize)

  UDF input parameters

Parameter	Type	Description
geoId	Long	Calculates the longitude and latitude based on GeoID.
oriLatitude	Double	Origin latitude, required for calculating the longitude and latitude.
gridSize	Int	Grid size, required for calculating the longitude and latitude.

  NOTE

  GeoID is generated based on the grid coordinates, which are the grid center. Therefore, the calculated longitude and latitude are the longitude and latitude of the grid center. There may be an error ranging from 0 degree to half of the grid size between the calculated longitude and latitude and the longitude and latitude of the generated GeoID.

  UDF output parameter

Parameter	Type	Description
latitudeAndLongitude	Array[Double]	Returns the longitude and latitude coordinates of the grid center that represent the GeoID in array. The first digit indicates the latitude, and the second digit indicates the longitude.

Example:

```
select longitude, latitude, mygeohash, GeoIdToLatLng(mygeohash, 39.832277, 50) as
LatitudeAndLongitude from geoTable;
```

- Calculating the upper-layer GeoID of the pyramid model

  ToUpperLayerGeoId(geoId)

  UDF input parameter

Parameter	Type	Description
geoId	Long	Calculates the upper-layer GeoID of the pyramid model based on the input GeoID.

  UDF output parameter

Parameter	Type	Description
geoId	Long	Returns the upper-layer GeoID of the pyramid model.

  Example:

```
select longitude, latitude, mygeohash, ToUpperLayerGeoId(mygeohash) as upperLayerGeoId from
geoTable;
```

- Obtaining the GeoID range list using the input polygon

  ToRangeList(polygon, oriLatitude, gridSize)

  UDF input parameters

Parameter	Type	Description
polygon	String	Input polygon string, which is a pair of longitude and latitude. Longitude and latitude are separated by a space. Each pair of longitude and latitude is separated by a comma (,). The longitude and latitude at the start and end must be the same.
oriLatitude	Double	Origin latitude, required for calculating GeoID.
gridSize	Int	Grid size, required for calculating GeoID.

  UDF output parameter

Parameter	Type	Description
geoIdList	Buffer[Array[Long]]	Converts polygons into GeoID range lists.

Example:

```
select ToRangeList('116.321011 40.123503, 116.137676 39.947911, 116.560993 39.935276, 116.321011 40.123503', 39.832277, 50) as rangeList from geoTable;
```

- Calculating the upper-layer longitude of the pyramid model

  ToUpperLongitude (longitude, gridSize, oriLat)

  UDF input parameters

Parameter	Type	Description
longitude	Long	Input longitude, which is a long integer.
gridSize	Int	Grid size, required for calculating longitude.
oriLatitude	Double	Origin latitude, required for calculating longitude.

  UDF output parameter

Parameter	Type	Description
longitude	Long	Returns the upper-layer longitude.

  Example:

```
select ToUpperLongitude (-23575161504L, 50, 39.832277) as upperLongitude from geoTable;
```

- Calculating the upper-layer latitude of the pyramid model

  ToUpperLatitude(Latitude, gridSize, oriLat)

  UDF input parameters

Parameter	Type	Description
latitude	Long	Input latitude, which is a long integer.
gridSize	Int	Grid size, required for calculating latitude.
oriLatitude	Double	Origin latitude, required for calculating latitude.

UDF output parameter

Parameter	Type	Description
Latitude	Long	Returns the upper-layer latitude.

Example:

```
select ToUpperLatitude (-23575161504L, 50, 39.832277) as upperLatitude from geoTable;
```

- Converting longitude and latitude to GeoSOT

  LatLngToGridCode(latitude, longitude, level)

  UDF input parameters

Parameter	Type	Description
latitude	Double	Latitude.
longitude	Double	Longitude.
level	Int	Level. The value range is [0, 32].

UDF output parameter

Parameter	Type	Description
geoId	Long	A number that indicates the longitude and latitude after GeoSOT encoding.

Example:

```
select LatLngToGridCode(39.930753, 116.302895, 21) as geoId;
```

1.8 Common Issues About CarbonData

1.8.1 Why Is Incorrect Output Displayed When I Perform Query with Filter on Decimal Data Type Values?

Question

Why is incorrect output displayed when I perform query with filter on decimal data type values?

For example:

select * from carbon_table where num = 1234567890123456.22;

Output:

```
+------+----------------------+--+
| name |        num           |
+------+----------------------+--+
| IAA  | 1234567890123456.22 |
| IAA  | 1234567890123456.21 |
+------+----------------------+--+
```

Answer

To obtain accurate output, append BD to the number.

For example:

select * from carbon_table where num = 1234567890123456.22BD;

Output:

```
+------+----------------------+--+
| name |        num           |
+------+----------------------+--+
| IAA  | 1234567890123456.22 |
+------+----------------------+--+
```

1.8.2 How to Avoid Minor Compaction for Historical Data?

Question

How to avoid minor compaction for historical data?

Answer

If you want to load historical data first and then the incremental data, perform following steps to avoid minor compaction of historical data:

1. Load all historical data.
2. Configure the major compaction size to a value smaller than the segment size of historical data.
3. Run the major compaction once on historical data so that these segments will not be considered later for minor compaction.
4. Load the incremental data.
5. You can configure the minor compaction threshold as required.

For example:

1. Assume that you have loaded all historical data to CarbonData and the size of each segment is 500 GB.
2. Set the threshold of major compaction property to **carbon.major.compaction.size** = **491520** (480 GB x 1024).
3. Run major compaction. All segments will be compacted because the size of each segment is more than configured size.
4. Perform incremental loading.
5. Configure the minor compaction threshold to **carbon.compaction.level.threshold** = **6,6**.
6. Run minor compaction. As a result, only incremental data is compacted.

1.8.3 How to Change the Default Group Name for CarbonData Data Loading?

Question

How to change the default group name for CarbonData data loading?

Answer

By default, the group name for CarbonData data loading is **ficommon**. You can perform the following operation to change the default group name:

1. Edit the **carbon.properties** file.
2. Change the value of the key **carbon.dataload.group.name** as required. The default value is **ficommon**.

1.8.4 Why Does INSERT INTO CARBON TABLE Command Fail?

Question

Why does the ***INSERT INTO CARBON TABLE*** command fail and the following error message is displayed?

```
Data load failed due to bad record
```

Answer

The ***INSERT INTO CARBON TABLE*** command fails in the following scenarios:

- If the data type of source and target table columns are not the same, the data from the source table will be treated as bad records and the ***INSERT INTO*** command fails.
- If the result of aggregation function on a source column exceeds the maximum range of the target column, then the ***INSERT INTO*** command fails.

  Solution:

  You can use the cast function on corresponding columns when inserting records.

  For example:

  a. Run the ***DESCRIBE*** command to query the target and source table.

     DESCRIBE *newcarbontable*;

     Result:

     ```
     col1 int
     col2 bigint
     ```

     DESCRIBE *sourcetable*;

     Result:

     ```
     col1 int
     col2 int
     ```

  b. Add the cast function to convert bigint value to integer.

     INSERT INTO *newcarbontable select col1, cast(col2 as integer) from sourcetable;*

1.8.5 Why Is the Data Logged in Bad Records Different from the Original Input Data with Escape Characters?

Question

Why is the data logged in bad records different from the original input data with escaped characters?

Answer

An escape character is a backslash (\) followed by one or more characters. If the input records contain escape characters such as \t, \b, \n, \r, \f, \', \", \\ , java will process the escape character '\' and the following characters together to obtain the escaped meaning.

For example, if the CSV data type **2010\\10,test** is inserted to String,int type, the value is treated as bad records, because **tes**t cannot be converted to int. The value logged in the bad records is **2010\10** because java processes **** as ****.

1.8.6 Why Data Load Performance Decreases due to Bad Records?

Question

Why data load performance decreases due to bad records?

Answer

The loaded data contains Bad Records, and the value of **BAD_RECORDS_LOGGER_ENABLE** is **true** or **BAD_RECORDS_ACTION** is **redirect**.

Data load performance degrades due to additional I/O overhead caused by writing failure causes to the log file or redirecting Bad Records to the original CSV file.

1.8.7 Why Data loading Fails During off heap?

Question

Why Data Loading fails during off heap?

Answer

YARN Resource Manager will consider (Java heap memory + **spark.yarn.am.memoryOverhead**) as memory limit, so during the off heap, the memory can exceed this limit.

You need to set **spark.yarn.am.memoryOverhead** in the **spark-defaults.conf** file to increase the memory size.

1.8.8 Why Do I Fail to Create a Hive Table?

Question

Why do I fail to create a hive table?

Answer

Creating a Hive table fails, when source table or sub query has more number of partitions. The implementation of the query requires a lot of tasks, then the number of files will be output a lot, resulting OOM in Driver.

It can be solved by using ***distribute by*** on suitable cardinality(distinct values) column in the statement of Hive table creation.

distribute by clause limits number of hive table partitions. It considers cardinality of given column or **spark.sql.shuffle.partitions** which ever is minimal. For example, if **spark.sql.shuffle.partitions** is 200, but cardinality of column is 100, out files is 200, but the other 100 files are empty. So using very low cardinality column like 1 will cause data skew and will effect later query distribution.

So we suggest using the column with cardinality greater than **spark.sql.shuffle.partitions**. It can be greater than 2 to 3 times.

Example:

create table hivetable1 as select * from sourcetable1 distribute by col_age;

1.8.9 How Do I Logically Split Data Across Different Namespaces?

Question

How do I logically split data across different namespaces?

Answer

- Configuration:

  To logically split data across different namespaces, you must update the following configuration in the **core-site.xml** file of HDFS, Hive, and Spark.

  NOTE

  Changing the Hive component will change the locations of carbonstore and warehouse.

  - Configuration in HDFS
    - **fs.defaultFS**: Name of the default file system. The URI mode must be set to **viewfs**. When **viewfs** is used, the permission part must be **ClusterX**.
    - **fs.viewfs.mountable.ClusterX.homedir**: Home directory base path. You can use the getHomeDirectory() method defined in **FileSystem/FileContext** to access the home directory.

- fs.viewfs.mountable.default.link.<dir_name>: ViewFS mount table.

Example:

```
<property>
<name>fs.defaultFS</name>
<value>viewfs://ClusterX/</value>
</property>
<property>
<name>fs.viewfs.mounttable.ClusterX.link./folder1</name>
<value>hdfs://NS1/folder1</value>
</property>
<property>
<name>fs.viewfs.mounttable.ClusterX.link./folder2</name>
<value>hdfs://NS2/folder2</value>
</property>
```

– Configurations in Hive and Spark

fs.defaultFS: Name of the default file system. The URI mode must be set to **viewfs**. When **viewfs** is used, the permission part must be **ClusterX**.

- Syntax:

  LOAD DATA INPATH *'path to data' INTO TABLE table_name OPTIONS ('...');*

  NOTE

  When Spark is configured with the viewFS file system and attempts to load data from HDFS, users must specify a path such as **viewfs://** or a relative path as the file path in the **LOAD** statement.

- Example:
  – Sample viewFS path:

    LOAD DATA INPATH *'viewfs://ClusterX/dir/data.csv' INTO TABLE table_name OPTIONS ('...');*

  – Sample relative path:

    LOAD DATA INPATH *'/apps/input_data1.txt'* ***INTO TABLE*** *table_name*;

1.8.10 Why the UPDATE Command Cannot Be Executed in Spark Shell?

Question

Why the UPDATE command cannot be executed in Spark Shell?

Answer

The syntax and examples provided in this document are about Beeline commands instead of Spark Shell commands.

To run the UPDATE command in Spark Shell, use the following syntax:

- Syntax 1

  <carbon_context>.sql("UPDATE <CARBON TABLE> SET (column_name1, column_name2, ... column_name n) = (column1_expression , column2_expression , column3_expression ... column n_expression) [WHERE { <filter_condition> }];").show

- Syntax 2

<carbon_context>.sql("UPDATE <CARBON TABLE> SET (column_name1, column_name2,) = (select sourceColumn1, sourceColumn2 from sourceTable [WHERE { <filter_condition> }]) [WHERE { <filter_condition> }];").show

Example:

If the context of CarbonData is **carbon**, run the following command:

carbon.sql("update carbonTable1 d set (d.column3,d.column5) = (select s.c33 ,s.c55 from sourceTable1 s where d.column1 = s.c11) where d.column1 = 'country' exists(select * from table3 o where o.c2 > 1);").show

1.8.11 How Do I Configure Unsafe Memory in CarbonData?

Question

How do I configure unsafe memory in CarbonData?

Answer

In the Spark configuration, the value of **spark.yarn.executor.memoryOverhead** must be greater than the sum of (**sort.inmemory.size.inmb** + **Netty offheapmemory required**), or the sum of (**carbon.unsafe.working.memory.in.mb** + **carbon.sort.inememory.storage.size.in.mb** + **Netty offheapmemory required**). Otherwise, if off-heap access exceeds the configured executor memory, Yarn may stop the executor.

If **spark.shuffle.io.preferDirectBufs** is set to **true**, the netty transfer service in Spark takes some heap memory (around 384 MB or 0.1 x executor memory) from **spark.yarn.executor.memoryOverhead**.

For details, see **Configuring Heap Memory Parameters for Spark Executor**.

1.8.12 Why Does CarbonData Become Abnormal After the Disk Space Quota of the HDFS Storage Directory Is Set?

Question

Why does CarbonData become abnormal after the disk space quota of the HDFS storage directory is set?

Answer

When a table is created, loaded, or updated, or other operations are performed, data is written to HDFS. If the disk space quota of the HDFS directory is insufficient, the operation fails and the exception is thrown.

```
org.apache.hadoop.hdfs.protocol.DSQuotaExceededException: The DiskSpace quota of /user/tenant is exceeded: quota = 314572800 B = 300 MB but diskspace consumed = 402653184 B = 384 MB at org.apache.hadoop.hdfs.server.namenode.DirectoryWithQuotaFeature.verifyStoragespaceQuota(DirectoryWithQuotaFeature.java:211) at org.apache.hadoop.hdfs.server.namenode.DirectoryWithQuotaFeature.verifyQuota(DirectoryWithQuotaFeature.java:239) at org.apache.hadoop.hdfs.server.namenode.FSDirectory.verifyQuota(FSDirectory.java:941) at org.apache.hadoop.hdfs.server.namenode.FSDirectory.updateCount(FSDirectory.java:745)
```

You need to set more disk space quota for the tenant.

The following is an example:

The required disk space can be calculated as follows:

If the number of HDFS replicas is 3 and the default block size is 128 MB, at least 384 MB disk space is required in the HDFS for writing table schema files. Formula: Number of block x **block_size** x **replication_factor** of the schema file = 1 x 128 x 3 = 384 MB

NOTE

When you load data, reserve at least 3072 MB for each **fact** file as the default block size is 1024 MB.

1.8.13 Why Do Files of a Carbon Table Exist in the Recycle Bin Even If the drop table Command Is Not Executed When Mis-deletion Prevention Is Enabled?

Question

Why do files of a Carbon table exist in the recycle bin even if the **drop table** command is not executed when mis-deletion prevention is enabled?

Answer

After the mis-deletion prevention is enabled for a Carbon table, calling a file deletion command will move the deleted files to the recycle bin.

The intermediate file **.carbonindex** is deleted duration the execution of the **insert** or **load** command. Therefore, the table files may exist in the recycle bin even through the **drop table** command is not executed.

If you run the **drop table** command, a table directory with a timestamp is generated. The files in the directory are complete.

1.8.14 How Do I Restore the Latest tablestatus File That Has Been Lost or Damaged When TableStatus Versioning Is Enabled?

Question

When the TableStatus versioning feature is enabled, how do I restore the latest **tablestatus** file if it is lost or damaged due to other exceptions?

Answer

Use the latest available **tablestatus** file to restore data in the following scenarios:

Scenario 1: The CarbonData data files and .segment files of the current batch are damaged and cannot be restored.

1. Log in to the client node and run the following commands to view the **tablestatus** file of the HDFS table and find the latest tablestatus version number:

   cd *Client installation path*

   source bigdata_env

   source Spark/component_env

   kinit *Component service user* (You do not need to run the **kinit** command for normal clusters.)

   hdfs dfs -ls /user/hive/warehouse/hrdb.db/car01/Metadata

   NOTE

   In the preceding figure, the **tablestatus_1669028899548** file of the current batch is damaged and the **tablestatus_1669028852132** file is required.

2. Go to Spark SQL and run the following command to change the value of **latestversion** to the latest version:

   alter table car01 set SERDEPROPERTIES ('latestversion'='1669082252132');

   You need to exit the current session, reconnect to the session, and perform the query. This method has been used to restore customer data as much as possible. Generally, segment data files on the live network cannot be restored in power-off scenarios.

Scenario 2: The CarbonData data files and .segment files of the current batch are complete and can be restored.

Use the TableStatusRecovery tool to restore non-partitioned tables. Log in to the Spark client node and run the following commands:

cd *Client installation path*

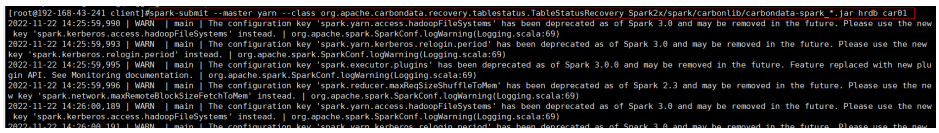
source bigdata_env

source Spark/component_env

kinit *Component service user* (You do not need to run the **kinit** command for normal clusters.)

spark-submit --master yarn --class org.apache.carbondata.recovery.tablestatus.TableStatusRecovery Spark/spark/carbonlib/carbondata-spark_*.jar *hrdb car01*

Parameter description: **hrdb car01** indicates the table name.



Restrictions on using TableStatusRecovery for restoration:

- After the merge, if the **tablestatus** file is lost or damaged, this tool cannot be used to restore the segments in the merge state because only the **tablestatus** file contains the segment merge information.
- After segments are deleted by ID or date, if the **tablestatus** file is lost or damaged, the deleted segment information cannot be restored because only the **tablestatus** file contains the segment deletion information.
- This tool cannot be used on materialized view tables.
- If the latest **tablestatus** file is faulty and query cannot be performed after using this tool for restoration, remove this latest file and use the previous **tablestatus** file for restoration.

1.9 CarbonData Troubleshooting

1.9.1 Filter Result Is not Consistent with Hive when a Big Double Type Value Is Used in Filter

Symptom

When double data type values with higher precision are used in filters, incorrect values are returned by filtering results.

Possible Causes

When double data type values with higher precision are used in filters, values are rounded off before comparison. Therefore, values of double data type with different fraction part are considered same.

Troubleshooting Method

NA.

Procedure

To avoid this problem, use decimal data type when high precision data comparisons are required, such as financial applications, equality and inequality checks, and rounding operations.

Reference Information

NA.

1.9.2 Query Performance Deteriorated Due to Insufficient Executor Memory

Symptom

The query performance fluctuates when the query is executed in different query periods.

Possible Causes

During data loading, the memory configured for each executor program instance may be insufficient, resulting in more Java GCs. When GC occurs, the query performance deteriorates.

Troubleshooting Method

On the Spark UI, the GC time of some executors is obviously higher than that of other executors, or all executors have high GC time.

Procedure

Log in to Manager and choose **Cluster** > **Services** > **Spark2x**. On the displayed page, click the **Configurations** tab and then **All Configurations**, search for **spark.executor.memory** in the search box, and set its value to a larger value.

Reference

None

1.9.3 Data Query or Loading Failed, and "org.apache.carbondata.core.memory.MemoryException: Not enough memory" Was Reported

Question

Why does data query or loading fail and "org.apache.carbondata.core.memory.MemoryException: Not enough memory" is displayed?

Answer

This exception is thrown when the out-of-heap memory required for data query and loading in the executor is insufficient.

In this case, increase the values of **carbon.unsafe.working.memory.in.mb** and **spark.yarn.executor.memoryOverhead**.

For details, see **How Do I Configure Unsafe Memory in CarbonData?**.

The memory is shared by data query and loading. Therefore, if the loading and query operations need to be performed at the same time, you are advised to set **carbon.unsafe.working.memory.in.mb** and **spark.yarn.executor.memoryOverhead** to a value greater than 2,048 MB.

The following formula can be used for estimation:

Memory required for data loading:

carbon.number.of.cores.while.loading [default value is 6] x Number of tables to load in parallel x offheap.sort.chunk.size.inmb [default value is 64 MB] + carbon.blockletgroup.size.in.mb [default value is 64 MB] + Current compaction ratio [64 MB/3.5])

= Around 900 MB per table

Memory required for data query:

(SPARK_EXECUTOR_INSTANCES. [default value is 2] x (carbon.blockletgroup.size.in.mb [default value: 64 MB] + carbon.blockletgroup.size.in.mb [default value = 64 MB x 3.5) x Number of cores per executor [default value: 1])

= ~ 600 MB

1.9.4 Why INSERT INTO/LOAD DATA Task Distribution Is Incorrect and the Opened Tasks Are Less Than the Available Executors when the Number of Initial Executors Is Zero?

Question

Why **INSERT INTO or LOAD DATA** task distribution is incorrect, and the openedtasks are less than the available executors when the number of initial executors is zero**?**

Answer

In case of INSERT INTO or LOAD DATA, CarbonData distributes one task per node. If the executors are not allocated from the distinct nodes then CarbonData will launch fewer tasks.

Solution:

Configure higher value for the executor memory and core so that the yarn can launch only one executor per node.

1. Configure the number of the Executor cores.
   - Configure the **spark.executor.cores** in **spark-defaults.conf** or the **SPARK_EXECUTOR_CORES** in **spark-env.sh** appropriately.
   - Add **--executor-cores NUM** parameter to configure the cores during use the spark-submit command.

2. Configure the Executor memory.
   - Configure the **spark.executor.memory** in **spark-defaults.conf** or the **SPARK_EXECUTOR_MEMORY** in **spark-env.sh** appropriately.
   - Add **--executor-memory MEM** parameter to configure the memory during use the spark-submit command.

1.9.5 Why Does CarbonData Require Additional Executors Even Though the Parallelism Is Greater Than the Number of Blocks to Be Processed?

Question

Why does CarbonData require additional executors even though the parallelism is greater than the number of blocks to be processed?

Answer

CarbonData block distribution optimizes data processing as follows:

1. Optimize data processing parallelism.
2. Optimize parallel reading of block data.

To optimize parallel processing and parallel read, CarbonData requests executors based on the locality of blocks so that it can obtain executors on all nodes.

If you are using dynamic allocation, you need to configure the following properties:

1. Set **spark.dynamicAllocation.executorIdleTimeout** to 15 minutes (or the average query time).
2. Set **spark.dynamicAllocation.maxExecutors** correctly. The default value **2048** is not recommended. Otherwise, CarbonData will request the maximum number of executors.
3. For a bigger cluster, set **carbon.dynamicAllocation.schedulerTimeout** to a value ranging from 10 to 15 seconds. The default value is 5 seconds.
4. Set **carbon.scheduler.minRegisteredResourcesRatio** to a value ranging from 0.1 to 1.0. The default value is **0.8**. Block distribution can be started as long as the value of **carbon.scheduler.minRegisteredResourcesRatio** is within the range.

2 Using CDL

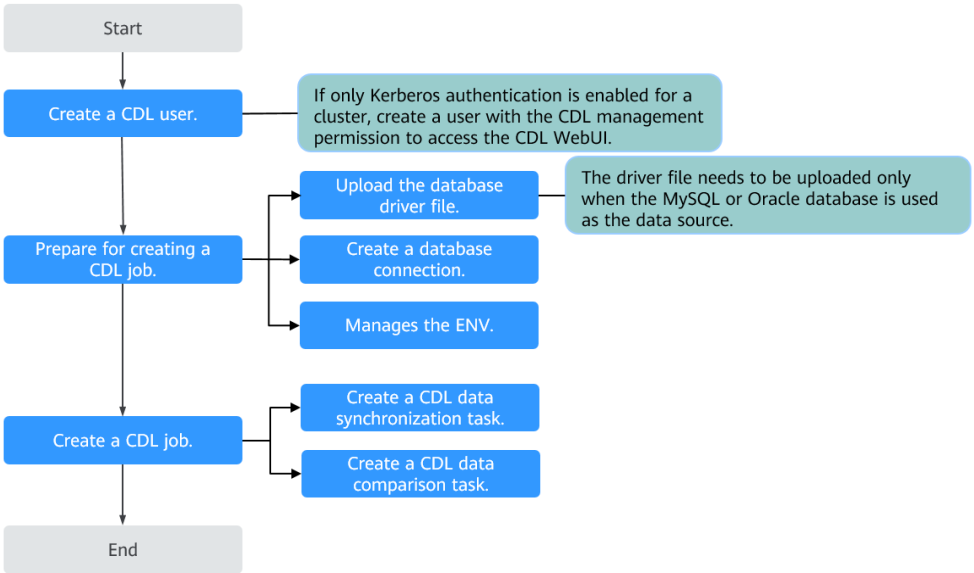
2.1 Integrating CDL Data

CDL is a simple and efficient real-time data integration service. It captures data change events from various OLTP databases and pushes them to Kafka. The Sink Connector consumes data in topics and imports the data to the software applications of big data ecosystems. In this way, data is imported to the data lake in real time.

The CDL service contains two roles: CDLConnector and CDLService. CDLConnector is the instance for executing a data capture job, and CDLService is the instance for managing and creating a job.

You can create data synchronization and comparison tasks on the CDLService WebUI. Figure 2-1 shows the process of using the CDL.

Figure 2-1 CDL usage process



Data synchronization task

- The CDL supports the following types of data synchronization tasks:

  Table 2-1 Data synchronization task types supported by the CDL

Data source	Destination end	Description
MySQL	Hudi	This task synchronizes data from the MySQL database to Hudi.
	Kafka	This task synchronizes data from the MySQL database to Kafka.
PgSQL	Hudi	This task synchronizes data from the PgSQL database to Hudi.
	Kafka	This task synchronizes data from the PgSQL database to Kafka.
Hudi	DWS	This task synchronizes data from the Hudi database to DWS.
	ClickHouse	This task synchronizes data from the Hudi database to ClickHouse.
ThirdKafka	Hudi	This task synchronizes data from the ThirdKafka database to Hudi.
	Kafka	This task synchronizes data from the ThirdKafka database to Kafka.
openGauss (supported by MRS 3.3.0 and later versions)	ThirdKafka (DMS/DRS) -> Hudi	Synchronizes data from GaussDB(for openGauss) to Hudi through ThirdKafka (DMS/DRS).
	Hudi	Synchronizes data from openGauss to Hudi.
	Kafka	Synchronizes data from openGauss to Kafka.
ogg-oracle-avro (supported by MRS 3.3.0 and later versions)	ThirdKafka (DMS/DRS) -> Hudi	Synchronizes data from avro-oracle to Hudi through ThirdKafka (DMS/DRS).

- Database versions supported by CDL in a data synchronization task:

  Kafka (including ThirdKafka that uses MRS Kafka as the source), Hudi, and ClickHouse use related components in the MRS cluster as data sources. For

details about the version numbers, see **List of MRS Component Versions**. **Table 2-2** lists the database versions.

Table 2-2 Database versions

Database Name	Data Source	Destination End	Version
MySQL	Support	Not supported	5.7 and 8.0.*x*
PostgreSQL	Support	Not supported	9.6, 10, 11, 12, and 13
Opengauss (Open source version)	Support	Not supported	2.1.0 or later
DWS	Not supported	Support	8.1.1 or later

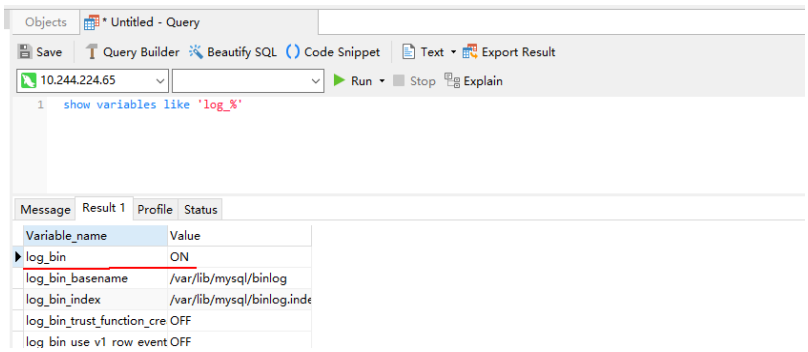
- Usage Constraints:
  - If CDL is required, the value of **log.cleanup.policy** of Kafka must be **delete**.
  - The CDL service has been installed in the MRS cluster.
  - CDL can capture incremental data only from non-system tables, but not from built-in databases of databases such as MySQL, and PostgreSQL.
  - When data is synchronized from Hudi to DWS or ClickHouse, the data that is deleted from Hudi will not be deleted from the destination. For example, if you run the **delete from** *tableName* command in Hudi to physically delete table data, the table data still exists on the destination DWS or ClickHouse.
  - Binary logging (enabled by default) and GTID have been enabled for the MySQL database. CDL cannot fetch tables whose names contain special characters such as the dollar sign ($) or Chinese characters.

    To check whether binary logging is enabled for the MySQL database:

    Use a tool (Navicat is used in this example) or CLI to connect to the MySQL database and run the **show variables like 'log_%'** command to view the configuration.

    For example, in Navicat, choose **File** > **New Query** to create a query, enter the following SQL statement, and click **Run**. If **log_bin** is displayed as **ON** in the result, the function is enabled successfully.

    show variables like 'log_%'

If the bin log function of the MySQL database is not enabled, perform the following operations:

Modify the MySQL configuration file **my.cnf** (**my.ini** for Windows) as follows:

```
server-id        = 223344
log_bin          = mysql-bin
binlog_format    = ROW
binlog_row_image  = FULL
expire_logs_days  = 10
```

After the modification, restart MySQL for the configurations to take effect.

To check whether GTID is enabled for the MySQL database:

Run the **show global variables like '%gtid%'** command to check whether GTID is enabled. For details, see the official documentation of the corresponding MySQL version. (For details about how to enable the function in MySQL 8.x, see **https://dev.mysql.com/doc/refman/8.0/en/replication-mode-change-online-enable-gtids.html**.)

```
mysql> show global variables like '%gtid%';
+---------------------------------+-------------------------------------------+
| Variable_name                   | Value                                     |
+---------------------------------+-------------------------------------------+
| binlog_gtid_simple_recovery     | ON                                        |

```

Set user permissions:

To execute MySQL tasks, users must have the **SELECT**, **RELOAD**, **SHOW DATABASES**, **REPLICATION SLAVE** and **REPLICATION CLIENT** permissions.

Run the following command to grant the permissions, Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

GRANT SELECT, RELOAD, SHOW DATABASES, REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO '*Username*' **IDENTIFIED BY** '*Password*';

Run the following command to update the permissions:

FLUSH PRIVILEGES;

- The write-ahead log policy is modified for the PostgreSQL database.

NOTE

- The user for connecting to the PostgreSQL database must have the replication permission, the CREATE permission on the database, and is the owner of tables.
- CDL cannot fetch tables whose names contain special characters such as the dollar sign ($) or Chinese characters.
- For PostgreSQL databases, you must have the permission to set the **statement_timeout** and **lock_timeout** parameters and the permission to query and delete slots and publications.
- You are advised to set **max_wal_senders** to 1.5 or 2 times the value of **Slot**.
- If the replication identifier of a PostgreSQL table is **default**, enable the full field completion function in the following scenarios:
  - Scenario 1:

    When the **delete** operation is performed on the source database, a **delete** event contains only the primary key information. In this case, for the **delete** data written to Hudi, only the primary key has values, and the values of other service fields are **null**.
  - Scenario 2:

    When the size of a single piece of data in the database exceeds 8 KB (including 8 KB), an **update** event contains only changed fields. In this case, the values of some fields in the Hudi data are **__debezium_unavailable_value**.

  The related commands are as follows:
  - Command for querying the replication identifier of a PostgreSQL table:

    SELECT CASE relreplident WHEN 'd' THEN 'default' WHEN 'n' THEN 'nothing' WHEN 'f' THEN 'full' WHEN 'i' THEN 'index' END AS replica_identity FROM pg_class WHERE oid = '*tablename***'::regclass;**
  - Command for enabling the full field completion function for a table:

    ALTER TABLE *tablename* **REPLICA IDENTITY FULL;**

i. Modify **wal_level = logical** in the database configuration file **postgresql.conf** (which is stored in the **data** folder in the PostgreSQL installation directory by default).

```
#------------------------------------------------
#WRITE-AHEAD LOG
#------------------------------------------------

# - Settings -
wal_level = logical         # minimal, replica, or logical
                    # (change requires restart)
#fsync = on             #flush data to disk for crash safety
...
```

ii. Restart the database service.

```
# Stop
pg_ctl stop
# Start
pg_ctl start
```

– Prerequisites for the DWS database

Before a synchronization task is started, both the source and target tables exist and have the same table structure. The value of **ads_last_update_date** in the DWS table is the current system time.

– Prerequisites for ThirdPartyKafka

The upper-layer source supports openGauss and OGG. Kafka topics at the source end can be consumed by Kafka in the MRS cluster.

NOTE

ThirdKafka does not support data synchronization from the distributed openGauss database to CDL.

- Prerequisites for ClickHouse

  You have the permissions to operate ClickHouse. For details, see **Creating a ClickHouse Role**.

- Write-ahead logging required for the openGauss database (supported in MRS 3.3.0 and later versions)

  NOTE

  - The user connecting to openGauss databases must have logical replication permission.
  - openGauss interval partitioned tables and Chinese table names cannot be synchronized.
  - If a table in the source openGauss database does not have a primary key, data in the table cannot be deleted.
  - If the data in the source openGauss database needs to be deleted, run the following commands to enable the field completion function:
    - Command for querying the replication identifier of a openGauss table:

      SELECT CASE relreplident WHEN 'd' THEN 'default' WHEN 'n' THEN 'nothing' WHEN 'f' THEN 'full' WHEN 'i' THEN 'index' END AS replica_identity FROM pg_class WHERE oid = '*tablename***'::regclass;**
    - Command for enabling the full field completion function for a table:

      ALTER TABLE *tablename* **REPLICA IDENTITY FULL;**

  i. Modify **wal_level = logical** in the database configuration file **postgresql.conf** (which is stored in the **data** folder in the openGauss installation directory by default).

  ```
  #------------------------------------------------
  #WRITE-AHEAD LOG
  #------------------------------------------------

  # - Settings -
  wal_level = logical         # minimal, replica, or logical
                              # (change requires restart)
  #fsync = on                 #flush data to disk for crash safety
  ...
  ```

  ii. Restart the database service.

  ```
  # Stop
  pg_ctl stop
  # Start
  pg_ctl start
  ```

Data Types and Mapping Supported by CDL Synchronization Tasks

This section describes the data types supported by CDL synchronization tasks and the mapping between data types of the source database and Spark data types.

Table 2-3 Mapping between PostgreSQL and Spark data types

PostgreSQL Data Type	Spark (Hudi) Data Type
int2	int

PostgreSQL Data Type	Spark (Hudi) Data Type
int4	int
int8	bigint
numeric(p, s)	decimal[p,s]
bool	boolean
char	string
varchar	string
text	string
timestamptz	timestamp
timestamp	timestamp
date	date
json, jsonb	string
float4	float
float8	double

Table 2-4 Mapping between MySQL and Spark data types

MySQL Data Type	Spark (Hudi) Data Type
int	int
integer	int
bigint	bigint
double	double
decimal[p,s]	decimal[p,s]
varchar	string
char	string
text	string
timestamp	timestamp
datetime	timestamp
date	date
json	string
float	double

Table 2-5 Mapping between Ogg/Ogg Oracle Avro (MRS 3.3.0 and later versions) and Spark data types

Oracle Data Type	Spark (Hudi) Data Type
NUMBER(3), NUMBER(5)	bigint
INTEGER	decimal
NUMBER(20)	decimal
NUMBER	decimal
BINARY_DOUBLE	double
CHAR	string
VARCHAR	string
TIMESTAMP, DATETIME	timestamp
timestamp with time zone	timestamp
DATE	timestamp

Table 2-6 Mapping Between DRS openGauss JSON types and Spark data types (supported in MRS 3.3.0 and later versions)

openGauss JSON	Spark (Hudi)
int2	int
int4	int
int8	bigint
numeric(p,s)	decimal[p,s]
bool	boolean
varchar	string
timestamp	timestamp
timestampz	timestamp
date	date
jsonb	string
json	string
float4	float
float8	double
text	string

Table 2-7 Mapping between DRS Oracle JSON types and Spark data types (supported in MRS 3.3.0 and later versions)

Oracle JSON	Spark (Hudi)
number(p,s)	decimal[p,s]
binary double	double
char	string
varchar2	string
nvarchar2	string
timestamp	timestamp
timestamp with time zone	timestamp
date	timestamp

Table 2-8 Mapping between DRS Oracle Avro types and Spark data types (supported in MRS 3.3.0 and later versions)

Oracle Avro	Spark (Hudi)
nuber[p,s]	decimal[p,s]
float(p)	float
binary_double	double
char(p)	string
varchar2(p)	string
timestamp(p)	timestamp
date	timestamp

Table 2-9 Mapping between openGauss data types and Spark data types (supported in MRS 3.3.0 and later versions)

openGauss	Spark (Hudi)
int1	int
int2	int
int4	int
int8	bigint
numeric(p,s)	decimal[p,s]

openGauss	Spark (Hudi)
bool	boolean
char	string
bpchar	string
nvarchar2	string
text	string
date	date
timestamp	timestamp
timestampz	timestamp
json	string
jsonb	string
float4	float
float8	double
real	float

Table 2-10 Mapping between Spark (Hudi) and DWS data types

Spark (Hudi) Data Type	DWS Data Type
int	int
long	bigint
float	float
double	double
decimal[p,s]	decimal[p,s]
boolean	boolean
string	varchar
date	date
timestamp	timestamp

Table 2-11 Mapping between Spark (Hudi) and ClickHouse data types

Spark (Hudi) Data Type	ClickHouse Data Type
int	Int32

Spark (Hudi) Data Type	ClickHouse Data Type
long	Int64 (bigint)
float	Float32 (float)
double	Float64 (double)
decimal[p,s]	Decimal(P,S)
boolean	bool
string	String (LONGTEXT, MEDIUMTEXT, TINYTEXT, TEXT, LONGBLOB, MEDIUMBLOB, TINYBLOB, BLOB, VARCHAR, CHAR)
date	Date
timestamp	DateTime

Data comparison task

Data comparison checks the consistency between data in the source database and that in the target Hive. If the data is inconsistent, CDL can attempt to repair the inconsistent data. For detail, see **Creating a CDL Data Comparison Job**.

2.2 CDL User Permission Management

Scenario

Before using the CDL service, a cluster administrator needs to create a user and grant operation permissions to the user to meet service requirements.

CDL users are classified into administrators and common users. The default CDL user group for administrators and common users is **cdladmin** and **cdl**, respectively.

- Users associated with the **cdladmin** user group can perform any CDL operations.
- Users associated with the **cdl** user group can perform creation and query operations on CDL.

If Ranger authentication is enabled and you need to configure the creation, execution, query, or deletion permission for CDL users, see **Adding a Ranger Access Permission Policy for CDL**.

If Ranger authentication is manually disabled for a cluster, enable Ranger authentication by referring to **Enabling Ranger Authentication for MRS Cluster Services**.

NOTE

This section applies only to clusters with Kerberos authentication enabled.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System**. On the navigation pane on the left, choose **Permission** > **User** and click **Create**.

Step 3 Enter a username, for example, **cdl_admin**.

Step 4 Set **User Type** to **Human-Machine**.

Step 5 Set **Password** and confirm your password.

Step 6 Set **User Group** and **Primary Group**.

- CDL administrator permissions: Add the **cdladmin** user group and set it to the primary group.
- Common CDL user permissions: Add the **cdl** user group and set it to the primary group.

Step 7 Click **OK**.

----End

2.3 Creating a Data Synchronization Job with CDL

CDL supports data synchronization or comparison tasks in multiple scenarios. This section describes how to import data from PgSQL to Kafka on the CDLService WebUI of a cluster with Kerberos authentication enabled. For more CDL job examples, see **Creating a CDL Job**.

Prerequisites

- The CDL and Kafka services have been installed in a cluster and are running properly.
- Write-ahead logging is enabled for the PostgreSQL database. For details, see **Policy for Modifying Write-Ahead Logs in PostgreSQL Databases**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, and **kafka**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon the first login) and choose **Cluster** > **Services** > **CDL**. On the **Dashboard** page, click the hyperlink next to **CDLService UI** to go to the native CDL page.

Step 2 Choose **Link Management** and click **Add Link**. On the displayed dialog box, set parameters for adding the **pgsql** and **kafka** links by referring to the following tables.

Table 2-12 PgSQL data link parameters

Parameter	Example Value
Link Type	pgsql
Name	pgsqllink
Host	10.10.10.10
Port	5432
DB Name	testDB
User	user
Password	*Password of the user user*
Description	-

Table 2-13 Kafka data link parameters

Parameter	Example Value
Link Type	kafka
Name	kafkalink
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 On the **Job Management** page, click **Add Job**. In the displayed dialog box, configure the parameters and click **Next**.

Specifically:

Parameter	Example Value
Name	job_pgsqltokafka
Desc	xxx

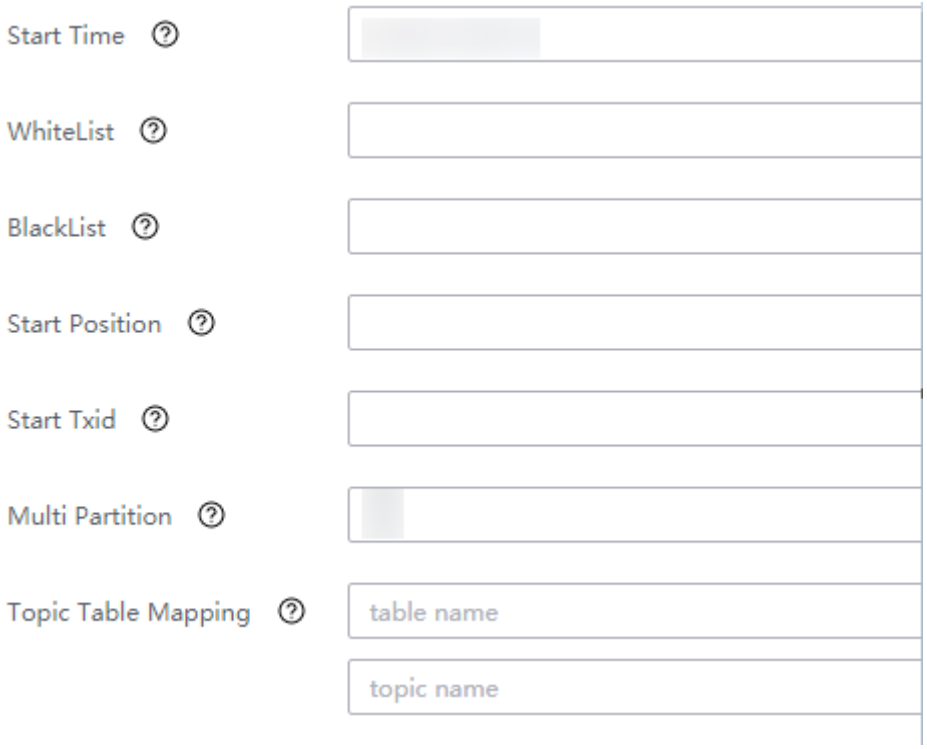
Step 5 Configure PgSQL job parameters.

1. On the **Job Management** page, drag the **pgsql** icon on the left to the editing area on the right and double-click the icon to go to the PgSQL job configuration page.

Table 2-14 PgSQL job parameters

Parameter	Example Value
Link	pgsqllink
Tasks Max	1
Mode	insert, update, and delete
Schema	public
dbName Alias	cdc
Slot Name	a4545sad
Slot Drop	No
Connect With Hudi	No
Use Exist Publication	Yes
Publication Name	test

2. Click the plus sign (+) to display more parameters.



NOTE

- **WhiteList**: Enter the name of the table in the database, for example, **myclass**.
- **Topic Table Mapping**: In the first text box, enter a topic name (the value must be different from that of **Name** in **Step 4**), for example, **myclass_topic**. In the second text box, enter a table name, for example, **myclass**. The value must be in one-to-one relationship with the topic name entered in the first text box.)

3. Click **OK**. The PgSQL job parameters are configured.

Step 6 Configure Kafka job parameters.

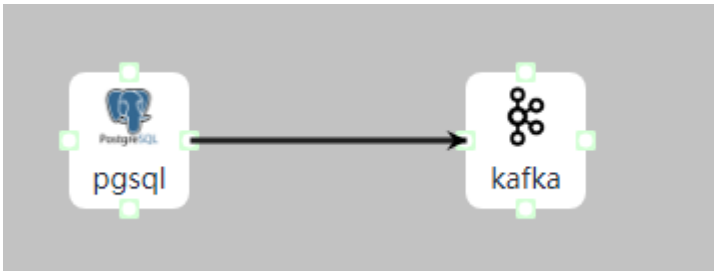
1. On the **Job Management** page, drag the **kafka** icon on the left to the editing area on the right and double-click the icon to go to the Kafka job configuration page. Configure parameters based on **Table 2-15**.

   Table 2-15 Kafka job parameter

Parameter	Example Value
Link	kafkalink

2. Click **OK**.

Step 7 After the job parameters are configured, drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 8 In the job list on the **Job Management** page, locate the created jobs, click **Start** in the **Operation** column, and wait until the jobs are started.

Check whether the data transmission takes effect. For example, insert data into the table in the PgSQL database, go to the Kafka UI to check whether data is generated in the Kafka topic by referring to **Viewing Kafka Data Production and Consumption Details**.

----End

2.4 Preparing for Creating a CDL Job

2.4.1 Enabling Kafka High Reliability

Scenario

To execute the CDL data synchronization tasks listed in **Table 2-16**, enable the Kafka high reliability function to prevent data loss when Kafka is faulty or restarted.

Table 2-16 CDL tasks that use MRS Kafka to synchronize data

Data Source	Destination	Description
MySQL	Hudi	Synchronizes data from MySQL to Hudi.
	Kafka	Synchronizes data from MySQL to Kafka.
PgSQL	Hudi	Synchronizes data from PgSQL to Hudi.
	Kafka	Synchronizes data from PgSQL to Kafka.
ThirdKafka	Hudi	Synchronizes data from ThirdKafka to Hudi.
	Kafka	Synchronizes data from ThirdKafka to Kafka.
opengauss (supported by MRS 3.3.0 and later versions)	ThirdKafka (DMS/DRS) -> Hudi	Synchronizes data from GaussDB(for openGauss) to Hudi through ThirdKafka (DMS/DRS).
avro-oracle (supported by MRS 3.3.0 and later versions)	ThirdKafka (DMS/DRS) -> Hudi	Synchronizes data from avro-oracle to Hudi through ThirdKafka (DMS/DRS).

Prerequisites

- The CDL component has been installed in an MRS cluster and is running properly.
- CDL data synchronization tasks use the Kafka component.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**.

Step 2 Search for the parameters listed in **Table 2-17** in the search box in the upper right corner and change their values.

Table 2-17 Modifying Kafka parameters

Parameter	Recommended Value	Description
unclean.leader.election.enable	false	Whether a replica that is not in the ISR can be elected as the leader. If this parameter is set to **true**, data may be lost.
min.insync.replicas	2	Minimum number of replicas to which data is written when **offsets.commit.required.acks** is set to **-1**.

Step 3 Click **Save**.

Step 4 Choose **Dashboard**, click **More**, and select **Rolling-restart Service** to roll-restart Kafka.

----End

2.4.2 Logging In to the CDLService WebUI

Scenario

After CDL is installed in an MRS cluster, you can manage data connections and visualized jobs using the CDL web UI.

This section describes how to access the CDL web UI in an MRS cluster.

NOTE

You are advised to use Google Chrome to access the CDLService web UI because it is incompatible with Internet Explorer.

CDL cannot fetch tables whose names contain the dollar sign ($) and special Chinese characters.

Prerequisites

- The CDL component has been installed in an MRS cluster and is running properly.
- A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled.

Procedure

Step 1 Log in to FusionInsight Manager as a user with the CDL management permissions or the **admin** user (for the cluster where Kerberos authentication is not enabled), and choose **Cluster** > **Services** > **CDL**.

Step 2 On the right of **CDLService UI**, click the link to access the CDLService web UI.

You can perform the following operations on the CDL web UI:

- **Driver Management**: You can upload, view, and delete a driver file corresponding to the connected database.
- **Link Management**: You can create, view, edit, and delete a data connection.
- **Job Management**: You can create, view, start, pause, restore, stop, restart, delete, or edit a job.
- **ENV Management**: You can create, view, edit, and delete Hudi environment variables.

----End

2.4.3 Uploading the Database Driver File

Scenario

CDL is a simple and efficient real-time data integration service. It captures events from various OLTP databases and pushes them to Kafka. When creating a database connection on the CDLService Web UI, you can upload the database's driver file to the Web UI for unified management.

Prerequisites

- You have obtained the driver JAR package of the database to be connected.
- You have downloaded the driver package of the MySQL or Oracle data source from their respective official website. **Table 2-18** lists the supported driver packages and their versions.

  Table 2-18 Drivers supported by MySQL and Oracle data sources

Data Source	Supported Driver Package
MySQL	mysql-connector-java-8.0.24.jar
Oracle	ojdbc8-12.2.0.1.jar

- A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled. For details, see **CDL User Permission Management**.

Procedure

Step 1 Access the CDLService web UI as a user with the CDL management permissions or the **admin** user (for the cluster where Kerberos authentication is not enabled). For details, see **Logging In to the CDLService WebUI**.

Step 2 Choose **Driver Management** and click **Upload Driver**. In the displayed dialog box, select the prepared database driver file and click **Open**.

Step 3 On the **Driver Management** page, check whether the list of driver file names is displayed properly.

NOTE

- If a driver is no longer used or is mistakenly uploaded, click **Delete** to delete its driver file.
- If there are a large number of driver files, you can enter a driver file name in the search box to quickly search for the desired driver file.

----End

2.4.4 Creating a CDL Database Connection

Scenario

Create a database link on the CDLService web UI.

Prerequisites

- You have obtained the driver JAR package of the data to be connected.
- A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled. For details, see **CDL User Permission Management**.

Procedure

Step 1 Access the CDLService web UI as a user with the CDL management permissions or the **admin** user (for the cluster where Kerberos authentication is not enabled). For details, see **Logging In to the CDLService WebUI**.

Step 2 Choose **Link Management** and click **Add Link**. In the displayed dialog box, enter the link name (cannot be the same as an existing one) and select the link type.

Step 3 Set other link parameters based on the link type.

Table 2-19 MySQL data link parameters

Parameter	Description	Example Value
Link Type	Link type	mysql
Name	Link name	mysqllink
DB driver	Uploaded MySQL driver file **mysql-connector-java-8.0.24.jar**	mysql-connector-java-8.0.24.jar
Host	IP address of the MySQL database	10.10.10.10
Port	MySQL database port	3306
User	User for accessing the MySQL database	user
Password	Password for accessing the MySQL database	*Password of the user user*

Parameter	Description	Example Value
Description	Data link description.	xxx

Table 2-20 PgSQL data link parameters

Parameter	Description	Example Value
Link Type	Link type	pgsql
Name	Link name	pgsqllink
Host	IP address of the PgSQL database	10.10.10.10
Port	PgSQL database port	5432
DB Name	PgSQL database name	testDB
User	User for accessing the PgSQL database	user
Password	Password for accessing the PgSQL database	*Password of the user user*
Description	Data link description	xxx

Table 2-21 Kafka data link parameters

Parameter	Description	Example Value
Link Type	Link type.	kafka
Name	Link name.	kafkalink
Description	Data link description.	-

Table 2-22 Hudi data link parameters

Parameter	Description	Example Value
Link Type	Link type.	hudi
Name	Link name.	hudilink
Storage Type	Storage type, which can be either of the following: **hdfs**: Data is stored in HDFS.	hdfs

Parameter	Description	Example Value
Auth KeytabFile	Keytab file of a user. You can click **Upload File** to upload the keytab file. Set this parameter only for a cluster in security mode. **NOTE** To obtain this file, log in to FusionInsight Manager and choose **System**. On the navigation pane on the left, choose **Permission** > **User** and choose **More** > **Download User Credential** in the **Operation** column.	${BIGDATA_HOME}/FusionInsight_CDL_*X.X.X*/install/FusionInsight-CDL-*X.X.X*/cdl/keytabs/cdl.keytab
Principal	Domain name of the user who accesses HDFS. Set this parameter only for a cluster in security mode.	cdl/test.com@HADOOP.COM
Description	Data link description.	xxx

Table 2-23 thirdparty-kafka data link parameters

Parameter	Description	Example Value
Link Type	Link type	thirdparty-kafka
Name	Link name	thirdparty-kafkalink
Bootstrap Servers	Kafka proxy instance, which can be set to a value in the format of *Service IP address of the Kafka Broker instance*:*Kafka port number*. **NOTE** If MRS Kafka is used as the source of thirdparty-kafka, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Configuration**, search for the port in the search box, and obtain the port number based on the encryption protocol.	10.10.10.10:21005

Parameter	Description	Example Value
Security Protocol	Encryption protocol. Value options are as follows: • **SASL_PLAINTEXT** • **PLAINTEXT** • **SASL_SSL** • **SSL**	SASL_SSL
Username	Username specified when **SASL_SSL** is enabled during instance creation **NOTE** This parameter is available only when **Security Protocol** is set to **SASL_PLAINTEXT** or **SASL_SSL**.	test
Password	Password configured when **SASL_SSL** is enabled during instance creation **NOTE** This parameter is available only when **Security Protocol** is set to **SASL_PLAINTEXT** or **SASL_SSL**.	xxx
SSL Truststore Location	Path where the **client.truststore.jks** authentication file is stored **NOTE** This parameter is available only when **Security Protocol** is set to **SASL_SSL** or **SSL**.	-
SSL Truststore Password	Password of the **client.truststore.jks** certificate file **NOTE** This parameter is available only when **Security Protocol** is set to **SASL_SSL** or **SSL**.	xxx

Parameter	Description	Example Value
Datastore Type	Type of the upper-layer source. Value options are as follows: • MRS 3.2.0: – opengauss – ogg – oracle – drs-avro-oracle • MRS 3.3.0 and later versions: – drs-opengauss-json – ogg-oracle-avro – drs-oracle-json – drs-oracle-avro	• opengauss • drs-opengauss-json
DB driver	Uploaded thirdparty-kafka driver file **NOTE** This parameter is displayed when **Datastore Type** is set to **ogg** (or **ogg-oracle-avro** for MRS 3.3.0 and later versions).	-
Host	IP address of the thirdparty-kafka database **NOTE** This parameter is not displayed when **Datastore Type** is set to **oracle** (or **drs-oracle-json** for MRS 3.3.0 and later versions).	11.11.xxx.xxx,12.12.xxx.xxx
Port	thirdparty-kafka database port **NOTE** This parameter is not displayed when **Datastore Type** is set to **oracle** (or **drs-oracle-json** for MRS 3.3.0 and later versions).	8000
DB Name	thirdparty-kafka database name **NOTE** This parameter is displayed when **Datastore Type** is set to **opengauss** (or **drs-opengauss-json** for MRS 3.3.0 and later versions).	opengaussdb

Parameter	Description	Example Value
User	thirdparty-kafka database access user **NOTE** This parameter is not displayed when **Datastore Type** is set to **oracle** (or **drs-oracle-json** for MRS 3.3.0 and later versions).	opengaussuser
DB Password	Password for accessing the thirdparty-kafka database **NOTE** This parameter is not displayed when **Datastore Type** is set to **oracle** (or **drs-oracle-json** for MRS 3.3.0 and later versions).	*Password of the opengaussuser user*
Sid	Service ID of Oracle **NOTE** This parameter is displayed when **Datastore Type** is set to **ogg** (or **ogg-oracle-avro** for MRS 3.3.0 and later versions).	-
Description	Data link description.	-

Table 2-24 DWS data link parameters

Parameter	Description	Example Value
Link Type	Link type	dws
Name	Link name	dwslink
Host	IP address of the DWS database to be connected	10.10.10.10
Port	Database port	8000
DB Name	Name of the database to be connected to	default
User	Database access user	test
Password	Password for accessing the database	xxx
Description	Data link description.	-

Table 2-25 opengauss data link parameters

Parameter	Description	Example Value
Link Type	Link type	opengauss
Name	Link name	opengausslink
Host	IP address of the opengauss database to be connected	10.10.10.10
Port	Database port	8000
DB Name	Name of the database to be connected to	default
User	Database access user	test
Password	Password for accessing the database	xxx
Description	Data link description.	-

Table 2-26 ClickHouse data link parameters

Parameter	Description	Example Value
Link Type	Link type	clickhouse
Name	Link name	clickhouselink
Host	*Service IP address of the ClickHouseBalancer instance of ClickHouse:HTTP balancer port number*. Multiple ClickHouse instances can be connected using commas (,). **NOTE** To obtain the HTTP balancer port number, log in to Manager, choose **Cluster** > **Services** > **ClickHouse**, click **Logic Cluster**, and obtain the port number from the **HTTP Balancer Port** column in the cluster list.	10.10.10.10:21428
User	Database access user	test
Password	Password for accessing the database	xxx

Parameter	Description	Example Value
Description	Data link description.	-

Step 4 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

----End

2.4.5 Configuring CDL ENV Variables

Scenario

To capture data to or from Hudi, create and manage Hudi environment variables by performing the operations in this section.

Prerequisites

A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled. For details, see **CDL User Permission Management**.

Procedure

Step 1 Access the CDLService web UI as a user with the CDL management permissions or the **admin** user (for the cluster where Kerberos authentication is not enabled). For details, see **Logging In to the CDLService WebUI**.

Step 2 Choose **ENV Management** and click **Add Env**. In the displayed dialog box, set related parameters.

Table 2-27 Parameters for adding an ENV

Parameter	Description	Example Value
Name	ENV name	spark-env
Type	ENV type	spark
Driver Memory	Memory for the driver process, in GB (by default).	1 GB
Executor Memory	Memory size for each Executor process, in GB by default. Its string format is the same as that of JVM.	1 GB

Parameter	Description	Example Value
Executor Cores	Number of CPU cores occupied by each Executor	1
Number Executors	Number of Executors	1
Queue	Name of the Yarn tenant queue. Jobs are submitted to the default queue if this parameter is not specified.	-
Description	ENV description	-

Step 3 Click **OK**.

After the ENV is created, you can click **Edit** or **Delete** in the **Operation** column to edit or delete the ENV, respectively.

----End

2.4.6 Configuring the Source Data Heartbeat Table for Data Integrity Check

Scenario

The heartbeat and data consistency check function is used to collect full-link information about CDL synchronization tasks, including the time required for sending data from the database management system RDBMS to Kafka, the time required for writing data from Kafka to Hudi, and the number of data records, and writes the data to a specific topic (cdl_snapshot_topic). You can consume the data in the topic and write the data to a specific Hudi table for data consistency check. The heartbeat data can be used not only to determine whether data before the heartbeat time has been synchronized to the data lake, but also to determine the data latency based on the transaction time, Kafka write time, data import start time, and data import end time.

In addition, for PgSQL tasks, configuring a heartbeat table can periodically push forward the LSN information recorded by the slot in the PgSQL database. This prevents database log stacking caused by the configuration of some tables with little changes in a task.

Configuring the Heartbeat Table for Capturing Data from Oracle GoldenGate (OGG) to a Hudi Job

Step 1 Run the following commands in the Oracle database where data needs to be synchronized to create a heartbeat table. The heartbeat table belongs to the **CDC_CDL** schema, the table name is **CDC_HEARTBEAT**, and the primary key is **CDL_JOB_ID**.

CREATE TABLE "CDC_CDL"."CDC_HEARTBEAT" (

"CDL_JOB_ID" VARCHAR(22) PRIMARY KEY,

"CDL_LAST_HEARTBEAT" TIMESTAMP,

SUPPLEMENTAL LOG DATA (ALL) COLUMNS

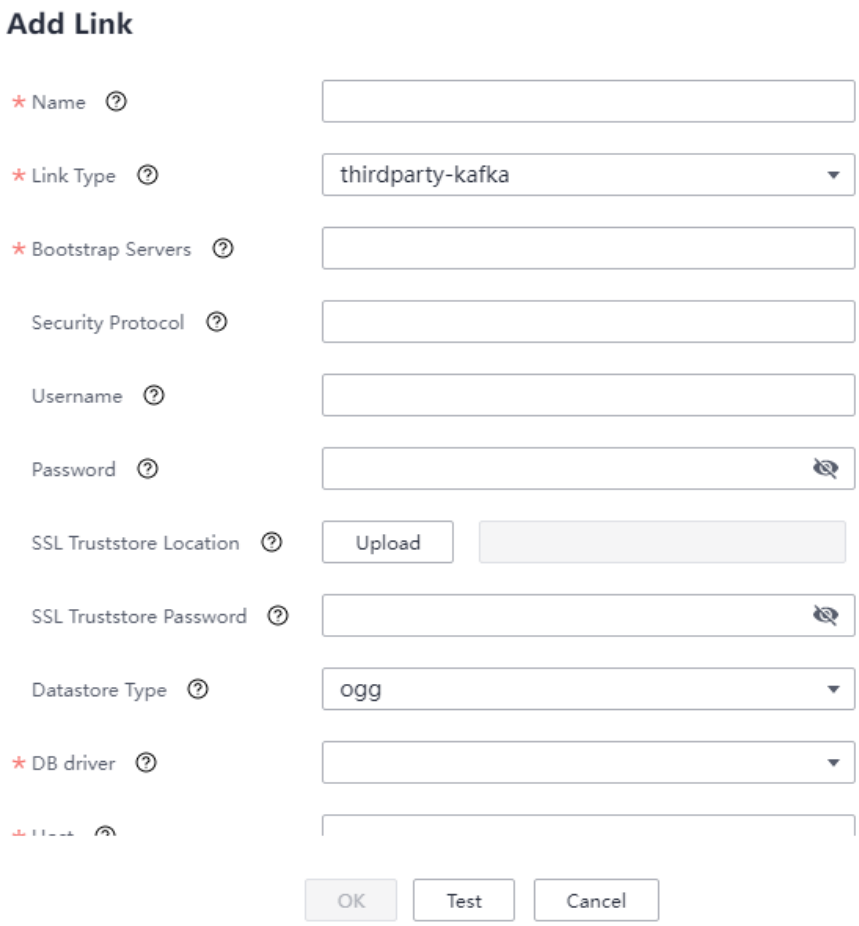
);

Step 2 Add the **CDC_HEARTBEAT** table to the Oracle or OGG job to ensure that heartbeat data can be properly sent to Kafka.

NOTE

For an Oracle job, go to **Step 4**.

Step 3 Configure the thirdparty-kafka (ogg) link on the CDL web UI and add the Oracle link information.



Step 4 After the configuration is complete, create a job for capturing data from OGG to Hudi on the CDL web UI and start the job to receive heartbeat data.

----End

Configuring the Heartbeat Table for Capturing Data from PostgreSQL to a Hudi Job

Step 1 Run the following commands in the PostgreSQL database to be synchronized to create a heartbeat table. The heartbeat table belongs to the **cdc_cdl** schema, the table name is **cdc_heartbeat**, and the primary key is **cdl_job_id**.

```
DROP TABLE IF EXISTS cdc_cdl.cdc_heartbeat;

CREATE TABLE cdc_cdl.cdc_heartbeat (

cdl_job_id int8 NOT NULL,

cdl_last_heartbeat timestamp(6)

);

ALTER TABLE cdc_cdl.cdc_heartbeat ADD CONSTRAINT cdc_heartbeat_pkey
PRIMARY KEY (cdl_job_id);
```

Step 2 After the heartbeat table is created, create a job for capturing data from PostgreSQL to Hudi on the CDL web UI and start the job to receive heartbeat data.

----End

Configuring the Heartbeat Table from openGauss to a Hudi Job

Step 1 Run the following commands in the openGauss database to be synchronized to create a heartbeat table. The heartbeat table belongs to the **cdc_cdl** schema, the table name is **cdc_heartbeat**, and the primary key is **cdl_job_id**.

```
DROP TABLE IF EXISTS cdc_cdl.cdc_heartbeat;

CREATE TABLE cdc_cdl.cdc_heartbeat (

cdl_job_id int8 NOT NULL,

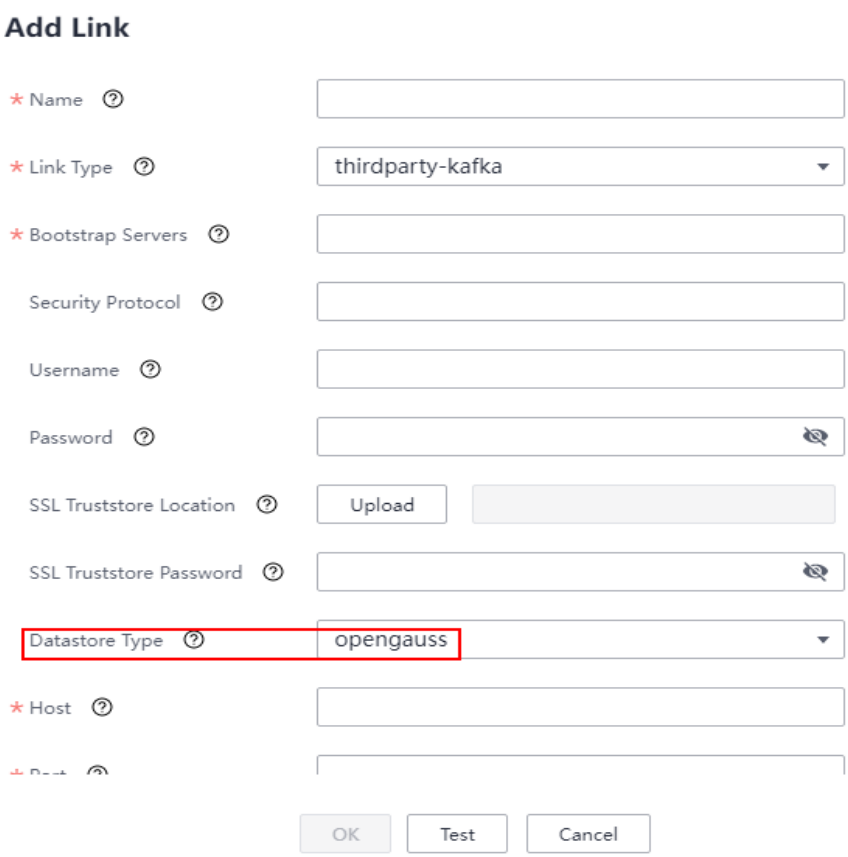
cdl_last_heartbeat timestamp(6)

);

ALTER TABLE cdc_cdl.cdc_heartbeat ADD CONSTRAINT cdc_heartbeat_pkey
PRIMARY KEY (cdl_job_id);
```

Step 2 Add the heartbeat table to the DRS job to ensure that the heartbeat table data is properly sent to the DRS Kafka.

Step 3 On the CDL web UI, add the openGauss link information when configuring the thirdparty-kafka link of openGauss. If one primary openGauss node and multiple standby openGauss nodes are deployed, enter all IP addresses in **Host**.



Step 4 After the configuration is complete, create a job for capturing data from thirdparty-kafka to Hudi on the CDL web UI and start the job to receive heartbeat data.

----End

Fields in a Data Consistency Check Message

Table 2-28 Fields in a data consistency check message

Field	Description
cdl_job_name	The name of the synchronization task to which the data in this batch belongs.
target_table_schema	The name of the schema to which the data in this batch is written.
target_table_name	The name of the Hudi table to which the data in this batch is written.
target_table_path	The path of the Hudi table to which the data in this batch is saved.
total_num	The total number of data records in this batch.

Field	Description
cdl_original_heartbeat	The maximum duration of heartbeat data in this batch. If this batch does not contain heartbeat data, the value is empty.
cdl_last_heartbeat	The minimum duration of heartbeat data in this batch. If this batch does not contain heartbeat data, the value of **event_time_min** is used.
insert_num	The total number of data **insert** events in this batch.
update_num	The total number of data **update** events in this batch.
delete_num	The total number of data **delete** events in this batch.
event_time_min	The minimum transaction submission time of the data source in this batch.
event_time_max	The maximum transaction submission time of the data source in this batch.
event_time_avg	The average transaction submission time of the data source in this batch.
kafka_timestamp_min	The minimum time for sending data in this batch to Kafka.
kafka_timestamp_max	The maximum time for sending data in this batch to Kafka.
begin_time	The time when the data in this batch starts to be written to Hudi.
end_time	The time when the data in this batch stops to be written to Hudi.
cdc_partitioned_time	The time partition field in the heartbeat table.
cdc_last_update_date	The time when the check record is written.

2.5 Creating a CDL Job

2.5.1 Creating a CDL Data Synchronization Job

Scenario

The CDLService web UI provides a visualized page for users to quickly create CDL jobs and import real-time data into the data lake.

Prerequisites

A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled.

Procedure

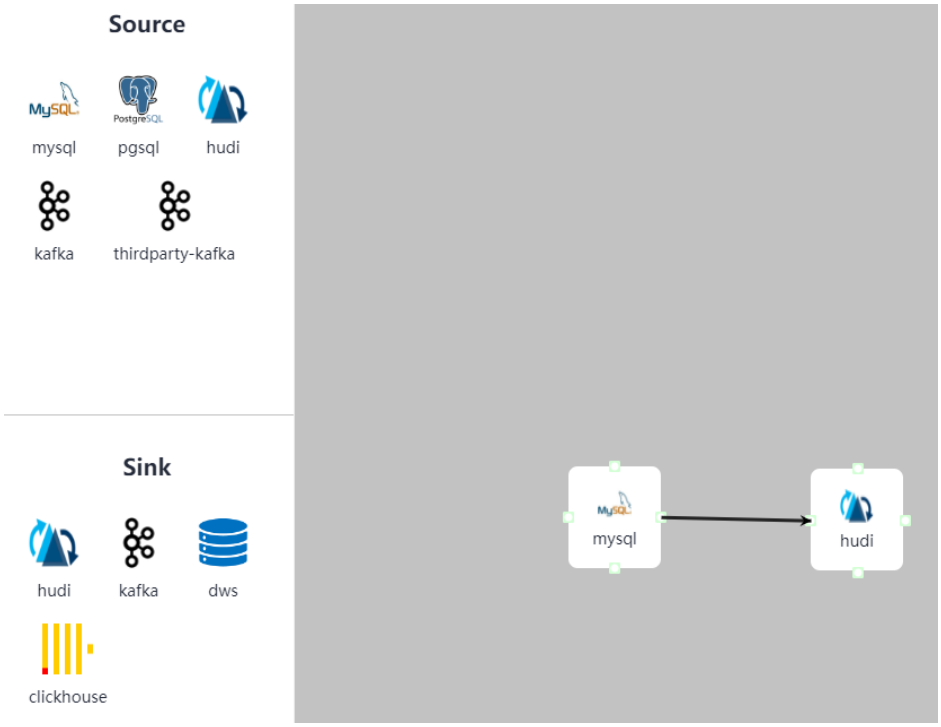
Step 1 Access the CDLService web UI as a user with the CDL management permissions or the **admin** user (for the cluster where Kerberos authentication is not enabled). For details, see **Logging In to the CDLService WebUI**.

Step 2 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set related job parameters and click **Next**.

Parameter	Description	Example Value
Name	Job name	job_pgsqltokafka
Desc	Job description	xxx

Step 3 On the **Job Management** page, select and drag the target element from **Source** and **Sink** to the GUI on the right.

MRS 3.2.0:



MRS 3.3.0 and later versions:

Double-click the two elements to connect them and set related parameters as required.

To delete an element, select the element to be deleted and click **Delete** in the lower right corner of the page.

Table 2-29 MySQL job parameters

Parameter	Description	Example Value
Link	Created MySQL link	mysqllink
Tasks Max	Maximum number of tasks that can be created by a connector. For a connector of the database type, this parameter must be set to **1**.	1

Parameter	Description	Example Value
Mode	Type of the CDC event to be captured by the job. Value options are as follows: • **insert** • **update** • **delete**	insert, update, and delete
DB Name	MySQL database name	cdl-test
Schema Auto Create	Whether to create table schemas after the job is started	No
Connect With Hudi	Whether to connect to Hudi	Yes
DBZ Snapshot Locking Mode	Lock mode used when a task starts to execute a snapshot. Value options are as follows: • **minimal**: A global read lock is held only when the database schema and other metadata are obtained. • **extend**: A global read lock is held during the entire snapshot execution process, blocking all write operations. • **none**: No lock mode. The schema cannot be changed when a CDL task is started. Optional. Click  to display this parameter.	none
WhiteList	Whitelisted tables to be captured. Separate multiple tables using commas (,). Wildcards are supported. (Optional) This parameter is displayed when you click  .	testtable

Parameter	Description	Example Value
BlackList	Whitelisted tables not to be captured. Separate multiple tables using commas (,). Wildcards are supported. (Optional) This parameter is displayed when you click  .	-

Parameter	Description	Example Value
Multi Partition	Whether to enable multi-partition mode for topics. If enabled, you need to set **Topic Table Mapping** and specify the number of topic partitions, and the data of a single table will be scattered in multiple partitions. (Optional) This parameter is displayed when you click ⊞. **NOTE** • The data receiving sequence cannot be ensured. Exercise caution when setting this parameter. • The default number of partitions is 5. To change the number of partitions, log in to FusionInsight Manager, choose **Cluster** > **Services** > **CDL**, click **Configurations**, search for **topics.max.partitions** in the search box, and change the value to the number of partitions to be changed. For example: Change the value to 10, save the configuration, and restart the CDL service. • In MRS 3.3.0 and later versions, if the source table is a partitioned table and this parameter is set to **No**, the number of topic partitioned tables created using CDL is the number of source table partitions plus 1.	No

Parameter	Description	Example Value
Topic Table Mapping	Mapping between topics and tables. If configured, table data can be sent to the specified topic. If multi-partitioning is enabled, you need to set the number of partitions, which must be greater than 1. In MRS 3.3.0 and later versions, when the time of the source data is earlier than the specified data filtering time, the data is discarded. When the time of the source data is later than the specified data filtering time, the data is sent to the downstream. This parameter is displayed when you click  . This parameter is mandatory if **Connect With Hudi** is set to **Yes**.	testtable testtable_topic 2023/03/10 11:33:37 (supported in MRS 3.3.0 and later versions)

Table 2-30 PgSQL job parameters

Parameter	Description	Example Value
Link	Created PgSQL link.	pgsqllink
Tasks Max	Maximum number of tasks that can be created by a connector. For a connector of the database type, this parameter must be set to **1**.	1
Mode	Type of the CDC event to be captured by the job. The options are as follows: • **insert** • **update** • **delete**	insert, update, and delete

Parameter	Description	Example Value
dbName Alias	Database name.	test
Schema	Schema of the database to be connected to.	public
Slot Name	Name of the PostgreSQL logical replication slot. The value can contain lowercase letters and underscores (_), and cannot be the same in any other job.	test_solt
Enable FailOver Slot	Whether to enable the failover slot function. After it is enabled, the information about the logical replication slot specified as the failover slot is synchronized from the active instance to the standby instance. In this manner, logical subscription can continue even upon an active/standby switchover, implementing the failover of the logical replication slot.	No
Slot Drop	Whether to delete the slot when a task is stopped	No
Connect With Hudi	Whether to connect to Hudi.	Yes
Use Exist Publication	Use a created publication	Yes
Publication Name	Name of a created publication This parameter is available when **Use Exist Publication** is set to **Yes**.	test
Start Time (MRS 3.2.0)	Start time for synchronizing tables	2022/03/16 11:33:37
Data Filter Time (MRS 3.3.0 and later versions)	Start time of data filtering	2022/03/16 11:33:37

Parameter	Description	Example Value
WhiteList	Whitelisted tables to be captured. Separate multiple tables using commas (,). Wildcards are supported. (Optional) This parameter is displayed when you click ⊞.	testtable
BlackList	Whitelisted tables not to be captured. Separate multiple tables using commas (,). Wildcards are supported. (Optional) This parameter is displayed when you click ⊞.	-
Start Position	Start LSN of the data captured by a task	-
Start Txid	Start TXID of the data captured by a task	-

Parameter	Description	Example Value
Multi Partition	Whether to enable multi-partition mode for topics. If enabled, you need to set **Topic Table Mapping** and specify the number of topic partitions, and the data of a single table will be scattered in multiple partitions. (Optional) This parameter is displayed when you click ⊞. **NOTE** • The data receiving sequence cannot be ensured. Exercise caution when setting this parameter. • The default number of partitions is 5. To change the number of partitions, log in to FusionInsight Manager, choose **Cluster** > **Services** > **CDL**, click **Configurations**, search for **topics.max.partitions** in the search box, and change the value to the number of partitions to be changed. For example: Change the value to 10, save the configuration, and restart the CDL service. • In MRS 3.3.0 and later versions, if the source table is a partitioned table and this parameter is set to **No**, the number of topic partitioned tables created using CDL is the number of source table partitions plus 1.	No

Parameter	Description	Example Value
Topic Table Mapping	Mapping between topics and tables. If configured, table data can be sent to the specified topic. If multi-partitioning is enabled, you need to set the number of partitions, which must be greater than 1. In MRS 3.3.0 and later versions, when the time of the source data is earlier than the specified data filtering time, the data is discarded. When the time of the source data is later than the specified data filtering time, the data is sent to the downstream. This parameter is displayed when you click ⊞. This parameter is mandatory if **Connect With Hudi** is set to **Yes**.	testtable testtable_topic

Table 2-31 Source Hudi job parameters (MRS 3.2.0)

Parameter	Description	Example Value
Link	Link used by the Hudi app	hudilink
Interval	Interval for synchronizing the Hudi table, in seconds	10
Start Time	Start time for synchronizing tables	2022/03/16 11:40:52
Max Commit Number	Maximum number of commits that can be pulled from an incremental view at a time.	10

Parameter	Description	Example Value
Hudi Custom Config	Customized configuration related to Hudi.	-
Table Info	Detailed configuration information about the synchronization table. Hudi and DWS must have the same table names and field types.	{"table1": [{"source.database":"base1","source.tablename":"table1"}],"table2": [{"source.database":"base2","source.tablename":"table2"}],"table3": [{"source.database":"base3","source.tablename":"table3"}]}
Execution Env	Environment variable required for running the Hudi App. If no ENV is available, manually create one.	defaultEnv

Table 2-32 Source Hudi job parameters (MRS 3.3.0 and later versions)

Parameter	Description	Example Value
Link	Link used by the Hudi app	hudilink
Interval	Interval for synchronizing the Hudi table, in seconds	10
Data Filter Time	Data filtering time	2023/08/16 11:40:52
Max Commit Number	Maximum number of commits that can be pulled from an incremental view at a time.	10
Configuring Hudi Table Attributes	View for configuring attributes of the Hudi table. The value can be: ● Visual View ● JSON View	Visual View
Hudi Custom Config	Customized configuration related to Hudi.	-

Parameter	Description	Example Value
Table Info	Detailed configuration information about the synchronization table. Hudi and DWS must have the same table names and field types.	{"table1":[{"source.database":"base1","source.tablename":"table1"}],"table2":[{"source.database":"base2","source.tablename":"table2"}],"table3":[{"source.database":"base3","source.tablename":"table3"}]}
Table Info-Section Name	Label name of a single table. Only digits, letters, and underscores (_) are supported.	-
Table Info-Source DataBase	Name of the Hudi database to be synchronized	base1
Table Info-Source TableName	Name of the Hudi table to be synchronized	table1
Table Info-Target SchemaName	Schema name of the target database to which data is written	-
Table Info-Target TableName	Table name of the target database to which data is written	-
Table Info-Enable Sink Precombine	Whether to enable pre-combine for the target database. Currently, the pre-combine function can be enabled only when the target database is DWS. This function is used to overwrite existing data at the target when new pre-combine fields are more than the target pre-combine fields. If the new pre-combine fields are less than the target pre-combine fields, new data is discarded	Yes
Table Info-Custom Config	Hudi custom configuration	-

Parameter	Description	Example Value
Execution Env	Environment variable required for running the Hudi App. If no ENV is available, manually create one.	defaultEnv

Table 2-33 Source Kafka job parameters (Applicable only to MRS 3.2.0)

Parameter	Description	Example Value
Link	Created Kafka link	kafkalink

Table 2-34 thirdparty-kafka job parameters

Parameter	Description	Example Value
Link	Created thirdparty-kafka link	thirdparty-kafkalink
DB Name	Name of the database to be connected to. The name can contain only letters, digits, underscores (_), and hyphens (-), and must start with a letter.	opengaussdb
Schema	Schema of the database to be checked	oprngaussschema
Datastore Type	Type of the upper-layer source. Value options are as follows: • MRS 3.2.0: – opengauss – ogg – oracle – drs-avro-oracle • MRS 3.3.0 and later versions – drs-opengauss-json – ogg-oracle-avro – drs-oracle-json – drs-oracle-avro	• opengauss • drs-opengauss-json

Parameter	Description	Example Value
Avro Schema Topic	Schema topic used by OGG Kafka to store table schemas in JSON format. **NOTE** This parameter is available when **Datastore Type** is set to **ogg**.	ogg_topic
Source Topics	Source topics can contain letters, digits, and special characters (-,_). Topics must be separated by commas (,).	topic1
Tasks Max	Maximum number of tasks that can be created by a connector. For a connector of the database type, this parameter must be set to **1**.	10
Tolerance	Fault tolerance policy. ● **none**: indicates low tolerance and the Connector task will fail if an error occurs. ● **all**: indicates high tolerance and all failed records will be ignored if an error occurs.	all
Start Time (MRS 3.2.0)	Start time for synchronizing tables	2022/03/16 14:14:50
Data Filter Time (MRS 3.3.0 and later versions)	Start time of data filtering	2022/03/16 11:33:37
Kaka Message Format	Supported formats. The options are as follows: ● Debezium Json ● CDL Json **NOTE** ● Only MRS 3.3.0 and later versions support this parameter. ● This parameter is available only when **Datastore Type** is set to **drs-opengauss-json**.	CDL Json

Parameter	Description	Example Value
Multi Partition	Whether to enable multi-partitioning for topics. If it is enabled, you need to set **Topic Table Mapping** and specify the number of topic partitions, and the data of a single table will be scattered in multiple partitions. ● In MRS 3.2.0, if **Datastore Type** is set to **ogg** or **drs-avro-oracle** or **oracle**, the topic multi-partition function cannot be enabled. ● In MRS 3.3.0 and later versions, when **Datastore Type** is set to **ogg-oracle-avro** or **drs-oracle-avro** or **drs-oracle-json**, the topic multi-partition function cannot be enabled. **NOTE** The default number of partitions is 5. To change the number of partitions, log in to FusionInsight Manager, choose **Cluster** > **Services** > **CDL**, click **Configurations**, search for **topics.max.partitions** in the search box, and change the value to the number of partitions to be changed. For example: Change the value to 10, save the configuration, and restart the CDL service.	No

Parameter	Description	Example Value
Topic Table Mapping	Mapping between topics and tables. If configured, table data can be sent to the specified topic. If multi-partitioning is enabled, you need to set the number of partitions, which must be greater than 1. In MRS 3.3.0 and later versions, when the time of the source data is earlier than the specified data filtering time, the data is discarded. When the time of the source data is later than the specified data filtering time, the data is sent to the downstream.	testtable testtable_topic 2023/03/10 11:33:37 (MRS 3.3.0 and later versions)

Table 2-35 opengauss job parameters (applicable only to MRS 3.3.0 and later versions)

Parameter	Description	Example Value
Link	Created openGauss link	opengausslink
Tasks Max	Maximum number of tasks that can be created by the connector. The value is **1**.	1
Mode	Type of the CDC event to be captured by the job. Value options are as follows: • **insert** • **update** • **delete**	insert, update, and delete
dbName Alias	Database name.	test

Parameter	Description	Example Value
Slot Name	Name of the openGauss logical replication slot The value can contain lowercase letters and underscores (_), and cannot be the same in any other job.	test_solt
Slot Drop	Whether to delete the slot when a task is stopped	No
Connect With Hudi	Whether to connect to Hudi	Yes
WhiteList	Whitelisted tables that will be captured. Separate multiple tables using commas (,). Wildcards are supported.	testtable
Data Filter Time	Data filtering time	-

Parameter	Description	Example Value
Multi Partition	Whether to enable multi-partition mode for topics. If enabled, you need to set **Topic Table Mapping** and specify the number of topic partitions, and the data of a single table will be scattered in multiple partitions. **NOTE** • The data receiving sequence cannot be ensured if this function is enabled. Exercise caution when setting this parameter. • The default number of partitions is 5. To change the number of partitions, log in to FusionInsight Manager, choose **Cluster** > **Services** > **CDL**, click **Configurations**, search for **topics.max.partitions** in the search box, and change the value to the number of partitions to be changed. For example: Change the value to 10, save the configuration, and restart the CDL service.	No
Key Management Tool	Key management tool. Currently, only **his_kms** is supported.	his_kms
Key Environment Information	Key information This parameter is available only when **Key Management Tool** is configured.	-
Custom Config	Custom decoding configuration	-

Parameter	Description	Example Value
Topic Table Mapping	Mapping between topics and table. The format of the table name is *Schema name*.*Table name*. If configured, table data can be sent to the specified topic. If multi-partitioning is enabled, you need to set the number of partitions, which must be greater than 1. When the time of the source data is earlier than the specified data filtering time, the data is discarded. When the time of the source data is later than the specified data filtering time, the data is sent to the downstream. This parameter is mandatory if **Connect With Hudi** is set to **Yes**.	cdlschema.testtable testtable_topic 2023/03/10 11:33:37

Table 2-36 Sink Hudi job parameters

Parameter	Description	Example Value
Link	Created Hudi link.	hudilink
Path	Path for storing data.	/cdldata
Interval	Spark RDD execution interval, in seconds.	1
Max Rate Per Partition	Maximum rate for reading data from each Kafka partition using the Kafka direct stream API. It is the number of records per second. **0** indicates that the rate is not limited.	0
Parallelism	Parallelism for writing data to Hudi.	100

Parameter	Description	Example Value
Target Hive Database	Database of the target Hive	default
Configuring Hudi Table Attributes	View for configuring attributes of the Hudi table. The value can be: • Visual View • JSON View	Visual View
Global Configuration of Hudi Table Attributes	Global parameters on Hudi.	-
Configuring the Attributes of the Hudi Table	Configuration of the Hudi table attributes.	-
Configuring the Attributes of the Hudi Table: Table Name/ Source Table Name (MRS 3.3.0 and later versions)	Source table name	-
Configuring the Attributes of the Hudi Table: Table Type Opt Key	Hudi table type. The options are as follows: • COPY_ON_WRITE • MERGE_ON_READ	MERGE_ON_READ
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	Hudi table name. If this parameter is not set, the name of the Hudi table is the same as that of the source table by default.	-
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	Mapping between Hudi tables and Hive tables.	-
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	Primary key mapping of the Hudi table	id

Parameter	Description	Example Value
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	Mapping between the Hudi table and partition fields. If the Hudi table uses partitioned tables, you need to configure the mapping between the table name and partition fields. The value can be **time** or **customized**.	time
Configuring the Attributes of the Hudi Table: Custom Config	Custom configuration **NOTE** In MRS 3.3.0 and later versions, when data is synchronized from MySQL to Hudi, you need to specify the **hoodie.datasource.write.precombine.field** parameter. If the timestamp and datetime of MySQL support only second-level precision, do not specify fields of timestamp or datetime type, or **_hoodie_event_time** as the pre-combine field. This function is used to overwrite existing data at Hudi when new pre-combine fields are more than Hudi pre-combine fields. If the new pre-combine fields are less than Hudi pre-combine fields, new data is discarded.	-
Execution Env	Environment variable required for running the Hudi App. If no ENV is available, create one by referring to **Configuring CDL ENV Variables**.	defaultEnv

Table 2-37 Sink Kafka job parameters

Parameter	Description	Example Value
Link	Created Kafka link	kafkalink

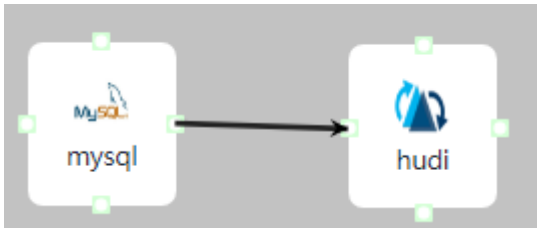
Table 2-38 DWS job parameters

Parameter	Description	Example Value
Link	Link used by Connector	dwslink
Query Timeout	Timeout interval for connecting to DWS, in milliseconds	180000
Batch Size	Amount of data batch written to DWS	50
Sink Task Number	Maximum number of concurrent jobs when a table is written to DWS.	-
DWS Custom Config	Custom configuration	-

Table 2-39 ClickHouse job parameters

Parameter	Description	Example Value
Link	Link used by Connector	clickhouselink
Query Timeout	Timeout interval for connecting to ClickHouse, in milliseconds	60000
Batch Size	Amount of data batch written to ClickHouse **NOTE** It is best practice to set this parameter to a large value. The recommended value range is 10000-100000.	100000

Step 4 After the job parameters are configured, drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 5 In the job list on the **Job Management** page, locate the created jobs, click **Start** in the **Operation** column, and wait until the jobs are started.

Check whether the data transmission takes effect, for example, insert data into the table in the MySQL database and view the content of the file imported to Hudi.

----End

2.5.2 Creating a CDL Data Comparison Job

Scenario

Data comparison checks the consistency between data in the source database and that in the target Hive. If the data is inconsistent, CDL can attempt to repair the inconsistent data.

The current data comparison task supports manual full comparison. The data comparison task runs in On Yarn mode, and the comparison result is uploaded to HDFS directories.

NOTE

- Currently, only basic data types can be compared. Special data types such as date, timestamp, decimal, numeric, and JSON cannot be compared.
- Data cannot be compared for tables whose field names contain database keywords.
- A data comparison task for a single table supports comparison of a maximum of 100 fields. If a table contains more than 100 fields, you can specify two whitelists of different comparison fields for data comparison.
- Currently, only the data captured from PgSQL to Hudi can be compared. If the comparison result is inconsistent, a report address is generated only when there are no more than 2000 inconsistent data records. If there are more than 2000 inconsistent data records, no report address is generated and data cannot be repaired.
- If the Kafka lag of the CDL task involved in the comparison is not 0, the comparison result is inconsistent.

Prerequisites

1. You have prepared the Hive UDF JAR package, copied **${BIGDATA_HOME}/FusionInsight_CDL_*/install/FusionInsight-CDL-*/cdl/hive-checksum/cdl-dc-hive-checksum-*.jar** from the CDL installation directory to the **${BIGDATA_HOME}/third_lib/Hive** directory of Hive, and set the permission on the JAR package to **750** or higher.

   ```
   [root@192-168-42-72 /opt/huawei/Bigdata/third_lib/Hive ]#ll
   total 16
   -rwxrwxrwx. 1 root root 4783 Mar  3 09:52 cdl-dc-hive-checksum-1.0-SNAPSHOT.jar
   -rwxrwxrwx. 1 root root 4628 Mar  2 17:13 cdl_md5_xor_v4-1.0.jar
   [root@192-168-42-72 /opt/huawei/Bigdata/third_lib/Hive ]#
   ```

2. A user with the CDL management permission has been created for the cluster with Kerberos authentication enabled.. If Ranger authentication is enabled for the current cluster, grant the Hive administrator permission and UDF operation permission to the user by referring to **Adding a Ranger Access Permission Policy for Hive**.
3. You have created a global UDF algorithm on the Hive client as a user with the Hive administrator permission.

   Run the following command to create the **CheckSum** function in the default database:

create function checksum_aggregate as 'com.huawei.hive.checksum.ChecksumUdaf'

4. A CDL synchronization task exists. The comparison task determines the data to be compared based on the synchronization task status and data synchronization status.
5. The database user in the data synchronization task associated with data comparison task must have the **create function** permission on the current schema.

Procedure

Step 1 Log in to the CDLService web UI as the created user user (for the cluster where Kerberos authentication is not enabled). For details, see **Logging In to the CDLService WebUI**.

Step 2 Choose **Job Management** > **Data comparison task** and click **Add Job**. In the displayed dialog box, set related job parameters and click **Next**.

Parameter	Description	Example
Name	Name of the data comparison task.	job_dc_test
CDL Job Name	Name of the associated synchronization task. (Note: The user who runs the comparison task is the user of the Hudi Link in the associated synchronization task.)	pg2hudi_test
Execution Env	Environment variable required for running Spark tasks. If no ENV is available, create one by referring to **Configuring CDL ENV Variables**.	dc_env
Desc	Description of the task.	-

Step 3 On the **Create Compare-Pair** page, set related parameters and click **Create**.

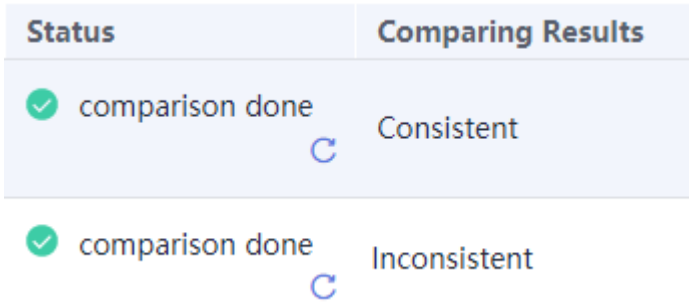
Parameter	Description	Example

Name	Name of the current comparison task.	test
Source Table	Source table name.	tabletest
Target Table	Target table name.	tabletest
WhiteList Columns	Column family involved in data comparison.	-
BlackList Columns	Column family not involved in data comparison.	-
Where Condition	User-defined comparison conditions.	-

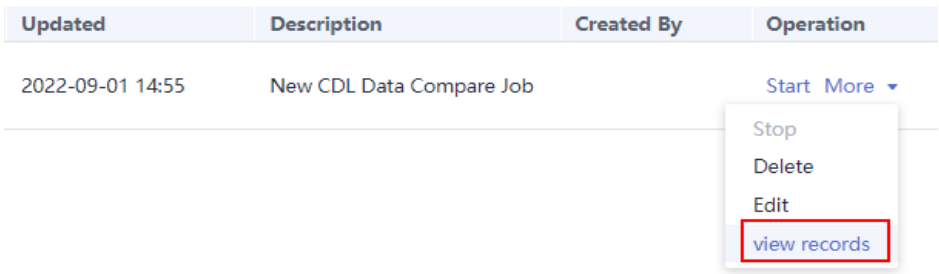
To compare multiple tables, click **Add**.

Step 4 In the data comparison task list, click **Start** in the row of the task to start data comparison.

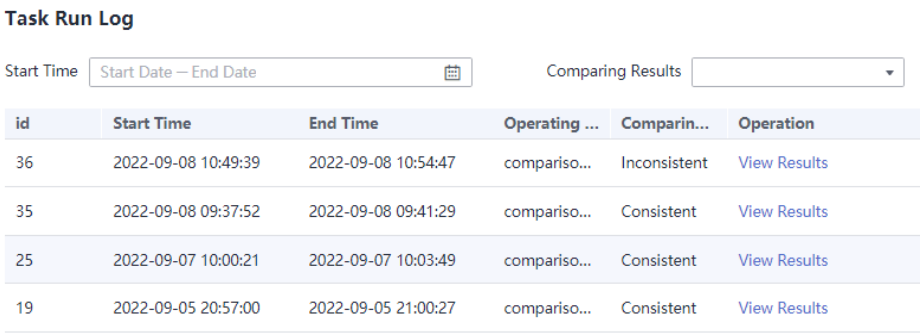
Step 5 After the execution is complete, view the result in the **Comparing Result** column.



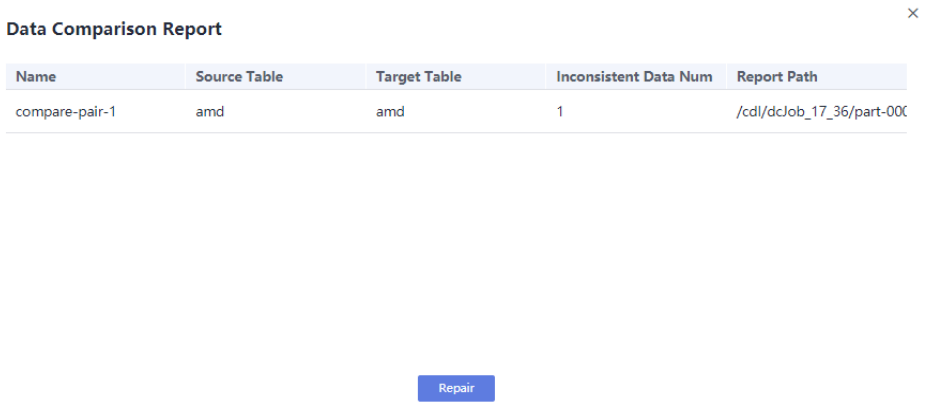
Step 6 If the result is **Inconsistent**, click **More** and select **view records**.



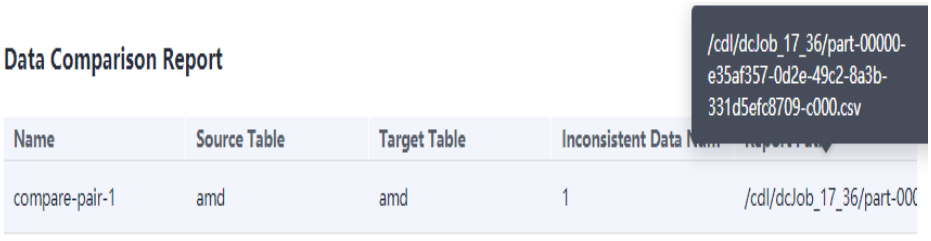
Step 7 In the **Task Run Log** window, locate the target task and click **View Results** in the **Operation** column.



Step 8 Click **Repair** to repair the data.



Step 9 After the repair is complete, check whether the value of **Comparing Result** is **Consistent**. If yes, data repair is successful. If not, the repair fails. In this case, obtain the report from the corresponding HDFS directory based on the value of **Report Path** and manually repair the data.



----End

2.5.3 Synchronizing Data from PgSQL to Kafka Using CDL

Scenario

This section describes how to import data from PgSQL to Kafka by using the CDLService web UI of a cluster with Kerberos authentication enabled in MRS 3.2.0.

Prerequisites

- The CDL and Kafka services have been installed in a cluster and are running properly.
- Write-ahead logging is enabled for the PostgreSQL database. For details, see **Policy for Modifying Write-Ahead Logs in PostgreSQL Databases**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, and **kafka**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon the first login) and choose **Cluster** > **Services** > **CDL**. On the **Dashboard** page, click the hyperlink next to **CDLService UI** to go to the native CDL page.

Step 2 Choose **Link Management** and click **Add Link**. On the displayed dialog box, set parameters for adding the **pgsql** and **kafka** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-40 PgSQL data link parameters

Parameter	Example Value
Link Type	pgsql
Name	pgsqllink
Host	10.10.10.10
Port	5432
DB Name	testDB
User	user
Password	*Password of the user user*
Description	-

Table 2-41 Kafka data link parameters

Parameter	Example Value
Link Type	kafka
Name	kafkalink
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 On the **Job Management** page, click **Add Job**. In the displayed dialog box, configure the parameters and click **Next**.

Specifically:

Parameter	Example Value
Name	job_pgsqltokafka
Desc	xxx

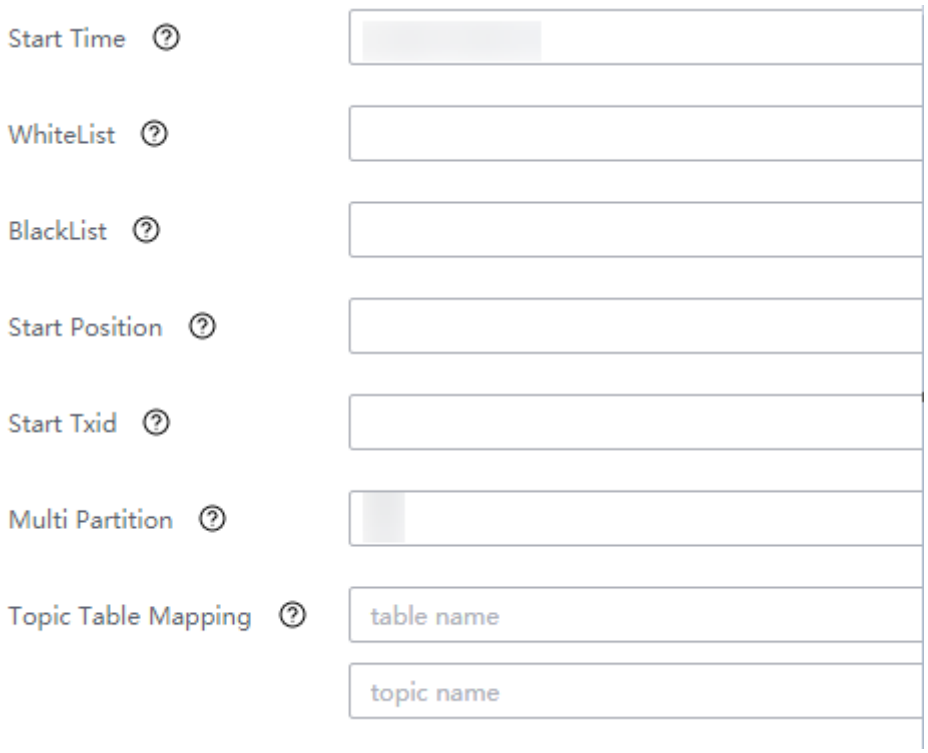
Step 5 Configure PgSQL job parameters.

1. On the **Job Management** page, drag the **pgsql** icon on the left to the editing area on the right and double-click the icon to go to the PgSQL job configuration page. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

   Table 2-42 PgSQL job parameters

Parameter	Example Value
Link	pgsqllink
Tasks Max	1
Mode	insert, update, and delete
Schema	public
dbName Alias	cdc
Slot Name	test_slot
Slot Drop	No
Connect With Hudi	No
Use Exist Publication	Yes
Publication Name	test

2. Click the plus sign (+) to display more parameters.



NOTE

- **WhiteList**: Enter the name of the table in the database, for example, **myclass**.
- **Topic Table Mapping**: In the first text box, enter a topic name (the value must be different from that of **Name** in **Step 4**), for example, **myclass_topic**. In the second text box, enter a table name, for example, **myclass**. The value must be in one-to-one relationship with the topic name entered in the first text box.)

3. Click **OK**. The PgSQL job parameters are configured.

Step 6 Configure Kafka job parameters.

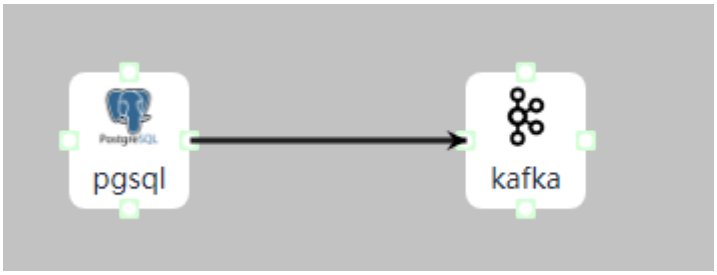
1. On the **Job Management** page, drag the **kafka** icon on the left to the editing area on the right and double-click the icon to go to the Kafka job configuration page. Configure parameters based on **Table 2-43**.

Table 2-43 Kafka job parameter

Parameter	Example Value
Link	kafkalink

2. Click **OK**.

Step 7 After the job parameters are configured, drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 8 In the job list on the **Job Management** page, locate the created jobs, click **Start** in the **Operation** column, and wait until the jobs are started.

Check whether the data transmission takes effect. For example, insert data into the table in the PgSQL database, go to the Kafka UI to check whether data is generated in the Kafka topic by referring to **Viewing Kafka Data Production and Consumption Details**.

----End

2.5.4 Synchronizing Data from PgSQL to Hudi Using CDL

Scenario

This section describes how to import data from PgSQL to Hudi by using the CDLService web UI of a cluster with Kerberos authentication enabled in MRS 3.2.0.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.
- The prerequisites for the PgSQL database have been met. For details, see **Policy for Modifying Write-Ahead Logs in PostgreSQL Databases**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

Step 2 Choose **Link Management** and click **Add Link**. In the displayed dialog box, set parameters for adding the **pgsql** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-44 PgSQL data link parameters

Parameter	Example
Link Type	pgsql

Parameter	Example
Name	pgsqllink
Host	10.10.10.10
Port	5432
DB Name	testDB
User	user
Password	*Password of the **user** user*
Description	-

Table 2-45 Hudi data link parameters

Parameter	Example
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	xxx

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-46 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1

Parameter	Example Value
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters and click **Next**.

Parameters are as follows.

Parameter	Example
Name	job_pgtohudi
Desc	-

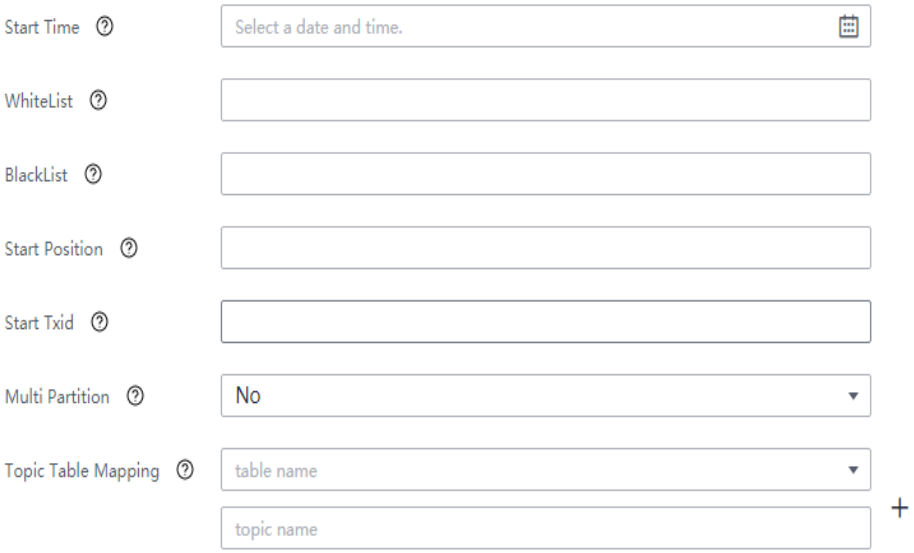
Step 6 Configure PgSQL job parameters.

1. On the **Job Management** page, drag the **pgsql** icon on the left to the editing area on the right and double-click the icon to go to the PgSQL job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

   Table 2-47 PgSQL job parameters

Parameter	Example
Link	pgsqllink
Tasks Max	1
Mode	insert, update, and delete
dbName Alias	pgsqldb
Schema	pgschema
Slot Name	pg_slot
Enable FailOver Slot	No
Slot Drop	No
Connect With Hudi	Yes
Use Exist Publication	No
Publication Name	publicationtest

2. Click the plus sign (+) to display more parameters.



NOTE

- **Start Time**: indicates the start time of table synchronization.
- **WhiteList**: Enter a table in the database.
- **Blacklist**: Enter the database table that does not need to capture data.
- **Topic Table Mapping**
  - This parameter is mandatory if **Connect With Hudi** is set to **Yes**.
  - Enter the table name in the first text box, for example, **test**. Enter a topic name in the second text box, for example, **test_topic**. The topic name must match the table name in the first text box.

3. Click **OK**. The PgSQL job parameters are configured.

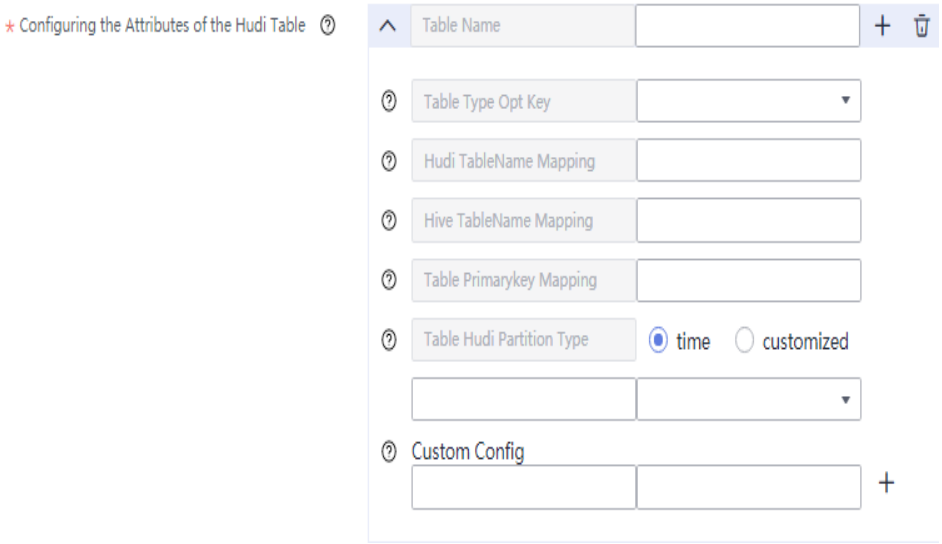
Step 7 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Sink area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

Table 2-48 Sink Hudi job parameters

Parameter	Example Value
Link	hudilink
Path	/cdl/test
Interval	10
Max Rate Per Partition	0
Parallelism	10
Target Hive Database	default

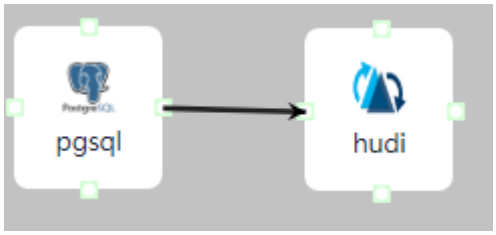
Parameter	Example Value
Configuring Hudi Table Attributes	Visual View
Global Configuration of Hudi Table Attributes	-
Configuring the Attributes of the Hudi Table: Table Name	test
Configuring the Attributes of the Hudi Table: Table Type Opt Key	COPY_ON_WRITE
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	-
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	-
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	id
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	-
Configuring the Attributes of the Hudi Table: Custom Config	-



2. (Optional) Click the plus sign (+) to display the **Execution Env** parameter. Select a created environment for it. The default value is **defaultEnv**.

3. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the table in the PgSQL database and view the content of the file imported to Hudi.

----End

2.5.5 Synchronizing Data from openGauss to Hudi Using CDL

Scenario

Import data from OpenGauss to Hudi on the CDLService web UI of a cluster with Kerberos authentication enabled.

This section applies to MRS 3.3.0 and later versions.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.
- The write-ahead log function has been enabled for the OpenGauss database by referring to **Enabling the Write-Ahead Log Function for the OpenGauss Database**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

Step 2 Choose **Link Management** and click **Add Link**. On the displayed dialog box, set parameters for adding the **opengauss** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-49 OpenGauss data link parameters

Parameter	Example
Link Type	opengauss
Name	opengausslink
Host	100.85.xxx.xxx
Port	8000
DB Name	opengaussdb
User	opengaussuser
Password	*opengauss user password*
Description	-

Table 2-50 Hudi data link parameters

Parameter	Example
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	xxx

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-51 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB

Parameter	Example Value
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters. Click **Next**.

The following table shows the job parameters.

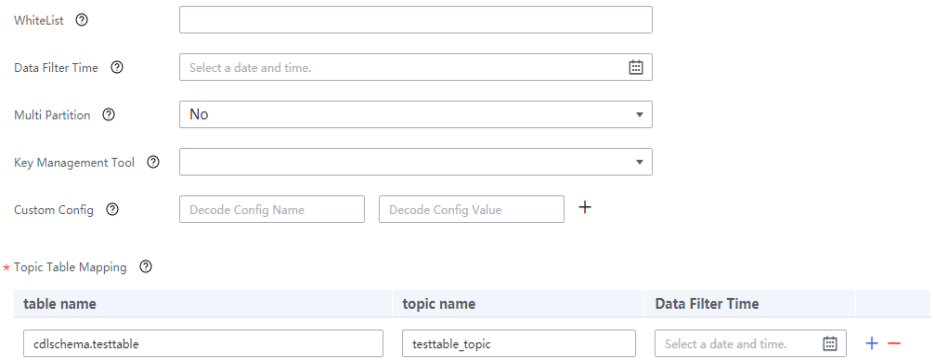
Parameter	Example
Name	job_opengaustohudi
Desc	-

Step 6 Configure OpenGauss job parameters.

1. On the **Job Management** page, drag the **opengauss** icon on the left to the editing area on the right and double-click the icon to go to the OpenGauss job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

   Table 2-52 OpenGauss job parameters

Parameter	Example
Link	opengausslink
Tasks Max	1
Mode	**insert**, **update**, and **delete**
dbName Alias	opengaussdb
Slot Name	oct_twenty_two
Slot Drop	No
Connect With Hudi	Yes
Topic Table Mapping	cdlschema.testtable/testtable_topic



2. Click **OK**. The OpenGauss job parameters are configured.

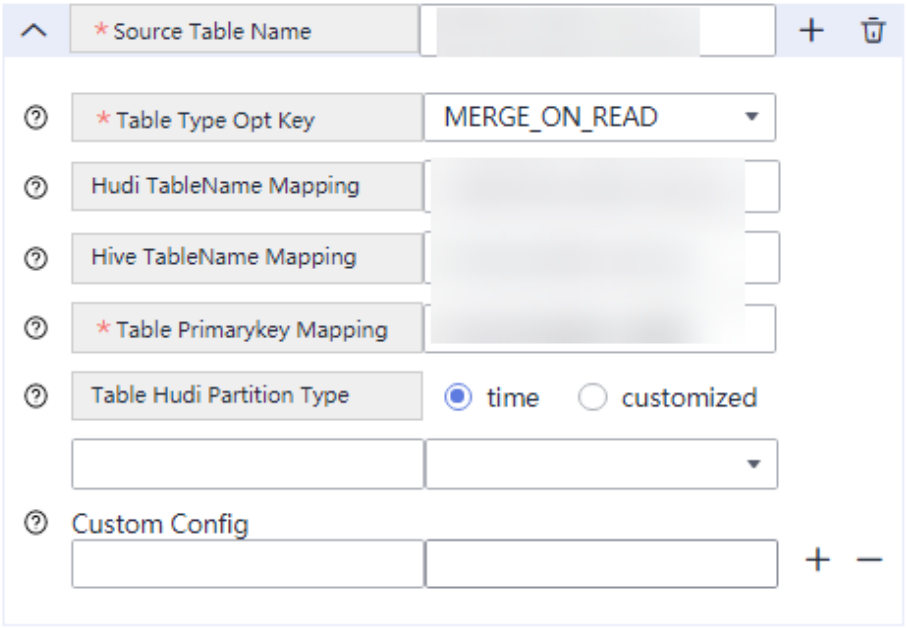
Step 7 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Sink area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

Table 2-53 Sink Hudi job parameters

Parameter	Example
Link	hudilink
Path	/cdl/test
Interval	5
Max Rate Per Partition	0
Parallelism	10
Configuring Hudi Table Attributes	Visual View
Global Configuration of Hudi Table Attributes	-
Configuring the Attributes of the Hudi Table: Source Table Name	cdlschema.testtable
Configuring the Attributes of the Hudi Table: Table Type Opt Key	MERGE_ON_READ
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	**testtable** or **/cdlschema/testtable**
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	cdlschema.testtable

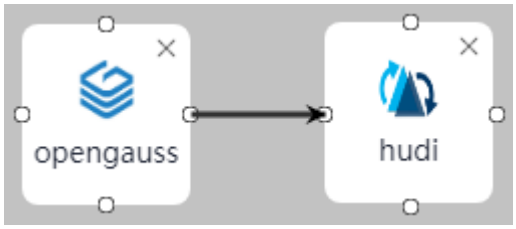
Parameter	Example
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	so_line_id,order_number
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	time
Configuring the Attributes of the Hudi Table: Custom Config	-



2. (Optional) Select the created ENV. The default value is **defaultEnv**.

3. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the table in the OpenGauss database and view the content of the file imported to Hudi.

----End

2.5.6 Synchronizing Data from Hudi to DWS Using CDL

Scenario

This section describes how to import data from Hudi to DWS by using the CDLService web UI of a cluster with Kerberos authentication enabled in MRS 3.2.0.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.
- The prerequisites for the DWS database have been met. For details, see **Prerequisites for the DWS database**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

Step 2 Choose **Link Management** and click **Add Link**. In the displayed dialog box, set parameters for adding the **dws** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-54 DWS data link parameters

Parameter	Example
Link Type	dws
Name	dwstest
Host	10.10.10.10
Port	8000
DB Name	dwsdb
User	dbuser
Password	*Password of the **dbuser** user*
Description	-

Table 2-55 Hudi data link parameters

Parameter	Example
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	xxx

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-56 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters and click **Next**.

Parameters are as follows.

Parameter	Example
Name	job_huditodws

Parameter	Example
Desc	-

Step 6 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Source area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

   Table 2-57 Source Hudi job parameters

Parameter	Example
Link	hudilink
Interval	10
Table Info	{"table1":[{"source.database":"dwsdb","source.tablename":"tabletest","target.tablename":"tabletest"}]}

2. Click **OK**. The Hudi job parameters are configured.

Step 7 Configure DWS job parameters.

1. On the **Job Management** page, drag the **dws** icon on the left to the editing area on the right and double-click the icon to go to the DWS job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

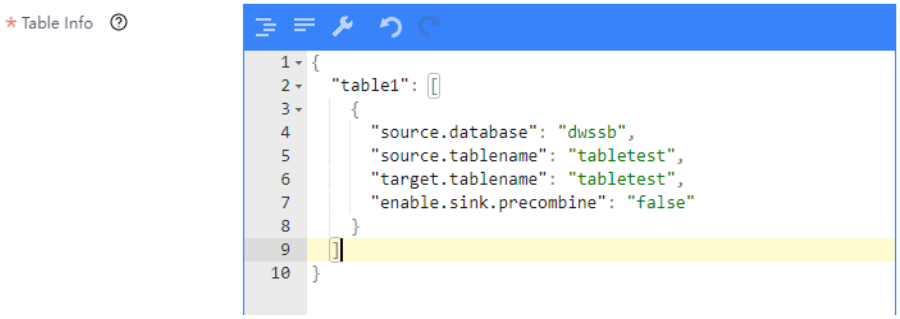
   Table 2-58 DWS job parameters

Parameter	Example
Link	dwstest

Parameter	Example
Query Timeout	180000
Batch Size	10

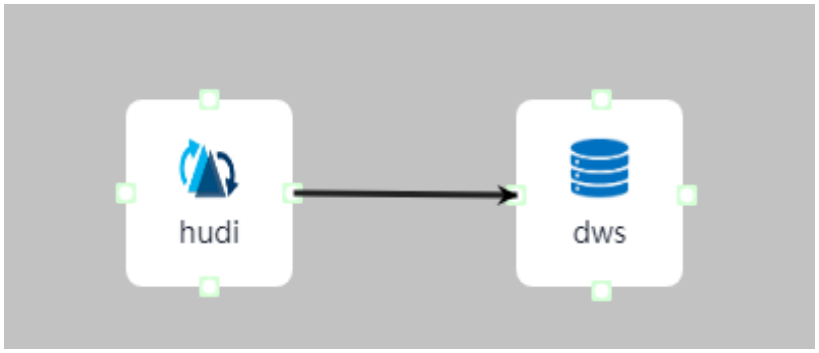
NOTE

- Data can be synchronized from Hudi to GaussDB(DWS) only when both Hudi and GaussDB(DWS) contain the **precombine** field.
- GaussDB(DWS) tables must contain the **precombine** field and the primary key.
- By default, the Hudi built-in field **_hoodie_event_time** is used. If this field is not used, **enable.sink.precombine** must be specified. An example is as follows:



2. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the Hudi table and view the content of the file imported to DWS.

----End

2.5.7 Synchronizing Data from Hudi to ClickHouse Using CDL

Scenario

This section describes how to import data from Hudi to ClickHouse by using the CDLService web UI of a cluster with Kerberos authentication enabled in MRS 3.2.0.

Prerequisites

- The CDL, Hudi, and ClickHouse services have been installed in a cluster and are running properly.
- You have operation permissions on ClickHouse. For details, see **Creating a ClickHouse Role**.
- You have created a human-machine user with the ClickHouse administrator permissions (for details, see **Creating a ClickHouse Role**), for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.
- You have manually created a local table and distributed table on ClickHouse. The local table uses the ReplicatedReplacingMergeTree engine. For details, see **ClickHouse Client Practices**.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

Step 2 Choose **Link Management** and click **Add Link**. In the displayed dialog box, set parameters for adding the **clickhouse** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-59 ClickHouse data link parameters

Parameter	Example
Link Type	clickhouse
Name	cklink
Host	10.10.10.10:21428
User	*cdluser*
Password	*Password of the **cdluser** user*
Description	-

Table 2-60 Hudi data link parameters

Parameter	Example
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-61 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters and click **Next**.

Parameters are as follows.

Parameter	Example
Name	job_huditock

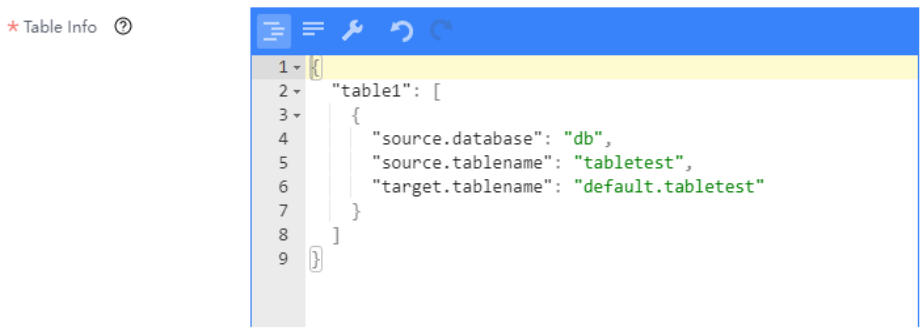
Parameter	Example
Desc	-

Step 6 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Source area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

   Table 2-62 Source Hudi job parameters

Parameter	Example
Link	hudilink
Interval	10
Table Info	{"table1":[{"source.database":"db","source.tablename":"tabletest","target.tablename":"default.tabletest"}]} **NOTE** You do not need to configure the fields provided by Hudi. You only need to configure the service fields that need to be synchronized to ClickHouse.



2. Click **OK**. The Hudi job parameters are configured.

Step 7 Configure ClickHouse job parameters.

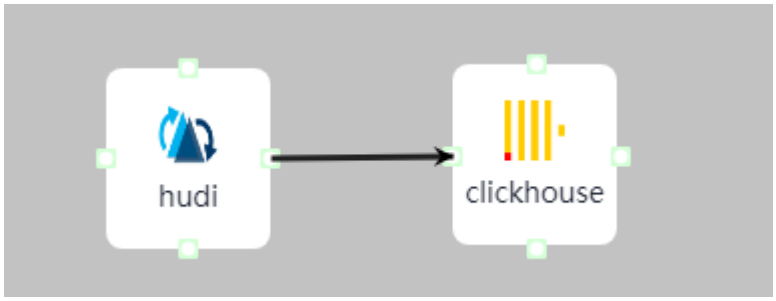
1. On the **Job Management** page, drag the **clickhouse** icon on the left to the editing area on the right and double-click the icon to go to the ClickHouse job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

Table 2-63 ClickHouse job parameters

Parameter	Example
Link	cklink
Query Timeout	60000
Batch Size	100

2. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the Hudi table and view the content of the file imported to ClickHouse.

----End

2.5.8 Synchronizing openGauss Data to Hudi Using CDL (ThirdKafka)

Scenario

This section describes how to import openGauss data from ThirdKafka to Hudi by using the CDLService web UI of a cluster with Kerberos authentication enabled in MRS 3.2.0.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.

- Topics of the ThirdKafka database can be consumed by the MRS cluster. For details, see **Prerequisites for ThirdPartyKafka**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

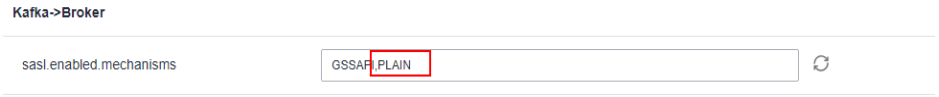
Step 2 Choose **Link Management** and click **Add Link**. In the displayed dialog box, set parameters for adding the **thirdparty-kafka** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-64 thirdparty-kafka data link parameters

Parameter	Example
Name	opengausslink
Link Type	thirdparty-kafka
Bootstrap Servers	10.10.10.10:9093
Security Protocol	SASL_SSL
Username	testuser
Password	*Password of the **testuser** user*
SSL Truststore Location	Click **Upload** to upload the authentication file.
SSL Truststore Password	-
Datastore Type	opengauss
Host	11.11.xxx.xxx,12.12.xxx.xxx
Port	8000
DB Name	opengaussdb
User	opengaussuser
DB Password	*Password of the **opengaussuser** user*
Description	-

NOTE

MRS Kafka can also be used as the source of thirdparty-kafka. If the username and password are used for login authentication, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Configuration**, search for the **sasl.enabled.mechanisms** parameter in the search box, add **PLAIN** as the parameter value, click **Save** to save the configuration, and restart the Kafka service for the configuration to take effect.



On the CDL web UI, configure the thirdparty-kafka link that uses MRS Kafka as the source. For example, the data link configuration is as follows:

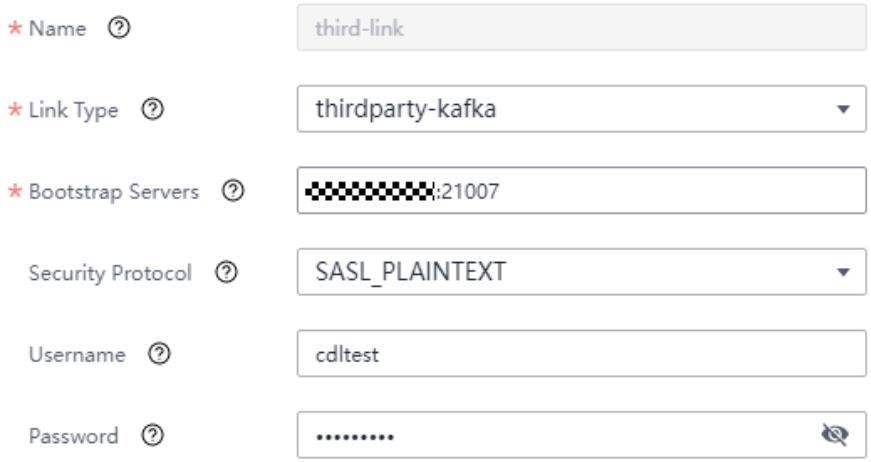


Table 2-65 Hudi data link parameters

Parameter	Example
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-66 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters and click **Next**.

Parameters are as follows.

Parameter	Example
Name	job_opengausstohudi
Desc	New CDL Job

Step 6 Configure ThirdKafka job parameters.

1. On the **Job Management** page, drag the **thirdparty-kafka** icon on the left to the editing area on the right and double-click the icon to go to the ThirdpartyKafka job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

   Table 2-67 thirdparty-kafka job parameters

Parameter	Example
Link	opengausslink
DB Name	opengaussdb
Schema	opengausssschema
Datastore Type	opengauss
Source Topics	source_topic
Tasks Max	1

Parameter	Example
Tolerance	none
Start Time	-
Multi Partition	No
Topic Table Mapping	test/hudi_topic

2. Click **OK**. The ThirdpartyKafka job parameters are configured.

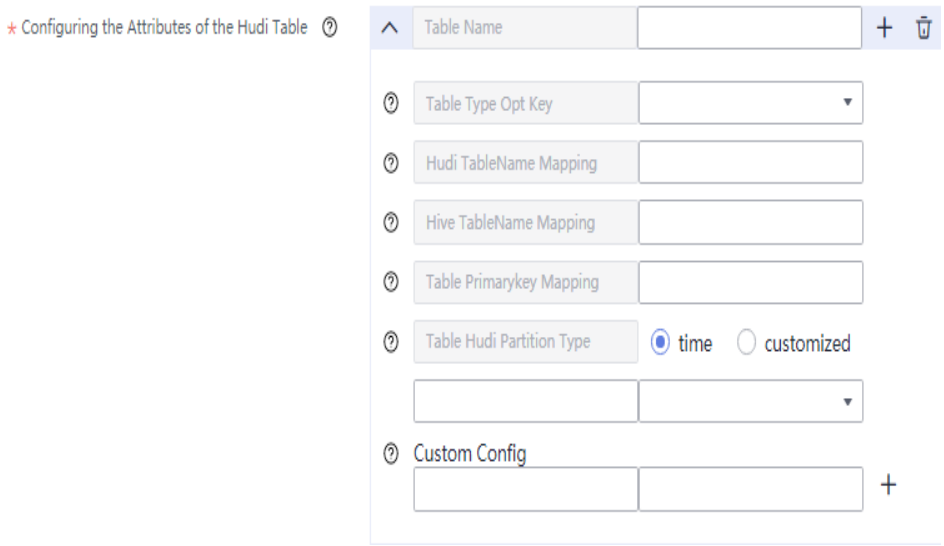
Step 7 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Sink area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Configure parameters based on the following table. For details about job parameters, see **Creating a CDL Data Synchronization Job**.

Table 2-68 Sink Hudi job parameters

Parameter	Example Value
Link	hudilink
Path	/cdl/test
Interval	10
Max Rate Per Partition	0
Parallelism	10
Target Hive Database	default
Configuring Hudi Table Attributes	Visual View
Global Configuration of Hudi Table Attributes	-

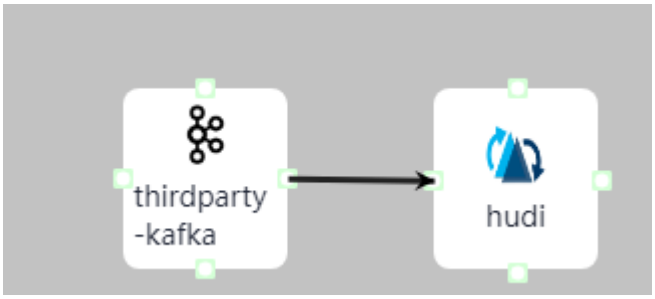
Parameter	Example Value
Configuring the Attributes of the Hudi Table: Table Name	test
Configuring the Attributes of the Hudi Table: Table Type Opt Key	COPY_ON_WRITE
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	-
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	-
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	id
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	-
Configuring the Attributes of the Hudi Table: Custom Config	-



2. (Optional) Click the plus sign (+) to display the **Execution Env** parameter. Select a created environment for it. The default value is **defaultEnv**.

3. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the table in the openGauss database and view the content of the file imported to Hudi.

----End

2.5.9 Synchronizing drs-oracle-json Database to Hudi Using CDL (ThirdKafka)

Scenario

Import Oracle database data from ThirdKafka to Hudi on the CDLService web UI of a cluster with Kerberos authentication enabled.

This section applies to MRS 3.3.0 or later.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.
- Topics of the ThirdKafka database can be consumed by the MRS cluster. For details, see **Prerequisites for ThirdPartyKafka**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

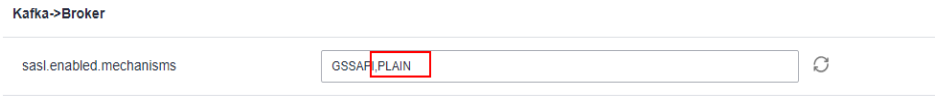
Step 2 Choose **Link Management** and click **Add Link**. On the displayed dialog box, set parameters for adding the **thirdparty-kafka** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-69 thirdparty-kafka data link parameters

Parameter	Example Value
Name	oraclelink
Link Type	thirdparty-kafka
Bootstrap Servers	10.10.10.10:9093
Security Protocol	SASL_SSL
Username	testuser
Password	*Password of the **testuser** user*
SSL Truststore Location	Click **Upload** to upload the authentication file.
SSL Truststore Password	-
Datastore Type	drs-oracle-json
Description	thirdparty-kafka Link

NOTE

MRS Kafka can also be used as the source of thirdparty-kafka. If the username and password are used for login authentication, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Configurations**, search for the **sasl.enabled.mechanisms** parameter in the search box, add **PLAIN** as the parameter value, click **Save** to save the configuration, and restart the Kafka service for the configuration to take effect.



On the CDL web UI, configure the thirdparty-kafka link that uses MRS Kafka as the source. For example, the data link configuration is as follows:

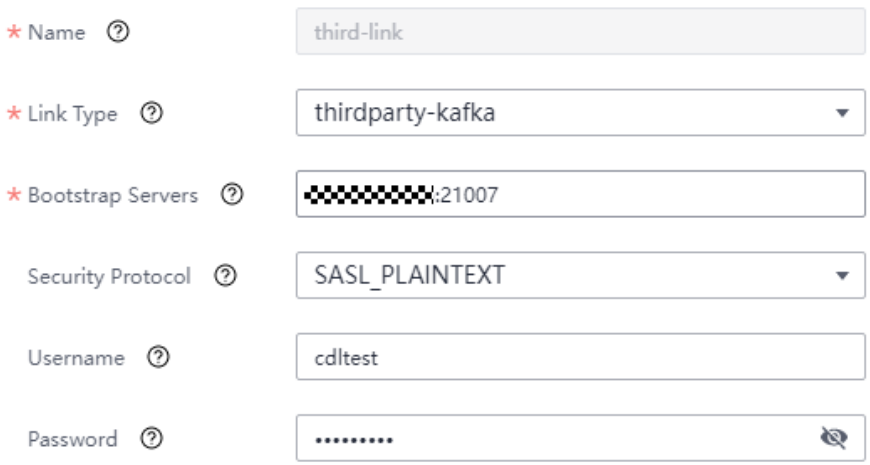


Table 2-70 Hudi data link parameters

Parameter	Example Value
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-71 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters. Click **Next**.

Specifically:

Parameter	Example Value
Name	job_oracletohudi

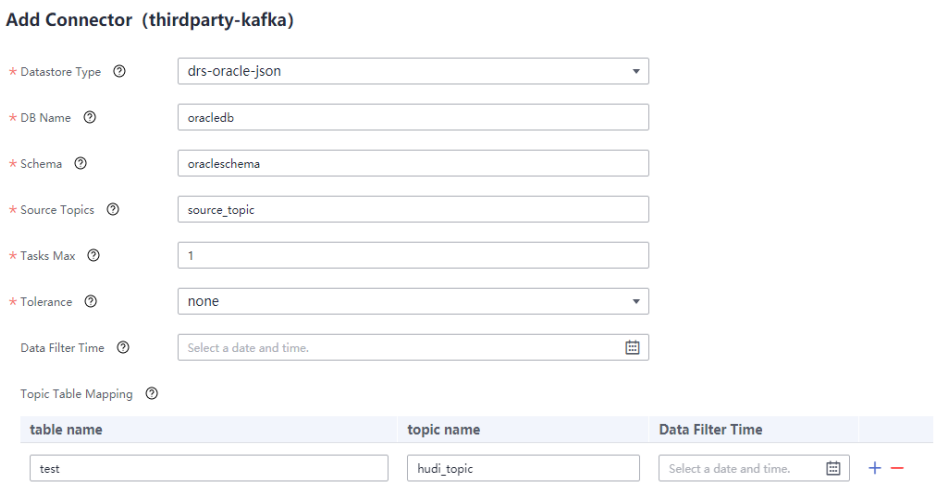
Parameter	Example Value
Desc	New CDL Job

Step 6 Configure ThirdKafka job parameters.

1. On the **Job Management** page, drag the **thirdparty-kafka** icon on the left to the editing area on the right and double-click the icon to go to the ThirdpartyKafka job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

   Table 2-72 thirdparty-kafka job parameters

Parameter	Example Value
Link	oraclelink
DB Name	oracledb
Schema	oracleschema
Datastore Type	drs-oracle-json
Source Topics	source_topic
Tasks Max	1
Tolerance	none
Data Filter Time	-
Topic Table Mapping	test/hudi_topic



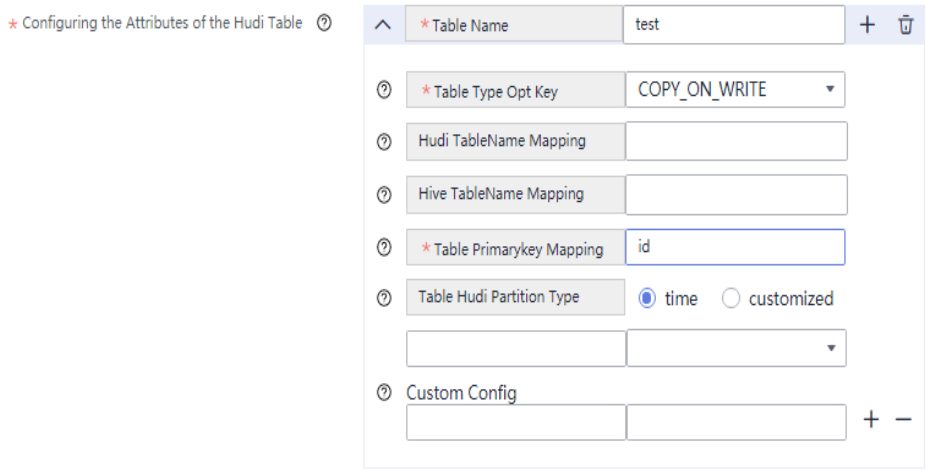
2. Click **OK**. The ThirdpartyKafka job parameters are configured.

Step 7 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Sink area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

   Table 2-73 Sink Hudi job parameters

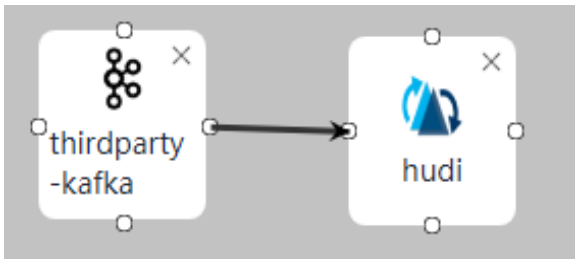
Parameter	Example Value
Link	hudilink
Path	/cdl/test
Interval	10
Max Rate Per Partition	0
Parallelism	10
Target Hive Database	default
Configuring Hudi Table Attributes	Visual View
Global Configuration of Hudi Table Attributes	-
Configuring the Attributes of the Hudi Table: Table Name	test
Configuring the Attributes of the Hudi Table: Table Type Opt Key	COPY_ON_WRITE
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	-
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	-
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	id
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	-
Configuring the Attributes of the Hudi Table: Custom Config	-



2. (Optional) Click the plus sign (+) to display the **Execution Env** parameter. Select a created environment for it. The default value is **defaultEnv**.

3. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the table in the Oracle database and view the content of the file imported to Hudi.

----End

2.5.10 Synchronizing drs-oracle-avro Database to Hudi Using CDL (ThirdKafka)

Scenario

Import drs-avro-oracle database data from ThirdKafka to Hudi on the CDLService web UI of a cluster with Kerberos authentication enabled.

This section applies to MRS 3.3.0 or later.

Prerequisites

- The CDL and Hudi services have been installed in a cluster and are running properly.
- Topics of the ThirdKafka database can be consumed by the MRS cluster. For details, see **Prerequisites for ThirdPartyKafka**.
- You have created a human-machine user, for example, **cdluser**, added the user to user groups **cdladmin** (primary group), **hadoop**, **kafka**, and **supergroup**, and associated the user with the **System_administrator** role on FusionInsight Manager.

Procedure

Step 1 Log in to FusionInsight Manager as user **cdluser** (change the password upon your first login), choose **Cluster** > **Services** > **CDL**, and click the link next to **CDLService UI** to go to the CDLService web UI.

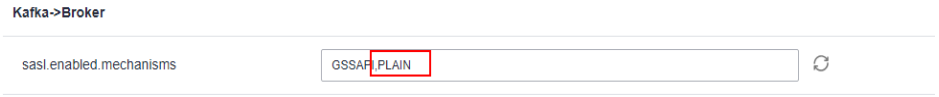
Step 2 Choose **Link Management** and click **Add Link**. On the displayed dialog box, set parameters for adding the **thirdparty-kafka** and **hudi** links by referring to the following tables. **Creating a CDL Database Connection** describes the data link parameters.

Table 2-74 thirdparty-kafka data link parameters

Parameter	Example Value
Name	drs_avro_oracle_link
Link Type	thirdparty-kafka
Bootstrap Servers	10.10.10.10:9093
Security Protocol	SASL_SSL
Username	testuser
Password	*Password of the **testuser** user*
SSL Truststore Location	Click **Upload** to upload the authentication file.
SSL Truststore Password	-
Datastore Type	drs-oracle-avro
Description	thirdparty-kafka Link

NOTE

MRS Kafka can also be used as the source of thirdparty-kafka. If the username and password are used for login authentication, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Configurations**, search for the **sasl.enabled.mechanisms** parameter in the search box, add **PLAIN** as the parameter value, click **Save** to save the configuration, and restart the Kafka service for the configuration to take effect.



On the CDL web UI, configure the thirdparty-kafka link that uses MRS Kafka as the source. For example, the data link configuration is as follows:

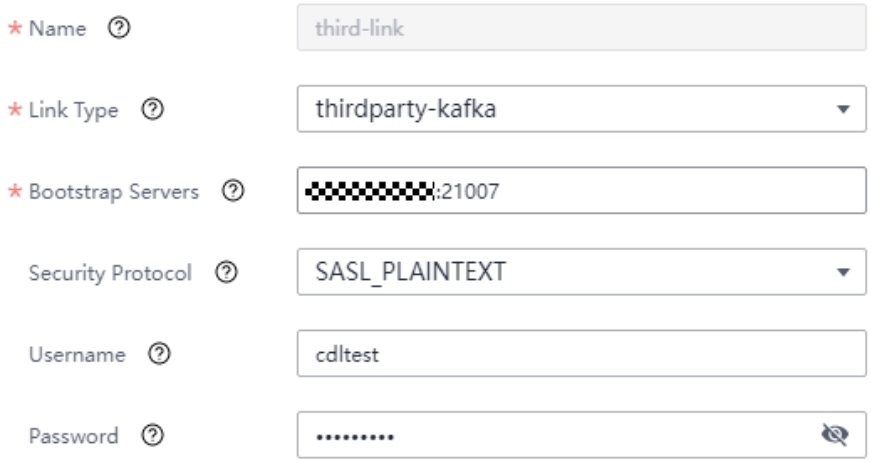


Table 2-75 Hudi data link parameters

Parameter	Example Value
Link Type	hudi
Name	hudilink
Storage Type	hdfs
Auth KeytabFile	/opt/Bigdata/third_lib/CDL/user_libs/cdluser.keytab
Principal	cdluser
Description	-

Step 3 After the parameters are configured, click **Test** to check whether the data link is normal.

After the test is successful, click **OK**.

Step 4 (Optional) Choose **ENV Management** and click **Add Env**. In the displayed dialog box, configure the parameters based on the following table.

Table 2-76 Parameters for adding an ENV

Parameter	Example Value
Name	test-env
Driver Memory	1 GB
Type	spark
Executor Memory	1 GB
Executor Cores	1
Number Executors	1
Queue	-
Description	-

Click **OK**.

Step 5 Choose **Job Management** > **Data synchronization task** and click **Add Job**. In the displayed dialog box, set parameters. Click **Next**.

Specifically:

Parameter	Example Value
Name	job_avro_oracletohudi
Desc	New CDL Job

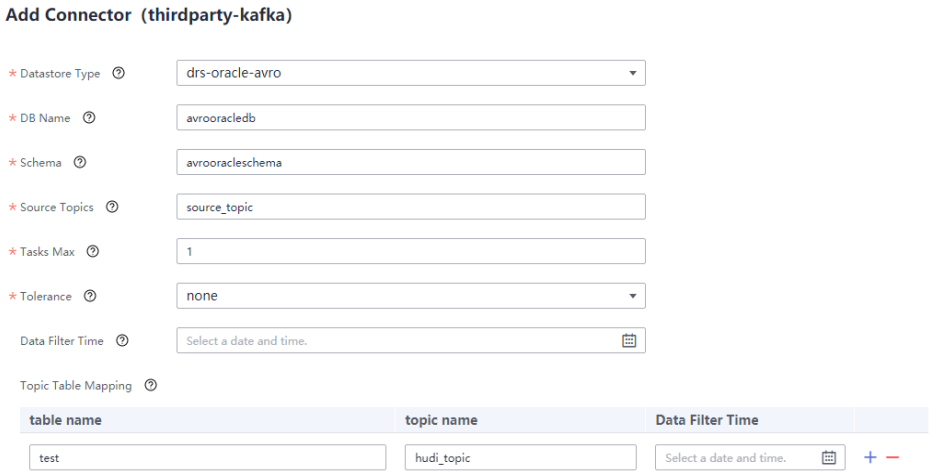
Step 6 Configure ThirdKafka job parameters.

1. On the **Job Management** page, drag the **thirdparty-kafka** icon on the left to the editing area on the right and double-click the icon to go to the ThirdpartyKafka job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

   Table 2-77 thirdparty-kafka job parameters

Parameter	Example Value
Link	job_avro_oracletohudi
DB Name	avrooracledb
Schema	avrooracleschema
Datastore Type	drs-oracle-avro
Source Topics	source_topic
Tasks Max	1

Parameter	Example Value
Tolerance	none
Data Filter Time	-
Topic Table Mapping	test/hudi_topic



2. Click **OK**. The ThirdpartyKafka job parameters are configured.

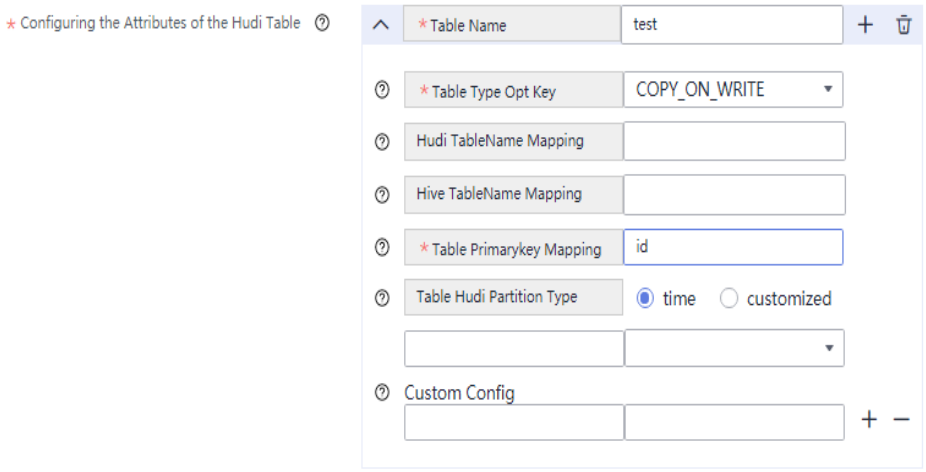
Step 7 Configure Hudi job parameters.

1. On the **Job Management** page, drag the **hudi** icon in the Sink area on the left to the editing area on the right and double-click the icon to go to the Hudi job configuration page. Set parameters by referring to the following table. **Creating a CDL Data Synchronization Job** describes the job parameters.

Table 2-78 Sink Hudi job parameters

Parameter	Example Value
Link	hudilink
Path	/cdl/test
Interval	10
Max Rate Per Partition	0
Parallelism	10
Target Hive Database	default
Configuring Hudi Table Attributes	Visual View
Global Configuration of Hudi Table Attributes	-

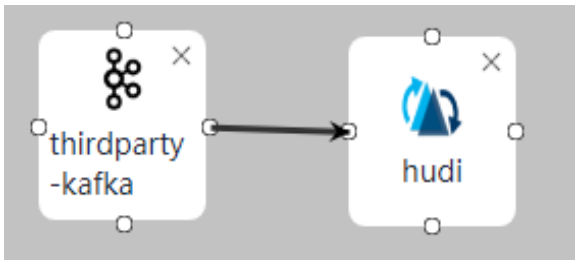
Parameter	Example Value
Configuring the Attributes of the Hudi Table: Table Name	test
Configuring the Attributes of the Hudi Table: Table Type Opt Key	COPY_ON_WRITE
Configuring the Attributes of the Hudi Table: Hudi TableName Mapping	-
Configuring the Attributes of the Hudi Table: Hive TableName Mapping	-
Configuring the Attributes of the Hudi Table: Table Primarykey Mapping	id
Configuring the Attributes of the Hudi Table: Table Hudi Partition Type	-
Configuring the Attributes of the Hudi Table: Custom Config	-



2. (Optional) Click the plus sign (+) to display the **Execution Env** parameter. Select a created environment for it. The default value is **defaultEnv**.

3. Click **OK**.

Step 8 Drag the two icons to associate the job parameters and click **Save**. The job configuration is complete.



Step 9 In the job list on the **Job Management** page, locate the created job, click **Start** in the **Operation** column, and wait until the job is started.

Check whether the data transmission takes effect, for example, insert data into the table in the drs-avro-oracle database and view the content of the file imported to Hudi.

----End

2.6 CDL Job DDL Changes

DDL operations include creating databases or tables, changing table field types and table field names, and adding or deleting table columns. Currently, MRS Change Data Loader (CDL) supports only DDL operations for synchronizing data from PostgreSQL to Hudi. The sequence of DDL operations is as follows:

1. Stop a CDL job.
2. Execute DDL operations on the Hudi side.
3. Perform DDL operations on the source database.

This section applies to MRS 3.3.0 and later versions. It provides guidance on DDL operations, such as adding fields, changing field types, changing field names, and deleting fields.

Adding a Field

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.

Step 2 Log in to the node where the client is installed as the client installation user and run the following commands:

cd *Client installation directory*

source bigdata_env

source Hudi/component_env

kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)

Step 3 Run the following commands to log in to the Spark SQL CLI:

cd Spark/spark/bin

./spark-sql

Step 4 Run the following command:

set hoodie.schema.evolution.enable=true;

Step 5 Run the following command to add a field to the table:

alter table *tableName* **add columns(***columnName columnType***);**

Step 6 Add the column name and data type same as those in Hudi to the source database.

Step 7 Start the CDL task stopped in **Step 1** on the CDL web UI.

----End

Modifying a Field

NOTE

During field type conversion, ensure that the data type of the source value can be correctly converted to the target type. If the data type is incompatible, the conversion may fail. As a result, the task fails.

- Change the data type from VARCHAR to NUMBER.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.
  b. Log in to the node where the client is installed as the client installation user and run the following commands:

     cd *Client installation directory*

     source bigdata_env

     source Hudi/component_env

     kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)
  c. Run the following commands to log in to the Spark SQL CLI:

     cd Spark/spark/bin

     ./spark-sql
  d. Run the following statement to change the data type from **string** to **decimal** on Hudi:

     ALTER TABLE *ddltest* **ALTER COLUMN string TYPE decimal(20,10);**
  e. Insert data into the source database. The data can be properly written to Hudi.
  f. In the source database, change the data type from **VARCHAR** to **NUMBER**.
  g. On the CDL web UI, start a task to update data in the source database.
- Change the data type from **NUMBER** to **VARCHAR**.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list

page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.

b. Log in to the node where the client is installed as the client installation user and run the following commands:

cd *Client installation directory*

source bigdata_env

source Hudi/component_env

kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)

c. Run the following commands to log in to the Spark SQL CLI:

cd Spark/spark/bin

./spark-sql

d. Run the following statement to change the data type from **decimal** to **string** on Hudi:

ALTER TABLE *ddltest* **ALTER COLUMN decimal TYPE string;**

e. Insert data into the source database. The data can be properly written to Hudi.

f. In the source database, change the data type from **NUMBER** to **VARCHAR**.

g. On the CDL web UI, start a task to update data in the source database.

- Change the data type from **DATE** to **VARCHAR**.

a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.

b. Log in to the node where the client is installed as the client installation user and run the following commands:

cd *Client installation directory*

source bigdata_env

source Hudi/component_env

kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)

c. Run the following commands to log in to the Spark SQL CLI:

cd Spark/spark/bin

./spark-sql

d. Run the following statement to change the data type from **date** to **string** on Hudi:

ALTER TABLE *ddltest2* **ALTER COLUMN date TYPE string;**

e. Insert data into the source database. The data can be properly written to Hudi.

f. In the source database, change the data type from **DATE** to **VARCHAR**.

g. On the CDL web UI, start a task to update data in the source database.

- Change the **DATA** type without a time zone to the **DATA** type with a time zone.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.
  b. In the source database, change the data type from **timestamp** to **timestamptz**.
  c. Insert data into the source database. The data can be properly written to Hudi.
  d. On the CDL web UI, start a task to update data in the source database.
- Extend strings.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.
  b. Extend the string length in the source database.
  c. Insert data into the source database. The data can be properly written to Hudi.
  d. On the CDL web UI, start a task to update data in the source database.
- Increase the decimal precision.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.
  b. Log in to the node where the client is installed as the client installation user and run the following commands:

     cd *Client installation directory*

     source bigdata_env

     source Hudi/component_env

     kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)
  c. Run the following commands to log in to the Spark SQL CLI:

     cd Spark/spark/bin

     ./spark-sql
  d. Run the following statement to increase the decimal precision on Hudi:

     ALTER TABLE *ddltest2* **ALTER COLUMN decimal TYPE decimal(***30***,***15***);**
  e. Increase the precision of the decimal type in the source database.
  f. Insert data into the source database. The data can be properly written to Hudi.
  g. On the CDL web UI, start a task to update data in the source database.

Changing a Field Name

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.

Step 2 Log in to the node where the client is installed as the client installation user and run the following commands:

cd *Client installation directory*

source bigdata_env

source Hudi/component_env

kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)

Step 3 Run the following commands to log in to the Spark SQL CLI:

cd Spark/spark/bin

./spark-sql

Step 4 Run the following statement on Hudi to change a field name:

ALTER TABLE *ddltest* **RENAME COLUMN** *columnName* **TO** *newColumnName;*

Step 5 Change the field name in the source database.

Step 6 On the CDL web UI, start a task to update data in the source database.

----End

Deleting a Field

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. On the displayed page, click the hyperlink on the right of **CDLService UI** to go to the CDLService web UI. On the data synchronization job list page, locate the row that contains the target DDL change job, and choose **More** > **Stop** to stop a CDL job.

Step 2 Log in to the node where the client is installed as the client installation user and run the following commands:

cd *Client installation directory*

source bigdata_env

source Hudi/component_env

kinit *Component service user* (Skip this step if Kerberos authentication is disabled for the cluster.)

Step 3 Run the following commands to log in to the Spark SQL CLI:

cd Spark/spark/bin

./spark-sql

Step 4 Run the following statement on Hudi to delete a field:

ALTER TABLE ddltest **DROP COLUMN** *columnName*;

Step 5 On the CDL web UI, start a task to update data in the source database.

----End

2.7 CDL Log Overview

Log Description

Log path: The default log storage path of CDL is **/var/log/Bigdata/cdl/***Role name abbreviation*.

- CDLService: **/var/log/Bigdata/cdl/service** (run logs) and **/var/log/Bigdata/audit/cdl/service** (audit logs).
- CDLConnector: **/var/log/Bigdata/cdl/connector** (run logs).

Log archive rule: The automatic CDL log compression function is enabled. By default, when the size of logs exceeds 50 MB, logs are automatically compressed into a log file named in the following format: *<Original log name>*.*<yyyy-mm-dd_hh-mm-ss>*.*[ID]*.**zip**. A maximum of 20 latest compressed files are reserved by default. The number of compressed files can be configured on Manager.

Table 2-79 Log list

Type	File	Description
Run logs	connect.log	CDLConnector run log.
	prestartDetail.log	Log that records cluster initialization before service startup.
	startDetail.log	Service startup log.
	stopDetail.log	Service stop log.
	cleanupDetail.log	Log that records the cleanup execution of services.
	check-serviceDetail.log	Log that records the verification of service status after service installation.
	cdl-db-operation.log	Log that records database initialization during service startup.
	cdl-app-launcher.log	Spark application startup log of CDL data synchronization tasks.
	cdl-dc-app-launcher.log	Spark application startup log of CDL data comparison tasks.
	serviceInstance-Check.log	Instance check log of CDLService.
	connectorInstance-Check.log	Instance check log of CDLConnector.

Type	File	Description
	ModifyDBPasswd.log	Log that records the resetting of the service database password.
	ranger-cdl-plugin-enable.log	Log that records the enabling or disabling of Ranger authentication.
	postinstallDetail.log	Service installation log.
	cdl_connector_pidxxx_gc.log.x	CDLConnector garbage collection (GC) log.
	cdl_service_pidxxx_gc.log.x	CDLService GC log.
	threadDump-CDLConnector-xxx.log	CDLConnector stack log.
	threadDump-CDLService-xxx.log	CDLService stack log.
Audit log	cdl-audit.log	Service audit log.

Log Level

Table 2-80 describes the log levels supported by CDL.

Levels of run logs are FATAL, ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 2-80 Log levels

Type	Level	Description
Run log and audit log	FATAL	Logs of this level record fatal information about system.
	ERROR	Logs of this level record error information about system running.
	WARN	Logs of this level record exception information about the current event processing.
	INFO	Logs of this level record normal running status information about the system and events.

Type	Level	Description
	DEBUG	Logs of this level record system running and debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of CDL. For details, see **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Format

The following table lists the CDL log formats:

Table 2-81 Log formats

Type	Format	Example
Run log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2021-06-15 17:25:19,658 | DEBUG | qtp2009591182-1754 | >fill SslConnection@5d04c5a0::SocketChannelEnd-Point@7c011c24{l=/10.244.224.65:21495,r=/10.244.224.83:53724,OPEN,fill=-,flush=-,to=1/30000}{io=0/0,kio=0,kro=1}->SslConnection@5d04c5a0{NOT_HANDSHAKING,eio=-1/-1,di=-1,fill=IDLE,flush=IDLE}~>DecryptedEndPoint@771f2f77{l=/10.244.224.65:21495,r=/10.244.224.83:53724,OPEN,fill=-,flush=-,to=19398/30000}=>HttpConnection@68c5859b[p=HttpParser{s=CONTENT,0 of -1},g=HttpGenerator@536e2de0{s=END}]=>HttpChannelOverHttp@7bf252bd{s=HttpChannelState@38be31e{s=IDLE rs=COMPLETED os=COMPLETED is=IDLE awp=false se=false i=false al=0},r=1,c=true/true,a=IDLE,uri=https://10.244.224.65:21495/api/v1/cdl/monitor/jobs/metrics,age=19382} | SslConnection.java:614

2.8 Common Issues About CDL

2.8.1 Hudi Does Not Receive Data After a CDL Job Is Executed

Symptom

After the CDL job for capturing data to Hudi is executed, related data exists in Kafka, but no record exists in Spark RDD, no related data exists in Hudi, and the error message "TopicAuthorizationException: No authorized to access topics" is displayed.

Possible Causes

The current user does not have the permission to consume Kafka data.

Procedure

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **User**. Locate the row containing the user who submitted the CDL job, click **Modify**, add the **kafkaadmin** user group, and click **OK**.

Step 2 On FusionInsight Manager, choose **Cluster** > **Services** > **CDL**. Click the hyperlink next to **CDLService UI** to access the CDLService web UI and restart the job.

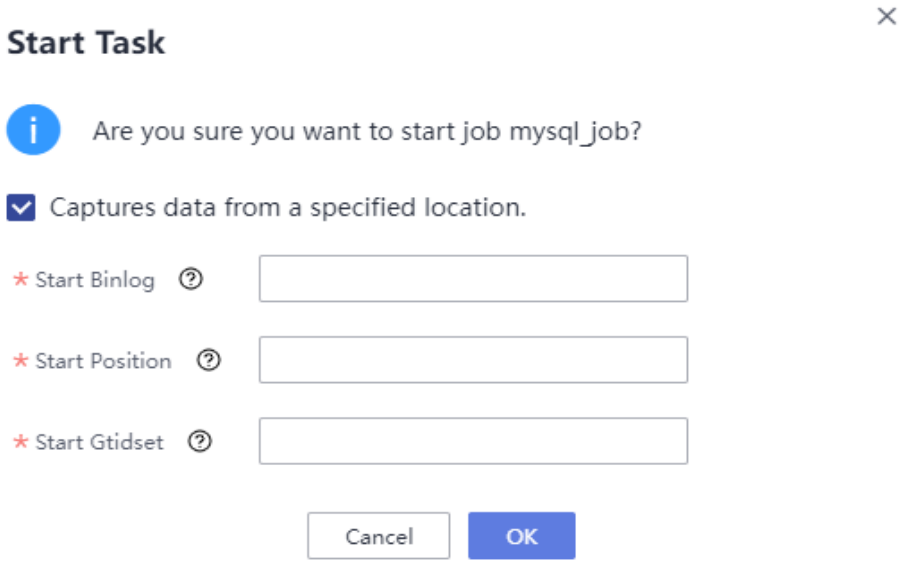
----End

2.8.2 How Do I Capture Data from a Specified Location When a MySQL Link Task Is Started?

Symptom

When a MySQL link task is started, data can be captured from a specified location. This section describes how to obtain parameter values of a specified location.

Figure 2-2 Start Task dialog box



Procedure

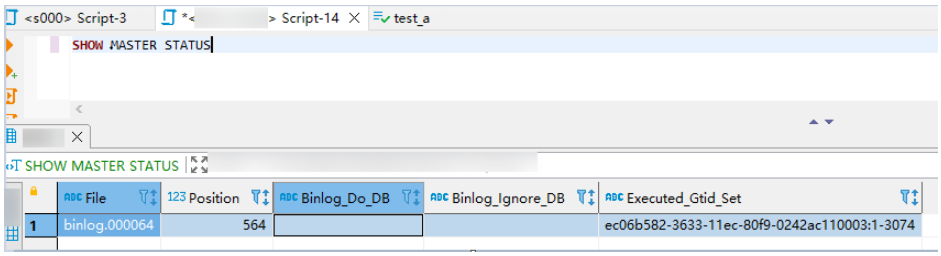
Step 1 Use a tool or CLI to connect to the MySQL database. In this example, Navicat is used.

Step 2 Run the following command:

SHOW MASTER STATUS

For example, on Navicat, choose **File** > **New Query** and enter **SHOW MASTER STATUS**. The command output is as follows:

Figure 2-3 SQL execution result



Step 3 In Figure 2-3, enter the value in the **File** column to **Start Binlog**, the value in the **Position** column to **Start Position**, and the value in the **Executed_Gtid_Set** column to **Start Gtidset**. Then, click **OK** to start the task.

NOTE

If there are two values (separated by a comma) of **Executed_Gtid_Set** in the query result in Step 2, set **Start Gtidset** to the first value. As shown in the following figure, the value of **Start Gtidset** is **13a90ad1-1f02-11ee-9ba9-fa163e6190d3:1-2794**.

File	Position	Binlog_Do_DB	Binlog_Ignore_DB	Executed_Gtid_Set
mysql-bin.000446	236			13a90ad1-1f02-11ee-9ba9-fa163e6190d3:1-2794,13d63a44-1f02-11ee-99c1-fa163e618eda:1-10766

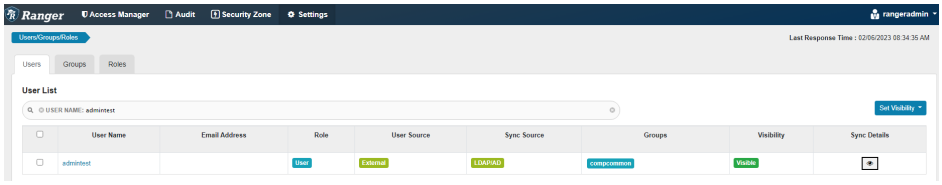
----End

2.8.3 Why Can a User Still Perform Operations on the Tasks Created by Itself After All Permissions of the User Are Deleted from Ranger?

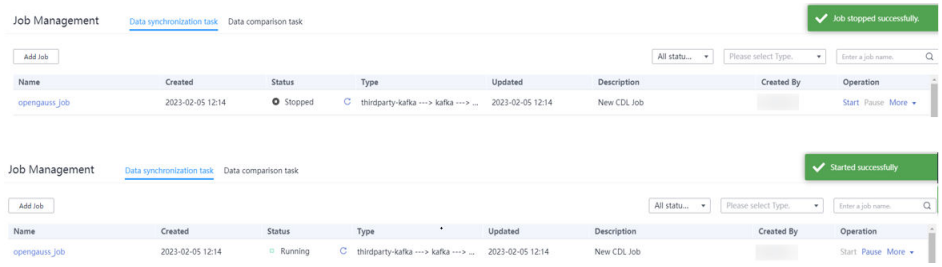
Symptom

In scenarios where Ranger authentication is enabled, after all permissions of a user are canceled, the user can still perform operations on the tasks created by itself. Example:

1. On the Ranger web UI, cancel all permissions of user **admintest**.



2. After logging in to the CDL web UI as user **admintest**, the user can still perform operations on the tasks created by itself on the **Job Management** page.



Possible Causes

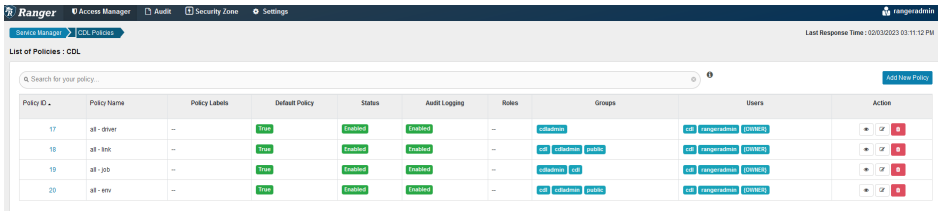
The **{OWNER}** permission is not deleted from the Ranger policy.

Procedure

Step 1 Log in to FusionInsight Manager as user **admin** and choose **Cluster** > **Services** > **Ranger**. On the page that is displayed, click the hyperlink next to **RangerAdmin UI** to access the Ranger web UI.

Step 2 On the Ranger web UI, click the username in the upper right corner, and choose **Log Out** to log out of the current user. Log in again as user **rangeradmin**.

Step 3 On the home page, click the component plug-in name in the **CDL** area, for example, **CDL**.



Step 4 Click in the **Action** column of each policy, delete user **{OWNER}** in the **Select User** column in the **Allow Conditions** area, and click **Save**.

Step 5 After 10 minutes, log in to the CDL web UI as the user whose **{OWNER}** permission has been deleted and attempt to perform operations on the jobs created by the user. It is found that the user does not have the permission to perform related operations.

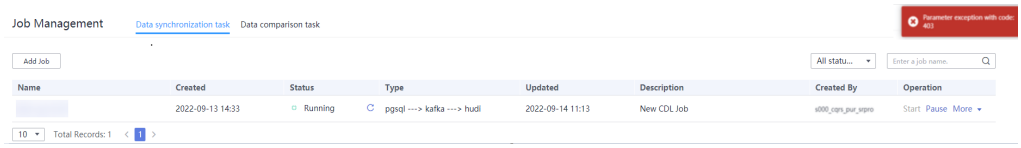
----End

2.9 CDL Troubleshooting

2.9.1 Error 403 Is Reported When a CDL Job Is Stopped

Symptom

The error message "parameter exception with code: 403" is displayed when a CDL job is stopped on the CDLService web UI.



Possible Causes

The current user does not have the permission to stop the job.

Procedure

Stop the job as the user who created the job. To view the job creator, log in to the CDLService web UI, locate the job in the job list, and view the creator in the **Creator** column.

2.9.2 Error 104 or 143 Is Reported After a CDL Job Runs for a Period of Time

Symptom

After an CDL job runs for a period of time, the YARN job fails and the status code **104** or **143** is returned. The following figure shows the returned status code 143.

Possible Causes

A large amount of data is captured to Hudi. As a result, the memory of the job is insufficient.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. Click the hyperlink next to **CDLService UI** to access the CDLService web UI. On the data synchronization job list page, locate the row that contains the target job and choose **More** > **Stop**. After the job is stopped, choose **More** > **Edit**.

Step 2 Change the value of **max.rate.per.partition** of Hudi to **6000** and click **Save**.

Step 3 On the data synchronization job list page, locate the row containing the target job and choose **More** > **Restart** to restart the job.

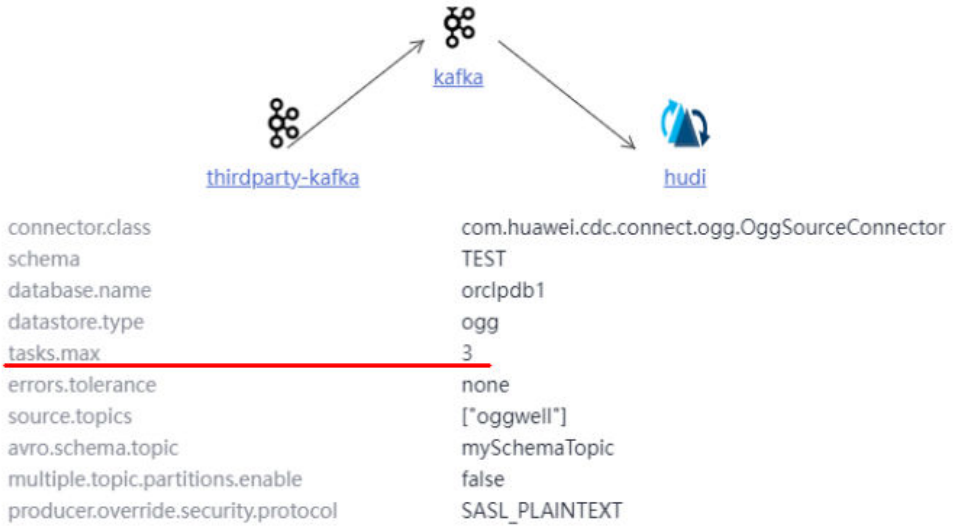
----End

2.9.3 Why Is the Value of Task configured for the OGG Source Different from the Actual Number of Running Tasks When Data Is Synchronized from OGG to Hudi?

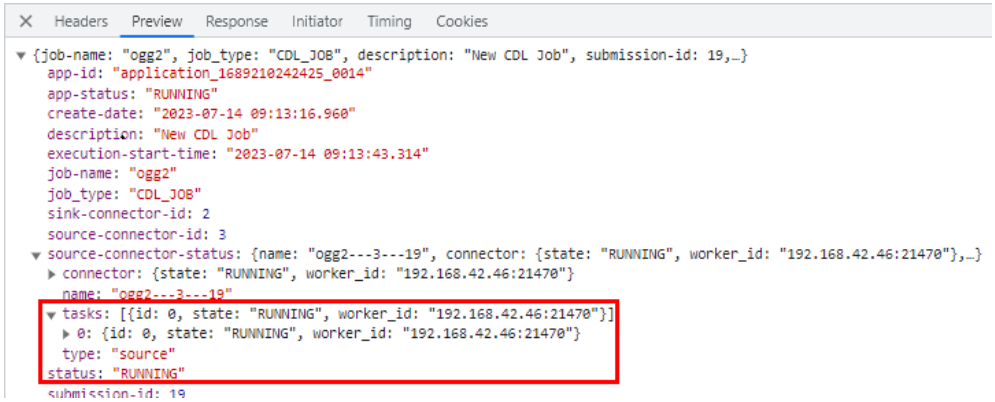
Symptom

When the CDL task for synchronizing data from OGG to Hudi is executed, the value of **tasks.max** specified in the source end (ThirdKafka) is different from the actual number of running tasks.

For example, on the CDL web UI, the value of **tasks.max** of the source job ThirdKafka is **3**.



However, the **tasks** information is **id: 0, state: xxx is**, indicating that there is only 1 task.



Possible Causes

The number of running tasks in OGG Source is calculated based on the smaller value between the values of **source.topics** and **tasks.max**.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. Click the hyperlink next to **CDLService UI** to access the CDLService web UI. On the data synchronization job list page, locate the row that contains the target job and choose **More** > **Stop**. After the job is stopped, choose **More** > **Edit**.

Step 2 Change the value of **tasks.max** of Thirdk Kafka to the number of topics specified by **source.topics** and click **Save**.

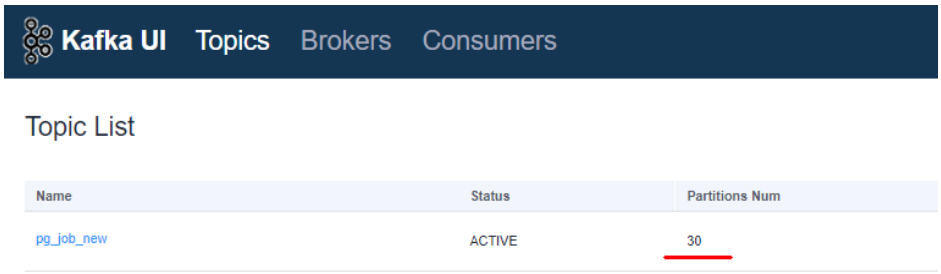
Step 3 On the data synchronization job list page, locate the row containing the target job and click **Start** to restart the job.

----End

2.9.4 Why Are There Too Many Topic Partitions Corresponding to the CDL Synchronization Task Names?

Symptom

After a CDL task is started, the value of **Partitions Num** of the CDL task name is too large in **Topic List** on the Kafka web UI.



Possible Causes

Topic Table Mapping is configured for CDL tasks, but the **WhiteList** parameter is not configured. CDL tasks of the schema configured for the CDL task have too many tables that are not synchronized. As a result, too many partitions are created for CDL task names.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. Click the hyperlink next to **CDLService UI** to access the CDLService web UI. On the data synchronization job list page, locate the row that contains the target job and choose **More** > **Stop**. After the job is stopped, choose **More** > **Edit**.

Step 2 Change the value of **WhiteList** of the Source to the configured number of Topic Table Mapping tables and click **Save**.

Step 3 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, and click the hyperlink on the right of **Kafka UI** to go to the Kafka web UI. On the **Topics** tab, search for the CDL task name and click **Action** > **Delete** in the **Operation** column.

Step 4 On the data synchronization job list page of CDL web UI, locate the row containing the target job and click **Start** to restart the job.

----End

2.9.5 What Should I When a CDL Task Is Executed to Synchronize Data to the Hudi, an Error Message Indicating that the Current User Does Not Have the Permission to Create Tables?

Symptom

After a CDL task is executed to synchronize data to Hudi, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Yarn**, and click **ResourceManager Web UI**

to access the Yarn web UI. In the task list, click the task ID, then **Logs**, and an error message is displayed, indicating that the current user does not have the permission to create a table. The error message is as follows:

```
org.apache.hadoop.hive.ql.security.authorization.plugin.HiveAccessControlException: Permission denied: Principal [name=xxx, type=USER] does not have following privileges for operation CREATETABLE [[CREATE] on Object [type=DATABASE, name=xxx]]
```

Possible Cause

The CDL service user does not have the permission to create tables in a database created by other users.

Procedure

Step 1 Log in to FusionInsight Manager, choose **System** > **Role** > **Add Role**, and enter the role name. In the **Configure Resource Permission** table, locate the cluster to be operated, choose **Hive** > **Hive Read and Write Permission**, select **Query**, **Delete**, **Insert**, **Create**, **Grant of Select**, **Grant of Delete**, **Grant of Insert**, and **Recursive**, and click **OK**.

Step 2 Click **User**, locate the user of the task, and click **Modify**. Add the role created in **Step 1**, and click **OK**.

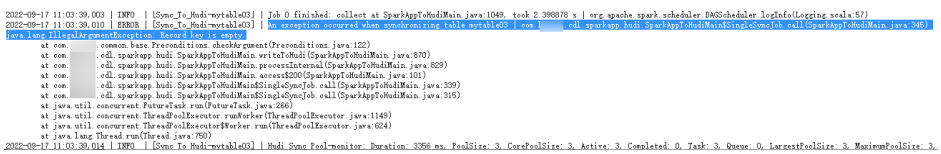
Step 3 Choose **Cluster** > **Services** > **CDL**. Click the hyperlink on the right of **CDLService UI** to go to the CDL web UI. In the row where the job is located, choose **More** > **Stop** to stop the CDL task. After the task is stopped, click **Start** to restart the task.

----End

2.9.6 Error Is Reported When the Job of Capturing Data From PgSQL to Hudi Is Started

Symptom

The error message "Record key is empty" is displayed when the job of capturing data from PgSQL to Hudi is started.



Possible Causes

The primary key parameter **table.primarykey.mapping** of the Hudi table is not configured.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **CDL**. Click the hyperlink next to **CDLService UI** to access the CDLService web UI. On the data synchronization job list page, locate the row that contains the target job and choose **More** > **Stop**. After the job is stopped, choose **More** > **Edit**.

Step 2 Configure the **table.primarykey.mapping** parameter on the Hudi table attribute configuration page and click **Save**. For details about the parameter, see **Table 2-36**.

Step 3 On the data synchronization job list page, locate the row containing the target job and click **Start** to restart the job.

----End

3 Using ClickHouse

3.1 ClickHouse Overview

ClickHouse Table Engines

Table engines play a key role in ClickHouse to determine:

- Where to write and read data
- Supported query modes
- Whether concurrent data access is supported
- Whether indexes can be used
- Whether multi-thread requests can be executed
- Parameters used for data replication

This section describes MergeTree and Distributed engine families, which are the most important and frequently used.

For details about other table engines, visit **https://clickhouse.tech/docs/en/engines/table-engines**.

- **MergeTree Family**

  Engines of the MergeTree family are the most universal and functional table engines for high-load tasks. They have the following key features:

  – Data is stored by partition and block based on partitioning keys.
  – Data index is sorted based on primary keys and the **ORDER BY** sorting keys.
  – Data replication is supported by table engines prefixed with "Replicated".
  – Data sampling is supported.

  When data is written, a table with this type of engine divides data into different folders based on the partitioning key. Each column of data in the folder is an independent file. A file that records serialized index sorting is created. This structure reduces the volume of data to be retrieved during data reading, greatly improving query efficiency.

– MergeTree

Syntax for creating a table:

```
CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
(
    name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1] [TTL expr1],
    name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2] [TTL expr2],
    ...
    INDEX index_name1 expr1 TYPE type1(...) GRANULARITY value1,
    INDEX index_name2 expr2 TYPE type2(...) GRANULARITY value2
) ENGINE = MergeTree()
ORDER BY expr
[PARTITION BY expr]
[PRIMARY KEY expr]
[SAMPLE BY expr]
[TTL expr [DELETE|TO DISK 'xxx'|TO VOLUME 'xxx'], ...]
[SETTINGS name=value, ...]
```

Example:

```
CREATE TABLE default.test (
  name1 DateTime,
  name2 String,
  name3 String,
  name4 String,
  name5 Date,
  ...
) ENGINE = MergeTree()
PARTITION BY toYYYYMM(name5)
ORDER BY (name1, name2)
SETTINGS index_granularity = 8192
```

Parameters in the example are described as follows:

- **ENGINE = MergeTree()**: specifies the MergeTree engine.
- **PARTITION BY toYYYYMM(name4)**: specifies the partition. The sample data is partitioned by month, and a folder is created for each month.
- **ORDER BY**: specifies the sorting field. A multi-field index can be sorted. If the first field is the same, the second field is used for sorting, and so on.
- **index_granularity = 8192**: specifies the index granularity. One index value is recorded for every 8,192 data records.

If the data to be queried exists in a partition or sorting field, the data query time can be greatly reduced.

– ReplacingMergeTree

Different from MergeTree, ReplacingMergeTree deletes duplicate entries with the same sorting key. ReplacingMergeTree is suitable for clearing duplicate data to save space, but it does not guarantee the absence of duplicate data. Generally, it is not recommended.

Syntax for creating a table:

```
CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
(
    name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
    name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
    ...
) ENGINE = ReplacingMergeTree([ver])
[PARTITION BY expr]
[ORDER BY expr]
[SAMPLE BY expr]
[SETTINGS name=value, ...]
```

- SummingMergeTree

  When merging data parts in SummingMergeTree tables, ClickHouse merges all rows with the same primary key into one row that contains summed values for the columns with the numeric data type. If the primary key is composed in a way that a single key value corresponds to large number of rows, storage volume can be significantly reduced and the data query speed can be accelerated.

  Syntax for creating a table:

```
CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
(
    name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
    name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
    ...
) ENGINE = SummingMergeTree([columns])
[PARTITION BY expr]
[ORDER BY expr]
[SAMPLE BY expr]
[SETTINGS name=value, ...]
```

  Example:

  Create a SummingMergeTree table named **testTable**.

```
CREATE TABLE testTable
(
    id UInt32,
    value UInt32
)
ENGINE = SummingMergeTree()
ORDER BY id
```

  Insert data into the table.

```
INSERT INTO testTable Values(5,9),(5,3),(4,6),(1,2),(2,5),(1,4),(3,8);
INSERT INTO testTable Values(88,5),(5,5),(3,7),(3,5),(1,6),(2,6),(4,7),(4,6),(43,5),(5,9),(3,6);
```

  Query all data in unmerged parts.

```
SELECT * FROM testTable
┌─id─┬─value─┐
│  1 │     6 │
│  2 │     5 │
│  3 │     8 │
│  4 │     6 │
│  5 │    12 │
└────┴───────┘
┌─id─┬─value─┐
│  1 │     6 │
│  2 │     6 │
│  3 │    18 │
│  4 │    13 │
│  5 │    14 │
│ 43 │     5 │
│ 88 │     5 │
└────┴───────┘
```

  If ClickHouse has not summed up all rows and you need to aggregate data by ID, use the **sum** function and **GROUP BY** statement.

```
SELECT id, sum(value) FROM testTable GROUP BY id
┌─id─┬─sum(value)─┐
│  4 │         19 │
│  3 │         26 │
│ 88 │          5 │
│  2 │         11 │
│  5 │         26 │
│  1 │         12 │
│ 43 │          5 │
└────┴────────────┘
```

Merge rows manually.

```
OPTIMIZE TABLE testTable
```

Query data in the **testTable** table again.

```
SELECT * FROM testTable
┌─id─┬─value─┐
│  1 │    12 │
│  2 │    11 │
│  3 │    26 │
│  4 │    19 │
│  5 │    26 │
│ 43 │     5 │
│ 88 │     5 │
└────┴───────┘
```

SummingMergeTree uses the **ORDER BY** sorting keys as the condition keys to aggregate data. That is, if sorting keys are the same, data records are merged into one and the specified merged fields are aggregated.

Data is pre-aggregated only when merging is executed in the background, and the merging execution time cannot be predicted. Therefore, it is possible that some data has been pre-aggregated and some data has not been aggregated. Therefore, the **GROUP BY** statement must be used during aggregation.

- AggregatingMergeTree

  AggregatingMergeTree is a pre-aggregation engine used to improve aggregation performance. When merging partitions, the AggregatingMergeTree engine aggregates data based on predefined conditions, calculates data based on predefined aggregate functions, and saves the data in binary format to tables.

  Syntax for creating a table:

  ```
  CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
  (
     name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
     name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
     ...
  ) ENGINE = AggregatingMergeTree()
  [PARTITION BY expr]
  [ORDER BY expr]
  [SAMPLE BY expr]
  [TTL expr]
  [SETTINGS name=value, ...]
  ```

  Example:

  You do not need to set the AggregatingMergeTree parameter separately. When partitions are merged, data in each partition is aggregated based on the **ORDER BY** sorting key. You can set the aggregate functions to be used and column fields to be calculated by defining the AggregateFunction type, as shown in the following example:

  ```
  create table test_table (
  name1 String,
  name2 String,
  name3 AggregateFunction(uniq,String),
  name4 AggregateFunction(sum,Int),
  name5 DateTime
  ) ENGINE = AggregatingMergeTree()
  PARTITION BY toYYYYMM(name5)
  ORDER BY (name1,name2)
  PRIMARY KEY name1;
  ```

  When data of the AggregateFunction type is written or queried, the ***state** and ***merge** functions need to be called. The asterisk (*) indicates

the aggregate functions used for defining the field type. For example, the **uniq** and **sum** functions are specified for the **name3** and **name4** fields defined in the **test_table**, respectively. Therefore, you need to call the **uniqState** and **sumState** functions and run the **INSERT** and **SELECT** statements when writing data into the table.

```
insert into test_table select '8','test1',uniqState('name1'),sumState(toInt32(100)),'2021-04-30 17:18:00';
insert into test_table select '8','test1',uniqState('name1'),sumState(toInt32(200)),'2021-04-30 17:18:00';
```

When querying data, you need to call the corresponding functions **uniqMerge** and **sumMerge**.

```
select name1,name2,uniqMerge(name3),sumMerge(name4) from test_table group by name1,name2;
┌─name1─┬─name2─┬─uniqMerge(name3)─┬─sumMerge(name4)─┐
│ 8     │ test1 │                1 │             300 │
└───────┴───────┴──────────────────┴─────────────────┘
```

AggregatingMergeTree is more commonly used together with materialized views, which are query views at the upper layer of other data tables. For details, visit **https://clickhouse.tech/docs/en/engines/table-engines/mergetree-family/aggregatingmergetree/**.

- CollapsingMergeTree

  CollapsingMergeTree defines a **Sign** field to record status of data rows. If **Sign** is **1**, the data in this row is valid. If **Sign** is **-1**, the data in this row needs to be deleted.

  Syntax for creating a table:

  ```
  CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
  (
     name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
     name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
     ...
  ) ENGINE = CollapsingMergeTree(sign)
  [PARTITION BY expr]
  [ORDER BY expr]
  [SAMPLE BY expr]
  [SETTINGS name=value, ...]
  ```

  Example:

  For details about the example, visit **https://clickhouse.tech/docs/en/engines/table-engines/mergetree-family/collapsingmergetree/**.

- VersionedCollapsingMergeTree

  The VersionedCollapsingMergeTree engine adds **Version** to the table creation statement to record the mapping between a **state** row and a **cancel** row in case that rows are out of order. The rows with the same primary key, same **Version**, and opposite **Sign** will be deleted during compaction.

  Syntax for creating a table:

  ```
  CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
  (
     name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
     name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
     ...
  ) ENGINE = VersionedCollapsingMergeTree(sign, version)
  [PARTITION BY expr]
  [ORDER BY expr]
  [SAMPLE BY expr]
  [SETTINGS name=value, ...]
  ```

  Example:

For details about the example, visit **https://clickhouse.tech/docs/en/engines/table-engines/mergetree-family/versionedcollapsingmergetree/**.

- GraphiteMergeTree

  The GraphiteMergeTree engine is used to store data in the time series database Graphite.

  Syntax for creating a table:

```
CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
(
    Path String,
    Time DateTime,
    Value <Numeric_type>,
    Version <Numeric_type>
    ...
) ENGINE = GraphiteMergeTree(config_section)
[PARTITION BY expr]
[ORDER BY expr]
[SAMPLE BY expr]
[SETTINGS name=value, ...]
```

  Example:

  For details about the example, visit **https://clickhouse.tech/docs/en/engines/table-engines/mergetree-family/graphitemergetree/**.

- **Replicated*MergeTree Engines**

  All engines of the MergeTree family in ClickHouse prefixed with Replicated become MergeTree engines that support replicas.

  Replicated series engines use ZooKeeper to synchronize data. When a replicated table is created, all replicas of the same shard are synchronized based on the information registered with ZooKeeper.

  Template for creating a Replicated engine:

```
ENGINE = Replicated*MergeTree('Storage path in ZooKeeper','Replica name', ...)
```

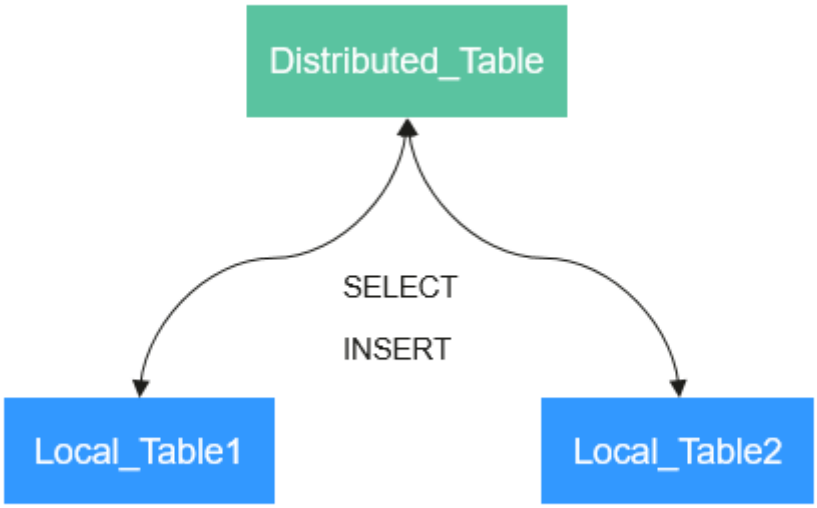
  Two parameters need to be specified for a Replicated engine:

  - *Storage path in ZooKeeper*: specifies the path for storing table data in ZooKeeper. The path format is ***/clickhouse/tables/{shard}/Database name/Table name***.
  - Replica name: Generally, **{replica}** is used.

- **Distributed Table Engines**

  The Distributed engine does not store any data. It serves as a transparent proxy for data shards and can automatically transmit data to each node in the cluster. Distributed tables need to work with other local data tables. Distributed tables distribute received read and write tasks to each local table where data is stored.

Figure 3-1 Distributed



Template for creating a Distributed engine:

```
ENGINE = Distributed(cluster_name, database_name, table_name, [sharding_key])
```

Parameters of a distributed table are described as follows:

- **cluster_name**: specifies the cluster name. When a distributed table is read or written, the cluster configuration information is used to search for the corresponding ClickHouse instance node.
- **database_name**: specifies the database name.
- **table_name**: specifies the name of a local table in the database. It is used to map a distributed table to a local table.
- **sharding_key** (optional): specifies the sharding key, based on which a distributed table distributes data to each local table.

Example:

```
-- Create a ReplicatedMergeTree local table named test.
CREATE TABLE default.test ON CLUSTER default_cluster_1
(
    `EventDate` DateTime,
    `id` UInt64
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/test', '{replica}')
PARTITION BY toYYYYMM(EventDate)
ORDER BY id

-- Create a distributed table named test_all based on the local table test.
CREATE TABLE default.test_all ON CLUSTER default_cluster_1
(
    `EventDate` DateTime,
    `id` UInt64
)
ENGINE = Distributed(default_cluster_1, default, test, rand())
```

Rules for creating a distributed table:

- When creating a distributed table, add **ON CLUSTER** *cluster_name* to the table creation statement so that the statement can be executed once on

a ClickHouse instance and then distributed to all instances in the cluster for execution.

- Generally, a distributed table is named in the following format: *Local table name*_all. It forms a one-to-many mapping with local tables. Then, multiple local tables can be operated using the distributed table proxy.
- Ensure that the structure of a distributed table is the same as that of local tables. If they are inconsistent, no error is reported during table creation, but an exception may be reported during data query or insertion.

ClickHouse Data Types

Table 3-1 describes the data types used in the ClickHouse component of MRS.

For details about the ClickHouse data types, see **ClickHouse Data Types**.

Table 3-1 Data types

Category	Keyword	Type	Description
Data type	Int8	Int8	Value range: -128 to 127
	Int16	Int16	Value Range: -32768 to 32767
	Int32	Int32	Value range: -2147483648 to 2147483647
	Int64	Int64	Value range: -9223372036854775808 to 9223372036854775807
Floating point type	Float32	Float	Similar to the Float type in C, a single-precision floating point number occupies 4 bytes in storage of a computer and is described in 32-bit binary mode.
	Float64	Double	Similar to the Double type in the C language, a double-precision floating point number occupies eight bytes in the machine and is described in 64-bit binary mode.

Category	Keyword	Type	Description
Decimal type	Decimal	Decimal	A signed fixed-point number that can maintain precision during addition, subtraction, and multiplication operations. The following formats are supported: • Decimal(P, S) • Decimal32(S) • Decimal64(S) • Decimal128(S) **NOTE** • P: precision. Valid range: [1:38]. It determines the number of decimal digits (including fractions) that can be contained. • S: scale. The value ranges from 0 to P, which determines the number of decimal places in the decimal part of a number.
String type	String	String	The character string can be of any length. It can contain any set of bytes, including empty bytes. Therefore, the String type can replace the VARCHAR, BLOB, and CLOB types in other database management systems.
	FixedString	Fixed-length string	When the length of the data happens to be N bytes, the FixedString type is efficient. In other cases, this may reduce efficiency. Examples of values that can be effectively stored in columns of the FixedString type: • IP address represented in binary • Language code (ru_RU, en_US...) • Currency code (RUB...) • Hash value represented in binary mode (FixedString (16) for MD5 and FixedString (32) for SHA256)

Category	Keyword	Type	Description
Time and date type	Date	Date	A Date value takes up two bytes, indicating the date value from 1970-01-01 (unsigned) to the current time. Date values are stored without the time zone.
	DateTime	Timestamp	A Unix timestamp value takes up four bytes (unsigned). Value range of this type is the same as the Date type. The minimum value is 1970-01-01 00:00:00. Timestamp values are accurate to seconds. Leap seconds are not supported. The system time zone will be used when the client or server is started.
	DateTime64	DateTime64	This type allows you to store both the date and time of a specific point in time.
Boolean type	Boolean	Boolean	ClickHouse does not support the Boolean type. You can use the UInt8 type for Boolean values. Valid values are 0 and 1.
Array type	Array	Array	An Array value is a collection of elements of the same data type. The elements can be of a random data type, even the Array type itself. However, multi-dimensional arrays are not recommended, because ClickHouse supports multi-dimensional arrays only to a limited extent. For example, you cannot store multi-dimensional arrays in MergeTree tables.

Category	Keyword	Type	Description
Tuple type	Tuple	Tuple	A Tuple value is a collection of elements of different data types. Tuple values cannot be stored in tables, except for memory tables. You can use Tuple values to group temporary columns. In queries, you can use **IN** expressions and **lambda** functions with specific parameters to group temporary columns.
Domains data type	Domains	Domains	The implementation of the Domains type varies based on different values: If the values are IPv4 addresses, the Domains type is binary compatible with the UInt32 type. Compared with the UInt32 type, the Domains type saves the binary storage space and supports more readable input and output formats.
Enumerated type	Enum8	Enum8	Value range: -128 to 127 An Enum value stores the mapping of 'string'= integer, for example, **Enum8('hello' = 1, 'world' = 2)**.
	Enum16	Enum16	Value Range: -32768 to 32767
Nullable type	Nullable	Nullable	Unless otherwise stated in ClickHouse server configurations, the default value of the NULLABLE type is NULL. Nullable values cannot be included in table indexes. Nullable values can be stored together with the normal values of TypeName. For example, columns of the Nullable(Int8) type can store values of the Int8 type, while rows without values store NULL.

Category	Keyword	Type	Description
Nested type	nested	nested	A nested data structure is similar to a table inside a cell. You can specify the parameters of a nested data structure, such as field name and data type, the same way that you specify parameters in a **CREATE TABLE** statement. Each row in a **CREATE TABLE** statement can correspond to a random number of rows in a nested data structure. Example: **Nested (Name1 Type1,Name2 Type2, ...)**

3.2 ClickHouse User Permission Management

3.2.1 ClickHouse User Rights

User Permission Model

ClickHouse user permission management enables unified management of users, roles, and permissions on each ClickHouse instance in the cluster. You can use the permission management module of the Manager UI to create users, create roles, and bind the ClickHouse access permissions. User permissions are controlled by binding roles to users.

- Resource management: **Table 3-2** lists the resources supported by ClickHouse permission management.
- Resource permissions: **Table 3-3** lists the resource permissions supported by ClickHouse.

Table 3-2 Permission management objects supported by ClickHouse

Resource	Integration	Remarks
Database	Yes (level 1)	-
Table	Yes (level 2)	-
View	Yes (level 2)	Same as tables

Table 3-3 Resource permission list

Resource	Available Permission	Remarks
Database	CREATE	CREATE DATABASE/TABLE/ VIEW/DICTIONARY
Table/View	SELECT/INSERT	-

3.2.2 Creating a ClickHouse Role

This topic describes how to create and configure a ClickHouse role on Manager as an MRS cluster administrator. You can grant the administrator permission and permissions to read and write tables and databases to the ClickHouse role.

Prerequisites

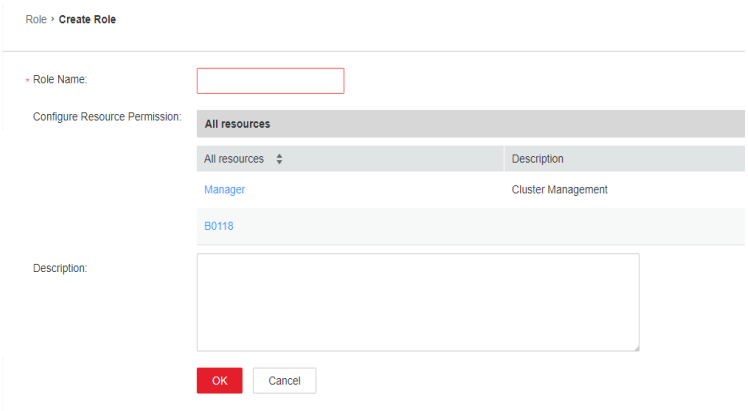
- The ClickHouse and Zookeeper services are running properly.
- The **ON CLUSTER** statement has been used to create a database or table in the cluster to ensure that the metadata of the database and table on each ClickHouse node is the same.

NOTE

After the permission is granted, it takes about 1 minute for the permission to take effect.

Adding the ClickHouse Role

Step 1 Log in to Manager and choose **System** > **Permission** > **Role**. On the **Role** page, click **Create Role**.



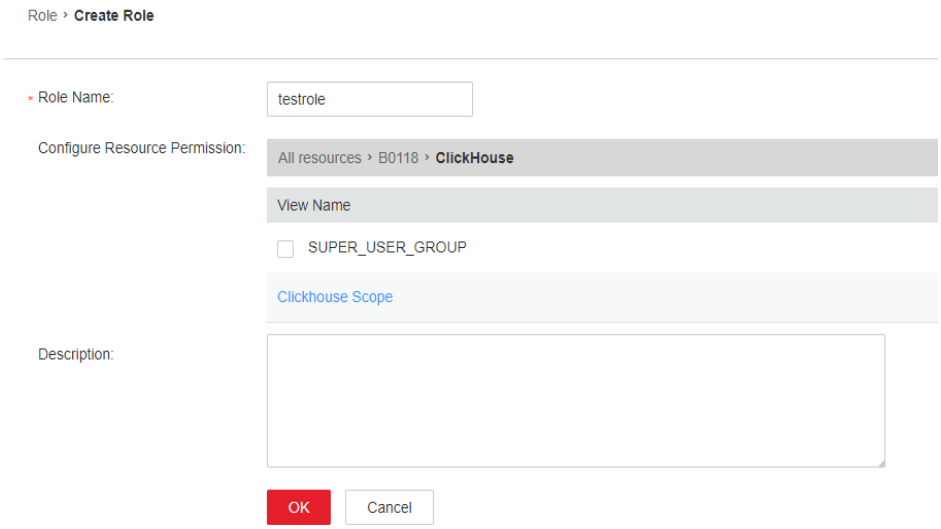
Step 2 On the **Create Role** page, specify **Role Name**. In the **Configure Resource Permission** area, click the cluster name. On the service list page that is displayed, click the ClickHouse service.

Determine whether to create a role with the ClickHouse administrator permissions based on service requirements.

NOTE

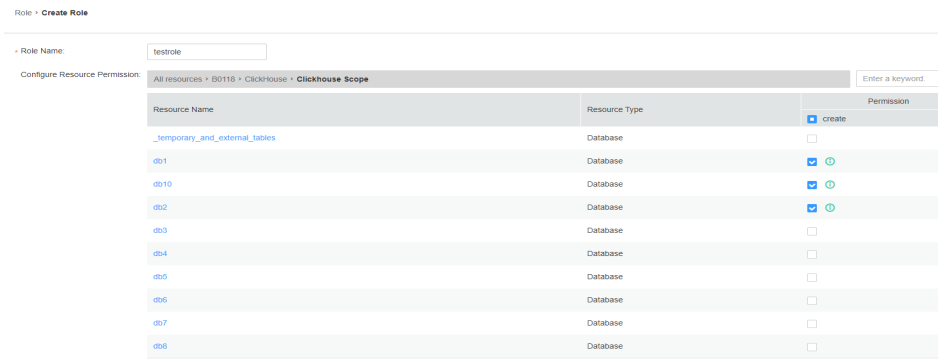
- The ClickHouse administrator has all the database operation permissions except the permissions to create, delete, and modify users and roles.
- Only the built-in user **clickhouse** of ClickHouse has the permission to manage users and roles.

- If yes, go to **Step 3**.
- If no, go to **Step 4**.



Step 3 Select **SUPER_USER_GROUP** and click **OK**.

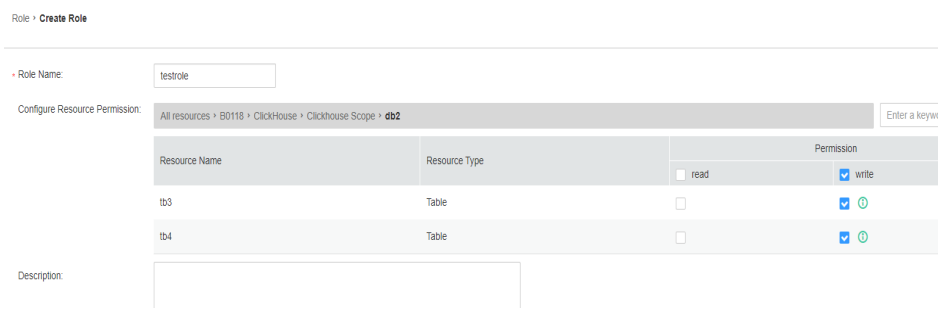
Step 4 Click **Clickhouse Scope**. The ClickHouse database resource list is displayed. If you select **create**, the role has the create permission on the database.



Determine whether to grant the permission based on the service requirements.

- If yes, click **OK**.
- If no, go to **Step 5**.

Step 5 Click the resource name and select the *Database resource name to be operated*. On the displayed page, select **READ** (SELECT permission) or **WRITE** (INSERT permission) based on service requirements, and click **OK**.



----End

Adding a User and Binding the ClickHouse Role to the User

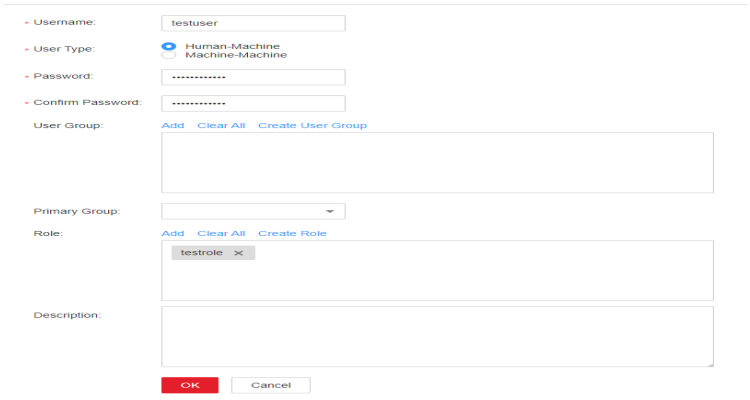
Step 1 Log in to Manager and choose **System** > **Permission** > **User** and click **Create**.

Step 2 Select **Human-Machine** for **User Type** and set **Password** and **Confirm Password** to the password of the user.

NOTE

- Username: The username cannot contain hyphens (-). Otherwise, the authentication will fail.
- Password: The password cannot contain special characters $, ., and #. Otherwise, the authentication will fail.

Step 3 In the **Role** area, click **Add**. In the displayed dialog box, select a role with the ClickHouse permission and click **OK** to add the role. Then, click **OK**.



Step 4 Log in to the node where the ClickHouse client is installed and use the new username and password to connect to the ClickHouse service.

- Run the following command to go to the client installation directory:

  cd /opt/*Client installation directory*

- Run the following command to configure environment variables:

  source bigdata_env

- If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The user must have the permission to create ClickHouse tables. Therefore, you need to bind the corresponding role to the user. For details, see **Adding the ClickHouse Role**. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *User added in* ***Step 1***

- Log in to the system as the new user.

  Cluster with Kerberos authentication disabled:

  clickhouse client --host *IP address of the ClickHouse instance* **--multiline --port** *ClickHouse port number* **--secure**

  Cluster with Kerberos authentication enabled:

  clickhouse client --host *IP address of the ClickHouse instance*--**user** *Username* **--password --port** 9440 **--secure**

  Enter the user password.

  NOTE

  The user in normal mode is the **default** user, or you can create an administrator using the open source capability provided by the ClickHouse community. You cannot use the users created on FusionInsight Manager.

----End

Granting Permissions Using the Client in Abnormal Scenarios

By default, the table metadata on each node of the ClickHouse cluster is the same. Therefore, the table information on a random ClickHouse node is collected on the permission management page of Manager. If the **ON CLUSTER** statement is not used when databases or tables are created on some nodes, the resource may fail to be displayed during permission management, and permissions may not be granted to the resource. To grant permissions on the local table on a single ClickHouse node, perform the following steps on the background client.

NOTE

The following operations are performed based on the obtained roles, database or table names, and IP addresses of the node where the corresponding ClickHouseServer instance is located.

- To obtain the IP address of the ClickHouseServer instance, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, and click the **Instances** tab.
- The default system domain name is **hadoop.com**. Log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust**. The value of **Local Domain** is the system domain name. Change the letters to lowercase letters when running a command.

Step 1 Log in to the node where the ClickHouseServer instance is located as user **root**.

Step 2 Run the following command to obtain the path of the **clickhouse.keytab** file:

ls ${BIGDATA_HOME}/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/keytab/clickhouse.keytab

Step 3 Log in to the node where the client is installed as the client installation user.

Step 4 Run the following command to go to the client installation directory:

cd /opt/client

Step 5 Run the following command to configure environment variables:

source bigdata_env

Step 6 Run the following command to connect to the ClickHouseServer instance:

If Kerberos authentication is enabled for the current cluster, run the following command:

clickhouse client --host *IP address of the node where the ClickHouseServer instance is located* **--user clickhouse/hadoop.***<System domain name>* **--password** *clickhouse.keytab path obtained in* ***Step 2*** **--port** *ClickHouse port number* **--secure**

If Kerberos authentication is disabled for the current cluster, run the following command:

clickhouse client --host *IP address of the node where the ClickHouseServer instance is located* **--user clickhouse --port** *ClickHouse port number*

Step 7 Run the following statement to grant permissions to a database:

In the syntax for granting permissions, *DATABASE* indicates the name of the target database, and *role* indicates the target role.

GRANT [ON CLUSTER *cluster_name***]** *privilege* **ON** *{DATABASE|TABLE}* **TO** *{user | role}*

For example, grant user **testuser** the CREATE permission on database **t2**:

GRANT CREATE ON *t2* **to** *testuser***;**

Step 8 Run the following commands to grant permissions on the table or view. In the following command, *TABLE* indicates the name of the table or view to be operated, and *user* indicates the role to be operated.

Run the following command to grant the query permission on tables in a database:

GRANT SELECT ON *TABLE* **TO** *user;*

Run the following command to grant the write permission on tables in a database:

GRANT INSERT ON *TABLE* **TO** *user***;**

NOTE

For details about ClickHouse **GRANT** operations and permission description, visit **https://clickhouse.tech/docs/en/sql-reference/statements/grant/**.

Step 9 Run the following command to exit the client:

quit;

----End

3.2.3 Configuring Interconnection Between ClickHouse and OpenLDAP Authentication System

ClickHouse can be interconnected with OpenLDAP. You can manage accounts and permissions in a centralized manner by adding the OpenLDAP server configuration and creating users on ClickHouse. You can use this method to import users from the OpenLDAP server to ClickHouse in batches.

This section applies only to MRS 3.1.0 or later.

Prerequisites

- The MRS cluster and ClickHouse instances are running properly, and the ClickHouse client has been installed.
- OpenLDAP has been installed and is running properly.

Creating a ClickHouse User for Interconnecting with the OpenLDAP Server

Step 1 Log in to Manager and choose **Cluster** > **Services** > **ClickHouse**. Click the **Configurations** tab and then **All Configurations**.

Step 2 Choose **ClickHouseServer(Role)** > **Customization**, and add the following OpenLDAP configuration parameters to the **clickhouse-config-customize** configuration item. See **Figure 3-2**.

Table 3-4 OpenLDAP parameters

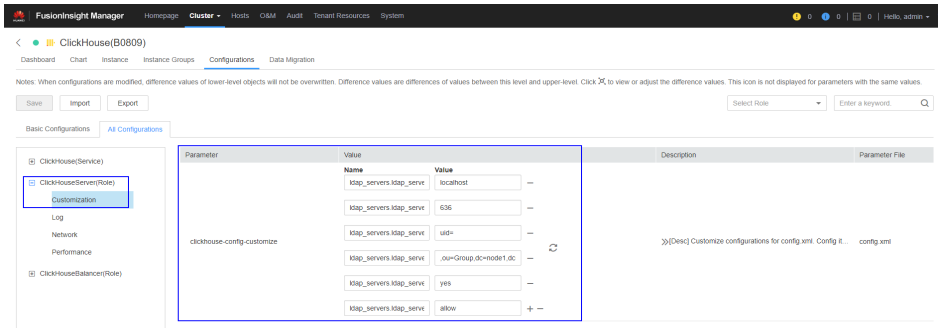
Parameter	Description	Example Value
ldap_servers.ldap_server_name.host	OpenLDAP server host name or IP address. This parameter cannot be empty.	localhost
ldap_servers.ldap_server_name.port	OpenLDAP server port number. If **enable_tls** is set to **true**, the default port number is **636**. Otherwise, the default port number is **389**.	636
ldap_servers.ldap_server_name.auth_dn_prefix	Prefix and suffix used to construct the DN to bind to. The generated DN will be constructed as a string in the following format: **auth_dn_prefix** + **escape(user_name)** + **auth_dn_suffix**. Use a comma (,) as the first non-space character of **auth_dn_suffix**.	uid=
ldap_servers.ldap_server_name.auth_dn_suffix		,ou=Group,dc=node1,dc=com
ldap_servers.ldap_server_name.enable_tls	A tag to trigger the use of the secure connection to the OpenLDAP server. • Set it to **no** for the plaintext (ldap://) protocol (not recommended). • Set it to **yes** for the LDAP over SSL/TLS (ldaps://) protocol.	yes

Parameter	Description	Example Value
ldap_servers.ldap_server_name.tls_require_cert	SSL/TLS peer certificate verification behavior. The value can be **never**, **allow**, **try**, or **require**.	allow

NOTE

For details about other parameters, see **<ldap_servers> Parameters**.

Figure 3-2 OpenLDAP configuration



Step 3 After the configuration is complete, click **Save**. In the displayed dialog box, click **OK**. After the configuration is saved, click **Finish**.

Step 4 On Manager, click **Instance**, select a ClickHouseServer instance, and choose **More** > **Restart Instance**. In the displayed dialog box, enter the password and click **OK**. In the displayed **Restart instance** dialog box, click **OK**. Confirm that the instance is restarted successfully as prompted and click **Finish**.

Step 5 Log in to the ClickHouseServer instance node and go to the **${BIGDATA_HOME}/FusionInsight_ClickHouse_***Version number*_*x_x*_**ClickHouseServer/etc** directory.

cd ${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*x_x*_ClickHouseServer/etc

Step 6 Run the following command to view the **config.xml** configuration file and check whether the OpenLDAP parameters are configured successfully:

cat config.xml

```
[root@k                3 etc]# cat config.xml
<yandex>
  <ldap_servers>
    <ldap_server_name>
      <auth_dn_prefix>uid=</auth_dn_prefix>
      <port>636</port>
      <host>localhost</host>
      <enable_tls>yes</enable_tls>
      <tls_require_cert>allow</tls_require_cert>
      <auth_dn_suffix>,ou=Group,dc=node1,dc=com</auth_dn_suffix>
    </ldap_server_name>
  </ldap_servers>
  <zookeeper>
```

Step 7 Log in to the node where the ClickHouseServer instance is located as user **root**.

Step 8 Run the following command to obtain the path of the **clickhouse.keytab** file:

ls ${BIGDATA_HOME}/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/keytab/clickhouse.keytab

Step 9 Log in to the node where the client is installed as the client installation user.

Step 10 Run the following command to go to the ClickHouse client installation directory:

cd /opt/client

Step 11 Run the following command to configure environment variables:

source bigdata_env

Step 12 Run the following command to connect to the ClickHouseServer instance:

- If Kerberos authentication is enabled for the current cluster, use **clickhouse.keytab** to connect to the ClickHouseServer instance.

  clickhouse client --host *IP address of the node where the ClickHouseServer instance is located* **--user clickhouse/hadoop.***<System domain name>* **--password** *clickhouse.keytab path obtained in* ***Step 8*** **--port** *ClickHouse port number*

  NOTE

  The default system domain name is **hadoop.com**. Log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust**. The value of **Local Domain** is the system domain name. Change the letters to lowercase letters when running a command.

- If Kerberos authentication is not enabled for the current cluster, connect to the ClickHouseServer instance as the ClickHouse administrator.

  clickhouse client --host *IP address of the node where the ClickHouseServer instance is located* **--user clickhouse --port** *ClickHouse port number*

Step 13 Create a common user of OpenLDAP.

Run the following statement to create user **testUser** in cluster **default_cluster** and set **ldap_server** to the OpenLDAP server name in the **<ldap_servers>** tag in **Step 6**. In this example, the name is **ldap_server_name**.

CREATE USER *testUser* **ON CLUSTER** *default_cluster* **IDENTIFIED WITH ldap_server BY** 'ldap_server_name'**;**

testUser indicates an existing username in OpenLDAP. Change it based on the site requirements.

Step 14 Log out of the client, and then log in to the client as the new user to check whether the configuration is successful.

exit;

clickhouse client --host *IP address of the ClickHouseServer instance* **--user** *testUser* **--password --port** *ClickHouse port number*

Enter the password of testUser.

----End

<ldap_servers> Parameters

- **host**: OpenLDAP server host name or IP address. This parameter is mandatory.
- **port**: port number of the OpenLDAP server. If **enable_tls** is set to **true**, the default value is **636**. Otherwise, the value is **389**.
- **auth_dn_prefix, auth_dn_suffix**: Prefix and suffix used to construct the DN to bind to. The generated DN will be constructed as a string in the following format: **auth_dn_prefix** + **escape(user_name)** + **auth_dn_suffix**. Use a comma (,) as the first non-space character of **auth_dn_suffix**.
- **enable_tls**: tag to trigger the use of the secure connection to the OpenLDAP server.

  Set it to **no** for the plaintext (ldap://) protocol (not recommended).

  Set it to **yes** for LDAP over SSL/TLS (ldaps://) protocol (recommended and default).
- **tls_minimum_protocol_version**: minimum protocol version of SSL/TLS

  The value can be **ssl2**, **ssl3**, **tls1.0**, **tls1.1**, or **tls1.2** (default).
- **tls_require_cert**: SSL/TLS peer certificate verification behavior

  The value can be **never**, **allow**, **try**, or **require** (default).
- **tls_cert_file**: certificate file
- **tls_key_file**: certificate key file
- **tls_ca_cert_file**: CA certificate file
- **tls_ca_cert_dir**: directory where the CA certificate is stored
- **tls_cipher_suite**: cipher suites allowed

3.3 ClickHouse Client Practices

ClickHouse is a column-based database oriented to online analysis and processing. It supports SQL query and provides good query performance. The aggregation analysis and query performance based on large and wide tables is excellent, which is one order of magnitude faster than other analytical databases.

ClickHouse uses the ReplicatedMergeTree engine and ZooKeeper to replicate tables. When creating a table, you can specify the engine to enable table replication for high availability. Shards and replicas of each table are independent from each other.

ClickHouse supports distributed tables by using the Distributed engine. Views are created on all shards (local tables) to ease distributed queries. ClickHouse supports data sharding, which is one of the features of distributed storage. This allows for parallel read and write for faster queries.

This topic uses the cluster client to quickly connect to the ClickHouse service in a cluster.

Prerequisites

- The cluster client has been installed, for example, in the **/opt/client** directory.
- For clusters with Kerberos authentication enabled, you have created a user with ClickHouse operation permissions on Manager, for example, **clickhouseuser**.

Using a ClickHouse Client

Step 1 Install the cluster client. For details, see **Installing a Client**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If Kerberos authentication has been enabled for the cluster, authenticate the user first. If not, skip this step.

The service user must have the permission to create ClickHouse tables. For details, see **Creating a ClickHouse Role**. Create a user on Manager and associate the user to the required role.

kinit *Component service user*

The following provides an example:

kinit *clickhouseuser*

Step 6 Run the **clickhouse client** command to connect to the ClickHouse server.

- Using a non-SSL method for login when Kerberos authentication is disabled for the ClickHouse cluster

  clickhouse client --host *IP address of the ClickHouse instance* **--port** *9000* **--user** *Username* **--password**

- Using SSL for login when Kerberos authentication is enabled for the current cluster:

  clickhouse client --host *IP address of the ClickHouse instance* **--port** *9440* **--user** *Username* **--password**

Table 3-5 Parameters of the **clickhouse client** command

Parameter	Description
--host	Name of the server node. You can use the host name or IP address of the node where the ClickHouse instance is deployed. To obtain the IP address of the ClickHouseServer instance, log in to FusionInsight Manager of the cluster and choose **Cluster** > **Services** > **ClickHouse** > **Instances**.

Parameter	Description
--port	Connection port. • Clusters with Kerberos authentication enabled use SSL connections by default. The default port is 9440, and the **--secure** parameter must be specified. You can also obtain the port number from the **tcp_port_secure** parameter of the ClickHouseServer instance. If a non-SSL connection is required in this scenario, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse** > **Configurations**, search for **SSL_NONESSL_BOTH_ENABLE**, change the value to **true**, and restart all ClickHouse instances. • Clusters with Kerberos authentication disabled use non-SSL connections by default. The default port is 9000, and the **--secure** parameter is not required. You can also obtain the port number from the **tcp_port** parameter of the ClickHouseServer instance. If an SSL connection is required in this scenario, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse** > **Configurations**, search for **SSL_NONESSL_BOTH_ENABLE**, change the value to **true**, and restart all ClickHouse instances. **NOTE** The preceding ports are open-source ports. If a custom port policy is used during cluster creation, replace the ports by referring to **Common Troubleshooting**. You can run the **clickhouse -h** command to view the command help of the ClickHouse component.
--user	Connection username. • If Kerberos authentication has been enabled for the cluster (the cluster is in security mode) and you have passed the kinit authentication, the **--user** and **--password** parameters are optional for client login. You must create a user with this name on Manager because there is no default user for Kerberos authentication. • If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), do not use the ClickHouse user created on FusionInsight Manager to log in to the client. You need to execute the **create user SQL** statement on the client to create a ClickHouse user. Alternatively, you can use the **default** user for login.
--password	User password for connection. This parameter is used together with the **--user** parameter.
--query	Query to process when using non-interactive mode.
--database	The current database is used by default. This parameter uses the default configuration on the server.

Parameter	Description
--multiline	If this parameter is specified, multiline queries are allowed. (**Enter** only indicates line feed and does not indicate that the query statement is complete.)
--multiquery	If this parameter is specified, multiple queries separated with semicolons (;) can be processed. This parameter is valid only in non-interactive mode.
--format	Specified default format used to output the result.
--vertical	If this parameter is specified, the result is output in vertical format by default. In this format, each value is printed on a separate line, which helps to display a wide table.
--time	If this parameter is specified, the query execution time is printed to **stderr** in non-interactive mode.
--stacktrace	If this parameter is specified, stack trace information will be printed when an exception occurs.
--config-file	Name of the configuration file.
--secure	If this parameter is specified, the server will be connected in SSL mode.
--history_file	Path of files that record command history.
--param_<name>	Query with parameters. Pass values from the client to the server. For details, see **https://clickhouse.tech/docs/en/interfaces/cli/#cli-queries-with-parameters**.

Step 7 Run the **quit;** command to exit the ClickHouse server connection.

----End

Viewing Environment Parameters (cluster) of ClickHouse

Step 1 Use the ClickHouse client to connect to the ClickHouse server.

Step 2 Query the **cluster** identifier and other information about the environment parameters.

select cluster,shard_num,replica_num,host_name from system.clusters;

```
SELECT
    cluster,
    shard_num,
    replica_num,
    host_name
FROM system.clusters

┌─cluster─────────────┬─shard_num─┬─replica_num─┬─host_name──────────┐
│ default_cluster_1   │         1 │           1 │ node-master1dOnG   │
│ default_cluster_1   │         1 │           2 │ node-group-1tXED0001 │
│ default_cluster_1   │         2 │           1 │ node-master2OXQS   │
│ default_cluster_1   │         2 │           2 │ node-group-1tXED0002 │
│ default_cluster_1   │         3 │           1 │ node-master3QsRI   │
```

```
┌─default_cluster_1─┬─3─┬─2─┬─node-group-1tXED0003─┐
└───────────────────┴───┴───┴──────────────────────┘

6 rows in set. Elapsed: 0.001 sec.
```

Step 3 Query the **shard** and **replica** identifiers.

select * from system.macros;

```
SELECT *
FROM system.macros

┌─macro───────┬─substitution─┐
│ id          │ 76           │
│ replica     │ 2            │
│ shard       │ 3            │
└─────────────┴──────────────┘

3 rows in set. Elapsed: 0.001 sec.
```

----End

Creating a Local Replicated Table and a Distributed Table

Step 1 Create a replicated table using the ReplicatedMergeTree engine.

For details about the syntax, see **https://clickhouse.tech/docs/en/engines/table-engines/mergetree-family/replication/#creating-replicated-tables**.

For example, to create the ReplicatedMergeTree table **test** in the **default** database on all **default_cluster_1** nodes, run the following command:

CREATE TABLE *default.test* **ON CLUSTER** *default_cluster_1*

(

`EventDate` DateTime,

`id` UInt64

)

ENGINE = ReplicatedMergeTree('*/clickhouse/tables/{shard}/default/test***', '***{replica}***')**

PARTITION BY toYYYYMM(EventDate)

ORDER BY id;

- **ON CLUSTER** is a distributed DDL clause that creates the same local table on all instances in the cluster in one execution.
- **default_cluster_1** is the cluster identifier used for viewing environment parameters of the ClickHouse service.

CAUTION

ReplicatedMergeTree engine receives the following two parameters:

- Storage path of the table data in ZooKeeper

  The path must be in the **/clickhouse** directory. Otherwise, data insertion may fail due to insufficient ZooKeeper quota.

  To avoid data conflict between different tables in ZooKeeper, the directory must be in the following format:

  /clickhouse/tables/{shard}/default/test, in which **/clickhouse/tables/{shard}** is fixed, *default* indicates the database name, and *text* indicates the name of the created table.

- Replica name: Generally, **{replica}** is used.

```
CREATE TABLE default.test ON CLUSTER default_cluster_1
(
   `EventDate` DateTime,
   `id` UInt64
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/test', '{replica}')
PARTITION BY toYYYYMM(EventDate)
ORDER BY id

┌─host──────────────────────┬─port─┬─status─┬─error─┬─num_hosts_remaining─┬─num_hosts_activ
e─┐
│ node-group-1tXED0002      │ 9000 │      0 │       │                   5 │               3 │
│ node-group-1tXED0003      │ 9000 │      0 │       │                   4 │               3 │
│ node-master1dOnG          │ 9000 │      0 │       │                   3 │               3 │
└───────────────────────────┴──────┴────────┴───────┴─────────────────────┴─────────────────┘
┌─host──────────────────────┬─port─┬─status─┬─error─┬─num_hosts_remaining─┬─num_hosts_activ
e─┐
│ node-master3QsRI          │ 9000 │      0 │       │                   2 │               0 │
│ node-group-1tXED0001      │ 9000 │      0 │       │                   1 │               0 │
│ node-master2OXQS          │ 9000 │      0 │       │                   0 │               0 │
└───────────────────────────┴──────┴────────┴───────┴─────────────────────┴─────────────────┘

6 rows in set. Elapsed: 0.189 sec.
```

Step 2 Create a distributed table using the Distributed engine.

For example, run the following statement to create the **test_all** table in the **default** database on all **default_cluster_1** nodes:

CREATE TABLE *default.test_all* **ON CLUSTER** *default_cluster_1*

(

`EventDate` DateTime,

`id` UInt64

)

ENGINE = Distributed(*default_cluster_1, default, test, rand()***);**

```
CREATE TABLE default.test_all ON CLUSTER default_cluster_1
(
   `EventDate` DateTime,
   `id` UInt64
)
ENGINE = Distributed(default_cluster_1, default, test, rand())

┌─host──────────────────────┬─port─┬─status─┬─error─┬─num_hosts_remaining─┬─num_hosts_activ
```

```
e┐
│ node-group-1tXED0002 │ 9000 │ 0 │ │ 5 │ 0 │
│ node-master3QsRI │ 9000 │ 0 │ │ 4 │ 0 │
│ node-group-1tXED0003 │ 9000 │ 0 │ │ 3 │ 0 │
│ node-group-1tXED0001 │ 9000 │ 0 │ │ 2 │ 0 │
│ node-master1dOnG │ 9000 │ 0 │ │ 1 │ 0 │
│ node-master2OXQS │ 9000 │ 0 │ │ 0 │ 0 │
└──────────────────┴──────┴───┴──┴──┴──┘
```

6 rows in set. Elapsed: 0.115 sec.

NOTE

Distributed requires the following parameters:

- **default_cluster_1** is the cluster identifier used for viewing environment parameters of the ClickHouse service.
- **default** indicates the name of the database where the local table is located.
- **test** is the name of the local table.
- (Optional) Sharding key

  This key and the weight configured in the **config.xml** file determine the route for writing data to the distributed table, that is, the physical table to which the data is written. It can be the original data (for example, **site_id**) of a column in the table or the result of the function call, for example, **rand()** is used in the preceding SQL statement. Note that data must be evenly distributed in this key. Another common operation is to use the hash value of a column with a large difference, for example, **intHash64(user_id)**.

----End

ClickHouse Table Data Operations

Step 1 Insert data to the local table.

For example, insert data to the **test** table.

insert into test values(toDateTime(now()), rand());

Step 2 Query local table information.

For example, query data in the **test** table.

select * from test;

```
SELECT *
FROM test

┌─────────EventDate─┬──────────id─┐
│ 2020-11-05 21:10:42 │ 1596238076 │
└─────────────────────┴────────────┘

1 rows in set. Elapsed: 0.002 sec.
```

Step 3 Query the distributed table.

The following example queries the distributed table**test_all**, which is created based on **test**, and gets the same result as querying the **test** table.

select * from test_all;

```
SELECT *
FROM test_all
```

```
┌─────────────EventDate─┬──────────id─┐
│ 2020-11-05 21:10:42   │ 1596238076  │
└───────────────────────┴─────────────┘

1 rows in set. Elapsed: 0.004 sec.
```

Step 4 Switch to the shard node with the same **shard_num** and query the information about the current table. The same table data can be queried.

For example, run the **exit;** command to exit the original node.

Run the following command to switch to the **node-group-1tXED0003** node:

clickhouse client --host *node-group-1tXED0003* **--multiline --port 9440 --secure;**

show tables;

```
SHOW TABLES

┌─name─────┐
│ test     │
│ test_all │
└──────────┘
```

Step 5 Query local table data. For example, query data in the **test** table on the **node-group-1tXED0003** node.

select * from test;

```
SELECT *
FROM test

┌─────────────EventDate─┬──────────id─┐
│ 2020-11-05 21:10:42   │ 1596238076  │
└───────────────────────┴─────────────┘

1 rows in set. Elapsed: 0.005 sec.
```

Step 6 Switch to the shard node with different **shard_num** value and query the data of the created table.

For example, exit the **node-group-1tXED0003** node.

exit;

Switch to the **node-group-1tXED0001** node.

clickhouse client --host *node-group-1tXED0001* **--multiline --port 9440 --secure;**

Query the local table **test**. The **test** table data cannot be queried on the different shard nodes.

select * from test;

```
SELECT *
FROM test

Ok.
```

Query data in the distributed table **test_all**. The data can be queried.

select * from test_all;

```
SELECT *
FROM test
```

```
┌─────────────EventDate─┬──────────id─┐
│ 2020-11-05 21:12:19   │ 3686805070  │
└───────────────────────┴─────────────┘

1 rows in set. Elapsed: 0.002 sec.
```

----End

Common Troubleshooting

After the command for connecting to the ClickHouse client is executed, error message "Connection refused" is displayed.

Check whether the cluster uses custom ports (**Component Port** is set to **Custom** during cluster creation). If custom ports are used, replace the ports used in the command for connecting to the ClickHouse component client with the default custom ports in the following table.

Parameter	Default Open Source Port	Default Custom Port	Port Description
interserver_http_port	9009	9009	HTTP port for the communication between ClickHouse servers.
interserver_https_port	9010	9010	HTTPS port for the communication between ClickHouse servers.
http_port	8123	8123	Port for connecting to the ClickHouse server through HTTP.
https_port	8443	8443	Port for connecting to the ClickHouse server through HTTPS.
tcp_port	9000	9000	Port for connecting the client to the ClickHouse server through TCP.
tcp_port_secure	9440	9440	Port for connecting the client to the ClickHouse server through TCP SSL.
lb_tcp_port	21424	21424	TCP port listened by ClickHouseBalancer
lb_http_port	21425	21425	HTTP port listened by ClickHouseBalancer
lb_https_port	21426	21426	HTTPS port listened by ClickHouseBalancer
lb_tcp_secure_port	21428	21428	TCP SSL port listened by ClickHouseBalancer

3.4 ClickHouse Data Import

3.4.1 Interconnecting ClickHouse with RDS for MySQL

ClickHouse provides efficient data analysis in OLAP scenarios. It can map a table on the remote database server to the ClickHouse cluster through a database engine such as MySQL, so data can be analyzed in the ClickHouse cluster. The following describes how to interconnect the ClickHouse cluster with the MySQL database instance of RDS.

Prerequisites

- You have prepared the RDS database instance to be interconnected with and the username and password of the database. For details, see **Creating and Connecting to an RDS DB Instance**.
- A ClickHouse cluster has been created and is running properly.

Constraints

- The RDS database instance and ClickHouse cluster are in the same VPC and subnet.
- Before synchronizing data, you need to evaluate the impact on the performance of the source and destination databases. You are advised to synchronize data during off-peak hours.
- Currently, ClickHouse can interconnect with MySQL and PostgreSQL instances of RDS, but cannot interconnect with SQL Server instances.

Interconnecting ClickHouse with RDS Using the MySQL Engine

The MySQL engine is used to map tables on the remote MySQL server to ClickHouse and allows you to run INSERT and SELECT statements on tables to facilitate data exchange between ClickHouse and MySQL.

Syntax for using the MySQL engine:

```
CREATE DATABASE [IF NOT EXISTS] db_name [ON CLUSTER cluster]
ENGINE = MySQL('host:port', ['database' | database], 'user', 'password')
```

Parameters of the MySQL engine:

- **host:port**: IP address and port number of the RDS MySQL database instance.
- **database**: Name of the RDS MySQL database.
- **user**: Username of the RDS MySQL database.
- **password**: Password of the RDS MySQL database user.

Example of using the MySQL engine:

Step 1 Connect to the MySQL database of RDS. For details, see **Connecting to a DB Instance**.

Step 2 Create a table in the MySQL database and insert data into the table.

Create table **mysql_table**.

CREATE TABLE `mysql_table` (

`int_id` INT NOT NULL AUTO_INCREMENT,

`float` FLOAT NOT NULL,

PRIMARY KEY (`int_id`));

Insert data into the table.

insert into mysql_table (`int_id`, `float`) VALUES (1,2);

Step 3 Log in to the node where the ClickHouse client is installed. Run the following command to go to the client installation directory:

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The user must have the permission to create ClickHouse tables. Therefore, you need to bind the corresponding role to the user. For details, see **Creating a ClickHouse Role**. If Kerberos authentication is disabled for the current cluster, skip this step.

1. Run the following command if it is an MRS 3.1.0 cluster:

   export CLICKHOUSE_SECURITY_ENABLED=true

2. **kinit** *Component service user*

   Example: **kinit clickhouseuser**

Step 6 Run the client command to connect to ClickHouse.

clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password --port** *Port number*

Enter the user password.

Step 7 Create a MySQL database in ClickHouse. After the database is created, it automatically exchanges data with a MySQL server.

CREATE DATABASE mysql_db ENGINE = MySQL('*IP address of the RDS MySQL database instance***:***Port number of the MySQL database instance***', '***MySQL database name***', '***MySQL database username***', '***Password of the MySQL database user***');**

Step 8 Switch to the created database **mysql_db** and query data in the table.

USE mysql_db;

Query the table data in the MySQL database in ClickHouse.

SELECT * FROM mysql_table;

```
┌─int_id─┬─float─┐
│      1 │     2 │
└────────┴───────┘
```

Data can be properly queried after being inserted.

INSERT INTO mysql_table VALUES (3,4);

SELECT * FROM mysql_table;

```
┌─int_id─┬─float─┐
│      1 │     2 │
│      3 │     4 │
└────────┴───────┘
```

----End

Enabling mysql_port for ClickHouse

Configure the ClickHouse port to connect the MySQL client to ClickHouse.

NOTE

This operation is available for MRS 3.1.2 only.

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Search for the **clickhouse-config-customize** parameter and add the following configuration: **Name**: **mysql_port** and **Value**: **9004**.

NOTE

The value is customizable.

Click **Save**.

Step 2 Click the **Dashboard** tab, click **More**, and select **Restart Instance**; alternatively, click **More** and select **Instance Rolling Restart**.

----End

3.4.2 Interconnecting ClickHouse with OBS

Using S3 Table Functions

Step 1 Log in to the active OMS node.

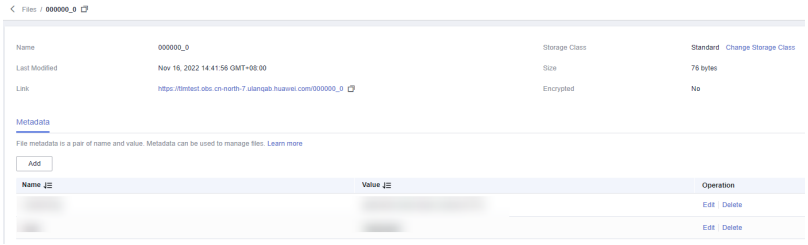
Step 2 Run the following command to obtain the data stored in OBS:

select * from S3(*path, [ak, sk,] format, structure, [compression]***)**

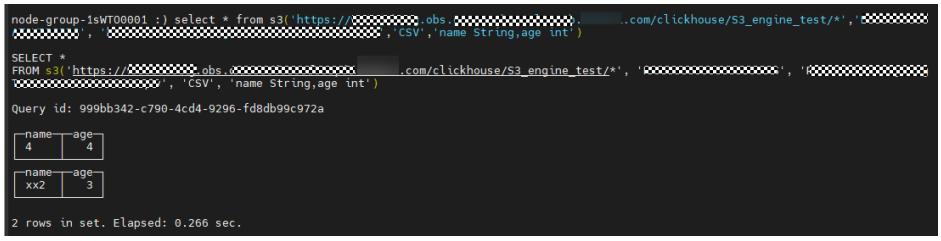
NOTE

- *path*: *Access domain name*/*OBS file path*. Log in to OBS console and choose **Parallel File Systems**. On the page that is displayed, click the file system name. On the **Files** tab page, click the file name. The value of **Link** is the path.

  Figure 3-3 File path



- **ak**: Optional. The AK that has the permission to access OBS.
- **sk**: Optional. The SK that has the permission to access OBS.
- **format**: The file format.
- **structure**: The table schema.
- **compression**: Optional. The compression type.



----End

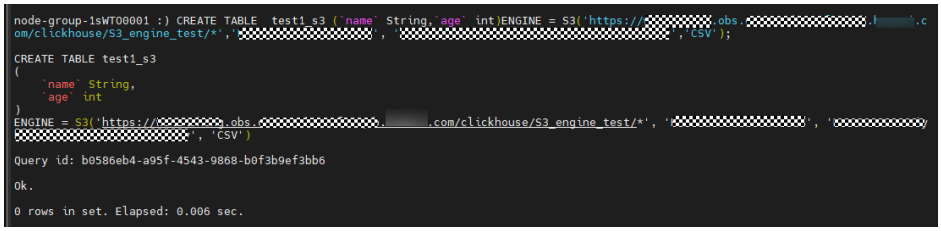
Using the S3 Table Engine

Step 1 Log in to the active OMS node.

Step 2 Run the following commands to create a table:

CREATE TABLE *test1_s3* **(***'name' String, 'age' int***)**

ENGINE = S3(*path, [ak, sk,] format, [compression]***)**



Step 3 Run the following command to query the table:

select * from *test1_s3*;

----End

Modifying Manager Configurations

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Search for the **clickhouse-config-customize** parameter and add values. The following table lists the parameter values.

Parameter	Value
s3.endpoint-name.endpoint	OBS bucket address
s3.endpoint-name.access_key_id	OBS AK. For details on how to obtain the AK, see **How Do I Obtain the Access Key AK/SK?**
s3.endpoint-name.secret_access_key	OBS SK. For details about how to obtain the OBS SK, see **How Do I Obtain the AK/SK?**

Step 2 Typically, the URL shared by OBS contains HTTPS. If the URL is inaccessible directly, perform the following operations to modify the configuration:

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Search for the **clickhouse-config-customize** parameter and add values. The following table lists the parameter values.

Parameter	Value
openSSL.client.loadDefaultCAFile	true
openSSL.client.cacheSessions	true
openSSL.client.disableProtocols	sslv2,sslv3
openSSL.client.preferServerCiphers	true
openSSL.client.invalidCertificateHandler.name	AcceptCertificateHandler

Step 3 After the modification, click **Save**.

----End

3.4.3 Interconnecting ClickHouse with HDFS (MRS 3.2.0-LTS)

NOTE

This topic is available for MRS 3.2.0-LTS version only.

Scenario

Connect ClickHouse to HDFS to read and write files.

Prerequisites

- The ClickHouse client has been installed in a directory, for example, **/opt/client**.
- A user, for example, **clickhouseuser**, who has permissions on ClickHouse tables and has the permission to access HDFS has been created on FusionInsight Manager.
- A corresponding directory exists in HDFS. The HDFS engine of ClickHouse only works with files but does not create or delete directories.
- Only the ClickHouse cluster deployed on x86 nodes can connect to HDFS. The ClickHouse cluster deployed on Arm nodes cannot connect to HDFS.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the current user. (Change the password upon the first authentication. Skip this step for a cluster with Kerberos authentication disabled.)

kinit clickhouseuser

Step 5 Run the client command of ClickHouse to log in to the ClickHouse client.

clickhouse client --host *Service IP address of the ClickHouseServer instance* **--secure --port 9440**

Step 6 Run the following command to connect ClickHouse to HDFS:

CREATE TABLE default.hdfs_engine_table (`name` String, `value` UInt32) ENGINE = HDFS('hdfs://*{namenode_ip}***:***{dfs.namenode.rpc.port}***/tmp/secure_ck.txt', 'TSV')**

NOTE

- To obtain the service IP address of the ClickHouseServer instance, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. On the page that is displayed, click the **Instances** tab. In this tab, obtain the service IP addresses of the ClickHouseServer instance.

- To obtain the value of *namenode_ip*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Instances** tab. In this tab, obtain the service IP addresses of the active NameNode.

- To obtain the value of *dfs.namenode.rpc.port*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. In this sub-tab, search for **dfs.namenode.rpc.port** to obtain its value.

- HDFS file path to be accessed:

  If multiple files need to be accessed, add an asterisk (*) to the end of the folder, for example, **hdfs://***{namenode_ip}*:***{dfs.namenode.rpc.port}***/tmp/***.

----End

3.4.4 Interconnecting ClickHouse with HDFS (MRS 3.3.0-LTS or later)

NOTE

This section applies to MRS 3.3.0-LTS or later.

Scenario

This section describes how to read and write files after connecting ClickHouse in security mode to HDFS in security mode. Functions same as those provided in the open source community are available after ClickHouse is connected to HDFS in normal mode. ClickHouse and HDFS deployed in clusters of different modes cannot be connected.

Prerequisites

- The ClickHouse client has been installed in a directory, for example, **/opt/client**.
- A user, for example, **clickhouseuser**, who has permissions on ClickHouse tables and has the permission to access HDFS has been created on FusionInsight Manager.
- A corresponding directory exists in HDFS. The HDFS engine of ClickHouse only works with files but does not create or delete directories.
- When ClickHouse accesses HDFS across clusters, a user, for example, **hdfsuser**, who has the permission to access HDFS has been created on FusionInsight Manager in the cluster where HDFS is.
- You have obtained the HDFS cluster domain name by logging in to FusionInsight Manager and choosing **System** > **Permission** > **Domain and Mutual Trust**.

- ClickHouse cannot connect to encrypted HDFS directories.

Interconnecting ClickHouse with HDFS in a Cluster

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS**, select **Configuration** > **All Configurations**, search for and change the value of **hadoop.rpc.protection** to **Authentication** or **Integrity**, save the settings, and restart the HDFS service.

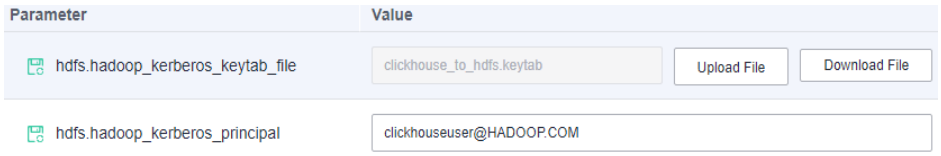
Step 2 Choose **System** > **User**, select **clickhouseuser**, and choose **More** > **Download Authentication Credential**.

NOTE

For the first authentication, change the initial password before downloading the authentication credential file. Otherwise, the security authentication will fail.

Step 3 Decompress the downloaded authentication credential package and change the name of **user.keytab** to **clickhouse_to_hdfs.keytab**.

Step 4 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, and click **Configurations** then **All Configurations**. Click **ClickHouseServer(Role)** and select **Engine**. Click **Upload File** next to **hdfs.hadoop_kerberos_keytab_file**. Then upload the authentication credential file in **Step 3**. Set **hdfs.hadoop_kerberos_principal** to a value in the format of *Username*@*Domain name*, for example, **clickhouseuser@HADOOP.COM**.



If you are connecting ClickHouse to the HDFS in HA mode, perform the following steps:

1. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Instances**, click any instance name, and click the **hdfs-site.xml** in the **Configuration File** area of the **Dashboard** tab.
2. Obtain the values of the following parameters from **hdfs-site.xml**. For example, if two NameServices are configured for HDFS, one is **hacluster** and the other is **ns1**, you need to obtain the values of the following parameters:

   dfs.nameservices, **dfs.ha.namenodes.***, **dfs.namenode.rpc-address.*.*** and **dfs.client.failover.proxy.provider.*** (change the value to **org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider**)

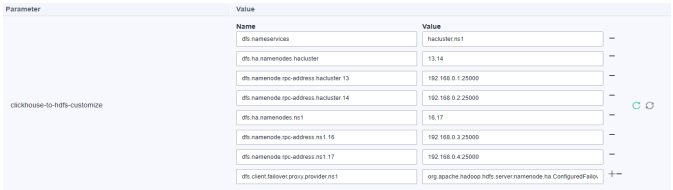
NOTICE

- Value of **dfs.namenode.rpc-address.*.*** can be obtained from the HDFS. If the value is a host name, change it to the service IP address of the host name.
- When configuring **clickhouse-to-hdfs-customize** parameters, use lowercase letters for NameService (regardless of the original letter case of the NameService). For example, if a NameService of the HDFS cluster is **NS1**, convert it to **ns1** in the **clickhouse-to-hdfs-customize** file.

The following is an example:

```
<property>
<name>dfs.nameservices</name>
<value>hacluster,ns1</value>
</property>
<property>
<name>dfs.namenode.rpc-address.hacluster.13</name>
<value>192.168.0.1:25000</value>
</property>
<property>
<name>dfs.namenode.rpc-address.hacluster.14</name>
<value>192.168.0.2:25000</value>
</property>
<property>
<name>dfs.ha.namenodes.hacluster</name>
<value>13,14</value>
</property>
<name>dfs.namenode.rpc-address.ns1.16</name>
<value>192.168.0.3:25000</value>
</property>
<property>
<name>dfs.namenode.rpc-address.ns1.17</name>
<value>192.168.0.4:25000</value>
</property>
<property>
<name>dfs.ha.namenodes.ns1</name>
<value>16,17</value>
</property>
<property>
<name>dfs.client.failover.proxy.provider.ns1</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
<property>
<name>dfs.client.failover.proxy.provider.hacluster</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
```

3. On FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations** > **ClickHouseServer(Role)** > **Engine**, and add the parameter values obtained in **Step 4.2** to the custom configuration **clickhouse-to-hdfs-customize**.



Step 5 Save the configuration and restart ClickHouse.

Step 6 Log in to the node where the client is installed as the client installation user.

Step 7 Run the following command to go to the client installation directory:

cd /opt/client

Step 8 Run the following command to configure environment variables:

source bigdata_env

Step 9 Run the following command to authenticate the current user. (Skip this step for a cluster with Kerberos authentication disabled.)

kinit clickhouseuser

Step 10 Run the client command of ClickHouse to log in to the ClickHouse client.

clickhouse client --host *Service IP address of the ClickHouseServer instance* **--secure --port 9440**

NOTE

- To obtain the service IP address of the ClickHouseServer instance, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. On the page that is displayed, click the **Instance** tab. On this tab page, obtain the service IP addresses of the ClickHouseServer instance.

Step 11 Connect ClickHouse to HDFS.

- Run the following command to connect to the HDFS component in HA mode:

  CREATE TABLE default.hdfs_engine_table (`name` String, `value` UInt32) ENGINE = HDFS('hdfs://*{nameservice}***/tmp/secure_ck.txt', 'TSV')**

- Run the following command to connect to the HDFS component in non-HA mode:

  CREATE TABLE default.hdfs_engine_table (`name` String, `value` UInt32) ENGINE = HDFS('hdfs://*{namenode_ip}***:***{dfs.namenode.rpc.port}***/tmp/secure_ck.txt', 'TSV')**

NOTE

- To obtain the value of *nameservice*, perform the following steps:

  On FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **NameService Management** and obtain the value of **NameService**. The **nameservice** used in the table creation statement must be in lowercase (regardless of whether the value in the HDFS cluster is in lowercase). For example, if the value in the HDFS cluster is **NS1**, the value in the table creation statement must be in lowercase **ns1**.

- To obtain the value of *namenode_ip*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Instance** tab. On this tab page, obtain the service IP addresses of the active NameNode.

- To obtain the value of *dfs.namenode.rpc.port*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On this sub-tab page, search for **dfs.namenode.rpc.port** to obtain its value.

- HDFS file path to be accessed:

  If multiple files need to be accessed, add an asterisk (*) to the end of the folder, for example, **hdfs://***{namenode_ip}*:*{dfs.namenode.rpc.port}*/**tmp/***.

  ClickHouse cannot connect to encrypted HDFS directories.

- Write data. For details, see **Process of Writing ClickHouse Data to HDFS**.

----End

Interconnecting ClickHouse with HDFS Across Clusters

Step 1 Log in to the FusionInsight Manager of the HDFS cluster, choose **Cluster** > **Services** > **HDFS**, select **Configuration** > **All Configurations**, search for and change the value of **hadoop.rpc.protection** to **Authentication** or **Integrity**, save the settings, and restart the HDFS service.

Step 2 Log in to FusionInsight Manager of the ClickHouse cluster and choose **System** > **Permission** > **Domain and Mutual Trust**. Configure mutual trust or unilateral mutual trust with the HDFS cluster. To configure unilateral mutual trust, configure mutual trust with the HDFS cluster only on the ClickHouse cluster.

Step 3 Log in to FusionInsight Manager of the HDFS cluster and choose **System** > **Permission** > **User**. On the page that is displayed, select **hdfsuser**, click **More**, and select **Download Authentication Credential**.

NOTE

For the first authentication, change the initial password before downloading the authentication credential file. Otherwise, the security authentication will fail.

Step 4 Decompress the downloaded authentication credential package and change the name of **user.keytab** to **clickhouse_to_hdfs.keytab**.

Step 5 Log in to FusionInsight Manager of the ClickHouse cluster, choose **Cluster** > **Services** > **ClickHouse**, and click **Configurations** then **All Configurations**. Click **ClickHouseServer(Role)** and select **Engine**. Click **Upload File** next to **hdfs.hadoop_kerberos_keytab_file** to upload the authentication credential file in **Step 3**. Set **hdfs.hadoop_kerberos_principal** to a value in the format of *Username*@*Domain name*, for example, **hdfsuser@HDFS_HADOOP.COM**.

If you are connecting ClickHouse to the HDFS in HA mode, perform the following steps:

1. Log in to FusionInsight Manager of the HDFS cluster, choose **Cluster** > **Service** > **HDFS** > **Instances**, click any instance name, and click the **hdfs-site.xml** in the **Configuration File** area in the **Dashboard** tab.
2. Obtain the values of the following parameters from **hdfs-site.xml**. For example, if two NameServices are configured for HDFS, one is **hacluster** and the other is **ns1**, you need to obtain the values of the following parameters:

   dfs.nameservices, **dfs.ha.namenodes.***, **dfs.namenode.rpc-address.*.*** and **dfs.client.failover.proxy.provider.*** (change the value to **org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider**)

NOTICE

- Value of **dfs.namenode.rpc-address.*.*** can be obtained from the HDFS. If the value is a host name, change it to the service IP address of the host name.
- When configuring **clickhouse-to-hdfs-customize** parameters, use lowercase letters for NameService (regardless of the original letter case of the NameService). For example, if a NameService of the HDFS cluster is **NS1**, convert it to **ns1** in the **clickhouse-to-hdfs-customize** file.

The following is an example:

```
<property>
<name>dfs.nameservices</name>
<value>hacluster,ns1</value>
</property>
<property>
<name>dfs.namenode.rpc-address.hacluster.13</name>
<value>192.168.0.1:25000</value>
</property>
<property>
<name>dfs.namenode.rpc-address.hacluster.14</name>
<value>192.168.0.2:25000</value>
</property>
<property>
<name>dfs.ha.namenodes.hacluster</name>
<value>13,14</value>
</property>
<name>dfs.namenode.rpc-address.ns1.16</name>
<value>192.168.0.3:25000</value>
</property>
<property>
<name>dfs.namenode.rpc-address.ns1.17</name>
<value>192.168.0.4:25000</value>
</property>
<property>
<name>dfs.ha.namenodes.ns1</name>
<value>16,17</value>
</property>
<property>
<name>dfs.client.failover.proxy.provider.ns1</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
<property>
<name>dfs.client.failover.proxy.provider.hacluster</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
```

3. On FusionInsight Manager of the ClickHouse cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations** > **ClickHouseServer(Role)** > **Engine**, and add the parameter values obtained in **Step 5.2** to the custom configuration **clickhouse-to-hdfs-customize**.

Step 6 Save the configuration and restart ClickHouse.

Step 7 Log in to the node where the client is installed as the client installation user.

Step 8 Run the following command to go to the client installation directory:

cd /opt/client

Step 9 Run the following command to configure environment variables:

source bigdata_env

Step 10 Run the following command to authenticate the current user. (Skip this step for a cluster with Kerberos authentication disabled.)

kinit clickhouseuser

Step 11 Run the client command of ClickHouse to log in to the ClickHouse client.

clickhouse client --host *Service IP address of the ClickHouseServer instance* **--secure --port 9440**

NOTE

To obtain the service IP address of the ClickHouseServer instance, perform the following steps:

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. On the page that is displayed, click the **Instances** tab. On this tab page, obtain the service IP addresses of the ClickHouseServer instance.

Step 12 Connect to the HDFS component.

- Run the following command to connect to the HDFS component in HA mode:

  CREATE TABLE default.hdfs_engine_table (`name` String, `value` UInt32) ENGINE = HDFS('hdfs://*{nameservice}***/tmp/secure_ck.txt', 'TSV')**

- Run the following command to connect to the HDFS component in non-HA mode:

  CREATE TABLE default.hdfs_engine_table (`name` String, `value` UInt32) ENGINE = HDFS('hdfs://*{namenode_ip}***:***{dfs.namenode.rpc.port}***/tmp/secure_ck.txt', 'TSV')**

NOTE

- To obtain the value of *nameservice*, perform the following steps:

  On FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **NameService Management** and obtain the value of **NameService**. The **nameservice** used in the table creation statement must be in lowercase (regardless of whether the value in the HDFS cluster is in lowercase). For example, if the value in the HDFS cluster is **NS1**, the value in the table creation statement must be in lowercase **ns1**.

- To obtain the value of *namenode_ip*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Instance** tab. On this tab page, obtain the service IP addresses of the active NameNode.

- To obtain the value of *dfs.namenode.rpc.port*, perform the following steps:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On this sub-tab page, search for **dfs.namenode.rpc.port** to obtain its value.

- HDFS file path to be accessed:

  If multiple files need to be accessed, add an asterisk (*) to the end of the folder, for example, **hdfs://***{namenode_ip}*:*{dfs.namenode.rpc.port}*/**tmp/***.

- Write data. For details, see **Process of Writing ClickHouse Data to HDFS**.

----End

Process of Writing ClickHouse Data to HDFS

To write ClickHouse data to HDFS, perform the following steps: For example, write the **secure_ck.txt** file in the **/tmp** directory of HDFS.

1. Create an HDFS table.

   CREATE TABLE *hdfs_engine_table* **(name String, value UInt32) ENGINE=HDFS('hdfs://***{namenode_ip}*:*{dfs.namenode.rpc.port}***/tmp/secure_ck.txt', 'TSV')**

2. Write an HDFS data file.

   INSERT INTO *hdfs_engine_table* **VALUES ('one', 1), ('two', 2), ('three', 3)**

3. Query the HDFS data file.

   SELECT * FROM *hdfs_engine_table* **LIMIT 2**

```
┌─name─┬─value─┐
│ one  │     1 │
│ two  │     2 │
└──────┴───────┘
```

CAUTION

- If you use ClickHouse to write data in an HDFS engine table and the target data file does not exist, it will be generated.
- ClickHouse does not support deletion, modification, and appending of HDFS engine table data.
- After the HDFS engine table is deleted from ClickHouse, data files in the HDFS remain unchanged.

3.4.5 Configuring Interconnection Between ClickHouse and Kafka

3.4.5.1 Connecting ClickHouse to the Kafka Using the Username and Password

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

This topic describes how to connect ClickHouse to Kafka using a username and password and consume Kafka data.

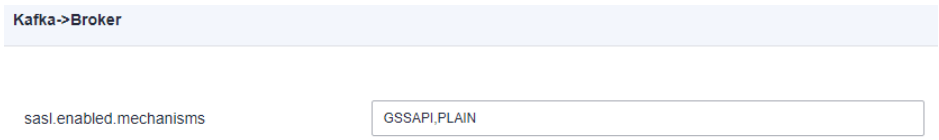
Prerequisites

- A Kafka cluster has been created and is in security mode (Kerberos authentication is enabled).
- The cluster client has been installed.
- If ClickHouse and Kafka are not in the same cluster, establish cross-cluster mutual trust between them. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**.

Procedure

Step 1 Log in to FusionInsight Manager, select **Kafka**, choose **System** > **Permission** > **User**, and click **Create User**. Create a human-machine user with Kafka permission. For example, create a human-machine user **ck_user1**. Change the initial password upon first login. For details about Kafka user permission, see **Kafka User Permissions**.

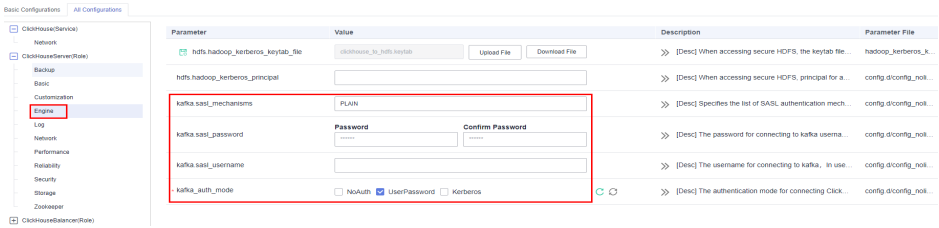
Step 2 Choose **Cluster** > **Services** > **Kafka** and choose **Configurations** > **All Configurations**. Search for **sasl.enabled.mechanisms**, and change the value to **GSSAPI,PLAIN**. Click **Save**.



Step 3 Log in to FusionInsight Manager, select **ClickHouse**, choose **Cluster** > **Services** > **ClickHouse**, and click **Configurations** > **All Configurations**. Select **ClickHouseServer (Role)** > **Engine**, and modify the parameters listed in the following table. Configure the username and password for connecting to Kafka.

Parameter	Description
kafka.sasl_mechanisms	SASL authentication for connecting to Kafka. The parameter value is **PLAIN**.

Parameter	Description
kafka.sasl_password	Password for connecting to Kafka. The initial password of the new user **ck_user1** must be changed. Otherwise, the authentication fails.
kafka.sasl_username	Username for connecting to Kafka. Enter the username created in **Step 1**.
kafka_auth_mode	Authentication mode for the ClickHouse to connect to the Kafka. Set this parameter to **UserPassword**.



Step 4 Click **Save**. In the displayed dialog box, click **OK** to save the configuration. Choose **Instances**, select **ClickHouseServer**, and click **More** > **Instance Rolling Restart**.

Step 5 Go to the Kafka client installation directory. For details, see **Using the Kafka Client**.

1. Log in to the node where the Kafka client is installed as the Kafka client installation user.
2. Run the following command to go to the client installation directory:

   cd /opt/client
3. Run the following command to configure environment variables:

   source bigdata_env
4. If Kerberos authentication is enabled for the cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the cluster, skip this step.

   kinit *Component service user*

Step 6 Run the following command to create a Kafka topic. For details, see **Creating a Kafka Topic**.

kafka-topics.sh --topic *topic1* **--create --zookeeper** *IP address of the Zookeeper role instance:Port used by ZooKeeper to listen to client*/**kafka --partitions** *2* **--replication-factor** *1*

NOTE

- **--topic**: name of the topic to be created, for example, **topic1**.
- **--zookeeper** is the IP address of the node where the ZooKeeper role instances are located, which can be the IP address of any of the three role instances. You can obtain the IP address of the node by performing the following steps:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Instances** tab to query the IP address of the ZooKeeper instance.
- **--partitions** and **--replication-factor** are the topic partitions and topic backup replicas, respectively. The number of the two parameters cannot exceed the number of Kafka role instances.
- To obtain the *Port used by ZooKeeper to listen to the client*, log in to FusionInsight Manager, click **Cluster**, choose **Services** > **ZooKeeper**, and view the value of **clientPort** on the **Configuration** tab page. The default port is 24002.

Step 7 Log in to the ClickHouse client node and connect it to the ClickHouse server. For details, see **ClickHouse Client Practices**.

Step 8 Create a Kafka table engine. The following is an example:

```
CREATE TABLE queue1 (
key String,
value String,
event_date DateTime
) ENGINE = Kafka()
SETTINGS kafka_broker_list = 'kafka_ip1:21007,kafka_ip2:21007,kafka_ip3:21007',
kafka_topic_list = 'topic1',
kafka_group_name = 'group1',
kafka_format = 'CSV',
kafka_row_delimiter = '\n',
kafka_handle_error_mode='stream';
```

The following table lists the related parameters.

Parameter	Description
kafka_broker_list	A list of IP addresses and port numbers of Kafka broker instances. For example, *:IP address 1 of Kafka broker instance*:9092,*IP address 2 of Kafka broker instance*:9092,*IP address 3 of Kafka broker instance*:9092 To obtain the IP address of a Kafka broker instance, perform the following operations: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click the **Instances** tab to query the IP addresses of the Kafka instances.
kafka_topic_list	Topic where Kafka data is consumed
kafka_group_name	Kafka consumer group
kafka_format	Formatting type of consumed data. **JSONEachRow** indicates the JSON format (a piece of data in each line). **CSV** indicates the data is in a line but separated by commas (,).
kafka_row_delimiter	Delimiter character, which ends a message.

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>kafka_handle_error_mode</td><td>If this parameter is set to stream, each message processing exception is printed. You need to create a view and query the specific exception of abnormal data through the view.

The following example shows you how to create a view:
<pre>
CREATE MATERIALIZED VIEW default.kafka_errors2
(
`topic` String,
`key` String,
`partition` Int64,
`offset` Int64,
`timestamp` Date,
`timestamp_ms` Int64,
`raw` String,
`error` String
)
ENGINE = MergeTree
ORDER BY (topic, partition, offset)
SETTINGS index_granularity = 8192 AS
SELECT
_topic AS topic,
_key AS key,
_partition AS partition,
_offset AS offset,
_timestamp AS timestamp,
_timestamp_ms AS timestamp_ms,
_raw_message AS raw,
_error AS error
FROM default.queue1;
</pre>
Query the view. The following is an example:
<pre>
host1 :) select * from kafka_errors2; SELECT * FROM kafka_errors2
Query id: bf4d788f-bcb9-44f5-95d0-a6c83c591ddb
┌─topic───┬─key─┬─partition─┬─offset─┬───timestamp─┬─timestam
p_ms─┬─raw─┬─error──
──
──┐ │ topic1
│   │   1 │   8 │ 2023-06-20 │   1687252213 │ 456 │ Cannot
parse date: value is too short: (at row 1) Buffer has gone, cannot extract
information about what has been parsed. │
└─────────┴───────┴───────────────┴──────────┴────────────
───┴────────────────┴───────┴─────────────────────────────
──
──
──────┘ 1 rows in set. Elapsed: 0.003 sec.   host1 :)
</pre></td></tr>
<tr><td>kafka_skip_broken_messages</td><td>(Optional) Number of Kafka data records where parsing exceptions are ignored. If N exceptions occur and the background thread ends, the materialized view is re-arranged to monitor the data.</td></tr>
<tr><td>kafka_num_consumers</td><td>(Optional) Number of consumers of a single Kafka engine. You can set this parameter to a larger value to improve the consumption data throughput. But the maximum value of this parameter cannot exceed the total number of partitions of the corresponding topic.</td></tr>
</table>

For details about other configurations, see **https://clickhouse.com/docs/en/engines/table-engines/integrations/kafka**.

Step 9 Connect the client to ClickHouse to create a local table. The following is an example:

```
CREATE TABLE daily1(
key String,
value String,
event_date DateTime
)ENGINE = MergeTree()
ORDER BY key;
```

Step 10 Connect the client to ClickHouse to create a materialized view. The following is an example:

```
CREATE MATERIALIZED VIEW default.consumer TO default.daily1 (
`event_date` DateTime,
`key` String,
`value` String
) AS
SELECT
event_date,
key,
value
FROM default.queue1;
```

Step 11 Perform **Step 5** again to go to the Kafka client installation directory.

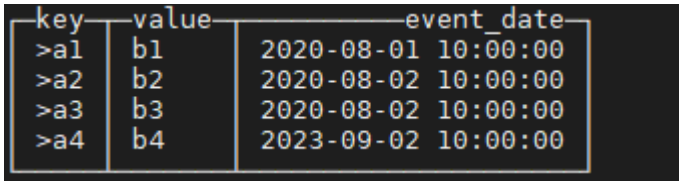
Step 12 Run the following command to send a message to the topic created in **Step 6**:

kafka-console-producer.sh --broker-list *IP address 1 of the Kafka broker instance*:**9092,***IP address 2 of the Kafka broker instance*:**9092,***IP address 3 of the Kafka broker instance*:**9092 --topic** *topic1*

```
>a1,b1,'2020-08-01 10:00:00'
>a2,b2,'2020-08-02 10:00:00'
>a3,b3,'2020-08-02 10:00:00'
>a4,b4,'2023-09-02 10:00:00'
```

Step 13 Query the consumed Kafka data and the preceding materialized view. The following is an example:

```
select * from daily1;
```



----End

3.4.5.2 Interconnecting ClickHouse with Kafka Through Kerberos Authentication

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

This topic describes how to connect ClickHouse to Kafka using Kerberos authentication and how to consume Kafka data.

Prerequisites

- A Kafka cluster has been created and is in security mode (Kerberos authentication is enabled).
- The cluster client has been installed.
- If ClickHouse and Kafka are not in the same cluster, establish cross-cluster mutual trust between them. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**.

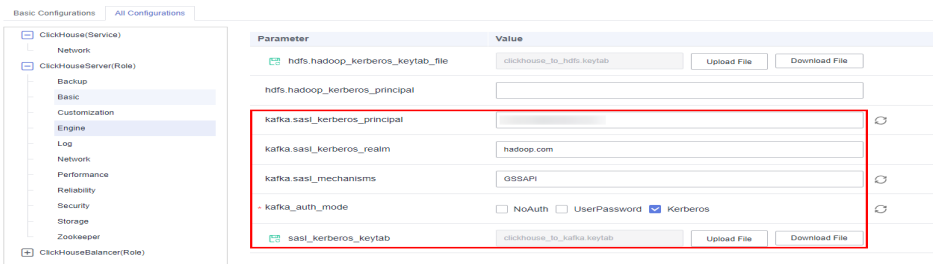
Procedure

Step 1 Log in to the FusionInsight Manager of the cluster where Kafka is deployed, choose **System** > **Permission** > **User** > **Create User**, and create a human-machine user with the Kafka permission. For example, create a human-machine user **ck_user1**. For details about Kafka user permission, see **Kafka User Permissions**.

Step 2 Choose **System** > **Permission** > **User**. On the displayed page, locate the **ck_user1** user, and click **More** > **Download Authentication Credential** in the **Operation** column of the user. Save the file and decompress it to obtain the **user.keytab** and **krb5.conf** files. Rename the **user.keytab** file **clickhouse_to_kafka.keytab**.

Step 3 Log in to the FusionInsight Manager of the cluster where ClickHouse is deployed, and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, and click **ClickHouseServer(Role)** > **Engine**. The following table shows the parameter needs to be configured.

Parameter	Description
kafka.sasl_kerberos_principal	Principal for connecting to Kafka. Enter the username created in **Step 1**.
kafka.sasl_kerberos_realm	Domain name of the Kafka cluster
kafka.sasl_mechanisms	SASL authentication for connecting to Kafka. The parameter value is **GSSAPI**.
kafka_auth_mode	Authentication mode for the ClickHouse to connect to the Kafka. Set this parameter to **Kerberos**.
sasl_kerberos_keytab	Authentication file for connecting to Kafka, which is the **clickhouse_to_kafka.keytab** file uploaded in **Step 2**.



Step 4 Click **Save**. In the displayed dialog box, click **OK** to save the configuration. Choose **Instances**, select **ClickHouseServer**, and click **More** > **Instance Rolling Restart**.

Step 5 Go to the Kafka client installation directory. For details, see **Using the Kafka Client**.

1. Log in to the node where the Kafka client is installed as the Kafka client installation user.
2. Run the following command to go to the client installation directory:

   cd /opt/client
3. Run the following command to configure environment variables:

   source bigdata_env
4. Run the following command to authenticate the user:

   kinit *Component service user*

Step 6 Run the following command to create a Kafka topic. For details, see **Creating a Kafka Topic**.

kafka-topics.sh --topic *topic1* **--create --zookeeper** *IP address of the Zookeeper role instance:Port used by ZooKeeper to listen to client*/**kafka --partitions** *2* **--replication-factor** *1*

NOTE

- **--topic**: name of the topic to be created, for example, **topic1**.
- **--zookeeper** is the IP address of the node where the ZooKeeper role instances are located, which can be the IP address of any of the three role instances. You can obtain the IP address of the node by performing the following steps:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Instances** tab to query the IP address of the ZooKeeper instance.
- **--partitions** and **--replication-factor** are the topic partitions and topic backup replicas, respectively. The number of the two parameters cannot exceed the number of Kafka role instances.
- To obtain the *Port used by ZooKeeper to listen to the client*, log in to FusionInsight Manager, click **Cluster**, choose **Services** > **ZooKeeper**, and view the value of **clientPort** on the **Configuration** tab page. The default port is 24002.

Step 7 Log in to the ClickHouse client node and connect it to the ClickHouse server. For details, see **ClickHouse Client Practices**.

Step 8 Create a Kafka table engine. The following is an example:

```
CREATE TABLE queue1 (
key String,
value String,
event_date DateTime
) ENGINE = Kafka()
SETTINGS kafka_broker_list = 'kafka_ip1:21007,kafka_ip2:21007,kafka_ip3:21007',
kafka_topic_list = 'topic1',
kafka_group_name = 'group2',
kafka_format = 'CSV',
kafka_row_delimiter = '\n',
kafka_handle_error_mode='stream';
```

The following table lists the related parameters.

Parameter	Description
kafka_broker_list	A list of IP addresses and port numbers of Kafka broker instances. For example, *:IP address 1 of Kafka broker instance*:9092,*IP address 2 of Kafka broker instance*:9092,*IP address 3 of Kafka broker instance*:9092 To obtain the IP address of a Kafka broker instance, perform the following operations: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click the **Instance** tab to query the IP addresses of the Kafka instances.
kafka_topic_list	Topic where Kafka data is consumed
kafka_group_name	Kafka consumer group
kafka_format	Formatting type of consumed data. **JSONEachRow** indicates the JSON format (a piece of data in each line). **CSV** indicates the data is in a line but separated by commas (,).
kafka_row_delimiter	Delimiter character, which ends a message.

Parameter	Description

kafka_handle_error_mode	If this parameter is set to **stream**, each message processing exception is printed. You need to create a view and query the specific exception of abnormal data through the view.
	The following example shows you how to create a view:
	`CREATE MATERIALIZED VIEW default.kafka_errors2`
	`(`
	`` `topic` String, ``
	`` `key` String, ``
	`` `partition` Int64, ``
	`` `offset` Int64, ``
	`` `timestamp` Date, ``
	`` `timestamp_ms` Int64, ``
	`` `raw` String, ``
	`` `error` String ``
	`)`
	`ENGINE = MergeTree`
	`ORDER BY (topic, partition, offset)`
	`SETTINGS index_granularity = 8192 AS`
	`SELECT`
	`_topic AS topic,`
	`_key  AS key,`
	`_partition AS partition,`
	`_offset AS offset,`
	`_timestamp AS timestamp,`
	`_timestamp_ms AS timestamp_ms,`
	`_raw_message AS raw,`
	`_error AS error`
	`FROM default.queue1;`
	Query the view. The following is an example:
	`host1 :) select * from kafka_errors2;  SELECT * FROM kafka_errors2`
	`Query id: bf4d788f-bcb9-44f5-95d0-a6c83c591ddb`
	`┌─topic──┬─key─┬─partition─┬─offset─┬──timestamp─┬─timestamp_ms─┬─raw─┬─error─────────────┐`
	`│ topic1 │     │         1 │      8 │ 2023-06-20 │   1687252213 │ 456 │ Cannot parse date: value is too short: (at row 1) Buffer has gone, cannot extract information about what has been parsed. │`
	`└────────┴─────┴───────────┴────────┴────────────┴──────────────┴─────┴───────────────────┘`
	`1 rows in set. Elapsed: 0.003 sec.   host1 :)`

kafka_skip_broken_messages	(Optional) Number of Kafka data records where parsing exceptions are ignored. If *N* exceptions occur and the background thread ends, the materialized view is re-arranged to monitor the data.
kafka_num_consumers	(Optional) Number of consumers of a single Kafka engine. You can set this parameter to a larger value to improve the data consumption throughput. But the maximum value of this parameter cannot exceed the total number of partitions of the corresponding topic.

For details about other configurations, see **https://clickhouse.com/docs/en/engines/table-engines/integrations/kafka**.

Step 9 Connect the client to ClickHouse to create a local table. The following is an example:

```
CREATE TABLE daily1(
key String,
value String,
event_date DateTime
)ENGINE = MergeTree()
ORDER BY key;
```

Step 10 Connect the client to ClickHouse to create a materialized view. The following is an example:

```
CREATE MATERIALIZED VIEW default.consumer1 TO default.daily1 (
`event_date` DateTime,
`key` String,
`value` String
) AS
SELECT
event_date,
key,
value
FROM default.queue1;
```

Step 11 Perform **Step 5** again to go to the Kafka client installation directory.

Step 12 Run the following command to send a message to the topic created in **Step 6**:

kafka-console-producer.sh --broker-list *IP address 1 of the Kafka broker instance*:**9092,***IP address 2 of the Kafka broker instance*:**9092,***IP address 3 of the Kafka broker instance*:**9092 --topic** *topic1*

```
>a1,b1,'2020-08-01 10:00:00'
>a2,b2,'2020-08-02 10:00:00'
>a3,b3,'2020-08-02 10:00:00'
>a4,b4,'2023-09-02 10:00:00'
```

Step 13 Query the consumed Kafka data and the preceding materialized view. The following is an example:

```
select * from daily1;
```

----End

3.4.5.3 Connecting ClickHouse to Kafka in Normal Mode

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

This topic describes how to connect to Kafka in normal mode and consume Kafka data.

Prerequisites

- A Kafka cluster has been created and is in normal mode (Kerberos authentication is disabled).
- You have created a ClickHouse cluster and installed the ClickHouse client. The ClickHouse and Kafka clusters can communicate with each other.

Procedure

Step 1 Log in to the FusionInsight Manager of the cluster where ClickHouse is deployed, and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, and click **ClickHouseServer(Role)** > **Engine**. The following table shows the parameter needs to be configured.

Parameter	Description
kafka_auth_mode	Authentication method for the connection between ClickHouse and Kafka. Set this parameter to **NoAuth**.

Step 2 Choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** > **All Configurations** > **ClickHouseServer (Role)** > **Customization**, and add the following parameters to **clickhouse-config-customize**.

Name	Value
kafka.security_protocol	plaintext

Step 3 Click **Save**. In the displayed dialog box, click **OK** to save the configuration. Choose **Instances**, select **ClickHouseServer**, and click **More** > **Instance Rolling Restart**.

Step 4 Go to the Kafka client installation directory. For details, see **Using the Kafka Client**.

1. Log in to the node where the Kafka client is installed as the Kafka client installation user.
2. Run the following command to go to the client installation directory:

   cd /opt/client
3. Run the following command to configure environment variables:

   source bigdata_env
4. If Kerberos authentication is enabled for the cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the cluster, skip this step.

   kinit *Component service user*

Step 5 Run the following command to create a Kafka topic. For details, see **Creating a Kafka Topic**.

kafka-topics.sh --topic *topic1* **--create --zookeeper** *IP address of the Zookeeper role instance:Port used by ZooKeeper to listen to client*/**kafka --partitions** *2* **--replication-factor** *1*

NOTE

- **--topic**: name of the topic to be created, for example, **topic1**.
- **--zookeeper** is the IP address of the node where the ZooKeeper role instances are located, which can be the IP address of any of the three role instances. You can obtain the IP address of the node by performing the following steps:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Instances** tab to query the IP address of the ZooKeeper instance.
- **--partitions** and **--replication-factor** are the topic partitions and topic backup replicas, respectively. The number of the two parameters cannot exceed the number of Kafka role instances.
- To obtain the *Port used by ZooKeeper to listen to the client*, log in to FusionInsight Manager, click **Cluster**, choose **Services** > **ZooKeeper**, and view the value of **clientPort** on the **Configuration** tab page. The default port is 24002.

Step 6 Log in to the ClickHouse client node and connect it to the ClickHouse server. For details, see **ClickHouse Client Practices**.

Step 7 Create a Kafka table engine. The following is an example:

```
CREATE TABLE queue1 (
key String,
value String,
event_date DateTime
) ENGINE = Kafka()
SETTINGS kafka_broker_list = 'kafka_ip1:21005,kafka_ip2:21005,kafka_ip3:21005',
kafka_topic_list = 'topic1',
kafka_group_name = 'group2',
kafka_format = 'CSV',
kafka_row_delimiter = '\n',
kafka_handle_error_mode='stream';
```

The following table lists the related parameters.

Parameter	Description
kafka_broker_list	A list of IP addresses and port numbers of Kafka broker instances. For example, *:IP address 1 of Kafka broker instance*:9092,*IP address 2 of Kafka broker instance*:9092,*IP address 3 of Kafka broker instance*:9092 To obtain the IP address of the Kafka broker instance, perform the following steps: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click the **Instance** tab to query the IP addresses of the Kafka instances.
kafka_topic_list	Topic where Kafka data is consumed
kafka_group_name	Kafka consumer group

<table>
<tr><th>Parameter</th><th>Description</th></tr>
<tr><td>kafka_format</td><td>Formatting type of consumed data. JSONEachRow indicates the JSON format (a piece of data in each line). CSV indicates the data is in a line but separated by commas (,). For more information, visit https://clickhouse.tech/docs/en/interfaces/formats/.</td></tr>
<tr><td>kafka_row_delimiter</td><td>Delimiter character, which ends a message.</td></tr>
<tr><td>kafka_handle_error_mode</td><td>If this parameter is set to stream, each message processing exception is printed. You need to create a view and query the specific exception of abnormal data through the view.

The following example shows you how to create a view:
CREATE MATERIALIZED VIEW default.kafka_errors2
(
`topic` String,
`key` String,
`partition` Int64,
`offset` Int64,
`timestamp` Date,
`timestamp_ms` Int64,
`raw` String,
`error` String
)
ENGINE = MergeTree
ORDER BY (topic, partition, offset)
SETTINGS index_granularity = 8192 AS
SELECT
_topic AS topic,
_key AS key,
_partition AS partition,
_offset AS offset,
_timestamp AS timestamp,
_timestamp_ms AS timestamp_ms,
_raw_message AS raw,
_error AS error
FROM default.queue1;

Query the view. The following is an example:
host1 :) select * from kafka_errors2; SELECT * FROM kafka_errors2
Query id: bf4d788f-bcb9-44f5-95d0-a6c83c591ddb
┌─topic──┬─key─┬─partition─┬─offset─┬──timestamp─┬─timestam
p_ms─┬─raw─┬─error───────────────────────────
──
──────────────────────────────┐ │ topic1
│ │ 1 │ 8 │ 2023-06-20 │ 1687252213 │ 456 │ Cannot
parse date: value is too short: (at row 1) Buffer has gone, cannot extract
information about what has been parsed. │
└──────┴──────┴──────┴──────────┴──────────
──┴──────────┴──────┴──────────────────
──
──
─────┘ 1 rows in set. Elapsed: 0.003 sec.   host1 :)</td></tr>
<tr><td>kafka_skip_broken_messages</td><td>(Optional) Number of Kafka data records where parsing exceptions are ignored. If N exceptions occur and the background thread ends, the materialized view is re-arranged to monitor the data.</td></tr>
</table>

Parameter	Description
kafka_num_consumers	(Optional) Number of consumers of a single Kafka engine. You can set this parameter to a larger value to improve the data consumption throughput. But the maximum value of this parameter cannot exceed the total number of partitions of the corresponding topic.

For details about other configurations, see **https://clickhouse.com/docs/en/engines/table-engines/integrations/kafka**.

Step 8 Connect the client to ClickHouse to create a local table. The following is an example:

```
CREATE TABLE daily1(
key String,
value String,
event_date DateTime
)ENGINE = MergeTree()
ORDER BY key;
```

Step 9 Connect the client to ClickHouse to create a materialized view. The following is an example:

```
CREATE MATERIALIZED VIEW default.consumer1 TO default.daily1 (
`event_date` DateTime,
`key` String,
`value` String
) AS
SELECT
event_date,
key,
value
FROM default.queue1;
```

Step 10 Perform **Step 4** again to go to the Kafka client installation directory.

Step 11 Run the following command to send a message to the topic created in **Step 5**:

kafka-console-producer.sh --broker-list *IP address 1 of the Kafka broker instance*:**9092,***IP address 2 of the Kafka broker instance*:**9092,***IP address 3 of the Kafka broker instance*:**9092 --topic** *topic1*

```
>a1,b1,'2020-08-01 10:00:00'
>a2,b2,'2020-08-02 10:00:00'
>a3,b3,'2020-08-02 10:00:00'
>a4,b4,'2023-09-02 10:00:00'
```

Step 12 Query the consumed Kafka data and the preceding materialized view. The following is an example:

```
select * from daily;
```

```
┌─key─┬─value─┬──────────event_date─┐
│ >a1 │ b1    │ 2020-08-01 10:00:00 │
│ >a2 │ b2    │ 2020-08-02 10:00:00 │
│ >a3 │ b3    │ 2020-08-02 10:00:00 │
│ >a4 │ b4    │ 2023-09-02 10:00:00 │
└─────┴───────┴─────────────────────┘
```

----End

3.4.6 Synchronizing Kafka Data to ClickHouse

This topic describes how to create a Kafka engine table to automatically synchronize Kafka data to the ClickHouse cluster.

Prerequisites

- You have created a Kafka cluster. The Kafka client has been installed.For details, see **Installing a Client**.
- You have created a ClickHouse cluster and installed the ClickHouse client. The ClickHouse and Kafka clusters are in the same VPC and can communicate with each other.

Constraints

Currently, ClickHouse cannot interconnect with Kafka clusters with security mode enabled.

Syntax of the Kafka Table

- **Syntax**

```
CREATE TABLE [IF NOT EXISTS] [db.]table_name [ON CLUSTER cluster]
(
    name1 [type1] [DEFAULT|MATERIALIZED|ALIAS expr1],
    name2 [type2] [DEFAULT|MATERIALIZED|ALIAS expr2],
    ...
) ENGINE = Kafka()
SETTINGS
    kafka_broker_list = 'host1:port1,host2:port2',
    kafka_topic_list = 'topic1,topic2,...',
    kafka_group_name = 'group_name',
    kafka_format = 'data_format';
    [kafka_row_delimiter = 'delimiter_symbol',]
    [kafka_schema = '',]
    [kafka_num_consumers = N]
```

- **Parameter description**

Table 3-6 Kafka table parameters

Parameter	Mandatory	Description
kafka_broker_list	Yes	A list of Kafka broker instances, separated by comma (,). For example, *IP address 1 of the Kafka broker instance*:**9092**,*IP address 2 of the Kafka broker instance*:**9092**,*IP address 3 of the Kafka broker instance*:**9092**. **NOTE** If the Kerberos authentication is enabled, parameter **allow.everyone.if.no.acl.found** must be set to **true** if port **21005** is used. Otherwise, an error will be reported. To obtain the IP address of the Kafka broker instance, perform the following steps: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click the **Instances** tab to query the IP addresses of the Kafka instances.
kafka_topic_list	Yes	A list of Kafka topics.
kafka_group_name	Yes	A group of Kafka consumers, which can be customized.
kafka_format	Yes	Kafka message format, for example, JSONEachRow, CSV, and XML.
kafka_row_delimiter	No	Delimiter character, which ends a message.
kafka_schema	No	Parameter that must be used if the format requires a schema definition.
kafka_num_consumers	No	Number of consumers in per table. The default value is **1**. If the throughput of a consumer is insufficient, more consumers are required. The total number of consumers cannot exceed the number of partitions in a topic because only one consumer can be allocated to each partition.

How to Synchronize Kafka Data to ClickHouse

Step 1 Switch to the Kafka client installation directory. For details, see **Using the Kafka Client**.

1. Log in to the node where the Kafka client is installed as the Kafka client installation user.
2. Run the following command to go to the client installation directory:

   cd /opt/client
3. Run the following command to configure environment variables:

source bigdata_env

4. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. If Kerberos authentication is disabled for the current cluster, skip this step.

   kinit *Component service user*

Step 2 Run the following command to create a Kafka topic. For details, see **Creating a Kafka Topic**.

kafka-topics.sh --topic *kafkacktest2* **--create --zookeeper** *IP address of the Zookeeper role instance:Port used by ZooKeeper to listen to client*/**kafka --partitions** *2* **--replication-factor** *1*

NOTE

- **--topic** is the name of the topic to be created, for example, **kafkacktest2**.
- **--zookeeper** is the IP address of the node where the ZooKeeper role instances are located, which can be the IP address of any of the three role instances. You can obtain the IP address of the node by performing the following steps:

  Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **ZooKeeper** > **Instances**. View the IP addresses of the ZooKeeper role instance.
- **--partitions** and **--replication-factor** are the topic partitions and topic backup replicas, respectively. The number of the two parameters cannot exceed the number of Kafka role instances.
- To obtain the *Port used by ZooKeeper to listen to client*, log in to FusionInsight Manager, click **Cluster**, choose **Services** > **ZooKeeper**, and view the value of **clientPort** on the **Configuration** tab page. The default value is **24002**.

Step 3 Log in to the ClickHouse client by referring to **ClickHouse Client Practices**.

1. Run the following command to go to the client installation directory:

   cd /opt/client

2. Run the following command to configure environment variables:

   source bigdata_env

3. If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The user must have the permission to create ClickHouse tables. Therefore, you need to bind the corresponding role to the user. For details, see **Creating a ClickHouse Role**. If Kerberos authentication is disabled for the current cluster, skip this step.

   kinit *Component service user*

   Example: **kinit clickhouseuser**

4. Run the following command to connect to the ClickHouse instance node to which data is to be imported:

   clickhouse client --host *IP address of the ClickHouse instance* **--user** *Login username* **--password --port** *ClickHouse port number* **--database** *Database name* **--multiline**

   Enter the user password.

Step 4 Create a Kafka table in ClickHouse by referring to **Syntax of the Kafka Table**. For example, the following table creation statement is used to create a Kafka table whose name is **kafka_src_tbl3**, topic name is **kafkacktest2**, and message format is **JSONEachRow** in the default database.

```
create table kafka_src_tbl3 on cluster default_cluster
(id UInt32, age UInt32, msg String)
ENGINE=Kafka()
SETTINGS
 kafka_broker_list='IP address 1 of the Kafka broker instance:9092,IP address 2 of the Kafka broker instance:9092,IP address 3 of the Kafka broker instance:9092',
 kafka_topic_list='kafkacktest2',
 kafka_group_name='cg12',
 kafka_format='JSONEachRow';
```

Step 5 Create a ClickHouse replicated table, for example, the ReplicatedMergeTree table named **kafka_dest_tbl3**.

```
create table kafka_dest_tbl3 on cluster default_cluster
( id UInt32, age UInt32, msg String )
engine = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/kafka_dest_tbl3', '{replica}')
partition by age
order by id;
```

Step 6 Create a materialized view, which converts data in Kafka in the background and saves the data to the created ClickHouse table.

```
create materialized view consumer3 on cluster default_cluster to kafka_dest_tbl3 as select * from kafka_src_tbl3;
```

Step 7 Perform **Step 1** again to go to the Kafka client installation directory.

Step 8 Run the following command to send a message to the topic created in **Step 2**:

kafka-console-producer.sh --broker-list *IP address 1 of the kafka broker instance*:**9092,***IP address 2 of the kafka broker instance*:**9092,***IP address 3 of the kafka broker instance*:**9092 --topic** *kafkacktest2*

```
>{"id":31, "age":30, "msg":"31 years old"}
>{"id":32, "age":30, "msg":"31 years old"}
>{"id":33, "age":30, "msg":"31 years old"}
>{"id":35, "age":30, "msg":"31 years old"}
```

Step 9 Use the ClickHouse client to log in to the ClickHouse instance node in **Step 3** and query the ClickHouse table data, for example, to query the replicated table **kafka_dest_tbl3**. It shows that the data in the Kafka message has been synchronized to this table.

```
select * from kafka_dest_tbl3;
```

----End

3.4.7 Importing DWS Table Data to ClickHouse

ClickHouse supports the import and export of files in CSV or JSON format. This section describes how to export table data from the Data Warehouse Service (DWS) to a CSV file and then import the CSV file to a ClickHouse table.

Prerequisites

- The ClickHouse cluster and instances are normal.
- You have created a DWS cluster and obtained the username and password of the database where the related table is located.
- You have installed the MRS client, for example, in the **/opt/client** directory. The client directory in the following operations is only an example. Change it to the actual installation directory. Before using the client, download and update the client configuration file, and ensure that the active management node of Manager is available.

Importing DWS Service Data to ClickHouse

Step 1 Download Data Studio. For details, see "Data Studio GUI Client" in **Downloading the Related Tools**.

Step 2 Connect to a DWS database using the username and password of the database in the DWS cluster. For details, see **Adding a Connection**.

Step 3 Export table data from the DWS database to a CSV file.

1. (Optional) If a table and data already exist in the DWS database, skip this step. The following demonstrates how to create a test table in DWS and insert test data.

   Use Data Studio to create a test table **warehouse_t1** and insert test data.

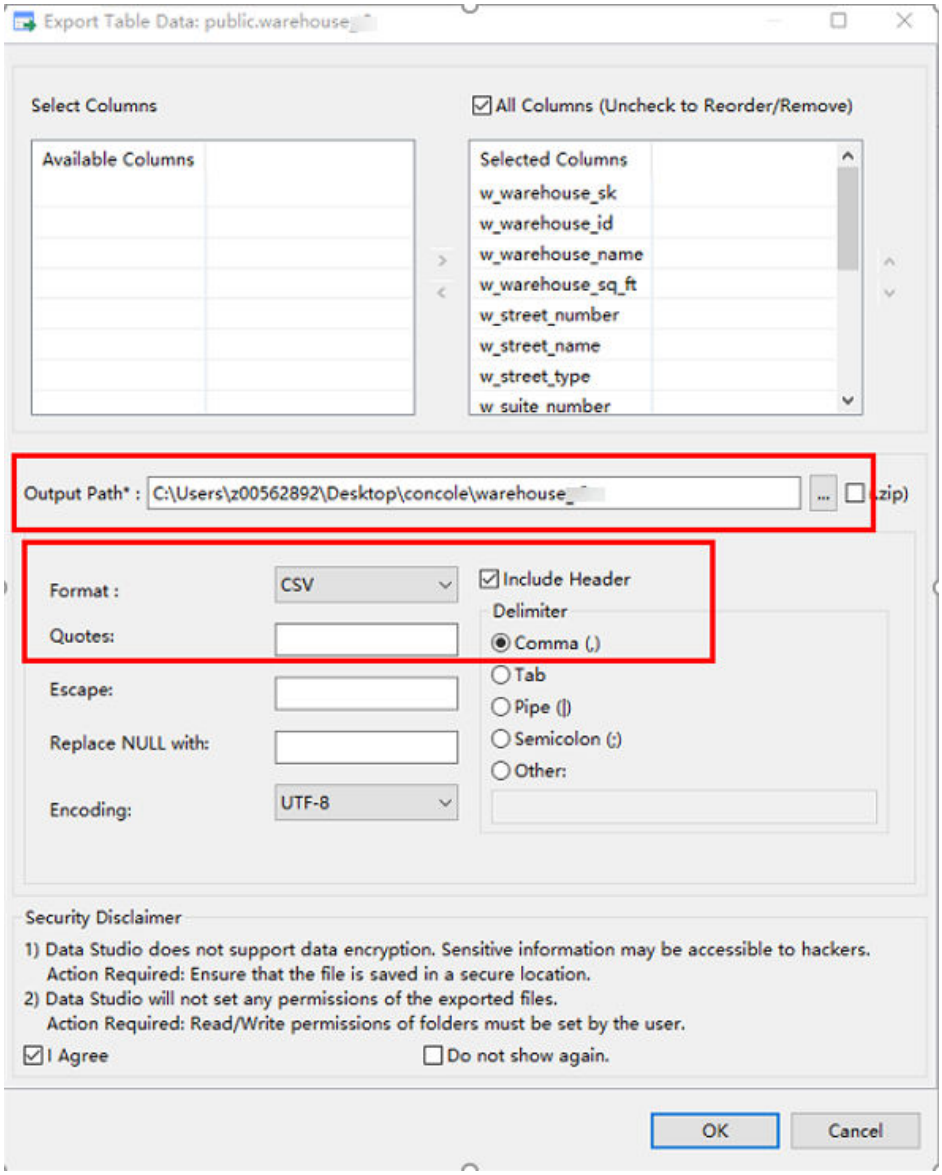
```
CREATE TABLE warehouse_t1
 (
  W_WAREHOUSE_SK INTEGER NOT NULL,
  W_WAREHOUSE_ID CHAR ( 16 ) NOT NULL,
  W_WAREHOUSE_NAME VARCHAR ( 20 ),
  W_WAREHOUSE_SQ_FT INTEGER,
  W_STREET_NUMBER CHAR ( 10 ),
  W_STREET_NAME VARCHAR ( 60 ),
  W_STREET_TYPE CHAR ( 15 ),
  W_SUITE_NUMBER CHAR ( 10 ),
  W_CITY VARCHAR ( 60 ),
  W_COUNTY VARCHAR ( 30 ),
  W_STATE CHAR ( 2 ),
  W_ZIP CHAR ( 10 ),
  W_COUNTRY VARCHAR ( 20 ),
  W_GMT_OFFSET DECIMAL ( 5,2 ),
  W_DATE DATE
 );

INSERT INTO warehouse_t1 VALUES(1314, 123, 'name1', 2324, 123, 'STREET_NAME1', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:07');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name2', 2324, 123, 'STREET_NAME2', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:08');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name3', 2324, 123, 'STREET_NAME3', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:09');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name4', 2324, 123, 'STREET_NAME4', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:00');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name5', 2324, 123, 'STREET_NAME5', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:01');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name6', 2324, 123, 'STREET_NAME6', '12', '12',
```

```
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:02');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name7', 2324, 123, 'STREET_NAME7', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:03');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name8', 2324, 123, 'STREET_NAME8', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:04');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name9', 2324, 123, 'STREET_NAME9', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:05');
INSERT INTO warehouse_t1 VALUES(1314, 123, 'name0', 2324, 123, 'STREET_NAME0', '12', '12',
'guangzhou', 'zhongguo', '1', '12', 'zn', 50.2, '2021-07-05 17:45:06');
INSERT INTO warehouse_t1(W_WAREHOUSE_SK, W_WAREHOUSE_ID, W_WAREHOUSE_NAME,
W_DATE) VALUES(1314, 123, 'name0', '2021-07-05 17:45:06');
```

2. Export the DWS table data to a CSV file.

   In **Object Browser** on the left of Data Studio, right-click the table to be exported and select **Export Table Data**. On the export page, select a specific output path, set **Format** to **CSV** and **Delimiter** to **Comma (,)**, select **I Agree** under **Security Disclaimer**, and click **OK**. In this example, the data file **warehouse_t1.csv** of the **warehouse_t1** table is exported.



Step 4 Use WinSCP to upload the exported CSV file to the directory of the ClickHouse instance node. For example, upload the **warehouse_t1.csv** file to the **/opt** directory.

Step 5 Log in to the node where the ClickHouse client is installed as the client installation user.

Step 6 Run the following command to go to the client installation directory:

cd /opt/client

Step 7 Run the following command to configure environment variables:

source bigdata_env

Step 8 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The user must have the permission to create ClickHouse tables. Therefore, you need to bind the corresponding role to the user. For details, see **Creating a ClickHouse Role**. If Kerberos authentication is disabled for the current cluster, skip this step.

1. Run the following command if it is an MRS 3.1.0 cluster:

   export CLICKHOUSE_SECURITY_ENABLED=true

2. **kinit** *Component service user*

   Example: **kinit clickhouseuser**

Step 9 Run the following command to connect to the ClickHouse instance node to which data is to be imported:

clickhouse client --host *IP address of the ClickHouse instance* **--user** *Login username* **--password --port** *ClickHouse port number* **--database** *Database name*

Enter the user password.

Step 10 Create a table with the same structure as the DWS table on the ClickHouse instance node.

For example, run the following table creation statements to create a ReplicatedMergeTree table **warehouse_t1** with the same table structure as that in **Step 3** under the default database and user on the ClickHouse instance.

```
CREATE TABLE warehouse_t1
(
    `W_WAREHOUSE_SK` Int32 NOT NULL,
    `W_WAREHOUSE_ID` String NOT NULL,
    `W_WAREHOUSE_NAME` String,
    `W_WAREHOUSE_SQ_FT` Int32,
    `W_STREET_NUMBER` String,
    `W_STREET_NAME` String,
    `W_STREET_TYPE` String,
    `W_SUITE_NUMBER` String,
    `W_CITY` String,
    `W_COUNTY` String,
    `W_STATE` String,
    `W_ZIP` String,
    `W_COUNTRY` String,
    `W_GMT_OFFSET` Decimal(5, 2),
    `W_DATE` DateTime
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/warehouse_t1', '{replica}')
PARTITION BY toYear(W_DATE)
ORDER BY (W_DATE, W_WAREHOUSE_ID);
```

Step 11 Exit the ClickHouse client.

exit;

Step 12 Run the following command to import the data in the exported CSV file to the ClickHouse table:

clickhouse client --host *ClickHouse instance IP address* **--database** *Database name* **--port** *Port number* **--format_csv_delimiter="***CSV file delimiter***" --query="INSERT INTO** *Table name* **FORMAT CSV" <** *Host path where the CSV file is stored*

For example, import the comma-separated CSV file **warehouse_t1.csv** to the **warehouse_t1** table under the default database and user.

clickhouse client --host 10.248.12.10 --format_csv_delimiter="," --query="INSERT INTO warehouse_t1 FORMAT CSV" < /opt/warehouse_t1.csv

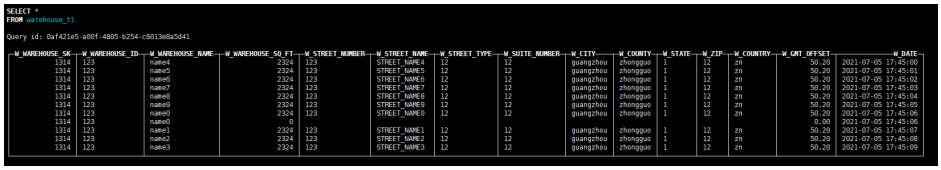
Step 13 After the import is complete, log in to the ClickHouse client, connect to the ClickHouse instance node where the data is imported, and run the query command to check the import result.

For example, query data in the **warehouse_t1** table after the import is complete. The result is shown in the following figure.

clickhouse client --host *ClickHouse instance IP address* **--user** *Login username* **--password** *Password* **--port** *ClickHouse port number* **--database** *Database name*

Enter the user password.

select * from warehouse_t1;



----End

3.4.8 Importing ClickHouse Data in Batches

NOTE

This topic is available in MRS 3.3.0 or later only.

Scenario

If a large number of data files need to be imported, you can use the multi-thread import tool to import ClickHouse data files in batches.

Prerequisites

- The ClickHouse client has been installed in a directory, for example, **/opt/client**.
- For a cluster in security mode, a user with ClickHouse permissions has been created, for example, **clickhouseuser**. For details, see **Creating a ClickHouse Role**.

- The data file to be imported has been uploaded to a client node directory, for example, **/opt/data**. For details about all data types supported by ClickHouse, visit **https://clickhouse.com/docs/en/interfaces/formats**.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Go to the directory where the multi-thread write tool **clickhouse_insert_tool** is deployed.

cd /opt/client/ClickHouse/clickhouse_insert_tool

Step 3 Use the text editor to open **clickhouse_insert_tool.sh** and enter required information based on the comments.

Parameter	Description	Example
datapath	Directory containing the data to be imported	/opt/data
balancer_ip_list	IP addresses of the ClickHouse Balancer instances. The IP addresses must be enclosed in parentheses. A single IP address must be enclosed in double quotation marks, and IP addresses must be separated by spaces.	("192.168.1.1" "192.168.1.2")
balancer_tcp_port	TCP port for the Balancer instance of the ClickHouse service	21428
local_table_name	Names of the local library and table to be imported	testdb1.testtb1
thread_num	Number of concurrent threads for importing data	10
data_format	Format of the data to be imported	CSV
is_security_cluster	Whether the security mode is used • **true** indicates that the security mode. • **false** indicates the normal mode.	true

Step 4 Save the modified **clickhouse_insert_tool.sh** file and run the following commands:

cd /opt/client

source bigdata_env

In security mode (Kerberos authentication is enabled), run the **kinit** command. In normal mode (Kerberos authentication is disabled), you do not need to run the following command:

kinit *clickhouseuser*

Step 5 Run the script to import data.

./ClickHouse/clickhouse_insert_tool/clickhouse_insert_tool.sh

Step 6 Log in to the ClickHouse client node and connect the server. For details, see **ClickHouse Client Practices**.

Step 7 Run the following command to query the distributed table corresponding to the local table where data is inserted and check the result:

select count(1) from testdb1.testtb1_all;

----End

3.4.9 Using ClickHouse to Import and Export Data

Using the ClickHouse Client to Import and Export Data

Use the ClickHouse client to import and export data.

- Importing data in CSV format

  clickhouse client --host *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **--secure --format_csv_delimiter="***CSV file delimiter***" --query="INSERT INTO** *Table name* **FORMAT CSV" <** *Host path where the CSV file is stored*

  Example

  ```
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 --secure --format_csv_delimiter="," --query="INSERT INTO testdb.csv_table FORMAT CSV" < /opt/data
  ```

  You need to create a table in advance.

- Exporting data in CSV format

  CAUTION

  Exporting data files in CSV format may cause CSV injection. Exercise caution when performing this operation.

  clickhouse client --host *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query=**"SELECT * **FROM** *Table name*" > *CSV file export path*

  Example

  ```
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="SELECT * FROM test_table" > /opt/test
  ```

- Importing data in Parquet format

  cat *Parquet file* **| clickhouse client --host** *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query="INSERT INTO** *Table name* **FORMAT Parquet"**

  Example

```
cat /opt/student.parquet | clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="INSERT INTO parquet_tab001 FORMAT Parquet"
```

- Exporting data in Parquet format

  clickhouse client --host *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query="select** * **from** *Table name* **FORMAT Parquet"** > *Parquet file export path*

  Example

  ```
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="select * from test_table FORMAT Parquet" > /opt/student.parquet
  ```

- Importing data in ORC format

  cat *ORC file path* **| clickhouse client --host** *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query="INSERT INTO** *Table name* **FORMAT ORC"**

  Example

  ```
  cat /opt/student.orc | clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="INSERT INTO orc_tab001 FORMAT ORC"
  # Data in the ORC file can be exported from HDFS. For example:
  hdfs dfs -cat /user/hive/warehouse/hivedb.db/emp_orc/000000_0_copy_1 | clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="INSERT INTO orc_tab001 FORMAT ORC"
  ```

- Exporting data in ORC format

  clickhouse client --host *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query="select** * **from** *Table name* **FORMAT ORC"** > *ORC file export path*

  Example

  ```
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="select * from csv_tab001 FORMAT ORC" > /opt/student.orc
  ```

- Importing data in JSON format

  INSERT INTO *Table name* **FORMAT JSONEachRow** *JSON string 1 JSON string 2*

  Example

  ```
  INSERT INTO test_table001 FORMAT JSONEachRow {"PageViews":5, "UserID":"4324182021466249494", "Duration":146,"Sign":-1}
  {"UserID":"4324182021466249494","PageViews":6,"Duration":185,"Sign":1}
  ```

- Exporting data in JSON format

  clickhouse client --host *Host name or IP address of the ClickHouse instance* **--database** *Database name* **--port** *Port number* **-m --secure --query="SELECT** * **FROM** *Table name* **FORMAT JSON|JSONEachRow|JSONCompact|..."** > *JSON file export path*

  Example

  ```
  # Export JSON file.
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="SELECT * FROM test_table FORMAT JSON" > /opt/test.json

  # Export json(JSONEachRow).
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="SELECT * FROM test_table FORMAT JSONEachRow" > /opt/test_jsoneachrow.json

  # Export json(JSONCompact).
  clickhouse client --host 10.5.208.5 --database testdb --port 9440 -m --secure --query="SELECT * FROM test_table FORMAT JSONCompact" > /opt/test_jsoncompact.json
  ```

3.5 Enterprise-Class Enhancements of ClickHouse

3.5.1 ClickHouse Multi-Tenancy

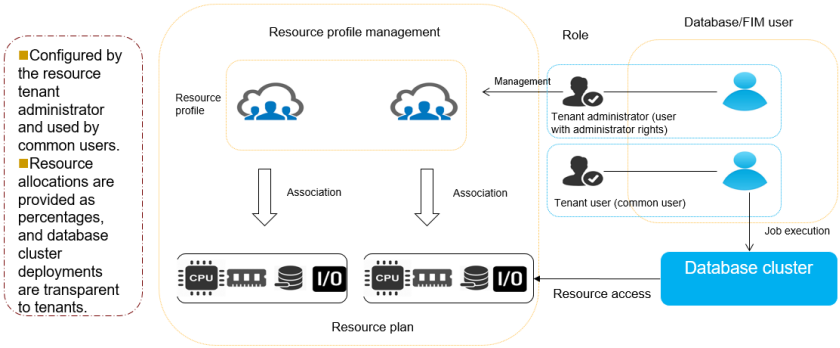
3.5.1.1 Overview

NOTE

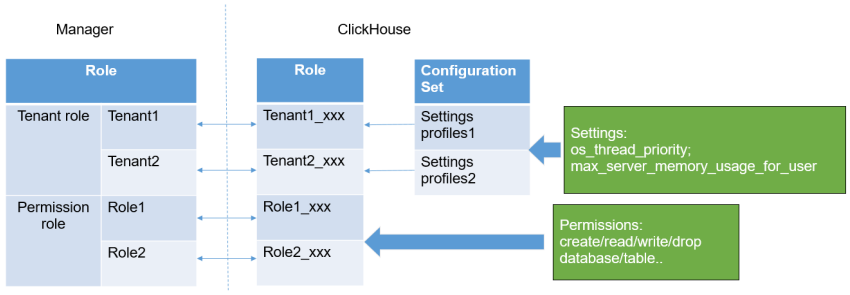
This section applies only to MRS 3.2.0 or later.

ClickHouse Multi-Tenancy

The ClickHouse multi-tenancy feature enables you to manage cluster resources through the user > tenant role > resource profile management model. Currently, memory and CPU priority management is supported. The following figure shows a multi-tenancy model.



On the service configuration and tenant management pages of FusionInsight Manager, you can configure memory quotas for services, create tenants, associate ClickHouse services, bind logical clusters, set available memory and CPU priorities for tenants, and associate tenants with users. The following figure illustrates the role association between Manager and ClickHouse.



The following table lists the resource configurations supported by the current version.

Resource	Value Range	Description	Remarks
Service-level memory resource limit	0–1	Percentage of available ClickHouse memory to total server memory	For example, if the physical memory of the server is 10 GB and the limit is set to **0.9**, the available memory of the ClickHouse service on the current server is 9 GB (10 GB x 0.9).
Tenant-level memory resource limit	0%–100%	Percentage of the available memory of the current tenant in ClickHouseServer	If this limit is set to **80**, the total memory that can be used by the current tenant is calculated as follows: Total memory that can be used by the service x 80%
Tenant-level CPU priority	–20 to 19	NICE value of the OS associated with this value. A smaller value indicates a higher CPU priority of the process.	This feature depends on **CAP_SYS_NICE** of the OS. By default, this feature is disabled after the cluster is installed. To use this feature, enable it by referring to **Configuring CPU Priority for ClickHouse Tenants**.

3.5.1.2 Configuring CPU Priority for ClickHouse Tenants

NOTE

This section applies only to MRS 3.2.0 or later.

Scenario

ClickHouse tenants support CPU priorities. This feature depends on CAP_SYS_NICE of the OS and takes effect only after being enabled.

Procedure

Step 1 Log in to the ClickHouseServer node as user **root** and run the following command:

setcap cap_sys_nice=+ep /opt/Bigdata/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/bin/clickhouse

NOTE

You need to run this command on all ClickHouseServer nodes.

Step 2 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click the **Instance** tab. Select all ClickHouseServer instances, and choose **More** > **Restart Instance**.

Step 3 Run the following command to check whether the CPU priority feature is enabled:

getcap /opt/Bigdata/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/bin/clickhouse

The following command output indicates that the feature has been enabled:

```
/opt/Bigdata/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse*/clickhouse/bin/clickhouse = cap_sys_nice+ep
```

----End

3.5.1.3 Creating a ClickHouse Tenant

NOTE

This section applies only to MRS 3.2.0 or later.

Scenario

On FusionInsight Manager, cluster administrators can create a ClickHouse tenant and associate it with a logical cluster. After a system user is bound to the tenant, the system user has the permissions on the logical cluster of the tenant.

Creating a ClickHouse Tenant

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 Click ⊕. On the page that is displayed, configure tenant attributes according to **Table 3-7**.

Table 3-7 Tenant parameters

Parameter	Description
Cluster	Cluster for which you want to create a tenant
Name	• Name of the current tenant. The value consists of 3 to 50 characters, including numbers, letters, and underscores (_). • Plan a tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or Yarn queue that exists in the current cluster.
Tenant Resource Type	Select **Leaf Tenant Resource**. **NOTE** Create a ClickHouse tenant. **Tenant Resource Type** can only be **Leaf Tenant**.

Parameter	Description
Computing Resource	Dynamic compute resources for the current tenant • When **Yarn** is selected, the system automatically creates a queue in Yarn and the queue is named the same as the tenant name. • If **Yarn** is not selected, the system does not automatically create a queue.
Configuration Mode	Configuration mode of compute resource parameters • If you select **Basic**, you only need to configure **Default Resource Pool Capacity (%)**. • If you select **Advanced**, you can manually configure the resource allocation weight and the minimum, maximum, and reserved resources of the tenant.
Default Resource Pool Capacity (%)	Percentage of compute resources used by the current tenant in the default resource pool. The value ranges from 0 to 100%.
Weight	Resource allocation weight. The value ranges from 0 to 100.
Minimum Resource	Resources guaranteed for the tenant (preemption supported). The value can be a percentage or an absolute value of the parent tenant's resources. When a tenant has a light workload, the resources of the tenant are automatically allocated to other tenants. When the available tenant resources are less than the value of **Minimum Resource**, the tenant can preempt the resources that have been lent to other tenants.
Maximum Resource	Maximum resources that can be used by the tenant. The tenant cannot obtain more resources than the value configured. The value can be a percentage or an absolute value of the parent tenant's resources.
Reserved Resource	Resources reserved for the tenant resource. The reserved resources cannot be used by other tenants even if no job is running in the current tenant resources. The value can be a percentage or an absolute value of the parent tenant's resources.
Storage Resource	Storage resources for the current tenant. • When **HDFS** is selected, the system automatically allocates storage resources. • If **HDFS** is not selected, the system does not automatically allocate storage resources.
Quota	Quota for files and directories

Parameter	Description
Space Quota	Quota for the HDFS storage space used by the current tenant • If the unit is set to **MB**, the value ranges from 1 to 8796093022208. If the unit is set to **GB**, the value ranges from 1 to 8589934592. • This parameter indicates the maximum HDFS storage space that can be used by the tenant, but not the actual space used. • If its value is greater than the size of the HDFS physical disk, the maximum space available is the full space of the HDFS physical disk.
Storage Path	HDFS storage directory for the tenant • The system automatically creates a folder named after the tenant name in the **/tenant** directory by default. For example, the default HDFS storage directory for tenant **ta1** is **/tenant/ta1**. • When a tenant is created for the first time, the system automatically creates the **/tenant** directory in the HDFS root directory. The storage path is customizable.
Service	• Select **ClickHouse** for **Service**. – **Association Type**: When **Service** is set to **ClickHouse**, **Association Type** can only be set to **Shared**. – **Associate Logical Cluster**: If the logical cluster function is not enabled for ClickHouse, **default_cluster** is selected by default. If the function is enabled, select the logical cluster to which you want to associate. – **CPU Priority**: The CPU priority ranges from –20 to 19. This value is associated with the NICE value of the OS. A smaller value indicates a higher CPU priority. For details about how to enable the CPU priority, see **Configuring CPU Priority for ClickHouse Tenants**. – **Memory**: The maximum value of this parameter is **100**, in percentage. For example, if this parameter is set to **80**, the total memory that can be used by the current tenant is calculated as follows: Available memory x 80%.
Description	Description of the current tenant

Step 3 Click **OK**. Wait until the tenant is created.

Step 4 After the ClickHouse tenant is created, you can view and modify tenant resources on the **Tenant Resources** page.

1. On FusionInsight Manager, choose **Tenant Resources**. In the tenant list, select the ClickHouse tenant whose information you want to view and view the tenant overview and resource quota.
2. Choose **Resources** and click  next to **Resource Details** to modify tenant resources.
3. After the modification is complete, click **OK**. The modified resource details are displayed on the **Resources** page.

   NOTE

   After modifying the resource quota of the ClickHouse tenant, you need to log in to the ClickHouse client again for the modification to take effect.

----End

Adding a User and Binding the User to a Tenant

- To create a user and bind the user to a tenant, log in to FusionInsight Manager, choose **System** > **Permission** > **User**, click **Create User** to add a human-machine user, and add the tenant created by referring to **Creating a ClickHouse Tenant**. Then, the user has the permissions on the ClickHouse logical cluster.
- To bind an existing user to a tenant, log in to FusionInsight Manager, choose **System** > **Permission** > **User**, click **Modify** in the **Operation** column of the user, and add the tenant created by referring to **Creating a ClickHouse Tenant**. Delete the ClickHouse tenant from the role if the tenant is no longer needed.

  NOTE

  - After a user is bound to a ClickHouse tenant, the user has the permission to modify the logical cluster of the tenant.
  - When multiple users are bound to the same tenant, the tenant-level memory limit of the current version does not support real-time total memory limit. For example, user1 and user2 are bound to tenant1, the memory limit for tenant1 is 10 GB, and the query performed by user1 uses 5 GB memory. When user2 initiates a query, the memory that can be used by user2 is limited to 5 GB. During the query, the service does not dynamically update this restriction.
  - In the current version, a user cannot be bound to multiple ClickHouse tenants. If user1 has been associated with tenant1, no error message is displayed when user1 is associated with tenant2, but the information is recorded in background logs, indicating that the user has been associated with a tenant and this association operation is invalid.

Associating an Existing Tenant with the ClickHouse Service

1. On FusionInsight Manager, choose **Tenant Resources**, select the tenant to which you want to associate a service, click the **Service Association** tab, and click **Associate Service**. The following table describes the parameters.

Parameter	Description
Service	Select **ClickHouse**.
Association Type	Select **Shared**.
Associate Logical Cluster	If the logical cluster function is not enabled for ClickHouse, **default_cluster** is selected by default. If the function is enabled, select the logical cluster to which you want to associate.
CPU Priority	The CPU priority ranges from –20 to 19. This value is associated with the NICE value of the OS. A smaller value indicates a higher CPU priority. For details about how to enable the CPU priority, see **Configuring CPU Priority for ClickHouse Tenants**.
Memory	The maximum value of this parameter is **100**, in percentage. For example, if this parameter is set to **80**, the total memory that can be used by the current tenant is calculated as follows: Available memory x 80%.

2. On the displayed tab page, configure the tenant based on service requirements and click **OK**. The tenant is associated with the service.
3. To disassociate the ClickHouse service, perform the following operations:

   On FusionInsight Manager, choose **Tenant Resources**, select the tenant whose ClickHouse service is to be disassociated, and click **Delete** in the **Operation** column. In the dialog box that is displayed, click **OK**.

   NOTE

   After the ClickHouse service is disassociated from a tenant, the tenant and its users no longer have the permissions on the ClickHouse logical cluster.

3.5.1.4 Modifying the Memory Limit of ClickHouse on a ClickHouseServer Node

NOTE

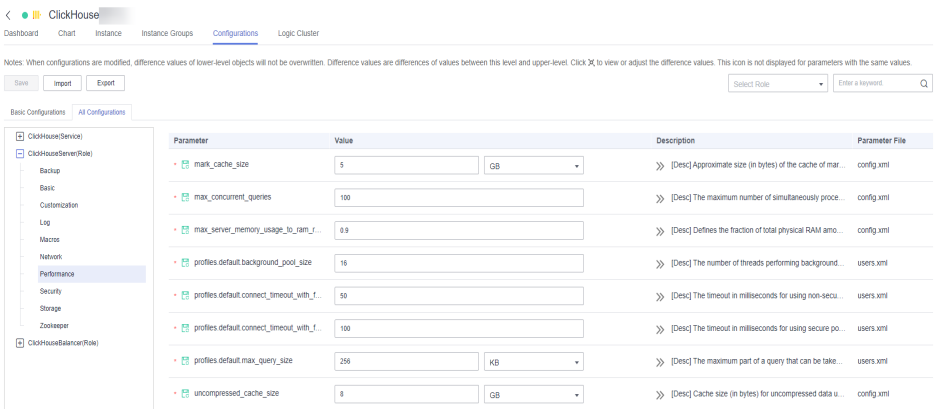
This section applies only to MRS 3.2.0 or later.

Scenario

Modify the maximum memory allowed for ClickHouse on a ClickHouseServer node to ensure the normal use of other service instances on the node.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configuration** then **All Configurations**, click **ClickHouseServer(Role)**, and select **Performance**.



Step 2 Change the value of **max_server_memory_usage_to_ram_ratio** as required and save the configuration.

NOTE

- Restart is not required for the modification to take effect.
- The value ranges from 0 to 1, indicating the ratio of the total physical RAM of the server that can be used for ClickHouse. For example, if the physical memory of the server is 10 GB and the value of this parameter is **0.9**, the available memory of the ClickHouse service on the current server is 9 GB (10 GB x 0.9). If the value of this parameter is **0**, it indicates that the memory is not limited and the ClickHouse service can use all the physical memory of the server. The value of this parameter can contain a maximum of two decimal places.

----End

3.5.2 Checking Slow SQL Statements in ClickHouse

Scenario

The SQL statement query in ClickHouse is slow because the conditions such as partitions, where conditions, and indexes of SQL statements are set improperly. As a result, the overall performance of the database is affected. To solve this problem, MRS provides the function of monitoring slow ClickHouse query statements.

Ongoing Slow Queries

You can query information about slow SQL statements that are being executed but do not return any result.

- **Procedure**

  For versions earlier than MRS 3.2.0, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. On the displayed page, click the **Query Management** tab and then the **Ongoing Slow Queries** tab.

  Log in to FusionInsight Manager of an MRS 3.2.0 cluster or later, click **Cluster**, choose **Services** > **ClickHouse**, click **Logic Cluster**, and click the name of the target logical cluster. On the displayed page, choose **Query Management** > **Ongoing Slow Queries**.

- **Parameters**

Table 3-8 Slow query parameters

Parameter	Description
Server Node IP Address	IP address of the ClickHouseServer instance. To view the IP address, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. On the displayed page, click the **Instance** tab.
Query ID	Unique ID generated internally.
Query	Slow query SQL statement.
Start Time	Time when the execution of a slow query SQL statement starts.
End Time	Time when the execution of a slow query SQL statement ends.
Duration (s)	Total execution time of a slow query SQL statement, in seconds.
User	ClickHouse user who executes a slow query SQL statement.
Client IP Address	IP address of the client that submits a slow query SQL statement.
Memory Used (MB)	Memory used by a slow query SQL statement, in MB.
Operation	You can click **Terminate** to terminate the slow query using a slow query SQL statement.

- **Filter conditions**

  Select the query condition as required and filter the query results.

  Table 3-9 Filter conditions

Condition	Description
Slow query duration exceeding	Filters the slow queries based on the duration. The value can be **3 (s)**, **9 (s)**, **15 (s)**, or **25 (s)**.
By Query ID	Filters the slow queries based on the query ID. Fuzzy search based on the query ID is supported. For example, if the query ID is **111-222-333-444-555**, you can enter part of it such as **111-222** or **-222-333** to query the needed information.
By User	Filters the slow queries based on the ClickHouse user. Fuzzy search based on part of a username is supported.

Condition	Description
By Client IP Address	Filters the slow queries based on the IP address of the client that submits slow query SQL statements. Fuzzy search based on part of the client IP address is supported. For example, if the client IP address is **192.168.0.1**, you can enter part of it such as **192.168** or **192.168.0** to query the information you need.

Completed Queries

You can query information about slow SQL statements that have been executed and returned results.

UI path:

Log in to FusionInsight Manager of a cluster earlier than MRS 3.2.0 and choose **Cluster** > **Services** > **ClickHouse**. On the displayed page, click the **Query Management** tab and then the **Completed Queries** tab.

Log in to FusionInsight Manager of an MRS 3.2.0 cluster or later, click **Cluster**, choose **Services** > **ClickHouse**, click **Logic Cluster**, and click the name of the target logical cluster. On the displayed page, choose **Query Management** > **Completed Queries**.

For details about slow query parameters and filter conditions, see **Table 3-8** and **Table 3-9**, respectively.

3.5.3 Checking Monitoring Metrics of ClickHouse Replication Table Data Synchronization

Scenario

MRS monitors the synchronization between multiple replicas of data in the same shard of a Replicated*MergeTree table.

Constraints

Currently, you can monitor and query only Replicated*MergeTree tables whose creation statements contain the key word **ON CLUSTER**.

Replication Table Data Synchronization

- **Procedure**

  Log in to FusionInsight Manager of a cluster earlier than MRS 3.2.0, click **Cluster**, choose **Services** > **ClickHouse**, and click **Data Synchronization Status**.

  Log in to FusionInsight Manager of an MRS 3.2.0 cluster or later, click **Cluster**, choose **Services** > **ClickHouse**, click **Logic Cluster**, and click the name of the

target logical cluster. Go to the logical cluster page and select **Data Synchronization Status**.

- **Data synchronization parameters**

  Table 3-10 Data synchronization parameters

Parameter	Description
Data Tables	Names of Replicated*MergeTree tables.
Database	Database where the data table is located.
Shard	ClickHouse shard where the data table is located.
Status	Data synchronization status. The options are as follows: • **No data**: The table has no data on this shard. • **Synchronized**: The table has data on this shard, and multiple instance copies of the same shard are the same. • **Not synchronized**: The table has data on this shard, but multiple instance copies of the same shard are not the same.
Details	Data synchronization details of the data table on the corresponding ClickHouseServer instance.

- **Filter conditions**

  You can select **By Data Tables** and enter a data table name in the search box to filter data tables.

3.5.4 Configuring Strong Data Consistency Between ClickHouse Replicas

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

ClickHouse supports multiple replicas. When data is written to a local table, the data on the current node is updated immediately, but the data between other replicas is asynchronously updated.

Configure ClickHouse to ensure strong data consistency between replicas.

Parameters

NOTE

The priority of configuring strong data consistency between ClickHouse replicas is as follows: single statements > sessions > global defaults.

Strong data consistency between replicas must be used together with atomicity. Otherwise, an exception occurs during data insertion and the rollback fails.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, click **Reliability**, and search for and modify the following parameters.

Parameter	Description
profiles.default.insert_quorum	Whether to enable strong data consistency between ClickHouse replicas. The default value is **0**, indicating that strong consistency between replicas is disabled. Value options are as follows: 0 to 9, **auto**, and **all**. • If this parameter is set to a number, the INSERT operation can succeed only when ClickHouse attempts to correctly write data to the **insert_quorum** of replicas during the **insert_quorum_timeout** period. • **auto** indicates that the INSERT operation is successful only when data is correctly written to more than half of the replicas. • **all** indicates that the INSERT operation is successful only when data is correctly written to all replicas.
profiles.default.insert_quorum_timeout	Timeout interval for writing strongly consistent data between replicas. The default value is **600000** ms. The value must be greater than 0.

3.5.5 Configuring the Support for Transactions on ClickHouse

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

Atomicity means that a transaction is an inseparable unit of work. A transaction can contain multiple operations, which are either all executed or none executed. However, some exceptions may occur during transaction execution, for example, a user rolls back a transaction, a connection is disconnected, or a power failure occurs. As a result, the transaction execution is interrupted.

ClickHouse supports atomic write and transaction capabilities. The atomicity of a transaction means that after an operation of a transaction fails, the transaction can be rolled back to the state before the transaction is executed.

Start a ClickHouse transaction.

NOTE

- Writing data to local tables achieves better performance. So, multi-replica distributed transactions are recommended for adding, deleting, modifying, and querying data on local tables.
- When data is written to a distributed table, the distributed table transaction **insert_distributed_sync** and local table transaction **Mergetree/ReplicateMergeTree** must be combined to support data writing.

Parameters

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, click **Reliability**, and search for and modify the following parameters.

Parameter	Description
allow_transactions	Whether to support transactions. The value can be **0** or **1**. • The default value is **0**, indicating that transactions are not supported. • Set this parameter to **1**, save the configuration, and restart the service for the support for transactions to take effect.
_clickhouse.metrika.cluster.internal_replication	Whether to write data to only one replica. The value can be **true** or **false**. • The default value is **true**, indicating that data is inserted only to one replica. • If this parameter is set to **false**, data is inserted to both replicas.

NOTE

- You can run the **set implicit_transaction='true';** statement to use session-level implicit transactions. Currently, ClickHouse does not support interruption of alter queries. If the execution of alter queries (for example, lightweight delete) is interrupted, it cannot be rolled back even if implicit transactions are enabled. This is the same as open-source ClickHouse.
- To insert data into a distributed table, perform the following steps:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, click **Configurations** then **All Configurations**, and change the value of **_clickhouse.metrika.cluster.internal_replication** to **false**. This means that data is written to all replicas of a shard when being inserted to a distributed table.

  At the session level, **set insert_distributed_sync='true';** indicates that data is inserted to each actual table in synchronous mode when being inserted to a distributed table.

3.5.6 Accessing ClickHouse Through ELB

Currently, ClickHouse is deployed in cluster mode regardless of whether replication or sharding is used. When ClickHouse provides services externally, multiple ClickHouse service nodes will be exposed and no unified access entry is available. ClickHouse provides the BalancedClickhouseDataSource class, which supports the load balancing capability by randomly allocating client's access requests to multiple nodes. However, it behaves unsatisfactorily in fault detection. Especially, the client needs to proactively detect changes of cluster nodes during scale-in or scale-out.

MRS work with Elastic Load Balance (ELB) to address the preceding issues. **Figure 3-4** shows the deployment architecture. This architecture can automatically distribute user access traffic evenly to multiple backend ClickHouse nodes, expanding external service capabilities and improving fault tolerance. When a backend ClickHouse node becomes faulty, ELB automatically fails over access traffic to another properly running node.

Figure 3-4 Accessing ClickHouse nodes through ELB

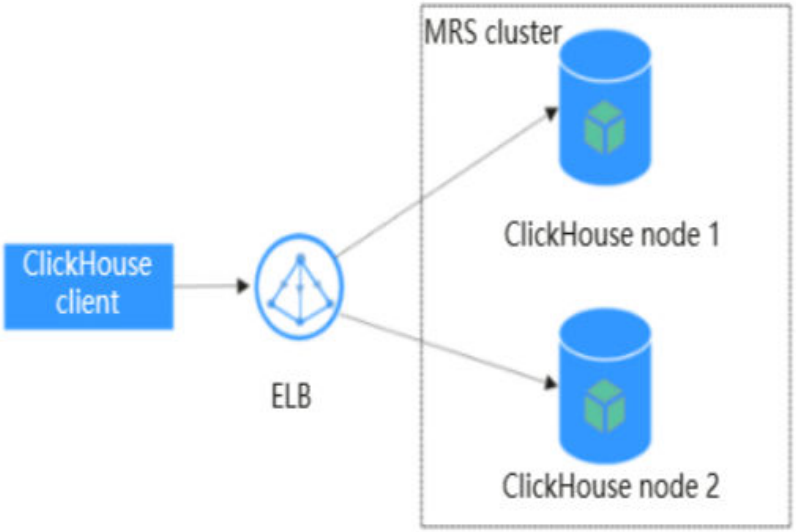


Table 3-11 lists the advantages of the ELB-based deployment over BalancedClickhouseDataSource.

Table 3-11 Differences between ELB-based deployment and BalancedClickhouse-DataSource

Load Balancing Method	Difference
ELB-based deployment	• Supports multiple request policies. • Supports automatic fault detection and failover. • Allows you to add ClickHouse backend nodes simply by changing ELB configurations.

Load Balancing Method	Difference
BalancedClickhouseData-Source	• Causes load imbalance due to random allocation of requests. • Lacks of sufficient fault detection capabilities.

Table 3-12 lists the supported protocols and ports for accessing ClickHouse through ELB. Configure them as required.

Table 3-12 Supported protocols and ports for accessing ClickHouse nodes through ELB

Protocol	Port Number	Used When
TCP	9000	A client request is sent to ELB to connect to ClickHouse. For example, if you run the **clickhouse client** command to connect to ClickHouse, set **host** to the private IP address of ELB.
HTTP	8123	An HTTP request is sent to ELB to connect to ClickHouse.

This section describes how to use a client to access ClickHouse through ELB. The procedure is as follows:

- **Step 1: Buy an ELB and obtain its private IP address.**
- **Step 2: Add an ELB listener and configure its protocol and port.**
- **Step 3: Add backend ClickHouse servers to the ELB.**
- **Step 4: Use a client to access ClickHouse through ELB.**

Prerequisites

- You have created an MRS cluster and its ClickHouse instances are running properly.
- You have installed the MRS client, for example, in the **/opt/client** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Buying an ELB and Connecting It to ClickHouse Nodes

Buying an ELB and obtaining its private IP address

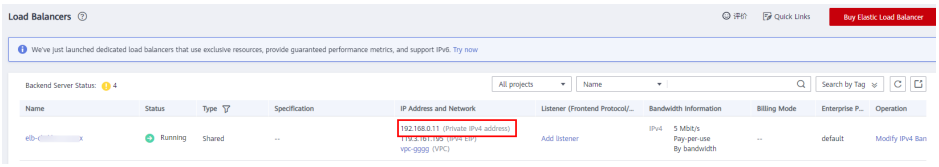
For details, see **Creating a Shared Load Balancer**.

Step 1 Log in to the ELB console and click **Buy Elastic Load Balancer**.

Step 2 On the **Buy Elastic Load Balancer** page, set **Type** to **Shared**, set **VPC** and **Subnet** to the same values as those of the MRS cluster, and retain the default values for other parameters.

Step 3 Click **Next**, confirm the configurations, and click **Submit**.

Step 4 On the **Load Balancers** page, obtain the private IP address of the newly created load balancer.



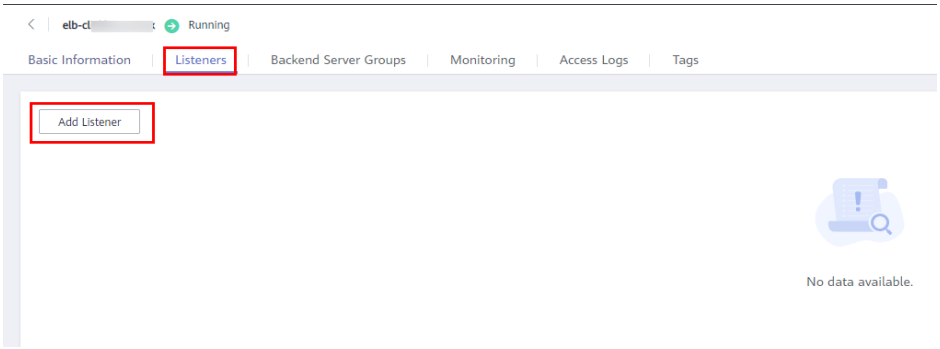
----End

Adding an ELB listener

For details, see **Adding a TCP Listener**.

Step 1 On the **Load Balancers** page, click the name of the created load balancer to go to its details page.

Step 2 Click the **Listeners** tab and then **Add Listener**.



Step 3 On the **Add Listener** page, complete the configuration as prompted.

1. Configure the listener.

   Set **Frontend Protocol/Port** to **TCP** and **9000**, respectively. Retain the default values for other parameters. Click **Next**.

   NOTE

   If an HTTP request is sent to access ClickHouse through ELB, set **Frontend Protocol/Port** to **HTTP** and **8123**, respectively.

2. Configure the backend server group.

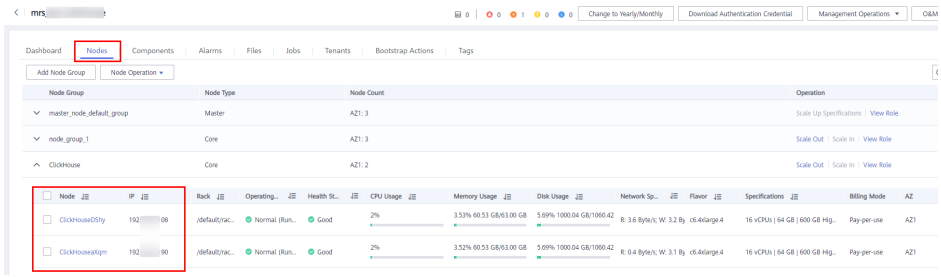
   Set **Load Balancing Algorithm** to **Weighted round robin** and click **Finish**. On the displayed page, click **OK**.

----End

Adding ClickHouse backend servers

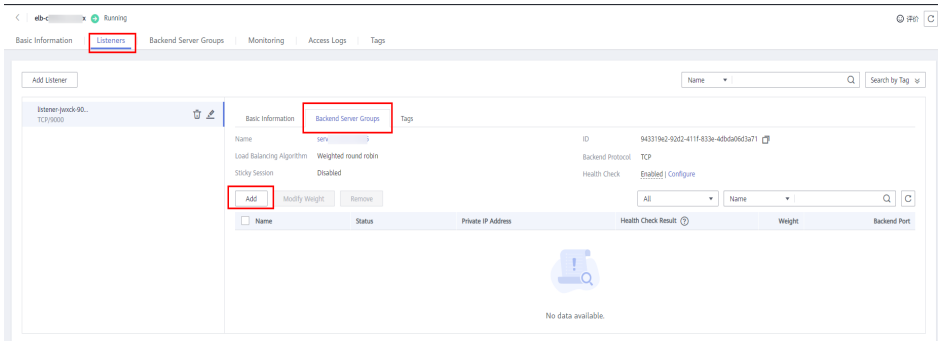
Step 1 Switch to the MRS console and click the MRS cluster to be interconnected.

Step 2 On the displayed page, click the **Nodes** tab and expand **ClickHouse** to obtain its node names and IP addresses.



Step 3 Switch to the ELB console, locate the created load balancer, and click its name.

Step 4 Click the **Listeners** tab and then **Backend Server Groups**. Click **Add**.



Step 5 On the **Add Backend Server** page, select the backend servers based on the node names and IP addresses of ClickHouse obtained in **Step 2**. Click **Next**.

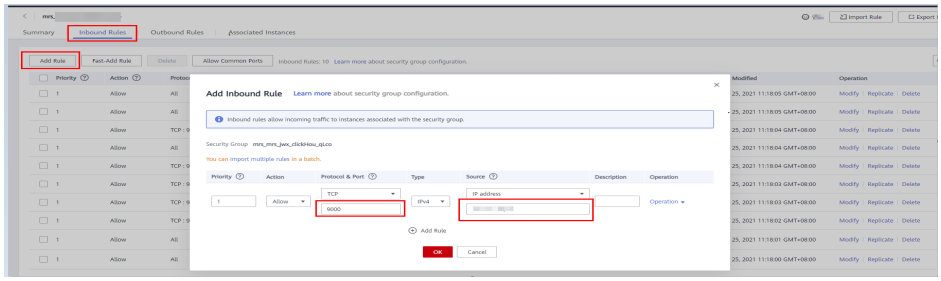
Step 6 On the displayed page, set **Batch Add Ports** to **9000** and click **OK**. Confirm your configurations and click **Finish**.

NOTE

If an HTTP request is sent to access ClickHouse through ELB, set **Batch Add Ports** to **8123**.

Step 7 Configure the security group.

After the configuration is complete, go to the **Backend Server Groups** tab on the **Listeners** page. The **Health Check Result** of the backend servers is **Unhealthy**.



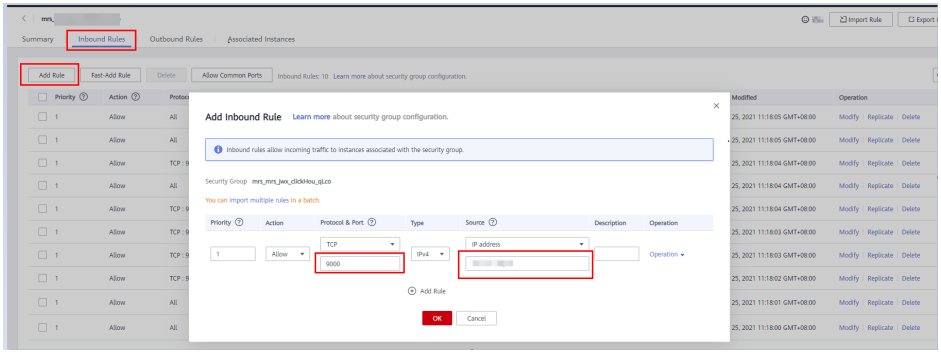
To solve this issue, you need to configure the inbound rule of the security group for the ClickHouse backend server to allow access from 100.125.0.0/16. The procedure is as follows:

1. Go back to the **Listeners** tab. Click the **Backend Server Groups** subtab and then the name of a backend server.
2. On the displayed page, click the **Security Groups** tab and then **Manage Rule**. Next, click the **Inbound Rules** tab and then **Add Rule**.

3. On the **Add Inbound Rule** page, set **Protocol & Port** to **TCP** and **9000**, and **IP address** to **100.125.0.0/16**. Click **OK**.

   NOTE

   If an HTTP request is sent to access ClickHouse through ELB, set **Batch Add Ports** to **8123**.



4. Go back to the ELB console, navigate to the details page of the created load balancer, and refresh the page. Click the **Listeners** tab and then the **Backend Server Groups** subtab. The **Health Check Status** changes to **Healthy**.

----End

Accessing ClickHouse through ELB

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and set **SSL_NONESSL_BOTH_ENABLE** to **true**.

Step 2 Use the client to log in to the node where the ClickHouse service instance is deployed. For details, see **ClickHouse Client Practices**. Note that the **host** parameter in the **clickhouse client** command must be set to the private IP address of ELB.

Step 3 Check the connection result on the client.

NOTE

If you manually run a client command to connect to the ClickHouse node, there may be only a few concurrent requests. In this case, the ELB may always send the requests to the same backend ClickHouse node. This is normal.

If there are a large number of concurrent requests, the ELB will distribute the requests to multiple ClickHouse nodes in polling mode.

----End

3.5.7 Storing ClickHouse Cold and Hot Data Separately

NOTE

This section applies to MRS 3.3.1-LTS or later.

Scenario

Based on the multi-volume storage of the open-source ClickHouse, MRS allows ClickHouse tables to be stored in volumes of multiple devices. You can define

different types of disks in a volume and store the cold and hot data separately. Cold data is stored in OBS, and hot data is stored in ClickHouse. ClickHouse clusters provide optimal query performance and long-term data storage at a low cost.

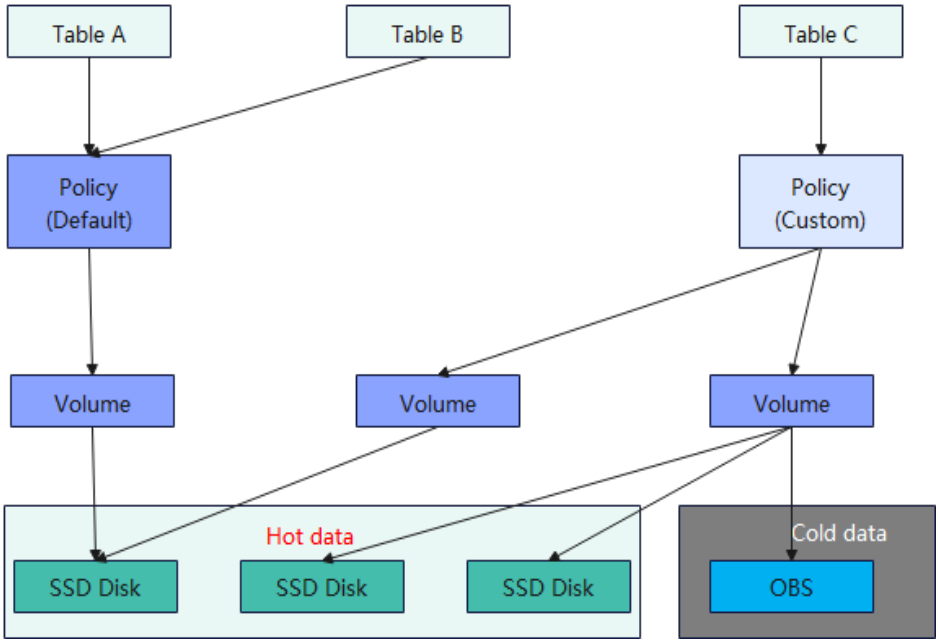
The process of configuring separated storage for cold and hot data in ClickHouse is as follows:

1. **Creating an OBS Parallel File System**
2. **Creating a Cloud Service Agency and Binding It to a Cluster**
3. **Creating a Common Account Agency and Binding It to a Cluster**
4. **Adding OBS Disk Information to the ClickHouse Cluster**
5. **Configuring Disk Storage Policies**
6. **Custom Cold-Hot Separation Policy**
7. **Importing Data into ClickHouse to Verify the Configuration**

Principles

OBS is a secure, reliable, and cost-effective distributed storage service that can handle large-scale data. ClickHouse adopts a cold and hot data separated architecture on top of OBS advantages. The SSD of the node where the ClickHouse instance is deployed stores the hot data (recently generated and frequently accessed). OBS stores the cold data (accessed less frequently than hot data). When creating a table, use TTL (a time policy) to store cold data and hot data separately.

Figure 3-5 Working principle of cold and hot data storage



Terms you need to know are described as follows:

Volume: a collection of ordered disks

Storage Policy: a storage policy, a collection of volumes, and rules for moving data among volumes

Creating an OBS Parallel File System

1. Log in to the management console.
2. Click **Service List** and choose **Storage** > **Object Storage Service**.
3. Click **Parallel File System** and click **Create Parallel File System**. On the displayed page, set the following parameters, and click **Create Now**.
   - **Region**: Select the region where the MRS cluster is located.
   - **File System Name**: Enter a file system name, for example, **mrs-ck-obs**.
4. Click the name of the created parallel file system. On the **Overview** page, view and record the value of **Endpoint**, which is the endpoint of OBS.
5. Obtain the IAM endpoint.
   - To obtain the system endpoint, remove the prefix of the OBS endpoint, that is, **obs.**.
   - The endpoint of IAM is **iam.***System endpoint*.

   For example, if the endpoint of OBS is **obs.xxx.huawei.com**, the system endpoint is **xxx.huawei.com** and the IAM endpoint is **iam.cxxx.huawei.com**.
6. Obtain the AK/SK information.
   a. Move the cursor to the login user name in the upper right corner and select **My Credentials** from the drop-down list.
   b. On the **API Credentials** page, obtain the **Account ID** whish is used as the domain ID.
   c. Click **Access Keys**, click **Create Access Key**, and enter the verification code or password. Click **OK** and download the access keys. Obtain the AK/SK information from the **.csv** file.

      NOTE

      After a service is deleted or a cluster is uninstalled, dirty data may remain in the parallel file system **3**. You need to delete the dirty data.

Creating a Cloud Service Agency and Binding It to a Cluster

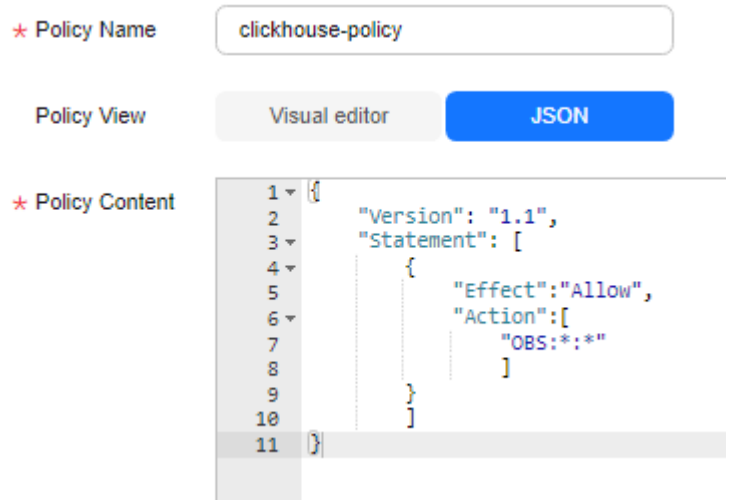
1. Log in to the management console.
2. In the service list, choose **Management & Governance** > **Identity and Access Management**.
3. In the navigation pane on the left, choose **Agencies** and click **Create Agency**. On the displayed page, set the following parameters and click **Next**:
   - **Agency Name**: Enter an agency name, for example, **mrs_clickhouse_obs**.
   - **Agency Type**: Select **Cloud service**.
   - **Cloud Service**: Select **ECS BMS**.
   - **Validity Period**: Select **Unlimited**.
4. On the displayed page, search for the **OBS OperateAccess** policy and select it.
5. Click **Next**, click **Show More**, select **Global services**, and click **OK**.
6. In the displayed dialog box, click **OK** to start authorization. Click **Finish** after the message "Authorization successful." is displayed.

7. On the MRS console, choose **Active Clusters** in the navigation pane on the left and click the name of the target cluster to access its details page.
8. On the **Dashboard** page, click **Synchronize** on the right of **IAM User Sync** to synchronize the IAM user.
9. Click **Manage Agency** on the right of **Agency**, select the created agency, for example, **mrs_clickhouse_obs**, and click **OK** to bind the agency to the cluster.

Creating a Common Account Agency and Binding It to a Cluster

1. Log in to the management console.
2. In the service list, choose **Management & Governance** > **Identity and Access Management**.
3. Choose **Permissions** > **Policies/Roles**, and click **Create Custom Policy**. Set the following parameters, and click **OK**:
   - **Policy Name**: Enter a policy name, for example, **clickhouse-policy**.
   - **Policy View**: Select **JSON**.
   - **Policy Content**: Enter the following content:

```
{
   "Version": "1.1",
   "Statement": [
      {
         "Effect":"Allow",
         "Action":[
            "OBS:*:*"
           ]
      }
      ]
}
```



4. In the navigation pane on the left, click **Agencies**. Click **Create Agency**. On the displayed page, set the following parameters and click **Next**:
   - **Agency Name**: Enter an agency name, for example, **agency-clickhouse-to-OBS**.
   - **Agency Type**: Select **Account**.
   - Enter your cloud account in the **Delegated Account** field, that is, the account you register using your mobile phone number. It cannot be a federated user or an IAM user created using your cloud account.

- **Validity Period**: Select **Unlimited**.

5. In the search box on the displayed **Authorize Agency** page, search for the custom policy created in **3** and select it, for example, **clickhouse-policy**.
6. Click **Next**, click **Show More**, select **Global services**, and click **OK**.
7. Check and record the agency ID.
8. On the **Identity and Access Management** page, click **Agencies**.
9. Click the name of the cloud service agency created in **3**, for example, **mrs_clickhouse_obs**.
10. Click the **Permissions** tab and click **Authorize**. On the displayed page, click **Create Policy** in the upper right corner, and set the parameters as follows:
    - **Policy Name**: Enter a policy name, for example, **clickhouse-assume-policy**.
    - **Policy View**: Select **JSON**.
    - **Policy Content**: Enter the following content. *{Agency ID}* indicates the ID recorded in **7**.

```
{
   "Version": "1.1",
   "Statement": [
      {
         "Action": [
            "iam:agencies:assume"
         ],
         "Resource": {
            "uri": [
               "/iam/agencies/{Agency ID}"
            ]
         },
         "Effect": "Allow"
      }
   ]
}
```

11. Click **Next**. On the **Select Policy/Role** page, select the policy created in **10**.
12. Click **Next**, click **Show More**, select **Global services**, and click **OK**.

Adding OBS Disk Information to the ClickHouse Cluster

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, click **ClickHouseServer(Role)**, and select **Storage**.
2. OBS access credentials can be an agency or AK/SK. Choose either of them.
    - Configure an agency to obtain OBS access credentials.

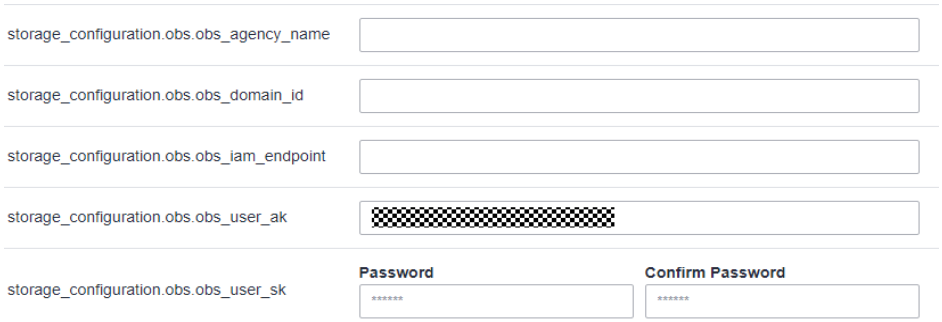
Parameter	Description
storage_configuration.obs.obs_domain_id	Domain ID of the user who accesses IAM For details, see the domain ID obtained in **Creating an OBS Parallel File System**.
storage_configuration.obs.obs_iam_endpoint	For details, see the IAM endpoint obtained in **Creating an OBS Parallel File System**.

Parameter	Description
storage_configuration.obs.obs_agency_name	Agency name. For details about how to obtain the agency name, see **Creating a Common Account Agency and Binding It to a Cluster**. Example value: **agency-clickhouse-to-OBS**

- Use AK/SK as the OBS access credentials.

Parameter	Description
storage_configuration.obs.obs_user_ak	AK of the IAM user in prerequisites To obtain the AK information, refer to **6**.
storage_configuration.obs.obs_user_sk	SK of the IAM user in prerequisites To obtain the SK information, refer to **6**.

Figure 3-6 Adding AK/SK to OBS credentials



3. In the **clickhouse-config-customize** parameter, add custom configuration items based on the following table to configure OBS disk information.

Table 3-13 OBS disk parameters

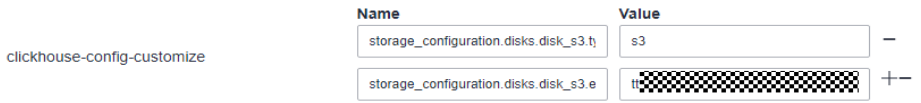
Parameter	Description
storage_configuration.disks.*disk_s3*.type	Fixed at **s3**

Parameter	Description
storage_configuration.disks.*disk_s3*.endpoint	Access path of the created OBS parallel file system. The format is as follows: *https://Parallel file system name.Parallel File Endpoint/Folder Name/* • Parallel file system name: Name of the OBS parallel file system you cerated • Parallel file endpoint: To obtain the endpoint, click the OBS parallel file name and check the basic information on the overview page. • Folder name: name of the folder created in the OBS parallel file system

NOTE

disk_s3 indicates the OBS disk name, which can be customized.

Figure 3-7 Configuring an OBS disk with **clickhouse-config-customize**



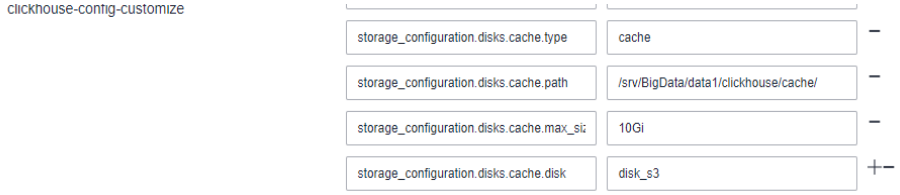
4. (Optional) Cache data stored on OBS to local storage to accelerate data query. To use the local cache, add configuration items to **clickhouse-config-customize**.

Parameter	Description
storage_configuration.disks.*obs_cache*.type	Fixed at **cache**
storage_configuration.disks.*obs_cache*.path	Path for caching data on a local disk, for example, **/srv/BigData/data1/clickhouse/cache/**
storage_configuration.disks.*obs_cache*.max_size	Cache size, for example, 10 Gi
storage_configuration.disks.*obs_cache*.disk	Name of the OBS storage disk, for example, **disk_s3**

NOTE

obs_cache indicates the OBS cache name, which can be customized.

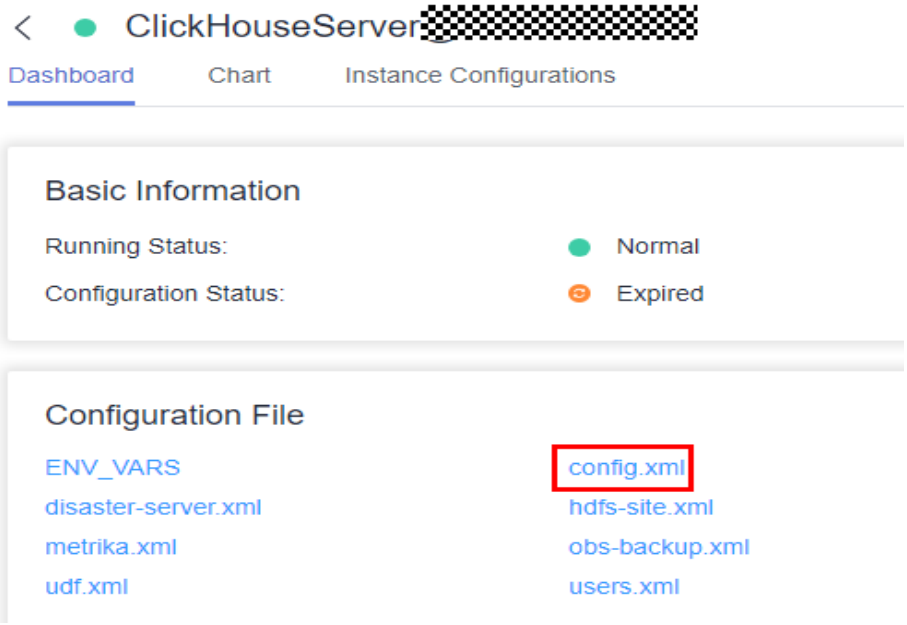
Figure 3-8 Configuring an OBS cache with **clickhouse-config-customize**



Configuring Disk Storage Policies

Configure disk storage policies on FusionInsight Manager.

1. Log in to FusionInsight Manager, choose **Cluster** > **ClickHouse** > **Instances**, and click a **ClickHouseServer**. On the displayed page, click the **config.xml** file.



2. In the **config.xml** file, obtain the value of **disk** of **storage_configuration**.

```
<grpc_port/>
<include_from>/opt/huawei/Bigdata/FusionInsight_ClickHouse_8.1.3/1_2_ClickHouseServer/e
<remote_servers incl="clickhouse_remote_servers"/>
<dictionaries_config>*_dictionary.xml</dictionaries_config>
<tcp_with_proxy_port/>
<users_config>users.xml</users_config>
<listen_host>server-2110081635-0001</listen_host>
<default_profile>default</default_profile>
<mark_cache_size>5368709120</mark_cache_size>
<storage_configuration>
  <disks>
    <disk1>
      <path>/srv/BigData/clickhouse/data1/clickhouse/</path>
      <keep_free_space_bytes>104857600</keep_free_space_bytes>
    </disk1>
  </disks>
  <policies>
    <default>
      <volumes>
        <volume1>
          <disk>disk1</disk>
          <max_data_part_size_bytes>0</max_data_part_size_bytes>
        </volume1>
      </volumes>
    </default>
  </policies>
</storage_configuration>
<zookeeper>
  <node index="1">
    <host>server-2110082001-0019</host>
```

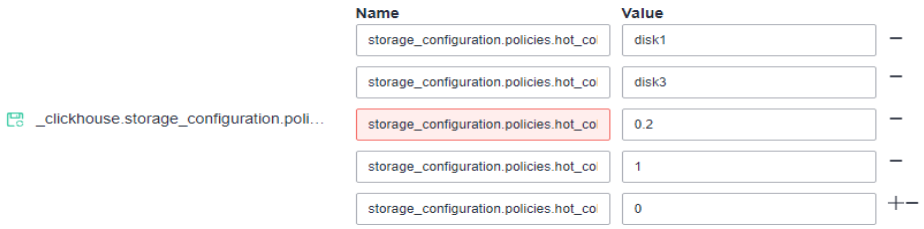
3. Choose **Cluster** > **ClickHouse** > **Configurations** > **All Configurations** > **ClickHouse(Service)** and search for the **_clickhouse.storage_configuration.policies** parameter.

   Set the following parameters listed in the table.

Configuration Item	Value	Description
storage_configuration.policies.*hot_cold_separation_policy*.volumes.*hot_volume*.disk[1]	disk1	This is a configuration item for local disks. You can configure multiple local disks as you need. The value ranges from **disk1** to **diskn**. For details about how to obtain the parameter value, see 2. **hot_cold_separation_policy** indicates the name of a policy item, which can be customized. **hot_volume** indicates the volume name in the hot data storage policy, which can be customized.
storage_configuration.policies.*hot_cold_separation_policy*.volumes.*hot_volume*.disk[2]	disk2	
storage_configuration.policies.*hot_cold_separation_policy*.volumes.*hot_volume*.disk[n]	diskn	

Configuration Item	Value	Description
storage_configuration.policies.*hot_cold_separation_policy*.volumes.hot_volume.priority	1	Priority of volumes in the hot data storage policy. If the value is greater than that of **storage_configuration.policies.*hot_cold_separation_policy*.volumes.cold_obs_volume.priority**, the hot data disk has a higher priority than the cold data disk.
storage_configuration.policies.*hot_cold_separation_policy*.volumes.cold_obs_volume.priority	0	Priority of volumes in the cold data storage policy. If the value is greater than that of **storage_configuration.policies.*hot_cold_separation_policy*.volumes.hot_volume.priority**, the cold data disk has a higher priority than the hot data disk.
storage_configuration.policies.*hot_cold_separation_policy*.volumes.*cold_obs_volume*.disk	OBS disk or cache name	**cold_obs_volume** indicates the volume name in the cold data OBS storage policy, which can be customized. ● If you do not use the local disk cache, set this parameter to the name of the OBS disk, for example, **disk_s3**. ● If you are using the local disk cache, set this parameter to the cache name, for example, **obs_cache**.
storage_configuration.policies.*hot_cold_separation_policy*.move_factor	0.2	**move_factor** indicates when data is moved to another volume. When the available space of a volume is less than **move_factor**, data is automatically moved to the next volume. In this example, when the available space of the hot volume is less than 20%, data in this volume is automatically moved to the cold volume. The value range is 0 to 1.

The following figure shows how to configure a storage policy.



4. Save the configuration and restart ClickHouse.

Custom Cold-Hot Separation Policy

1. Run the **clickhouse client** command to connect to the ClickHouseServer node. For details, see **ClickHouse Client Practices**.
2. Create a **ReplicatedMergeTree** table for configuring the TTL for cold and hot storage.

   ClickHouse supports table-level TTLs and allows you to set time-based rules to move data between specified disks or volumes. Data is stored at different storage layers.

   The following is a table creation statement:

```
CREATE TABLE example_table on cluster default_cluster
 (
d DateTime,
a Int
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/example_table', '{replica}')
PARTITION BY toYYYYMM(d)
ORDER BY d
TTL d + INTERVAL 3 YEAR,
d + INTERVAL 1 YEAR TO VOLUME 'cold_obs_volume'
SETTINGS storage_policy = 'hot_cold_separation_policy';
```

   NOTE

   In this statement, the TTL configuration is in bold. This example deletes cold data older than three years from the **example_table** table, and moves cold data older than one year to OBS. The **d** column stores the time information about the data.

   The TTL policy is specified using a simple SQL expression that contains the time and time interval. For example:

   - The data will expire in three days since its creation (**date_time**).
     ```
     TTL date_time + INTERVAL 3 DAY
     ```
   - The data will expire one year later since its creation (**date_time**).
     ```
     TTL date_time + INTERVAL 1 YEAR
     ```

   The INTERVAL keyword supports **second**, **minute**, **hour**, **day**, **week**, **month**, **quarter**, and **year**.

   storage_policy indicates the specified custom storage policy. In this example, the value is the policy name **_clickhouse.storage_configuration.disks** defined in **3**.

Importing Data into ClickHouse to Verify the Configuration

1. Insert data for verification.

```
insert into example_table values('2023-12-27','10086');  -- hot data
insert into example_table values('2023-12-26','10086');  -- hot data
```

```
insert into example_table values('2022-12-24','10086');  -- cold data
insert into example_table values('2022-11-24','10086');  -- cold data
insert into example_table values('2018-10-01','10086');  -- deleted data
insert into example_table values('2017-10-01','10086');  -- deleted data
```

2. Query table data.

```
tesspmrB0002.mrs-dviw.com :) select * from example_table FORMAT CSV;
SELECT *
FROM example_table
FORMAT CSV
Query id: 3d6bfcb4-f082-4e97-8d95-f885e22ae689

"2023-12-27 00:00:00",10086
"2023-12-26 00:00:00",10086
"2022-11-24 00:00:00",10086
"2022-12-24 00:00:00",10086

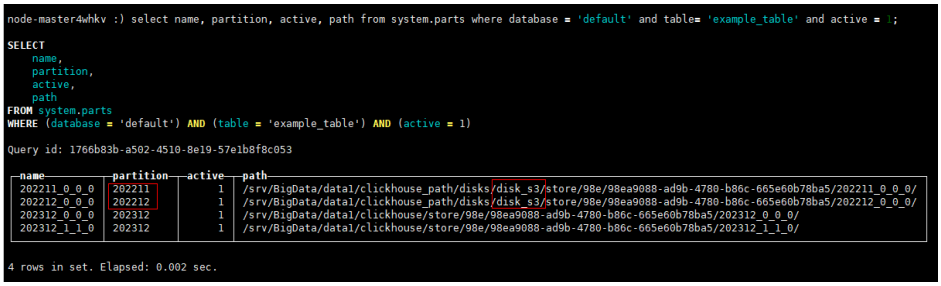
4 rows in set. Elapsed: 0.037 sec.
```

Assume that current system time is April 2024. According to the TTL policy rule **example_table**, the data generated on 2018-10-01 and 2017-10-01 will be deleted.

3. Query the storage paths of hot data and cold data.

select name, partition, active, path from system.parts where database ='*database name*'**and table='***table name*' **and active = 1;**

Figure 3-9 Query result



Assume that the current system time is April 2024. Data older than one year (**d** column values: **202211** and **202212**) in the **example_table** table is stored in the **disk_s3** OBS bucket.

3.5.8 Configuring the Connection Between ClickHouse and Open-Source ClickHouse

NOTE

This section applies to MRS 3.3.0-LTS.1 or later.

Scenario

For clusters in normal mode (Kerberos authentication disabled), you need to configure CLICKHOUSE_OPENSOURCE_COMMUNITY to connect to the open-source or other vendors' ClickHouse. For clusters in security mode (Kerberos authentication enabled), the connection is not supported.

Parameter Configuration

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**, click **ClickHouseServer(Role)** > **Security**, and search for and modify the following parameters.

Parameter	Description
CLICKHOUSE_OPENSOURCE_COMMUNITY	Whether to support the connection to the open-source ClickHouse. The default value is **false**, indicating that ClickHouse cannot be connected to an open-source ClickHouse. Value **true** indicates that ClickHouse can be connected to an open-source ClickHouse.

Step 2 Click **Save**. In the displayed dialog box, click **OK** to save the configuration. Choose **Instances**, select **ClickHouseServer**, and click **More** > **Instance Rolling Restart**.

----End

3.5.9 Pre-Caching ClickHouse Metadata to the Memory

NOTE

This section applies to MRS 3.3.1-LTS or later.

Scenario

If there are a large number of service tables holding a large amount of data, loading metadata during rolling restart is time-consuming. You can use RocksDB to pre-cache the metadata to the memory to accelerate metadata loading.

Enabling Metadata Pre-Caching

You can set **use_metadata_cache** to **1** or **true** to cache metadata to the memory through RocksDB.

1. Use the ClickHouse client to connect to the ClickHouse server by referring to **ClickHouse Client Practices**.
2. Configure metadata pre-caching.
   - Enable metadata pre-caching for historical tables.

     ALTER TABLE *<table name>* **MODIFY SETTING use_metadata_cache=1;**

     Or

     ALTER TABLE *<table name>* **MODIFY SETTING use_metadata_cache=true;**
   - Enable metadata pre-caching when you create a table.

     CREATE TABLE *<table name>*

     (

     `x` UInt32,

     `y` UInt32,

```
`z` UInt32,
`t` UInt32
)
ENGINE = MergeTree
PARTITION BY x % 10
ORDER BY (x, y)
SETTINGS index_granularity = 8192, use_metadata_cache = 1
```

or

```
CREATE TABLE <table name>
(
`x` UInt32,
`y` UInt32,
`z` UInt32,
`t` UInt32
)
ENGINE = MergeTree
PARTITION BY x % 10
ORDER BY (x, y)
SETTINGS index_granularity = 8192, use_metadata_cache = true
```

Parameter Tuning

Metadata pre-caching can be optimized as follows:

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, click **Configurations** and then **All Configurations**, and modify the following parameters:

Parameter	Value	Description
merge_tree_metadata_cache.continue_if_corrupted	true	If the local RocksDB directory fails to be read, **false** indicates that you can exit the process, and **true** indicates that dirty data is cleared.
merge_tree_metadata_cache.lru_cache_size	1GB	Size of the LRU in the RocksDB instance used to cache part metadata

3.6 ClickHouse Performance Tuning

3.6.1 Optimizing ClickHouse Table Partitioning

Troubleshooting

1. Log in to the ClickHouse client and check whether abnormal merge exists.

   select database, table, elapsed, progress, merge_type from system.merges;

2. Do not perform the INSERT operation too frequently, do not insert a small amount of data, and increase the interval for inserting data.
3. The data table partitions are not properly allocated. As a result, too many partitions are generated and data tables need to be re-partitioned.
4. If the MERGE operations are not triggered or slow, adjust the following parameters to accelerate them.

   For details, see **Accelerating ClickHouse Merge**.

Configuration Item	Reference Value
max_threads	Number of CPU cores x 2
background_pool_size	Number of CPU cores
merge_max_block_size	The value is an integer multiple of 8192 and is adjusted based on the CPU and memory resources.
cleanup_delay_period	Set this parameter to a value that is appropriately less than the default value 30.

Changing the Value of parts_to_throw_insert

CAUTION

Increase the value of this parameter only in special scenarios. This configuration acts as a warning for potential issues to some extent. If the cluster hardware resources are insufficient and this configuration is not adjusted properly, potential service issues cannot be detected in a timely manner, which may cause other faults and increase the difficulty of fault recovery.

- For versions earlier MRS 3.2.0, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Click **ClickHouseServer** > **Customization**, find the **clickhouse-config-customize** parameter, add the configuration in **Table 3-14**, save it, and restart the service.
- For MRS 3.2.0 and later versions, log in to FusionInsight Manager, choose **Cluster** > **ClickHouse** > **Configurations** > **All Configurations**, search for and change the value of **merge_tree.parts_to_throw_insert**, save the configurations, and restart the service.

Table 3-14 Parameters

Name	Value
merge_tree.parts_to_throw_insert	Memory of ClickHouse instances/32 GB x 300 (conservative estimation)

Verify the modification.

Log in to the ClickHouse client and run the **select * from system.merge_tree_settings where name = 'parts_to_throw_insert';** command.

3.6.2 Accelerating ClickHouse Merge

To accelerate background tasks, adjust the ZooKeeper service configuration first. Otherwise, the ClickHouse service and background tasks will be abnormal due to insufficient ZooKeeper resources such as znodes.

1. Adjust the ZooKeeper configuration. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Zookeeper**. Click **Configurations** then **All Configurations**. Click **quorumpeer** > **System**, change the value of **GC_OPTS** according to the following table, save the configuration, and roll restart the ZooKeeper service.

Configuration Item	Reference Value	Description
GC_OPTS	Xmx = (Memory size of master nodes – 16 GB) x 0.65 (conservative estimation)	JVM parameter used for garbage collection (GC). This parameter is valid only when **GC_PROFILE** is set to **custom**. Ensure that the **GC_OPT** parameter is set correctly. Otherwise, the process will fail to be started. **CAUTION** Exercise caution when modifying this item. If this parameter is set incorrectly, the service will be unavailable.

2. Adjust the ClickHouse configuration. On FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Click **ClickHouseServer** > **Zookeeper**, modify the following parameters, and save the configuration. You do not need to restart the service.

Configuration Item	Reference Value	Description
clickhouse.zookeeper.quota.node.count	Xmx/4 GB x 1,500,000	Node quantity quota of ClickHouse in the top directory on ZooKeeper. This parameter cannot be set to **0**, but can be set to a minimum value of **–1**. **–1** indicates that there is no limit on the number of ClickHouse nodes in the top directory. **CAUTION** If the quantity quota is less than the actual value of the current ZooKeeper directory, the configuration can be saved but does not take effect and an alarm is reported on the GUI.
clickhouse.zookeeper.quota.size	Xmx/4 GB x 1 GB	Capacity quota of ClickHouse in the top directory on ZooKeeper. **CAUTION** If the quantity quota is less than the actual value of the current ZooKeeper directory, the configuration can be saved but does not take effect and an alarm is reported on the GUI.

3.6.3 Accelerating ClickHouse TTL Operations

When TTL is triggered in ClickHouse, a large amount of CPU and memory are consumed.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Configurations** then **All Configurations**. Click **ClickHouseServer** > **Customization**, find the **clickhouse-config-customize** parameter, add the following parameters, save the configuration, and restart the service.

Configuration Item	Reference Value	Description
merge_tree.max_replicated_merges_with_ttl_in_queue	Half of number of CPU cores	Number of tasks that allow TTL to merge parts concurrently in the ReplicatedMergeTree queue.
merge_tree.max_number_of_merges_with_ttl_in_pool	Number of CPU cores	The thread pool that allows TTL to merge parts in the ReplicatedMergeTree queue.

NOTE

Do not modify these configurations when the cluster writes heavily. Idle threads need to be reserved for regular Merge operations to avoid the "Too many parts" issue.

3.7 ClickHouse O&M Management

3.7.1 ClickHouse Log Overview

Logs of MRS 3.2.0 and Later Versions

Log path: ClickHouse logs are stored in **${BIGDATA_LOG_HOME}/clickhouse** by default.

- ClickHouse run logs: **/var/log/Bigdata/clickhouse/clickhouseServer/ *.log**
- Balancer run logs: **/var/log/Bigdata/clickhouse/balance/*.log**
- Data migration logs: **/var/log/Bigdata/clickhouse/migration/${task_name}/clickhouse-copier_{timestamp}_{processId}/copier.log**
- ClickHouse audit logs: **/var/log/Bigdata/audit/clickhouse/clickhouse-server.audit.log**

Log archiving rules:

- ClickHouse compresses and archives logs. By default, when the size of a log file exceeds 100 MB, the log file will be compressed.
- The file generated after log files are compressed is named in the format of **<***Original log name***>.[***ID***].gz**.
- A maximum of 10 latest compressed files are reserved by default. The number of compressed files can be configured on Manager.

Table 3-15 ClickHouse log list

Log Type	Log File Name	Description
ClickHouse log	/var/log/Bigdata/clickhouse/clickhouseServer/clickhouse-server.err.log	Path of ClickHouseServer error log files
	/var/log/Bigdata/clickhouse/clickhouseServer/checkService.log	Path of key ClickHouseServer run log files
	/var/log/Bigdata/clickhouse/clickhouseServer/clickhouse-server.log	
	/var/log/Bigdata/clickhouse/clickhouseServer/ugsync.log	User role synchronization tool log
	/var/log/Bigdata/clickhouse/clickhouseServer/prestart.log	ClickHouse prestart log
	/var/log/Bigdata/clickhouse/clickhouseServer/start.log	ClickHouse startup log

Log Type	Log File Name	Description
	/var/log/Bigdata/clickhouse/clickhouseServer/checkServiceHealthCheck.log	ClickHouse health check log
	/var/log/Bigdata/clickhouse/clickhouseServer/checkugsync.log	User role synchronization check log
	/var/log/Bigdata/clickhouse/clickhouseServer/checkDisk.log	Path of ClickHouse disk check log files
	/var/log/Bigdata/clickhouse/clickhouseServer/backup.log	Path of log files generated when ClickHouse performs the backup and restoration operations on Manager
	/var/log/Bigdata/clickhouse/clickhouseServer/stop.log	ClickHouse stop log
	/var/log/Bigdata/clickhouse/clickhouseServer/postinstall.log	postinstall.sh script invoking log of ClickHouse
	/var/log/Bigdata/clickhouse/balance/start.log	Path of ClickHouseBalancer startup log files
	/var/log/Bigdata/clickhouse/balance/error.log	Path of ClickHouseBalancer error log files
	/var/log/Bigdata/clickhouse/balance/access_http.log	Path of the HTTP log files generated during ClickHouseBalancer running
	/var/log/Bigdata/clickhouse/balance/access_tcp.log	Path of the TCP log files generated during ClickHouseBalancer running
	/var/log/Bigdata/clickhouse/balance/checkService.log	ClickHouseBalancer service check log
	/var/log/Bigdata/clickhouse/balance/postinstall.log	Invoking log of the **postinstall.sh** script of ClickHouseBalcer
	/var/log/Bigdata/clickhouse/balance/prestart.log	Path of prestart log files of ClickHouseBalancer
	/var/log/Bigdata/clickhouse/balance/stop.log	Path of stop log files of ClickHouseBalancer
	/var/log/coredump/clickhouse-*.core.gz	Compressed package of memory dump files generated after the ClickHouse process breaks down This log is available in MRS 3.3.0 or later versions only.

Log Type	Log File Name	Description
Data migration log	/var/log/Bigdata/clickhouse/migration/*Data migration task name*/clickhouse-copier_*{timestamp}_{processId}*/copier.log	Run log generated when you use the migration tool by referring to **Migrating Data Between ClickHouseServer Nodes in a Cluster**
	/var/log/Bigdata/clickhouse/migration/*Data migration task name*/clickhouse-copier_*{timestamp}_{processId}*/copier.err.log	Error log generated when you use the migration tool by referring to **Migrating Data Between ClickHouseServer Nodes in a Cluster**
clickhouse-tomcat log	/var/log/Bigdata/tomcat/clickhouse/web_clickhouse.log	ClickHouse custom UI run log
	/var/log/Bigdata/tomcat/audit/clickhouse/clickhouse_web_audit.log	Clickhouse data migration audit log
ClickHouse audit log	/var/log/Bigdata/audit/clickhouse/clickhouse-server-audit.log	Path of ClickHouse audit log files

Logs of MRS 3.2.0 and Earlier Versions

Log path: The default storage path of ClickHouse log files is as follows: **${BIGDATA_LOG_HOME}/clickhouse**

Log archive rule: The automatic log compression and archiving function are enabled. By default, when the size of logs exceeds 100 MB, logs are compressed into a log file named in the format of *<Original log file name>.[No.]***.gz**. A maximum of 10 latest compressed files are reserved by default. The number of compressed files can be configured on Manager.

Table 3-16 ClickHouse log list

Log Type	Log File Name	Description
Run log	/var/log/Bigdata/clickhouse/clickhouseServer/clickhouse-server.err.log	Path of ClickHouseServer error log files
	/var/log/Bigdata/clickhouse/clickhouseServer/checkService.log	Path of key ClickHouseServer run log files
	/var/log/Bigdata/clickhouse/clickhouseServer/clickhouse-server.log	
	/var/log/Bigdata/clickhouse/balance/start.log	Path of ClickHouseBalancer startup log files
	/var/log/Bigdata/clickhouse/balance/error.log	Path of ClickHouseBalancer error log files

Log Type	Log File Name	Description
	/var/log/Bigdata/clickhouse/balance/access_http.log	Path of ClickHouseBalancer run log files
Data migration log	/var/log/Bigdata/clickhouse/migration/*Data migration task name*/clickhouse-copier_{timestamp}_{processId}/copier.log	Run log generated when you use the migration tool by referring to **Migrating Data Between ClickHouseServer Nodes in a Cluster**
	/var/log/Bigdata/clickhouse/migration/*Data migration task name*/clickhouse-copier_{timestamp}_{processId}/copier.err.log	Error log generated when you use the migration tool by referring to **Migrating Data Between ClickHouseServer Nodes in a Cluster**

Log Level

Table 3-17 describes the log levels supported by ClickHouse.

Levels of run logs are error, warning, trace, information, and debug from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 3-17 Log levels

Level	Description
error	Logs of this level record error information about system running
warning	Logs of this level record exception information about the current event processing
trace	Logs of this level record trace information about the current event processing
information	Logs of this level record normal running status information about the system and events
debug	Logs of this level record system running and debugging information

To modify log levels, perform the following operations:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **ClickHouse** > **Configurations**.

Step 3 Select **All Configurations**.

Step 4 On the menu bar on the left, select the log menu of the target role.

Step 5 Select a desired log level.

Step 6 Click **Save**. Then, click **OK**.

----End

NOTE

The configurations take effect immediately without the need to restart the service.

Log Format

The following table lists the ClickHouse log format:

Table 3-18 Log formats

Log Type	Format	Example
ClickHouse run log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2021.02.23 15:26:30.691301 [6085] {} <Error> DynamicQueryHandler: Code: 516, e.displayText() = DB::Exception: default: Authentication failed: password is incorrect or there is no user with such name, Stack trace (when copying this message, always include the lines below): 0. Poco::Exception::Exception(std::__1::basic_string<char, std::__1::char_traits<char>, std::__1::allocator<char> > const&, int) @ 0x1250e59c
clickhouse-tomcat run log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2022-08-16 12:55:12,109 | INFO | pool-7-thread-1 | zookeeper is secure. | com.huawei.bigdata.om.extui.clickhouse.service.impl.QueryServiceImpl.initAuthContext(QueryServiceImpl.java:136)
Data migration log	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2022.08.07 14:41:01.814235 [28651] {} <Debug> ClusterCopier: Task / clickhouse/copier_tasks/TEST0807_02/tables/dblv85.startsea_zh_imoriginck_new/20201031/piece_4/shards/1 has been successfully executed by 8%2D5%2D226%2D156#20220807124849_28651

Log Type	Format	Example
Audit log	<*yyyy-MM-dd HH:mm:ss,SSS*>|*query id*|<*Log Level*><*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2022.08.16 20:58:16.723643 [11382] {cc9554b6-8a26-42e9-8ab8-d848500544e6} <Information> executeQuery_audit [executeQuery.cpp:202] : (0 from 192.168.64.81:45204, user: clickhouse, using experimental parser) select shard_num, host_name, host_address from system.clusters format JSON

3.7.2 Collecting Dumping Logs of the ClickHouse System Tables

NOTE

This topic is available for MRS 3.3.0-LTS and later versions only.

Scenario

If an exception occurs, you need to restart ClickHouse to restore services. Before restart, you need to dump the status information of each ClickHouse system table for efficient ClickHouse fault locating.

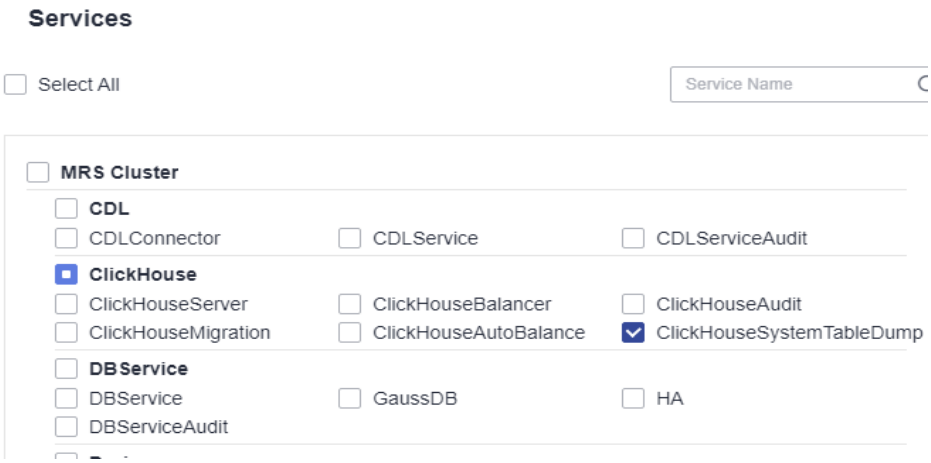
System table logs can be dumped in real time or in one-click mode, as shown in the following table.

Log Dumping Type	System Tables
Real-time dumping	• system.asynchronous_metrics • system.clusters • system.distribution_queue • system.events • system.grants • system.mutations • system.processes • system.metrics • system.part_moves_between_shards • system.replicas • system.replicated_fetches • system.replication_queue

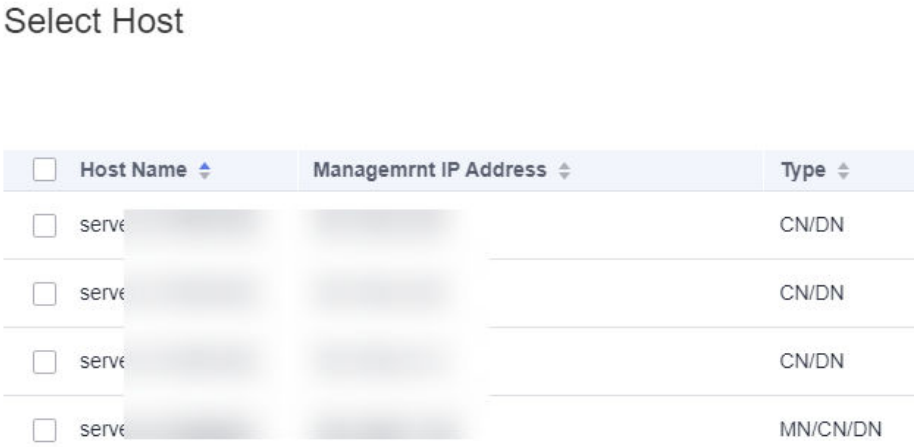
Log Dumping Type	System Tables
One-click dumping	• system.distributed_ddl_queue • system.errors • system.parts • system.parts_columns • system.query_log • system.query_thread_log • system.trace_log

Collecting Real-Time Dumping Logs

Step 1 Log in to FusionInsight Manager, choose **O&M** > **Log** > **Download**, and select **ClickHouseSystemTableDump** for **Service**.



Step 2 Select the hosts where you want to collect dumping logs and click **OK**.



Step 3 Click the time editing button in the upper right corner and set **Start Time** and **End Time** for log collection.

NOTE

For details about how long it takes to collect logs, contact technical support engineers.

Step 4 Click **Download**. The real-time system table dumping logs are saved to the local PC.

----End

Collecting One-Click Dumping Logs

Step 1 Log in to any ClickHouseServer node as the **root** user and go to the **sbin** directory.

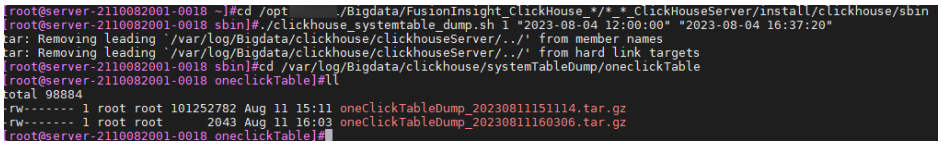
cd ${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*_*_ClickHouseServer/install/clickhouse/sbin

Step 2 Run the following command to obtain dumping logs:

./clickhouse_systemtable_dump.sh 1 "*Start time***" "***End time***"**

Example: **./clickhouse_systemtable_dump.sh 1 "2023-08-04 12:00:00" "2023-08-04 16:37:20"**

Step 3 Go to the **/var/log/Bigdata/clickhouse/systemTableDump/oneclickTable** directory and view the compressed one-click dumping logs.



----End

3.7.3 Enabling the Read-Only Mode for ClickHouse Tables

NOTE

This topic is available for MRS 3.2.0 or later only.

Scenario

During data migration, one-click balancing, decommissioning and capacity reduction, ClickHouse allows you to set the **only_allow_select_statement** parameter for MergeTree series tables to enable SELECT operations instead of ALTER, RENAME, DROP, and INSERT operations.

Procedure for Enabling the Read-Only Mode of the ClickHouse Table

Step 1 Install the client. For details, see **Installing a Client**.

Step 2 Run the following commands to log in to the node where the client is installed as user **root**:

cd *Client installation directory*

source bigdata_env

Step 3 Run the following command to authenticate the user if the cluster is in security mode (with Kerberos authentication enabled). Otherwise, skip this step.

kinit *Component service user*

NOTE

The user must have the ClickHouse administrator permissions.

Step 4 Run the proper client command to connect to the ClickHouse server.

- Normal mode

  clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password --port** 9440 **--secure**

  Enter the user password.

- Security mode

  clickhouse client --host *IP address of the ClickHouse instance* **--port** 9440 **--secure**

NOTE

- For a cluster in normal mode, the username is **default**. Alternatively, you can create an administrator using the open source ClickHouse web UI. Do not use the users created on FusionInsight Manager.
- To obtain the IP address of the ClickHouseServer instance, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse**, and click the **Instance** tab.

Step 5 Run the following statement to set the table to read-only:

ALTER TABLE *{table_name}* **MODIFY SETTING only_allow_select_statement = true;**

----End

Disabling the Read-Only Mode of the Table

Step 1 Log in to the ClickHouse client by referring to **Step 2** to **Step 4**.

Step 2 Run the following statement to disable the read-only mode of the table:

ALTER TABLE *{table_name}* **MODIFY SETTING only_allow_select_statement = false settings hw_internal_operation = true;**

----End

3.7.4 Migrating Data Between ClickHouseServer Nodes in a Cluster

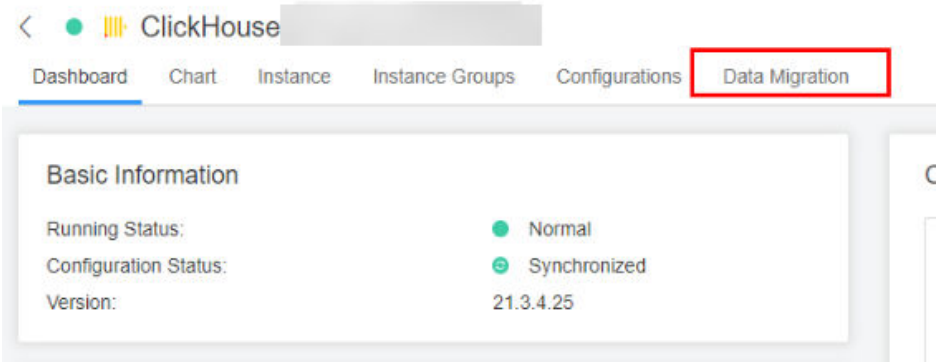
The ClickHouse data migration tool can migrate some partitions of one or more partitioned MergeTree tables on several ClickHouseServer nodes to the same tables on other ClickHouseServer nodes. In the capacity expansion scenario, you can use this tool to migrate data from an original node to a new node to balance data after capacity expansion.

Prerequisites

- The ClickHouse and Zookeeper services are running properly. The ClickHouseServer instances on the source and destination nodes are normal.
- The destination node has the data table to be migrated and the table is a partitioned MergeTree table.
- Before creating a migration task, ensure that all tasks for writing data to a table to be migrated have been stopped. After the task is started, you can only query the table to be migrated and cannot write data to or delete data from the table. Otherwise, data may be inconsistent before and after the migration.
- The ClickHouse data directory on the destination node has sufficient space.

Procedure

Step 1 Log in to Manager and choose **Cluster** > **Services** > **ClickHouse**. On the ClickHouse service page, click the **Data Migration** tab.



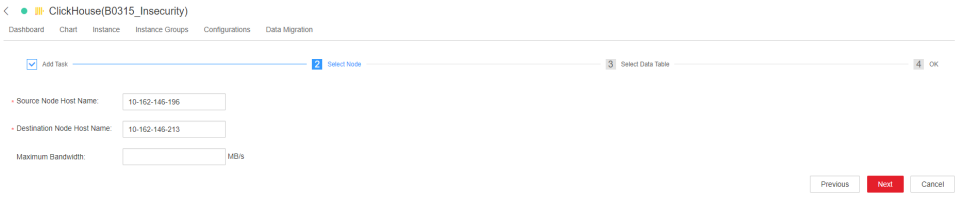
Step 2 Click **Add Task**.

Step 3 On the page for creating a migration task, set the migration task parameters. For details, see **Table 3-19**.

Table 3-19 Migration task parameters

Parameter	Description
Task Name	Enter a specific task name. The value can contain 1 to 50 characters, including letters, arrays, and underscores (_), and cannot be the same as that of an existing migration task.
Task Type	• **Scheduled Task**: When the scheduled task is selected, you can set **Started** to specify a time point later than the current time to execute the task. • **Immediate task**: The task is executed immediately after it is started.
Started	Set this parameter when **Task Type** is set to **Scheduled Task**. The valid value is a time point within 90 days from now.

Step 4 On the **Select Node** page, specify **Source Node Host Name** and **Destination Node Host Name**, and click **Next**.

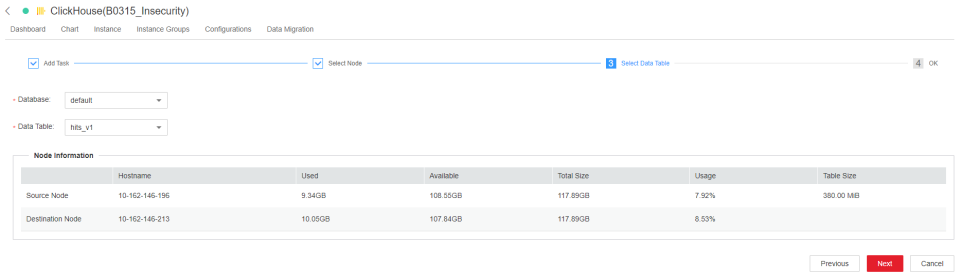


NOTE

- Only one host name can be entered in **Source Node Host Name** and **Destination Node Host Name**, respectively. Multi-node migration is not supported.

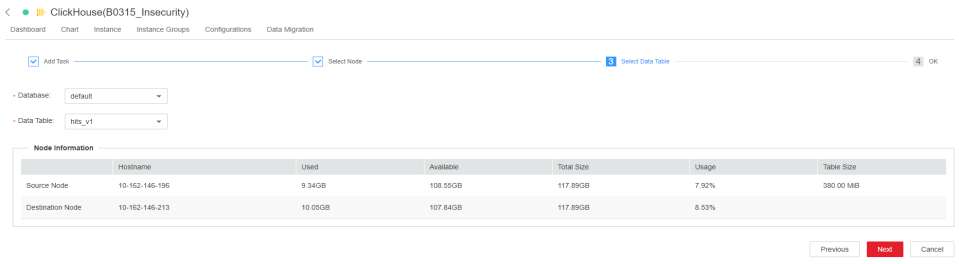
  To obtain the parameter values, click the **Instance** tab on the ClickHouse service page and view the **Host Name** column of the current ClickHouseServer instance.
- **Maximum Bandwidth** is optional. If it is not specified, there is no upper limit. The maximum bandwidth can be set to **10000** MB/s.

Step 5 On the **Select Data Table** page, click next to **Database**, select the database to be migrated on the source node, and select the data table to be migrated for **Data Table**. The data table drop-down list displays the partitioned MergeTree tables in the selected database. In the **Node Information** area, the space usage of the ClickHouse service data directory on the current source and destination nodes is displayed. Click **Next**.



Step 6 Confirm the task information and click **Submit**.

The data migration tool automatically calculates the partitions to be migrated based on the size of the data table. The amount of data to be migrated is the total size of the partitions to be migrated.



Step 7 After the migration task is submitted, click **Start** in the **Operation** column. If the task is an immediate task, the task starts to be executed. If the task is a scheduled task, the countdown starts.

Step 8 During the migration task execution, you can click **Cancel** to cancel the migration task that is being executed. If you cancel the task, the migrated data on the destination node will be rolled back.

You can choose **More** > **Details** to view the log information during the migration.

Step 9 After the migration is complete, choose **More** > **Results** to view the migration result and choose **More** > **Delete** to delete the directories related to the migration task on ZooKeeper and the source node.

----End

3.7.5 Migrating ClickHouse Data from One MRS Cluster to Another

NOTE

This section applies only to MRS 3.2.0 or later.

Scenario

Scenario 1: As the number of MRS ClickHouse services increases, the storage and compute resources of clusters cannot meet service requirements. Thus, the clusters need to be split so that part of user service and database data can be migrated to new clusters.

Scenario 2: The data center where the backend hosts of MRS ClickHouse clusters are located needs to be migrated, so does the ClickHouse cluster data.

To meet the migration requirements, MRS provides a one-click data migration tool for migrating the databases, table objects (DDL), and service data of ClickHouse from a source cluster to the new cluster.

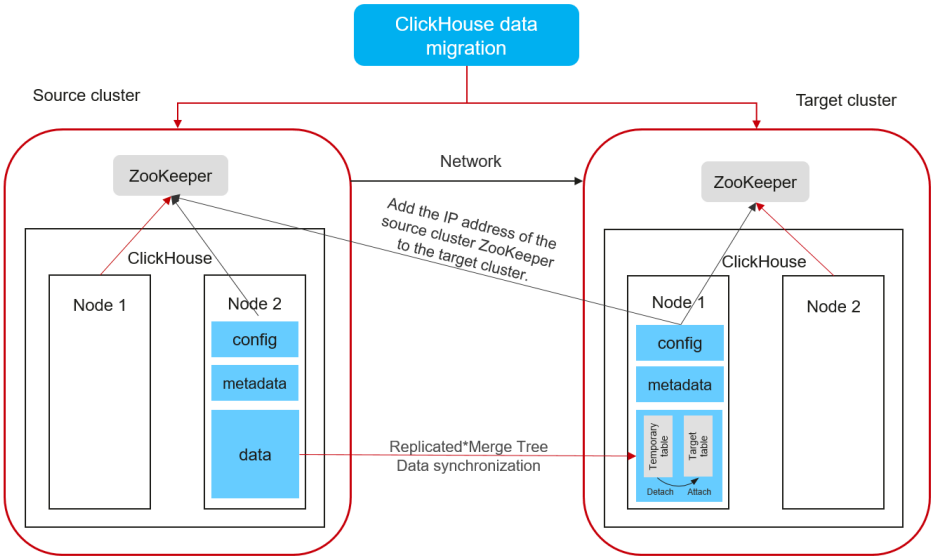
Migration Mechanism

- Replicated*MergeTree table migration

  In this migration solution, ClickHouse uses ZooKeeper to automatically synchronize the data of Replicated*MergeTree tables of different replicas in the same shard. The logical procedure is as follows:

  First, add the ZooKeeper information of the source cluster to the configuration file of the destination cluster as the auxiliary ZooKeeper. Then, in the destination cluster, create a temporary table that has the same ZooKeeper path and structure as the source cluster but different replicas from it. After the temporary table is created, data in the source cluster will be automatically synchronized to the temporary table. Once data synchronization is complete, copy data from the temporary table to the formal table.

Figure 3-10 Replicated*MergeTree table migration architecture



- Distributed table migration

  During the migration of a replicated table, its metadata in the source cluster is exported and changed to the ZooKeeper path and replica of the destination cluster. Then, you can create a table in the destination cluster based on the modified metadata.

- Non-replicated table and materialized view migration

  To migrate data in the non-replicated tables and materialized views, you can call the **remote** function.

The preceding migration operations are encapsulated using the migration tool script. In this way, you can modify the related configuration files and run the migration scripts to complete the migration by one click. For details, see the procedure description.

Prerequisites

- The status of the ClickHouse cluster you want to migrate is normal, and the source and destination clusters must be both in security mode or normal mode. If the clusters are in normal mode, contact O&M personnel for migration.
- A destination ClickHouse cluster of MRS 3.1.3 or later has been created for data migration. The cluster must be in security mode. The number of ClickHouseserver instances in the ClickHouse cluster is greater than or equal to that of the source cluster.
- Currently, logical clusters support only data migration to clusters with the same number of replicas.

Constraints

- Only table data and table object metadata (DDL) can be migrated. SQL statements like ETL need to be manually migrated.
- To ensure data consistency before and after the migration, stop the ClickHouse service of the source cluster before the migration. For details, see the procedure description.

- If the table of the source cluster is deleted during the migration, this issue can only be solved manually.

Procedure

The overall migration procedure is as follows:

Figure 3-11 Migration flowchart

Table 3-20 Migration description

Step	Description
Step 1: Connect the source cluster to the destination cluster.	This step ensures that the source and target ClickHouse clusters as well as their nodes can communicate with each other.
Step 2: Add the ZooKeeper information of the source cluster to the configuration file of the destination cluster.	By doing so, ZooKeeper in the source cluster can be used as the auxiliary ZooKeeper during data migration.
Step 3: Migrate metadata of databases and tables in the source ClickHouse cluster to the destination cluster.	You can run the corresponding script to migrate metadata such as the database name, table name, and table structure of the ClickHouse database and tables in the source cluster to the destination cluster.
Step 4: Migrate data of the databases and tables in the source ClickHouse cluster to the destination cluster.	You can run the corresponding script to migrate the ClickHouse database and table data from the source cluster to the destination cluster.

Connecting the Source Cluster to the Destination Cluster

1. Connect the source cluster to the destination cluster so that the ClickHouse instance nodes in the two clusters can communicate with each other.
2. Add the hosts information of the source cluster to the configuration of all nodes in the destination cluster, and add the hosts information of the destination cluster to the configuration of all nodes in the source cluster.
   a. Log in to FusionInsight Manager of the source ClickHouse cluster, choose **Cluster** > **ClickHouse**, click the **Instance** tab, and view the service IP address of the ClickHouseServer instance node.

b. Log in to any ClickHouseServer node using SSH and run the following command to check the host configurations of the ClickHouse instance in the source cluster:

cat /etc/hosts

The following figure shows the host configurations of the ClickHouse instance:

```
[root@19                ~]# cat /etc/hosts
127.0.0.1   localhost localhost.localdomain localhost4 localhost4.localdomain4
::1         localhost localhost.localdomain localhost6 localhost6.localdomain6

192.168.64.59 100-93-30-239 100-93-30-239.
192.168.64.157 100-95-140-144 100-95-140-144.
192.168.64.139 100-94-12-218 100-94-12-218.
192.168.64.81 100-94-163-99 100-94-163-99.
192.168.64.66 192-168-64-66 192-168-64-66.
192.168.64.24 192-168-64-24 192-168-64-24.
192.168.64.91 192-168-64-91 192-168-64-91.
192.168.64.162 192-168-64-162 192-168-64-162.
10.10.10.10 hadoop.hadoop.com
```

c. Log in to FusionInsight Manager of the destination ClickHouse cluster, choose **Cluster** > **ClickHouse**, click the **Instance** tab, and view the service IP address of the ClickHouseServer instance node in the destination cluster.

d. Log in to all ClickHouse nodes in the destination cluster as user **root** and run the following command to modify the **/etc/hosts** configuration of the nodes:

vi /etc/hosts

Copy the host information of the ClickHouse instance of the source cluster obtained in **2.b** to the **hosts** file.

e. Repeat **2.a** to **2.d** to add the node IP addresses of the destination cluster to the hosts files of the source cluster.

3. Configure system mutual trust between the source cluster and the destination cluster. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**.

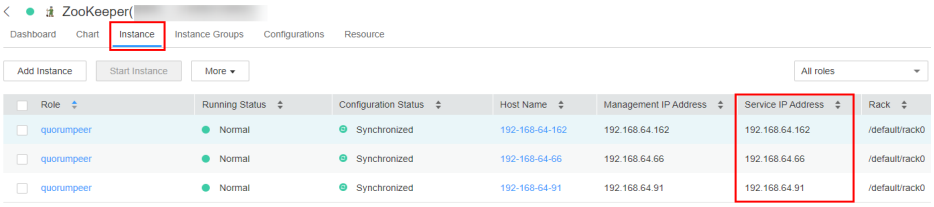
NOTE

If both the source and destination clusters are in normal mode, you do not need to configure mutual trust.

Adding the ZooKeeper Information of the Source Cluster to the Configuration File of the Destination Cluster

1. Log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ZooKeeper**, and click the **Instance** tab. On the displayed page, view the service IP addresses of the ZooKeeper quorumpeer instance , as shown in **Figure 3-12**.

Figure 3-12 Addresses of the source Zookeeper quorumpeer instance



2. Log in to FusionInsight Manager of the destination cluster, choose **Cluster** > **Services** > **ClickHouse** and click the **Configurations** tab and then **All Configurations**. On the displayed page, search for the **clickhouse-config-customize** parameter.
3. Add ZooKeeper instance information of the source cluster to the **clickhouse-config-customize** parameter by referring to **Table 3-21**.

Table 3-21 Configurations of **clickhouse-config-customize**

Parameter	Value
auxiliary_zookeepers.zookeeper2.node[1].host	Service IP address of the first ZooKeeper quorumpeer instance in the source cluster obtained in **1**. Currently, only the IP address of the ZooKeeper instance can be configured.
auxiliary_zookeepers.zookeeper2.node[1].port	2181
auxiliary_zookeepers.zookeeper2.node[2].host	Service IP address of the second ZooKeeper quorumpeer instance in the source cluster obtained in **1**. Currently, only the IP address of the ZooKeeper instance can be configured.
auxiliary_zookeepers.zookeeper2.node[2].port	2181
auxiliary_zookeepers.zookeeper2.node[3].host	Service IP address of the third ZooKeeper quorumpeer instance in the source cluster obtained in **1**. Currently, only the IP address of the ZooKeeper instance can be configured.
auxiliary_zookeepers.zookeeper2.node[3].port	2181

4. After the configuration is complete, click **Save**. In the displayed dialog box, click **OK**.
5. Log in to any ClickHouseServer node of the destination cluster as user **root**. Run the following command to view the ClickHouseServer instance information:

   ps -ef |grep clickhouse

   Obtain the value of **--config-file**, that is, the configuration file directory of the ClickHouseServer, from the query result.

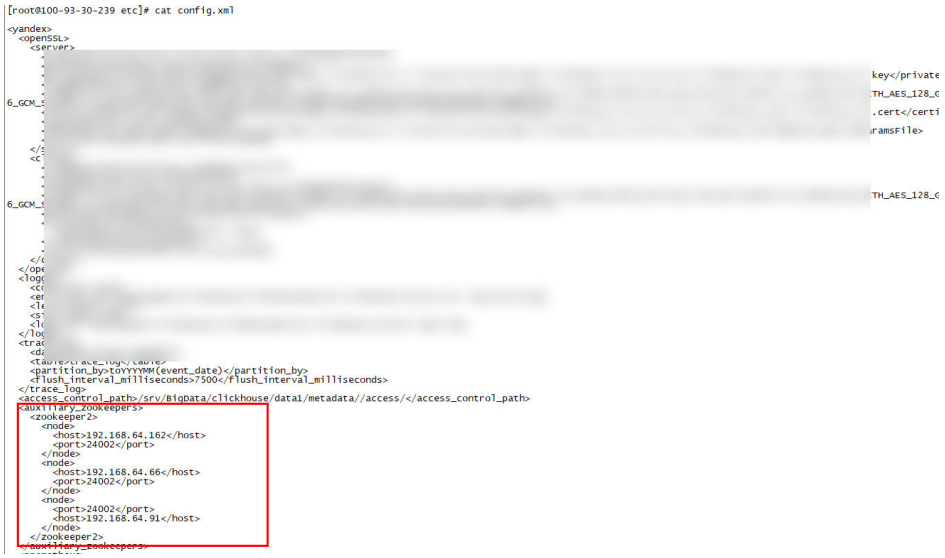
Figure 3-13 Obtaining the configuration file directory of ClickHouseServer

6. Run the corresponding command to check whether the information about **<auxiliary_zookeepers>** is added in the ClickHouse configuration file **config.xml**.

   cat *Directory of the config.xml file obtained in 5*

- If both the source and destination clusters are in security mode, go to **7**.
- If both the source and destination clusters are in normal mode, go to **11**.

Figure 3-14 Viewing the added ZooKeeper information of the source cluster



7. In the configuration file directory obtained in **5**, run the following command to obtain the ZooKeeper authentication information of the source cluster:

   cat ENV_VARS | grep ZK

   Obtain the values of **ZK_SERVER_FQDN**, **ZK_USER_PRINCIPAL** and **ZK_USER_REALM**.

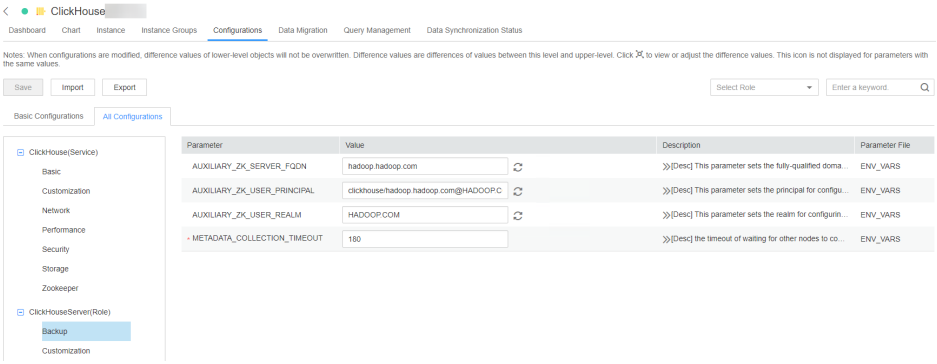
8. Log in to FusionInsight Manager of the destination cluster, choose **Cluster** > **Services** > **ClickHouse**, click the **Configurations** tab and then **All Configurations**. In the navigation pane on the left, choose **ClickHouseServer(Role)** > **Backup** and set the parameters by referring to the following table.

Table 3-22 Configuring the cluster authentication information

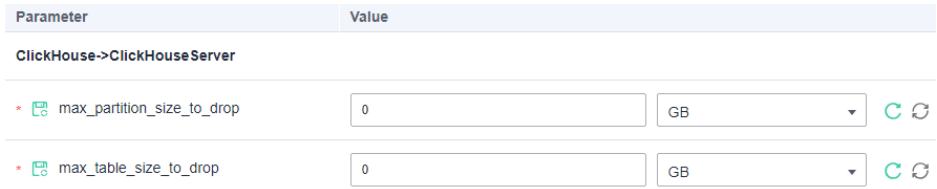
Parameter	Value
AUXILIARY_ZK_SERVER_FQDN	Value of **ZK_SERVER_FQDN** obtained in **7**

Parameter	Value
AUXILIARY_ZK_SERVER_PRINCIPAL	Value of **ZK_USER_PRINCIPAL** obtained in **7**
AUXILIARY_ZK_SERVER_REALM	Value of **ZK_USER_REALM** obtained in **7**
METADATA_COLLECTION_TIMEOUT	**180**. This parameter specifies the timeout interval for waiting for the completion of metadata backup on other nodes, in seconds.

Figure 3-15 Configuring the cluster authentication information



9. Select **Storage** under **ClickHouseServer(Role)**, and change the value of **max_partition_size_to_drop** and **max_table_size_to_drop** to **0**.



10. Click **Save**. In the dialog box that is displayed, click **OK**.
11. On the ClickHouse service page, click the **Instance** tab. On this tab page, select the ClickHouseServer instance from the instance list, and choose **More** > **Restart Instance** in the **Operation** column to restart the ClickHouseServer instance.

Migrating Metadata of Databases and Tables in the Source ClickHouse Cluster to the Destination Cluster

1. Log in to FusionInsight Manager of the source and destination clusters, and create the username and password required for the migration. The procedure is as follows:
   a. Log in to Manager and choose **System** > **Permission** > **Role**. On the displayed page, click **Create Role**.

b. Specify **Role Name**, for example, **ckrole**. In the **Configure Resource Permission** area, click the cluster name. On the displayed service list page, click the ClickHouse service.

c. Select **SUPER_USER_GROUP** and click **OK**.

d. Choose **System**. On the navigation pane on the left, choose **Permission** > **User** and click **Create**.

e. Select **Human-Machine** for **User Type** and set **Password** and **Confirm Password** to the password of the user.

NOTE

- Username: The username cannot contain hyphens (-). Otherwise, the authentication will fail.
- Password: The password cannot contain special characters $, ., and #. Otherwise, the authentication will fail.

f. In the **Role** area, click **Add** . In the displayed dialog box, select the role name in **1.b** and click **OK** to add the role. Then, click **OK**.

g. After the user is created, click the user name in the upper right corner to log out of the system. Log in to FusionInsight Manager as the new user and change its password as prompted.

2. Download the ClickHouse client and install it as user **omm** to the destination cluster.

3. Log in to the client node as user **omm**, go to the *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-metadata-migration** directory, and configure migration information. Run the following command to modify the **example_config.yaml** configuration file by referring to **Table 3-23**:

cd *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-metadata-migration**

vi example_config.yaml

After the configuration is modified, you must delete all comment with number sign(#) and retain only valid configurations. Otherwise, an error may occur during script migration.

Table 3-23 Parameters in **the example_config.yaml** file

Configuration Item	Sub-item	Value and Description
source_cluster	host	IP address of any ClickHouseServer node in the source cluster.

Configuration Item	Sub-item	Value and Description
	cluster_name	Name of the source ClickHouse cluster. You can log in to the ClickHouse client by referring to **ClickHouse Client Practices** and run the following command to obtain the value. If the source cluster name has not been changed, the default value is **default_cluster**. **select cluster,shard_num,replica_num,host_name from system.clusters;**
	https_port	• For security mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **https_port**. • For normal mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **http_port**.
	zookeeper_root_path	To obtain the value, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **clickhouse.zookeeper.root.path**.
	system	System parameter. Retain the default value.

	databases	Optional.
		• If this parameter is specified, data in the specified database of the source ClickHouse cluster is migrated. You can specify multiple databases. The following configuration is for your reference:
		`databases:`
		`  - "database"`
		`  - "database_1"`
		Data in the **database** and **database_1** databases of the source cluster is migrated.
		• If this parameter is not specified, table data of all databases in the source ClickHouse cluster is migrated. Leave the **databases** parameter empty. The following is an example:
		`databases:`
		Table information of all databases in the source ClickHouse cluster is migrated.

Configuration Item	Sub-item	Value and Description
	tables	Optional. The value is in the format of *Database name.Table name*. The database name must be in the databases parameter list. • If this parameter is specified, data in specified tables in the source ClickHouse cluster database is migrated. You can configure multiple tables. The following configuration is for your reference: tables: - "database.table_1" - "database_1.table_2" Data in **table_1** of **database** and **table_2** of database_1 of the source cluster is migrated. • If this parameter is not specified and the **databases** parameter is specified, all table data in the **databases** database is migrated. If the **databases** parameter is not specified, all table data in all databases of the source ClickHouse cluster is migrated. The following configuration is for your reference: tables:
destination_cluster	host	IP address of any ClickHouseServer node in the destination cluster.
	cluster_name	Name of the destination ClickHouse cluster. You can log in to the ClickHouse client by referring to **ClickHouse Client Practices** and run the following command to obtain the value. If the destination cluster name has not been changed, the default value is **default_cluster**. **select cluster,shard_num,replica_num,host_name from system.clusters;**
	user	Username created in **1** for logging in to FusionInsight Manager of the destination ClickHouse cluster.
	https_port	• For security mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **https_port**. • For normal mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **http_port**.

Configuration Item	Sub-item	Value and Description
	zookeeper_root_path	To obtain the value, log in to FusionInsight Manager of the destination cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **clickhouse.zookeeper.root.path**.
	system	System parameter. Retain the default value.

4. Run the following command to migrate data and wait until the script execution is complete:

   ./clickhouse_migrate_metadata.sh -f yaml_file

   Enter the usernames and passwords of the source and destination clusters.

   ```
   please input source cluster user name:
   please input source cluster user password:
   please input destination cluster user name:
   please input destination cluster user password:
   ```

   NOTE

   If metadata migration fails, perform the following steps:

   1. Locate the failure cause. Specifically, check whether any parameters in the configuration file are incorrectly configured.
      - If yes, reconfigure the parameters and perform metadata migration.
      - If no, go to 2.
   2. Set the names of the tables that fail to be migrated in the metadata migration configuration file based on the **databases** and **tables** parameters in Table 3-23 and run the metadata migration command again. If the migration fails, contact O&M personnel.

Migrating Data of the Databases and Tables in the Source ClickHouse Cluster to the Destination Cluster

1. Log in to the ClickHouse client node in the destination cluster as user **omm** and go to *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-data-migration**.

   cd *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-data-migration**

2. Run the following command to modify the **example_config.yaml** configuration file by referring to Table 3-24:

   vi example_config.yaml

   After the configuration is modified, you must delete all comment with number sign(#) and retain only valid configurations. Otherwise, an error may occur during script migration.

Table 3-24 Parameters in **example_config.yaml**

Configuration Item	Sub-item	Value and Description
source_cluster	host	IP address of any ClickHouseServer node in the source cluster.
	cluster_name	Name of the source ClickHouse cluster. You can log in to the ClickHouse client by referring to **ClickHouse Client Practices** and run the following command to obtain the value. If the source cluster name has not been changed, the default value is **default_cluster**. **select cluster,shard_num,replica_num,host_name from system.clusters;**
	user	Username created in **1** for logging in to FusionInsight Manager of the source ClickHouse cluster.
	https_port	• For security mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **https_port**. • For normal mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **http_port**.
	tcp_port	To obtain the value, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **tcp_port_secure** if the cluster is in security mode. Otherwise, search for **tcp_port**.
	zookeeper_root_path	To obtain the value, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **clickhouse.zookeeper.root.path**.
	system	System parameter. Retain the default value.

Configuration Item	Sub-item	Value and Description
	databases	Optional. ● If this parameter is specified, data in the specified database of the source ClickHouse cluster is migrated. You can specify multiple databases. The following configuration is for your reference: databases: - "database" - "database_1" Data in the **database** and **database_1** databases of the source cluster is migrated. ● If this parameter is not specified, table data of all databases in the source ClickHouse cluster is migrated. Leave the **databases** parameter empty. The following is an example: databases: Table information of all databases in the source ClickHouse cluster is migrated.
	tables	Optional. The value is in the format of *Database name*.*Table name*. The database name must be in the databases parameter list. ● If this parameter is specified, data in specified tables in the source ClickHouse cluster database is migrated. You can configure multiple tables. The following configuration is for your reference: tables: - "database.table_1" - "database_1.table_2" Data in **table_1** of **database** and **table_2** of database_1 of the source cluster is migrated. ● If this parameter is not specified and the **databases** parameter is specified, all table data in the **databases** database is migrated. If the **databases** parameter is not specified, all table data in all databases of the source ClickHouse cluster is migrated. The following configuration is for your reference: tables:
destination_cluster	host	IP address of any ClickHouseServer node in the destination cluster.

Configuration Item	Sub-item	Value and Description
	cluster_name	Name of the destination ClickHouse cluster. You can log in to the ClickHouse client by referring to **ClickHouse Client Practices** and run the following command to obtain the value. If the destination cluster name has not been changed, the default value is **default_cluster**. **select cluster,shard_num,replica_num,host_name from system.clusters;**
	user	Username created in **1** for logging in to FusionInsight Manager of the destination ClickHouse cluster.
	https_port	• For security mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **https_port**. • For normal mode, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ClickHouse** > **Configurations** > **All Configurations**, and search for **http_port**.
	tcp_port	To obtain the value, log in to FusionInsight Manager of the destination cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **tcp_port_secure** if the cluster is in security mode. Otherwise, search for **tcp_port**.
	zookeeper_root_path	To obtain the value, log in to FusionInsight Manager of the destination cluster, choose **Cluster** > **Services** > **ClickHouse**, and click the **Configurations** tab and then **All Configurations**. In the displayed page, search for **clickhouse.zookeeper.root.path**.
	system	System parameter. Retain the default value.
auxiliary_zookeepers	name	ZooKeeper name of the source ClickHouse cluster configured in **3**, for example, **zookeeper2**.

Configuration Item	Sub-item	Value and Description
	hosts	IP address of the ZooKeeper instance of the source ClickHouse. To obtain the IP address, log in to FusionInsight Manager of the source cluster, choose **Cluster** > **Services** > **ZooKeeper**, and click the **Instance** tab. On the displayed page, view the service IP addresses of the ZooKeeper quorumpeer instance , as shown in **Figure 3-12**. The format is as follows: hosts: - "192.168.1.2" - "192.168.1.3" - "192.168.1.4"
	port	2181
execution_procedure	-	This parameter is left blank by default, indicating that the script is executed once to synchronize service data. Value options are **firststep** and **secondstep**. ● **firststep**: Only the temporary replication table is created. The auxiliary ZooKeeper can synchronize data from the original cluster to the temporary table in real time. ● **secondstep**: data in the temporary replication table is attached to the local table of the destination cluster. **CAUTION** If this parameter is set to **secondstep**, O&M personnel and users need to confirm that ClickHouse-related services have been stopped before script execution.
onereplica_use_auxiliaryzookeeper	-	● If this parameter is set to **1**, temporary tables are created for only one replica of each shard. ● If this parameter is set to **0**, temporary tables are created for two replicas of each shard.
migrate_timeout	-	ClickHouse data migration timeout. If the migration duration exceeds the specified value, the migration is considered complete and the temporary table clearing starts. The default value is **1440**, in minutes. Set this parameter based on the data volume. **NOTE** This parameter applies to MRS 3.3.0-LTS.1.1.

3. Stop the ClickHouse service of the source cluster.

4. Run the following command to migrate data and wait until the script execution is complete:

   ./clickhouse_migrate_data.sh -f yaml_file

   Enter the usernames and passwords of the source and destination clusters.

5. After the script is executed successfully, perform the following steps to check whether the migrated data in the source cluster is consistent with that in the destination cluster based on the migration result logs:

   Log in to the ClickHouse client node in the destination cluster and go to the *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-data-migration/comparison_result** directory.

   Compare the following result file information to check the data consistency between the source cluster and the destination cluster:

   - **source_cluster_table_info**: statistics of data migrated from the source cluster
   - **destination_cluster_table_info**: statistics of data migrated to the destination cluster
   - **compare_result_file.txt**: data consistency comparison result before and after migration

   If the data is inconsistent before and after the migration, clear the data in the table of the destination cluster and migrate the data in the table separately or manually.

   In addition, you can log in to the ClickHouse databases of the source and destination clusters to manually check whether the number of table data records and partitions are consistent.

6. Log in to FusionInsight Manager of the destination cluster and delete the ZooKeeper information added to **clickhouse-config-customize** in 2.

   Click **Save**. In the displayed dialog box, click **OK**.

7. After data migration is complete, switch services to the target ClickHouse cluster.

8. Go to *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-data-migration** and *Client installation directory*/**ClickHouse/clickhouse_migration_tool/clickhouse-metadata-migration** on the ClickHouse node in the destination cluster.

   vi example_config.yaml

   Delete the password from the configuration file to prevent password leakage.

NOTE

If service data migration fails, perform the following steps:

1. Locate the failure cause. Specifically, check whether any parameters in the configuration file are incorrectly configured.
   - If yes, reconfigure the parameters and perform service data migration.
   - If no, go to 2.
2. Run the **drop table** *table_name* command to delete the data tables related to the table from the node that fails to be migrated in the destination cluster.
3. Run the **show create table** *table_name* command to query the table creation statements related to the table in the source cluster and create the table in the destination cluster again.
4. Set the names of the tables that fail to be migrated in the service data migration configuration file based on the **databases** and **tables** parameters in Table 3-24 and run the service data migration command again. If the command fails to execute, contact O&M personnel.

3.7.6 Expanding the Disk Capacity of the ClickHouse Node

With the service volume increase, the data disk capacity of the ClickHouse node cannot meet service requirements and needs to be expanded.

CAUTION

For a pay-per-use MRS cluster, the billing mode cannot be changed to yearly/monthly after the disk capacity is expanded.

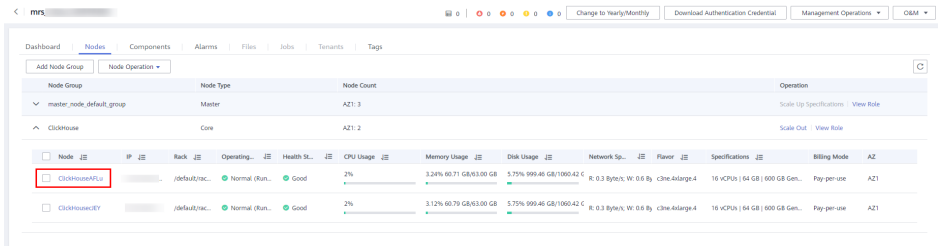
Prerequisites

- The ClickHouse cluster and instances are normal.
- You have evaluated the data disk capacity of the ClickHouse node to be expanded.

Expanding the Capacity of a Data Disk

Step 1 Log in to the MRS console. In the left navigation pane, choose **Active Clusters** and click a cluster name.

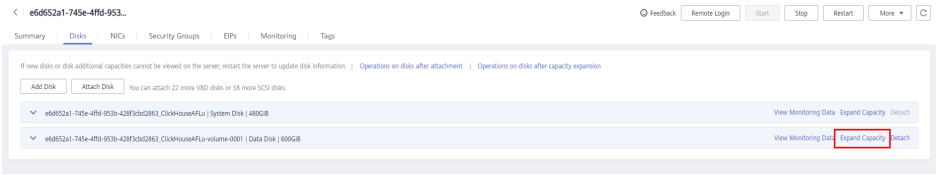
Step 2 Click **Nodes**. In the corresponding ClickHouse node group, click the name of the node to be expanded. The **Disks** page is displayed.



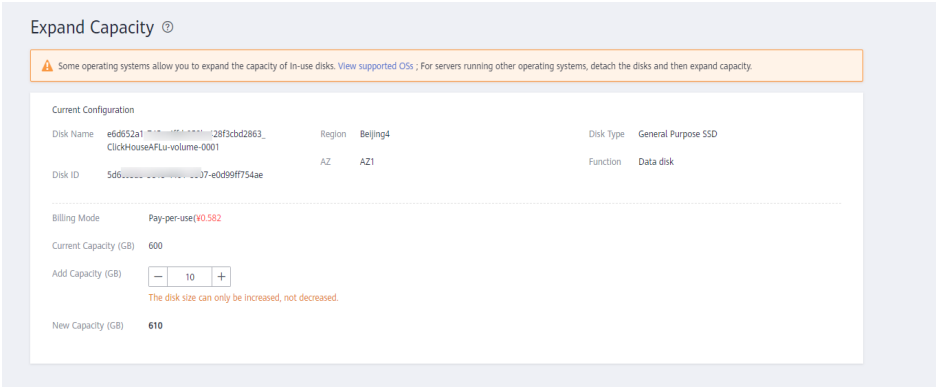
Step 3 In the row of the target data disk, click **Expand Capacity**.

NOTE

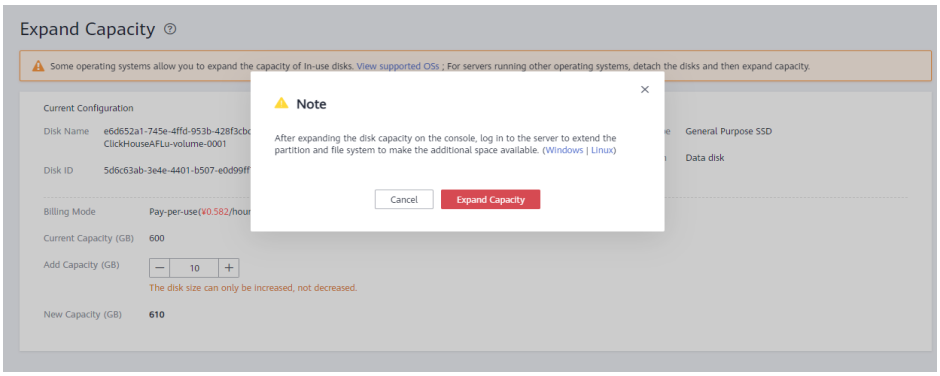
If only the system disk is displayed on the current page and no data disk exists, the data disk of the ClickHouse node cannot be expanded using this method.

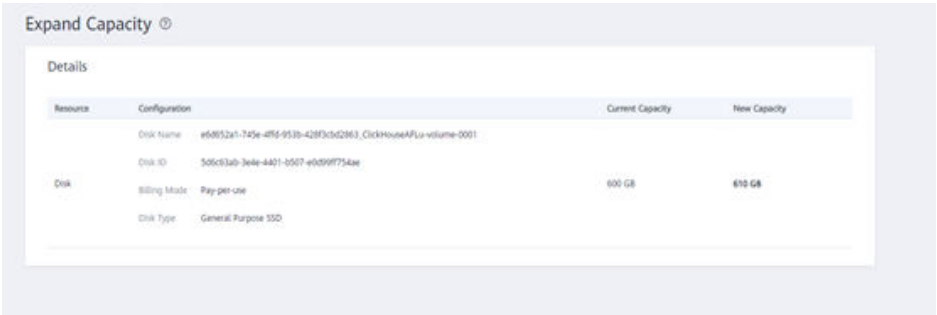


Step 4 Modify the disk capacity to be added in **Add Capacity (GB)** and click **Next**.



Step 5 Read the note for capacity expansion carefully, click **Expand Capacity**, confirm the information about the expanded disk capacity, and click **Submit**.





Step 6 Log in to the expanded ClickHouse node as user **root** and run the **df -hl** command to view information about the existing data directory and disk partition.

```
[root@ClickHouseAFLu ~]# df -hl
Filesystem      Size  Used Avail Use% Mounted on
/dev/vda1       217G   38G  170G  19% /
devtmpfs         32G     0   32G   0% /dev
tmpfs            32G     0   32G   0% /dev/shm
tmpfs            32G   73M   32G   1% /run
tmpfs            32G     0   32G   0% /sys/fs/cgroup
/dev/vda5       9.8G   37M  9.3G   1% /tmp
/dev/vda7        59G  147M   56G   1% /srv/BigData
/dev/vda6       9.8G  583M  8.7G   7% /var
/dev/vda8       177G  154M  168G   1% /var/log
/dev/vdb1       590G   75M  590G   1% /srv/BigData/data1
tmpfs           6.3G     0  6.3G   0% /run/user/2000
```

The default format of a ClickHouse data directory is **/srv/BigData/data*N***. The preceding figure shows that the ClickHouse data directory is **/srv/BigData/data1** and the corresponding partition is **/dev/vdb1**.

Step 7 Perform the following operations to make the new disk capacity take effect.

- To add a partition, go to **Step 8**. Adding a partition is to allocate the added disk capacity to a new partition and mount a new ClickHouse data directory to the new partition. This operation does not interrupt services.
- To extend an existing partition, go to **Step 15**. Extending an existing partition is to allocate the added disk capacity to an existing partition. Services will be interrupted during the operation. You are advised to stop services before the operation.

Step 8 For details about how to add a partition, see "Creating a New MBR Partition" or "Creating a New GPT Partition" in **Extending Partitions and File Systems for Data Disks (Linux)**.

Step 9 Log in to the expanded ClickHouse node as user **root** and run the following commands to create a ClickHouse data directory and create a mount point for the new partition. It is recommended that the directories be numbered in ascending order based on the current number.

For example, if the current data directory is **/srv/BigData/data1**, the added directory should be **/srv/BigData/data2**.

cd /srv/BigData/

mkdir data2

cd data2

mkdir clickhouse

cd /srv/BigData/

chmod 750 -R data2

chown omm:wheel -R data2

Step 10 Run the following command to mount the new partition:

mount *Disk partition Mounted directory*

For example, if the new partition is **/dev/vdb2** and the mounted directory is **/srv/BigData/data2**, run the following command:

mount /dev/vdb2 /srv/BigData/data2

NOTE

If the ECS is restarted, the mounting will become invalid. You can set automatic partition mounting upon system startup by modifying the **/etc/fstab** file. For details, see **Configuring Automatic Mounting at System Start**.

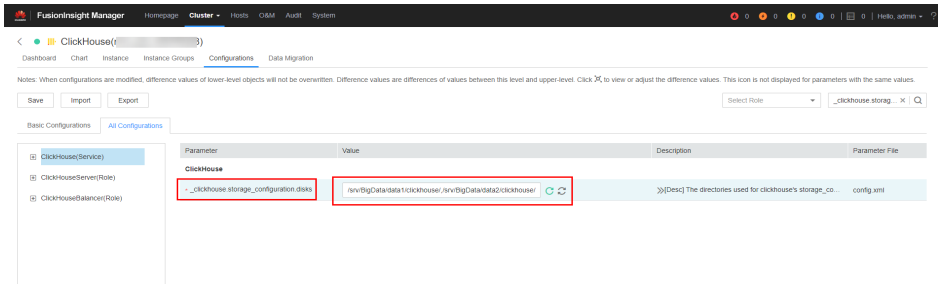
Step 11 Log in to FusionInsight Manager. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **ClickHouse** > **Configurations** > **All Configurations**.

Step 12 Search for **_clickhouse.storage_configuration.disks** and add the new ClickHouse data directory to the configuration item.

NOTE

Separate multiple directories with commas (,) and ensure that each directory ends with a slash (/).

For example, **/srv/BigData/data2/clickhouse/** is added in addition to the **/srv/BigData/data1/clickhouse/** directory. After the addition, the value is **/srv/BigData/data1/clickhouse/,/srv/BigData/data2/clickhouse/**.



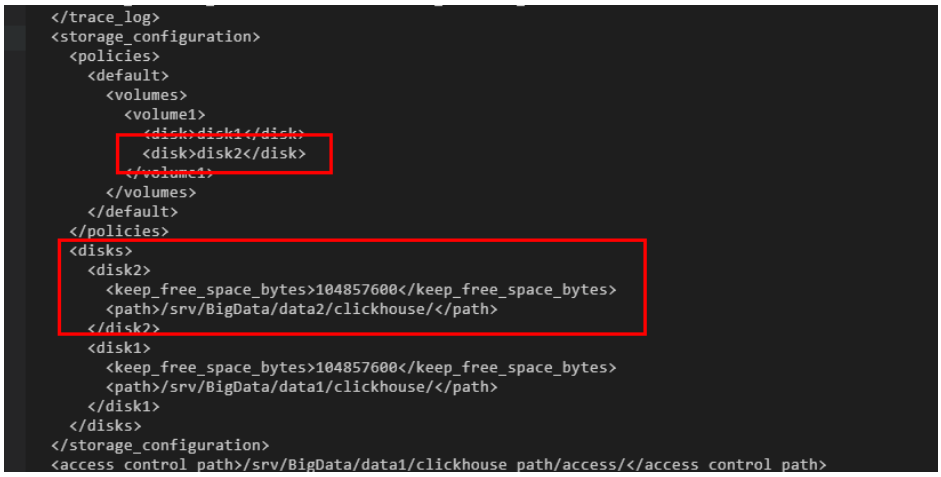
Step 13 After the new directory is added, click **Save** to save the configuration. Click **Dashboard**, choose **More** > **Synchronize Configuration**, and click **OK**.

Step 14 Log in to the expanded ClickHouse node, go to the following directory, and check whether the new data directory has been updated to the configuration file. After confirming that the information is correct, the operation is complete.

cd ${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*x_x_ClickHouse instance name***/etc**

cat config.xml

The following figure shows an example that the **/srv/BigData/data2/clickhouse/** directory has been added to the **config.xml** file.



Step 15 To extend an existing partition, ensure that the ClickHouse service has been stopped before the operation. Otherwise, services will be interrupted during the operation.

Step 16 Determine the partition to be extended based on **Step 6** and extend the partition by referring to "Extending an Existing MBR or GPT Partition" in **Extending Partitions and File Systems for Data Disks (Linux)**.

Step 17 After the existing partition is extended, run the ClickHouse service again.

----End

3.7.7 Backing Up and Restoring ClickHouse Data Using a Data File

Scenario

This section describes how to back up data by exporting ClickHouse data to a CSV file and restore data using the CSV file.

Prerequisites

- You have installed the ClickHouse client.
- You have created a user with related permissions on ClickHouse tables on Manager.
- You have prepared a server for backup.

Backing Up Data

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create ClickHouse tables. If Kerberos authentication is disabled for the current cluster, skip this step.

1. Run the following command if it is an MRS 3.1.0 cluster:

   export CLICKHOUSE_SECURITY_ENABLED=true

2. **kinit** *Component service user*

   Example: **kinit clickhouseuser**

Step 5 Run the ClickHouse client command to export the ClickHouse table data to be backed up to a specified directory.

clickhouse client --host *Host name/Instance IP address* **--secure --port 9440 --query="***Table query statement***" > *Path of the exported CSV file***

The following shows an example of backing up data in the **test** table to the **default_test.csv** file on the ClickHouse instance **10.244.225.167**.

clickhouse client --host 10.244.225.167 --secure --port 9440 --query="select * from default.test FORMAT CSV" > /opt/clickhouse/default_test.csv

Step 6 Upload the exported CSV file to the backup server.

----End

Restoring Data

Step 1 Upload the backup data file on the backup server to the directory where the ClickHouse client is located.

For example, upload the **default_test.csv** backup file to the **/opt/clickhouse** directory.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create ClickHouse tables. If Kerberos authentication is disabled for the current cluster, skip this step.

1. Run the following command if it is an MRS 3.1.0 cluster:

   export CLICKHOUSE_SECURITY_ENABLED=true

2. **kinit** *Component service user*

   Example: **kinit clickhouseuser**

Step 6 Run the ClickHouse client command to log in to the ClickHouse cluster.

clickhouse client --host *Host name/Instance IP address* **--secure --port 9440**

Step 7 Create a table with the format corresponding to the CSV file.

CREATE TABLE [IF NOT EXISTS] *[database_name.]table_name* **[ON CLUSTER** *Cluster name***]**

(

name1 **[***type1***] [DEFAULT|***materialized***|ALIAS** *expr1***],**

name2 **[***type2***] [DEFAULT|***materialized***|ALIAS** *expr2***],**

...

) *ENGINE = engine*

Step 8 Import the content in the backup file to the table created in **Step 7** to restore data.

clickhouse client --host *Host name/Instance IP address* **--secure --port 9440 --query="insert into** *Table name* **FORMAT CSV"** < *CSV file path*

The following shows an example of restoring data from the **default_test.csv** backup file to the **test_cpy** table on the ClickHouse instance **10.244.225.167**.

clickhouse client --host 10.244.225.167 --secure --port 9440 --query="insert into default.test_cpy FORMAT CSV" < /opt/clickhouse/default_test.csv

----End

3.7.8 Configuring the Default ClickHouse User Password (MRS 3.1.2-LTS)

After a ClickHouse cluster is created, you can use the ClickHouse client to connect to the ClickHouse server. The default username is **default**.

This section describes how to set ClickHouse username and password after a ClickHouse cluster is successfully created.

NOTE

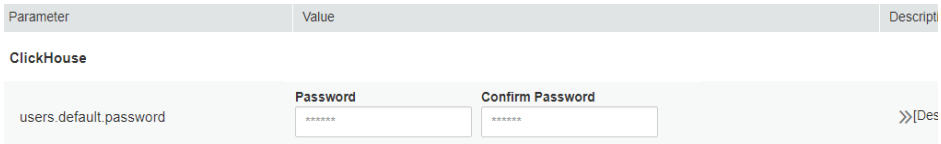
- This section applies to MRS 3.1.2.
- The **default** user is the ClickHouse administrator user that can be used only in normal mode (kerberos authentication is disabled).

Configuring the Password of the Default Account of a ClickHouse Cluster

Step 1 Log in to Manager and choose **Cluster** > **Services** > **ClickHouse**. Click the **Configurations** tab and then **All Configurations**.

Step 2 Search for the **users.default.password** parameter in the search box and change its password, as shown in **Figure 3-16**.

Figure 3-16 Changing the default user password



Step 3 Log in to the node where the client is installed and run the following command to switch to the client installation directory.

cd*Cluster client installation directory*

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 Log in to ClickHouse using the new password.

clickhouse client --host *IP address of the ClickHouse instance***--user** *default* **--password**

Enter the user password.

NOTE

To obtain the IP address of the ClickHouse instance, choose **Components** > **ClickHouse** > **Instances** on the cluster details page.

----End

3.7.9 Configuring the Default ClickHouse User Password (MRS 3.3.0-LTS or later)

After a ClickHouse cluster is created, you can use the ClickHouse client to connect to the ClickHouse server.

Set the passwords of default ClickHouse users **default** and **clickhouse** after creating a ClickHouse cluster in normal mode.

NOTE

- This section applies to MRS 3.3.0-LTS or later.
- **default** and **clickhouse** are default internal administrators of a ClickHouse cluster in normal mode (with Kerberos authentication disabled).
- For a ClickHouse cluster in normal mode, if the default passwords of the default users **default** and **clickhouse** have been changed and the ClickHouseServer node is reinstalled, the passwords will be reset. You need to change the passwords again.

Changing the Password of the Default ClickHouse User

Step 1 Log in to the node where ClickHouse is installed as user **root**, switch to user **omm**, and go to the **$BIGDATA_HOME/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/clickhouse_change_password** directory.

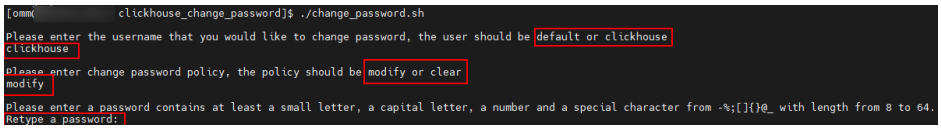
su - omm

cd $BIGDATA_HOME/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/clickhouse_change_password

Step 2 Run the following command to change the password of user **default** or **clickhouse**:

./change_password.sh

In the following figure, user **clickhouse** is used as an example. Enter **clickhouse** and its password as prompted, and wait until the password is changed.



NOTE

The password must meet the following complexity requirements:

- Contains 8 to 64 characters.
- Contains at least one lowercase letter, one uppercase letter, one number, and one special character (-%;[]{}@_).

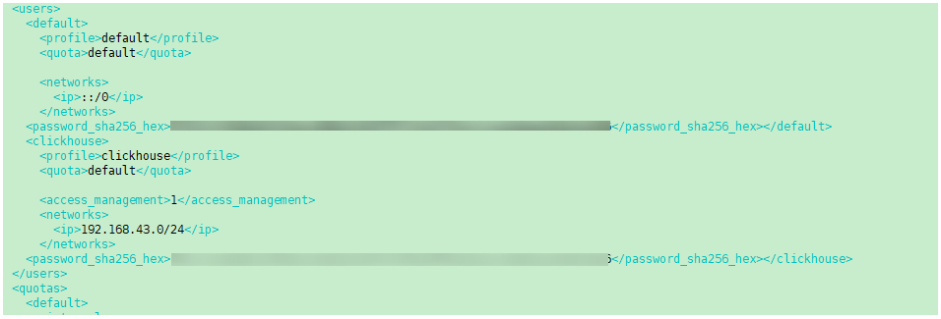
Step 3 Check the changed password.

- For MRS 3.3.0-LTS version: Log in to the ClickHouse Server node and check the value of **password_sha256_hex** in the **${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*_ClickHouseServer/etc/users.xml** file. The value is the new password.

  cd ${BIGDATA_HOME}/*FusionInsight_ClickHouse_*/*_ClickHouseServer***/etc/**

  vi users.xml

  As shown in the following figure, the new password is stored in the **password_sha256_hex** file.

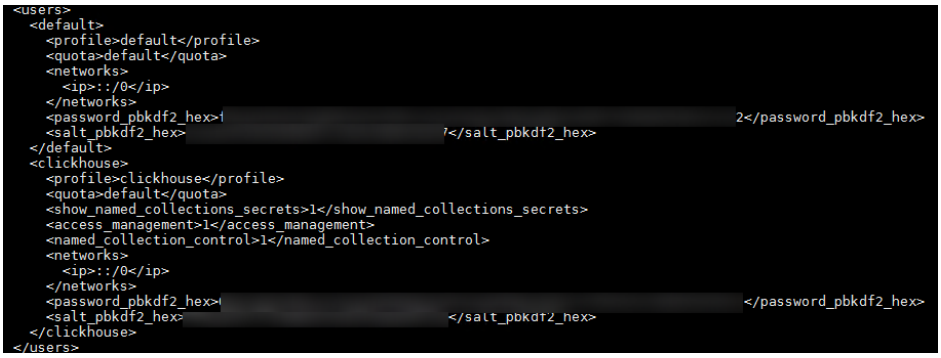


- For MRS 3.3.1-LTS and later versions: Log in to the ClickHouse Server node and check the value of **password_PBKDF2_hex** in the **${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*_ClickHouseServer/etc/users.xml** file. The value is the new password.

  cd ${BIGDATA_HOME}/*FusionInsight_ClickHouse_*/*_ClickHouseServer***/etc/**

  vi users.xml

  As shown in the following figure, the new password is stored in the **password_PBKDF2_hex** file.



----End

3.7.10 Clearing the Passwords of Default ClickHouse Users

After a ClickHouse cluster in normal mode is created, clear the passwords of default users **default** and **clickhouse**.

NOTE

- This topic is available in MRS 3.3.0 or later only.
- **default** and **clickhouse** are default internal administrators of a ClickHouse cluster in normal mode (with Kerberos authentication disabled).

Clearing Default User Passwords

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Service** > **ClickHouse** > **Configurations** > **All Configurations**, search for **ALLOW_CLEAR_INTERNAL_ACCOUNT_PASSWORD**, and change the value to **true**.

Step 2 Log in to the node where ClickHouse is installed as user **root**, switch to user **omm**, and go to the **$BIGDATA_HOME/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/clickhouse_change_password** directory.

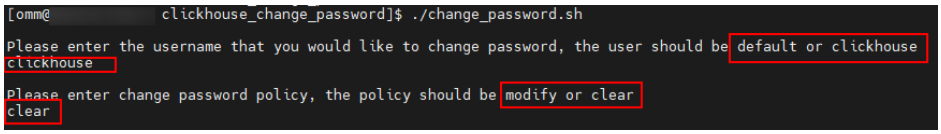
su - omm

cd $BIGDATA_HOME/FusionInsight_ClickHouse_*/install/FusionInsight-ClickHouse-*/clickhouse/clickhouse_change_password

Step 3 Run the following command to clear the password of user **default** or **clickhouse**:

./change_password.sh

In the following figure, user **clickhouse** is used as an example. Enter **clickhouse** and its password as prompted, and wait until the password is cleared.



Step 4 Verify that the password is cleared.

Log in to the ClickHouse Server node and check whether the value of **password** in the **${BIGDATA_HOME}/FusionInsight_ClickHouse_*/*_ClickHouseServer/etc/users.xml** file is empty.

cd ${BIGDATA_HOME}/*FusionInsight_ClickHouse_*/*_ClickHouseServer***/etc/**

vi users.xml

The following is an example.

```
<clickhouse>
  <profile>clickhouse</profile>
  <quota>default</quota>
  <password/>
  <access_management>1</access_management>
  <networks>
    <ip>192.168.67.0/24</ip>
  </networks>
</clickhouse>
```

----End

3.8 Common ClickHouse SQL Syntax

3.8.1 CREATE DATABASE: Creating a Database

This section describes the basic syntax and usage of the SQL statement for creating a ClickHouse database.

Basic Syntax

CREATE DATABASE [IF NOT EXISTS] *database_name* **[ON CLUSTER** *ClickHouse cluster name***]**

NOTE

The syntax **ON CLUSTER** *ClickHouse cluster name* enables the Data Definition Language (DDL) statement to be executed on all instances in the cluster at a time. You can run the following statement to obtain the cluster name from the **cluster** field:

select cluster,shard_num,replica_num,host_name from system.clusters;

Example

```
-- Create a database named test.
CREATE DATABASE test ON CLUSTER default_cluster;
-- After the creation is successful, run the query command for verification.
show databases;
┌─name────┐
│ default │
│ system  │
│ test    │
└─────────┘
```

3.8.2 CREATE TABLE: Creating a Table

This section describes the basic syntax and usage of the SQL statement for creating a ClickHouse table.

Basic Syntax

- Method 1: Creating a table named **table_name** in the specified **database_name** database.

  If the table creation statement does not contain **database_name**, the name of the database selected during client login is used by default.

CREATE TABLE [IF NOT EXISTS] *[database_name.]table_name* **[ON CLUSTER** *ClickHouse cluster name***]**

(

name1 **[***type1***] [DEFAULT|MATERIALIZED|ALIAS** *expr1***],**

name2 **[***type2***] [DEFAULT|MATERIALIZED|ALIAS** *expr2***],**

...

) *ENGINE = engine_name()*

[**PARTITION BY** *expr_list*]

[**ORDER BY** *expr_list*]

CAUTION

You are advised to use **PARTITION BY** to create table partitions when creating a ClickHouse table. The ClickHouse data migration tool works on table partitions. If you do not use **PARTITION BY** to create table partitions in table creation, the table data cannot be migrated on the UI in **Migrating Data Between ClickHouseServer Nodes in a Cluster**.

- Method 2: Creating a table with the same structure as **database_name2.table_name2** and specifying a different table engine for the table

  If no table engine is specified, the created table uses the same table engine as **database_name2.table_name2**.

  CREATE TABLE [IF NOT EXISTS] *[database_name.]table_name* **AS** [*database_name2.*]*table_name2* [ENGINE = *engine_name*]

- Method 3: Using the specified engine to create a table with the same structure as the result of the **SELECT** clause and filling it with the result of the **SELECT** clause

  CREATE TABLE [IF NOT EXISTS] *[database_name.]table_name ENGINE = engine_name* **AS SELECT** ...

Example

```
-- Create a table named test in the default database and default_cluster cluster.
CREATE TABLE default.test ON CLUSTER default_cluster
(
    `EventDate` DateTime,
    `id` UInt64
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}/default/test', '{replica}')
PARTITION BY toYYYYMM(EventDate)
ORDER BY id
```

3.8.3 INSERT INTO: Inserting Data into a Table

This section describes the basic syntax and usage of the SQL statement for inserting data to a table in ClickHouse.

Basic Syntax

- Method 1: Inserting data in standard format

INSERT INTO *[database_name.]table* [(*c1, c2, c3*)] **VALUES** (*v11, v12, v13*), (*v21, v22, v23*), ...

- Method 2: Using the **SELECT** result to insert data

  INSERT INTO *[database_name.]table* [(c1, c2, c3)] **SELECT** ...

Example

```
-- Insert data into the test2 table.
insert into test2 (id, name) values (1, 'abc'), (2, 'bbbb');
-- Query data in the test2 table.
select * from test2;
┌─id─┬─name─┐
│  1 │ abc  │
│  2 │ bbbb │
└────┴──────┘
```

3.8.4 DELETE: Lightweight Deleting Table Data

This topic describes the basic syntax and usage of the SQL statement for deleting table data in a lightweight way.

NOTE

This topic is available for MRS 3.3.0 or later only.

Basic Syntax

DELETE FROM *[db.]table [ON CLUSTER cluster]* **WHERE** *expr*

Example

- Create a table.

```
CREATE TABLE default.test_ligtwight_delete
(
`id`    Int32,
`pdate` Date,
`name`  String,
`class` Int32
)
ENGINE = ReplicatedMergeTree('/clickhouse/tables/distributed_tests/{shard}/test_ligtwight_delete',
'{replica}')
PARTITION BY toYYYYMM(pdate)
PRIMARY KEY id
ORDER BY id
SETTINGS index_granularity = 8192, vertical_merge_algorithm_min_rows_to_activate = 1,
vertical_merge_algorithm_min_columns_to_activate = 1, min_rows_for_wide_part = 1,
min_bytes_for_wide_part = 1;
```

- Insert data.

```
insert into default.test_ligtwight_delete select rand(), rand() % 365, rand(), rand() from numbers(10);
```

- Delete data.

```
delete from default.test_ligtwight_delete where id > 0;
```

Precautions

- Deleted rows are immediately marked as deleted and automatically filtered out from all subsequent queries. Data cleanup occurs asynchronously in the background. This function is only available for the MergeTree table engine series.

- Currently, only lightweight deletion is supported for local tables and replication tables, but not for distributed tables.
- The lightweight deletion performance depends on the number of merge and mutation (alter table update/delete) tasks. Mutation tasks in a queue have the lowest priority (mutation tasks in the same table are executed serially). The number of concurrent delete tasks is directly affected by the execution of the merge tasks.
- The number of parts in the table also determines the lightweight deletion performance. The more parts, the slower the deletion.
- Data parts in Wide format can be deleted quickly, and those in compact files can be deleted slowly because all column data is stored in one file.

3.8.5 SELECT: Querying Table Data

This section describes the basic syntax and usage of the SQL statement for querying table data in ClickHouse.

Basic Syntax

SELECT [**DISTINCT**] expr_list

[**FROM** [*database_name*.]*table* | (subquery) | table_function] [**FINAL**]

[SAMPLE sample_coeff]

[ARRAY **JOIN** ...]

[**GLOBAL**] [**ANY**|**ALL**|**ASOF**] [**INNER**|**LEFT**|**RIGHT**|**FULL**|**CROSS**] [**OUTER**|SEMI|ANTI] **JOIN** (subquery)|**table** (**ON** <expr_list>)|(**USING** <column_list>)

[PREWHERE expr]

[**WHERE** expr]

[**GROUP BY** expr_list] [**WITH** TOTALS]

[**HAVING** expr]

[**ORDER BY** expr_list] [**WITH** FILL] [**FROM** expr] [**TO** expr] [STEP expr]

[**LIMIT** [offset_value,]n **BY** columns]

[**LIMIT** [n,]m] [**WITH** TIES]

[**UNION ALL** ...]

[**INTO** OUTFILE filename]

[FORMAT format]

Example

```
-- View ClickHouse cluster information.
select * from system.clusters;
-- View the macros set for the current node.
select * from system.macros;
-- Check the database capacity.
select
sum(rows) as "Total number of rows",
formatReadableSize(sum(data_uncompressed_bytes)) as "Original size",
```

```
formatReadableSize(sum(data_compressed_bytes)) as "Compression size",
round(sum(data_compressed_bytes) / sum(data_uncompressed_bytes) * 100,
0) "Compression rate"
from system.parts;
-- Query the capacity of the test table. Add or modify the where clause based on the site requirements.
select
sum(rows) as "Total number of rows",
formatReadableSize(sum(data_uncompressed_bytes)) as "Original size",
formatReadableSize(sum(data_compressed_bytes)) as "Compression size",
round(sum(data_compressed_bytes) / sum(data_uncompressed_bytes) * 100,
0) "Compression rate"
from system.parts
where table in ('test')
and partition like '2020-11-%'
group by table;
```

3.8.6 ALTER TABLE: Modifying a Table Structure

This section describes the basic syntax and usage of the SQL statement for modifying a table structure in ClickHouse.

Basic Syntax

ALTER TABLE [*database_name*].*name* [**ON CLUSTER** *cluster*] **ADD**|**DROP**|**CLEAR**|**COMMENT**|**MODIFY COLUMN** ...

NOTE

ALTER supports only *MergeTree, Merge, and Distributed engine tables.

Example

```
-- Add the test01 column to the t1 table.
ALTER TABLE t1 ADD COLUMN test01 String DEFAULT 'defaultvalue';
-- Query the modified table t1.
desc t1
┌─name─────┬─type───┬─default_type─┬─default_expression─┬─comment─┬─codec_expression─┬─ttl_expression─┐
│ id       │ UInt8  │              │                    │         │                  │                │
│ name     │ String │              │                    │         │                  │                │
│ address  │ String │              │                    │         │                  │                │
│ test01   │ String │ DEFAULT      │ 'defaultvalue'     │         │                  │                │
└──────────┴────────┴──────────────┴────────────────────┴─────────┴──────────────────┴────────────────┘
-- Change the type of the name column in the t1 table to UInt8.
ALTER TABLE t1 MODIFY COLUMN name UInt8;
-- Query the modified table t1.
desc t1
┌─name─────┬─type───┬─default_type─┬─default_expression─┬─comment─┬─codec_expression─┬─ttl_expression─┐
│ id       │ UInt8  │              │                    │         │                  │                │
│ name     │ UInt8  │              │                    │         │                  │                │
│ address  │ String │              │                    │         │                  │                │
│ test01   │ String │ DEFAULT      │ 'defaultvalue'     │         │                  │                │
└──────────┴────────┴──────────────┴────────────────────┴─────────┴──────────────────┴────────────────┘
-- Delete the test01 column from the t1 table.
ALTER TABLE t1 DROP COLUMN test01;
-- Query the modified table t1.
desc t1
┌─name─────┬─type───┬─default_type─┬─default_expression─┬─comment─┬─codec_expression─┬─ttl_expression─┐
│ id       │ UInt8  │              │                    │         │                  │                │
│ name     │ UInt8  │              │                    │         │                  │                │
│ address  │ String │              │                    │         │                  │                │
└──────────┴────────┴──────────────┴────────────────────┴─────────┴──────────────────┴────────────────┘
```

3.8.7 ALTER TABLE: Modifying Table Data

- Exercise caution when doing delete, update, and mutation operations.

  The update and delete of standard SQL statements are synchronous operations. That is, the client needs to wait for the server to return the execution results (usually an **int** value). In contrast, the update and delete of ClickHouse are asynchronous operations. When an update statement is processed, the server immediately returns the request status: success or fail, while the operation is not complete. At that time, the update request is accepted and queued in the background. As a result, the operation may be overwritten, and atomicity of operations cannot be ensured.

  To solve this problem, you are advised to use the ReplacingMergeTree, CollapsingMergeTree, and VersionedCollapsingMergeTree engines to update and delete data. For details, see **https://clickhouse.com/docs/en/engines/table-engines/mergetree-family/collapsingmergetree**.

- Try to avoid adding or deleting data columns.

  Plan the number of columns for future use, reserve enough columns to avoid a large number of alter table modify operations during service running in the production system. Otherwise, unpredictable performance problem and data inconsistency may occur.

3.8.8 DESC: Querying a Table Structure

This section describes the basic syntax and usage of the SQL statement for querying a table structure in ClickHouse.

Basic Syntax

DESC|**DESCRIBE TABLE** [*database_name*.]*table* [**INTO** OUTFILE filename] [FORMAT format]

Example

Query the **t1** table structure:

```
desc t1;
┌─name────┬─type───┬─default_type─┬─default_expression─┬─comment─┬─codec_expression─┬─ttl_expression─┐
│ id      │ UInt8  │              │                    │         │                  │                │
│ name    │ UInt8  │              │                    │         │                  │                │
│ address │ String │              │                    │         │                  │                │
└─────────┴────────┴──────────────┴────────────────────┴─────────┴──────────────────┴────────────────┘
```

3.8.9 DROP: Deleting a Table

This section describes the basic syntax and usage of the SQL statement for deleting a ClickHouse table.

Basic Syntax

DROP [**TEMPORARY**] **TABLE** [**IF EXISTS**] [*database_name*.]*name* [**ON CLUSTER** *cluster*] [SYNC]

Example

```
-- Delete the t1 table.
drop table t1 SYNC;
```

NOTE

When you delete a replication table, create a path on ZooKeeper to store related data. The default library engine of ClickHouse is the atomic database engine. After a table in the atomic database is deleted, it is not deleted immediately but deleted 480 seconds later. To resolve this issue, when deleting a table, add the **SYNC** field to the deletion command, for example, **drop table** *t1* **SYNC;**.

This issue does not occur when a local or distributed table is deleted. The **SYNC** field is not required in your deletion command, for example, **drop table** *t1***;**.

3.8.10 SHOW: Displaying Information About Databases and Tables

This section describes the basic syntax and usage of the SQL statement for displaying information about databases and tables in ClickHouse.

Basic Syntax

show databases

show tables

Example

```
-- Query database information.
show databases;
┌─name───┐
│ default │
│ system  │
│ test    │
└─────────┘
-- Query table information.
show tables;
┌─name─┐
│ t1   │
│ test │
│ test2 │
│ test5 │
└──────┘
```

3.8.11 UPSERT: Writing Data

This topic describes the basic SQL syntax and usage of the upsert function when ClickHouse data is written.

NOTE

This topic is available for MRS 3.3.0 or later only.

Basic Syntax

- INSERT VALUES

  UPSERT INTO *[database_name.]table* [(*c1, c2, c3*)] **VALUES** (*v11, v12, v13*), (*v21, v22, v23*), ...

- INSERT SELECT

  UPSERT INTO *[database_name.]table* [(c1, c2, c3)] **SELECT** ...

Example

- Create a table.

```
CREATE TABLE default.upsert_tab ON CLUSTER default_cluster
(
`id`    Int32,
`pdate`  Date,
`name`   String
)ENGINE = ReplicatedMergeTree('/clickhouse/tables/default/{shard}/upsert_tab', '{replica}')
PARTITION BY toYYYYMM(pdate)
PRIMARY KEY id
ORDER BY id
SETTINGS index_granularity = 8192;
```

- Upsert data.

```
Upsert into upsert_tab(id, pdate, name) values (1, rand() % 365, 'abc'), (2, rand() % 365, 'bcd'), (1, rand() % 365, 'def');
```

- Query data in the **test_upsert** table.

```
select * from upsert_tab;
┌─id─┬──────pdate─┬─name─┐
│  2 │ 1970-06-09 │ bcd  │
│  1 │ 1970-11-30 │ def  │
└────┴────────────┴──────┘
```

- Upsert for transactions

  Similar to other SQL syntax, Upsert also supports explicit and implicit transactions. Before using transactions, you need to enable the transaction function.

Precautions

- When creating MergeTree and ReplicatedMergeTree tables, specify the primary key or order by field as the unique key for deduplication. If no primary key is specified and only the order by property is specified during table creation, the order by field is used for deduplication.
- The key for deduplication must be sharded in advance to ensure that same key fields are in the same shard to ensure deduplication accuracy.

3.9 Common Issues About ClickHouse

3.9.1 How Do I Do If the Disk Status Displayed in the System.disks Table Is fault or abnormal?

Question

How do I do if the disk status displayed in the System.disks table is fault or abnormal?

Answer

This problem is caused by I/O errors on the disk. To rectify the fault, perform the following steps:

- Method 1: Log in to FusionInsight Manager and check whether an alarm is generated indicating that the disk I/O is abnormal. If yes, replace the faulty disk by referring to the alarm help.
- Method 2: Log in to FusionInsight Manager and restart the ClickHouse instance to restore the disk status.

  NOTE

  If an I/O error occurs but the disk is not replaced, the disk status will still turn to fault or abnormal.

3.9.2 How Do I Migrate Data from Hive/HDFS to ClickHouse?

Question

How do I migrate Hive/HDFS data to ClickHouse?

Answer

You can export data from Hive as CSV files and import the CSV files to ClickHouse.

1. Export data from Hive as CSV files.

   hive -e "select * from db_hive.student limit 1000"| tr "\t" "," > /data/bigdata/hive/student.csv;

2. Import the CSV files to the **student_hive** table in the default database of ClickHouse.

   clickhouse --client --port 9002 --password *xxx* **-m --query='INSERT INTO default.student_hive FORMAT CSV' < /data/bigdata/hive/student.csv**

   Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

3.9.3 How Do I Migrate Data from OBS/S3 to ClickHouse?

Question

How do I migrate data from OBS/S3 to ClickHouse?

Answer

1. Query data stored in S3.

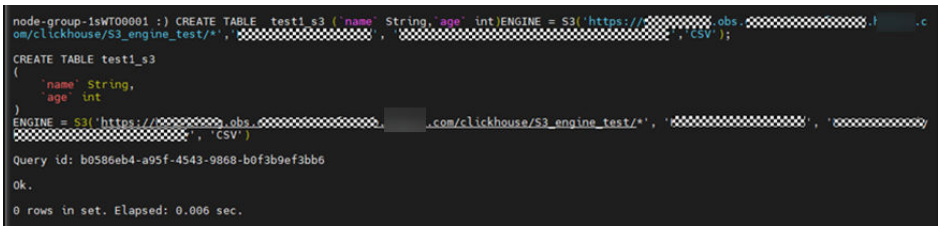
   select * from s3(*path [,access_key_id, secret_access_key] [,format] [,structure]*)

NOTE

- **path**: bucket URL with a file path.
- **format**: The file format.
- **access_key_id** and **secret_access_key**: long-term credentials of an account. Credentials can be used to authenticate requests. These parameters are optional. If no credential is specified, credentials are read from the configuration file.
- **structure**: The table schema.

2. Obtain data from S3 to create a table.

   CREATE TABLE test1_s3 (name String, value UInt32) ENGINE = S3(*path, [access_key_id, secret_access_key,] format*)



3. View the created table.

   select * from test1_s3

3.9.4 An Error Is Reported in Logs When the Auxiliary ZooKeeper or Replica Data Is Used to Synchronize Table Data

Question

An error is reported in logs when the auxiliary ZooKeeper or replica data is used to synchronize table data.

```
DB::Exception: Cannot parse input: expected 'quorum:' before: 'merge_type: 2'...
Too many parts (315). Merges are processing significantly slower than inserts...
```

Answer

The versions of replication table replicas are inconsistent, causing compatibility issues. The table schema contains TTL statements. TTL_DELETE is added in versions later than ClickHouse 20.9, which cannot be identified in earlier versions.

This issue occurs when the replication table replica of a later version is elected as the leader.

You can modify the **config.xml** file of ClickHouse of a later version to avoid such an issue. Ensure that the replication table replicas are the same as those of ClickHouse.

3.9.5 How Do I Grant the Select Permission at the Database Level to ClickHouse Users?

Procedure

Step 1 Log in to the node where the ClickHouse client is installed in the MRS cluster and run the following commands:

su - omm

source *{Client installation directory}*/**bigdata_env**

kinit *Component user* (You do not need to run the **kinit** command for normal clusters.)

clickhouse client --host *IP address of the ClickHouse node* **--port 9000 -m --user clickhouse –password '***Password of the ClickHouse user***'**

NOTE

- View the password of the ClickHouse user.

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ClickHouse**. Click **Instance** and click any ClickHouseServer role name. Go to the **Dashboard** tab page of ClickHouseServer, click the **users.xml** file in **Configuration File** area, and view the password of the ClickHouse user.
- Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

Step 2 You can use either of the following methods to create a role with the read-only permission for a specified database:

Method 1

1. Creating a role with the read-only permission for a specified database (the **default** database is used as an example)

   create role ck_role on cluster default_cluster;

   GRANT SELECT ON default.* TO ck_role on cluster default_cluster;
2. Creating a common user

   CREATE USER user_01 on cluster default_cluster IDENTIFIED WITH PLAINTEXT_PASSWORD BY '*password***';**
3. Granting the read-only permission role to a common user

   GRANT ck_role to user_01 on cluster default_cluster;
4. Viewing user permissions

   show grants for user_01;

   select * from system.grants where role_name = 'ck_role';

Method 2

Creating a user with the read-only permission for a specified database

1. Creating a user:

   CREATE USER user_01 on cluster default_cluster IDENTIFIED WITH PLAINTEXT_PASSWORD BY '*password*';

2. Granting the query permission on a specified database to the created user:

   grant select on default.* to user_01 on cluster default_cluster;

3. Querying user permissions:

   select * from system.grants where user_name = 'user_01';

----End

3.9.6 How Do I Quickly Restore ClickHouse When Concurrent Requests Are Stacked for a Long Time?

Symptom

When there are too many concurrent ClickHouse requests, new requests cannot be handled, affecting service availability. The error information is as follows:

```
DB::Exception: Too many simultaneous queries. Maximum: 100
```

Procedure

Step 1 Log in to the ClickHouse client node and connect to the server where the error is reported. For details, see **ClickHouse Client Practices**.

Step 2 Run the following command to check the number of concurrent SQL jobs that are being executed:

select count(*) from system.processes;

Verify that the obtained value is greater than or equal to 100.

Step 3 Run the following command to stop large query SQL statements that are being executed:

kill query where query_kind='Select' and elapsed > 60;

Step 4 Wait for 30 seconds and run the following command to collect statistics on the SQL jobs that are being executed:

select count(*) from system.processes;

Check whether the obtained value is less than 60.

Step 5 If the number of concurrent jobs is greater than 60, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ClickHouse** > **Instances**, select the ClickHouseServer instance that reports the error, and choose **More** > **Restart Instance**.

----End

4 Using DBService

4.1 Configuring SSL for the HA Module

Scenario

This section describes how to manually configure SSL for the HA module of DBService in the cluster where DBService is installed.

NOTE

After this operation is performed, if you need to restore the SSL configuration, go to **Restoring SSL for the HA Module**.

Prerequisites

- The cluster has been installed.
- The **root-ca.crt** and **root-ca.pem** files in the **$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/security** directory on the active and standby DBService nodes are the same.

Procedure

Step 1 Log in to the DBService node where SSL needs to be configured as user **omm**.

Step 2 Go to the **$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/sbin/** directory and run the following command:

./proceed_ha_ssl_cert.sh *DBService installation directoryService IP address of the node*

Example:

cd $BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/sbin/

./proceed_ha_ssl_cert.sh $BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0 10.10.10.10

NOTE

$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0 is the installation directory of DBService. Modify it based on site requirements.

Step 3 Go to the **$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/ha/module/hacom/script/** directory and run the following command to restart the HA process:

./stop_ha.sh

./start_ha.sh

Step 4 Run the following command on the preceding node to obtain the PID of the HA process:

ps -ef |grep "ha.bin" |grep DBSERVICE

Step 5 Run the following command to check whether the protocol is changed to TCP:

netstat -nap | grep *pid* **| grep -v unix**

- If yes, no further action is required.
- If no, go to **Step 2**.

```
(Not all processes could be identified, non-owned process info
 will not be shown, you would have to be root to see it all.)
tcp        0      0 127.0.0.1:20054         0.0.0.0:*               LISTEN      11896/ha.bin
tcp        0      0 10.10.10.10:20052       10.10.10.14:20052       ESTABLISHED 11896/ha.bin
tcp        0      0 10.10.10.10:20053       10.10.10.14:20053       ESTABLISHED 11896/ha.bin
```

----End

4.2 Restoring SSL for the HA Module

Scenario

This section describes how to restore SSL for the HA module of DBService in the cluster where DBService is installed.

Prerequisites

SSL has been enabled for the HA module of DBService.

NOTE

Check whether SSL is enabled for the HA module of DBService.

Check **$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/ha/module/hacom/conf/hacom.xml**. If the file contains **<hadataprotocol value="ssl"></hadataprotocol>**, SSL is enabled.

Procedure

Step 1 Log in to the DBService node where SSL needs to be restored as user **omm**.

Step 2 Run the following commands to restore the DBService configuration file **hacom_local.xml**:

cd $BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/ha/local/hacom/conf/

cp hacom_local.xml $BIGDATA_HOME/tmp/

cat hacom_local.xml | grep "ssl>" -n | cut -d':' -f1 | xargs | sed 's/ /,/g' |xargs -n 1 -i sed -i '{}d' hacom_local.xml

Step 3 Run the following commands to restore the DBService configuration file **hacom.xml**:

cd $BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/ha/module/hacom/conf/

cp hacom.xml $BIGDATA_HOME/tmp/

sed -i 's#<hadataprotocol.*#<hadataprotocol value="udp"/>#g' hacom.xml

sed -i 's#<rpcsupportssl.*#<rpcsupportssl value="true"/>#g' hacom.xml

NOTE

$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0 is the installation directory of DBService. Modify it based on the upgrade environment.

Step 4 Go to the **$BIGDATA_HOME/FusionInsight_BASE_*x.x.x*/install/FusionInsight-dbservice-2.7.0/ha/module/hacom/script/** directory and run the following command to restart the HA process:

./stop_ha.sh

./start_ha.sh

Step 5 Run the following command to obtain the PID of the HA process:

ps -ef |grep "ha.bin" |grep DBSERVICE

Step 6 Run the following command to check whether the protocol is changed to TCP:

netstat -nap | grep *pid* | grep -v unix

- If yes, no further action is required.
- If no, contact O&M support.

```
[omm@host03]\>netstat -nap | grep 49989
(Not all processes could be identified, non-owned process info
 will not be shown, you would have to be root to see it all.)
tcp        0      0 127.0.0.1:20054         0.0.0.0:*               LISTEN      49989/ha.bin
udp        0      0 10.10.10.10:20052       0.0.0.0:*                           49989/ha.bin
udp        0      0 10.10.10.10:20053       0.0.0.0:*                           49989/ha.bin
```

----End

4.3 Configuring the Timeout Interval of DBService Backup Tasks

Scenario

The default timeout interval of DBService backup tasks is 2 hours. When the data volume in DBService is too large, the backup task may fail to be executed because the timeout interval is reached.

This section describes how to customize the timeout interval of a DBService backup task.

Prerequisites

- Clusters have been properly installed.
- DBService is running properly.

Procedure

Step 1 Log in to the active OMS node as user **omm** using PuTTY. In the **${CONTROLLER_HOME}/etc/om/controller.properties** configuration file, change the value of **controller.backup.conf.script.execute.timeout** to **10000000** (Set the timeout interval based on the data volume of DBService).

Step 2 Log in to the active OMS node as user **omm** using PuTTY and repeat step **Step 1**.

Step 3 Log in to the active OMS node as user **omm** using PuTTY, run the following command to query the ID of **BackupRecoveryPluginProcess** process, and stop the process.

jps|grep -i BackupRecoveryPluginProcess

kill -9 *Queried process ID*

Step 4 Log in to FusionInsight Manager and perform the DBService backup task again.

Step 5 Run the following command to check whether the **BackupRecoveryPluginProcess** process is started:

jps|grep -i BackupRecoveryPluginProcess

----End

4.4 DBService Log Overview

Log Description

Log path: The default storage path of DBService log files is **/var/log/Bigdata/dbservice**.

- GaussDB: **/var/log/Bigdata/dbservice/DB** (GaussDB run log directory), **/var/log/Bigdata/dbservice/scriptlog/gaussdbinstall.log**

(GaussDB installation log), and **/var/log/gaussdbuninstall.log** (GaussDB uninstallation log).

- HA: **/var/log/Bigdata/dbservice/ha/runlog** (HA run log directory) and **/var/log/Bigdata/dbservice/ha/scriptlog** (HA script log directory)
- DBServer: **/var/log/Bigdata/dbservice/healthCheck** (Directory of service and process health check logs)

  /var/log/Bigdata/dbservice/scriptlog (run log directory), **/var/log/Bigdata/audit/dbservice/** (audit log directory)

Log archive rule: The automatic DBService log compression function is enabled. By default, when the size of logs exceeds 1 MB, logs are automatically compressed into a log file named in the following format: *<Original log file name>-[No.]*.**gz**. A maximum of 20 latest compressed files are reserved.

NOTE

Log archive rules cannot be modified.

Table 4-1 DBService log list

Type	Log File Name	Description
DBServer run log	dbservice_serviceCheck.log	Run log file of the service check script
	dbservice_processCheck.log	Run log file of the process check script
	backup.log	Run logs of backup and restoration operations (The DBService backup and restoration operations need to be performed.)
	checkHaStatus.log	Log file of HA check records
	cleanupDBService.log	Uninstallation log file (You need to uninstall DBService logs.)
	componentUserManager.log	Log file that records the adding and deleting operations on the database by users (Services that depend on DBService need to be added.)
	install.log	Installation log file
	preStartDBService.log	Pre-startup log file

Type	Log File Name	Description
	start_dbserver.log	DBServer startup operation log file (DBService needs to be started.)
	stop_dbserver.log	DBServer stop operation log file (DBService needs to be stopped.)
	status_dbserver.log	Log file of the DBServer status check (You need to execute the **$DBSERVICE_HOME/sbin/status-dbserver.sh** script.)
	modifyPassword.log	Run log file of changing the DBService password script. (You need to execute the **$DBSERVICE_HOME/sbin/modifyDBPwd.sh** script.)
	modifyDBPwd_yyyy-mm-dd.log	Run log file that records the DBService password change tool (You need to execute the **$DBSERVICE_HOME/sbin/modifyDBPwd.sh** script.)
	dbserver_switchover.log	Log for DBServer to execute the active/standby switchover script (the active/standby switchover needs to be performed)
GaussDB run log	gaussdb.log	Log file that records database running information
	gs_ctl-current.log	Log file that records operations performed by using the **gs_ctl** tool
	gs_guc-current.log	Log file that records operations, mainly parameter modification performed by using the **gs_guc** tool

Type	Log File Name	Description
	gaussdbinstall.log	GaussDB installation log file
	gaussdbuninstall.log	GaussDB uninstallation log file
HA script run log	floatip_ha.log	Log file that records the script of floating IP addresses
	gaussDB_ha.log	Log file that records the script of GaussDB resources
	ha_monitor.log	Log file that records the HA process monitoring information
	send_alarm.log	Alarm sending log file
	ha.log	HA run log file
DBService audit log	dbservice_audit.log	Audit log file that records DBService operations, such as backup and restoration operations

Log Level

Table 4-2 describes the log levels supported by DBService. The priorities of log levels are ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 4-2 Log levels

Level	Description
ERROR	Error information about the current event processing
WARN	Exception information about the current event processing
INFO	Normal running status information about the system and events
DEBUG	System information and system debugging information

Log Format

The following table lists the DBService log formats.

Table 4-3 Log format

Type	Format	Example
Run log	[<*yyyy-MM-dd HH:mm:ss*>] <*Log level*>: [< *Name of the script that generates the log*: *Line number* >]: < *Message in the log*>	[2020-12-19 15:56:42] INFO [postinstall.sh:653] Is cloud flag is false. (main)
Audit log	[<*yyyy-MM-dd HH:mm:ss,SSS*>] UserName:<*Username*> UserIP:<*User IP address*> Operation:<*Operation content*> Result:<*Operation results*> Detail:<*Detailed information*>	[2020-05-26 22:00:23] UserName:omm UserIP:192.168.10.21 Operation:DBService data backup Result: SUCCESS Detail: DBService data backup is successful.

5 Using Doris

5.1 Overview of the Doris Data Model

Basic Concepts

In Doris, data is logically described in the form of tables. A table consists of rows and columns. A row is a row of user data, and a column is used to describe different fields in a row of data. Columns are classified into keys and values. From the service perspective, Key and Value can correspond to dimension columns and metric columns, respectively.

Doris data models are classified into the following types:

- Aggregate
- Unique
- Duplicate

AGGREGATE KEY

The statement for creating an Aggregate model table is as follows:

CREATE TABLE IF NOT EXISTS *example_db.example_tbl*

(

`user_id` LARGEINT NOT NULL COMMENT "User ID",

`date` DATE NOT NULL COMMENT "Data import date and time",

`city` VARCHAR(20) COMMENT "City of the user",

`age` SMALLINT COMMENT "User age",

`gender` TINYINT COMMENT "User Gender",

`last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT " Last access time of the user",

`cost` BIGINT SUM DEFAULT "0" COMMENT "Total consumption",

`max_dwell_time` INT MAX DEFAULT "0" COMMENT "Dwell time",

`min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum dwell time"

)

AGGREGATE KEY(`user_id`, `date`, `city`, `age`, `gender`)

DISTRIBUTED BY HASH(`user_id`) BUCKETS 1

PROPERTIES (

"replication_allocation" = "tag.location.default: 1"

);

NOTE

When data is imported, rows with the same contents in the Key columns will be aggregated into one row, and their values in the Value columns will be aggregated as their **AggregationType** specify. Currently, AggregationType has the following four aggregation modes:

- SUM: Accumulate the values in multiple rows.
- REPLACE: The newly imported value replaces the previous value.
- MAX: Keep the maximum value.
- MIN: Keep the minimum value.

Columns in a table are classified into Key (dimension column) and Value (metric column) based on whether AggregationType is set. For example, if AggregationType is not set, such as user_id, date, and age, is called Key, and if AggregationType is set, is called Value.

UNIQUE KEY model

- Read-on-Read Combination

  These tables do not need to be aggregated. You only need to ensure that the primary keys (user_id and username) are unique. In addition, the read-time combination implementation of the Unique model can be replaced by the REPLACE mode of the Aggregate model. The following is an example:

  CREATE TABLE IF NOT EXISTS *example_db.example_tbl*

  (

  `user_id` LARGEINT NOT NULL COMMENT "User ID",

  `username` VARCHAR(50) NOT NULL COMMENT "Username",

  `city` VARCHAR(20) COMMENT "City of the user",

  `age` SMALLINT COMMENT "User age",

  `gender` TINYINT COMMENT "User Gender",

  `phone` LARGEINT COMMENT "User phone number",

  `address` VARCHAR(500) COMMENT "User address",

  `register_time` DATETIME COMMENT "User registration time"

)

  UNIQUE KEY(`user_id`, `username`)

  DISTRIBUTED BY HASH(`user_id`) BUCKETS 1

  PROPERTIES (

"replication_allocation" = "tag.location.default: 1"

);

- Merge-on-Write

  The Unique model is different from the Aggregate model. The query performance of the Unique model is closer to that of the Duplicate model. Compared with the Aggregate model, the Unique model has great advantages in query performance in scenarios where primary key constraints are required. The Unique model is applicable to aggregation query and query scenarios where a large amount of data needs to be filtered using indexes.

  When creating a table, you can specify the following property to enable the Unique model:

  "enable_unique_key_merge_on_write" = "true"

  For example:

  CREATE TABLE IF NOT EXISTS *example_db.example_tbl*

  (

  `user_id` LARGEINT,

  `username` VARCHAR(50) NOT NULL,

  `city` VARCHAR(20),

  `age` SMALLINT,

  `gender` TINYINT,

  `phone` LARGEINT,

  `address` VARCHAR(500),

  `register_time` DATETIME

)

  UNIQUE KEY(`user_id`, `username`)

  DISTRIBUTED BY HASH(`user_id`) BUCKETS 1

  PROPERTIES (

  "replication_allocation" = "tag.location.default: 1",

  "enable_unique_key_merge_on_write" = "true"

  );

  NOTE

  If the merge-on-write option is enabled for a unique table, the overwritten and updated data is marked and deleted during data import, and new data is written to a new file. During query, all data marked for deletion is filtered at the file level. The read data is the latest data, eliminating the data aggregation process in read-time combination. In addition, multiple predicates can be pushed down, therefore, the performance can be greatly improved in the aggregation query scenario.

Duplicate model

If data does not have a primary key or aggregation requirement, you can use the Duplicate data model to create a table. Duplicate model data is stored based on the data in the imported file and is not aggregated. Even if there are two identical rows of data, they will both be retained. The DUPLICATE KEY specified in the table creation statement is only used to specify that the underlying data is sorted by the specified column.

The statement for creating a duplicate model table is as follows:

CREATE TABLE IF NOT EXISTS *example_db.example_tbl*

(

`timestamp` DATETIME NOT NULL COMMENT " Log time",

`type` INT NOT NULL COMMENT " Log type",

`error_code` INT COMMENT "Error code",

`error_msg` VARCHAR(1024) COMMENT "Error details",

`op_id` BIGINT COMMENT "Owner ID",

`op_time` DATETIME COMMENT "Processing time"

)

DUPLICATE KEY(`timestamp`, `type`, `error_code`)

DISTRIBUTED BY HASH(`type`) BUCKETS 1

PROPERTIES (

"replication_allocation" = "tag.location.default: 1"

);

Key column

For the Duplicate, Aggregate, and Unique models, the Key column is specified during table creation. The differences are as follows:

- Duplicate model: The Key column of a table is only a sequence and does not uniquely identify the table.
- Aggregate and Unique models: For tables of the two aggregation types, the Key column is a real Key column that considers both sorting and unique identifier columns.

Suggestions on Data Model Selection

The data model is determined when the table is created and cannot be modified. Therefore, it is important to select a proper data model.

- The Aggregate model can greatly reduce the amount of data to be scanned and the calculation workload during aggregation query through pre-aggregation. This model is applicable to report query scenarios with fixed modes. However, this model is not applicable to count(*) query. In addition, because the aggregation function in Value columns is fixed, semantic correctness needs to be considered when aggregation queries using other functions are performed.
- The Unique model ensures that the primary key is unique in scenarios where a unique primary key constraint is required. However, the query advantages brought by pre-aggregation such as ROLLUP cannot be used.
  - For users who have high performance requirements for aggregate query, merge-on-write is recommended.

  - The Unique model supports only the update of an entire row. If you need to update both the unique primary key constraint and some columns (for example, in the scenario where multiple source tables are imported to one Doris table), you can use the Aggregate model and set the aggregation type of non-primary key columns to REPLACE_IF_NOT_NULL.
- Duplicate is suitable for ad-hoc query in any dimension. Although the pre-aggregation feature cannot be used, it is not restricted by the aggregation model. The advantages of the column-store model can be brought into full play (only related columns are read, and all key columns do not need to be read).

5.2 Managing Doris User Permissions

5.2.1 About Doris User Permissions

Table 5-1 lists the permissions supported by the Doris.

Table 5-1 Doris Permission List

Permission	Permission Introduction
Node_priv	Node change permission. Add, delete, and bring offline FE, BE, and DBroker nodes. This permission can be granted only to the Global level.
Admin_priv	All permissions except NODE_PRIV.
Grant_priv	Permission change permission, including granting permissions, revoking permissions, and adding, deleting, and changing users and roles. Users with this permission cannot grant the node_priv permission to other users unless they already have the node_priv permission.
Select_priv	Read-only permission on databases and tables.
Load_priv	Write permission on databases and tables, including Load, Insert, and Delete.
Alter_priv	Permission to modify databases and tables. including renaming databases or tables, adding, deleting, or changing columns, and adding or deleting partitions.
Create_priv	Permission to create databases, tables, and views.
Drop_priv	Delete permissions on databases, tables, and views.
Usage_priv	Permissions to use resources and workload groups.

Database table permissions are classified into the following four levels based on the permission application scope:

- CATALOG LEVEL: data directory-level permission. The granted permission applies to any database table in the specified catalog.
- DATABASE LEVEL: database-level permission. The granted permissions apply to any table in the specified database.
- TABLE LEVEL: table-level permission. The granted permissions apply to the specified table in the specified database.
- RESOURCE LEVEL: resource-level permission. The granted permission applies to the specified resource.

5.2.2 Creating a Doris Permission Role

The Doris permission management system implements row-level fine-grained permission control and role-based permission access control.

NOTE

- Only clusters of MRS 3.3.0 and later versions support role assignment on FusionInsight Manager. If the cluster is of MRS 3.3.0 or earlier, you need to connect to the database as user **root** (the default password is empty) regardless of whether Kerberos authentication is enabled.
- In MRS 3.5.0 and later versions, if Kerberos authentication is disabled for the cluster (the cluster is in normal mode), you can also create a user on FusionInsight Manager and bind the user to a role to obtain the required permission.

Prerequisite

- The Doris service is running properly.
- The role name cannot be operator or admin.
- When Kerberos authentication is enabled for the cluster (the cluster is in security mode), it takes about 2 minutes for the permission to take effect after the Doris permission is successfully assigned.

Adding the Doris Role

Step 1 Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**. On the displayed page, click **Create Role**.

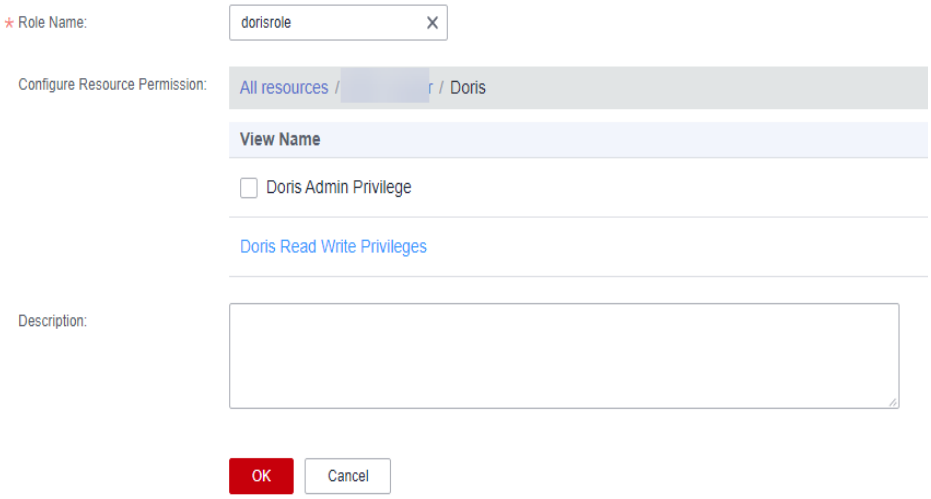
Step 2 Specify **Role Name**. In the **Configure Resource Permission** area, click the cluster name. On the displayed service list page, click the **Doris** service.

Determine whether to create a role with the Doris administrator rights based on service requirements.

NOTE

- The Doris administrator has all the rights except the node operation rights.
- Role Name: The name of the role to be added cannot contain hyphens (-) and cannot start with a digit.

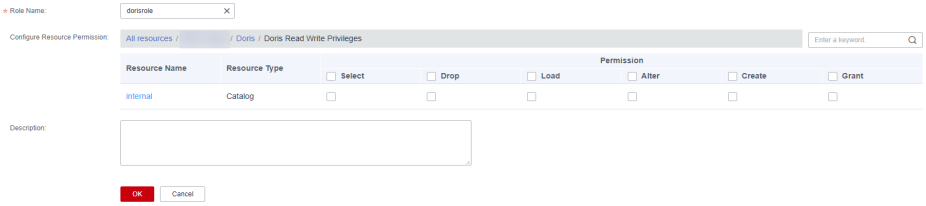
- If yes, go to **Step 3**.
- If no, go to **Step 4**.



Step 3 Select **Doris Admin Privilege** and click **OK**.

Step 4 Click **Doris Read Write Privileges** and select **Select**, **Drop**, **Load**, **Alter**, **Create**, or **Grant** for the corresponding resource.

Determine whether to grant the permission based on the service requirements.



Step 5 After the authorization is complete, click **OK**.

----End

Adding a User and Binding the User to the Doris Role

Step 1 Log in to FusionInsight Managerr and choose **System** > **Permission** > **User** and click **Create**.

- **Username**: Enter the name of the user you want to create.
- **User Type**:
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), select **Human-Machine**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), select **Machine-Machine**.
- **Password** and **Confirm New Password**: Enter a password for the human-machine user and enter it again.
- **Role**: Click **Add**. In the displayed dialog box, select a role with the Doris permission and click **OK**.

NOTE

- Username: The username to be added cannot contain hyphens (-). Otherwise, the authentication fails.
- Password: The password cannot contain special characters $, ., and #. Otherwise, the authentication will fail.

Step 2 Click **OK**.

Step 3 Use the newly created user to connect to the Doris service.

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)
  a. Log in to FusionInsight Manager as the new human-machine user and change the initial password.
  b. Log in to the node where the MySQL client is installed and use the new username and new password to connect to the Doris service.

     export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

     mysql -u*dorisuser* **-P -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

     Enter the password for logging in to the database.

     NOTE

     - To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
     - To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the service IP address of any FE instance.
     - You can also use the MySQL connection software or Doris web UI to connect to the database.
- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)
  a. Log in to the node where the MySQL client is installed and connect to the Doris service as user **admin**.

     mysql -uadmin-P*Connection port for FE queries* **-h***IP address of the Doris FE instance*

     NOTE

     The default password of user **admin** is empty.
  b. Set a password for the machine-machine user.

     SET PASSWORD FOR '*Machine-Machine Username***' = PASSWORD('***xxx***')**
  c. Connect to Doris on the MySQL client using the machine-machine user.

     mysql -u*Machine-machine username* **-p-P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

     Enter the password of the user.

----End

Adding a Role and Binding It to a User (Kerberos authentication is disabled for the cluster (the cluster is in normal mode))

This operation applies only to versions earlier than MRS 3.5.0.

Step 1 Log in to the node where the MySQL client is installed and connect to the Doris service as user **admin**.

mysql -uadmin -P*Database connection port* **-h***IP address of Doris FE instance*

NOTE

- The default password of user **admin** is empty.
- The database connection port is the query connection port of the Doris FE. You can also log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following command to create a role:

CREATE ROLE *dorisrole***;**

Step 3 Run the following command to grant permissions to the role. For details about the permissions, see **About Doris User Permissions**. For example, to grant the ADMIN_PRIV permission to the role, run the following command:

GRANT *ADMIN_PRIV* **ON *.*.* TO ROLE '***dorisrole***';**

Step 4 Create a user.

- Create a user and grant the user a role.

  CREATE USER '*dorisuser***'@'%' IDENTIFIED BY '***password***' DEFAULT ROLE '***dorisrole***';**

- Create a user, add a password expiration policy, and grant the user a role.

  For example, run the following commands to create the **dorisuser** user, set the user password to expire in 180 days, and grant the user the **dorisrole**:

  CREATE USER '*dorisuser***'@'%' IDENTIFIED BY '***password***' PASSWORD_EXPIRE INTERVAL** *180 DAY***;**

  GRANT '*dorisrole***' TO '***dorisuser***'@'%';**

  NOTE

  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the user password never expires by default, which poses security risks. You are advised to set a password expiration policy to request the user to change the password periodically.
  - After the password expires, the user is unavailable. You must change the password as a user with the same level of rights as the Doris user.

----End

5.2.3 Column Permission Management

Scenarios

You can manage column-level permission in Doris by adding the **enable_col_auth** parameter to the custom configuration of the FE service.

NOTE

- This feature is available for MRS 3.3.1 or later only.
- Only the **Select_priv** permission is supported by this function.
- You must use a user with the **Grant_priv** permission to manage column permission.
- If a user with the column-level **Select_priv** permission runs **select *** to query table data, it can access only the columns allowed by the permission.
- If a user with the column-level **Select_priv** permission runs **desc** *tbl* to query table details, it can access only the information of columns allowed by the permission.
- Column-level permission is also available for views and materialized views.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The nodes to be connected to the Doris database can communicate with the MRS cluster.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Procedure

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris**, and click **Configurations** and then **All Configurations**.

Step 2 Choose **FE(Role)** > **Customization**. Enter the custom parameter **enable_col_auth**, set its value to **true**, and add it to the **fe.conf** file.

Step 3 Click **Save** and then **OK**.

Step 4 Click **Instances**, select all FE instances, and choose **More** > **Restart Instance**.

Step 5 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the service IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect to the database.

Step 6 Run the following commands to grant the **Select_priv** permission:

- Grant permission to a user.
  GRANT select_priv [(col1, col2...)] ON *ctl.db.tbl* **TO '***user***';**
- Grant permission to a role.
  GRANT select_priv [(col1, col2...)] ON *ctl.db.tbl* **TO ROLE '***role***';**

Step 7 Check the user permission.

show grants for *user***;**

Step 8 Revoke the **Select_priv** permission.

- Revoke permission from a user.
  revoke select_priv [(col1, col2...)] ON *ctl.db.tbl* **from '***user***';**
- Revoke permission from a role.
  revoke select_priv [(col1, col2...)] ON *ctl.db.tbl* **from ROLE '***role***';**

Step 9 Check user permission.

show grants for *user***;**

----End

5.3 Using the MySQL Client to Connect to Doris

Doris supports the MySQL protocol. Therefore, most clients that support the MySQL protocol can access Doris, including the CLI or IDE, such as MariaDB, DBeaver, and Navicat for MySQL.

This section uses the MySQL 8.0.22 client to connect to Doris as an example.

Prerequisite

The node where the MySQL client is to be installed can communicate with the MRS cluster.

Procedure

Step 1 Log in to the node where the MySQL client is to be installed as the root user.

Step 2 Run the following command to check the version of the ncurses-libs library on which the MySQL client depends:

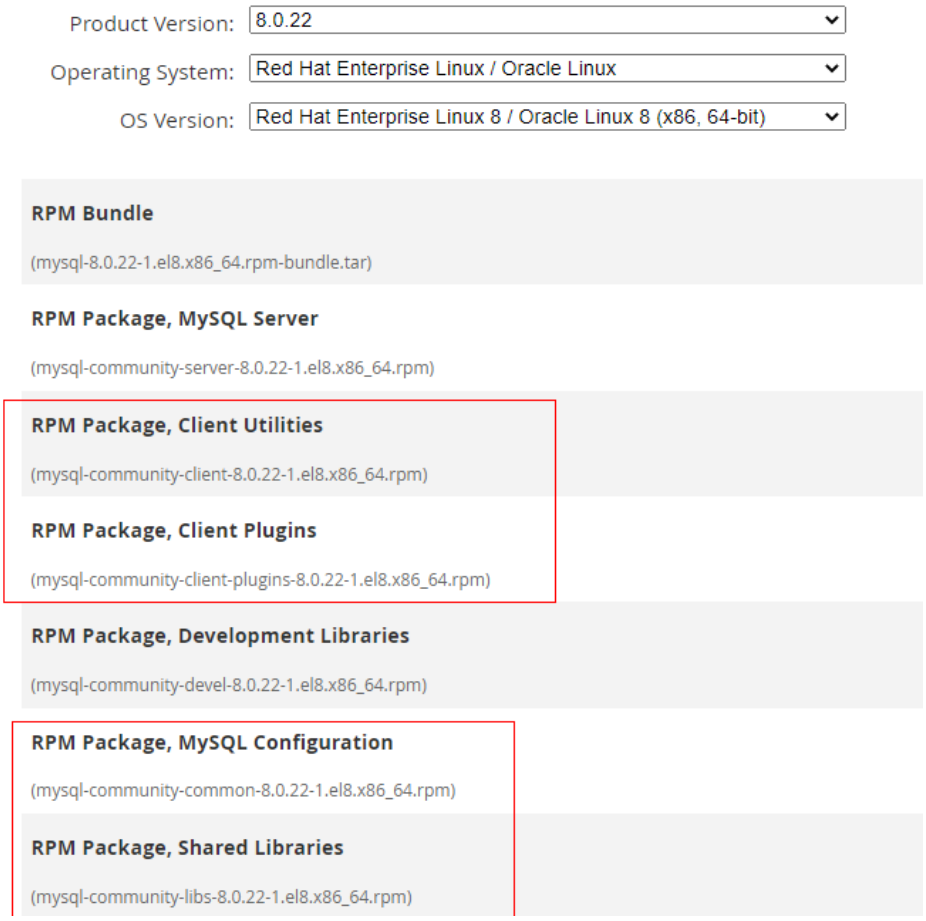
rpm -qa | grep ncurses

```
[root@node-master1hlrt ~]# rpm -qa | grep ncurses
ncurses-base-6.3-2.r2.hce2.noarch
ncurses-libs-6.3-2.r2.hce2.x86_64
ncurses-6.3-2.r2.hce2.x86_64
```

Step 3 Download the software package corresponding to the MySQL client from **https://downloads.mysql.com/archives/community/**. You are advised to install MySQL 8.x. The following uses Red Hat as an example:

- If the dependent library in **Step 2** is 6.x, you are advised to download the MySQL software package whose OS version is Red Hat 8.
- If the dependent library in **Step 2** is 5.x, you are advised to download the MySQL software package whose OS version is Red Hat 7.

For example, to install the MySQL 8.0.22 client of Red Hat, download the following software packages:



Step 4 Upload the downloaded software package to the node where the MySQL client is to be installed.

Step 5 Run the following command in the directory where the uploaded file is stored to install the MySQL client and the corresponding dependency package:

rpm -ivh mysql-community-client-8.0.22-1.el8.x86_64.rpm --nodeps --force

rpm -ivh mysql-community-client-plugins-8.0.22-1.el8.x86_64.rpm --nodeps --force

rpm -ivh mysql-community-common-8.0.22-1.el8.x86_64.rpm --nodeps --force

rpm -ivh mysql-community-libs-8.0.22-1.el8.x86_64.rpm --nodeps --force

Step 6 Run the following command to check the MySQL client version:

mysql --version

```
[root@node-master1hlrt ~]# mysql --version
mysql  Ver 8.0.22 for Linux on x86_64 (MySQL Community Server - GPL)
```

Step 7 After the MySQL client is successfully installed, you can access Doris. For details, see **Getting Started with Doris**.

----End

5.4 Getting Started with Doris

Doris is a high-performance and real-time analytical database based on the MPP architecture. It supports not only high-concurrency point query scenarios, but also high-throughput complex analysis scenarios.

This document uses examples to describe how to use an MRS Doris cluster to perform basic table creation and query operations.

NOTE

Doris database names and table names are case sensitive.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Procedure

Step 1 Create a user with the Doris management permission.

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)
  a. Log in to FusionInsight Manager and choose **System**. In the navigation pane on the left, click **Permission** > **Role**, and click **Create Role**. On the displayed page, enter the role name, for example, **dorisrole**. In the **Configure Resource Permission** area, select *target cluster* > **Doris**, select **Doris Admin Privilege**, and click **OK**.
  b. Choose **User** > **Create**, enter a username, for example, **dorisuser**, set **User Type** to **Human-Machine**, retain the **default** value for **Password Policy**, enter the user password, confirm the password, associate the user with the **dorisrole** role, and click **OK**.

c. Log in to FusionInsight Manager as the new dorisuser user and change the initial password of the user.

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  a. Log in to the node where the MySQL client is installed and connect to the Doris service as user **admin**.

     mysql -uadmin -P*Database connection port* **-h***IP address of Doris FE instance*

     NOTE

     - The default password of user **admin** is empty.
     - The database connection port is the query connection port of the Doris FE. You can also log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
     - To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
     - You can also use the MySQL connection software or Doris WebUI to connect to the database.
     - Only clusters of MRS 3.3.0 and later versions with Kerberos authentication enabled support role assignment on FusionInsight Manager. If the cluster is of MRS 3.3.0 or earlier, you need to connect to the database as user **root** (the default password is empty) regardless of whether Kerberos authentication is enabled.

  b. Run the following command to create a role:

     CREATE ROLE *dorisrole***;**

  c. Run the following command to grant permissions to the role. For details about the permissions, see **About Doris User Permissions**. For example, to grant the ADMIN_PRIV permission to the role, run the following command:

     GRANT *ADMIN_PRIV* **ON *.*.* TO ROLE '***dorisrole***';**

  d. Run the following commands to create a user and bind the user to a role:

     CREATE USER '*dorisuser***'@'%' IDENTIFIED BY '***password***' DEFAULT ROLE '***dorisrole***';**

     There can be security risks if a command contains the authentication password. You are advised to disable the command recording function (history) before running the command.

Step 2 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***Doris FE instance IP address*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 3 Run the following command to check the running status of the FE:

SHOW FRONTENDS\G;

SHOW BACKENDS\G;

Step 4 Create a database.

create database if not exists *mrs_demo*;

use *mrs_demo*;

NOTE

For more information about Doris SQL commands and syntax, see the **Doris SQL Manual**.

Step 5 Run the following command to create a data table in the database:

CREATE TABLE IF NOT EXISTS *mrs_table*

(

`user_id` LARGEINT NOT NULL COMMENT "User ID",

`date` DATE NOT NULL COMMENT " Data Import Date",

`city` VARCHAR(20) COMMENT "city",

`age` SMALLINT COMMENT "age",

`gender` TINYINT COMMENT "Gender",

`last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT " Last access time of the user",

`cost` BIGINT SUM DEFAULT "0" COMMENT "Total consumption",

`max_dwell_time` INT MAX DEFAULT "0" COMMENT "Dwell time",

`min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum dwell time"

)

AGGREGATE KEY(`user_id`, `date`, `city`, `age`, `gender`)

DISTRIBUTED BY HASH(`user_id`) BUCKETS 1

PROPERTIES (

"replication_allocation" = "tag.location.default: 1"

);

Step 6 Create the test.csv file in any directory on the current node. The file content is as follows:

```
10000,2017-10-01,city1,20,0,2017-10-01 06:00:00,20,10,10
10000,2017-10-01,city2,20,0,2017-10-01 07:00:00,15,2,2
10001,2017-10-01,city3,30,1,2017-10-01 17:05:45,2,22,22
10002,2017-10-02,city4,20,1,2017-10-02 12:59:12,200,5,5
10003,2017-10-02,city5,32,0,2017-10-02 11:20:00,30,11,11
10004,2017-10-01,city6,35,0,2017-10-01 10:00:15,100,3,3
10004,2017-10-03,city7,35,0,2017-10-03 10:20:22,11,6,6
```

Step 7 Import data in the test.csv file to the table created in **Step 5** using Stream Load.

cd Directory where test.csv is stored

curl -k --location-trusted -u *doris User name*:*User password* **-H "***label:table1_20230217***" -H "***column_separator:,***" -T test.csv http://***Doris FE Instance IP address*:*HTTP port*/api/mrs_demo/mrs_table/_stream_load**

NOTE

- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- To view the HTTP port number, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and search for **http_port**.

Step 8 Run the following command to query the data:

select * from *mrs_table* **where city='city1';**

----End

5.5 Importing Doris Data

5.5.1 Importing Data to Doris with Broker Load

Broker load is an asynchronous import method, and the supported data sources depend on the data sources supported by the Broker process.

Data in the Doris table is ordered. When importing data, Broker Load uses Doris cluster resources to sort data. Compared with Spark Load which is used to migrate massive historical data, Broker Load occupies a large number of Doris cluster resources. The Broker Load mode is used when users do not have Spark compute resources. If Spark compute resources are available, Spark Load is recommended.

You need to import data with Broker Load using MySQL protocol and check the import result by viewing the import command. Broker Load is used for the following scenarios:

- The source data is in a storage system that the broker can access, such as HDFS.
- The data volume ranges from tens to hundreds of GB.
- Data in CSV, Parquet, and ORC formats can be imported. Only data in CSV format is supported by default.

Prerequisites

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- The DBroker instance has been installed and started in Doris.
- The Hive client has been installed.
- If Doris imports data across clusters through Broker Load, you need to configure cross-cluster mutual trust. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**.

Importing Hive Table Data to Doris

- Import Hive table data in Text format to Doris.
  a. Log in to the node where the Hive client is installed as the client installation user and run the following commands to log in to the Hive beeline CLI:

     cd *Client installation directory*

     source bigdata_env

     kinit *Component service user* (If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), skip this step.)

  b. Run the following statements to create a Hive table in the **default** database (the partition field is **c4**):

     CREATE TABLE *test_table***(**

     `c1` int,

     `c2` int,

     `c3` string)

     PARTITIONED BY (c4 string)

     row format delimited fields terminated by ','lines terminated by '\n' stored as textfile ;

  c. Run the following command to insert data to the Hive table:

insert into table *test_table* **values(1,1,'1','2022-04-10'), (2,2,'2','2022-04-22');**

d. Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***IP address of Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can also log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.
- If the Hive and Doris components are deployed across clusters, modify the following configurations:
  - The value of **hadoop.rpc.protection** of Doris in the cluster where Doris is located must be the same as that of HDFS in the cluster where Hive is located.
  - Change the value of **-Djava.security.krb5.conf** in configuration item **BROKER_GC_OPTS** of DBRoker in the cluster where Doris is located. Copy the **$BIGDATA_HOME/FusionInsight_HD_*/*_HiveServer/etc/kdc.conf** file of any HiveServer node in the Hive cluster to any directory of any DBRoker node in the Doris cluster.

e. Run the following command to create a Doris table:

```
CREATE TABLE example_db.test_t1 (
`c1` int NOT NULL,
`c4` date NULL,
`c2` int NOT NULL,
`c3` String NOT NULL
) ENGINE=OLAP
UNIQUE KEY(`c1`, `c4`)
PARTITION BY RANGE(`c4`)
(
PARTITION P_202204 VALUES [('2022-04-01'), ('2022-05-01')))
DISTRIBUTED BY HASH(`c1`) BUCKETS 1
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"dynamic_partition.enable" = "true",
"dynamic_partition.time_unit" = "MONTH",
"dynamic_partition.start" = "-2147483648",
```

"dynamic_partition.end" = "2",

"dynamic_partition.prefix" = "P_",

"dynamic_partition.buckets" = "1",

"in_memory" = "false",

"storage_format" = "V2"

);

f. Run the following command to import data:

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)

  LOAD LABEL *broker_load_2022_03_23*

  (

  DATA INFILE("hdfs://IP address of the active NameNode instance:RPC port number/user/hive/warehouse/test_table/*/*")

  INTO TABLE *test_t1*

  COLUMNS TERMINATED BY ","

  (c1,c2,c3)

  COLUMNS FROM PATH AS (`c4`)

  SET

  (

  c4 = str_to_date(`c4`,'%Y-%m-%d'),c1=c1,c2=c2,c3=c3

)

)

  WITH BROKER "*broker_192_168_67_78***"**

  (

  "hadoop.security.authentication"="kerberos",

  "kerberos_principal"="doris/hadoop.hadoop.com@HADOOP.COM",

  "kerberos_keytab"="${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-fe/bin/doris.keytab"

)

  PROPERTIES

  (

  "timeout"="1200",

  "max_filter_ratio"="0.1"

  );

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  LOAD LABEL *broker_load_2022_03_23*

  (

  DATA INFILE("hdfs://*IP address of the active NameNode instance***:***RPC port number***/user/hive/warehouse/***test_table***/*/*")**

```
INTO TABLE test_t1
COLUMNS TERMINATED BY ","
(c1,c2,c3)
COLUMNS FROM PATH AS (`c4`)
SET
(
c4 = str_to_date(`c4`,'%Y-%m-%d'),c1=c1,c2=c2,c3=c3
)
)
WITH BROKER "broker_192_168_67_78"
(
"username"="hdfs",
"password"=""
)
PROPERTIES
(
"timeout"="1200",
"max_filter_ratio"="0.1"
);
```

NOTE

- To view the IP address of the active NameNode instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS** > **Instances**.
- You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**, and search for **dfs.namenode.rpc.port** to view the RPC port number.
- *broker_192_168_67_78* indicates the broker name. You can run the **show broker;** command on the MySQL client to view the broker name.

g. Run the following command to check the status of the import task:

show load order by createtime desc limit 1\G;

```
JobId: 41326624
Label: broker_load_2022_03_23
State: FINISHED
Progress: ETL:100%; LOAD:100%
Type: BROKER
EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=27
TaskInfo: cluster:N/A; timeout(s):1200; max_filter_ratio:0.1
ErrorMsg: NULL
CreateTime: 2022-04-01 18:59:06
EtlStartTime: 2022-04-01 18:59:11
EtlFinishTime: 2022-04-01 18:59:11
LoadStartTime: 2022-04-01 18:59:11
LoadFinishTime: 2022-04-01 18:59:11
URL: NULL
JobDetails: {"Unfinished backends":{"5072bde59b74b65-8d2c0ee5b029adc0":
[]},"ScannedRows":27,"TaskNumber":1,"All backends":{"5072bde59b74b65-8d2c0ee5b029adc0":
[36728051]},"FileNumber":1,"FileSize":5540}
1 row in set (0.01 sec)
```

h. You can manually cancel an import task whose Broker Load job status is not **CANCELLED** or **FINISHED**. To cancel an import task, you need to specify the label of the import task. The statement is as follows:

CANCEL LOAD FROM *Database name* WHERE LABEL = "*Label name*";

For example, to cancel the import job whose label is **broker_load_2022_03_23** in database **demo**, run the following command:

CANCEL LOAD FROM demo WHERE LABEL = "broker_load_2022_03_23";

- Importing Hive Table Data in ORC Format to Doris

  a. Log in to the node where the Hive client is installed as the client installation user and run the following commands to log in to the Hive beeline CLI:

  cd *Client installation directory*

  source bigdata_env

  kinit *Component service user* (If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), skip this step.)

  b. Run the following command to create a Hive table in ORC format in the **default** database:

  CREATE TABLE *test_orc_tbl*(

  `c1` int,

  `c2` int,

  `c3` string)

  PARTITIONED BY (c4 string)

  row format delimited fields terminated by ','lines terminated by '\n' stored as orc;

  c. Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

  If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

  export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

  mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***IP address of Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can also log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.
- If the Hive and Doris components are deployed across clusters, modify the following configurations:
  - The value of **hadoop.rpc.protection** of Doris in the cluster where Doris is located must be the same as that of HDFS in the cluster where Hive is located.
  - Change the value of **-Djava.security.krb5.conf** in configuration item **BROKER_GC_OPTS** of DBRoker in the cluster where Doris is located. Copy the **$BIGDATA_HOME/FusionInsight_HD_*/*_HiveServer/etc/kdc.conf** file of any HiveServer node in the Hive cluster to any directory of any DBRoker node in the Doris cluster.

d. Run the following command to create a Doris table:

CREATE TABLE *example_db.test_orc_t1* **(**
`c1` int NOT NULL,
`c4` date NULL,
`c2` int NOT NULL,
`c3` String NOT NULL
) ENGINE=OLAP
UNIQUE KEY(`c1`, `c4`)
PARTITION BY RANGE(`c4`)
(
PARTITION P_202204 VALUES [('2022-04-01'), ('2022-05-01')))
DISTRIBUTED BY HASH(`c1`) BUCKETS 1
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"dynamic_partition.enable" = "true",
"dynamic_partition.time_unit" = "MONTH",
"dynamic_partition.start" = "-2147483648",
"dynamic_partition.end" = "2",
"dynamic_partition.prefix" = "P_",
"dynamic_partition.buckets" = "1",
"in_memory" = "false",
"storage_format" = "V2"
);

e. Run the following command to import data using Broker Load:

- Kerberos authentication is enabled for the cluster (the cluster is in security mode):

  LOAD LABEL *broker_load_2022_03_24*

  (

  DATA INFILE("hdfs://*IP address of the active NameNode instance*:*RPC port number*/**user/hive/warehouse/***test_orc_tbl*/***/*")**

  INTO TABLE *test_orc_t1*

  FORMAT AS "orc"

  (c1,c2,c3)

  COLUMNS FROM PATH AS (`c4`)

  SET

  (

  c4 = str_to_date(`c4`,'%Y-%m-%d'),c1=c1,c2=c2,c3=c3

)

)

  WITH BROKER "broker_192_168_67_78"

  (

  "hadoop.security.authentication"="kerberos",

  "kerberos_principal"="doris/hadoop.hadoop.com@HADOOP.COM",

  "kerberos_keytab"="${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-fe/bin/doris.keytab"

)

  PROPERTIES

  (

  "timeout"="1200",

  "max_filter_ratio"="0.1"

  );

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  LOAD LABEL *broker_load_2022_03_24*

  (

  DATA INFILE("hdfs://*IP address of the active NameNode instance*:*RPC port number*/**user/hive/warehouse/***test_orc_tbl*/***/*")**

  INTO TABLE *test_orc_t1*

  FORMAT AS "orc"

  (c1,c2,c3)

  COLUMNS FROM PATH AS (`c4`)

  SET

  (

  c4 = str_to_date(`c4`,'%Y-%m-%d'),c1=c1,c2=c2,c3=c3

```
)
)
WITH BROKER "broker_192_168_67_78"
(
'username"="hdfs",
'password"=""
)
PROPERTIES
(
"timeout"="1200",
"max_filter_ratio"="0.1"
);
```

NOTE

- **FORMAT AS "orc"** : The format of the data to be imported is ORC.
- **SET**: The field mapping between Hive tables and Doris tables and field conversion rules.
- To view the IP address of the active NameNode instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS** > **Instances**.
- You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**, and search for **dfs.namenode.rpc.port** to view the RPC port number.
- *broker_192_168_67_78* indicates the broker name. You can run the **show broker;** command on the MySQL client to view the broker name.

f. Run the following statement to check the status of the imported task:

show load order by createtime desc limit 1\G;

g. You can manually cancel an import task whose Broker Load job status is not **CANCELLED** or **FINISHED**. To cancel an import task, you need to specify the label of the import task. The statement is as follows:

CANCEL LOAD FROM *Database name* WHERE LABEL = "*Label name*";

For example, to cancel the import job whose label is **broker_load_2022_03_23** in database **demo**, run the following command:

CANCEL LOAD FROM demo WHERE LABEL = "broker_load_2022_03_23";

Related Parameter Configurations

The following configurations are system-level configurations of Broker Load and apply to all Broker Load import tasks.

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations** > **FE (Role)** > **Customization**, and add the following parameters to the customized parameter fe.conf.customized.configs:

- **min_bytes_per_broker_scanner**: specifies the minimum amount of data that can be processed by a single BE. The default value is **64 MB**.
- **max_bytes_per_broker_scanner**: specifies the maximum amount of data that can be processed by a single BE. The default value is **3 GB**.

- **max_broker_concurrency**: specifies the maximum number of concurrent import tasks in a job. The default value is **10**.

The minimum amount of data to be processed, maximum number of concurrent tasks, source file size, and number of BE nodes in the current cluster determine the number of concurrent tasks to be imported.

- Number of concurrent import tasks = Math.min (Source file size/Minimum processing volume, Maximum number of concurrent import tasks, Number of current BE nodes)
- Processing volume of a single BE = Size of the source file/Number of concurrent import tasks

Usually the maximum amount of data supported by an import job is the product of the value of **max_bytes_per_broker_scanner** and the number of BE nodes. To import a larger amount of data, you need to adjust the value of **max_bytes_per_broker_scanner**.

5.5.2 Importing OBS Data to Doris with Broker Load

To import data to Doris with Stream Load, you need to read the data first by the client. Broker Load simplifies this process by sending import requests to Doris, and Doris pulls data. If the data you want to import is stored in object storage, Broker Load is the most convenient tool. With Broker Load, data is directly read and imported by Doris without passing through the client.

You need to import data with Broker Load through MySQL protocol and check the import result with the import command. Broker Load is suitable for the following scenes:

- The source data is in a storage system that the broker can access, such as OBS.
- The amount of data is at the level of tens to hundreds of GB.
- Data in CSV, Parquet, ORC, and JSON formats can be imported. Only data in CSV format is supported by default.

The operations in this section are applicable to MRS 3.5.0 and later versions.

Prerequisites

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The nodes to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the new user **dorisuser** and change the initial password.

  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- You have prepared the data files to be imported to Doris.

Creating an OBS Parallel File System and Obtaining the AK/SK

Create an OBS parallel file system.

Step 1 Log in to the OBS console.

Step 2 Choose **Parallel File Systems** > **Create Parallel File System**.

Step 3 Enter a file system name, for example, **doris-obs**.

The name of an enterprise project must be the same as that of the MRS cluster. Set other parameters.

Step 4 Click **Create Now**.

Step 5 In the parallel file system list, click the name of the one you just created and click **Overview** to obtain the endpoint information.

NOTE

After a service is deleted or a cluster is uninstalled, dirty data may remain in the parallel file system created in **Step 2** to **Step 4**. You need to delete the dirty data.

Step 6 Click **Files** in the navigation pane, click **Create Folder**, enter a folder name, for example, **test**, and click **OK**.

Step 7 Click the name of the new folder and click **Upload File** to upload the data, for example, to **test_data.csv**.

Obtain AK/SK information.

Step 8 Move the cursor on the username in the upper right corner, and select **My Credentials** from the drop-down list.

Step 9 Click **Access Keys**, click **Create Access Key**, and enter the verification code or password. Click **OK** and download the access keys. Obtain the AK/SK information from the **.csv** file.

----End

Importing OBS Data to a Doris Table

Step 1 Log in to the node where MySQL is installed and connect the Doris database.

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect the database.

Step 2 Create a database.

create database *test_broker_load*;

use *test_broker_load*;

Step 3 Create a table and import OBS data to the table.

CREATE TABLE IF NOT EXISTS *test*

(

`user_id` LARGEINT NOT NULL COMMENT "User ID",

`city` VARCHAR(20) COMMENT "City",

`age` SMALLINT COMMENT "Age",

`gender` TINYINT COMMENT "Gender",

`cost` BIGINT SUM DEFAULT "0" COMMENT "Total consumption",

`max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum dwell time",

`min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum dwell time"

)

AGGREGATE KEY(`user_id`, `city`, `age`, `gender`)

DISTRIBUTED BY HASH(`user_id`) BUCKETS 100

PROPERTIES (

"replication_allocation" = "tag.location.default: 3"

);

LOAD LABEL *brokerload_test_label001*

(

DATA INFILE("obs://*Parallel file system name***/test/***test_data.csv***")**

INTO TABLE `***test***`

COLUMNS TERMINATED BY ','

FORMAT AS "*csv***"**

)

WITH BROKER "broker1"

(

"fs.obs.access.key" = "*xxx*",

"fs.obs.secret.key" = "*xxx*",

"fs.obs.endpoint" = "*xxx*"

);

NOTE

- **LOAD LABEL**: unique label that must be specified for each import task. You can use this label to view the job progress.
- **DATA INFILE**: OBS path of the data files (uploaded in **Step 7**) you want to import to Doris.
- **COLUMNS TERMINATED BY**: column separator. This parameter is required only when the CSV format is used. Only a single-byte separator can be specified.
- **FORMAT AS**: file type. The value can be **CSV**, **JSON**, **PARQUET**, or **ORC**. The default value is CSV.
- **WITH BROKER**: name of the broker service to be used. You can run the following command to view the broker information of the cluster:

  show broker;

  ```
  mysql> show broker;
  +----------------+----------+-------+-------+---------------------+---------------------+--------+
  | Name           | Host     | Port  | Alive | LastStartTime       | LastUpdateTime      | ErrMsg |
  +----------------+----------+-------+-------+---------------------+---------------------+--------+
  | broker_[redacted] | [redacted] | 29990 | true  | 2024-07-26 17:19:21 | 2024-07-29 17:44:05 |        |
  | broker_[redacted] | [redacted] | 29990 | true  | 2024-07-26 17:19:21 | 2024-07-29 17:44:05 |        |
  +----------------+----------+-------+-------+---------------------+---------------------+--------+
  2 rows in set (0.02 sec)
  ```

- **fs.obs.access.key**: AK information obtained in **Step 9**
- **fs.obs.secret.key**: SK information obtained in **Step 9**
- **fs.obs.endpoint**: endpoint information obtained in **Step 5**

Step 4 Check the task progress.

show load order by createtime desc limit 1\G;

If the value of **State** in the command output changes to **FINISHED**, the data import is complete.

```
JobId: 296805
Label: brokerload_test_csv_label001
State: FINISHED
Progress: ETL:100%; LOAD:100%
Type: BROKER
EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=1000000
TaskInfo: cluster:N/A; timeout(s):14400; max_filter_ratio:0.0
 ErrorMsg: NULL
...
```

Step 5 Query table data.

select * from *test*;

----End

5.5.3 Importing Data to Doris with Stream Load

Stream Load is a synchronous import mode. Users send requests through HTTP to import local files or data streams to the Doris. Stream Load synchronously executes the import and returns the import result. You can determine whether the import is successful based on the return body of the request.

Stream Load is used to import local files or import data in data flows through programs. Data in CSV, Parquet, and ORC formats can be imported. Only data in CSV format is supported by default.

Syntax

- Creating a Stream Load Import Task

  Stream load submits and transfers data through HTTP protocol. This operation uses the curl command to demonstrate how to submit the import. You can also use other HTTP clients to perform this operation.

  – Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    curl -k --location-trusted -u *user:passwd* **[-H ""...] -T data.file -XPUT https://***Doris FE instance IP address:HTTPS port number*/api/*{Database name}*/*{Table name}*/**_stream_load**

  – Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    curl --location-trusted -u *user:passwd* **[-H ""...] -T data.file -XPUT http://***Doris FE instance IP address:HTTP port number*/api/*{Database name}*/*{Table name}*/**_stream_load**

  To view the IP address of the Doris FE instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Instances**.

  You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and search for **https_port** to view the HTTPS port.

  . To view the port, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and search for **http_port**.

  Table 5-2 describes other parameters for creating a stream load task.

Table 5-2 Parameters of the Stream Load Task

Parameter		Description
Signature parameters	user:passwd	The HTTP protocol is used for stream load creation and import, and the basic access authentication is used for signature. The Doris system verifies user identity and import permissions based on signatures.

Parameter		Description
Import task parameters (format: **-H "key1:value1"**)	label	Identity of import task. Each import task has a unique label inside a single database. Label is a user-defined name in the import command. Through this label, you can view the execution status of the corresponding import task.
	column_separator	Specifies the column separator in the file to be imported. The default value is **\t**. You can use a combination of multiple characters as the column separator. If it is an invisible character, you need to add **\x** as a prefix and hexadecimal to indicate the separator. For example, the separator **\x01** of the hive file needs to be specified as **-H "column_separator:\x01"**.
	line_delimiter	Specifies the newline character in the file to be imported. The default value is **\n**. You can use to combine multiple characters as the newline character.
	max_filter_ratio	The maximum tolerance rate of the import task is 0 by default, and the range of values is 0-1. When the import error rate exceeds this value, the import fails.
	where	Filter criteria specified for an import task. Stream Load allows you to specify **where** statements to filter raw data. The filtered data will not be imported or involved in **filter ratio** calculation, but will be counted in **num_rows_unselected**.
	Partitions	Partition information of the table to be imported. If the data to be imported does not belong to the specified partition, the data will not be imported and will be counted in dpp.abnorm.ALL.
	columns	Function transformation configuration of the data to be imported. Currently, the function transformation methods supported by Stream Load include column sequence transformation and expression transformation. The expression transformation method is the same as that of the query statement.
	format	Format of the data to be imported. The value can be CSV, JSON, Parquet, or ORC. The default value is CSV.
	exec_mem_limit	Memory limit for data import. The default value is 2 GB. The unit is byte.

Parameter		Description
	strict_mode	The strict mode can be enabled for stream load import. You can declare **strict_mode=true** in the header to enable the strict mode. By default, the strict mode is disabled. The strict mode is used to strictly filter column type conversion during data import. The policy is as follows: ● For column type conversion, if **strict mode** is true, incorrect data will be filtered. Error data refers to the data whose original data is not null and whose result is null after column type conversion. ● If a column to be imported is converted by a function, the strict mode does not affect the column. ● If the type of a column to be imported contains a range restriction and the original data can be converted but cannot pass the range restriction, the strict mode does not affect the column. For example, if the type is decimal (1,0) and the original data is 10, the data can be converted but is not within the range specified by the column. The strict data does not affect the data.
	merge_type	Data combination type. The options are APPEND, DELETE, and MERGE. The default value is APPEND. ● APPEND indicates that the batch of data needs to be added to the existing data. ● DELETE indicates that all rows that have the same key as the batch of data are deleted. ● MERGE semantics must be used together with the **delete** condition. Data that meets the delete condition is processed based on DELETE semantics, and other data is processed based on APPEND semantics.
	two_phase_commit	The two-phase transaction commit mode can be enabled for stream load import. During stream loading, a message is returned to you after data is written. In this case, the data is invisible and the transaction status is PRECOMMITTED. The data is visible only after you manually trigger the **commit** operation.
	enable_profile	If enable_profile is set to true, the stream load profile is recorded in logs. Otherwise, the stream load profile is not recorded in logs.

- Returned Result

  Stream Load is a synchronous import mode. Therefore, the import result is directly returned through the return value of the import creation. For example:

  ```
  {
  "TxnId": 1003,
  ```

```
"Label": "b6f3bc78-0d2c-45d9-9e4c-faa0a0149bee",
"Status": "Success",
"ExistingJobStatus": "FINISHED", // optional
"Message": "OK",
"NumberTotalRows": 1000000,
"NumberLoadedRows": 1000000,
"NumberFilteredRows": 1,
"NumberUnselectedRows": 0,
"LoadBytes": 40888898,
"LoadTimeMs": 2144,
"BeginTxnTimeMs": 1,
"StreamLoadPutTimeMs": 2,
"ReadDataTimeMs": 325,
"WriteDataTimeMs": 1933,
"CommitAndPublishTimeMs": 106,
"ErrorURL": "http://192.168.1.1:8042/api/_load_error_log?file=__shard_0/
error_log_insert_stmt_db18266d4d9b4ee5-
abb00ddd64bdf005_db18266d4d9b4ee5_abb00ddd64bdf005"
}
```

Table 5-3 describes the parameters in the import result.

Table 5-3 Parameters in the Stream Load Import Task Result

Parameter	Description
TxnId	The imported transaction ID.
Label	Import labels, which are specified by users or automatically generated by the system.
Status	Import completion status. The options are as follows: • Success: indicates that the import is successful. • Publish Timeout: This status also indicates that the import is complete. The only difference is that the data may be visible after a delay and does not need to be retried. • Label Already Exists: The label already exists and needs to be replaced. • Fail: Import failed.
ExistingJobStatus	Status of the import job corresponding to an existing label. This field is displayed only when Status is **"Label Already Exists"**. You can view the status of the import job corresponding to the existing label. **"RUNNING"** indicates that the job is still being executed, and **"FINISHED"** indicates that the job is successfully executed.
Message	Import error information.
NumberTotalRows	Number of rows imported for total processing.
NumberLoadedRows	Number of rows successfully imported.
NumberFilteredRows	Number of rows in which data does not meet requirements.

Parameter	Description
NumberUnselectedRows	Number of rows filtered by the **where** condition.
LoadBytes	Number of imported bytes
LoadTimeMs	Import completion time, in milliseconds.
BeginTxnTimeMs	This parameter specifies the time taken to request the FE to start a transaction. The unit is millisecond.
StreamLoadPutTimeMs	Time taken to obtain the data import plan from the FE. The unit is millisecond.
ReadDataTimeMs	Time taken to read data, in milliseconds.
WriteDataTimeMs	Time taken to write data, in milliseconds.
CommitAndPublishTimeMs	Time taken to submit a request to the FE and release a transaction, in milliseconds.
ErrorURL	If a data error occurs, access the URL to view the error line.

NOTE

Stream Load is imported in synchronous mode. Therefore, the import information is not recorded in the Doris system. Users cannot view Stream Load asynchronously by running the import command. You need to view the return value of the import request to obtain the import result.

- Cancel Import

  You cannot manually cancel stream load tasks. Stream load will be automatically canceled by the system after a timeout or import error.

- Viewing Stream Load

  You can view completed stream load tasks on the **show stream load**.

  By default, the BE does not record the stream load import information. To view the information, you need to set the **enable_stream_load_record=true** parameter.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Stream Load Task Example

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***Doris FE instance IP address*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following command to create a database:

create database if not exists *example_db*;

Step 3 Run the following statement to create a table:

CREATE TABLE *example_db.test_stream_tbl* **(**

`c1` int NOT NULL,

`c2` int NOT NULL,

`c3` string NOT NULL,

`c4` date NOT NULL

) ENGINE=OLAP

UNIQUE KEY(`c1`, `c2`)

DISTRIBUTED BY HASH(`c1`) BUCKETS 1;

Step 4 Create the data.csv file. The file content is as follows:

```
1,1,1,2020-02-21
2,2,2,2020-03-21
3,3,3,2020-04-21
```

Step 5 Use Stream Load to import data in the **data.csv** file to the table created in **Step 3**.

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)

  curl -k --location-trusted -u *user:passwd* -H "*label:table1_20230217***" -H "***column_separator:,***" -T data.csv https://***IP address of the Doris FE instance:HTTPS port***/api/***example_db***/***test_stream_tbl***/_stream_load**

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  curl --location-trusted -u *user:passwd* -H "*label:table1_20230217***" -H "***column_separator:,***" -T data.csv http://***IP address of the Doris FE instance:HTTP port***/api/***example_db***/***test_stream_tbl***/_stream_load**

Step 6 Run the following command to view the table data:

select * from *example_db.test_stream_tbl*;

----End

Related Parameter Configurations

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations**, and add the following parameters:

- Choose **FE(Role)** > **Customization**, and add the following parameters to the customized parameter **fe.conf.customized.configs**:

  stream_load_default_timeout_second: timeout interval of an import task, in seconds. If an import task is not complete within the specified time, the system cancels the task and the task status changes to CANCELLED. The default timeout period is 600 seconds. If the source file to be imported cannot be imported within the specified period, you can set a separate timeout period in the Stream Load request or change the value of **stream_load_default_timeout_second** to set the global default timeout period.

- Choose **BE(Role)** > **Customization** and add the following parameters to the custom parameter **be.conf.customized.configs**:

  streaming_load_max_mb: maximum size of a file to be imported for Stream Load. The default value is 10 GB, in MB. If the size of the original file exceeds the value of this parameter, you need to adjust the value of this parameter.

5.6 Analyzing Doris Data

5.6.1 Exporting Doris Data to HDFS

The data export function can export data in specified tables or partitions to remote storage devices in text format through the Broker process, such as HDFS and object storage (supporting the S3 protocol).

NOTE

- You are not advised to export a large amount of data at a time. It is recommended that a maximum of dozens of GB data be exported for an export job. Large exports result in more junk files and higher retry costs.
- If the table contains a large amount of data, you are advised to export the data by partition.
- If the FE is restarted or an active/standby switchover occurs during the running of the Export job, the Export job fails and you need to submit the job again.
- If the export job fails, the temporary directory **__doris_export_tmp_***xxx* generated in the remote storage and the generated files will not be deleted. You need to manually delete them.
- If the export job is successfully executed, the **__doris_export_tmp_***xxx* directory generated in the remote storage may be retained or cleared based on the file system semantics of the remote storage.

  For example, in object storage (supporting the S3 protocol), after the last file in a directory is moved through the **rename** operation, the directory is also deleted. If the directory is not cleared, you can manually clear it.
- After the export is complete (successful or failed), if the FE is restarted or an active/standby switchover occurs, some job information displayed in **SHOW EXPORT** will be lost and cannot be viewed.
- The Export job exports only Base table data and does not export Rollup Index data.
- The Export job scans data and occupies I/O resources, which may affect the query delay of the system.

Syntax

- Exporting Doris Data to HDFS
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    EXPORT TABLE *db1.tbl1*

    PARTITION (p1,p2)

    [WHERE [expr]]

    TO "hdfs://*IP address of the active NameNode instance*:*RPC port number*/**tmp/export/"**

    PROPERTIES

    (

    "label" = "*mylabel***",**

    "column_separator"=",",

    "columns" = "col1,col2",

    "exec_mem_limit"="2147483648",

    "timeout" = "3600"

)

    WITH BROKER "broker_name"

    (

    "hadoop.security.authentication"="kerberos",

    "kerberos_principal"="doris/hadoop.hadoop.com@HADOOP.COM",

    "kerberos_keytab"="${BIGDATA_HOME}/FusionInsight_Doris_*/install/FusionInsight-Doris-*/doris-fe/bin/doris.keytab"

);

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  EXPORT TABLE *db1.tbl1*

  PARTITION (p1,p2)

  [WHERE [expr]]

  TO "hdfs://*IP address of the active NameNode instance***:***RPC port number***/tmp/export/"**

  PROPERTIES

  (

  "label" = "*mylabel***",**

  "column_separator"=",",

  "columns" = "col1,col2",

  "exec_mem_limit"="2147483648",

  "timeout" = "3600"

)

  WITH BROKER "broker_name"

  (

  "username" = "*user***",**

  "password" = "*passwd***"**

  );

To view the IP address of the active NameNode instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS** > **Instances**.

You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**, and search for **dfs.namenode.rpc.port** to view the RPC port.

Table 5-4 describes other parameters.

Table 5-4 Parameters in the command for exporting Doris data to HDFS

Parameter	Description
label	URN of the export job. You can use this identifier to view the job status.
column_separator	Column separator. The default value is **\t**. Invisible characters are supported, for example, **'\x07'**.
columns	Columns to be exported. Use commas (,) to separate them. If this parameter is not set, all columns in the table are exported by default.
line_delimiter	Line separator. The default value is **\n**. Invisible characters are supported, for example, **'\x07'**.
exec_mem_limit	Memory usage limit of a query plan on a BE in an export job. The default value is 2 GB, in bytes.

Parameter	Description
timeout	Job timeout interval. The default value is 2 hours. The unit is second.
tablet_num_per_task	Maximum number of shards allocated to each query plan. The default value is 5.

- Viewing the Status of an Export Job

  After submitting a job, you can run the **SHOW EXPORT;** command to query the status of the export job. For example:

```
JobId: 14008
State: FINISHED
Progress: 100%
TaskInfo: {"partitions":["*"],"exec mem limit":2147483648,"column separator":",","line
delimiter":"\n","tablet num":1,"broker":"hdfs","coord num":1,"db":"default_cluster:db1","tbl":"tbl3"}
Path: hdfs://host/path/to/export/
CreateTime: 2019-06-25 17:08:24
StartTime: 2019-06-25 17:08:28
FinishTime: 2019-06-25 17:08:34
Timeout: 3600
ErrorMsg: NULL
1 row in set (0.01 sec)
```

  Table 5-5 describes the parameters.

  Table 5-5 Parameters for exporting job status

Parameter	Description
JobId	Job ID, which is unique.
State	Job status. The options are as follows: • PENDING: The job is to be scheduled. • EXPORTING: Data is being exported. • FINISHED: The job is successfully exported. • ANCELLED: The export job fails to be executed.
Progress	Job progress, in the unit of query plan. Assume that there are 10 query plans in total and three of them have been completed. The progress is 30%.

Parameter	Description
TaskInfo	Job information displayed in JSON format, where: • db: database name. • tbl: table name • partitions: specifies the partition to be exported. * indicates all partitions. • exec mem limit: queries the memory usage limit of the plan. in byte. • column separator: column separator of the exported file. • line delimiter: line delimiter of the exported file. • tablet num: total number of tablets. • broker: name of the used broker. • coord num: number of query plans.
Path	Export path on the remote storage device.
CreateTime/ StartTime/ FinishTime:	Creation time, scheduling start time, and end time of a job.
Timeout	Job timeout interval, in seconds. The time starts from CreateTime.
ErrorMsg	If an error occurs in the job, ErrorMsg displays the cause of the error.

- Canceling an Export Task

  After submitting a job, you can run the **CANCEL_EXPORT** command to cancel the export job. The cancellation command is as follows:

  CANCEL EXPORT

  FROM *example_db*

  WHERE LABEL like "*%example%***";**

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.

  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Example of Exporting Doris Data to HDFS

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***Doris FE instance IP address*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following command to create a database:

create database if not exists *example_db*;

Step 3 Run the following command to create a table:

CREATE TABLE *example_db.test_export_tbl* **(**

`c1` int NOT NULL,

`c2` int NOT NULL,

`c3` string NOT NULL,

`c4` date NOT NULL

) ENGINE=OLAP

DUPLICATE KEY(`c1`, `c2`)

DISTRIBUTED BY HASH(`c1`) BUCKETS 1;

Step 4 Run the following command to insert data:

insert into example_db.test_export_tbl values(1,1,1,"2020-02-21"), (2,2,2,"2020-03-21"),(3,3,3,"2020-04-21");

Step 5 Run the following command to export data from the test_export_tbl table to HDFS:

EXPORT TABLE *example_db.test_export_tbl*

TO "hdfs:// IP address of the active NameNode instance:RPC port number */tmp/export/***"**

PROPERTIES

(

"label" = "*label_exporthdfs_20230218031***",**

"column_separator"=",",

"columns" = "c1,c2,c3,c4",

"exec_mem_limit"="2147483648",

"timeout" = "3600"

)

with broker "broker_192_168_67_78"

(

"hadoop.security.authentication"="kerberos",

"kerberos_principal"="doris/hadoop.hadoop.com@HADOOP.COM",

"kerberos_keytab"="${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-fe/bin/doris.keytab"

);

Step 6 Run the following command to query the status of the export job:

SHOW EXPORT;

----End

Related Configuration Parameters

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations** > **FE(Role)** > **Customization**, and add the following parameters to the customized parameter fe.conf.customized.configs:

- export_checker_interval_second: scheduling interval of the Export job scheduler. The default value is 5 seconds. After setting this parameter, restart the FE.
- export_running_job_num_limit: specifies the maximum number of running export jobs. If the value is exceeded, the job waits and is in the **PENDING** state. The default value is 5, which can be adjusted during running.
- export_task_default_timeout_second: default timeout interval of an export job. The default value is 2 hours, which can be adjusted during running.
- export_tablet_num_per_task: maximum number of shards that a query plan is responsible for. The default value is 5.
- label: label of an EXPORT task manually specified by a user. If this parameter is not specified, a label is automatically generated.

5.6.2 Exporting the Query Result Set

This section describes how to use the **SELECT INTO OUTFILE** command to export the Doris query result set to a specified storage system in a specified file format.

NOTE

- The export command does not check whether the file and file path exist. The semantics of the remote storage system determines whether to automatically create a path or overwrite an existing file.
- If an error occurs during the export, some exported files may remain on the remote storage system. Doris does not clear these files. You need to manually clear them.
- The timeout period of the export command is the same as that of the query command. You can set the timeout period through **SET query_timeout=***xxx*.
- For a query whose result set is empty, a file whose size is 0 is still generated.
- File splitting ensures that a row of data is completely stored in a single file. Therefore, the file size is not strictly equal to the value of max_file_size.
- For some functions whose output is invisible characters, such as BITMAP and HLL, the output is **\N**, that is, NULL.
- Currently, the output type of some geographic information functions, such as ST_Point, is VARCHAR. However, the actual output value is encoded binary characters. These functions output garbled characters. For geographic functions, use ST_AsText for output.

Syntax

query_stmt

INTO OUTFILE "file_path"

[format_as]

[properties]

file_path

format_as

properties

NOTE

format_as: indicates the export format. The value can be CSV, PARQUET, CSV_WITH_NAMES, CSV_WITH_NAMES_AND_TYPES or ORC. The default value is CSV.

Example

- Export to HDFS

  Export the simple query result to the hdfs://path/to/result.txt file in CSV format.

  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    SELECT * FROM example_db.test_export_tbl

    INTO OUTFILE "hdfs://*192.168.67.78:25000***/tmp/result_"**

    FORMAT AS CSV

    PROPERTIES

(

"broker.name" = "broker_192_168_67_78",

"column_separator" = ",",

"line_delimiter" = "\n",

"max_file_size" = "100MB",

"broker.hadoop.security.authentication" = "kerberos",

"broker.kerberos_principal" = "doris/hadoop.hadoop.com@HADOOP.COM",

"broker.kerberos_keytab" = "${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-fe/bin/doris.keytab"

);

– Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

SELECT * FROM example_db.test_export_tbl

INTO OUTFILE "hdfs://*192.168.67.78:25000***/tmp/result_"**

FORMAT AS CSV

PROPERTIES

(

"broker.name" = "broker_192_168_67_78",

"column_separator" = ",",

"line_delimiter" = "\n",

"max_file_size" = "100MB",

"broker.username"="hdfs",

"broker.password"=""

);

- Export to Local File

  Before exporting data to a local file, you need to configure **enable_outfile_to_local=true in the fe.conf file**.

  select * from *tbl1* **limit 10**

  INTO OUTFILE "file:///*home/work/path/result_***";**

5.7 Enterprise-Class Enhancements of Doris

5.7.1 Configuring HA for the Doris Cluster

5.7.1.1 About Doris Cluster HA

Clients that support the MySQL protocol can be connected to the Doris cluster through FE nodes. To avoid single points of failure (SPOFs), multiple FE nodes are used and ELB instances are deployed on these nodes to ensure high availability of Doris.

You can configure Doris HA use any of the following methods base on your needs:

- Write code on the service side.
- Use an SDK.
- Configure an ELB instance.

Writing Code on the Service Side

At the service application layer, write code to test the connection and balance loads. If a connection is interrupted, the connection is automatically set up on other FEs for retry. To retry the connection, you need to make intrusive modification of addresses of multiple Doris FE nodes.

Using an SDK

The MySQL protocol is used to connect to Doris. SDKs of some languages have provided high availability. For example, MySQL JDBC can use the automatic retry mechanism. When establishing a connection, set the data source as follows:

jdbc:mysql:loadbalance://[host1][:port],[host2][:port][,[host3][:port]]...[/[database]][?
propertyName1=propertyValue1[&propertyName2=propertyValue2]...]

For details, see **https://dev.mysql.com/doc/connector-j/en/connector-j-usagenotes-j2ee-concepts-managing-load-balanced-connections.html**.

Configuring an ELB Instance

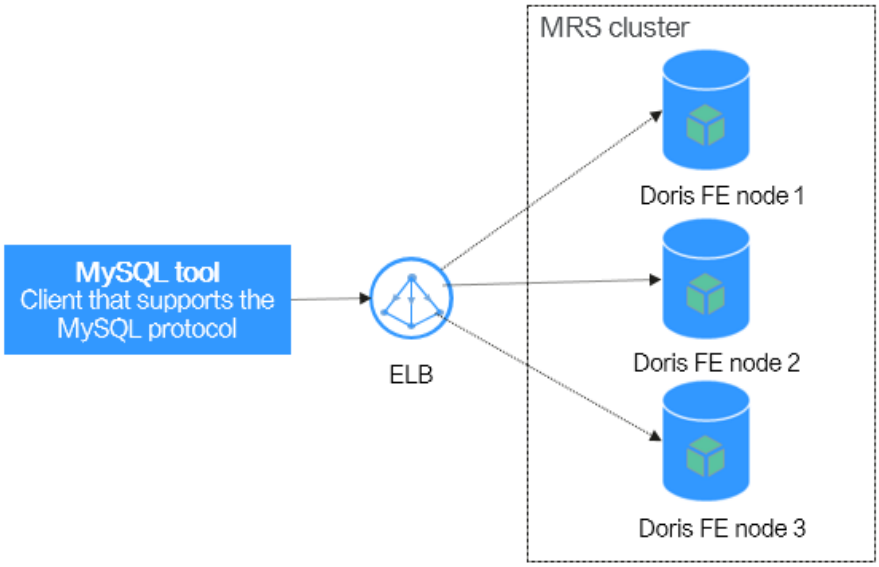
Doris uses the ELB-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a backend Doris node becomes faulty, ELB automatically fails over access traffic to another properly running node. For details, see **Configuring Access to the Doris Cluster Through ELB**.

5.7.1.2 Configuring Access to the Doris Cluster Through ELB

Doris can use a client that supports the MySQL protocol to access a single FE node to perform service operations. If FE nodes are faulty, Doris cannot provide services for external systems. To solve this problem, MRS can be deployed with the Elastic Load Balance (ELB) service in the architecture shown in **Figure 5-1**.

Doris uses the ELB-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a backend Doris node becomes faulty, ELB automatically fails over access traffic to another properly running node.

Figure 5-1 Accessing Doris nodes through ELB



Enable the MySQL client to access Doris through ELB. The procedure is as follows:

- **Step 1: Purchase an ELB and obtain its public IP address.**
- **Step 2: Add an ELB listener and configure its protocol and port.**
- **Step 3: Access Doris through ELB on the MySQL client.**

Prerequisite

- A Doris cluster has been created and is running properly.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Purchasing ELB and Interconnecting It with Doris

Buy an ELB instance and obtain its public IP address.

For details, see **Creating a Shared Load Balancer**.

Step 1 Log in to the management console and choose **Networking** > **Elastic Load Balance (ELB)** from the service list.

Step 2 In the upper right corner of the ELB console, click **Buy Elastic Load Balancer**.

Step 3 On the displayed page, set the following parameters and retain the default values for other parameters:

- **Type**: **Shared load balancer**
- **Billing Mode**: **Pay-per-use**
- **Enterprise Project**: **default**
- The values of **VPC** and **Frontend Subnet** must be the same as those of the MRS Doris cluster.

Step 4 Click **Next**, confirm the configurations, and click **Submit**.

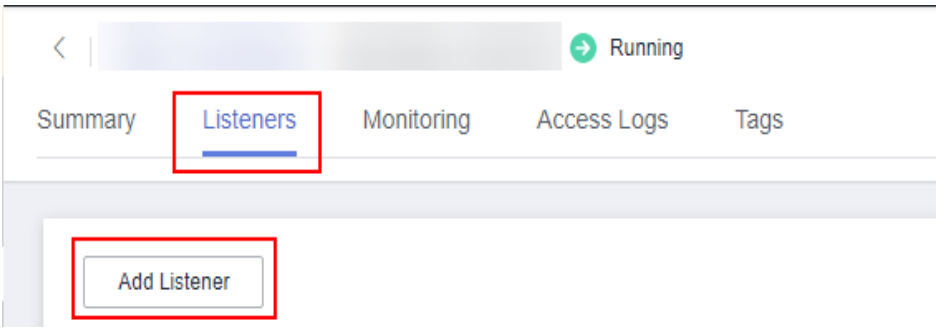
Step 5 On the **Load Balancers** page, view and obtain the public IP address of the newly created load balancer.

Add an ELB listener.

For details, see **Adding a Listener**.

Step 6 On the **Load Balancers** page, click the name of the created load balancer to go to its details page.

Step 7 Click the **Listeners** tab and then **Add Listener**.



Step 8 On the **Add Listener** page, set the parameters as prompted. Retain the default values for the parameters that are not mentioned in the following steps.

1. Configure the listener.

   Set **Frontend Protocol** to **TCP**, set **Frontend Port** to the access port, and click **Next: Configure Request Routing Policy**.

2. Configure a routing policy.

   Set **Load Balancing Algorithm** to **Weighted round robin**, enable **Sticky Session**, and click **Next: Add Backend Server**.

3. Add backend servers.

   In the **Backend Servers** pane, click **Add Backend Server**, add all nodes where Doris FE is deployed, and click **OK**.

   NOTE

   To view the service IP address of a Doris FE instance, log in to the MRS cluster management console, choose **Components**, click **Doris**, and click the **Instances** tab.

4. Set **Backend Port** of the servers to the MySQL protocol query connection port of the Doris FE service. The default port is 9030. You can search for **query_port** on the service configuration page of the Doris component to view the port.
5. Click **Next: Confirm**.
6. Confirm the configuration and click **Submit**.
7. Click **View/Add Backend Server** in the row where the created listener is located. In the **Backend Servers** pane, check whether the connection between the ELB and backend server is normal.

Use ELB to access Doris on the MySQL client.

Step 9 Log in to a node where MySQL is installed and run the following command to connect to Doris. For details, see **Getting Started with Doris**.

mysql -u *Database login user* **-p***Password* **-P***ELB frontend port* **-h***ELB public IP address*

NOTE

- The ELB frontend port is that configured in **8.1**.
- Replace the ELB public IP address with the IP address obtained in **Step 5**.

Step 10 Run the following command to check the connection status of the FE service:

show frontends;

If the query result is successful, Doris can be successfully accessed through ELB.

----End

5.7.2 Configuring Multi-Source Data for Doris

5.7.2.1 About Doris Multi-Source Data

The multi-source data catalog aims to facilitate interconnection with external data catalogs to enhance Doris' data lake analysis and federated data query capabilities.

The multi-source data catalog function adds a catalog layer to the original metadata layer to form the three metadata layers of the Catalog -> Database -> Table. The catalog may directly correspond to the external data catalog.

Basic Concepts

- Internal Catalog

  The original databases and tables of the Doris belong to the Internal Catalog. Internal Catalog is a built-in default catalog and cannot be modified or deleted by users.

- External Catalog

  You can run the **CREATE CATALOG** command to create an External Catalog, and view the existing Catalogs using the **SHOW CATALOGS** command.

- Switching Catalogs

  After login, you will enter the Internal Catalog by default (the default usage is the same as that in earlier versions). Then, you can view or switch to your target database via **SHOW DATABASES** and **USE DB**.

  You can run the SWITCH command to switch the catalog. For example:

  ```
  SWITCH internal;
  SWITCH hive_catalog;
  ```

  After the switchover, you can run the **SHOW DATABASES** and **USE DB** commands to view and switch the database in the corresponding catalog. The Doris automatically synchronizes the databases and tables in the catalog. You can view and access data in External Catalogs the same way as doing that in Internal Catalogs.

Currently, the Doris supports only read-only access to data in the External Catalog.

- Delete Catalog

  Databases and tables in External Catalog are read-only. However, the catalog can be deleted (the internal catalog cannot be deleted). You can run the **DROP CATALOG** command to delete an External Catalog.

  This operation only deletes the mapping information of the Catalog in Doris, but does not modify or change the content of any external data catalog.

- Resource

  Resource is a set of configurations. You can run the CREATE RESOURCE command to create a resource. Then, you can use the resource when creating a catalog.

  A resource can be used by multiple catalogs to reuse the configuration in the resource.

5.7.2.2 Interconnecting Doris with the Hive Data Source

By connecting to Hive Metastore, or a metadata service compatible with Hive Metatore, Doris can automatically obtain Hive database table information and perform data queries.

In addition to Hive, many other systems also use Hive Metastore to store metadata. Through Hive Catalog, you can access not only Hive but also systems that use Hive Metastore as metadata storage, such as Iceberg and Hudi.

NOTE

- Managed tables are supported.
- Hive and Hudi metadata stored in Hive Metastore can be identified.
- If you want to access the catalog that is not created by the current user, you need to grant the user the permission to operate the OBS path where the catalog resides.
- The Hive table format can only be Parquet, ORC, or TextFile.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- If Doris imports data across clusters through Broker Load, you need to configure cross-cluster mutual trust. For details, see **Configuring Cross-Manager Mutual Trust Between Clusters**.

Hive Table Operations

Step 1 To use Doris to read Hive data stored in OBS, perform the following operations:

1. Log in to the Huawei Cloud management console. On the console page, move the cursor to the username in the upper right corner and select **My Credentials** from the drop-down list.
2. Click **Access Keys**, click **Create Access Key**, and enter the verification code or password. Click **OK** to generate an access key, and download it.

   Obtain the values of AWS_ACCESS_KEY and AWS_SECRET_KEY required for creating a catalog from the .csv file. The mapping is as follows:

   - The value of AWS_ACCESS_KEY is the value in the Access Key Id column in the .csv file.
   - The value of AWS_SECRET_KEY is the value in the Secret Access Key column of the .csv file.

   NOTE

   - Keep the CSV file properly. You can only download the file right after the access key is created. If you cannot find the file, you can create an access key again.
   - Keep your access keys secure and change them periodically for security purposes.
   - In MRS 3.3.1 and later versions, **AWS_ACCESS_KEY** and **AWS_SECRET_KEY** are replaced with **obs.access_key** and **obs.secret_key**.
3. You can obtain the value of **AWS_REGION** (**obs.region** in MRS 3.3.1 and later versions) from **Regions and Endpoints**.
4. Log in to the OBS management console, click **Parallel File System**, click the name of the OBS parallel file system where the Hive table resides, and view the value of **Endpoint** on the overview page. The value is the same as that of **AWS_ENDPOINT** (**obs.endpoint** in MRS 3.3.1 and later versions) set during catalog creation.

Step 2 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login username* **-p***Database login password* **-P***Database connection port* **-h***IP address of the Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 3 Create a catalog.

- Hive table data is stored in HDFS. Run the following command to create a catalog:
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode):

    CREATE CATALOG hive_catalog PROPERTIES (

    'type'='hms',

    'hive.metastore.uris' = 'thrift://*192.168.67.161:21088***',**

    'hive.metastore.sasl.enabled' = 'true',

    'hive.server2.thrift.sasl.qop' = 'auth-conf',

    'hive.server2.authentication' = 'KERBEROS',

    'dfs.nameservices'='hacluster',

    'dfs.ha.namenodes.hacluster'='*24,25***',**

    'dfs.namenode.rpc-address.hacluster.*24***='** IP address of the active NameNode:RPC communication port **',**

    'dfs.namenode.rpc-address.hacluster.*25***='** IP address of the standby NameNode:RPC communication port **',**

    'dfs.client.failover.proxy.provider.hacluster'='org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider',

    'hive.version' = '3.1.0',

    'yarn.resourcemanager.address' = '*192.168.67.78:26004***',**

    'yarn.resourcemanager.principal' = 'mapred/hadoop.hadoop.com@HADOOP.COM',

    'hive.metastore.kerberos.principal' = 'hive/hadoop.hadoop.com@HADOOP.COM',

    'hadoop.security.authentication' = 'kerberos',

    'hadoop.kerberos.keytab' = '${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-be/bin/doris.keytab',

    'hadoop.kerberos.principal' = 'doris/hadoop.hadoop.com@HADOOP.COM',

    'java.security.krb5.conf' = '${BIGDATA_HOME}/FusionInsight_BASE_*/1_16_KerberosClient/etc/krb5.conf',

    'hadoop.rpc.protection' = 'privacy'

    );

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode):

  CREATE CATALOG hive_catalog PROPERTIES (

  'type'='hms',

  'hive.metastore.uris' = 'thrift://*192.168.67.161:21088***',**

  'hive.version' = '3.1.0',

  'hadoop.username' = 'hive',

  'yarn.resourcemanager.address' = '*192.168.67.78:26004***',**

  'dfs.nameservices'='hacluster',

  'dfs.ha.namenodes.hacluster'='24,25',

  'dfs.namenode.rpc-address.hacluster.24'='192-168-67-172:25000',

  'dfs.namenode.rpc-address.hacluster.25'='192-168-67-78:25000',

  'dfs.client.failover.proxy.provider.hacluster'='org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider'

  );

NOTE

- hive.metastore.uris: URL of Hive MetaStore. The format is **thrift://***<Hive MetaStore IP address>***:***<Port number>*. Multiple values are supported and separated by commas (,).
- dfs.nameservices: NameService name of the cluster. The value can be found in **hdfs-site.xml**, which is in the **${BIGDATA_HOME}/FusionInsight_HD_*/1_*_NameNode/etc** directory where NameNode is deployed.
- dfs.ha.namenodes.hacluster: cluster NameService prefix, which contains two values. The value can be found in **hdfs-site.xml**, which is in the **${BIGDATA_HOME}/FusionInsight_HD_*/1_*_NameNode/etc** directory where NameNode is deployed.
- dfs.namenode.rpc-address.hacluster.*xx1*: specifies the RPC communication address of the active NameNode. You can search for the value of this configuration item in **hdfs-site.xml** in the **${BIGDATA_HOME}/FusionInsight_HD_*/1_*_NameNode/etc** directory on the node where NameNode resides. *xx* is the value of **dfs.ha.namenodes.hacluster**.
- dfs.namenode.rpc-address.hacluster.*xx2*: RPC communication address of the standby NameNode. You can search for the value of this configuration item in **hdfs-site.xml** in the **${BIGDATA_HOME}/FusionInsight_HD_*/1_*_NameNode/etc** directory on the node where NameNode resides. *xx* is the value of **dfs.ha.namenodes.hacluster**.
- To query the IP address of the active/standby instance, choose **Cluster** > **Services** > **HDFS** > **Instances** on FusionInsight Manager.
- The default RPC port number is **25000**. To query it, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**.
- dfs.client.failover.proxy.provider.hacluster: specifies the Java class for the HDFS client to connect to the active node in the cluster. The value is **org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider**.
- hive.version: Hive version. To obtain the version, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Hive**, and view the version on the **Dashboard** page.
- yarn.resourcemanager.address: indicates the IP address of the active ResourceManager instance. On FusionInsight Manager, choose **Cluster** > **Services** > **Yarn** > **Instances** to view the service IP address of the active ResourceManager instance. To obtain the port number, click **Configurations** and search for **yarn.resourcemanager.port** in the search box.
- hadoop.rpc.protection: specifies whether to encrypt the RPC stream of each Hadoop module. The default value is privacy. To obtain the value, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**, and search for **hadoop.rpc.protection**.
- Kerberos authentication is enabled for the cluster (the cluster is in security mode):
  - hive.metastore.sasl.enabled: indicates whether to enable the MetaStore management permission. The value is **true**.
  - hive.server2.thrift.sasl.qop: indicates whether to encrypt the interaction between HiveServer2 and the client. The value is **auth-conf**.
  - hive.server2.authentication: security authentication mode for accessing HiveServer. The value is **KERBEROS**.
  - yarn.resourcemanager.principal: Principal for accessing the Yarn cluster. The value is **mapred/hadoop.hadoop.com@HADOOP.COM**.
  - hive.metastore.kerberos.principal: Principal for accessing the Hive cluster. The value is **hive/hadoop.hadoop.com@HADOOP.COM**.
  - hadoop.security.authentication: security authentication mode for accessing Hadoop. The value is **KERBEROS**.

    - hadoop.kerberos.keytab: keytab for accessing the Hadoop cluster. The value is the path of the **${BIGDATA_HOME}/FusionInsight_Doris_*/install/FusionInsight-Doris-*/doris-be/bin/doris.keytab** file.
    - hadoop.kerberos.principal: Principal for accessing the Hadoop cluster. The value is **doris/hadoop.hadoop.com@HADOOP.COM**.
    - java.security.krb5.conf: krb5 file. The value is the path of the **${BIGDATA_HOME}/FusionInsight_BASE_*/1_*_KerberosClient/etc/krb5.conf** file.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode):

    hadoop.username: user name for accessing the Hadoop cluster. The value is **hdfs**.

- Hive table data is stored in OBS. Run the following command to create a catalog. For details about related parameter values, see **Step 1**.

  CREATE CATALOG *hive_obs_catalog* **PROPERTIES (**

  'type'='hms',

  'hive.version' = '3.1.0',

  'hive.metastore.uris' = 'thrift://*192.168.67.161:21088***',**

  'hive.metastore.sasl.enabled' = 'true',

  'hive.server2.thrift.sasl.qop' = 'auth-conf',

  'hive.server2.authentication' = 'KERBEROS',

  'dfs.nameservices'='hacluster',

  'dfs.ha.namenodes.hacluster'='*24***,***25***',**

  'dfs.namenode.rpc-address.hacluster.*24***='** *IP address of the active NameNode:RPC communication port* **',**

  'dfs.namenode.rpc-address.hacluster.*25***='** *IP address of the standby NameNode:RPC communication port* **',**

  'dfs.client.failover.proxy.provider.hacluster'='org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider',

  'yarn.resourcemanager.address' = '*192.168.67.78:26004***',**

  'yarn.resourcemanager.principal' = 'mapred/hadoop.hadoop.com@HADOOP.COM',

  'hive.metastore.kerberos.principal' = 'hive/hadoop.hadoop.com@HADOOP.COM',

  'hadoop.security.authentication' = 'kerberos',

  'hadoop.kerberos.keytab' = '${BIGDATA_HOME}/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-be/bin/doris.keytab',

  'hadoop.kerberos.principal' = 'doris/hadoop.hadoop.com@HADOOP.COM',

  'java.security.krb5.conf' = '${BIGDATA_HOME}/FusionInsight_BASE_*/1_16_KerberosClient/etc/krb5.conf',

  'AWS_ACCESS_KEY' = '*AK***',**

  'AWS_SECRET_KEY' = '*SK***',**

  'AWS_ENDPOINT' = ' Endpoint address of the OBS parallel file system **',**

  'AWS_REGION' = '*sa-fb-1***',**

  'hadoop.rpc.protection' = 'privacy'

  );

Step 4 Run the following command to query the Hive table:

- Run the following command to query Catalog:
  show catalogs;
- Run the following command to query the database in the Catalog:
  show databases from *hive_catalog*;
- Run the following command to switch to the Catalog and access the database:
  switch *hive_catalog*;
  use *default*;
- To query all tables in a database in Catalog, run the following command:
  show tables from **`***hive_catalog***`.`***default***`;**
  To query a specified table, run the following command:
  select * from **`***hive_catalog***`.`***default***`.`***test_table***`;**
  Run the following command to view the schema of the table:
  DESC *test_table*;

Step 5 After creating or operating a Hive table, you need to refresh the table in the Doris.

refresh catalog *hive_catalog*;

Step 6 Run the following command to perform associated query with tables in other data directories:

SELECT h.h_shipdate FROM *hive_catalog.default.htable* **h WHERE h.h_partkey IN (SELECT p_partkey FROM internal.db1.part) LIMIT 10;**

NOTE

- A table is identified in **catalog.database.table** full restriction mode, for example, internal.db1.part.
- **catalog** and **database** can be omitted. By default, the Catalog and Database after the switchover of **SWITCH** and **USE** are used.
- You can run the **INSERT INTO** command to insert table data in Hive Catalog to an internal table in Interal Catalog to import external data catalog data.

----End

5.7.2.3 Interconnecting Doris with the Hudi Data Source

When MRS cluster metadata is stored in Hive MetaStore, Doris 2.0.13 can connect to data sources of Hudi 0.15.0 using Catalog and supports all data field types of Hudi.

Hudi Table Types Can Be Queried by Doris

The supported Hudi table types and corresponding query types are as follows:

- COW table: Snapshot Query and TimeTravel Query
- MOR table: Snapshot Query, TimeTravel Query, and Read Optimized Query

The following uses TimeTravel Query as an example to describe how to query a Hudi COW table.

Step 1 Log in to the node where MySQL is installed and connect the Doris database.

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect the database.

Step 2 Create a Hudi Catalog, for example, **hudi_catalog**. For details about how to create, see **Step 3**.

Step 3 Connect the MySQL client to Doris by referring to **Step 1** and run the following command to switch to the Hudi Catalog created in **Step 2**:

switch *hudi_catalog*;

Step 4 Run the following command to view the created Hudi table:

refresh catalog *hudi_catalog*;

use *Database name*;

show tables;

Step 5 Use TimeTravel Query to view the table data inserted before a certain time:

select * from *hudi_cow* **for time as of** '*20240409162842365*' **where id =** *1*;

----End

Doris on Hudi Query Acceleration

Doris on Hudi supports the following query acceleration:

- Bucket Shuffle Joins on Hudi Parquet Table

  Bucket Shuffle Join is available in Doris to accelerate the queries on Hudi data sources. This operation is supported for all Hudi field types and Hudi tables stored on OBS. The session-level variable **enable_hudi_bucket_shuffle** controls whether to enable this function, which is defaulted to disabled. You can connect to Doris and run the **set enable_hudi_bucket_shuffle=true** command to enable this function.

NOTE

- The inner join condition contains bucketing columns of two tables. When the bucketing columns of the left table are inner join conditions, there is a high probability that bucket shuffle join is planned.
- The type of the bucketing column in the left table must be the same as that of the inner join column in the right table.
- The bucket shuffle join function is available only in inner joins.
- The bucket shuffle join function is available only when the left table has a single partition.
- Two tables to be joined, one can be a Hudi table, and the other can be a Doris internal table.

- Hudi Implicit Partitioning (Restricted Feature)

  Doris supports Hudi's implicit partitioning for query acceleration. You can use **the enable_hudi_hidden_partition** parameter to enable or disable this function (which is disabled by default). To enable it, run the **ADMIN SET FRONTEND CONFIG ("enable_hudi_hidden_partition" = "true");** command after connecting to Doris.

- Hudi Table Bucket Pruning (Restricted Feature)

  Doris supports Hudi bucket pruning for faster queries. You can use **enable_hudi_bucket_prunning** parameter to enable or disable this function (which is disabled by default). To enable it, run the **ADMIN SET FRONTEND CONFIG ("enable_hudi_bucket_prunning" = "true");** command after connecting to Doris.

Step 1 Log in to the node where MySQL is installed and connect the Doris database.

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect the database.

Step 2 Create a Hudi Catalog, for example, **hudi_catalog**. For details about how to create, see **Step 3**.

Step 3 Connect to Doris on the MySQL client by referring to **Step 1** and run the following command to switch to Hudi Catalog:

switch *hudi_catalog*;

Step 4 Run the following commands to view the created Hudi table:

refresh catalog *hudi_catalog*;

use *Database name*;

show tables;

Step 5 Enable Doris on Hudi query acceleration and perform a query.

- Enable Bucket Shuffle Join and perform a query.

  Only Hudi bucket index tables are supported. That is, the Hudi table to be queried has the **hoodie.index.type='BUCKET'**, **hoodie.bucket.index.num.buckets='***xxx***'** and **hoodie.bucket.index.hash.field='***xxx***'** properties.

  set enable_hudi_bucket_shuffle = true;

  select t1.name, t2.age from *hudi_testt1* **t1,** *hudi_testt2* **t2 where t1.id=t2.id;**

  NOTE

  Check whether the Bucket Shuffle Join is hit.

  explain select t1.name, t2.age from *hudi_testt1* **t1,** *hudi_testt2* **t2 where t1.id=t2.id;**

  Check whether the keyword **BUCKET_SHUFFLE** exists in the command output. If it exists, the query hits the Bucket Shuffle Join.

- Enable implicit partitioning and query a Hudi table.

  Only implicitly partitioned Hudi tables are supported. That is, Hudi table to be queried has the **hoodie.hidden.partitioning.rule = '***xxx***'** and **hoodie.hidden.partitioning.enabled = 'true'** properties.

  ADMIN SET FRONTEND CONFIG ("enable_hudi_hidden_partition" = "true");

  select * from hudi1 where col0 like '%2';

- Enable the bucket pruning function and query a Hudi table.

  Only Hudi simple bucket index tables are supported. That is, the Hudi table to be queried has the **hoodie.index.type = 'BUCKET'**, **hoodie.bucket.index.num.buckets = '***xxx***'**, **hoodie.bucket.index.hash.field = '***xxx***'**, **hoodie.index.bucket.engine = 'SIMPLE'**, and **hoodie.metadata.index.column.stats.enable = 'true'** properties.

  ADMIN SET FRONTEND CONFIG ("enable_hudi_bucket_prunning" = "true");

  select * from hudi_cow_tbl where id > 1 and id < 3;

----End

5.7.2.4 Configuring Spark to Read and Write Doris Data

The Spark Doris Connector can read data stored in the Doris through Spark and write data to the Doris through Spark.

- Data can be read from the Doris.
- Spark DataFrame can be written to Doris in batches or in streaming mode.
- You can map a Doris table to a DataFrame or RDD. DataFrame is recommended.

- Data can be filtered at the Doris end to reduce the amount of data to be transferred.
- The operations in this section are applicable to MRS 3.5.0 and later versions.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- The Spark client has been installed.

Procedure

Create a table in Doris and insert data into the table.

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login username* **-p***Database login password* **-P***Database connection port* **-h***IP address of the Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following commands to create a database and switch the database:

create database if not exists *sparkconnector*;

use *sparkconnector*;

Step 3 Run the following statement to create a table:

CREATE TABLE *spark_connector_test_decimal* **(**

c1 int NOT NULL,

c2 VARCHAR(25) NOT NULL,

c3 VARCHAR(152),

c4 boolean,

c5 tinyint,

c6 smallint,

c7 bigint,

c8 float,

c9 double,

c10 date,

c11 datetime,

c12 char,

c13 largeint,

c14 varchar,

c15 decimal(15, 5)

)

DUPLICATE KEY(`c1`)

COMMENT "OLAP"

DISTRIBUTED BY HASH(`c1`) BUCKETS 1;

Step 4 Run the following commands to insert data to the table:

insert into *spark_connector_test_decimal* **values(10000,'aaa','abc',true, 100, 3000, 100000, 1234.567, 12345.678, '2022-12-01','2022-12-01 12:00:00', 'a', 200000, 'g', 1000.12345);**

insert into *spark_connector_test_decimal* **values(10001,'aaa','abc',false, 100, 3000, 100000, 1234.567, 12345.678, '2022-12-01','2022-12-01 12:00:00', 'a', 200000, 'g', 1000.12345);**

insert into *spark_connector_test_decimal* **values(10002,'aaa','abc',True, 100, 3000, 100000, 1234.567, 12345.678, '2022-12-01','2022-12-01 12:00:00', 'a', 200000, 'g', 1000.12345);**

insert into *spark_connector_test_decimal* **values(10003,'aaa','abc',False, 100, 3000, 100000, 1234.567, 12345.678, '2022-12-01','2022-12-01 12:00:00', 'a', 200000, 'g', 1000.12345);**

Perform operations on Spark.

Step 5 Run the following command to log in to the spark-sql client:

cd Spark client installation directory

source bigdata_env

kinit *Component service user* (skip this step if Kerberos authentication is disabled for the cluster (the cluster is in normal mode))

spark-sql --master yarn

Step 6 Run the following command to create a temporary view:

CREATE TEMPORARY VIEW *spark_doris_decimal*

USING doris

OPTIONS(

"table.identifier"="sparkconnector.spark_connector_test_decimal",

"fenodes=" FE instance IP address **:***Port number***",**

"user"="*dorisuser***",**

"password"="*User password***",**

'doris.enable.https' = 'true',

'doris.ignore.https.ca' = 'true'

);

Run the following command to query the data in the Doris table:

select * from *spark_doris_decimal***;**

Run the following command to insert data into the Doris table:

insert into *spark_doris_decimal* **values(10005,'aaa','abc',False, 100, 3000, 100000, 1234.567, 12345.678, '2022-12-01','2022-12-01 12:00:00', 'a', 200000, 'g', 1000.12345);**

NOTE

- After switching to HTTP, delete the following configuration parameters from the WITH clause for creating a table:
  - **'doris.enable.https' = 'true'**
  - **'doris.ignore.https.ca' = 'true'**
- The port number is the HTTPS port of the FE service (for clusters with Kerberos authentication enabled) or HTTP port (for clusters with Kerberos authentication disabled). You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and enter **https_port** or **http_port** in the search box.
- When the amount of data to be imported is too large, you can adjust the following parameters to improve the performance:
  - **sink.batch.size**: maximum number of rows that can be written to a BE at a time. The default value is **10000**.
  - **doris.sink.batch.interval.ms**: indicates the interval between each batch of sinks, in milliseconds. The default value is **50**.

----End

5.7.2.5 Configuring Flink to Read and Write Doris Data

Flink Doris Connector allows you to perform operations (read, insert, modify, and delete) on data stored in Doris through Flink.

NOTE

- Only tables of the Unique Key model can be modified or deleted.
- The operations in this section are applicable to MRS 3.5.0 and later versions.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    Log in to FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permissions, and bind the role to the user.

    Log in to FusionInsight Manager as the created **dorisuser** user, and change the initial password.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- The Flink client has been installed.

Procedure

Doris side operation.

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login username* **-p***Database login password* **-P***Database connection port* **-h***IP address of the Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following commands to create a database and switch the database:

create database if not exists *testdb***;**

use *testdb***;**

Step 3 Run the following commands to create the **z_test** table and insert data into the table:

create table *z_test***(id int, name string) distributed by hash(id) buckets 10;**

insert into *z_test* **values(123, 'aaa'), (234, 'bbb'), (345, 'ccc');**

Step 4 Run the following command to create the **z_test_sink_3** table:

create *table z_test_sink_3***(id int, name string) distributed by hash(id) buckets 10;**

Perform operations on Flink.

Step 5 Log in to the node where the Flink client is installed as the client installation user and run the following command:

cd *Client installation directory*

source bigdata_env

kinit *Component service user* (If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), skip this step.)

Step 6 Run the following command to log in to the Flink SQL client:

cd Flink/flink/bin/

sql-client.sh

Step 7 Create a stream or batch Flink streaming SQL job on the Flink client. The following command is an example:

CREATE TABLE *flink_doris_source* **(id INT, name STRING) WITH (**

'connector' = 'doris',

'fenodes' ='FE instance IP address:*Port number*',

'table.identifier' = 'testdb.z_test',

'username' = '*user***',**

'password' = '*password***',**

'doris.enable.https' = 'true',

'doris.ignore.https.ca' = 'true'

);

CREATE TABLE *flink_doris_sink* **(id INT, name STRING) WITH (**

'connector' = 'doris',

'fenodes' = ' FE instance IP address **:***Port number***',**

'table.identifier' = 'testdb.z_test_sink_3',

'username' = '*user***',**

'password' = '*password***',**

'sink.label-prefix' = 'doris_label_6',

'doris.enable.https' = 'true',

'doris.ignore.https.ca' = 'true'

);

Run the following commands to insert data:

INSERT INTO

flink_doris_sink

select

id,

name

from

*flink_doris_source***;**

NOTE

- After HTTPS is enabled, add the following configuration parameters to the **with** clause for creating a table:
  - **'doris.enable.https' = 'true'**
  - **'doris.ignore.https.ca' = 'true'**
- The fields in the source and sink tables must be the same as those in the Doris table.
- The port number is the HTTPS port of the FE service (for clusters with Kerberos authentication enabled) or HTTP port (for clusters with Kerberos authentication disabled). You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and enter **https_port** or **http_port** in the search box.
- When you create a Flink job, set **username** to the Doris user and **password** to the password of the Doris user.
- If Kerberos authentication (security mode) has been enabled for the cluster, only the HTTPS mode can be configured.

----End

5.7.2.6 Connecting to the MySQL/Doris Data Source Through JDBC Catalog

Scenario

JDBC Catalog can connect to data sources such as MySQL and Doris through the standard JDBC protocol. This topic describes how to use JDBC Catalog to read MySQL or Doris data.

The operations in this section are applicable to MRS 3.3.1 and later versions.

Prerequisites

- An MRS cluster has been created and the Doris service has been deployed.
- A source cluster, for example, a MySQL server cluster, has been prepared.
- The Doris cluster can communicate with the MySQL server cluster.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Querying MySQL/Doris Data Through JDBC Catalog

Step 1 Visit the MySQL official website at **https://www.mysql.com/**, choose **DOWNLOADS** > **MySQL Community(GPL) DownLoads** > **Connector/J**, and download the driver package of the required version.

NOTE

The recommended MySQL driver version is 5.1.*x* or later.

Step 2 Upload the downloaded MySQL driver package to the same directory on all FE and BE nodes, for example, **/home/omm**, and change the owner group of the driver package to **omm:wheel**.

NOTE

If Doris FE and BE are deployed on the same nodes, upload the MySQL driver package to the **${BIGDATA_HOME}/FusionInsight_Doris_*/install/FusionInsight-Doris-*/doris-fe/jdbc_drivers/** directory.

Step 3 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations** > **FE(Role)** > **Customization**.

Step 4 Add the **jdbc_drivers_dir** parameter to the custom parameter **fe.conf.customized.configs**. The value is the directory where the driver package uploaded to in **Step 2**, for example, **/home/omm**.

Step 5 Choose **All Configurations** > **BE(Role)** > **Customization**. Add the **jdbc_drivers_dir** parameter to the **fe.conf.customized.configs** parameter and set it to the directory where the driver package uploaded to in **Step 2**, for example, **/home/omm**.

Step 6 Search for the **enable_udf_sandbox** parameter of BE and set it to **false**.

Step 7 Click **Save**. On the **Dashboard** page, click **More** > **Restart Service** in the upper right corner. Enter the password of the user and click **OK** to restart the Doris service.

Step 8 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the service IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect to the database.

Step 9 Create a JDBC catalog in the target Doris cluster.

- If the source cluster is a MySQL server and Kerberos authentication is disabled for the target Doris cluster, run the following commands:

  CREATE CATALOG *doris_jdbc_catalog* **PROPERTIES (**

  "type"="jdbc",

  "user"=" *MySQL username* **",**

  "password"="*MySQL user password***",**

  "jdbc_url" = "jdbc:mysql://*IP address of MySQL*:*MySQL port* **?useSSL = false",**

  "driver_url" = "mysql-connector-java-*xxx***.jar",**

  "driver_class" = "com.mysql.jdbc.Driver"

  );

- If both the source and destination are MRS Doris clusters and Kerberos authentication is disabled for the clusters, run the following commands:

  CREATE CATALOG *doris_jdbc_catalog* **PROPERTIES (**

  "type"="jdbc",

  "user"=" *Doris username* **",**

  "password"="*Doris user password***",**

  "jdbc_url" = "jdbc:mysql:// *IP address of the source Doris FE instance*:*FE query connection port* **?useSSL = false",**

  "driver_url" = "mysql-connector-java-*xxx***.jar",**

  "driver_class" = "com.mysql.jdbc.Driver"

  );

- If both the source and destination are MRS Doris clusters and Kerberos authentication is enabled for the clusters, run the following commands:

  CREATE CATALOG *doris_jdbc_catalog* **PROPERTIES (**

  "type"="jdbc",

  "user"=" *Doris username* **",**

  "password"="*Doris user password***",**

  "jdbc_url" = "jdbc:mysql://*IP address of the source Doris FE instance*:*FE query connection port***?allowPublicKeyRetrieval=true&useSSL=true&verifyServerCertificate=false"**

  ,

  "driver_url" = "mysql-connector-java-*xxx***.jar",**

  "driver_class" = "com.mysql.jdbc.Driver"

  );

NOTE

- If the MySQL driver version is 6.x or later, add the **serverTimezone=GMT%2B8** parameter to **jdbc_url** when creating a JDBC catalog to prevent creation failure caused by time zone inconsistency between the source cluster and the current Doris cluster.
- If the MySQL driver version is 6.x or later, the value of **driver_class** is **com.mysql.cj.jdbc.Driver**. If the MySQL driver version is 5.x, the value of **drive_class** is **com.mysql.jdbc.Driver**.
- To obtain the query connection port of the Doris FE instance, you can log in to Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance on the source cluster, log in to the Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.

Step 10 Run the following commands to switch to the newly created catalog and view the database:

switch doris_jdbc_catalog;

show databases;

If the MySQL database name and table name are displayed in the command output, Doris can access the MySQL cluster through JDBC Catalog.

----End

5.7.3 Configuring Doris Multi-Tenancy

5.7.3.1 Overview

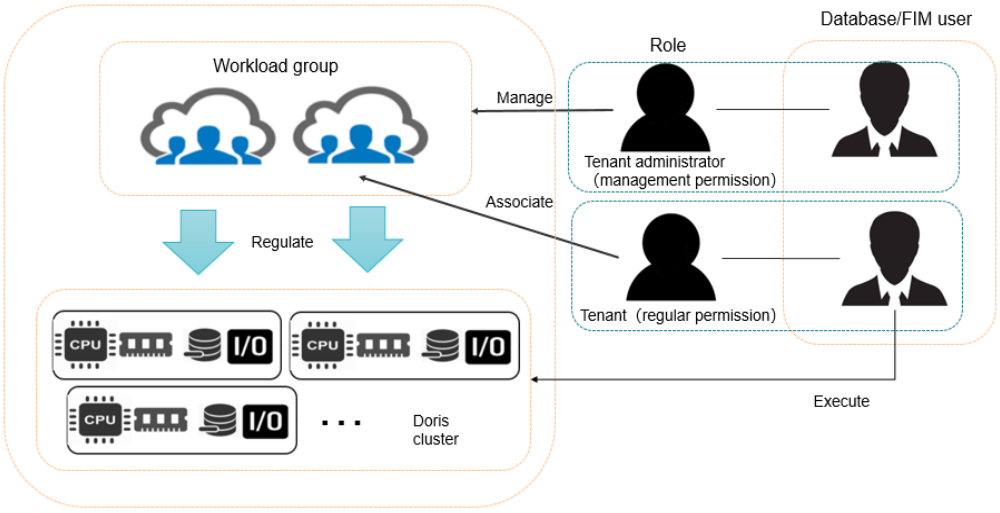
Doris Multi-Tenancy

Doris multi-tenancy is built on top of the Workload Group Resource soft limit of the kernel. Workloads are managed by group to ensure flexible allocation and control of memory and CPU resources. Each tenant role of a user can have many workload groups. You can manage CPU, memory, concurrency, and queues with this model shown in **Figure 5-2**.

NOTE

- (This feature is available for MRS 3.3.1 or later only.)
- Multiple tenants can be created and managed only on FusionInsight Manager when Kerberos authentication is enabled for the cluster (the cluster is in security mode).
- In MRS 3.5.0 and later versions: The default memory usage of the **normal** tenant is 90%, and the number of concurrent requests is 10,000.

Figure 5-2 Doris tenant model

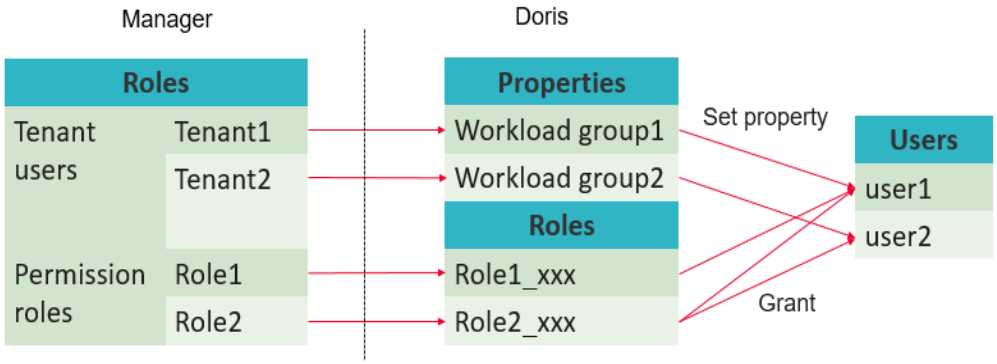


After a user is associated with a tenant, all query tasks submitted by the user are added to the workload group. You can limit the percentage of CPU and memory resources on BE nodes for a single query and configure a soft memory limit for the workload group.

When cluster resources are insufficient, the system automatically stops several query tasks that occupy memory the most in the group. If the resources used by a workload group exceed the preset limit, multiple workloads share idle resources in the cluster and use resources more than the limit. This ensures stable execution of query tasks. In addition, the query queuing function is introduced to relieve system pressure in heavy-load scenarios. When creating a workload group, you can set the maximum number of concurrent queries to queue the exceeding queries.

Associations Between Doris Tenant Roles and Users

On the FusionInsight Manager service configuration and tenant management pages, you can create tenants, associate tenants with services, configure tenant resources, and associate tenants with users. The following figure shows the association between roles and users on the Manager and Doris sides.



A user, a tenant role, and a workload group are in one-on-one relationship. A user can have multiple permission roles.

Table 5-6 lists the Doris tenant resource configurations supported by the current version.

Table 5-6 tenant resource configuration

Configuration	Value Range	Description	Remarks
CPU Quota Usage	1 to 100	Weight of CPU resources that can be used by a tenant	The value specifies a relative ratio that is valid during resource competition. For example, if this value for tenant A is 10 and that for tenant B is 20, the CPU resources can be used by the query tasks of tenant A is one-third of total resources, that is, 10/(10 + 20). If tenant C starts query tasks and its CPU quota usage is 30, a CPU quota of tenant A is one-sixth of total resources, that is, 10/(10 + 20 + 30).

Configuration	Value Range	Description	Remarks
Memory Quota	• MRS 3.3.1: 1%~70% • MRS 3.5.0 and later versions: 1%~90%	Maximum proportion of memory that can be used by a tenant	The available memory of a tenant is calculated as follows: Physical memory x **mem_limit** x Memory quota. The upper limit of the memory quota is 70% (90% for MRS 3.5.0 and later versions). The default Doris tenant **normal** occupies 70% (90% for MRS 3.5.0 and later versions) of memory.
Concurrency	• MRS 3.3.1: 1~2147483647 • MRS 3.5.0 and later versions: 1~10000	Maximum number of concurrent query tasks that a tenant can run	This parameter specifies the maximum number of tasks on each FE node. For example, if the number of concurrent SQL statements is set to 1 and the Doris has three FE nodes, the maximum number of SQL statements that can be executed in a cluster is 3.
Queue Length	• MRS 3.3.1: 0~2147483647 • MRS 3.5.0 and later versions: 0~1000	Maximum number of waiting query tasks	Excessive SQL statements are queued. When the queue is full, newly submitted queries are rejected.
Waiting Duration	• MRS 3.3.1: 0~2147483647 • MRS 3.5.0 and later versions: 0~86400000	Maximum waiting duration of a tenant query task	If the query waiting duration exceeds the value of this parameter, the query is rejected. The unit is millisecond.

Configuration	Value Range	Description	Remarks
Soft Memory Limit	• On • Off	Whether a tenant can use more memory resources than the limit	• If this function is disabled, the system immediately cancels the tasks that occupy the most memory in the tenant groups when detecting that the memory usage of the tenant exceeds the upper limit. • If this function is enabled and the cluster has idle memory resources, the tenant can use the system memory more than the limit. The tasks that occupy the most memory in the tenant groups are canceled only when cluster resources are insufficient.

5.7.3.2 Managing Doris Tenants

The cluster administrator can create a Doris tenant on FusionInsight Manager.

Creating a Doris Tenant

Step 1 Log in to FusionInsight Manager and choose **Tenant Resources**.

Step 2 On the **Tenant Resources Management** page, click . On the displayed page, configure tenant properties by referring to **Table 5-7**.

Table 5-7 Tenant parameters

Parameter	Description
Name	Specify the name of the current tenant. The value can contain 3 to 50 characters but cannot contain only digits. Only digits, letters, and underscores (_) are allowed. Plan a tenant name based on service requirements. The name cannot be the same as that of a role, HDFS directory, or YARN queue that exists in the current cluster.
Tenant Type	Select **Leaf Tenant**. **NOTE** A Doris tenant can only be a leaf tenant.

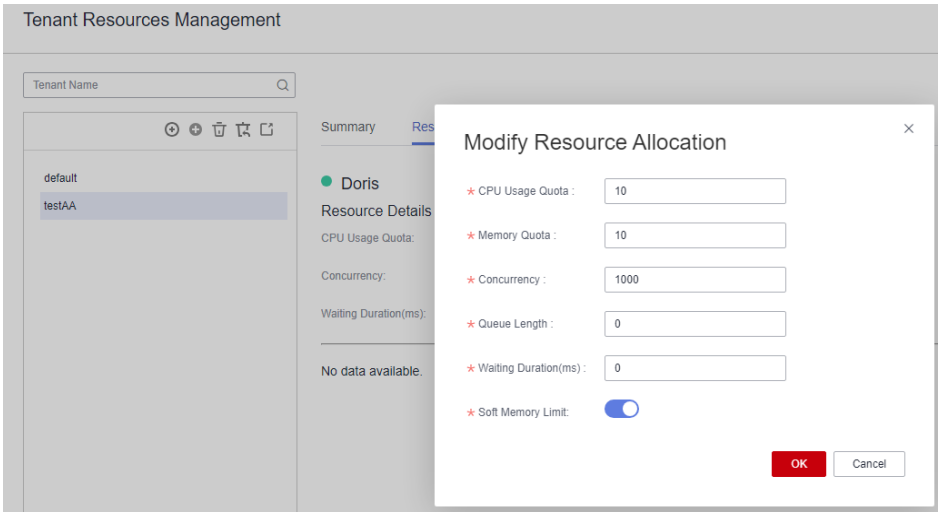
Parameter	Description
Compute Resource	Do not select **Yarn** if only Doris-related tenants are created.
Storage Resource	Do not select **HDFS** if only Doris-related tenants are created.
Service	Click **Associate Service**. In the displayed dialog box, set the following parameters and click **OK**: • **Service**: Select **Doris**. • **Association Type**: Maintain the default option **Shared**. For details about the following parameters, see **Table 5-6**. • **CPU Usage Quota**: specifies the weight of CPU resources occupied by a tenant. This parameter is valid during resource competition. • **Memory Quota**: specifies the maximum percentage of memory resources occupied by a tenant. For example, if this parameter is set to 10, the available memory of the tenant on each BE node is 10% of the available memory on the BE node. The default Doris tenant **normal** occupies 90% of the resources. Therefore, for other tenants this parameter can be set up to 10%. If the sum exceeds 100%, the Doris tenant fails to be created. • **Concurrency**: specifies the maximum number of concurrent query tasks a tenant can run. Excessive query tasks are queued. • **Queue Length**: specifies the maximum number of query tasks waiting in the queue. • **Waiting Duration**: specifies the maximum waiting duration of a query task. The unit is milliseconds. • **Soft Memory Limit**: By default, soft memory limit is disabled. If this option is enabled and when resources are sufficient, query tasks can use resources more than the limit. When resources are insufficient, the occupied memory is released. If this function is disabled and when the memory limit of a workload group is reached, som SQL statements will be canceled or rejected.
Description	Description of the tenant.

Step 3 Click **OK**. Wait until the tenant is created.

Step 4 View and modify the tenant in the **Tenant Resources Management** page.

1. On FusionInsight Manager, click **Tenant Resources**. In the tenant list, select the desired Doris tenant and view the tenant information and the resource quota.

2. Click **Resource** and click next to **Resource Details** to modify tenant resources.



3. Click **OK**. The details are displayed in the **Resource** tab.

NOTE

- In the **Summary** tab, resource quota is not updated in real time. It is updated only when it is loaded.
- A Doris tenant represents a workload group, which limits the compute resources of tasks in the group on a single instance node. The **Resource Quota** and **Chart** information show monitoring data of the average metric values. The chart is refreshed every 30 seconds.

----End

Associating an Existing Tenant with Doris and a User

Step 1 On FusionInsight Manager, choose **Tenant Resources**. In the tenant list, select the desired tenant, click the **Service Associations** tab, and click **Associate Service**.

Step 2 On the displayed dialog box, set **Service** to **Doris**, set other parameters as you need, and click **OK** to associate the tenant with the Doris service.

Step 3 Click the **User** tab, and then click **Associate User** on the displayed page. Associate the tenant with a user, and click **OK**.

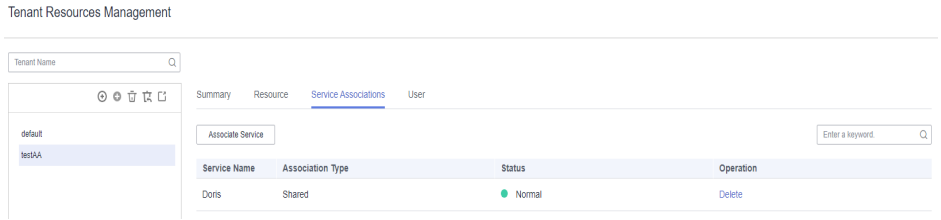
NOTE

- You can also create a user or associate a tenant with an existing user on the user list page by referring to **Adding a User and Binding It to a Tenant**.
- A tenant can be associated with multiple users.
- Doris tenants can be associated with human-machine and machine-machine users created on Manager.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), associate the tenant with a human-machine user.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), associate the tenant with a machine-machine user.
- If a common Doris user is associated (that is, the role of the user does not have the Doris administrator permission), the following error is reported when the user connects to Doris on the MySQL client, creates a table, and queries the table data:
  ERROR 1227 (42000): errCode = 2, detailMessage = Access denied; you need (at least one of) the USAGE/ADMIN privilege(s) to use workload group '*Tenant name*'.

  Connect to Doris on the MySQL client as a user with the Doris administrator permission and run the following command to grant permission to the current user:

  GRANT USAGE_PRIV ON workload group '*Tenant name* **' to '***User ame* **';**

Step 4 To disassociate the Doris service, click **Delete** in the **Operation** column of the Doris service. In the displayed dialog box, click **OK**.



NOTE

After a tenant is disassociated from the Doris service, the workload group of the Doris kernel is deleted, and the workload group of the users bound to the tenant is also set to **normal**.

----End

Adding a User and Binding It to a Tenant

- Create a user and bind it to a tenant: Log in to FusionInsight Manager, choose **System** > **Permission** > **User**, click **Create**, add a human-machine user (a machine-machine user if Kerberos authentication is disabled for the cluster (the cluster is in normal mode)), and add the created Doris tenant to the role.
- Bind a tenant to an existing user: Log in to FusionInsight Manager, choose **System** > **Permission** > **User**, click **Modify** in the **Operation** column of the user, and add the created Doris tenant to the role.

NOTE

- To delete a Doris tenant, choose **System** > **User**, locate the row that contains the user in the user list, click **Modify**, and delete the Doris tenant bound added to the role.
- A user cannot be bound to multiple Doris tenants. For example, if **user1** has been associated with **tenant1** of **Doris**, unbind **user1** from **tenant1** and then associate **user1** with **tenant2**.
- If Kerberos authentication is enabled for the cluster (the cluster is in security mode), associate a human-machine user with a Doris tenant. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), associate a machine-machine user with the Doris tenant.
- If a common Doris user is associated (that is, the role of the user does not have the Doris administrator permission), the following error is reported when the user connects to Doris on the MySQL client, creates a table, and queries the table data:
  ERROR 1227 (42000): errCode = 2, detailMessage = Access denied; you need (at least one of) the USAGE/ADMIN privilege(s) to use workload group '*Tenant name*'.

  Connect to Doris on the MySQL client as a user with the Doris administrator permission and run the following command to grant permission to the current user:

  GRANT USAGE_PRIV ON workload group '*Tenant name* **' to '***User ame* **';**

5.7.3.3 Multi-Tenancy Alarms

Doris multi-tenancy is built on top of the Workload Group Resource soft limit of the kernel. Workload groups only restrict the compute and memory resources used by tasks in a group on a single BE node. There is no resource pool for tenants. When query tasks are executed, resources are dynamically allocated to each BE node.

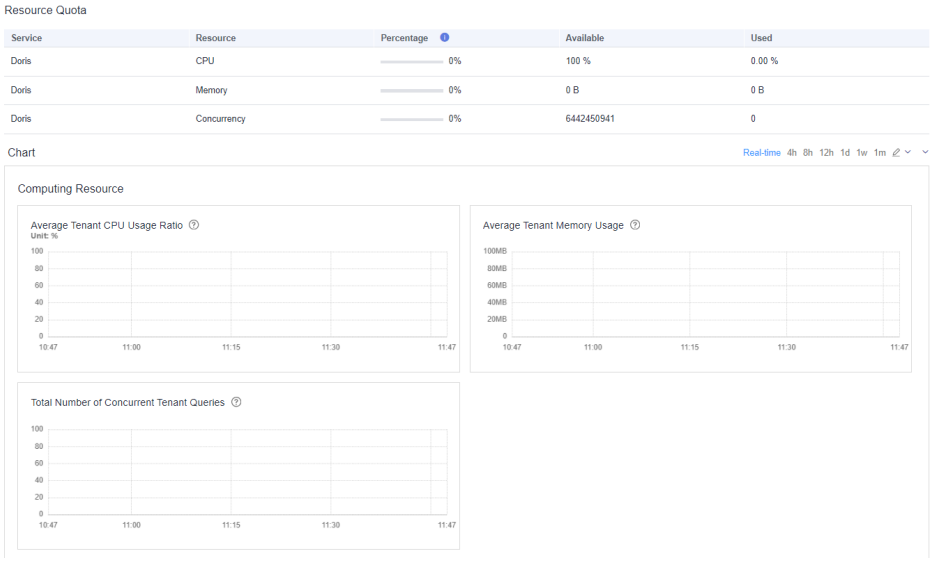
Doris multi-tenancy alarms are reported for nodes. The monitoring metric data can be aggregated by service or tenant.

Multi-Tenancy Monitoring

- Tenant monitoring

  On the FusionInsight Manager homepage, click **Tenant Resources**. In the tenant list, click the name of a Doris tenant. In the **Summary** tab, you can view monitoring information of the tenant in the **Resource Quota** and **Chart** areas.

  - CPU: average CPU usage of all BE nodes used by the tenant
  - Memory: average memory usage of all BE nodes used by the tenant
  - Concurrency: total number of concurrent queries on all FE nodes used by the tenant

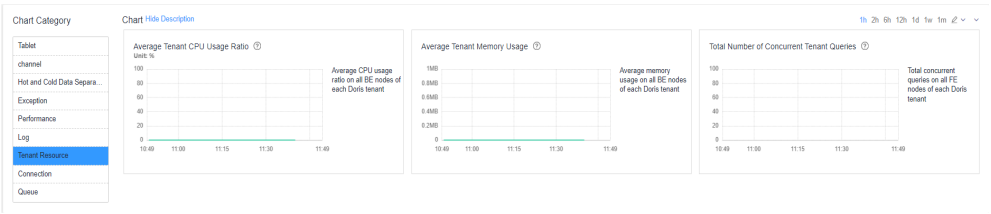


NOTE

- Resource quota is not refreshed in real time. The resource usage is queried only when you go to the **Summary** tab. The monitoring is in real time but monitoring data is refreshed every 30 seconds.
- The **Average Tenant CPU Usage Ratio** chart shows the average percentage of the time when the query tasks of the tenant occupy the CPU resources of all BE nodes.
- The number of FEs is not counted when jobs are queued. Therefore, the number of concurrent queries set by a tenant takes effect only on FE nodes. The**Total Number of Concurrent Tenant Queries** chart indicates the overall number of concurrent queries of a tenant.

- Service monitoring

  On the FusionInsight Manager homepage, choose **Cluster** > **Services** > **Doris** and click **Chart**. In **Chart Category**, select **Tenant Resource** to view the resource usage of all Doris tenants.



- Instance monitoring

  On the FusionInsight Manager homepage, choose **Cluster** > **Services** > **Doris** and click **Instances**, click the FE or BE instance of the desired tenant. In the **Chart** tab, select **Tenant Resource** from **Chart Category**. You can view the node resources used by all tenants.

Figure 5-3 FE instance resource monitoring

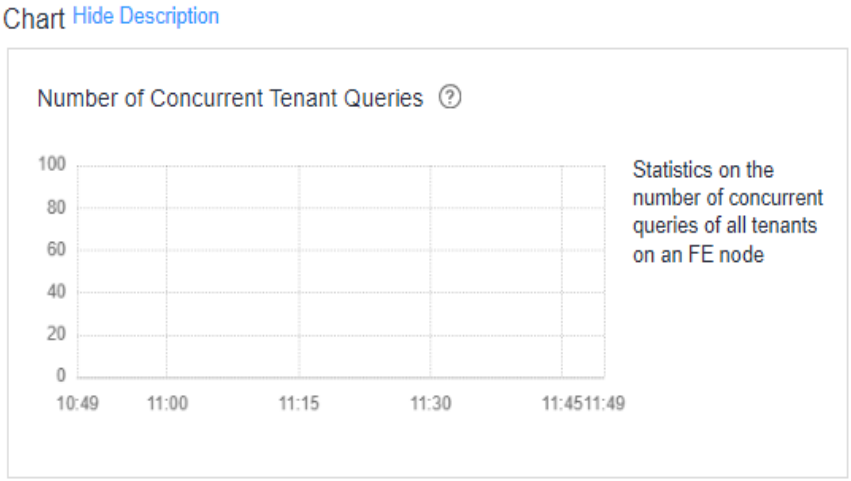


Figure 5-4 BE instance resource monitoring

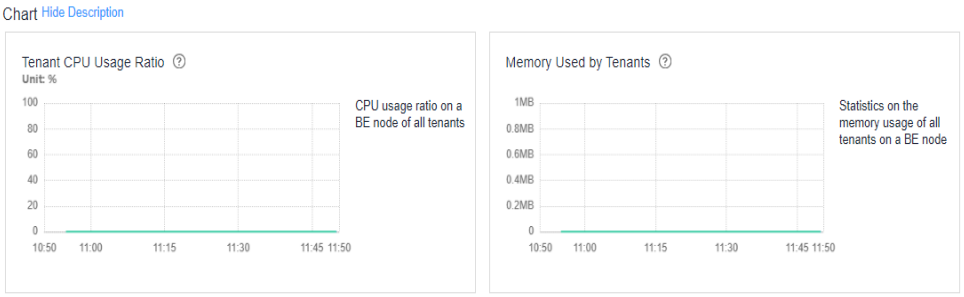


Multi-Tenancy Alarms

Doris multi-tenancy alarms include:

- Number of concurrent requests (alarm ID: 50227): The alarm is generated when the number of concurrent tenant requests on an FE node exceeds the threshold (90% by default).
- Memory usage (alarm ID: 50228): The alarm is generated when the memory usage of a BE node exceeds the threshold (90% for critical alarms and 85% for major alarms).

NOTE

- The memory usage alarm is generated only for tenants who disabled soft memory soft limit.
- On FusionInsight Manager, choose **O&M** > **Alarm** > **Alarms**, click on the left of an alarm name, and determine the role and node for which the alarm is generated in the **Location** field. To identify the tenant for which the alarm is generated, view the monitoring chart on the FE or BE node for which the alarm is generated.

5.7.4 Doris Cold and Hot Data Separation

5.7.4.1 Introduction

For data analysis, it is common to query hot and cold data at varying frequencies and response speed. For example, to analyze user behavior, traffic data must be frequently queried and and the requests need to be quickly responded. Historical data that is seldomly accessed needs to be backed up over a long period for audit and backtracking. Query demands on such data decrease sharply as time goes by. If all data is stored locally, a large number of resources will be wasted.

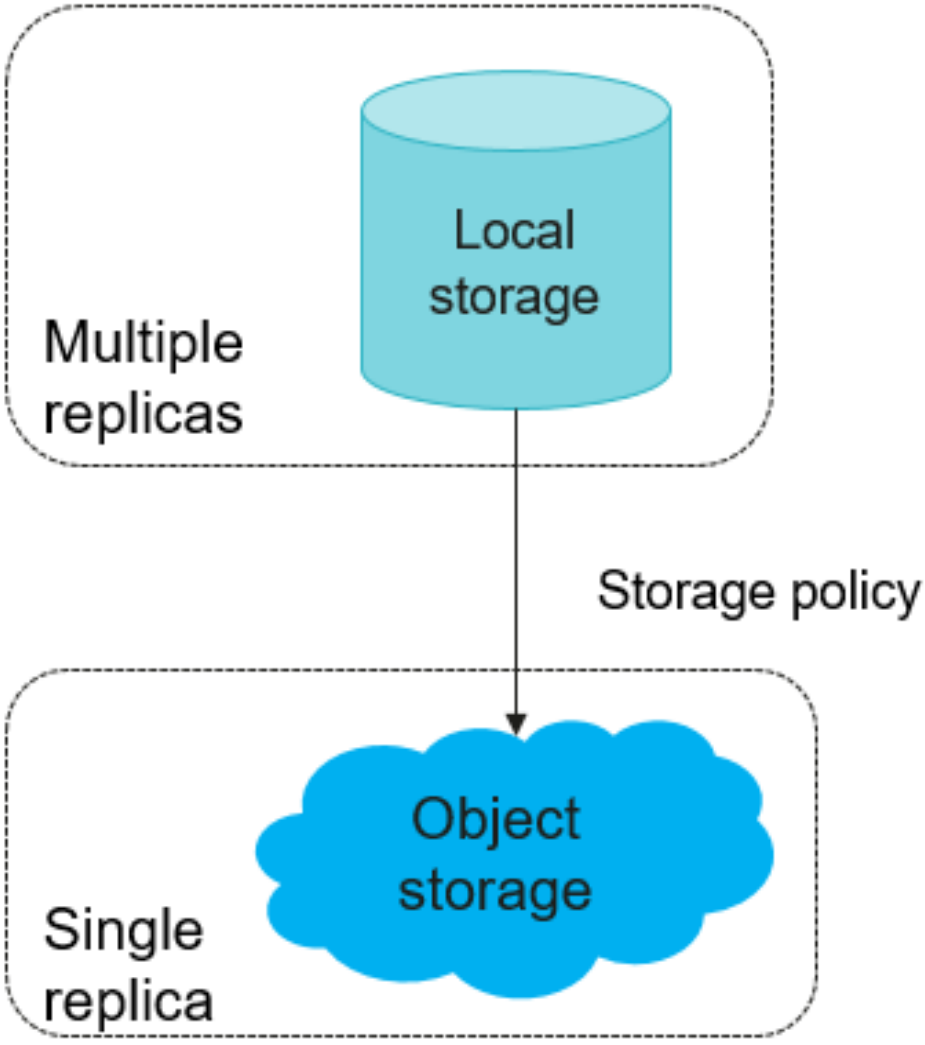
NOTE

This topic is available for MRS 3.3.1 or later only.

Principles

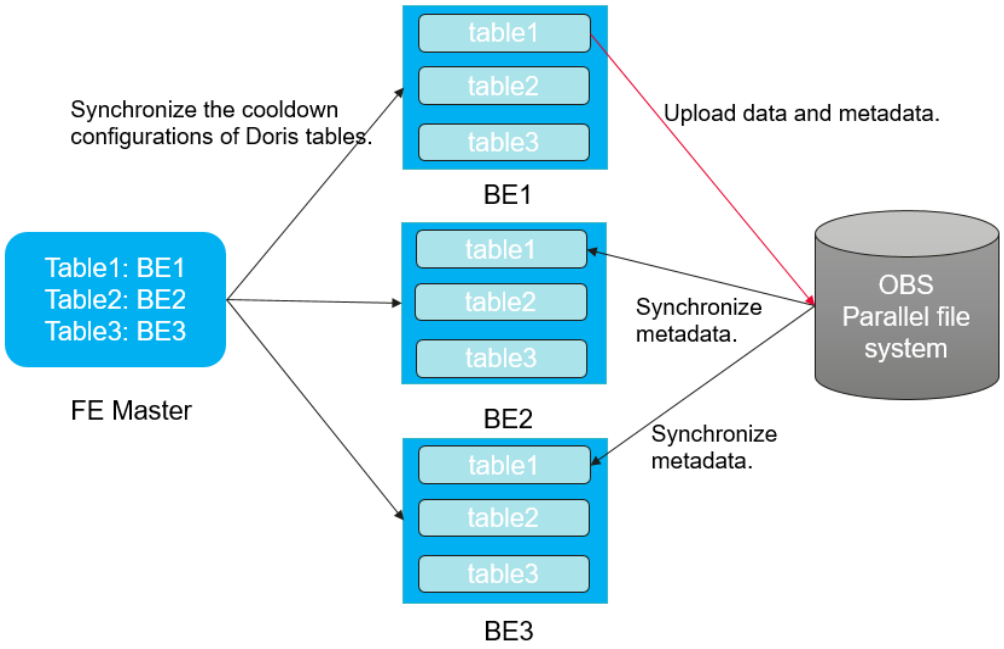
Apache Doris 2.0 supports the separation storage of cold and hot data. You can use this function to sink data from the local host to the object storage.

Figure 5-5 Hot and cold data separation



OBS provides secure, reliable, and cost-effective distributed storage service that supports large-scale data. Doris uses OBS to store data separately. **Figure 5-6** shows the principle.

Figure 5-6 Cold and hot data separation principle



5.7.4.2 Storing Cold and Hot Data Separately in Doris

This topic describes how to configure cold and hot data separation in Doris.

Prerequisite

The Doris cluster can communicate with OBS. For details, see **Initial Configuration**.

Creating an OBS Parallel File System and Obtaining the AK/SK and Domain ID

Create an OBS parallel file system.

Step 1 Log in to the OBS console.

Step 2 Choose **Parallel File Systems** > **Create Parallel File System**.

Step 3 Enter a file system name, for example, **doris-obs**.

The name of an enterprise project must be the same as that of the MRS cluster. Set other parameters.

Step 4 Click **Create Now**.

Step 5 In the parallel file system list, click the name of the one you just created and click **Overview** to obtain the endpoint information.

NOTE

After a service is deleted or a cluster is uninstalled, dirty data may remain in the parallel file system created in **Step 2** to **Step 4**. You need to delete the dirty data.

Obtain AK/SK information.

Step 6 Move the cursor on the username in the upper right corner, and select **My Credentials** from the drop-down list.

Step 7 On the **API Credentials** page, obtain the **Account ID** whish is used as the domain ID.

Step 8 Click **Access Keys**, click **Create Access Key**, and enter the verification code or password. Click **OK** and download the access keys. Obtain the AK/SK information from the **.csv** file.

----End

Creating a Cloud Service Agency and Binding It to a Cluster

Step 1 Log in to the MRS management console.

Step 2 In the service list, choose **Management & Governance** > **Identity and Access Management**.

Step 3 In the navigation pane on the left, choose **Agencies** and click **Create Agency**. On the displayed page, set the following parameters and click **Next**:

- **Agency Name**: Enter an agency name, for example, **mrs_ecs_obs**.
- **Agency Type**: Select **Cloud service**.
- **Cloud Service**: Select **Elastic Cloud Server (ECS) and Bare Metal Server (BMS)**.
- **Validity Period**: Select **Unlimited**.

Step 4 On the displayed page, search for the **OBS OperateAccess** policy and select it.

Step 5 Click **Next**, click **Show More**, select **Global services**, and click **OK**.

Step 6 In the displayed dialog box, click **OK** to start authorization. Click **Finish** after the message "Authorization successful." is displayed.

Step 7 On the MRS console, choose **Active Clusters** in the navigation pane on the left and click the name of the target cluster to access its details page.

Step 8 On the **Dashboard** page, click **Synchronize** on the right of **IAM User Sync** to synchronize the IAM user.

Step 9 Click **Manage Agency** on the right of **Agency**, select the created agency, for example, **mrs_ecs_obs**, and click **OK** to bind the agency to the cluster.

----End

Creating a Common Account Agency and Binding It to a Cluster

Step 1 Log in to the management console.

Step 2 In the service list, choose **Management & Governance** > **Identity and Access Management**.

Step 3 Choose **Permissions** > **Policies/Roles**, and click **Create Custom Policy**. Set the following parameters, and click **OK**:

- **Policy Name**: Enter a policy name, for example, **doris-policy**.
- **Policy View**: Select **JSON**.
- **Policy Content**: Enter the following content.

```
{
   "Version": "1.1",
   "Statement": [
      {
         "Effect":"Allow",
         "Action":[
            "OBS:*:*"
            ]
      }
      ]
}
```

Step 4 In the navigation pane on the left, click **Agencies**. Click **Create Agency**. On the displayed page, set the following parameters and click **Next**:

- **Agency Name**: Enter an agency name, for example, **agency-MRS-to-OBS**.
- **Agency Type**: Select **Account**.
- Enter your cloud account in the **Delegated Account** field, that is, the account you register using your mobile phone number. It cannot be a federated user or an IAM user created using your cloud account.
- **Validity Period**: Select **Unlimited**.

Step 5 In the search box on the displayed **Authorize Agency** page, search for the custom policy created in **Step 3** and select it, for example, **doris-policy**.

Step 6 Click **Next**, click **Show More**, select **Global services**, and click **OK**.

Step 7 Check and record the agency ID.

Step 8 On the **Identity and Access Management** page, click **Agencies**.

Step 9 Click the name of the cloud service agency created in **Step 3**, for example, **mrs_ecs_obs**.

Step 10 Click the **Permissions** tab and click **Authorize**. On the displayed page, click **Create Policy** in the upper right corner, and set the parameters as follows:

- **Policy Name**: Enter a policy name, for example, **doris-assume-policy**.
- **Policy View**: Select **JSON**.
- **Policy Content**: Enter the following content. *{Agency ID}* indicates the ID recorded in **Step 7**.

```
{
   "Version": "1.1",
   "Statement": [
      {
         "Action": [
            "iam:agencies:assume"
         ],
         "Resource": {
            "uri": [
               "/iam/agencies/{Agency ID}"
            ]
         },
         "Effect": "Allow"
      }
   ]
}
```

Step 11 Click **Next**. On the **Select Policy/Role** page, select the policy created in **Step 10**.

Step 12 Click **Next**, click **Show More**, select **Global services**, and click **OK**.

----End

Enabling Cold and Hot Data Separation

By default, cold and hot data separation is disabled. To use this function, perform the following operations:

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**. Click the **Configurations** tab.

Step 2 Search for the **obs_cooldown_enable** parameter and set it to **true**.

Step 3 (Optional) If the data on the local disk is cooled down and stored on OBS, and related data needs to be stored on the local disk in a certain period of time, select **All Configurations** > **BE(Role)** > **Customization**, add the **moveback_enable** parameter to the customized parameter **be.conf.customized.configs** and set the parameter value to **true**.

Step 4 Click **Save** and then **OK**.

Step 5 Click **Instances**, select the affected FE and BE instances, choose **More** > **Restart Instance**, and enter the password of the current user to restart the FE and BE instances.

----End

Use Case

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the service IP address of any FE instance.
- You can also use the MySQL connection software or Doris web UI to connect to the database.

Step 2 Create a resource.

- Create a resource that supports an agency for OBS authentication.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**. Click **Configurations** then **All Configurations**, choose **FE(Role)** > **OBS**, and modify the following parameters and save the changes:
     - **obs_authentication_method**: Change the value to **agency**.
     - **obs_endpoint**: endpoint information queried in **Step 5**, for example, **obs.***XXX*.
     - **object_storage_security_provider**: Retain the default value **com.huawei.mrs.MrsObsCredentialsProvider**.
  b. On the **Dashboard** page, click **More** > **Restart Service**. Enter the password of the current user and click **OK** to restart the Doris service.
  c. Connect the node where the MySQL client is installed to Doris. For details, see **Using the MySQL Client to Connect to Doris**.
  d. Run the following statement to create a resource:

     CREATE RESOURCE IF NOT EXISTS *resource_obs_hot_cold* **PROPERTIES (**

     "type" = "obs",

     "obs.bucket" = "*Name of the OBS parallel file system created in **Step 3***",**

     "obs.root.path" = "*Root directory for storing data***"**

     "obs.region" = " *Region of the cluster where the Doris service is deployed***"**

     );
- Create a resource that supports permanent OBS authentication.
  a. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**. Click **Configurations** then **All Configurations**, choose **FE(Role)** > **OBS**, and modify the following parameters and save the changes:
     - **obs_authentication_method**: Change the value to **permanent**.

- **object_storage_security_provider**: Retain the default value **com.huawei.mrs.MrsObsCredentialsProvider**.

b. On the **Dashboard** page, click **More** > **Restart Service**. Enter the password of the current user and click **OK** to restart the Doris service.

c. Connect the node where the MySQL client is installed to Doris. For details, see **Using the MySQL Client to Connect to Doris**.

d. Run the following statement to create a resource:

CREATE RESOURCE IF NOT EXISTS *resource_obs_hot_cold* **PROPERTIES (**

"type" = "obs",

"obs.endpoint" = "*xxx***",**

"obs.region" = "*xxx***",**

"obs.bucket" = "*xxx***",**

"obs.root.path" = "*xxx***",**

"obs.access_key" = "*xxx***",**

"obs.secret_key" = "*xxx***"**

);

NOTE

- **type**: data storage type. The value is **obs**.
- **obs.endpoint**: endpoint information viewed in **Step 5**
- **obs.region**: region of the cluster where the Doris service is deployed
- **obs.bucket**: name of the OBS parallel file system created in **Step 3**
- **obs.root.path**: root directory for storing data
- **obs.access_key**: AK information obtained in **Step 8**
- **obs.secret_key**: SK information obtained in **Step 8**

Step 3 Set the data cooling policy using the storage policy.

- Set the time to live (TTL) to cool down data.

  CREATE STORAGE POLICY IF NOT EXISTS *policy_doris_hot_cold* **PROPERTIES("storage_resource" = "***resource_obs_hot_cold***", "cooldown_ttl" = "***1d***");**

  If the value of **cooldown_ttl** is **1d**, newly imported data will be cooled one day later and the cooled data will be stored in the OBS path configured during resource creation in **Step 2**.

- Set a time point to cool down data.

  In addition to setting the TTL, you can also set a time point in the cooling policy.

  CREATE STORAGE POLICY IF NOT EXISTS *policy_doris_hot_cold2* **PROPERTIES("storage_resource" = "resource_obs_hot_cold", "cooldown_datetime" = "***2024-01-01 10:00:00***");**

Step 4 Set the storage policy of a table or partition.

- Set the storage policy when creating a table.

  CREATE TABLE *ORDERS* **(**

  ORDER_ID VARCHAR(50),

```
USER_ID BIGINT,
PRODUCT_ID VARCHAR(10),
PRICE DECIMAL(15,2),
CHANNEL VARCHAR(20),
CREATE_DT DATE
)
DUPLICATE KEY(`ORDER_ID`)
PARTITION BY RANGE(`CREATE_DT`)
(
PARTITION `p202401` VALUES LESS THAN ("2024-02-01"),
PARTITION `p202402` VALUES LESS THAN ("2024-03-01")
)
DISTRIBUTED BY HASH(`ORDER_ID`) BUCKETS 3
PROPERTIES (
"replication_num" = "3",
"storage_policy" = "policy_doris_hot_cold "
);
```

- Modify the properties of an existing table.

  ALTER TABLE *ORDERS* **SET("storage_policy" = "policy_doris_hot_cold");**

- Set the cold and hot separation policy for a partition when creating a table.

```
CREATE TABLE ORDERS (
ORDER_ID VARCHAR(50),
USER_ID BIGINT,
PRODUCT_ID VARCHAR(10),
PRICE DECIMAL(15,2),
CHANNEL VARCHAR(20),
CREATE_DT DATE
)
DUPLICATE KEY(`ORDER_ID`)
PARTITION BY RANGE(`CREATE_DT`)
(
PARTITION `p202401` VALUES LESS THAN ("2024-02-01")
("storage_policy" = "policy_doris_hot_cold"),
PARTITION `p202402` VALUES LESS THAN ("2024-03-01")
)
DISTRIBUTED BY HASH(`ORDER_ID`) BUCKETS 3
PROPERTIES (
"replication_num" = "3"
);
```

- Modify the partition properties of an existing table.

ALTER TABLE *ORDERS* **MODIFY PARTITION (`p202401`) SET("storage_policy"="policy_doris_hot_cold");**

NOTE

- A single table or partition can be associated with only one storage policy. Associated storage policies cannot be deleted before disassociation.
- Information about the object associated with a storage policy cannot be modified, such as bucket, endpoint, and root_path.
- A storage policy can be created, modified, and deleted. Before deleting a storage policy, ensure that no table references the storage policy.
- When the Merge-on-Write feature is enabled for the Unique model, storage policies cannot be set.

Step 5 Run the following statement to query data:

show tablets from *ORDERS*;

This command views the tablet information of the table. In the tablet information, LocalDataSize and RemoteDataSize are distinguished. LocalDataSize indicates the data stored locally, and RemoteDataSize indicates the data that has been cooled and stored on OBS.

Before the data is cooled, the tablet information of the table is as follows.

```
*************************** 1. row ***************************
              TabletId: 10210
             ReplicaId: 10211
             BackendId: 10002
            SchemaHash: 1629210097
               Version: 26
      LstSuccessVersion: 26
       LstFailedVersion: -1
          LstFailedTime: NULL
         LocalDataSize: 2718
        RemoteDataSize: 0
              RowCount: 25
                 State: NORMAL
LstConsistencyCheckTime: NULL
          CheckVersion: -1
          VersionCount: 2
             QueryHits: 0
              PathHash: -2692135266043659989
               MetaUrl: http://192.165.0.218:29986/api/meta/header/10210
      CompactionStatus: http://192.165.0.218:29986/api/compaction/show?tablet_id=10210
      CooldownReplicaId: 10211
        CooldownMetaId: TUniqueId(hi:-629967361863696654, lo:-8577590943874589763)
1 row in set (0.00 sec)
```

After the data is cooled, the tablet information of the table is as follows.

```
*************************** 1. row ***************************
              TabletId: 10210
             ReplicaId: 10211
             BackendId: 10002
            SchemaHash: 1629210097
               Version: 26
        LstSuccessVersion: 26
         LstFailedVersion: -1
            LstFailedTime: NULL
           LocalDataSize: 0
          RemoteDataSize: 2718
                RowCount: 25
                   State: NORMAL
LstConsistencyCheckTime: NULL
            CheckVersion: -1
            VersionCount: 2
               QueryHits: 0
                PathHash: -2692135266043659989
                 MetaUrl: http://192.165.0.218:29986/api/meta/header/10210
        CompactionStatus: http://192.165.0.218:29986/api/compaction/show?tablet_id=10210
        CooldownReplicaId: 10211
           CooldownMetaId: TUniqueId(hi:-629967361863696654, lo:-8577590943874589763)
1 row in set (0.01 sec)
```

----End

5.7.5 Doris Slow Query Detection

Scenario

As a ROLAP database, Doris relies on a powerful relational database engine at its foundation. High concurrency and aggregation queries are commonly used. MRS Doris lacks slow query detection capabilities, making it difficult to monitor query execution for troubleshooting. To improve Doris's O&M capabilities, we developed the slow query detection function.

Doris slow query information can be displayed and managed on Manager only after this function enabled. By default, this function is disabled to reduce the impact on environment resources. You can enable this function with custom parameter **query_history_enable**.

This function is available only for MRS 3.5.0 and later versions.

Prerequisites

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The nodes to be connected to the Doris database can communicate with the MRS cluster.
- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.

Enabling Slow Query Detection

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations** > **FE(Role)** > **Customization**.

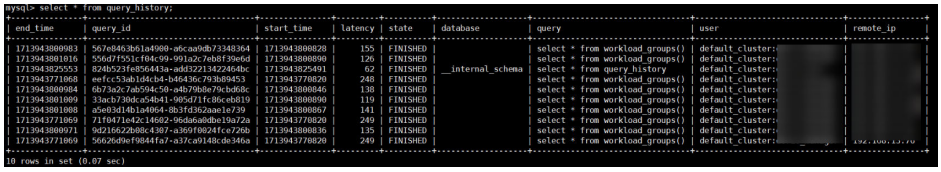
Step 2 Add the **query_history_enable** parameter to the custom parameter **fe.conf.customized.configs** and set the parameter value to **true**.

Step 3 Click **Save**, and then click **OK** to save the configurations.

Step 4 Click **Instances**, select the affected FE instances, choose **More** > **Restart Instance**. Enter the password of the user and click **OK** to apply the configuration.

Step 5 After connecting the MySQL client to Doris, run the following command to view the slow queries executed by the Doris:

select * from __internal_schema.query_history;



Step 6 On FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Queries** to view **Ongoing Slow Queries** and **Completed Slow Queries**. You can also view the top 10 users who execute slow queries, IP addresses of the clients that submit slow SQL statements, and slow query statements.

- **Top 10 Users**: top 10 Doris users who perform slow queries
- **Top 10 IP Addresses**: IP addresses of top 10 Doris clients that execute slow queries
- **Top 10 SQL Statements**: top 10 most executed slow query SQL statements on the Doris client

----End

Ongoing Slow Queries

You can query information about slow SQL statements that are being executed but do not return any result.

- **Access path**

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Queries**, and click the **Ongoing Slow Queries** tab. For details about the parameters, see **Table 5-9**.

- **Filter conditions**

  Select the query condition as required and filter the query results.

  Table 5-8 Filter conditions

Conditions	Parameter Description
Slow query duration exceeding	Filters the slow SQL queries based on the duration. The value can be **3 (s)**, **9 (s)**, **15 (s)**, or **25 (s)**.
By Query ID	Filters the slow queries based on the query ID. Fuzzy search based on the query ID is supported. For example, if the query ID is **111-222-333-444-555**, you can enter part of it such as **111-222** or **-222-333** to query the needed information.

Conditions	Parameter Description
By User	Filters the slow queries based on Doris users who execute the SQL statements. Fuzzy search based on part of a username is supported.
By Client IP Address	Filters the slow queries based on the IP address of the client that submits slow query SQL statements. Fuzzy search based on part of the client IP address is supported. For example, if the client IP address is **192.168.0.1**, you can enter part of it such as **192.168** or **192.168.0** to query the information you need.

Completed Slow Queries

You can query information about slow query SQL statements that have been executed and returned results.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**. On the displayed page, click the **Query Management** tab and then the **Completed Queries** tab.

For details about slow query parameters and filter conditions, see **Table 5-9** and **Table 5-8**, respectively.

Slow Query Detection Parameters

Table 5-9 Slow query parameters

Parameter	Description
Query ID	Unique ID generated internally.
Query	Slow query SQL statement.
Start Time	Time when the query starts.
End Time	Time when the query is complete.
Database	Name of the database where the table in the query is.
Instance Name	FE instance node that executes the query. It is displayed for **Ongoing Slow Queries** only.
Memory Used	Memory space consumed by the query, in bytes. This field is displayed for **Completed Queries** only.
Duration	Total execution time of the query, in seconds.
User	Doris user who executes the query.
Client IP Address	IP address of the client that submits the query.

Parameter	Description
Status	Execution status of the query. Possible values are as follows: • **Running**: queries being executed • **Cancelled**: slow queries stopped by clicking **Terminate** in the **Operation** column in the **Ongoing Slow Queries** tab • **Completed**: slow queries that have been properly executed
Operation	Column available for **Ongoing Slow Queries** only. You can click **Terminate** to stop a query.

5.8 Doris O&M Management

5.8.1 Doris Log Overview

Log Description

Log path: The default storage path of Doris logs is **/var/log/Bigdata/doris/***role name*.

- FE: **/var/log/Bigdata/doris/fe** (run logs) and **/var/log/Bigdata/audit/doris/fe** (audit logs)
- BE: **/var/log/Bigdata/doris/be** (run logs)
- DBroker: **/var/log/Bigdata/doris/dbroker** (run logs)

Log archive rule: The automatic compression and archive function is enabled for Doris logs. By default, when the size of a log file exceeds the specified size (configurable), the log file is automatically compressed. The naming rule of the compressed log file is as follows: *Original log file name* **>-**<*yyyy-mm-dd_hh-mm-ss*>**.** *[ID]***.log.zip**. A maximum of 20 latest compressed files are retained. The number of compressed files and compression threshold can be configured.

Table 5-10 Hive log list

Log type	Log File	Description
Run log	/fe/fe.out	Standard/Error output logs (stdout and stderr)
	/fe/fe.log	Main log, including all contents except fe.out
	/fe/fe.warn.log	Subset of fe.log. Only WARN and ERROR logs are recorded.

Log type	Log File	Description
	/fe/fe-omm-<Date>-<PID>-gc.log.<No.>	GC logs of the FE process
	/fe/preStart.log	Work logs before the FE is started
	/fe/check_fe_status.log.log	Log file that records whether the FE service is started successfully
	/fe/cleanup.log	Cleanup log file for FE uninstallation
	/fe/start_fe.log	FE process startup logs
	/fe/stop_fe.log	FE process stop log
	/fe/postinstallDetail.log	Work logs generated after the FE is installed and before the FE is started
	/be/be.INFO	Run log of the BE process
	be.WARNING	Subset of be.log. Only WARN and FATAL logs are recorded.
	/be/be-omm-<Date>-<PID>-gc.log.<No.>	GC logs of the BE process
	/be/postinstallDetail.log	Work logs generated after BE installation and before BE startup
	/be/preStart.log	Work logs before BE startup
	/be/cleanup.log	Cleanup log file for BE uninstallation
	/be/start_be.log	BE process startup logs
	/be/stop_be.log	BE process stop log
	/be/check_be_status.log	Log file that records whether the BE service is started successfully
	/be/be.out	Standard/Error output logs of the BE process (stdout and stderr)
	/dbroker/start_broker.log	Logs indicating that the DBroker process is started or stopped properly
	/dbroker/stop_broker.log	DBroker process startup and stop exception logs
	/dbroker/preStart.log	Work log before the DBroker is started
	/dbroker/cleanup.log	Cleanup log file generated during or before DBroker uninstallation

Log type	Log File	Description
	/dbroker/check_db_status.log	Log file that records whether the DBroker service is started successfully
	/dbroker/dbroker-omm-<Date>-<PID>-gc.log.<No.>	GC log of the DBroker process
	/dbroker/apache_hdfs_broker.log	Run log of the DBroker process
Viewing Audit Logs	fe.audit.log	Audit log, which records all SQL requests received by the FE

Log Levels

Table 5-11 describes the log levels provided by the Doris.

The priorities of run log levels are FATAL, ERROR, WARN, and INFO in descending order. Logs whose levels are higher than or equal to the set level are printed. The number of printed logs decreases as the set log level increases.

Table 5-11 Log Levels

Level	Description
FATAL	FATAL usually indicates a program assertion error.
ERROR	Logs of this level record error information about system running
WARN	Logs of this level record exception information about the current event processing
INFO	Logs of this level record normal running status information about the system and events

To change log levels, perform the following operations:

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations**. The **All Configurations** page of the Doris service is displayed.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level and save the configuration.

Step 4 Click **DashBoard**, choose **More** > **Restart Service**, and enter the password of the current user to restart the Doris service.

----End

Log Formats

The Doris log format is as follows:

Table 5-12 Log format

Log type	Format	Example Value
FE run log	<yyyy-MM-dd HH:mm:ss,SSS><LogLevel>(Thread name|Thread ID)<Location where the log event occurs>|<message in log>	2023-04-13 11:17:14,371 INFO (tablet stat mgr|34) [TabletStatMgr.runAfterCatalogReady():125] finished to update index row num of all databases. cost: 0 ms
BE run logs	Log level. I indicates INFO, W indicates WARN, and F indicates FATAL|MMdd HH:mm:ss.SSS. Thread ID. Location where a log event occurs. message&gt in log;	I0413 11:26:03.439189 25248 tablet_manager.cpp:895] begin to build all report tablets info
DBroker run log	<MMdd HH:mm:ss.SSS> <Thread ID> <LogLevel><message in log>	2023-04-11 11:43:13 [main:0] - [INFO] starting apache hdfs broker....

Log type	Format	Example Value

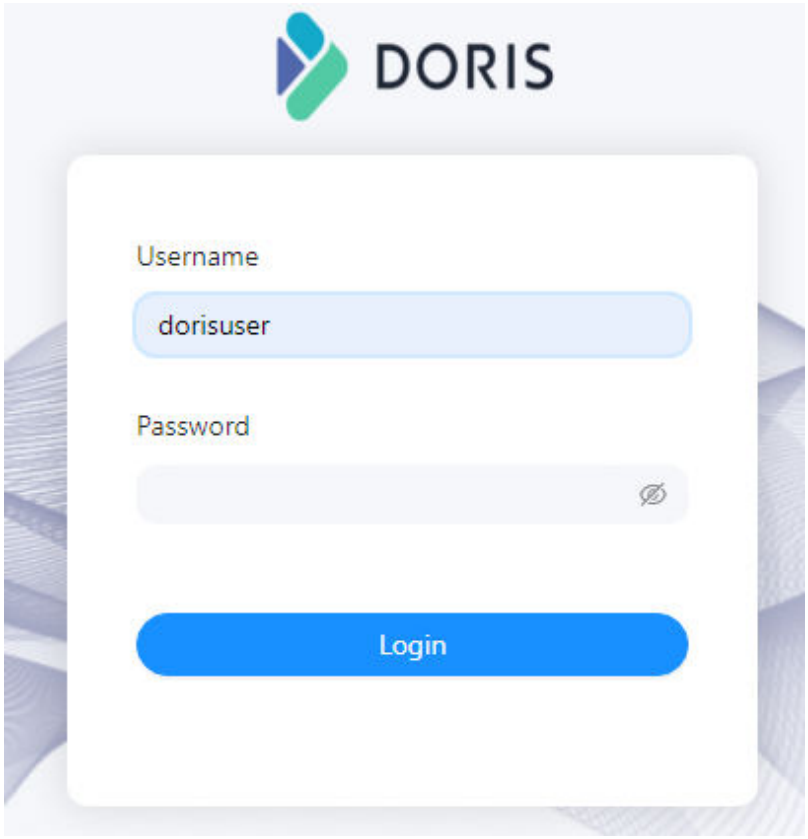
5.8.2 Accessing the Doris Web UI for Component Status

Step 1 Log in to FusionInsight Manager as a user with administrator rights. Choose **Cluster** > **Services** > **Doris**.

Step 2 On the **Dashboard** page, click the hyperlink on the right of **FE WebUI**. On the displayed Doris web UI login page, enter the username and password of the account with the Doris management permission. The initial password must have been changed if Kerberos authentication is enabled for the cluster (the cluster is in security mode). For details about how to create a user, see **Creating a Doris Permission Role**. Then, click **Login**.



Step 3 On the home page of the Doris web UI, view the Doris cluster information. You can also view the Doris table information in **Playground** and run a SQL query statement.

----End

5.8.3 Backing Up Doris Data

Doris can back up current data as files to a remote storage system through Broker. Doris data can be periodically backed up using snapshots and migrated.

NOTE

- Currently, only users with the **ADMIN** permission can perform backup and restoration operations.
- Only one backup job can be being executed in a database.
- Doris data backup supports operations at the minimum partition level. When a table contains a large amount of data, you are advised to perform operations by partition to reduce the cost of retry upon failure.
- The backup and restoration operations are performed on the actual data files. Therefore, when a table has too many shards or a shard has too many minor versions, the backup may take a long time even if the total data volume is small.
- When you run the **SHOW BACKUP** or **SHOW RESTORE** command to view the job status, error information may be displayed in the TaskErrMsg column. If the value in the **State** column is not **CANCELLED**, the job continues. These tasks may be retried successfully. However, some tasks are incorrect, causing job failures.

Data Backup Principles

The backup operation is to upload the data of a specified table or partition to the remote repository as a file stored in the Doris. After a user submits a backup request, the system performs the following operations:

1. Snapshot and Snapshot Upload

   Backup is performed on snapshots. In the snapshot phase, snapshots are taken for specified tables or partition data files. A snapshot only generates a hard link for the current data file, which is time-consuming. After a snapshot is created, operations such as modification and import on the table do not affect the backup result. After the snapshot is complete, the system starts to upload the snapshot files one by one. The snapshot files are concurrently uploaded by each backend.

2. Preparing and Uploading Metadata

   After the data file snapshot is uploaded, Frontend writes the corresponding metadata into a local file and uploads the local metadata file to the remote repository through Broker to complete the backup job.

NOTE

- If the table to be backed up is a dynamic partition table, the dynamic partition attribute is automatically disabled after the backup. Before restoring data, run the following command to manually enable the dynamic partition attribute of the table:

  ALTER TABLE *tbl1* **SET ("dynamic_partition.enable"="true")**

- The data backup operation does not retain the **colocate_with** attribute of the table.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- The MySQL client has been installed. For details about related operations, see **Using the MySQL Client to Connect to Doris**
- Create a user with the Doris management permission.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    On FusionInsight Manager, create a human-machine user, for example, dorisuser, create a role with the Doris administrator rights, and bind the role to the user.

    Log in to FusionInsight Manager as the new user **dorisuser** and change the initial password of the user.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

Backing Up Doris Data

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login username* **-p***Database login password* **-P***Database connection port* **-h***IP address of the Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Run the following command to create a remote repository **example_repo** in HDFS:

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)

  CREATE REPOSITORY `example_repo`

  WITH BROKER `hdfs_broker`

  ON LOCATION "hdfs://hadoop-name-node:25000/path/to/repo/"

  PROPERTIES

  (

  "hadoop.security.authentication"="kerberos",

  "kerberos_principal"="doris/hadoop.hadoop.com@HADOOP.COM",

  "kerberos_keytab"="/opt/huawei/Bigdata/FusionInsight_Doris_8.3.0/install/FusionInsight-Doris-1.2.3/doris-fe/bin/doris.keytab"

  );

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  CREATE REPOSITORY `example_repo`

  WITH BROKER `hdfs_broker`

  ON LOCATION "hdfs://hadoop-name-node:25000/path/to/repo/"

  PROPERTIES

  (

  "username" = "hdfs",

  "password" = ""

  );

Step 3 View the created repository.

SHOW REPOSITORIES;

Step 4 Back up data to the **example_repo**. You can back up table data or partition data. For example:

- To fully back up data in the **example_tbl** table in **example_db** to **example_repo**, run the following command:

  BACKUP SNAPSHOT example_db.snapshot_label1

  TO example_repo

  ON (example_tbl)

  PROPERTIES ("type" = "full");

- Fully back up the **p1** and **p2** partitions of the **example_tbl** table in the **example_db** and the **example_tbl2** table to the **example_repo**.

  BACKUP SNAPSHOT example_db.snapshot_label2

  TO example_repo

  ON

  (

  example_tbl PARTITION (p1,p2),

  example_tbl2

  );

Step 5 Run the following command to check the execution status of the backup job:

show BACKUP;

Step 6 Check whether the backup is successful in the remote repository.

SHOW SNAPSHOT ON example_repo WHERE SNAPSHOT = "snapshot_label1";

```
+-----------------+---------------------+--------+
| Snapshot        | Timestamp           | Status |
+-----------------+---------------------+--------+
| snapshot_label1 | 2022-04-08-15-52-29 | OK     |
+-----------------+---------------------+--------+
1 row in set (0.15 sec)
```

----End

5.8.4 Restoring Doris Data

Doris can back up current data as files to a remote storage system through Broker. Run the restoration command to restore data from the remote storage system to any Doris cluster. Doris data can be periodically backed up using snapshots and migrated.

NOTE

- Currently, only users with the **ADMIN** permission can perform backup and restoration operations.
- Only one recovery job can be being executed in a database.
- Doris data restoration supports operations at the minimum partition level. When a table contains a large amount of data, you are advised to perform operations by partition to reduce the cost of retry upon failure.
- The backup and restoration operations are performed on the actual data files. Therefore, when a table has too many shards or a shard has too many minor versions, it may take a long time to restore the table even if the total data volume is small.
- When you run the **SHOW BACKUP** or **SHOW RESTORE** command to view the job status, error information may be displayed in the TaskErrMsg column. If the value in the **State** column is not **CANCELLED**, the job continues. These tasks may be retried successfully. However, some tasks are incorrect, causing job failures.
- If the recovery job is an overwrite operation (specifying that data is restored to an existing table or partition), the overwritten data in the current cluster may not be restored from the COMMIT phase of the recovery job. If the recovery job fails or is canceled, the previous data may be damaged and cannot be accessed. In this case, you need to perform the restoration operation again and wait until the job is complete. Therefore, you are not advised to restore data by overwriting data unless you confirm that the current data is no longer used.

Data Restoration Principles

To restore Doris data, you need to specify an existing backup data in a remote repository and then restore the backup data to the local cluster. After a restore request is submitted, the system performs the following operations:

1. Create the corresponding metadata locally.

   Structures such as table partitions are created and restored in the local cluster. After the table is created, it is visible but inaccessible.

2. Local snapshot

   Create a snapshot for the table created in the local cluster. The snapshot is an empty snapshot (the newly created table has no data). The snapshot is used to generate the corresponding snapshot directory on the Backend and receive the snapshot file downloaded from the remote repository.

3. Downloading a snapshot

   Snapshot files in the remote repository are downloaded to the corresponding snapshot directory and concurrently completed by each backend.

4. Making a Snapshot Take Effect

   After the snapshot is downloaded, map each snapshot to the metadata of the current local table. Then reload these snapshots for them to take effect and complete the final recovery job.

Prerequisite

- A cluster containing the Doris service has been created, and all services in the cluster are running properly.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- The MySQL client has been installed. For details about related operations, see **Using the MySQL Client to Connect to Doris**

- Create a user with the Doris management permission.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    On FusionInsight Manager, create a human-machine user, for example, dorisuser, create a role with the Doris administrator rights, and bind the role to the user.

    Log in to FusionInsight Manager as the new user **dorisuser** and change the initial password of the user.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.
- You have backed up the Doris table or partition data to be restored by referring to **Backing Up Doris Data**.

Restoring Doris Data

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login username* **-p***Database login password* **-P***Database connection port* **-h***IP address of the Doris FE instance*

NOTE

- The database connection port is the query connection port of the Doris FE. You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the IP address of the Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the IP address of any FE instance.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

Step 2 Restore table or partition data from the remote warehouse where data has been backed up. For example:

- Run the following command to restore the **example_tbl** table in **snapshot_label1** from **example_repo** to the **example_db2** database. The table is restored to one backup.

  RESTORE SNAPSHOT *example_db2*.`*snapshot_label1*`

  FROM `*example_repo*`

  ON (`*example_tbl*` **)**

  PROPERTIES

  (

  "backup_timestamp"="*2023-08-16-20-13-55***",**

  "replication_num" = "*1***"**

);

You can run the **SHOW SNAPSHOT ON example_repo WHERE SNAPSHOT = "snapshot_label1";** command to obtain the value of backup_timestamp.

- Restore the partitions **p1** and **p2** of the **example_tbl** table in the backup **snapshot_label2** from **example_repo**, restore the **example_tbl2** table to the **example_db1** database, rename the table **new_tbl**. By default, three copies are restored.

  RESTORE SNAPSHOT *example_db1*.`*snapshot_2*`

  FROM `*example_repo*`

  ON

  (

  `*backup_tbl*` **PARTITION (**`*p1*`**,** `*p2*`**),**

  `*backup_tbl2*` **AS** `*new_tbl*`

)

  PROPERTIES

  (

  "backup_timestamp"="*2023-08-16-20-13-55***"**

  );

  Note: You can run the **SHOW SNAPSHOT ON example_repo WHERE SNAPSHOT = "snapshot_label2";** command to obtain the value of **backup_timestamp**.

Step 3 Run the following command to check the execution status of the recovery job:

SHOW RESTORE\G;

----End

5.8.5 Table of Audit Logs

This function enables direct SQL statement execution for viewing and analyzing audit logs, eliminating the need to manually collect and analyze FE audit log files to check service volume and types. You can periodically import FE audit logs into a specified Doris table using Stream Load. The audit log table function is disabled by default. You can use the **enable_audit_log_table** parameter to enable this function.

This function is available only for MRS 3.5.0 and later versions.

NOTE

- Currently, the audit log table does not record operations such as Broker Load, Export, and Stream Load. You need to view the operations in the audit log.
- To record the Stream Load operation with the audit log table, set the BE parameter **enable_stream_load_record** to **true**.
- The audit log table records only information about SQL statements that have been executed.
- By default, the maximum interval for writing data to the audit log table is 60 seconds, and the maximum amount of data that can be written in each batch is 50 MB. You can adjust the interval and amount by setting the **max_batch_interval_sec** and **max_batch_size** parameters.

Enabling Audit Log Table

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations** > **FE(Role)** > **Log**, and change the value of **enable_audit_log_table** to **true**.

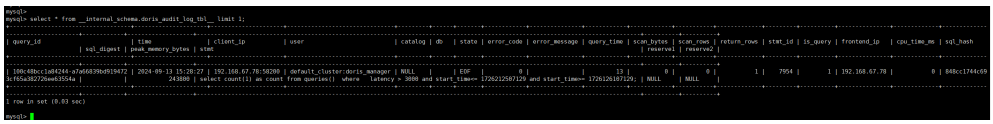
Step 2 Click **Save**, and then click **OK** to save the configurations.

Step 3 Click **Instances**, select the affected FE instances, choose **More** > **Restart Instance**. Enter the password of the user and click **OK** to apply the configurations.

Step 4 After the MySQL client is connected to Doris (for details, see **Getting Started with Doris**), run the following command to view the SQL statements that have been executed by Doris:

select * from __internal_schema.doris_audit_log_tbl__ limit 1;

Figure 5-7 SQL statements that have been executed



For details about each field, see **Table 5-13**.

----End

Fields in the Audit Log Table

Table 5-13 Audit log table fields

Field	Type	Description
query_id	varchar(48)	Query task ID.
time	datetime	Query start time.
client_ip	varchar(200)	IP address and port of the client.
user	varchar(64)	Name of the user who performs the query.
catalog	varchar(128)	Name of the catalog to which the query belongs.
db	varchar(96)	Name of the database to which the query belongs.
state	varchar(8)	Status of the query result.
error_code	int	Error code if the query fails

Field	Type	Description
error_message	string	Error message if the query fails
query_time	bigint	Query execution time, in ms.
scan_bytes	bigint	Total number of bytes scanned by the query.
scan_rows	bigint	Total number of rows scanned by the query.
return_rows	bigint	Number of rows returned in the query result.
stmt_id	int	Serially numbered statement ID.
is_query	tinyint	Whether the statement is a query statement. • **1**: indicates a query statement. • **0**: indicates a non-query statement.
frontend_ip	varchar(200)	IP address of the FE that executes the query.
cpu_time_ms	bigint	Total CPU time of the query.
sql_hash	varchar(48)	Hash value of the query.
sql_digest	varchar(48)	SQL summary. The value is empty for non-slow queries.
peak_memory_bytes	bigint	Peak memory usage of all BE nodes, in bytes.
stmt	string	Information about the SQL statement that is executed.
reserve1	string	Reserved field 1
reserve2	string	Reserved field 2

5.9 Typical SQL Syntax of Doris

5.9.1 CREATE DATABASE

This section describes the basic SQL syntax and usage of the Doris database.

Basic Syntax

CREATE DATABASE [IF NOT EXISTS] *db_name*

[PROPERTIES ("key"="value", ...)];

Use Example

Step 1 Connect to Doris through MySQL client as a user with Doris administrator permissions.

Step 2 Run the following command to create the database **example_db**:

create database if not exists example_db;

Step 3 Run the following command to view the database information:

SHOW DATABASES;

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| example_db         |
| information_schema |
+--------------------+
2 rows in set (0.00 sec)
```

Step 4 Run the following command to switch to **example_db**:

use example_db;

----End

5.9.2 CREATE TABLE

This section describes the basic SQL syntax and usage of Doris for creating tables.

Basic Syntax

CREATE TABLE [IF NOT EXISTS] [database.]*table*

(

column_definition_list,

[index_definition_list]

)

[engine_type]

[keys_type]

[table_comment]

[partition_info]

distribution_desc

[rollup_list]

[properties]

[extra_properties]

Use Example

- To create an ordinary table named **table1**, run the following command:

  CREATE TABLE example_db.table1
  (
  k1 TINYINT,
  k2 DECIMAL(10, 2) DEFAULT "10.5",
  k3 CHAR(10) COMMENT "string column",
  k4 INT NOT NULL DEFAULT "1" COMMENT "int column"
)
  COMMENT "table comment"
  DISTRIBUTED BY HASH(k1) BUCKETS 32;

- Create a partitioned table named **table2**.

  Use the **event_day** column as the partition column and create three partitions: p201706, p201707, and p201708. The values are as follows:

  - p201706: The value range is [Minimum value, 2017-07-01).
  - p201707: The value range is [2017-07-01, 2017-08-01).
  - p201708: The value range is [2017-08-01, 2017-09-01).

  Each partition uses **siteid** for hash bucketing. The number of buckets is 10.

  The command for creating a table is as follows:

  CREATE TABLE table2
  (
  event_day DATE,
  siteid INT DEFAULT '10',
  citycode SMALLINT,
  username VARCHAR(32) DEFAULT '',
  pv BIGINT SUM DEFAULT '0'
)
  AGGREGATE KEY(event_day, siteid, citycode, username)
  PARTITION BY RANGE(event_day)
  (
  PARTITION p201706 VALUES LESS THAN ('2017-07-01'),
  PARTITION p201707 VALUES LESS THAN ('2017-08-01'),
  PARTITION p201708 VALUES LESS THAN ('2017-09-01')
)
  DISTRIBUTED BY HASH(siteid) BUCKETS 10

PROPERTIES("replication_num" = "1");

NOTE

- When Doris creates a table, at least two copies must be specified to ensure high availability.
- You can add a rollup table to a table to improve query performance.
- By default, the Null attribute of a column in a table is **true**, which affects the query performance.
- The bucket column must be specified for the Doris table.

- View the table content.
  - **SHOW TABLES;**

```
+----------------------+
| Tables_in_example_db |
+----------------------+
| table1               |
| table2               |
+----------------------+
2 rows in set (0.01 sec)
```

  - **DESC table1;**

```
+----------+-------------+------+-------+---------+-------+
| Field    | Type        | Null | Key   | Default | Extra |
+----------+-------------+------+-------+---------+-------+
| siteid   | int(11)     | Yes  | true  | 10      |       |
| citycode | smallint(6) | Yes  | true  | N/A     |       |
| username | varchar(32) | Yes  | true  |         |       |
| pv       | bigint(20)  | Yes  | false | 0       | SUM   |
+----------+-------------+------+-------+---------+-------+
4 rows in set (0.00 sec)
```

  - **DESC table2;**

```
+-----------+-------------+------+-------+---------+-------+
| Field     | Type        | Null | Key   | Default | Extra |
+-----------+-------------+------+-------+---------+-------+
| event_day | date        | Yes  | true  | N/A     |       |
| siteid    | int(11)     | Yes  | true  | 10      |       |
| citycode  | smallint(6) | Yes  | true  | N/A     |       |
| username  | varchar(32) | Yes  | true  |         |       |
| pv        | bigint(20)  | Yes  | false | 0       | SUM   |
+-----------+-------------+------+-------+---------+-------+
5 rows in set (0.00 sec)
```

5.9.3 INSERT INTO

This section describes the basic syntax and usage of SQL statements for inserting table data to the Doris.

Basic Syntax

INSERT INTO *table_name*

[PARTITION (p1, ...)]

[WITH LABEL label]

[(column [, ...])]

[[hint [, ...]]]

{ VALUES ({ expression | DEFAULT } [, ...]) [, ...] | query }

Use Example

- Insert multiple rows of data into the **test** table at a time.

  INSERT INTO test VALUES (1, 2), (3, 4);

- Import the result of a query statement to the **test** table.

  INSERT INTO test (c1, c2) SELECT * from test2;

5.9.4 ALTER TABLE

When you modify the table structure, the methods for modifying the aggregation model and non-aggregation model are different. The methods for modifying the Key and Value columns are also different. The command parameters are as follows:

- If **AGGREGATE KEY** is specified during table creation, the model is an aggregation model. In other scenarios, the model is a non-aggregation model.
- In the table creation statement, the column following the keyword **'unique key'**, **'aggregate key'**, or **'duplicate key'** is the Key column, and the remaining column is the Value column.

Aggregation Model Example

The aggregation type of an aggregation column cannot be changed.

- Add the **new_col** column (key column) after the **col1** column.

  ALTER TABLE example_db.my_table ADD COLUMN new_col INT DEFAULT "0" AFTER col1;

- Add the **new_col** column (sum aggregation type in the Value column) after **col1**.

  ALTER TABLE example_db.my_table ADD COLUMN new_col INT SUM DEFAULT "0" AFTER col1;

- Change the type of the **col1** column to BIGINT(Key column).

  ALTER TABLE example_db.my_table MODIFY COLUMN col1 BIGINT DEFAULT "1";

- Change the type of the **col1** column to BIGINT(Value column).

  ALTER TABLE example_db.my_table MODIFY COLUMN col1 BIGINT MAX DEFAULT "1";

- Delete the **col1** column.

  ALTER TABLE example_db.my_table DROP COLUMN col1;

Example of a non-aggregation model

- Add the **new_col** column after the **col1** column (add the Key column):

  ALTER TABLE example_db.my_table ADD COLUMN new_col INT KEY DEFAULT "0" AFTER col1;

- Add the **new_col** column (Value column) after the **col1** column.

  ALTER TABLE example_db.my_table ADD COLUMN new_col INT DEFAULT "0" AFTER col1;

- Change the type of the **col1** column to BIGINT(Key column).

ALTER TABLE example_db.my_table MODIFY COLUMN col1 BIGINT KEY DEFAULT "1";

- Change the type of the **col1** column to BIGINT(Value column).

  ALTER TABLE example_db.my_table MODIFY COLUMN col1 BIGINT DEFAULT "1";

- Delete the **col1** column.

  ALTER TABLE example_db.my_table DROP COLUMN col1;

5.9.5 DROP TABLE

This section describes the basic SQL syntax and usage of Doris for deleting tables.

Basic Syntax

DROP TABLE [IF EXISTS] [db_name.]*table_name* [FORCE]**;**

Use Example

Delete the **my_table** table.

DROP TABLE IF EXISTS example_db.my_table;

5.10 Common Issues About Doris

5.10.1 What Should I Do If Occasionally Occurs During Table Creation Due to the Configuration of the SSD and HDD Data Directories?

Symptom

Error message "Failed to find enough host with storage medium and tag" was occasionally displayed during table creation.

Cause Analysis

Doris allows you to configure multiple storage paths for a BE node and specify the storage medium of the paths, such as SSDs or HDDs. Generally, only one storage path needs to be configured for each disk.

The **default_storage_medium** parameter of FE nodes is HDD by default. If only the SSD is specified in the **be.conf** file, an error is reported because no HDD medium is available during table creation. Doris does not automatically detect the actual storage medium of disks where the storage path is located. You need to explicitly indicate the storage medium in the path configuration. **.HDD** and **.SSD** are used only to identify the speed of the storage paths. They are not the actual storage medium types. If the storage medium of the BE node has no difference, you do not need to enter the suffix.

Procedure

- Change the value of **default_storage_medium** of the FE node to the correct storage medium and restart the FE node for the modification to take effect.
- Delete the explicit SSD configuration from the **be.conf** file.
- Add the properties parameter **properties {"storage_medium" = "ssd"}** when creating a table.

5.10.2 What Should I Do If RPC Timeout Error Is Reported When Stream Load Is Used?

Symptom

During data import, RPC startup timed out when the tablet writer was opened by a BE node. The following error was reported:

```
failed to open tablet writer, error=RPC call is timeout, error_text=[E1008] Reached timeout=xxx ms
```

Cause Analysis

When data is imported, a BE node opens the tablet writer, which may involve the write operation of multiple memory blocks. As a result, the RPC times out. You can adjust the RPC timeout interval to avoid the timeout error.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Configurations** > **All Configurations**.

Step 2 In the navigation pane on the left, choose **BE(Role)** > **Customization**. Add the custom parameter **tablet_writer_open_rpc_timeout_sec** to **be.conf.customized.configs**. The parameter value is the RPC timeout interval. The default value is 60. You can increase the value, for example, set this parameter to **300**.

Step 3 Click **Instance**, select all BE instances, and choose **More** > **Restart Instance** to restart the BE instances.

----End

5.10.3 What Do I Do If the Error Message "plugin not enabled" Is Displayed When the MySQL Client Is Used to Connect to the Doris Database?

Symptom

The following error message is displayed when the MySQL client is used to connect to the Doris database:

```
ERROR 2059 (HY000): Authentication plugin 'mysql_clear_password' cannot be loaded: plugin not enabled
```

Cause Analysis

The mysql_clear_password plug-in is disabled.

Procedure

- When you use the MySQL client to connect to the Doris database, run the following command with **--enable-cleartext-plugin** added:

  mysql --enable-cleartext-plugin -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***Doris FE instance IP address*

- Run the following command on the node where the MySQL client is installed to enable the mysql_clear_password plug-in, and then reconnect to Doris:

  export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

5.10.4 How Do I Handle the FE Startup Failure?

Symptom

The FE instance failed to be started, and the **/var/log/Bigdata/doris/fe/fe.log** file kept showing the following error message:

```
wait catalog to be ready. FE type UNKNOWN
```

Cause Analysis

- The FE installation node has multiple network adapter IP addresses. The **priority_network** parameter is incorrectly set. As a result, an incorrect IP address is matched during FE startup.
- Most follower FE nodes in the cluster are not started. For example, there are three follower FE nodes and only one follower FE node is started.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**, and click **Configurations**.

Step 2 Search for the **priority_network** parameter and set it correctly for the FE service. You can view the IP address of the network adapter bound to the FE node by checking the **CURRENT_INSTANCE_IP** variable in *FE installation directory*/**FusionInsight_Doris_*/1_*_FE/etc/ENV_VARS**.

The **priority_network** parameter is used to help the system select the correct IP address of the network adapter as the IP address of the FE or BE. You are advised to set this parameter explicitly in any case to prevent incorrect IP address selection after network adapters are added. The value of **priority_network** is in CIDR format and is used to ensure that all nodes can use the same configuration value. The parameter value consists of two parts. The first part is the IP address in dotted decimal notation, and the second part is the prefix length.

For example, 10.168.1.0/8 matches all 10.xx.xx.xx IP addresses, and 10.168.1.0/16 matches all 10.168.xx.xx IP addresses. If there are two nodes: 10.168.10.1 and 10.168.10.2, **10.168.10.0/24** can be the value of **priority_network**.

Step 3 Click **Instance**, select the follower FE to be started, and click **Start Instance**. For example, if there are three followers and only one follower is started, you need to

start at least one FE so that a master node can be elected from the FE election group to provide services.

Step 4 If the FE still fails to be started, contact O&M engineers to rectify the fault.

----End

5.10.5 How Do I Handle the Startup Failure Due to Incorrect IP Address Matching for the BE Instance?

Symptom

The BE instance failed to be started and the following error message was displayed:

```
backend ip saved in master does not equal to backend local ipx.x.x.x vs. x.x.x.x
```

Cause Analysis

The BE installation node has multiple network adapter IP addresses. The **priority_network** parameter is incorrectly set. As a result, an incorrect IP address is matched during BE startup.

Procedure

Step 1 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**, and click **Configurations**.

Step 2 Search for the **priority_network** parameter and set it correctly for the BE service. You can view the IP address of the network adapter bound to the BE node by checking the **CURRENT_INSTANCE_IP** variable in *BE installation directory*/**FusionInsight_Doris_*/1_*_BE/etc/ENV_VARS**.

The **priority_network** parameter is used to help the system select the correct IP address of the network adapter as the IP address of the FE or BE. You are advised to set this parameter explicitly in any case to prevent incorrect IP address selection after network adapters are added. The value of **priority_network** is in CIDR format and is used to ensure that all nodes can use the same configuration value. The parameter value consists of two parts. The first part is the IP address in dotted decimal notation, and the second part is the prefix length.

For example, 10.168.1.0/8 matches all 10.xx.xx.xx IP addresses, and 10.168.1.0/16 matches all 10.168.xx.xx IP addresses. If there are two nodes: 10.168.10.1 and 10.168.10.2, **10.168.10.0/24** can be the value of **priority_network**.

----End

5.10.6 What Should I Do If Error Message "Read timed out" Is Displayed When the MySQL Client Connects to the Doris?

Symptom

An error was reported when the MySQL client is connected to Doris.

```
java.net.SocketTimeoutException: Read timed out
```

Cause Analysis

The Doris server responds slowly.

Procedure

When you use the MySQL client to connect to the Doris database, run the following command with **connect_timeout** added (default value: 10 seconds):

mysql -u*Database login user* **-p***Database login user password* **-P***Database connection port* **-h***IP address of Doris FE instance* **--connect_timeout=***120*

5.10.7 What Should I Do If an Error Is Reported When the BE Runs a Data Import or Query Task?

Symptom

When data is imported or queried, the following error message is displayed:

```
Not connected to 192.168.100.1:8060 yet, server_id=384
```

Cause Analysis

- The BE node where the task is running breaks down.
- RPC congestion or other errors occur.

Procedure

- If the BE node where the task is running breaks down, check the breakdown cause and rectify the fault.
- If a large amount of unsent data on the RPC source exceeds the threshold, set the following parameters:
  - **brpc_socket_max_unwritten_bytes**: specifies the threshold of the amount of data that is not sent. The default value is 1 GB. If the amount of data that is not sent exceeds the threshold value, the OVERCROWDED error is reported. You need to increase the value.
  - **tablet_writer_ignore_eovercrowded**: specifies whether to ignore OVERCROWDED error that occurs during data import. The default value is **false**. This parameter is used to prevent import failures and improve stability.
  - **max_body_size**: specifies the maximum packet size allowed. The default value is 3 GB. If the query contains data of the string or bitmap type, you can modify this parameter to avoid this problem.

5.10.8 What Should I Do If a Timeout Error Is Reported When Broker Load Imports Data?

Symptom

The following error message was displayed when Broker Load was used to import data:

```
org.apache.thrift.transport.TTransportException: java.net.SocketException: Broken pipe
```

Cause Analysis

When data is imported from an external storage device (for example, HDFS), file directory query times out because there are too many files in the directory.

Procedure

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** and click **Configurations** > **All Configurations**. Select **FE (Role)** > **Customization**, and add the custom parameter **broker_timeout_ms**. The default value is 10 seconds. You need to increase the value of this parameter, for example, to **1000**, and restart the FE instance whose configuration has expired.

5.10.9 What Should I Do If an Error Message Is Displayed When Broker Load Is Used to Import Data?

Symptom

When Broker Load is used to import data, the error message "failed to send batch" or "TabletWriter add batch with unknown id" is displayed.

Cause Analysis

The task execution times out due to a large number of concurrent requests or a large amount of data.

Procedure

Step 1 Log in to the MySQL client and run the following command to increase the value of **query_timeout**. The default value is 300 seconds.

SET GLOBAL query_timeout = *xxx*;

Step 2 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** and click **Configurations** > **All Configurations**. Select **BE (Role)** > **Customization**, and add the custom parameter **streaming_load_rpc_max_alive_time_sec**. The default value is 1200 seconds. You need to increase the value of this parameter and restart the BE instance whose configuration has expired.

----End

5.11 Doris Troubleshooting

5.11.1 What Should I Do If a Query Is Performed on the BE Node Where Some Copies Are Lost or Damaged and an Error Is Reported?

Symptom

If multiple copies were lost from the disk, for example, **mv** was renamed, the kernel could not detect the loss of the copies. If the query request runs on the BE node where the copies are lost, the following error is reported:

Procedure

Step 1 Log in to the node where MySQL is installed and connect to the Doris database.

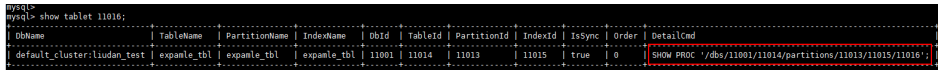
Step 2 Call **check_tablet_segment_lost** of the BE node to request automatic recovery of lost copies.

curl -X POST http://*192.168.67.78:29986***/api/check_tablet_segment_lost?repair=true** (

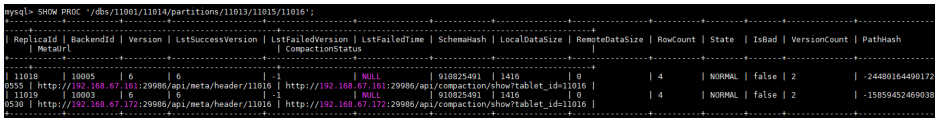
In the preceding command, *192.168.67.78* indicates the IP address of the abnormal BE node, and *29986* indicates the service port of the HTTP server of the BE node. You can search for **webserver_port** on the Doris configuration page of Manager to view the port.

Step 3 Run the following command to obtain DetailCmd:

show tablet *tabletId*



Step 4 Run DetailCmd. If the copies of the abnormal node have been removed, run the query again.



----End

5.11.2 How Do I Restore the FE Service from a Fault?

Symptom

The FE service failed to start bdbje, data could not be synchronized between FE nodes, metadata could not be written, or no master node was available. To restore the FE service, start a new master node based on the metadata in **meta_dir**, and then add FE nodes one by one.

Procedure

Step 1 Stop all FE processes and stop all service access to prevent unexpected problems caused by external access during metadata restoration.

Step 2 Search for the metadata on all FE instance nodes and locate the latest FE node as the master node to be restored.

1. Log in to the FE background node and check the value of **meta_dir** in the **${BIGDATA_HOME}/FusionInsight_Doris_x.x.x/x_x_FE/etc/fe.conf** file. The value is the metadata storage directory.
2. Search for the metadata storage directories of all FE nodes and check the **image/image.***xxxx* files in the directories. A larger value of **image.***xxxx* indicates a newer metadata. Locate the latest FE node and use it as the first FE to be restored, that is, the master FE.
3. Back up the metadata storage directories of all FEs.

   For example, if the metadata storage directory is **/srv/BigData/doris_fe/doris-meta**, run the following command:

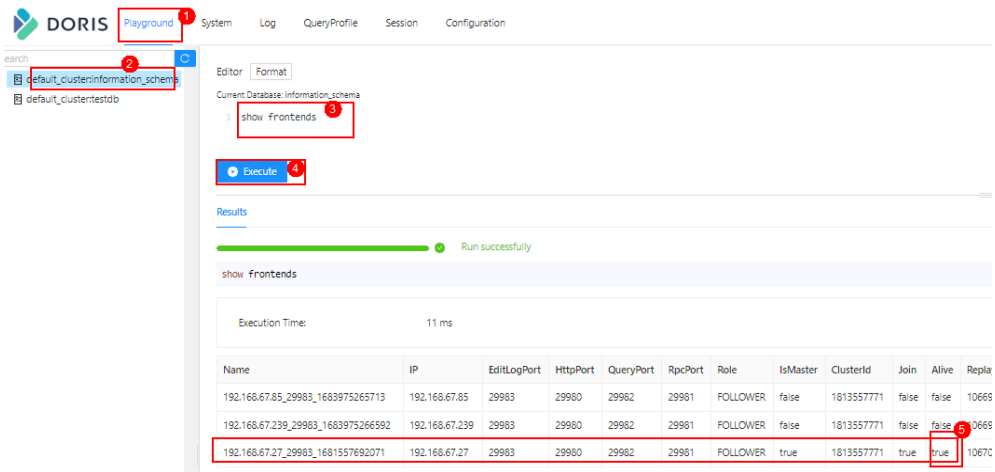
   cp -r /srv/BigData/doris_fe/doris-meta /srv/BigData/doris_fe/doris-meta.bak

Step 3 Go to **Step 2** and locate the node where the FE node with the latest metadata is deployed (that is, the master node) and add **metadata_failure_recovery=true** to **${BIGDATA_HOME}/FusionInsight_Doris_x.x.x/x_x_FE/etc/fe.conf**. If the **${BIGDATA_HOME}/FusionInsight_Doris_x.x.x/x_x_FE_UPDATE** directory exists, add the configuration to **fe.conf** in **x_x_FE_UPDATE**.

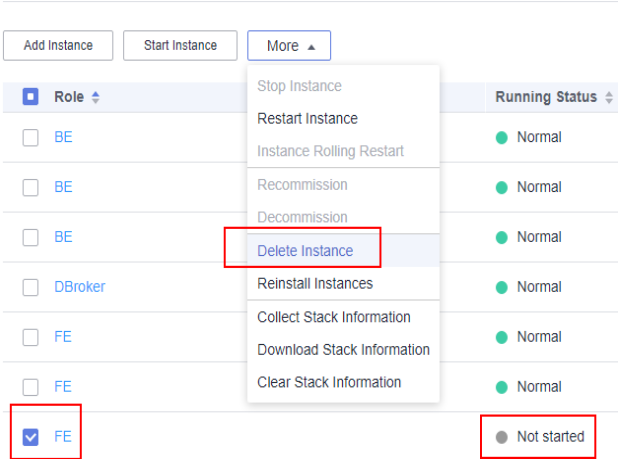
Step 4 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Instances**, select the FE node whose configuration is modified in **Step 3**, and choose **More** > **Restart Instance** to restart the FE instance. Other instances are still stopped.

Step 5 Check the status of the FE instance after it is started. After the FE instance is started, enter **http://***192.168.67.27*:*29980* in the address box of the browser to connect to the FE instance.

Log in to the FE web UI, click **Playground**, select **default_cluster:information_schema**, enter the **show frontends** command in the command box on the right, and click **Execute**. If the value in the **Alive** column of the current FE instance in the **Results** list is **true**, the FE is restored.

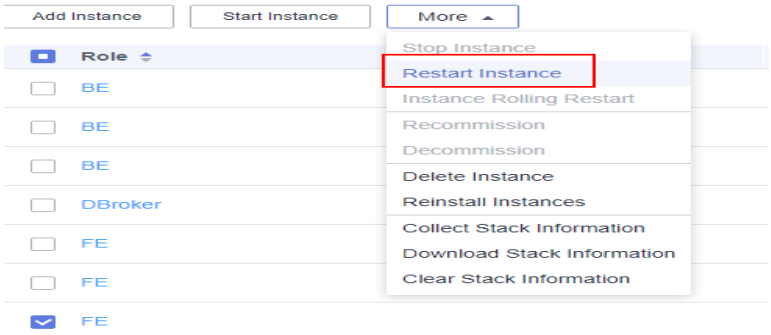


Step 6 On FusionInsight Manager, choose **Cluster** > **Services** > **Instances**, select the FE instance that is not a Master node and is not started, and choose **More** > **Delete Instance**.



Step 7 After the FE instance is deleted, click **Add Instance** to add the FE instance deleted in **Step 6**.

Step 8 Select the instance whose configuration has expired, choose **More** > **Restart Instance** to restart the FE instance whose configuration has expired, and delete the **metadata_failure_recovery** parameter added to the **fe.conf** file on the node where the FE instance is deployed.

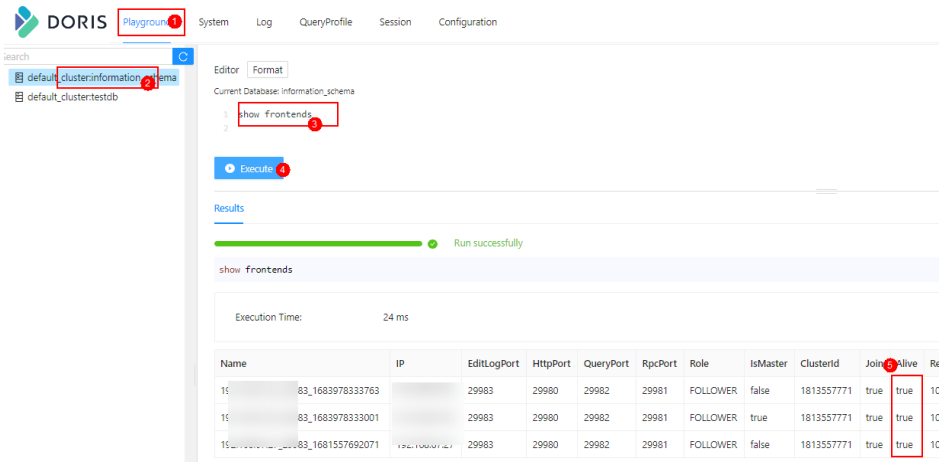


Step 9 Check whether the cluster is running properly. On the FE web UI, run the following command to check whether the FE, BE, and DBroker processes are healthy and in the same cluster. If the value of **Alive** for all instances in the **Results** list is **true**, the processes are healthy.

For example, the following commands are executed in **default_cluster:information_schema** of **Playground** on the Doris web UI:

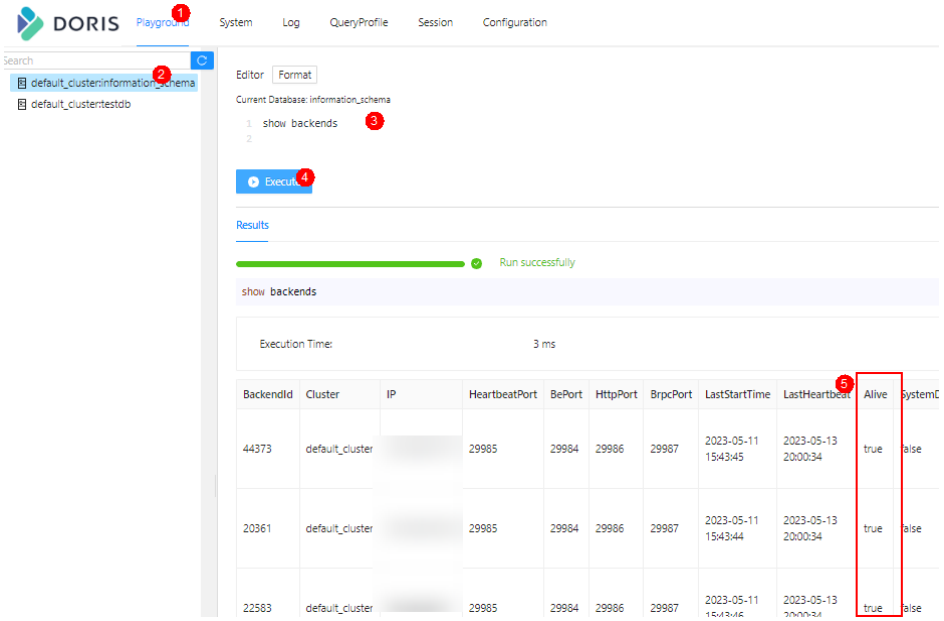
- Run the following command to check whether all FE processes are healthy:

  show frontends;



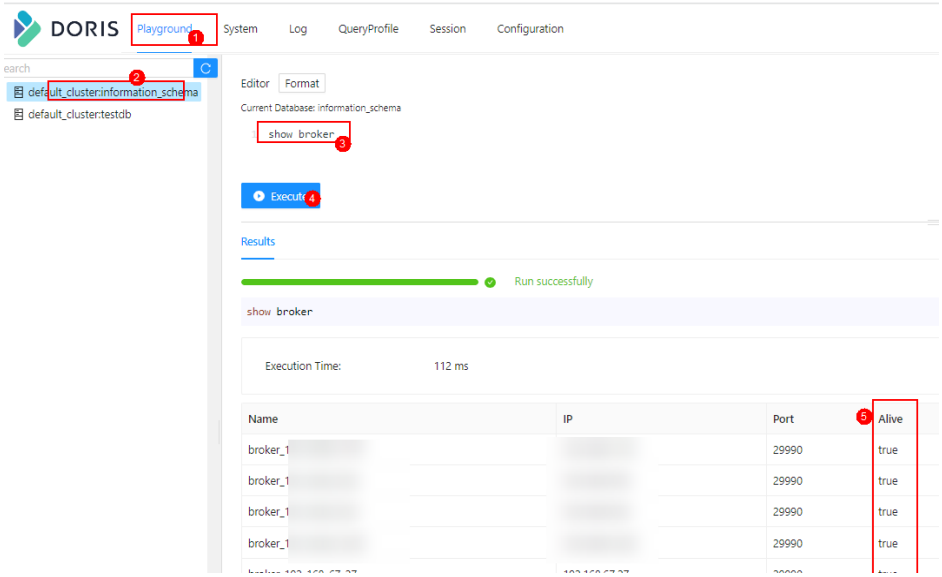
- Run the following command to check whether all BE processes are healthy:

  show backends;



- Run the following command to check whether all DBroker processes are healthy:

  show broker;



----End

5.11.3 What Should I Do If the Data Volume of a Broker Load Import Task Exceeds the Threshold?

Symptom

The following error message was displayed when Broker Load was used to import data:

```
Scan bytes per broker scanner exceed limit:xxx
```

Cause Analysis

The maximum data volume of a single import task processed by the BE process is 3 GB. You can adjust the import parameters of Broker Load for large files.

Procedure

Modify the maximum scan amount and maximum concurrent number of tasks of a single BE node according to the current number of BE instances and the size of the files to be imported. Perform the following steps to modify the parameters:

1. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris**. On the dashboard page, view the IP address of leader host to determine the node where the active FE node is deployed.
2. Click **Instance**, and click the BE instance whose IP address was viewed in **1**. Click **Configurations** > **All Configurations**, select **BE (Role)** > **Customization**, and add the following parameters:
   - **max_broker_concurrency**: number of BE nodes
   - **max_bytes_per_broker_scanner**: size of the file to be imported/number of BE nodes

NOTE

The configuration items take effect only when they are modified in the **fe.conf** file of the leader FE.

3. Click **Save** to save the configuration and restart the instance whose configuration has expired.

6 Using Flink

6.1 Flink Job Engine

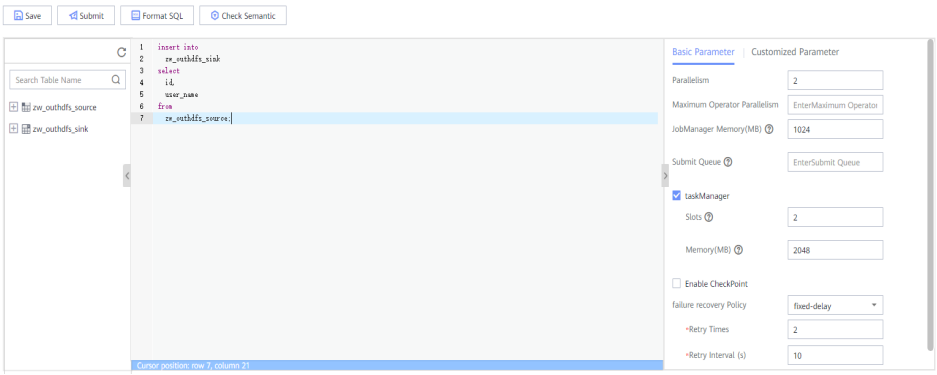
Flink web UI provides a web-based visual development platform. You only need to compile SQL statements to develop jobs, slashing the job development threshold. In addition, the exposure of platform capabilities allows service personnel to compile SQL statements for job development to quickly respond to requirements, greatly reducing the Flink job development workload.

Flink Web UI Features

The Flink web UI has the following features:

- Enterprise-class visual O&M: GUI-based O&M management, job monitoring, and standardization of Flink SQL statements for job development.

  Figure 6-1 Operations management

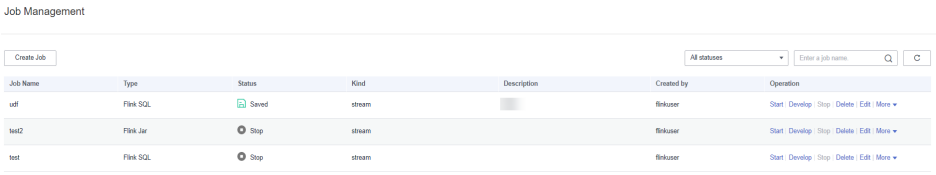
- Quick cluster connection: After configuring the client and user credential key file, you can quickly access a cluster using the cluster connection function.
- Quick data connection: You can access a component by configuring the data connection function. If **Data Connection Type** is set to **HDFS**, you need to create a cluster connection. If **Authentication Mode** is set to **KERBEROS** for other data connection types, you need to create a cluster connection. If **Authentication Mode** is set to **SIMPLE**, you do not need to create a cluster connection.

NOTE

If **Data Connection Type** is set to **Kafka**, **Authentication Type** cannot be set to **KERBEROS**.

- Visual development platform: The input/output mapping table can be customized to meet the requirements of different input sources and output destinations.
- Easy to use GUI-based job management

Figure 6-2 Job management



Key Web UI Capabilities

Table 6-1 shows the key capabilities provided by Flink web UI.

Table 6-1 Key web UI capabilities

Item	Description
Batch-Stream convergence	• Batch jobs and stream jobs can be processed with a unified set of Flink SQL statements.
Flink SQL kernel capabilities	• Flink SQL supports customized window size, stream compute within 24 hours, and batch processing beyond 24 hours. • Flink SQL supports reading data from Kafka and HDFS, writing data to Kafka and HDFS. • A job can define multiple Flink SQL statements, and multiple metrics can be combined into one computing job. If a job contains same primary keys as well as same inputs and outputs, the job supports the computing of multiple windows. • The AVG, SUM, COUNT, MAX, and MIN statistical methods are supported.
Flink SQL functions on the console	• Cluster connection management allows you to configure clusters where services such as Kafka and HDFS reside. • Data connection management allows you to configure services such as Kafka and HDFS. • Data table management allows you to define data tables accessed by SQL statements and generate DDL statements. • Flink SQL job definition allows you to use SQL statements to verify, parse, optimize, convert a job into a Flink job, and submit the job.

Item	Description
Flink job visual management	• Stream jobs and batch jobs can be defined in a visual manner. • Job resources, fault recovery policies, and checkpoint policies can be configured in a visual manner. • Status monitoring of stream and batch jobs are supported. • The Flink job O&M is enhanced, including redirection of the native monitoring page.
Performance and reliability	• Stream processing supports 24-hour window aggregation computing and millisecond-level performance. • Batch processing supports 90-day window aggregation computing, which can be completed in minutes. • Invalid data of stream processing and batch processing can be filtered out. • When HDFS data is read, the data can be filtered based on the calculation period in advance. • If the job definition platform is faulty or the service is degraded, jobs cannot be redefined, but the computing of existing jobs is not affected. • The automatic restart mechanism is provided for job failures. You can configure restart policies.

Flink Web UI Application Process

The Flink web UI application process is shown as follows:

Figure 6-3 Flink web UI application process

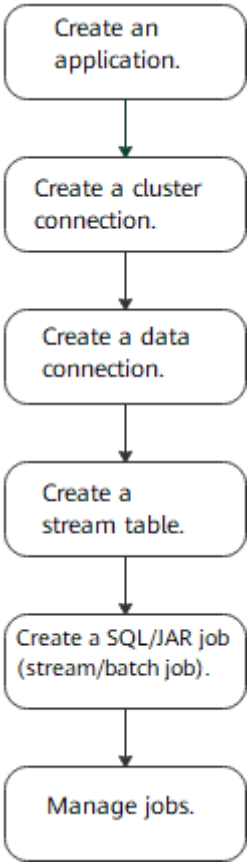


Table 6-2 Description of the Flink web UI application process

Step	Description	Reference
Creating an application	Applications can be used to isolate different upper-layer services.	**Creating a FlinkServer Application**
Creating a cluster connection	Different clusters can be accessed by configuring the cluster connection.	**Creating a FlinkServer Cluster Connection**
Creating a Data Connection	Through data connections, you can access different data services, including HDFS and Kafka.	**Creating a FlinkServer Data Connection**
Creating a stream table	Data tables can be used to define basic attributes and parameters of source tables, dimension tables, and output tables.	**Creating a FlinkServer Stream Table Source**
Creating a SQL/JAR job (stream/batch job)	APIs can be used to define Flink jobs, including Flink SQL and Flink Jar jobs.	**Creating a FlinkServer Job**

Step	Description	Reference
Managing jobs	A created job can be managed, including starting, developing, stopping, deleting, and editing the job.	Creating a FlinkServer Job

6.2 Flink User Permission Management

6.2.1 Flink Security Authentication

Flink Authentication and Encryption

- In a Flink cluster, all components support authentication.
  - The kerberos authentication is supported between Flink cluster components and external components, such as YARN, HDFS, and ZooKeeper.
  - The security cookie authentication between Flink cluster components, for example, Flink client and JobManager, JobManager and TaskManager, and TaskManager and TaskManager, are supported.
- SSL encrypted transmission is supported by components of a Flink cluster and between components in a cluster, such as Flink client and JobManager, JobManager and TaskManager, as well as TaskManager and TaskManager.

ACL Control

In HA mode, ACL control is supported.

In HA mode of Flink, ZooKeeper can be used to manage clusters and discover services. Zookeeper supports SASL ACL control. Only users who have passed the SASL (Kerberos) authentication have the permission to operate files on ZooKeeper. To enable SASL ACL control, perform following configurations in the Flink configuration file.

```
high-availability.zookeeper.client.acl: creator
zookeeper.sasl.disable: false
```

For details about configuration items, see **HA**.

Web Security

Security of the Flink web UI is hardened, the whitelist filtering feature is provided, the Flink web UI is accessible only through a YARN proxy, and security headers are enhanced. In Flink clusters, listening ports of components can be configured.

- Encoding rules
  - Description: The same encoding mode is used on the web service client and server to prevent garbled characters and to implement input verification.
  - Security hardening: Response messages of web servers are encoded using UTF-8.

- Whitelist-based filter of IP addresses
  - Note: IP filter must be added to the web server to filter unauthorized requests from the source IP address and prevent unauthorized login.
  - Security hardening: Add **jobmanager.web.allow-access-address** to enable the IP filter. By default, only YARN users are supported.

    NOTE

    After the client is installed, you need to add the IP address of the client node to the **jobmanager.web.allow-access-address** configuration item.
- Preventing sending the absolute paths to the client
  - Note: If an absolute path is sent to a client, the directory structure of the server is exposed, increasing the risk that attackers know and attack the system.
  - Security hardening: If the Flink configuration file contains a parameter starting with a slash (/), the first-level directory is deleted.
- Same-origin policy
  - If two URL protocols have same hosts and ports, they are of the same origin. Protocols of different origins cannot access each other, unless the source of the visitor is specified on the host of the service to be visited.
  - Security hardening: The default value of the header of the response header **Access-Control-Allow-Origin** is the IP address of ResourceManager on Yarn clusters. If the IP address is not from Yarn, mutual access is not allowed.
- Preventing sensitive information disclosure
  - Web pages containing sensitive data must not be cached, to avoid leakage of sensitive information or data crosstalk among users who visit the internet through the proxy server.
  - Security hardening: Add **Cache-control**, **Pragma**, **Expires** security header. The default value is **Cache-Control: no-store**, **Pragma: no-cache**, and **Expires: 0**. The security hardening stops contents interacted between Flink and web server from being cached.
- Anti-hijacking
  - Since hotlinking and clickjacking use framing technologies, security hardening is required to prevent attacks.
  - Security hardening: Add **X-Frame-Options** security header to specify whether the browser will load the pages from **iframe**, **frame** or **object**. The default value is **X-Frame-Options: DENY**, indicating that no pages can be nested to **iframe**, **frame** or **object**.
- Logging calls of the Web Service APIs
  - Calls of the **Flink webmonitor restful** APIs are logged.
  - The **jobmanager.web.accesslog.enable** can be added in the **access log**. The default value is **true**. Logs are stored in a separate **webaccess.log** file.
- Cross-site request forgery prevention
  - In **Browser/Server** applications, CSRF must be prevented for operations involving server data modification, such as adding, modifying, and deleting. The CSRF forces end users to execute non-intended operations on the current web application.

  - Security hardening: Only two post APIs, one delete API, and get interfaces are reserve for modification requests. All other APIs are deleted.
- Troubleshooting:
  - When the application is abnormal, exception information is filtered, logged, and returned to the client.
  - Security hardening: A default error message page to filter information and log detailed error information. Four configuration parameters are added to ensure that the error page is switched to a specified URL provided by FusionInsight, preventing exposure of unnecessary information.

Table 6-3 Parameters

Parameter	Description	Mandatory
jobmanager.web.403-redirect-url	Web page access error 403. If 403 error occurs, the specified page will be redirected to.	Yes
jobmanager.web.404-redirect-url	Web page access error 404. If 404 error occurs, the specified page will be redirected to.	Yes
jobmanager.web.415-redirect-url	Web page access error 415. If 415 error occurs, the specified page will be redirected to.	Yes
jobmanager.web.500-redirect-url	Web page access error 500. If 500 error occurs, the specified page will be redirected to.	Yes

- HTML5 security
  - HTML5 is a next generation web development specification that provides new functions and extend the labels for developers. These new labels and functions increase the attack surface and pose attack risks (such as cross-domain resource sharing, client storage, WebWorker, WebRTC, and WebSocket).
  - Security hardening: Add the **Access-Control-Allow-Origin** parameter. For example, if you want to enable the cross-domain resource sharing, configure the **Access-Control-Allow-Origin** parameter of the HTTP response header.

    NOTE

    Flink does not involve security risks of functions such as storage on the client, WebWorker, WebRTC, and WebSocket.

Security Statement

- All security functions of Flink are provided by the open source community or self-developed. Security features that need to be configured by users, such as authentication and SSL encrypted transmission, may affect performance.

- As a big data computing and analysis platform, Flink does not detect sensitive information. Therefore, you need to ensure that the input data is not sensitive.
- You can evaluate whether configurations are secure as required.
- For any security-related problems, contact O&M support.

6.2.2 Flink User Permissions

To access and use the Flink web UI to perform service operations, you need to assign FlinkServer-related permissions to users. User **admin** on FusionInsight Manager does not have FlinkServer service operation permissions.

Applications (tenants) in FlinkServer are the maximum management scope, including cluster connection management, data connection management, application management, stream table management, and job management.

There are three types of resource permissions for FlinkServer, as shown in **Table 6-4**.

Table 6-4 FlinkServer resource permissions

Name	Description	Remarks
FlinkServer administrator permission	Users who have the permission can edit and view all applications.	This is the highest-level permission of FlinkServer. If you have the FlinkServer administrator permission, you have the permission on all applications by default.
Application edit permission	Users who have the permission can create, edit, and delete cluster connections and data connections. They can also create stream tables as well as create and run jobs.	In addition, users who have the permission can view current applications.
Application view permission	Users who have the permission can view applications.	-

6.2.3 Creating a FlinkServer Role

Create and configure a FlinkServer role on Manager as an MRS cluster administrator. A FlinkServer role can be configured with the FlinkServer administrator permission and the permissions to edit and view applications.

You need to set permissions for the specified user in FlinkServer so that they can update, query, and delete data.

Prerequisites

The cluster administrator has planned permissions based on service requirements.

Procedure

Step 1 Log in to Manager.

Step 2 Choose **System** > **Permission** > **Role**.

Step 3 On the displayed page, click **Create Role** and specify **Role Name** and **Description**.

Step 4 Set **Configure Resource Permission**.

FlinkServer permissions are as follows:

- **FlinkServer Admin Privilege**: highest-level permission. Users with the permission can perform service operations on all FlinkServer applications.
- **FlinkServer Application**: Users can set **application view** and **applications management** permissions on applications.

Table 6-5 Setting a role

Scenario	Role Authorization
Setting the FlinkServer administrator permission	In **Configure Resource Permission**, choose *Name of the desired cluster* > **Flink** and select **FlinkServer Admin Privilege**.
Setting FlinkServer application permissions	In the **Configure Resource Permission** table, choose *Name of the desired cluster* > **Flink** > **FlinkServer Application**. In the **Permission** column, select **application view** or **applications management**.

Step 5 Click **OK**. Return to role management page.

Step 6 (Optional) Create a user with FlinkServer-related permissions.

After the FlinkServer role is created, create a FlinkServer user and bind the user to the configured FlinkServer role and user group.

----End

6.2.4 Configuring Security Authentication for Interconnecting with Kafka

Sample project data of Flink is stored in Kafka. A user with Kafka permission can send data to Kafka and receive data from it.

Step 1 Ensure that clusters, including HDFS, Yarn, Flink, and Kafka are installed.

Step 2 Create a topic.

- Run Linux command line to create a topic. Before running commands, ensure that the kinit command, for example, **kinit flinkuser**, is run for authentication.

  NOTE

  To create a Flink user, you need to have the permission to create Kafka topics.

The format of the command is shown as follows, in which **{zkQuorum}** indicates ZooKeeper cluster information and the format is *IP.port*, and **{Topic}** indicates the topic name.

bin/kafka-topics.sh --create --zookeeper {zkQuorum}/kafka --replication-factor 1 --partitions 5 --topic {Topic}

Assume the topic name is **topic 1**. The command for creating this topic is displayed as follows:

```
/opt/client/Kafka/kafka/bin/kafka-topics.sh --create --zookeeper 10.96.101.32:2181,10.96.101.251:2181,10.96.101.177:2181,10.91.8.160:2181/kafka --replication-factor 1 --partitions 5 --topic topic1
```

NOTE

The ZooKeeper cluster information is as follows:

- Service IP address of the ZooKeeper quorumpeer instance:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Instance** tab and view the service IP addresses of all nodes where the quorumpeer instances reside.

- Port number of the ZooKeeper client:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Configurations** tab. On this tab page, view the value of **clientPort**.

- Configure the permission of the topic on the server.

  Set the **allow.everyone.if.no.acl.found** parameter of Kafka Broker to **true**.

Step 3 Perform the security authentication.

The Kerberos authentication, SSL encryption authentication, or Kerberos + SSL authentication mode can be used.

- **Kerberos authentication**
  - Client configuration

    In the Flink configuration file **flink-conf.yaml**, add configurations about Kerberos authentication. For example, add **KafkaClient** in **contexts** as follows:

    ```
    security.kerberos.login.keytab: /home/demo/keytab/flinkuser.keytab
    security.kerberos.login.principal: flinkuser
    security.kerberos.login.contexts: Client,KafkaClient
    security.kerberos.login.use-ticket-cache: false
    ```

  - Running parameter

    Running parameters about the **SASL_PLAINTEXT** protocol are as follows:

    --topic topic1 --bootstrap.servers 10.96.101.32:21007 --security.protocol SASL_PLAINTEXT --sasl.kerberos.service.name kafka --kerberos.domain.name hadoop.*System domain name***.com //10.96.101.32:21007** indicates the IP address and port of the Kafka server.

- **SSL encryption**
  - Configure the server.

    Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka** > **Configurations**, and set **Type** to **All**. Search for **ssl.mode.enable** and set it to **true**.

  - Configure the client.

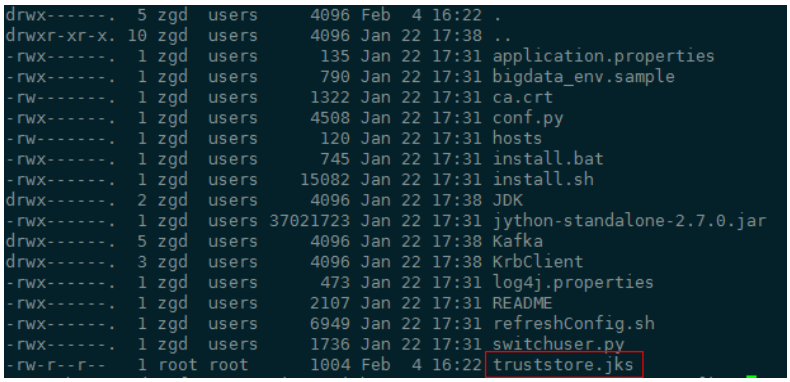
    i. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **More**, and choose **Download Client** to download the Kafka client.

ii. Use the **ca.crt** certificate file in the client root directory to generate the **truststore** file for the client.

Run the following command:

```
keytool -noprompt -import -alias myservercert -file ca.crt -keystore truststore.jks
```

The command execution result is similar to the following:



iii. Run parameters.

The value of **ssl.truststore.password** must be the same as the password you entered when creating **truststore**. Run the following command to run parameters. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

```
--topic topic1 --bootstrap.servers 10.96.101.32:9093 --security.protocol SSL --ssl.truststore.location /home/zgd/software/FusionInsight_Kafka_ClientConfig/truststore.jks --ssl.truststore.password XXX
```

- **Kerberos+SSL encryption**

  After completing preceding configurations of the client and server of Kerberos and SSL, modify the port number and protocol type in running parameters to enable the Kerberos+SSL encryption mode.

  ```
  --topic topic1 --bootstrap.servers 10.96.101.32:21009 --security.protocol SASL_SSL --sasl.kerberos.service.name kafka --ssl.truststore.location --kerberos.domain.name hadoop.System domain name.com /home/zgd/software/FusionInsight_Kafka_ClientConfig/truststore.jks --ssl.truststore.password XXX
  ```

----End

6.2.5 Configuring Flink Authentication and Encryption

Security Authentication

Flink supports the following authentication modes:

- Kerberos authentication: It is used between the Flink Yarn client and Yarn ResourceManager, JobManager and ZooKeeper, JobManager and HDFS, TaskManager and HDFS, Kafka and TaskManager, as well as TaskManager and ZooKeeper.
- Security cookie authentication: Security cookie authentication is used between Flink Yarn client and JobManager, JobManager and TaskManager, as well as TaskManager and TaskManager.
- Internal authentication of Yarn: The Internal authentication mechanism of Yarn is used between Yarn ResourceManager and ApplicationMaster (AM).

NOTE

- Flink JobManager and Yarn ApplicationMaster are in the same process.
- If Kerberos authentication is enabled for the user's cluster, Kerberos authentication is required.

Table 6-6 Authentication modes

Authentication Mode	Description	Configuration Method

Kerberos authentication	Currently, only keytab authentication mode is supported.	1. Download the user keytab file from FusionInsight Manager and save the keytab file to a folder on the host where the Flink client is located.
		2. Configure the following parameters in the **flink-conf.yaml** file:
		a. Keytab path
		`security.kerberos.login.keytab: /home/flinkuser/keytab/abc222.keytab`
		NOTE
		/home/flinkuser/keytab/abc222.keytab indicates the user directory.
		b. Principal name
		`security.kerberos.login.principal: abc222`
		c. In HA mode, if ZooKeeper is configured, the Kerberos authentication configuration items must be configured as follows:
		`zookeeper.sasl.disable: false`
		`security.kerberos.login.contexts: Client`
		d. If you want to perform Kerberos authentication between Kafka client and Kafka broker, set the value as follows:
		`security.kerberos.login.contexts: Client,KafkaClient`

Authentication Mode	Description	Configuration Method
Security cookie authentication	-	1. In the **bin** directory of the Flink client, call the **generate_keystore.sh** script to generate **Security cookie**, **flink.keystore**, and **flink.truststore**. Run the **sh generate_keystore.sh** command and enter the user-defined password. The password cannot contain **#**. **NOTE** After the script is executed, the **flink.keystore** and **flink.truststore** files are generated in the **conf** directory on the Flink client. In the **flink-conf.yaml** file, default values are specified for following parameters: • Set **security.ssl.keystore** to the absolute path of the **flink.keystore** file. • Set **security.ssl.truststore** to the absolute path of the **flink.truststore** file. • Set **security.cookie** to a random password automatically generated by the **generate_keystore.sh** script. • By default, **security.ssl.encrypt.enabled: false** is set in the **flink-conf.yaml** file by default. The **generate_keystore.sh** script sets **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password** to the password entered when the **generate_keystore.sh** script is called. • If ciphertext is required and **security.ssl.encrypt.enabled** is **true** in the **flink-conf.yaml** file, the **generate_keystore.sh** script does not set **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password**. To obtain the values, use the Manager plaintext encryption API by running the following command: **curl -k -i -u** *Username*:*Password* **-X POST -HContent-type:application/json -d '{"plainText":"***Password***"}' 'https://***x.x.x.x***:28443/web/api/v2/tools/encrypt'** In the preceding command, *Username*:*Password* indicates the user name and password for logging in to the system. The password of **"plainText"** indicates the one used to call the **generate_keystore.sh** script. *x.x.x.x* indicates the floating IP address of Manager. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage. 2. Check whether **Security Cookie** is enabled. That is, check **security.enable: true** in the **flink-conf.yaml** file and check whether **security cookie** is configured. An example is as follows: `security.cookie: ae70acc9-9795-4c48-ad35-8b5adc8071744f605d1d-2726-432e-88ae-dd39bfec40a9`

Authentication Mode	Description	Configuration Method
		NOTE The validity period of the SSL certificate obtained by using the **generate_keystore.sh** script preset on the MRS client is 5 years. To disable the default SSL authentication mode, set **security.ssl.enabled** to **false** in the **flink-conf.yaml** file and comment out **security.ssl.key-password**, **security.ssl.keystore-password**, **security.ssl.keystore**, **security.ssl.truststore-password**, and **security.ssl.trustore**.
Internal authentication of Yarn	This authentication mode does not need to be configured by the user.	-

NOTE

One Flink cluster supports only one user. One user can create multiple Flink clusters.

Encrypted Transmission

Flink supports three encrypted transmission modes:

- Encrypted transmission inside Yarn: It is used between the Flink Yarn client and Yarn ResourceManager, as well as Yarn ResourceManager and JobManager.
- SSL transmission: SSL transmission is used between Flink Yarn client and JobManager, JobManager and TaskManager, as well as TaskManager and TaskManager.
- Encrypted transmission inside Hadoop: The internal encrypted transmission mode of Hadoop used between JobManager and HDFS, TaskManager and HDFS, JobManager and ZooKeeper, as well as TaskManager and ZooKeeper.

NOTE

Configuration about SSL encrypted transmission is mandatory while configuration about encryption of Yarn and Hadoop is not required.

To configure SSL encrypted transmission, configure the following parameters in the **flink-conf.yaml** file on the client:

1. Turn on the SSL switch and set SSL encryption algorithms. **Table 6-7** describes the parameters. Set the parameters based on your need.

Table 6-7 Parameter description

Parameter	Example Value	Description
security.ssl.enabled	true	Enable SSL.
akka.ssl.enabled	true	Enable Akka SSL.
blob.service.ssl.enabled	true	Enable SSL for the Blob channel.
taskmanager.data.ssl.enabled	true	Enable SSL transmissions between TaskManagers.
security.ssl.algorithms	TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	Configure the SSL encryption algorithm.

NOTE

Enabling SSL for data transmission between TaskManagers may pose great impact on the system performance.

2. In the **bin** directory of the Flink client, run the ***sh generate_keystore.sh*** *<Password>* command. The configuration items in **Table 6-8** are set by default. You can change the configurations. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

Table 6-8 Parameter description

Parameter	Example Value	Description
security.ssl.keystore	${path}/flink.keystore	Path for storing the **keystore**. **flink.keystore** indicates the name of the **keystore** file generated by the **generate_keystore.sh*** tool.
security.ssl.keystore-password	-	A user-defined password of **keystore**.
security.ssl.key-password	-	A user-defined password of the SSL key.

Parameter	Example Value	Description
security.ssl.truststore	${path}/flink.truststore	Path for storing the **truststore**. **flink.truststore** indicates the name of the **truststore** file generated by the **generate_keystore.sh*** tool.
security.ssl.truststore-password	-	A user-defined password of **truststore**.

NOTE

The **path** directory is a user-defined directory for storing configuration files of the SSL keystore and truststore.

3. Configure the paths for the client to access the **keystore** or **truststore** file.
   - Relative path (recommended)

     Perform the following steps to set the file paths of **flink.keystore** and **flink.truststore** to relative paths and ensure that the directory where the Flink client command is executed can directly access the relative paths.

     i. In the **conf/** directory of the Flink client, create a directory, for example, **ssl**.

     cd / *Flink client directory*/**Flink/flink/conf/**

     mkdir ssl

     ii. Move the **flink.keystore** and **flink.truststore** files to the new paths.

     mv flink.keystore ssl/

     mv flink.truststore ssl/

     iii. Change the values of the following parameters to relative paths in the **flink-conf.yaml** file:

     vi / *Flink client directory*/**Flink/flink/conf/flink-conf.yaml**

     ```
     security.ssl.keystore: ssl/flink.keystore
     security.ssl.truststore: ssl/flink.truststore
     ```

   - Absolute path

     After the **generate_keystore.sh** script is executed, the **flink.keystore** and **flink.truststore** file paths are automatically set to absolute paths in the **flink-conf.yaml** file by default. In this case, you need to place the **flink.keystore** and **flink.truststore** files in the **conf** directory to the absolute paths of the Flink client and each Yarn node, respectively.

6.3 Using the Flink Client

This section describes how to use Flink to run wordcount jobs.

Prerequisites

- Flink has been installed in an MRS cluster.

- The cluster runs properly and the client has been correctly installed, for example, in the **/opt/hadoopclient** directory. The client directory in the following operations is only an example. Change it to the actual installation directory.

Procedure

Step 1 Install a client.

The following uses installing a Flink client on a node in the cluster as an example:

1. Log in to FusionInsight Manager, choose **Cluster**, click the name of the desired cluster, click **More**, and select **Download Client**.
2. In the **Download Cluster Client** dialog box that is displayed, select **Complete Client** for **Select Client Type**, select the platform type that matches the architecture of the node where the client is to install, select **Save to Path**, and click **OK**.
   - The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active management node by default.
   - The name of the client software package is in the following format: **FusionInsight_Cluster_*<Cluster ID>*_Services_Client.tar**. In this section, the cluster ID **1** is used as an example. Replace it with the actual cluster ID.
3. Log in to the server where the client is to be installed as the client installation user.
4. Go to the directory where the installation package is stored and run the following commands to decompress the package:

   cd /tmp/FusionInsight-Client

   tar -xvf FusionInsight_Cluster_1_Services_Client.tar
5. Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file:

   sha256sum -c FusionInsight_Cluster_1_Services_ClientConfig.tar.sha256

   ```
   FusionInsight_Cluster_1_Services_ClientConfig.tar: OK
   ```
6. Decompress the obtained installation file.

   tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar
7. Go to the directory where the installation package is stored, and run the following command to install the client to a specified directory (absolute path), for example, **/opt/hadoopclient**:

   cd /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Services_ClientConfig

   ./install.sh /opt/hadoopclient

   The client is installed if information similar to the following is displayed:

   ```
   The component client is installed successfully
   ```

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 4 Run the following command to initialize environment variables:

source /opt/hadoopclient/bigdata_env

Step 5 Perform the following operations if Kerberos authentication is enabled for the cluster. Otherwise, skip these operations.

1. Prepare a user for submitting Flink jobs.

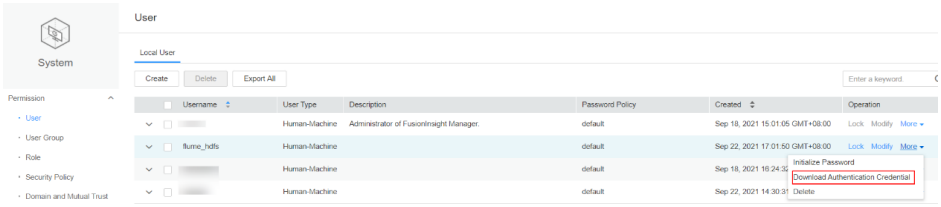
   Log in to FusionInsight Manager and choose **System** > **Permission** > **Role**. Click **Create Role** and configure **Role Name** and **Description**. In **Configure Resource Permission**, choose *Name of the desired cluster* > **Flink** and select **FlinkServer Admin Privilege**. Then click **OK**.

   Choose **System** > **Permission** > **User** and click **Create User**. Configure **Username**, set **User Type** to **Human-Machine**, configure **Password** and **Confirm Password**, click **Add** next to **User Group** to add the **hadoop**, **yarnviewgroup**, and **hadooppmanager** user groups as needed, click **Add** next to **Role** to add the **System_administrator**, **default**, and the created role, and click **OK**. (If you create a Flink job user for the first time, log in to FusionInsight Manager as the user and change the password.)

2. Log in to Manager and download the authentication credential.

   Log in to Manager and choose **System** > **Permission** > **User**. On the displayed page, locate the row that contains the added user, click **More** in the **Operation** column, and select **Download Authentication Credential**.

   Figure 6-4 Downloading the authentication credential

3. Decompress the downloaded authentication credential package and copy the obtained file to the client node, for example, the **/opt/hadoopclient/Flink/flink/conf** directory. If the client is installed on a node outside the cluster, copy the obtained files to the **/etc/** directory on the node.

4. Add the service IP address of the node where the client is installed and IP address of the master node to the **jobmanager.web.access-control-allow-origin** and **jobmanager.web.allow-access-address** configuration items in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file. Use commas (,) to separate the IP addresses.

   jobmanager.web.access-control-allow-origin: *xx.xx.xxx.xxx,xx.xx.xxx.xxx,xx.xx.xxx.xxx*
   jobmanager.web.allow-access-address: *xx.xx.xxx.xxx,xx.xx.xxx.xxx,xx.xx.xxx.xxx*

NOTE

To obtain the service IP address of the node where the client is installed, perform the following operations:

- Node inside the cluster:

  In the navigation pane of the MRS management console, choose **Active Clusters**, select a cluster, and click its name to switch to the cluster details page.

  On the **Nodes** tab page, view the IP address of the node where the client is installed.

- Node outside the cluster: IP address of the ECS where the client is installed.

5. Configure security authentication by adding the **keytab** path and username in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** configuration file.

   security.kerberos.login.keytab: *<user.keytab file path>*
   security.kerberos.login.principal: *<Username>*

   Example:

   ```
   security.kerberos.login.keytab: /opt/hadoopclient/Flink/flink/conf/user.keytab
   security.kerberos.login.principal: test
   ```

6. In the **bin** directory of the Flink client, run the following commands to perform security hardening. Then, set a password for submitting jobs.

   cd /opt/hadoopclient/Flink/flink/bin

   sh generate_keystore.sh

   The script automatically replaces the SSL value in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file.

   NOTE

   After authentication and encryption, the **flink.keystore** and **flink.truststore** files are generated in the **conf** directory on the Flink client and the following configuration items are set to the default values in the **flink-conf.yaml** file:

   - Set **security.ssl.keystore** to the absolute path of the **flink.keystore** file.
   - Set **security.ssl.truststore** to the absolute path of the **flink.truststore** file.
   - Set **security.cookie** to a random password automatically generated by the **generate_keystore.sh** script.
   - By default, **security.ssl.encrypt.enabled** is set to **false** in the **flink-conf.yaml** file by default. The **generate_keystore.sh** script sets **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password** to the password entered when the **generate_keystore.sh** script is called.
   - If ciphertext is required and **security.ssl.encrypt.enabled** is **true** in the **flink-conf.yaml** file, the **generate_keystore.sh** script does not set **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password**. To obtain the values, use the Manager plaintext encryption API by running the following command: **curl -k -i -u** *Username*:*Password* **-X POST -HContent-type:application/json -d '{"plainText":"***Password***"}' 'https://***x.x.x.x***:28443/web/api/v2/tools/encrypt'**

     In the preceding command, *Username*:*Password* indicates the user name and password for logging in to the system. The password of **"plainText"** indicates the one used to call the **generate_keystore.sh** script. *x.x.x.x* indicates the floating IP address of Manager. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

7. Configure paths for the client to access the **flink.keystore** and **flink.truststore** files.

   - Relative path (recommended):

Perform the following steps to set the file path of **flink.keystore** and **flink.truststore** to the relative path and ensure that the directory where the Flink client command is executed can directly access the relative paths.

i. Create a directory, for example, **ssl**, in **/opt/hadoopclient/Flink/flink/conf/**.

cd /opt/hadoopclient/Flink/flink/conf/

mkdir ssl

ii. Move the **flink.keystore** and **flink.truststore** files to the **/opt/hadoopclient/Flink/flink/conf/ssl/** directory.

mv flink.keystore ssl/

mv flink.truststore ssl/

iii. Change the values of the following parameters to relative paths in the **flink-conf.yaml** file:

```
security.ssl.keystore: ssl/flink.keystore
security.ssl.truststore: ssl/flink.truststore
```

– Absolute path:

After the **generate_keystore.sh** script is executed, the file path of **flink.keystore** and **flink.truststore** is automatically set to the absolute path **/opt/hadoopclient/Flink/flink/conf/** in the **flink-conf.yaml** file. In this case, you need to move the **flink.keystore** and **flink.truststore** files from the **conf** directory to this absolute path on the Flink client and YARN nodes.

Step 6 Run a wordcount job.

NOTICE

To submit or run jobs on Flink, the user must have the following permissions:

- If Ranger authentication is enabled, the current user must belong to the **hadoop** group or the user has been granted the **/flink** read and write permissions in Ranger.
- If Ranger authentication is disabled, the current user must belong to the **hadoop** group.

- For a normal cluster (Kerberos authentication disabled), you can submit jobs in either of the following ways:
  – Run the following commands to start a session and submit a job in the session:

    yarn-session.sh -nm "*session-name***" -d**

    flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar

  – Run the following command to submit a single job on Yarn:

    flink run -m yarn-cluster /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
- For a security cluster (Kerberos authentication enabled), you can submit jobs in either of the following ways based on the paths of the **flink.keystore** and **flink.truststore** files:

- If the **flink.keystore** and **flink.truststore** files are stored in the relative path:
  - Run the following command in the directory at the same level as **ssl** to start the session and submit the job in the session:

    ssl is a relative path. For example, if **ssl** is in **opt/hadoopclient/Flink/flink/conf/**, run the command in the **opt/hadoopclient/Flink/flink/conf/** directory.

    cd /opt/hadoopclient/Flink/flink/conf

    yarn-session.sh -t ssl/ -nm "*session-name***" -d**

    flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
  - Run the following command to submit a single job on Yarn:

    cd /opt/hadoopclient/Flink/flink/conf

    flink run -m yarn-cluster -yt ssl/ /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
- If the **flink.keystore** and **flink.truststore** files are stored in the absolute path:
  - Run the following commands to start a session and submit a job in the session:

    cd /opt/hadoopclient/Flink/flink/conf

    yarn-session.sh -nm "*session-name***" -d**

    flink run /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar
  - Run the following command to submit a single job on Yarn:

    flink run -m yarn-cluster /opt/hadoopclient/Flink/flink/examples/streaming/WordCount.jar

Step 7 After the job has been successfully submitted, the following information is displayed on the client:

Figure 6-5 Job submitted successfully on Yarn

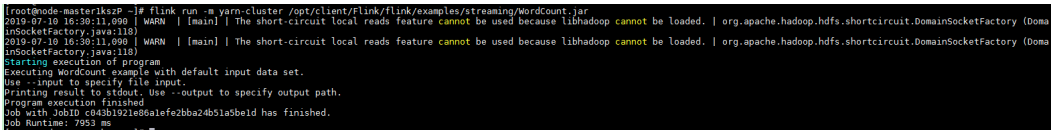


Figure 6-6 Session started successfully

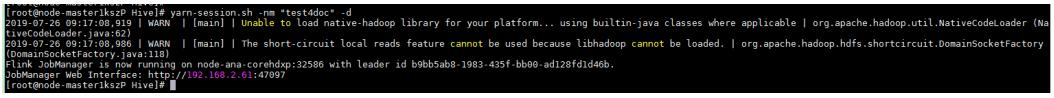

Figure 6-7 Job submitted successfully in the session

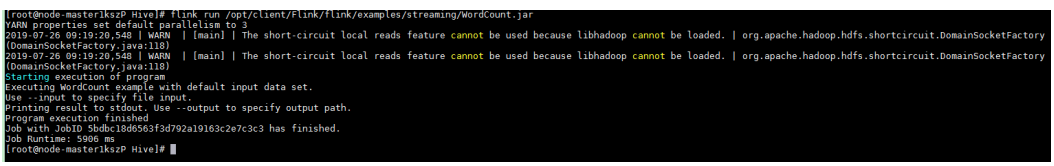
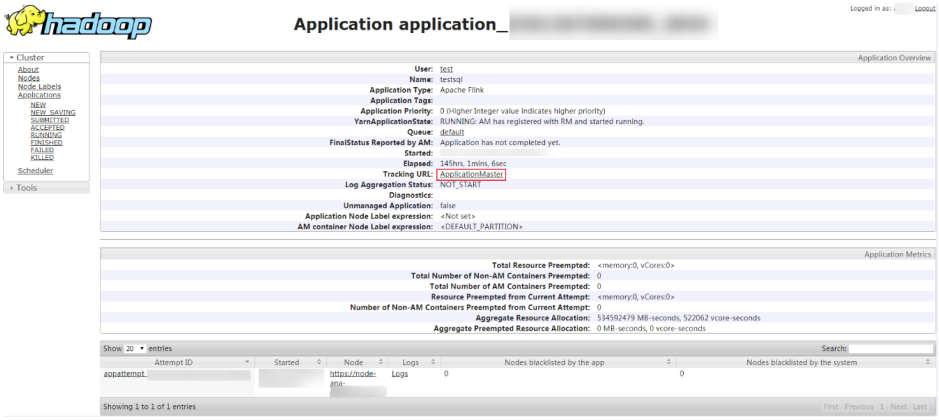


Step 8 Go to the native page of the YARN service, find the application of the corresponding job, and click the application name to go to the job details page.

- If the job is not completed, click **Tracking URL** to go to the native Flink page and view the job running information.
- If the job submitted in a session has been completed, you can click **Tracking URL** to log in to the native Flink service page to view job information.

Figure 6-8 application



----End

6.4 Preparing for Creating a FlinkServer Job

6.4.1 Accessing the FlinkServer Web UI

Scenario

After Flink is installed in an MRS cluster, you can connect to clusters and data as well as manage stream tables and jobs using the Flink web UI.

This section describes how to access the Flink web UI in an MRS cluster. Site trust must be added to the browser when you access Manager and the Flink web UI for the first time. Otherwise, the Flink web UI cannot be accessed.

Accessing the FlinkServer Web UI

Step 1 Log in to FusionInsight Manager as a user with **FlinkServer Admin Privilege**. Choose **Cluster** > **Services** > **Flink**.

NOTE

If your MRS cluster requires Kerberos authentication, create a role with the FlinkServer administrator permission or the application viewing and editing permission, and associate the role to the user. Then, you can access the Flink web UI. For details about how to create a role, see **Creating a FlinkServer Role**.

Step 2 On the right of **Flink WebUI**, click the link to access the Flink web UI.

Figure 6-9 Accessing the Flink Web UI

The Flink web UI provides the following functions:

- System management:
  - Cluster connection management allows you to create, view, edit, test, and delete a cluster connection.
  - Data connection management allows you to create, view, edit, test, and delete a data connection. Data connection types include HDFS and Kafka.
  - Application management allows you to create, view, and delete an application.
- Stream table management allows you to create, view, edit, and delete a stream table.
- Job management allows you to create, view, start, develop, edit, stop, and delete a job.

----End

6.4.2 Creating a FlinkServer Application

Applications can be used to isolate different upper-layer services.

Step 1 Access the Flink web UI as a user with **FlinkServer Admin Privilege**. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Choose **System Management** > **Application Management**.

Step 3 Click **Create Application**. On the displayed page, set parameters and click **OK**.

After the application is created, you can switch to the application to be operated in the upper left corner of the Flink web UI and develop jobs.

----End

6.4.3 Creating a FlinkServer Cluster Connection

Different clusters can be accessed by configuring the cluster connection.

Procedure

Step 1 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Choose **System Management** > **Cluster Connection Management**. The **Cluster Connection Management** page is displayed.

Step 3 Click **Create Cluster Connection**. On the displayed page, set parameters by referring to **Table 6-9** and click **OK**. After the cluster connection is created, you can edit, test, or delete the cluster connection in the **Operation** column.

Figure 6-10 Creating a cluster connection

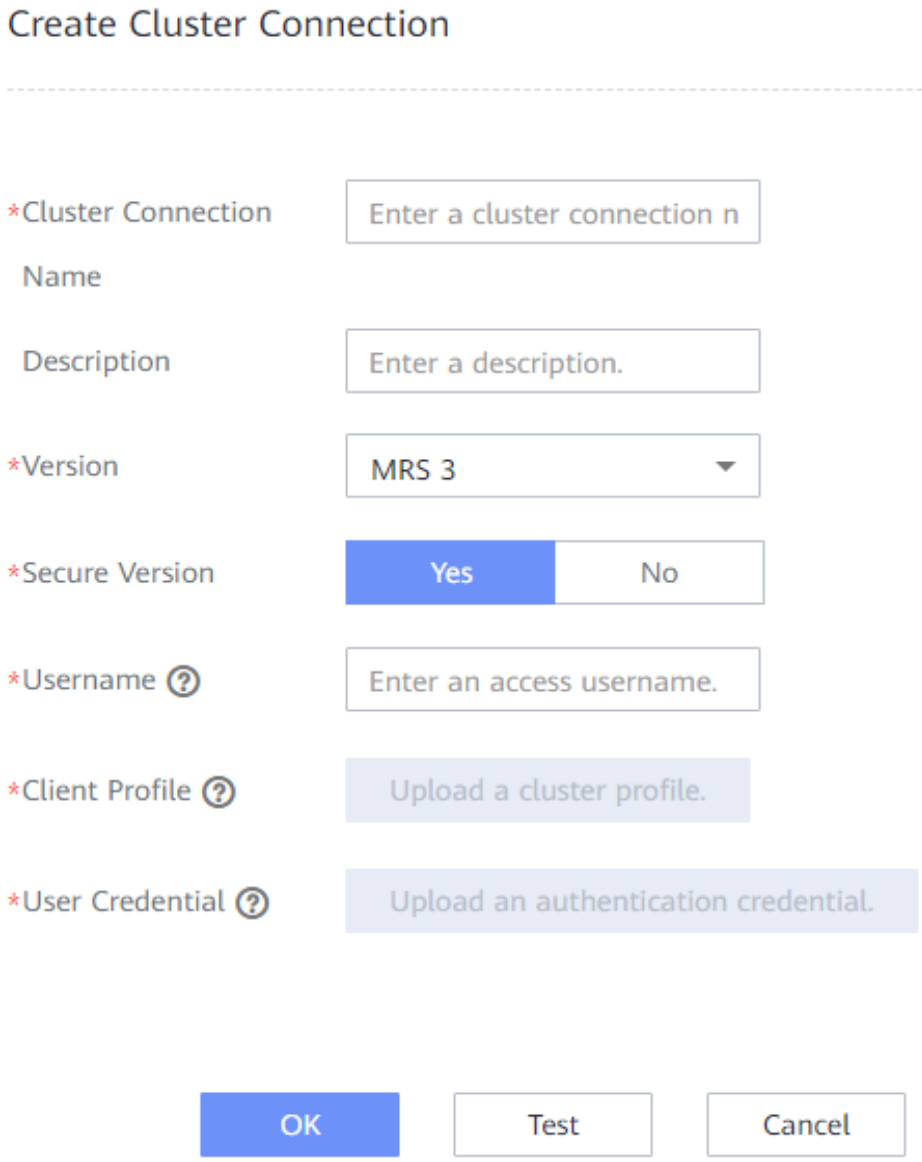


Table 6-9 Parameters for creating a cluster connection

Parameter	Description
Cluster Connection Name	Enter the name of the cluster connection.
Description	Enter the description of the cluster connection name.
FusionInsight HD Version	Set a cluster version.
Secure Version	• If the secure version is used, select **Yes** for a security cluster. Enter the username and upload the user credential. • If not, select **No**.
Username	The user must have the minimum permissions for accessing services in the cluster. This parameter is available only when **Secure Version** is set to **Yes**.
Client Profile	Client profile of the cluster, in TAR format.
User Credential	User authentication credential in FusionInsight Manager in TAR format. This parameter is available only when **Secure Version** is set to **Yes**. Files can be uploaded only after the username is entered.

NOTE

To obtain the cluster client configuration files, perform the following steps:

1. Log in to FusionInsight Manager and choose **Cluster** > **Dashboard**.
2. Choose **More** > **Download Client** > **Configuration Files Only**, select a platform type, and click **OK**.

To obtain the user credential, perform the following steps:

1. Log in to FusionInsight Manager and click **System**.
2. In the **Operation** column of the user, choose **More** > **Download Authentication Credential**, select a cluster, and click **OK**.

----End

6.4.4 Creating a FlinkServer Data Connection

You can use data connections to access different data services. Currently, FlinkServer supports HDFS, Redis, and Kafka data connections.

Procedure

Step 1 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Choose **System Management** > **Data Connection Management**. The **Data Connection Management** page is displayed.

Step 3 Click **Create Data Connection**. On the displayed page, select a data connection type, enter information by referring to **Table 6-10**, and click **OK**. After the data connection is created, you can edit, test, or delete the data connection in the **Operation** column.

Table 6-10 Parameters for creating a data connection

Parameter	Description	Example Value
Data Connection Type	Type of the data connection, which can be **HDFS**, **Redis**, or **Kafka**. If you select the Redis data connection type, prepare a DCS (for Redis) instance in advance. Ensure that **Instance Type** is **Redis Cluster**, **Password Protected** is **No**, and **Region** and **VPC** are the same as those of the cluster where Flink is located.	-
Data Connection Name	Name of the data connection.	-
Cluster Connection	Cluster connection name in configuration management. This parameter is mandatory for HDFS data connections.	-
Kafka broker	Connection information about Kafka broker instances. The format is *IP address*:*Port number*. Use commas (,) to separate multiple instances. This parameter is mandatory for Kafka data connections.	192.168.0.1:21005,192.168.0.2:21005
Redis Deployment Method	Redis deployment mode. Currently, only **Cluster** is supported. This parameter is mandatory for Redis data connections.	Cluster
Redis Server List	Connection information about Redis instances. The format is *IP address*:*Port number*. Use commas (,) to separate multiple instances. This parameter is mandatory for Redis data connections.	192.168.0.1:6379,192.168.0.2:6379

Parameter	Description	Example Value
Authentication Mode	• **SIMPLE**: indicates that the connected service is in non-security mode and does not need to be authenticated. The Kafka data connection created using this method supports only the SIMPLE authentication type. • **KERBEROS**: indicates that the connected service is in security mode and the Kerberos protocol for security authentication is used for authentication.	-

----End

6.4.5 Creating a FlinkServer Stream Table Source

Data tables can be used to define basic attributes and parameters of source tables, dimension tables, and output tables.

Procedure

Step 1 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Click **Table Management**. The table management page is displayed.

Step 3 Click **Create Stream Table**. On the stream table creation page, set parameters by referring to **Table 6-11** and click **OK**. After the stream table is created, you can edit or delete the stream table in the **Operation** column.

Figure 6-11 Creating a stream table

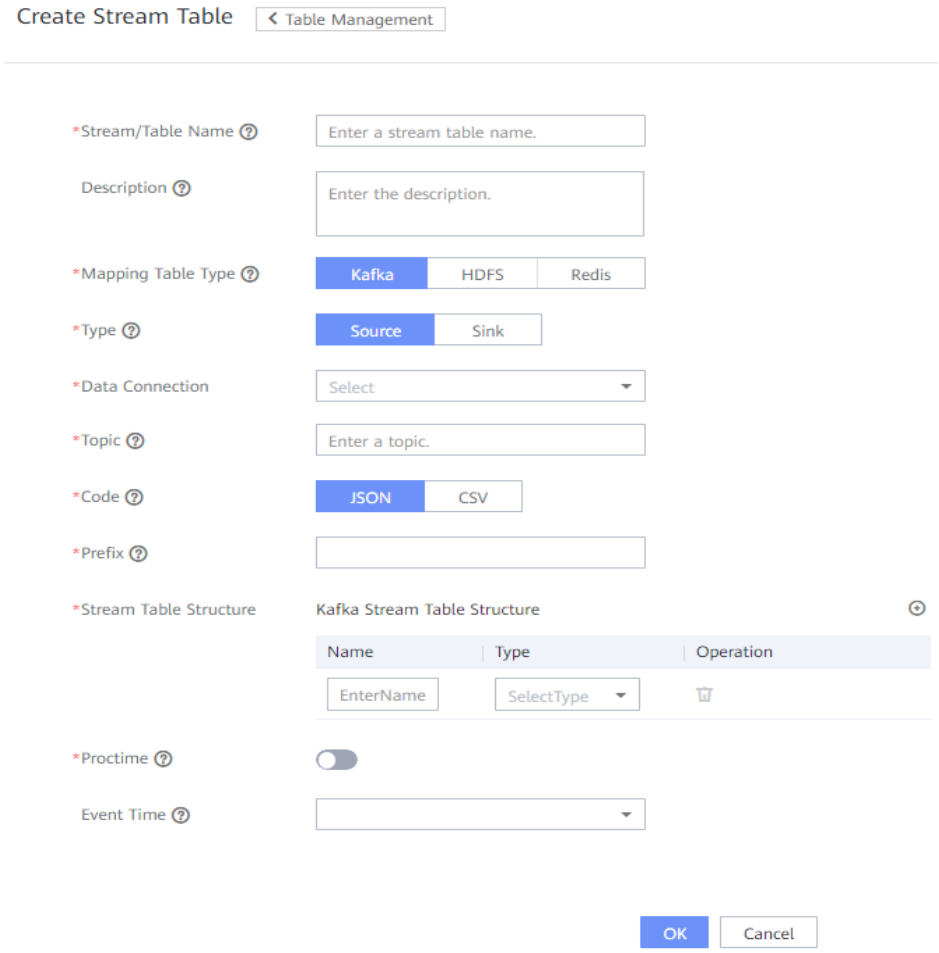

Table 6-11 Parameters for creating a stream table

Parameter	Description	Remarks
Stream/Table Name	Stream/Table name	Example: **flink_sink**
Description	Stream/Table description information	-
Mapping Table Type	Flink SQL does not provide the data storage function. Table creation is actually the creation of mapping for external data tables or storage. The value can be **Kafka** or **HDFS**.	-
Type	Includes data source table **Source** and data result table **Sink**. Tables included in different mapping table types are as follows: • Kafka: **Source** and **Sink** • HDFS: **Source** and **Sink**	-

Parameter	Description	Remarks
Data Connection	Name of the data connection	-
Topic	Kafka topic to be read. Multiple Kafka topics can be read. Use separators to separate topics. This parameter is available when **Mapping Table Type** is set to **Kafka**.	-
File Path	HDFS directory or a single file path to be transferred. This parameter is available when **Mapping Table Type** is set to **HDFS**.	Example: **/user/sqoop/** or **/user/sqoop/example.csv**
Code	Codes corresponding to different mapping table types are as follows: ● Kafka: **CSV** and **JSON** ● HDFS: **CSV**	-
Prefix	When **Mapping Table Type** is set to **Kafka**, **Type** is set to **Source**, and **Code** is set to **JSON**, this parameter indicates the hierarchical prefixes of multi-layer nested JSON, which are separated by commas (,).	For example, **data,info** indicates that the content under **data** and **info** in the nested JSON file is used as the data input in JSON format.
Separator	Has different meanings when **Mapping Table Type** is set to the following values: It is used as the separator of specified CSV fields. This parameter is available only when **Code** is set to **CSV**.	Example: comma (**,**)
Row Separator	Line break in the file, including **\r**, **\n**, and **\r\n**. This parameter is available when **Mapping Table Type** is set to **HDFS**.	-
Column Separator	Field separator in the file. This parameter is available when **Mapping Table Type** is set to **HDFS**.	Example: comma (**,**)
Stream Table Structure	Stream/Table structure, including **Name** and **Type**.	-

Parameter	Description	Remarks
Proctime	System time, which is irrelevant to the data timestamp. That is, the time when the calculation is complete in Flink operators. This parameter is available when **Type** is set to **Source**.	-
Event Time	Time when an event is generated, that is, the timestamp generated during data generation. This parameter is available when **Type** is set to **Source**.	-

----End

6.5 Creating a FlinkServer Job

6.5.1 Creating a FlinkServer Job and Writing Data to a ClickHouse Table

This section applies to MRS 3.1.2 or later clusters.

Scenario

Flink interconnects with the ClickHouseBalancer instance of ClickHouse to read and write data, preventing ClickHouse traffic distribution problems. The following table lists the mapping between Flink SQL and ClickHouse data types.

NOTICE

When "FlinkSQL" is displayed in the command output on the FlinkServer web UI in MRS 3.2.0 or later clusters, the **password** field in the SQL statement is left blank to meet security requirements. Before you submit a job, manually enter the password.

Table 6-12 Mapping between Flink SQL and ClickHouse data types

Flink SQL Data Type	ClickHouse Data Type
BOOLEAN	UInt8
TINYINT	Int8
SMALLINT	Int16
INTEGER	Int32

Flink SQL Data Type	ClickHouse Data Type
BIGINT	Int64
FLOAT	Float32
DOUBLE	Float64
CHAR	String
VARCHAR	String
VARBINARY	FixedString
DATE	Date
TIMESTAMP	DateTime
DECIMAL	Decimal

Prerequisites

- Services such as ClickHouse, HDFS, YARN, Flink, and Kafka have been installed in the cluster.
- The client has been installed, for example, in **/opt/client**.

Creating a Job

Step 1 Log in to the node where the client is installed as user **root**.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create ClickHouse tables. If Kerberos authentication is disabled for the current cluster, skip this step:

kinit *Component service user*

Example: **kinit clickhouseuser**

Step 5 Connect to the ClickHouse client. For details, see **ClickHouse Client Practices**. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.

- Normal mode:

  clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password** '*Password*' **--port** *ClickHouse port number* **--multiline**

- Security mode:

clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password** '*Password*'**--port** *ClickHouse port number* **--secure --multiline**

Step 6 Run the following statements to create a replication table and a distributed table.

1. Create a replication table **default.test1**.

```
CREATE TABLE default.test1 on cluster default_cluster
(
`pid` Int8,
`uid` UInt8,
`Int_16` Int16,
`Int_32` Int32,
`Int_64` Int64,
`String_x` String,
`String_y` String,
`float_32` Float32,
`float_64` Float64,
`Decimal_x` Decimal32(2),
`Date_x` Date,
`DateTime_x` DateTime
)
ENGINE = ReplicatedReplacingMergeTree('/clickhouse/tables/{shard}/test1','{replica}')
PARTITION BY pid
ORDER BY (pid, DateTime_x);
```

2. Create a distributed table **test1_all**.

```
CREATE TABLE test1_all ON CLUSTER default_cluster
(
`pid` Int8,
`uid` UInt8,
`Int_16` Int16,
`Int_32` Int32,
`Int_64` Int64,
`String_x` String,
`String_y` String,
`float_32` Float32,
`float_64` Float64,
`Decimal_x` Decimal32(2),
`Date_x` Date,
`DateTime_x` DateTime
)
ENGINE = Distributed(default_cluster, default, test1, rand());
```

Step 7 Log in to Manager and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.

Step 8 Create a Flink SQL job and set **Task Type** to **Stream job**. For details, see **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job. In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

- If the current MRS cluster is in security mode, perform the following operations:

```
create table kafkasource(
`pid` TINYINT,
`uid` BOOLEAN,
`Int_16` SMALLINT,
`Int_32` INTEGER,
`Int_64` BIGINT,
`String_x` CHAR,
`String_y` VARCHAR(10),
`float_32` FLOAT,
`float_64` DOUBLE,
`Decimal_x` DECIMAL(9,2),
`Date_x` DATE,
```

```
`DateTime_x` TIMESTAMP
) with(
  'connector' = 'kafka',
  'topic' = 'input',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'properties.group.id' = 'group1',
  'scan.startup.mode' = 'earliest-offset',
  'format' = 'json',
  'properties.sasl.kerberos.service.name' = 'kafka',
  'properties.security.protocol' = 'SASL_PLAINTEXT',
  'properties.kerberos.domain.name' = 'hadoop.System domain name'
);
CREATE TABLE cksink (
`pid` TINYINT,
`uid` BOOLEAN,
`Int_16` SMALLINT,
`Int_32` INTEGER,
`Int_64` BIGINT,
`String_x` CHAR,
`String_y` VARCHAR(10),
`float_32` FLOAT,
`float_64` DOUBLE,
`Decimal_x` DECIMAL(9,2),
`Date_x` DATE,
`DateTime_x` TIMESTAMP
) WITH (
'connector' = 'jdbc',
'url' = 'jdbc:clickhouse://IP address 1 of the ClickHouseBalancer instance:ClickHouseBalancer port number,IP address 2 of the ClickHouseBalancer instance:ClickHouseBalancer port number/default?
ssl=true&sslmode=none',
'username' = 'ClickHouse user. For details, see the note below.',
'password' = 'ClickHouse user password. For details, see the note below.',
'table-name' = 'test1_all',
'driver' = 'com.clickhouse.jdbc.ClickHouseDriver',
'sink.buffer-flush.max-rows' = '0',
'sink.buffer-flush.interval' = '60s'
);
Insert into cksink
select
*
from
kafkasource;
```

- If the current MRS cluster is in normal mode, perform the following operations:

```
create table kafkasource(
`pid` TINYINT,
`uid` BOOLEAN,
`Int_16` SMALLINT,
`Int_32` INTEGER,
`Int_64` BIGINT,
`String_x` CHAR,
`String_y` VARCHAR(10),
`float_32` FLOAT,
`float_64` DOUBLE,
`Decimal_x` DECIMAL(9,2),
`Date_x` DATE,
`DateTime_x` TIMESTAMP
) with(
  'connector' = 'kafka',
  'topic' = 'kinput',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'properties.group.id' = 'kafka_test',
  'scan.startup.mode' = 'earliest-offset',
  'format' = 'json'
);
CREATE TABLE cksink (
`pid` TINYINT,
`uid` BOOLEAN,
`Int_16` SMALLINT,
```

```
`Int_32` INTEGER,
`Int_64` BIGINT,
`String_x` CHAR,
`String_y` VARCHAR(10),
`float_32` FLOAT,
`float_64` DOUBLE,
`Decimal_x` DECIMAL(9,2),
`Date_x` DATE,
`DateTime_x` TIMESTAMP
) WITH (
'connector' = 'jdbc',
'url' = 'jdbc:clickhouse://IP address 1 of the ClickHouseBalancer instance:ClickHouseBalancer port number,IP address 2 of the ClickHouseBalancer instance:ClickHouseBalancer port number/default',
'table-name' = 'test1_all',
'username' = 'ClickHouse user. For details, see the note below.',
'password' = 'ClickHouse user password. For details, see the note below.',
'driver' = 'com.clickhouse.jdbc.ClickHouseDriver',
'sink.buffer-flush.max-rows' = '0',
'sink.buffer-flush.interval' = '60s'
);
Insert into cksink
select
*
from
kafkasource;
```

NOTE

- If an MRS cluster is in the security mode, the user in the **cksink** table must have related permissions on the ClickHouse tables. For details, see **Creating a ClickHouse Role**.
- Kafka port number
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default.

    If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- ClickHouseBalancer port:
  - If the cluster where ClickHouse is deployed is in security mode, the ClickHouseBalancer port is **21426** by default.
  - If the cluster where ClickHouse is deployed is in normal mode, the ClickHouseBalancer port is **21425** by default.
- **url**: You can configure multiple IP addresses for ClickHouseBalancer instances to avoid single points of failure (SPOFs) of the instances.
- DELETE messages generated during Flink computing are filtered out when data is written to ClickHouse.
- Parameters for batch write: Flink stores data in the memory and then flushes the data to the database table when the trigger condition is met. The configurations are as follows:

  sink.buffer-flush.max-rows: Number of rows written to ClickHouse. The default value is **100**.

  sink.buffer-flush.interval: Interval for batch write. The default value is **1s**.

  If either of the two conditions is met, a sink operation is triggered. That is, data will be flushed to the database table.
  - Scenario 1: sink every 60s

    'sink.buffer-flush.max-rows' = '0',

    'sink.buffer-flush.interval' = '60s'
  - Scenario 2: sink every 100 rows

    'sink.buffer-flush.max-rows' = '100',

    'sink.buffer-flush.interval' = '0s'
  - Scenario 3: no sink

    'sink.buffer-flush.max-rows' = '0',

    'sink.buffer-flush.interval' = '0s'

Step 9 On the job management page, check whether the job status is **Running**.

Step 10 Execute the following script to write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic***Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

For example, if the topic name is **kinput**, the script is **sh kafka-console-producer.sh --broker-list** *IP address of the node where the Kafka instance is deployed*:*Kafka port* **--topic kinput --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
{"pid": "3","uid":false,"Int_16": "6533","Int_32": "429496294","Int_64": "1844674407370955614","String_x": "abc1","String_y": "abc1defghi","float_32": "0.1234","float_64": "95.1","Decimal_x": "0.451236414","Date_x": "2021-05-29","DateTime_x": "2021-05-21 10:05:10"}
{"pid": "4","uid":false,"Int_16": "6533","Int_32": "429496294","Int_64": "1844674407370955614","String_x": "abc1","String_y": "abc1defghi","float_32": "0.1234","float_64": "95.1","Decimal_x": "0.4512314","Date_x": "2021-05-29","DateTime_x": "2021-05-21 10:05:10"}
```

Press **Enter** to send the message.

Step 11 Interconnect with ClickHouse to query the table data.

clickhouse client --host *IP address of the ClickHouse instance* **--user** *Username* **--password '***Password***' --port** *ClickHouse port number* **--secure --multiline**

Run the following command to check whether data is written to a specified ClickHouse table, for example, **test1_all**.

select * from test1_all;

----End

6.5.2 Creating a FlinkServer Job to Interconnect with a Doris Table

This section applies to MRS 3.5.0 and later.

Scenario

This topic describes how to use FlinkServer to write Kafka data to Doris and how to perform Lookup Join on Doris and Kafka data.

Prerequisites

- Services such as Doris, HDFS, YARN, Flink, and Kafka have been installed in the cluster.
- The node to be connected to the Doris database can communicate with the MRS cluster.
- A user with the Doris management permission has been created.
  - Kerberos authentication is enabled for the cluster (the cluster is in security mode)

    On FusionInsight Manager, create a human-machine user, for example, **dorisuser**, create a role with Doris administrator permission, and bind the role to the user.

    Log in to FusionInsight Manager as the new user **dorisuser** and change the initial password.
  - Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

    After connecting to Doris as user **admin**, create a role with administrator permissions, and bind the role to the user.

- The MySQL client has been installed. For details, see **Using the MySQL Client to Connect to Doris**.
- The Flink client has been installed.

Using FlinkServer to Write Kafka Data to Doris

Operations on the Doris side

Step 1 Log in to the node where MySQL is installed and run the following command to connect to the Doris database:

If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to connect to the Doris database:

export LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN=1

mysql -u*Database login user* **-p -P***Connection port for FE queries* **-h***IP address of the Doris FE instance*

Enter the password for logging in to the database.

NOTE

- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **balancer_tcp_port** of the Doris service.
- To obtain the IP address of the Doris FE or DBalancer instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster** > **Services** > **Doris** > **Instances** to view the service IP address of any FE or DBalancer instance.
- You can also use the MySQL connection software or Doris web UI to connect to the database.

Step 2 Run the following commands to create a database and table **usertable2** to which data is written:

create database *sink*;

use *sink*;

create table *usertable2*(

`user_id` VARCHAR(10),

`user_name` VARCHAR(10),

`age` INT

)

DISTRIBUTED BY HASH(user_id) BUCKETS 32;

Operations on the Flink side

Step 3 Log in to FusionInsight Manager as a user with **FlinkServer Admin Privilege**. Choose **Cluster** > **Services** > **Flink**.

NOTE

If your MRS cluster requires Kerberos authentication, create a role with the FlinkServer administrator permission or the application viewing and editing permission, and bind the role to the user. Then, you can access the Flink Web UI. For details about how to create a role, see **Creating a FlinkServer Role**.

Step 4 On the right of Flink web UI, click the link to access FlinkServer.

Step 5 On the FlinkServer page, choose **Job Management** > **Create Job**. On the displayed dialog box, set the following parameters and click **OK**. The **Job Management** page is displayed.

- **Type**: Select **Flink SQL**.
- **Name**: Enter a job name, for example, **FlinkSQL1**.

Step 6 Create a stream or batch Flink SQL job on the Flink job management page. The following are some examples:

1. Create a Kafka data source table.

   CREATE TABLE *KafkaSource* **(**
   `user_id` VARCHAR,
   `user_name` VARCHAR,
   `age` INT
) WITH (
   'connector' = 'kafka',
   'topic' ='*Topic name***',**
   'properties.bootstrap.servers' ='*Service IP address of the Kafka Broker instance:Port of the Broker instance***',**
   'properties.group.id' = 'testGroup',
   'scan.startup.mode' = 'latest-offset',
   'format' = 'csv',
   'properties.sasl.kerberos.service.name' = '*kafka***',**
   'properties.security.protocol' = '*SASL_PLAINTEXT***',**
   'properties.kerberos.domain.name' = '*hadoop.hadoop.com***'**
   );

   NOTE

   - **properties.bootstrap.servers**: If there are multiple parameter values, separate them with commas (,).

     To view the service IP address of the Kafka Broker instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka** > **Instances**. To view the port of the Broker instance, click **Configurations**. If Kerberos authentication is enabled for the cluster (the cluster is in security mode), search for **sasl.port**. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), search for **port**.
   - The values of **properties.sasl.kerberos.service.name**, **properties.security.protocol**, and **properties.kerberos.domain.name** can be obtained from *Client installation directory*/**Kafka/kafka/config** on the node where the Kafka client is installed. Search for **sasl.kerberos.service.name**, **security.protocol**, or **kerberos.domain.name** in the **server.properties** file in the directory.

2. Create a Doris Sink table:

   CREATE TABLE *dorisSink* **(**
   `user_id` VARCHAR,
   `user_name` VARCHAR,
   `age` INT
) WITH (
   'connector' = 'doris',
   'fenodes' ='*IP address of any FE instance:HTTPS port or HTTP port***',**
   'table.identifier' = '*sink.usertable2***',**
   'username' = '*user***',**
   'password' = '*password***',**
   'doris.enable.https' = 'true',
   'doris.ignore.https.ca' = 'true',
   'sink.label-prefix' = 'doris_label1'
   );

   NOTE

   - To view the IP addresses of FE instances, choose **Cluster** > **Services** > **Doris** > **Instances** on FusionInsight Manager.
   - To view the HTTPS port, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and search for **https_port**. To view the HTTP port, search for **http_port**.
   - **table.identifier**: The parameter value is the Doris database and table created in **Step 2**.
   - **username** and **password** are the username and password for connecting to the Doris.
   - After HTTPS is disabled for a cluster in normal or security mode, remove the following configuration parameters from the **with** clause of the Doris Sink table creation statement:

     'doris.enable.https' = 'true'

     'doris.ignore.https.ca' = 'true'
   - When creating a Doris Sink table, you can also set the parameters listed in **Table 6-13**.

3. Run the following command to write Kafka data to Doris:

   insert into *dorisSink* **select * from** *KafkaSource***;**

Step 7 In the basic parameters area on the right of the **Job Management** page, select **Enable CheckPoint** and set **Time Interval(ms)** as required. The recommended interval ranges from 30000 to 60000.

Step 8 Click **Check Semantic** to verify the semantics of the statements. Then, click **Save** and **Submit**.

Operations on the Kafka side

Step 9 Log in to the node where the Kafka client is installed and perform the following operations to create a Kafka topic:

cd *Client installation directory*/**Kafka/kafka/bin**

1. Run the following command to create a Kafka topic. The topic name must be the same as that configured in **6.1**:

   sh kafka-topics.sh --create --topic *Topic name* **--partitions 1 --replication-factor 1 --bootstrap-server** *IP address of the host where the Controller of the Kafka Broker instance is deployed*:*Port of the Broker instance* **--command-config ../config/client.properties**

2. Run the following command to view the topic list:

   sh kafka-topics.sh --list --bootstrap-server Kafka*IP address of the host where the Controller of the Broker instance is deployed:Port of the Broker instance* **--command-config ../config/client.properties**

3. Run the following command to connect to the Kafka client:

   sh kafka-console-producer.sh --broker-list *IP address of the host where the Controller of the Kafka Broker instance is deployed:Port of the Broker instance* **--topic TopicTest --producer.config ../config/producer.properties**

NOTE

To obtain the IP address of the host where the Controller of the Broker instance is deployed, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, and view the value of **Controller Host** in the basic information area on the **Dashboard** page.

Step 10 Connect to Doris on the node where the MySQL client is installed and run the following command to check whether the data in the Doris table is the same as the data inserted in **9.3**:

select * from *sink.usertable2*;

----End

Lookup Join

Step 1 Log in to FusionInsight Manager as a user with **FlinkServer Admin Privilege**. Choose **Cluster** > **Services** > **Flink**.

NOTE

If your MRS cluster requires Kerberos authentication, create a role with the FlinkServer administrator permission or the application viewing and editing permission, and bind the role to the user. Then, you can access the Flink Web UI. For details about how to create a role, see **Creating a FlinkServer Role**.

Step 2 On the right of Flink web UI, click the link to access FlinkServer.

Step 3 On the Flink web UI, click **Job Management** and then **Create Job**. In the **Create Job** dialog box, set the following parameters and click **OK**:

- **Type**: Select **Flink SQL**.
- **Name**: Enter a job name, for example, **FlinkSQL2**.

Step 4 Create a stream or batch Flink SQL job on the Flink job management page. The following are some examples:

1. Create a Kafka Source table.

   CREATE TABLE *fact_table* **(**

   `id` BIGINT,

   `name` STRING,

```
`city` STRING,
`process_time` as proctime()
) WITH (
'connector' = 'kafka',
'topic' ='Topic name',
'properties.bootstrap.servers' ='IP address of the Kafka Broker instance:21007',
'properties.group.id' = 'testGroup',
'scan.startup.mode' = 'latest-offset',
'format' = 'csv',
'properties.sasl.kerberos.service.name' = 'kafka',
'properties.security.protocol' = 'SASL_PLAINTEXT',
'properties.kerberos.domain.name' = 'hadoop.hadoop.com'
);
```

NOTE

- **properties.bootstrap.servers**: If there are multiple parameter values, separate them with commas (,).

  To view the service IP address of the Kafka Broker instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka** > **Instances**. To view the port of the Broker instance, click **Configurations**. If Kerberos authentication is enabled for the cluster (the cluster is in security mode), search for **sasl.port**. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), search for **port**.

- The values of **properties.sasl.kerberos.service.name**, **properties.security.protocol**, and **properties.kerberos.domain.name** can be obtained from *Client installation directory*/**Kafka/kafka/config** on the node where the Kafka client is installed. Search for **sasl.kerberos.service.name**, **security.protocol**, or **kerberos.domain.name** in the **server.properties** file in the directory.

2. Create a Flink table.

```
create table dim_city(
`city` STRING,
`level` INT ,
`province` STRING,
`country` STRING
) WITH (
'connector' = 'doris',
'fenodes' ='IP address of an FE instance:HTTPS port or HTTP port',
'jdbc-url' = 'jdbc:mysql://IP address of an FE instance:FE query connection port',
'table.identifier' = 'dim.dim_city',
'username' = 'user',
'password' = 'password'
);
```

NOTE

- To view the IP addresses of FE instances, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Doris** > **Instances**.
- To view the HTTPS port, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and search for **https_port**. To view the HTTP port, search for **http_port**.
- To obtain the query connection port of the Doris FE instance, you can log in to FusionInsight Manager, choose **Cluster** > **Services** > **Doris** > **Configurations**, and query the value of **query_port** of the Doris service.
- When creating a Flink table, you can also set the parameters listed in **Table 6-14**.

3. Run the following command to perform a join:

   SELECT a.id, a.name, a.city, c.province, c.country,c.level

   FROM *fact_table* **a**

   LEFT JOIN dim_city FOR SYSTEM_TIME AS OF a.process_time AS c

   ON a.city = c.city

Step 5 In the basic parameters area on the right of the **Job Management** page, select **Enable CheckPoint** and set **Time Interval(ms)** as required. The recommended interval ranges from 30000 to 60000.

Step 6 Click **Check Semantic** to verify the semantics of the statements. Then, click **Save** and **Submit**.

----End

Table Creation Configurations

Table 6-13 Optional parameters for creating a Doris Sink table

Parameter	Default Value	Mandatory	Description
doris.request.retries	3	No	Number of retry times for sending requests to Doris.
doris.request.connect.timeout.ms	30000	No	Connection timeout interval for sending requests to Doris.
doris.request.read.timeout.ms	30000	No	Read timeout interval for sending requests to Doris.
sink.max-retries	3	No	Maximum number of retry times after a commit is failed. The default value is 3.
sink.enable.batch-mode	false	No	Whether to write data to Doris in batch mode. If this is enabled, the write time does not depend on checkpoints. You can use **sink.buffer-flush.max-rows**, **sink.buffer-flush.max-bytes**, or **sink.buffer-flush.interval** to control the write time.

Parameter	Default Value	Mandatory	Description
sink.buffer-flush.max-rows	50000	No	Maximum number of data rows that can be written in a batch.
sink.buffer-flush.max-bytes	10MB	No	Maximum number of bytes that can be written in a batch.
sink.buffer-flush.interval	10s	No	Interval for asynchronously refreshing the cache in batches

Table 6-14 Optional parameters for creating a Flink table in Lookup Joins

Parameter	Default Value	Mandatory	Description
lookup.cache.max-rows	-1	No	Maximum number of rows that can be cached in the lookup table. The default value is **-1**, indicating that the cache function is disabled.
lookup.cache.ttl	10s	No	Maximum duration for caching lookup data. The default value is **10s**.
lookup.max-retries	1	No	Number of retry times after the lookup query fails
lookup.jdbc.async	false	No	Whether to enable asynchronous lookup. The default value is **false**.
lookup.jdbc.read.batch.size	128	No	Maximum batch size for each query when asynchronous lookup is enabled
lookup.jdbc.read.batch.queue-size	256	No	Size of the intermediate buffer queue when asynchronous lookup is enabled
lookup.jdbc.read.thread-size	3	No	Number of Lookup JDBC threads in each task

6.5.3 Creating a FlinkServer Job to Interconnect with a GaussDB(DWS) Table

This section applies to MRS 3.2.0 and to MRS 3.3.1.

Scenario

FlinkServer can interconnect with GaussDB(DWS) 8.1.*x* or later. This section describes the DDL definitions when GaussDB(DWS) serves as source tables, sink

tables, and dimension tables, as well as the **WITH** parameter and code examples used during table creation, and describes how to perform operations on the FlinkServer job management page. The following table lists the mapping between Flink SQL and GaussDB(DWS) data types.

In this example, FlinkServer and Kafka in security mode are used to interconnect with GaussDB(DWS) in security mode.

NOTICE

When "FlinkSQL" is displayed in the command output on the FlinkServer web UI, the **password** field in the SQL statement is left blank to meet security requirements. Before you submit a job, manually enter the password.

Table 6-15 Mappings Between Flink SQL and GaussDB(DWS) Data Types

Flink SQL Data Type	GaussDB(DWS) Data Type
BOOLEAN	BOOLEAN
TINYINT	-
SMALLINT	SMALLINT(INT2)
	SMALLSERIAL(SERIAL2)
INTEGER	INTEGER
	SERIAL
BIGINT	BIGINT
	BIGSERIAL
FLOAT	REAL
	FLOAT4
DOUBLE	DOUBLE
	FLOAT8
CHAR	CHAR(n)
VARCHAR	VARCHAR(n)
DATE	DATE
TIMESTAMP	TIMESTAMP[(p)] [WITHOUT TIME ZONE]
DECIMAL	NUMERIC[(p[,s])]
	DECIMAL[(p[,s])]

Prerequisites

- The cluster where FlinkServer is deployed must be able to communicate with the cluster where GaussDB(DWS) is deployed. The AZ, VPC, and security group configurations of the two clusters must be the same.
- Cluster where FlinkServer resides (security mode):
  - HDFS, YARN, Kafka, ZooKeeper, and Flink have been installed in the cluster.
  - The client that contains the Kafka service has been installed, for example, in the **/opt/client** directory.
  - You have created a user with the **FlinkServer Admin Privilege** (for example, **flinkuser**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.
- Cluster of the GaussDB(DWS) to be interconnected (security mode):

  Run the following commands to connect to the database and create a table for receiving data:

  gsql -d *postgres* **-h** *IP* **-U** *username* **–p** *port* **-W** *password* **–r**

  NOTE

  - **postgres** indicates the name of the database to be connected.
  - **IP**: indicates the IP address of the GaussDB(DWS) cluster. If a public network address is used for connection, set this parameter to the public network domain name. If a private network address is used for connection, set this parameter to the private network domain name. If an ELB is used for connection, set this parameter to the ELB address.
  - **username** and **password** indicate the username and password for connecting to the database. Commands containing authentication passwords pose security risks. Disable the command recording function (history) before running such commands to prevent information leakage.
  - **port**: indicates the port number of the Coordinator. Replace it with the actual port number. You can run the **gs_om -t status --detail** command to query the Coordinator data path and view the port number in the **postgresql.conf** file in the path.

  Create an empty table for receiving data, for example, **customer_t1**.

```
CREATE TABLE customer_t1
(
    c_customer_sk             INTEGER,
    c_customer_name           VARCHAR(32)
)
with (orientation = column,compression=middle)
distribute by hash (c_customer_name);
```

GaussDB as a Sink Table

Step 1 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE MyUserTable(
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH(
  'connector' = 'jdbc',
  'url'='jdbc:gaussdb://IP address of the GaussDB server:Database port number/postgres',
  'table-name' = 'customer_t1',--If table customer_t1 is created in schema base, the configuration rule is 'table-name' = 'base."customer_t1"'.
  'username' = 'username',--Username for logging in to the GaussDB(DWS) database
  'password'='password'--Password for connecting to the GaussDB(DWS) database. You need to specify the password when submitting the job.
  'write.mode' = 'upsert',--When data is written in upsert mode, you can set whether to ignore null values. (applicable to MRS 3.3.0 and later versions)
  'ignoreNullWhenUpsert' = 'false'--true indicates that null values are ignored, and false indicates that null values are not ignored and written to the database.
);
CREATE TABLE KafkaSource (
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_source',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
);
Insert into
  MyUserTable
select
  *
from
  KafkaSource;
```

NOTE

- The Kafka port can be:
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 3 On the job management page, check whether the job is in the **Running** status.

Step 4 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list --zookeeper *Service IP address of the ZooKeeper quorumpeer instance*:*Port number of the ZooKeeper client*/**kafka**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

In this example, the topic name is **customer_source**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka instance is deployed*:*Kafka port number* --**topic customer_source --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,zhangsan
4,wangwu
8,zhaosi
```

Press **Enter** to send the message.

NOTE

- Service IP address of the ZooKeeper quorumpeer instance:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Instance** tab and view the service IP addresses of all nodes where the quorumpeer instances reside.
- Port number of the ZooKeeper client:

  Log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the page that is displayed, click the **Configurations** tab and check the value of **clientPort**.

Step 5 Log in to the GaussDB client and run the following command to check whether data has been sent to the sink table:

Select * from customer_t1;

```
postgres=> select * from customer_t1;
 c_customer_sk | c_customer_name
---------------+-----------------
             1 | new Data
             8 | zhaosi
             0 | data 0
             3 | zhangsan
             4 | wangwu
             2 | data 2
(6 rows)
```

----End

GaussDB as a Source Table

Step 1 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **5000**, and retain the default value for **Mode**.

```
CREATE TABLE MyUserTable(
  --GaussDB functions as a source table.
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH(
  'connector' = 'jdbc',
  'url'='jdbc:gaussdb://IP address of the GaussDB server:Database port number/postgres',
  'table-name' = 'customer_t1',
  'username' = 'username ',
  'password' = 'password '
);
CREATE TABLE KafkaSink (
  -- Kafka functions as a sink table.
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_sink',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
);
Insert into
  KafkaSink
select
  *
from
  MyUserTable;
```

NOTE

- The Kafka port can be:
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 3 On the job management page, check whether the job is in the **Running** status.

Step 4 Run the following command to check whether data is received in the sink table, that is, check whether data is properly written to the Kafka topic. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-consumer.sh --topic customer_sink --bootstrap-server *IP address of the node where the Kafka instance is deployed:Kafka port number* **--consumer.config /opt/client/Kafka/kafka/config/ consumer.properties**

```
[root@... ... bin]# sh kafka-console-consumer.sh --topic customer_sink --bootstrap-server ...:21007 --consumer.config /opt/client/Kafka/kafka/config/producer.properties
[2022-04-12 11:49:37,957] WARN The configuration 'acks' was supplied but isn't a known config. (org.apache.kafka.clients.consumer.ConsumerConfig)
1,"new Data"
8,zhaosi
4,wangwu
0,"data 0"
3,zhangsan
2,"data 2"
```

----End

GaussDB as a Dimension Table

kafkaSource is used as the fact table, **customer_t2** is used as the dimension table, and the result is written to kafkaSink.

Step 1 Create dimension table **customer_t2** on the GaussDB client. An example of the table creation statement is as follows:

```
CREATE TABLE customer_t2(
c_customer_sk INTEGER PRIMARY KEY,
c_customer_age INTEGER,
c_customer_address VARCHAR(32)
)DISTRIBUTE BY HASH(c_customer_sk);

INSERT INTO customer_t2 VALUES(1,18,'city a');
INSERT INTO customer_t2 VALUES(2,14,'city b');
INSERT INTO customer_t2 VALUES(3,16,'city c');
INSERT INTO customer_t2 VALUES(4,24,'city d');
INSERT INTO customer_t2 VALUES(5,32,'city e');
INSERT INTO customer_t2 VALUES(6,27,'city f');
INSERT INTO customer_t2 VALUES(7,41,'city a');
INSERT INTO customer_t2 VALUES(8,35,'city h');
INSERT INTO customer_t2 VALUES(9,16,'city j');
```

Step 2 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 3 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **5000**, and retain the default value for **Mode**.

```
CREATE TABLE KafkaSource (
  -- Kafka as a source table
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32),
  proctime as proctime()
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_source',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
);
CREATE TABLE KafkaSink (
  -- Kafka as a sink table
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32),
  c_customer_age INTEGER,
  c_customer_address VARCHAR(32)
) WITH (
```

```
  'connector' = 'kafka',
  'topic' = 'customer_sink',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer resides is in non-security mode.
);
CREATE TABLE MyUserTable (
  -- GaussDB as a dimension table
  c_customer_sk INTEGER PRIMARY KEY,
  c_customer_age INTEGER,
  c_customer_address VARCHAR(32)
) WITH (
  'connector' = 'jdbc',
  'url'='jdbc:gaussdb://IP address of the GaussDB server:Database port number/postgres',
  'table-name' = 'customer_t2',
  'username' = 'username',
  'password' = 'password'
);
INSERT INTO
  KafkaSink
SELECT
  t.c_customer_sk,
  t.c_customer_name,
  d.c_customer_age,
  d.c_customer_address
FROM
  KafkaSource as t
  JOIN MyUserTable FOR SYSTEM_TIME AS OF t.proctime as d ON t.c_customer_sk = d.c_customer_sk;
```

NOTE

- The Kafka port can be:
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 4 Run the following command to check whether data is received in the sink table, that is, check whether data is properly written to the Kafka topic after **Step 5** is performed. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-consumer.sh --topic customer_sink --bootstrap-server *IP address of the node where the Kafka instance is deployed:Kafka port number* **--consumer.config /opt/client/Kafka/kafka/config/ consumer.properties**

Step 5 View the topic and write data to the Kafka topic by referring to **Managing Messages in Kafka Topics**. After the data is written, view the execution result in the window in **Step 4**.

./kafka-topics.sh --list --zookeeper *Service IP address of the ZooKeeper quorumpeer instance*:*Port number of the ZooKeeper client*/**kafka**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

NOTE

- IP address of the ZooKeeper quorumpeer instance

  To obtain the IP addresses of all ZooKeeper quorumpeer instances, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the displayed page, click **Instance** and view the IP addresses of all the hosts where the quorumpeer instances locate.

- Port number of the ZooKeeper client

  Log in to FusionInsight Manager and choose **Cluster** > **Service** > **ZooKeeper**. On the displayed page, click **Configurations** and check the value of **clientPort**.

In this example, the topic name is **customer_source**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka instance is deployed*:*Kafka port number* --**topic customer_source --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,zhangsan
5,zhaosi
1,xiaoming
2,liuyang
7,liubei
10,guanyu
20,zhaoyun
```

Press **Enter** to send the message. The output in the kafka-console-consumer window in **Step 4** is as follows:

```
3,zhangsan,16,city c
5,zhaosi,32,city e
1,xiaoming,18,city a
2,liuyang,14,city b
7,liubei,41,city a
```

6.5.4 Creating a FlinkServer Job to Interconnect with JDBC

This section applies to MRS 3.3.1 and later.

Scenario

FlinkServer can interconnect with JDBC. This topic uses FlinkServer and Kafka in security mode as an example to describe the DDL definition for JDBC MySQL source tables, sink tables, and dimension tables. This topic also explains the WITH parameters for creating a table and code examples. You will learn how to connect to JDBC on the FlinkServer job management page.

NOTICE

When "FlinkSQL" is displayed in the command output on the FlinkServer web UI in MRS 3.2.0 or later clusters, the **password** field in the SQL statement is left blank. Before you submit a job, manually enter the password.

Mapping between Flink SQL and JDBC data types

Flink SQL	MySQL	Oracle	PostgreSQL	SQL Server
BOOLEAN	BOOLEAN TINYINT(1)	-	BOOLEAN	BIT
TINYINT	TINYINT	-	-	TINYINT
SMALLINT	SMALLINT TINYINT UNSIGNED	-	SMALLINT INT2 SMALLSERIAL SERIAL2	SMALLINT
INT	INT MEDIUMINT SMALLINT UNSIGNED	-	INTEGER SERIAL	INT
BIGINT	BIGINT INT UNSIGNED	-	BIGINT BIGSERIAL	BIGINT
FLOAT	FLOAT	BINARY_FLOAT	REAL FLOAT4	REAL
DOUBLE	DOUBLE DOUBLE PRECISION	BINARY_DOUBLE	FLOAT8 DOUBLE PRECISION	FLOAT
STRING	CHAR(n) VARCHAR(n) TEXT	CHAR(n) VARCHAR(n) CLOB	CHAR(n) CHARACTER(n) VARCHAR(n) CHARACTER VARYING(n) TEXT	CHAR(n) NCHAR(n) VARCHAR(n) NVARCHAR(n) TEXT NTEXT
BYTES	BINARY VARBINARY BLOB	RAW(s) BLOB	BYTEA	BINARY(n) VARBINARY(n)

Flink SQL	MySQL	Oracle	PostgreSQL	SQL Server
ARRAY	-	-	ARRAY	-
DATE	DATE	DATE	DATE	DATE
TIME [(p)] [WITHOUT TIMEZONE]	TIME [(p)]	DATE	TIME [(p)] [WITHOUT TIMEZONE]	TIME(0)
TIMESTAMP [(p)] [WITHOUT TIMEZONE]	DATETIME [(p)]	TIMESTAMP [(p)] [WITHOUT TIMEZONE]	TIMESTAMP [(p)] [WITHOUT TIMEZONE]	DATETIME DATETIME2
DECIMAL(20, 0)	BIGINT UNSIGNED	-	-	-
DECIMAL(p, s)	NUMERIC(p, s) DECIMAL(p, s)	SMALLINT FLOAT(s) DOUBLE PRECISION REAL NUMBER(p, s)	NUMERIC(p, s) DECIMAL(p, s)	DECIMAL(p, s)

Prerequisites

Cluster where FlinkServer resides:

- HDFS, Yarn, Kafka, ZooKeeper, and Flink have been installed in the cluster.
- The client that contains the Kafka service has been installed, for example, in the **/opt/client** directory.
- You have created a user with the **FlinkServer Admin Privilege** (for example, **flinkuser**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.

JDBC Sink Table (MySQL as an Example)

Step 1 Create an empty table for receiving data in a database, for example, MySQL database **customer_t1**.

Step 2 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 3 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE MyUserTable(
  c_customer_sk INTEGER,
```

```
  c_customer_name VARCHAR(32)
) WITH(
  'connector' = 'jdbc',
  'url' = 'jdbc:mysql://IP address of the MySQL server:MySQL server port/mysql',
  'table-name' = 'customer_t1',
  'username' ='MySQL database username',
  'password' ='Password of the MySQL database user'
);
CREATE TABLE KafkaSource (
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_source',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
);
Insert into
  MyUserTable
select
  *
from
  KafkaSource;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: To obtain the value, log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- **properties.kerberos.domain.name**: Set it to **hadoop.***System domain name*. To obtain the actual domain name of the cluster, log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust**.

Step 4 On the job management page, check whether the job status is **Running**.

Step 5 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list *--bootstrap-server* *Service IP address of the Kafka Broker instance*:*Kafka port* --command-config *Client directory*/Kafka/kafka/config/client.properties

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instances reside*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/Kafka/kafka/config/producer.properties**

In this example, the topic name is **customer_source**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka Broker instance is located*:*Kafka port* --**topic customer_source --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,zhangsan
4,wangwu
8,zhaosi
```

Press **Enter** to send the message.

Step 6 Log in to the MySQL client and run the following statement to check whether the sink table received data:

Select * from customer_t1;

----End

JDBC Source Table (MySQL as an Example)

Step 1 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **5000**, and retain the default value for **Mode**.

```
CREATE TABLE MyUserTable(
  --MySQL source table
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH(
  'connector' = 'jdbc',
  'url' = 'jdbc:mysql://IP address of the MySQL server:MySQL server port/mysql',
  'table-name' = 'customer_t1',
  'username' ='MySQL database username',
  'password' ='Password of the MySQL database user'
);
CREATE TABLE KafkaSink (
  -- Kafka functions as a sink table.
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_sink',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is
```

```
deployed is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
);
Insert into
  KafkaSink
select
  *
from
  MyUserTable;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- **properties.kerberos.domain.name**: Set it to **hadoop.***System domain name*. You can log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust** to view the actual domain name of the cluster.

Step 3 On the job management page, check whether the job status is **Running**.

Step 4 Obtain the required Kafka IP address and port by referring to **Managing Messages in Kafka Topics**, and run the following command to check whether data is written from the Kafka topic to the sink table:

sh kafka-console-consumer.sh --topic customer_sink --bootstrap-server *IP address of the node where the Kafka instance is deployed*:*Kafka port number* **--consumer.config /opt/client/Kafka/kafka/config/ consumer.properties**

----End

JDBC Dimension Table (MySQL as an Example)

kafkaSource is used as the fact table, **customer_t2** is used as the dimension table, and the result is written to kafkaSink.

Step 1 Create the dimension table **customer_t2** on the MySQL client. An example of the table creation statement is as follows:

```
CREATE TABLE customer_t2(
c_customer_sk INTEGER PRIMARY KEY,
c_customer_age INTEGER,
c_customer_address VARCHAR(32)
);

INSERT INTO customer_t2 VALUES(1,18,'city a');
INSERT INTO customer_t2 VALUES(2,14,'city b');
INSERT INTO customer_t2 VALUES(3,16,'city c');
INSERT INTO customer_t2 VALUES(4,24,'city d');
INSERT INTO customer_t2 VALUES(5,32,'city e');
INSERT INTO customer_t2 VALUES(6,27,'city f');
INSERT INTO customer_t2 VALUES(7,41,'city a');
INSERT INTO customer_t2 VALUES(8,35,'city h');
INSERT INTO customer_t2 VALUES(9,16,'city j');
```

Step 2 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 3 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **5000**, and retain the default value for **Mode**.

```
CREATE TABLE KafkaSource (
  -- Kafka as a source table
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32),
  proctime as proctime()
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_source',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
);
CREATE TABLE KafkaSink (
  -- Kafka sink table.
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32),
  c_customer_age INTEGER,
  c_customer_address VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_sink',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
);
CREATE TABLE MyUserTable (
  -- MySQL dimension table
  c_customer_sk INTEGER PRIMARY KEY NOT ENFORCED,
```

```
  c_customer_age INTEGER,
  c_customer_address VARCHAR(32)
) WITH (
  'connector' = 'jdbc',
  'url' = 'jdbc:mysql://IP address of the MySQL server:MySQL server port/mysql',
  'table-name' = 'customer_t2',
  'username' ='MySQL database username',
  'password' ='Password of the MySQL database user'
);
INSERT INTO
  KafkaSink
SELECT
  t.c_customer_sk,
  t.c_customer_name,
  d.c_customer_age,
  d.c_customer_address
FROM
  KafkaSource as t
  JOIN MyUserTable FOR SYSTEM_TIME AS OF t.proctime as d ON t.c_customer_sk = d.c_customer_sk;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- **properties.kerberos.domain.name**: Set it to **hadoop.***System domain name*. You can log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust** to view the actual domain name of the cluster.

Step 4 Run the following command to check whether data is received in the sink table, that is, check whether data is properly written to the Kafka topic after **Step 5** is performed. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-consumer.sh --topic customer_sink --bootstrap-server *IP address of the node where the Kafka instance is deployed*:*Kafka port number* **--consumer.config /opt/client/Kafka/kafka/config/ consumer.properties**

Step 5 View the topic and write data to the Kafka topic by referring to **Managing Messages in Kafka Topics**. After the data is written, view the execution result in the window in **Step 4**.

./kafka-topics.sh --list *Service IP address of the Kafka Broker instance*:*Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instances are deployed*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

In this example, the topic name is **customer_source**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka Broker instance is deployed*:*Kafka port* **--topic customer_source --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,zhangsan
5,zhaosi
1,xiaoming
2,liuyang
7,liubei
10,guanyu
20,zhaoyun
```

Press **Enter** to send the message. The output in the kafka-console-consumer window in **Step 4** is as follows:

```
3,zhangsan,16,city c
5,zhaosi,32,city e
1,xiaoming,18,city a
2,liuyang,14,city b
7,liubei,41,city a
```

----End

6.5.5 Creating a FlinkServer Job to Write Data to a DWS

This section applies to MRS 3.3.1 and later.

Scenario

Data Warehouse Service (DWS) is an online data analysis and processing database. This topic uses the FlinkServer and Kafka in security mode, and takes DWS as the sink table to explain the "with" parameters for creating a table and code examples. You will learn how to interconnect with DWS on the FlinkServer job management page.

NOTICE

When "FlinkSQL" is displayed in the command output on the FlinkServer web UI in MRS 3.2.0 or later clusters, the **password** field in the SQL statement is left blank. Before you submit a job, manually enter the password.

Prerequisites

In the cluster where FlinkServer is deployed:

- HDFS, Yarn, Kafka, ZooKeeper, and Flink have been installed.
- The client that contains the Kafka service has been installed, for example, in the **/opt/client** directory.
- You have created a user with the **FlinkServer Admin Privilege** (for example, **flinkuser**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.

Procedure

Step 1 Create an empty table for receiving data in a DWS database, for example, **dws_test**.

Step 2 Log in to Manager as user **flinkuser** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 3 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE dws_test(
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH(
  'connector' = 'dws',
  'url' = 'jdbc:postgresql://DWS connection address/gaussdb',
  'table-name' = 'dws_test',
  'username' ='DWS username',
  'password' ='DWS user password'

);
CREATE TABLE KafkaSource (
  c_customer_sk INTEGER,
  c_customer_name VARCHAR(32)
) WITH (
  'connector' = 'kafka',
  'topic' = 'customer_source',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka Broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in non-security mode.
);
Insert into
  dws_test
select
  *
from
  KafkaSource;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: To obtain the value, log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- **properties.group.id** indicates the Kafka user group ID. This parameter is mandatory when Kafka functions as the source.
- **properties.kerberos.domain.name**: Set it to **hadoop.***System domain name*. To obtain the actual domain name of the cluster, log in to FusionInsight Manager and choose **System** > **Permission** > **Domain and Mutual Trust**.
- The DWS sink supports the configuration of batch parameters. When one of the conditions is met, the sink is triggered.
  - **autoFlushBatchSize**: size of the batch for automatically refreshing the database. Default value: **5000**.
  - **autoFlushMaxInterval**: maximum interval for automatically refreshing the database (duration to form a batch). Default value: **5s**.

Step 4 On the job management page, check whether the job status is **Running**.

Step 5 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list *--bootstrap-server* *Service IP address of the Kafka Broker instance*:*Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instances reside*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

In this example, the topic name is **customer_source**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka Broker instance is located*:*Kafka port* --**topic customer_source --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,zhangsan
4,wangwu
8,zhaosi
```

Press **Enter** to send the message.

Step 6 Log in to the DWS client and run the following command to check whether the sink table received data:

Select * from dws_test;

----End

6.5.6 Creating a FlinkServer Job to Write Data to an HBase Table

This section applies to MRS 3.1.2 or later clusters.

Scenario

FlinkServer can be interconnected with HBase. The details are as follows:

- It can be interconnected with dimension tables and sink tables.
- When HBase and Flink are in the same cluster or clusters with mutual trust, FlinkServer can be interconnected with HBase.
- If HBase and Flink are in different clusters without mutual trust, Flink in a normal cluster can be interconnected with HBase in a normal cluster.

Prerequisites

- The HDFS, Yarn, Flink, and HBase services have been installed in a cluster.
- The client that contains the HBase service has been installed, for example, in the **/opt/client** directory.

Creating a Job

Scenario 1: HBase Functioning as a Sink Table

Step 1 Create a table on the HBase client.

Log in to the HBase client by referring to **Using the HBase Client** and run the **create'dim_province', "f1"** command to create the **dim_province** table.

Step 2 Copy the HBase configuration file to the node where FlinkServer is deployed.

1. Log in to the node where the client is installed as the client installation user and copy all configuration files in the **/opt/client/HBase/hbase/conf/** directory of HBase to an empty directory of all nodes where FlinkServer is deployed, for example, **/tmp/client/HBase/hbase/conf/**.
2. Change the owner of the configuration file directory and its upper-layer directory on the FlinkServer node to **omm**.

   chown omm: /tmp/client/HBase/ -R

   NOTE

   - FlinkServer nodes:

     Log in to Manager, choose **Cluster** > **Services** > **Flink** > **Instance**, and check the **Service IP Address** of FlinkServer.
   - If the node where a FlinkServer instance is located is the node where the HBase client is installed, skip this step on this node.

Step 3 Add the local path for FlinkServer to access the HBase cluster.

Log in to Manager and choose **Cluster** > **Services** > **Flink**. Click **Configurations** then **All Configurations**, search for the **HBASE_CONF_DIR** parameter, and enter the FlinkServer directory (for example, **/tmp/client/HBase/hbase/conf/**) to which the HBase configuration files are copied from **Value**. After the parameters are configured, click **Save**. After confirming the modification, click **OK**.

NOTE

If the node where a FlinkServer instance is deployed is the node where the HBase client is installed, enter the **/opt/client/HBase/hbase/conf/** directory of HBase in **Value** of the **HBASE_CONF_DIR** parameter.

Step 4 Restart the affected FlinkServer instance.

Click **Instance**, select all FlinkServer instances, choose **More** > **Restart Instance**, enter the password, and click **OK** to restart the instances.

Step 5 Access FlinkServer and create a Flink SQL job.

1. Log in to Manager and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.
2. Create a Flink SQL job and set Task Type to Stream job. For details, see **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

   In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

   If the cluster is in security mode and the HBase authentication setting is **hbase.rpc.protection=authentication**, create a Flink SQL job by referring to the following example:

```
CREATE TABLE ksource1 (
user_id STRING,
item_id STRING,
proctime as PROCTIME()
) WITH (
'connector' = 'kafka',
'topic' = 'ksource1',
'properties.group.id' = 'group1',
'properties.bootstrap.servers' = 'IP address of the Kafka broker instance 1:Kafka port number,IP address of the Kafka broker instance 2:Kafka port number',
'format' = 'json',
'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);

CREATE TABLE hsink1 (
rowkey STRING,
f1 ROW < item_id STRING >,
PRIMARY KEY (rowkey) NOT ENFORCED
) WITH (
'connector' = 'hbase-2.2',
'table-name' = 'dim_province',
'zookeeper.quorum' = 'IP address of the ZooKeeper quorumpeer instance 1:ZooKeeper port number,IP address of the ZooKeeper quorumpeer instance 2:ZooKeeper port number'
);

INSERT INTO
```

```
hsink1
SELECT
user_id as rowkey,
ROW(item_id) as f1
FROM
ksource1;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- IP address of the ZooKeeper quorumpeer instance

  To obtain IP addresses of all ZooKeeper quorumpeer instances, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the displayed page, click **Instance** and view the IP addresses of all the hosts where the quorumpeer instances locate.
- Port number of the ZooKeeper client

  Log in to FusionInsight Manager and choose **Cluster** > **Service** > **ZooKeeper**. On the displayed page, click **Configurations** and check the value of **clientPort**.
- HBase authentication

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase**, click **Configuration** and then **All Configurations**, search for **hbase.rpc.protection**, and check the HBase authentication mode. If the authentication mode is **integrity** or **privacy**, add the following parameters:

  'properties.hbase.rpc.protection' = '*HBase authentication mode*'

  'properties.zookeeper.znode.parent' = '/hbase'

  'properties.hbase.security.authorization' = 'true'

  'properties.hbase.security.authentication' = 'kerberos'

3. On the job management page, check whether the job status is **Running**.

Step 6 Execute the following script to write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instance is deployed*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

For example, if the topic name is **ksource1**, the script is **sh kafka-console-producer.sh --broker-list** *IP address of the node where the Kafka Broker instance is located*:*Kafka port* **--topic ksource1 --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content and press **Enter** to send the message.

```
{"user_id": "3","item_id":"333333"}
{"user_id": "4","item_id":"44444444"}
```

Step 7 Log in to the HBase client and view the table data.

hbase shell

scan 'dim_province'

----End

Scenario 2: HBase Functioning as a Dimension Table

Step 1 Create a table on the HBase client and write data into the table.

Log in to the HBase client, use **create 'hbase_dim_table','f1"** to create the **hbase_dim_table** table, and write data into the table. For details, see **Using the HBase Client**.

```
put 'hbase_dim_table','1','f1:address','city1'
put 'hbase_dim_table','2','f1:address','city2'
put 'hbase_dim_table','3','f1:address','city3'
```

Step 2 Copy the HBase configuration file to the node where FlinkServer is deployed.

1. Log in to the node where the client is installed as the client installation user and copy all configuration files in the **/opt/client/HBase/hbase/conf/** directory of HBase to an empty directory of all nodes where FlinkServer is deployed, for example, **/tmp1/client/HBase/hbase/conf/**.
2. Change the owner of the configuration file directory and its upper-layer directory on the FlinkServer node to **omm**.

   chown omm: /tmp1/client/HBase/ -R

   NOTE

   - FlinkServer nodes:

     Log in to Manager, choose **Cluster** > **Services** > **Flink** > **Instance**, and check the **Service IP Address** of FlinkServer.
   - If the node where a FlinkServer instance is located is the node where the HBase client is installed, skip this step on this node.

Step 3 Add the local path for FlinkServer to access the HBase cluster.

Log in to Manager and choose **Cluster** > **Services** > **Flink**. Click **Configurations** then **All Configurations**, search for the **HBASE_CONF_DIR** parameter, and enter the FlinkServer directory (for example, **/tmp1/client/HBase/hbase/conf/**) to which the HBase configuration files are copied from **Value**. After the parameters are configured, click **Save**. After confirming the modification, click **OK**.

NOTE

If the node where a FlinkServer instance is deployed is the node where the HBase client is installed, enter the **/opt/client/HBase/hbase/conf/** directory of HBase in **Value** of the **HBASE_CONF_DIR** parameter.

Step 4 Restart the affected FlinkServer instance.

Click **Instance**, select all FlinkServer instances, choose **More** > **Restart Instance**, enter the password, and click **OK** to restart the instances.

Step 5 Access FlinkServer and create a Flink SQL job.

1. Log in to Manager and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.
2. Create a Flink SQL job and set Task Type to Stream job. For details, see **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

   In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

   If the cluster is in security mode and the HBase authentication setting is **hbase.rpc.protection=authentication**, create a Flink SQL job by referring to the following example:

```
CREATE TABLE KafkaSource (
  `user_id` STRING,
  `user_name` STRING,
  proctime as proctime()
) WITH (
  'connector' = 'kafka',
  'topic' = 'user_source',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);
CREATE TABLE KafkaSink (
  -- Kafka functions as a sink table.
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `address` VARCHAR
) WITH (
  'connector' = 'kafka',
  'topic' = 'user_sink',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);
CREATE TABLE hbaseTable (
  -- HBase dimension table
  user_id STRING,
  f1 ROW < address STRING >,
  PRIMARY KEY (user_id) NOT ENFORCED
) WITH (
  'connector' = 'hbase-2.2',
  'table-name' = 'hbase_dim_table',
  'zookeeper.quorum' = 'IP address of the ZooKeeper quorumpeer instance 1:ZooKeeper port number,IP address of the ZooKeeper quorumpeer instance 2:ZooKeeper port number'
);
INSERT INTO
  KafkaSink
SELECT
  t.user_id,
```

```
  t.user_name,
  d.address
FROM
  KafkaSource as t
  JOIN hbaseTable FOR SYSTEM_TIME AS OF t.proctime as d ON t.user_id = d.user_id;
```

3. On the job management page, check whether the job status is **Running**.

Step 6 Execute the following script to write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instance is deployed*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

Enter the message content and press **Enter** to send the message.

```
1,name1
2,name2
3,name3
```

Step 7 Run the following commands to check whether data is written from the Kafka topic to the sink table:

sh kafka-console-consumer.sh --topic *Topic name* **--bootstrap-server** *Service IP address of the Kafka broker instance*:*Kafka port number* --**consumer.config** *Client directory*/**Kafka/kafka/config/consumer.properties**

The result is as follows:

```
1,name1,city1
2,name2,city2
3,name3,city3
```

----End

Submitting a Job Using the Application

- If the Flink run mode is used, you are advised to use the **export HBASE_CONF_DIR=** *HBase configuration directory*, for example, **export HBASE_CONF_DIR=/opt/hbaseconf**.
- If the Flink run-application mode is used, you can use either of the following methods to submit jobs:
  - (Recommended) Add the following configurations to a table creation statement.

Table 6-16 Related configurations

Parameter	Description
'properties.hbase.rpc.protection' = 'authentication'	This parameter must be consistent with that on the HBase server.
'properties.zookeeper.znode.parent' = '/hbase'	If there are multiple services, hbase1 and hbase2 coexist. You must clarify the cluster to be accessed.
'properties.hbase.security.authorization' = 'true'	Authentication is enabled.

Parameter	Description
'properties.hbase.security.authentication' = 'kerberos'	Kerberos authentication is enabled.

Example:

```
CREATE TABLE hsink1 (
    rowkey STRING,
    f1 ROW < q1 STRING >,
    PRIMARY KEY (rowkey) NOT ENFORCED
  ) WITH (
    'connector' = 'hbase-2.2',
    'table-name' = 'cc',
    'zookeeper.quorum' = 'x.x.x.x:clientPort',
    'properties.hbase.rpc.protection' = 'authentication',
    'properties.zookeeper.znode.parent' = '/hbase',
    'properties.hbase.security.authorization' = 'true',
    'properties.hbase.security.authentication' = 'kerberos'
  );
```

- Add the HBase configuration to YarnShip.

  Example: Dyarn.ship-files=/opt/hbaseconf

6.5.7 Creating a FlinkServer Job to Write Data to an HDFS

This section applies to MRS 3.1.2 or later clusters.

Scenario

This section describes the data definition language (DDL) of HDFS as a sink table, as well as the WITH parameters and example code for creating a sink table, and provides guidance on how to perform operations on the FlinkServer job management page.

If your Kafka cluster is in security mode, the following example SQL statements can be used.

Prerequisites

- The HDFS, Yarn, and Flink services have been installed in a cluster.
- The client that contains the HDFS service has been installed, for example, in the **/opt/client** directory.
- You have created a user assigned with the **FlinkServer Admin Privilege** (for example, **flink_admin**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.

Creating a Job

Step 1 Log in to Manager as user **flink_admin** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE kafka_table (
  user_id STRING,
  order_amount DOUBLE,
  log_ts TIMESTAMP(3),
  WATERMARK FOR log_ts AS log_ts - INTERVAL '5' SECOND
) WITH (
  'connector' = 'kafka',
  'topic' = 'user_source',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'csv',
   --Ignore the CSV data that fails to be parsed.
  'csv.ignore-parse-errors' = 'true',--If the data is in JSON format, set json.ignore-parse-errors to true.
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.

);

CREATE TABLE fs_table (
  user_id STRING,
  order_amount DOUBLE,
  dt STRING,
  `hour` STRING
) PARTITIONED BY (dt, `hour`) WITH ( --Date-specific file partitioning
  'connector'='filesystem',
  'path'='hdfs:///sql/parquet',
  'format'='parquet',
  'sink.partition-commit.delay'='0 s',-- Partitions will not be committed before the delay time. If the files are partitioned by day, set this parameter to '1 d'. If the files are partitioned by hour, set this parameter to '1 h'.
  'sink.partition-commit.policy.kind'='success-file'
);
-- streaming sql, insert into file system table
INSERT INTO fs_table SELECT user_id, order_amount, DATE_FORMAT(log_ts, 'yyyy-MM-dd'), DATE_FORMAT(log_ts, 'HH') FROM kafka_table;
```

NOTE

- Kafka port
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 3 On the job management page, check whether the job status is **Running**.

Step 4 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list *--bootstrap-server* *Service IP address of the Kafka Broker instance:Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

For example, if the topic name is **user_source**, the script is **sh kafka-console-producer.sh --broker-list** *IP address of the node where Kafka instances are deployed*:*Kafka port* **--topic user_source** --**producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
3,3333,"2021-09-10 14:00"
4,4444,"2021-09-10 14:01"
```

Press **Enter** to send the message.

Step 5 Run the following command to check whether data is written from the HDFS directory to the sink table:

hdfs dfs -ls -R /sql/parquet

----End

Interconnecting Flink with HDFS Partitions

- Customized partitioning

  Flink's file system supports partitions in the standard Hive format. You do not need to register partitions with a table catalog. Partitions are inferred based on the directory structure.

  For example, a table that is partitioned based on the following directory is inferred to contain datetime and hour partitions.

```
path
└── datetime=2021-09-03
    └── hour=11
        ├── part-0.parquet
        ├── part-1.parquet
    └── hour=12
        ├── part-0.parquet
└── datetime=2021-09-24
    └── hour=6
        ├── part-0.parquet
```

- Rolling policy of partition files

  Data in the partition directories is split into part files. Each partition contains at least one part file, which is used to receive the data written by the subtask of the sink.

  The following parameters describe the rolling policies of partition files.

  Table 6-17 Rolling policy of partition files

Parameter	Default Value	Type	Description
sink.rolling-policy.file-size	128 MB	Memory Size	Maximum size of a partition file before it is rolled.

Parameter	Default Value	Type	Description
sink.rolling-policy.rollover-interval	30 minutes	Duration	Maximum duration that a partition file can stay open before it is rolled.
sink.rolling-policy.check-interval	1 minute	Duration	Interval for checking time-based rolling policies.

- File merging

  File compression is supported, allowing applications to have a shorter checkpoint interval without generating a large number of files.

  NOTE

  Only files in a single checkpoint are compressed. That is, the number of generated files is at least the same as the number of checkpoints. Files are invisible before merged. They are visible after both the checkpoint and compression are complete. If file compression takes too much time, the checkpoint will be prolonged.

  Table 6-18 File merging in partition directories

Parameter	Default Value	Type	Description
auto-compaction	false	Boolean	Whether to enable automatic compression. Data will be written to temporary files. After a checkpoint is complete, the temporary files generated by the checkpoint are compressed. These temporary files are invisible before compression.
compaction.file-size	none	Memory Size	Size of the target file to be compressed. The default value is the size of the file to be rolled.

- Partition commit

  After a file is written to a partition, for example, a partition is added to Hive metastore (HMS) or a **_SUCCESS** file is written to a directory, the downstream application needs to be notified. Triggers and policies are used to commit partition files.

Table 6-19 Trigger parameters for committing partition files

Parameter	Default Value	Type	Description
sink.partition-commit.trigger	process-time	String	• process-time: System time of the compute node. It does not need to extract the partition time or generate watermarks. If the current system time exceeds the system time generated when a partition is created plus the delay time, the partition should be submitted. • partition-time: Time extracted from the partition. Watermarks are required. If the time for generating watermarks exceeds the time extracted from a partition plus the delay time, the partition should be submitted.
sink.partition-commit.delay	0 s	Duration	Partitions will not be committed before the delay time. If it is a daily partition, the value is **1 d**. If it is an hourly one, the value is **1 h**.

Table 6-20 Policy parameters for committing partition files

Configuration Item	Default Value	Type	Description
sink.partition-commit.policy.kind	-	String	Policy for committing partitions: • **metastore**: used to add partitions to metastore. Only Hive tables support the metastore policy. The file system manages partitions based on the directory structure. • **success-file**: used to add **success-file** files to a directory. • The two policies can be configured at the same time, that is, **'sink.partition-commit.policy.kind'='metastore,success-file'**.
sink.partition-commit.policy.class	-	String	Class that implements partition commit policy interfaces. This parameter takes effect only in the customized submission policies.

Configuration Item	Default Value	Type	Description
sink.partition-commit.success-file.name	_SUCCESS	String	File name of the success-file partition commit policy. The default value is **_SUCCESS**.

6.5.8 Creating a FlinkServer Job to Write Data to a Hive Table

This section applies to MRS 3.1.2 or later clusters.

Scenario

Currently, FlinkServer interconnects with Hive MetaStore. Therefore, the MetaStore function must be enabled for Hive. Hive can be used as sink, and dimension tables.

If your Kafka cluster is in security mode, the following example SQL statements can be used.

Prerequisites

- Services such as HDFS, Yarn, Kafka, Flink, and Hive (the service name must be **Hive**) have been installed in the cluster.
- The client that contains the Hive service has been installed, for example, in the **/opt/client** directory.
- Flink 1.12.2 or later and Hive 3.1.0 or later are supported.
- You have created a user assigned with the **FlinkServer Admin Privilege** (for example, **flink_admin**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.
- You have obtained the client configuration file and credential of the user for accessing the Flink web UI. For details, see "Note" in **Procedure**.

Creating a Job

Scenario 1: Hive Functioning as a Sink Table

The following uses the process of interconnecting a Kafka mapping table to Hive as an example.

Step 1 Log in to the Flink web UI as user **flink_admin**. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Create a cluster connection, for example, **flink_hive**.

1. Choose **System Management** > **Cluster Connection Management**. The **Cluster Connection Management** page is displayed.
2. Click **Create Cluster Connection**. On the displayed page, enter information by referring to **Table 6-21** and click **Test**. After the test is successful, click **OK**.

Table 6-21 Parameters for creating a cluster connection

Parameter	Description	Example Value
Cluster Connection Name	Name of the cluster connection, which can contain a maximum of 100 characters. Only letters, digits, and underscores (_) are allowed.	flink_hive
Description	Description of the cluster connection name.	-
Version	Select a cluster version.	MRS 3
Secure Version	– If the secure version is used, select **Yes** for a security cluster. Enter the username and upload the user credential. – If not, select **No**.	Yes
Username	The user must have the minimum permissions for accessing services in the cluster. The name can contain a maximum of 100 characters. Only letters, digits, and underscores (_) are allowed. This parameter is available only when **Secure Version** is set to **Yes**.	flink_admin
Client Profile	Client profile of the cluster, in TAR format.	-
User Credential	User authentication credential in FusionInsight Manager in TAR format. This parameter is available only when **Secure Version** is set to **Yes**. Files can be uploaded only after the username is entered.	User credential of **flink_admin**

Step 3 Create a Flink SQL job, for example, **flinktest1**.

1. Click **Job Management**. The job management page is displayed.
2. Click **Create Job**. On the displayed job creation page, set parameters by referring to **Table 6-22** and click **OK**. The job development page is displayed.

Table 6-22 Parameters for creating a job

Parameter	Description	Example Value
Type	Job type, which can be **Flink SQL** or **Flink Jar**.	Flink SQL
Name	Job name, which can contain a maximum of 64 characters. Only letters, digits, and underscores (_) are allowed.	flinktest1

Parameter	Description	Example Value
Task Type	Type of the job data source, which can be a stream job or a batch job.	Stream job
Description	Job description, which can contain a maximum of 100 characters.	-

Step 4 On the job development page, enter the following statements and click **Check Semantic** to check the input content.

```
CREATE TABLE test_kafka (
  user_id varchar,
  item_id varchar,
  cat_id varchar,
  zw_test timestamp
) WITH (
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'format' = 'json',
  'topic' = 'zw_tset_kafka',
  'connector' = 'kafka',
  'scan.startup.mode' = 'latest-offset',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.

);
CREATE CATALOG myhive WITH (
  'type' = 'hive',
  'hive-version' = '3.1.0',
  'default-database' = 'default',
  'cluster.name' = 'flink_hive'
);
use catalog myhive;
set table.sql-dialect = hive;create table user_behavior_hive_tbl (
    user_id STRING,
    item_id STRING,
    cat_id STRING,
    ts timestamp
  ) PARTITIONED BY (dy STRING, ho STRING, mi STRING) stored as textfile TBLPROPERTIES (
    'partition.time-extractor.timestamp-pattern' = '$dy $ho:$mi:00',
    'sink.partition-commit.trigger' = 'process-time',
    'sink.partition-commit.delay' = '0S',
    'sink.partition-commit.policy.kind' = 'metastore,success-file'
  );
INSERT into
  user_behavior_hive_tbl
SELECT
  user_id,
  item_id,
  cat_id,
  zw_test,
  DATE_FORMAT(zw_test, 'yyyy-MM-dd'),
  DATE_FORMAT(zw_test, 'HH'),
  DATE_FORMAT(zw_test, 'mm')
FROM
  default_catalog.default_database.test_kafka;
```

NOTE

- Kafka port
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- The value of **'cluster.name'** is the name of the cluster connection created in **Step 2**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 5 After the job is developed, in **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

Step 6 Click **Submit** in the upper left corner to submit the job.

Step 7 After the job is successfully executed, choose **More** > **Job Monitoring** to view the job running details.

Step 8 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list *--bootstrap-server* *Service IP address of the Kafka Broker instance*:*Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

For example, if the topic name is **zw_tset_kafka**, the script is **sh kafka-console-producer.sh --broker-list** *IP address of the node where Kafka instances are deployed*:*Kafka port* **--topic zw_tset_kafka** --**producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
{"user_id": "3","item_id":"333333","cat_id":"cat333","zw_test":"2021-09-08 09:08:01"}
{"user_id": "4","item_id":"444444","cat_id":"cat444","zw_test":"2021-09-08 09:08:01"}
```

Press **Enter** to send the message.

Step 9 Run the following command to check whether data is written from the Hive table to the sink table:

beeline

select * from user_behavior_hive_tbl;

----End

Scenario 2: Hive Functioning as a Dimension Table

Step 1 Log in to the Hive client by referring to **Using the Hive Client**, create a Hive table, and insert data.

```
CREATE TABLE hive3 ( id  int, name string ) PARTITIONED BY (dy STRING,ho STRING,mi STRING)
STORED AS textfile TBLPROPERTIES (
'partition.time-extractor.timestamp-pattern'='$dy $ho:$mi:00',
'streaming-source.partition.include'='all',
'streaming-source.enable'='true',
'streaming-source.partition.include'='all',
'streaming-source.monitor-interval'='2m');

insert into table hive3  values('1','aname','sss','name1','company1');
insert into table hive3  values('2','bname','sss','name1','company1');
```

Step 2 Log in to the Flink web UI as user **flink_admin**. For details, see **Accessing the FlinkServer Web UI**.

Step 3 Create a cluster connection, for example, **flink_hive1**.

1. Choose **System Management** > **Cluster Connection Management**. The **Cluster Connection Management** page is displayed.
2. Click **Create Cluster Connection**. On the displayed page, enter information by referring to **Table 6-23** and click **Test**. After the test is successful, click **OK**.

Table 6-23 Parameters for creating a cluster connection

Parameter	Description	Example Value
Cluster Connection Name	Name of the cluster connection, which can contain a maximum of 100 characters. Only letters, digits, and underscores (_) are allowed.	flink_hive1
Description	Description of the cluster connection name.	-
Version	Select a cluster version.	MRS 3
Secure Version	– If the secure version is used, select **Yes** for a security cluster. Enter the username and upload the user credential. – If not, select **No**.	Yes
Username	The user must have the minimum permissions for accessing services in the cluster. The name can contain a maximum of 100 characters. Only letters, digits, and underscores (_) are allowed. This parameter is available only when **Secure Version** is set to **Yes**.	flink_admin
Client Profile	Client profile of the cluster, in TAR format.	-
User Credential	User authentication credential in FusionInsight Manager in TAR format. This parameter is available only when **Secure Version** is set to **Yes**. Files can be uploaded only after the username is entered.	User credential of **flink_admin**

Step 4 Create a Flink SQL job, for example, **flinktest2**.

1. Click **Job Management**. The job management page is displayed.
2. Click **Create Job**. On the displayed job creation page, set parameters by referring to **Table 6-24** and click **OK**. The job development page is displayed.

Table 6-24 Parameters for creating a job

Parameter	Description	Example Value
Type	Job type, which can be **Flink SQL** or **Flink Jar**.	Flink SQL
Name	Job name, which can contain a maximum of 64 characters. Only letters, digits, and underscores (_) are allowed.	flinktest2
Job Type	Type of the job data source, which can be a stream job or a batch job.	Stream job
Description	Job description, which can contain a maximum of 100 characters.	-

Step 5 On the job development page, enter the following statements and click **Check Semantic** to check the input content.

```
CREATE TABLE kafka_source (
  id int,
  address string,
  proctime as PROCTIME()
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_source',
  'properties.bootstrap.servers' = '<i>IP address of the Kafka broker instance</i>:<i>Kafka port</i>',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.<i>System domain name</i>'--This parameter is not required for clusters in normal mode.
);
CREATE TABLE kafka_sink(
  id int,
  address string,
  name string
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_sink',
  'properties.bootstrap.servers' = '<i>IP address of the Kafka broker instance</i>:<i>Kafka port</i>',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.<i>System domain name</i>'--This parameter is not required for clusters in normal mode.
);
CREATE CATALOG myhive WITH (
  'type' = 'hive',
  'hive-version' = '3.1.0',
```

```
  'default-database' = 'default',
  'cluster.name' = 'flink_hive1'
);
use catalog myhive;
set
  table.sql-dialect = hive;
create table if not exists hive3 (id int, name string) stored as textfile TBLPROPERTIES (
  'streaming-source.enable' = 'false',
  'streaming-source.partition.include' = 'all',
  'lookup.join.cache.ttl' = '5 min'
);
INSERT INTO
  default_catalog.default_database.kafka_sink
select
  t1.id,
  t1.address,
  t2.name
from
  default_catalog.default_database.kafka_source as t1
  join hive3 FOR SYSTEM_TIME AS OF t1.proctime AS t2 ON t1.id = t2.id;
```

NOTE

- The IP address and port number of the Kafka broker instance are as follows:
  - To obtain the instance IP address, log in to FusionInsight Manager, choose **Cluster** > **Services** > **Kafka**, click **Instance**, and query the instance IP address on the instance list page.
  - If Kerberos authentication is enabled for the cluster (the cluster is in security mode), the Broker port number is the value of **sasl.port**. The default value is **21007**.
  - If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the broker port number is the value of **port**. The default value is **9092**. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. Click **Configurations** then **All Configurations**. On the page that is displayed, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- The value of **'cluster.name'** is the name of the cluster connection created in **Step 3**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 6 After the job is developed, in **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

Step 7 Click **Submit** in the upper left corner to submit the job.

Step 8 After the job is successfully executed, choose **More** > **Job Monitoring** to view the job running details.

Step 9 Execute the following commands to view the topic and write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

./kafka-topics.sh --list ***--bootstrap-server*** *Service IP address of the Kafka Broker instance*:*Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka Broker instance is deployed*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

Enter the message content.

```
1,city1
2,city2
```

Press **Enter** to send the message.

Step 10 Run the following command to check whether data is received in the sink table, that is, check whether data is properly written to the Kafka topic after **Step 9** is performed. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-consumer.sh --topic test_sink --bootstrap-server *Service IP address of the Kafka broker instance*:*Kafka port number* --**consumer.config /opt/client/Kafka/kafka/config/consumer.properties**

The result is as follows:

```
1,city1,aname
2,city2,bname
```

----End

6.5.9 Creating a FlinkServer Job to Write Data to a Hudi Table

This section applies to MRS 3.1.2 or later clusters.

Scenario

This section describes how to interconnect FlinkServer with Hudi through Flink SQL jobs. When you use Flink SQL to read data from or write data to Hudi, the TINYINT, SMALLINT, and TIME types cannot be defined.

Table 6-25 lists the read and write operations supported by Flink on Hudi COW and MOR tables.

Table 6-25 Flink SQL read and write operations on Hudi tables

Flink SQL	COW Table	MOR Table
Batch write	Supported	Supported
Batch read	Supported	Supported
Stream write	Supported	Supported
Stream read	Supported	Supported

Prerequisites

- The HDFS, Yarn, Flink, and Hudi services have been installed in a cluster.
- The client that contains the Hudi service has been installed, for example, in the **/opt/client** directory.
- Flink 1.12.2 or later and Hudi 0.9.0 or later are required.
- You have created a user assigned with the **FlinkServer Admin Privilege** (for example, **flink_admin**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**. The user has been added to the **hadoop**, **hive**, and **kafkaadmin** user groups and granted the **Manager_administrator** role.

Creating a Job

Step 1 Log in to Manager as user **flink_admin** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job as follows: Enter the SQL statement. After the SQL statement passes the verification, start the job. The following SQL examples are added as three jobs and run in sequence.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

NOTE

- CheckPoint should be enabled on the Flink web UI because data is written to a Hudi table only when a Flink SQL job triggers CheckPoint. Adjust the CheckPoint interval based on service requirements. You are advised to set the interval to a large number.
- If the CheckPoint interval is too short, job exceptions may occur due to untimely data updates. It is recommended that the CheckPoint interval be configured at the minute level.
- Asynchronous compaction is required when a Flink SQL job writes an MOR table. For details about the parameter for controlling the compaction interval, visit Hudi official website **https://hudi.apache.org/docs/configurations.html**.
- The following content is available in MRS 3.2.1 or later. By default, Hudi table write statements use Flink status index. To use the bucket index, add the following parameters to the statement:

```
'index.type'='BUCKET',
'hoodie.bucket.index.num.buckets'='Number of buckets in each partition of a Hudi table'
'hoodie.bucket.index.hash.field'='recordkey.field'
```

  - **hoodie.bucket.index.num.buckets**: Number of buckets in each partition of a Hudi table. Data in each partition is stored in each bucket in hash mode. This parameter cannot be modified after being set during table creation or data writing for the first time. Otherwise, an exception occurs during data update.
  - **hoodie.bucket.index.hash.field**: Field for calculating the hash value during bucketing. The field must be a subset of the primary key. The default value is the primary key of the Hudi table. If this parameter is left blank, the default value **recordkey.field** is used.
- The following content is available in MRS 3.2.1 or later. The same Hudi table can be written by the bucket indexes across the Flink and Spark engines.

1. Job 1: This Flink SQL job writes data to an MOR table in streams.

```
CREATE TABLE stream_mor(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_mor',
'table.type' = 'MERGE_ON_READ',
'hoodie.datasource.write.recordkey.field' = 'uuid',
'write.precombine.field' = 'ts',
'write.tasks' = '4'
);

CREATE TABLE kafka(
uuid VARCHAR(20),
name VARCHAR(10),
```

```
age INT,
ts INT,
`p` VARCHAR(20)
) WITH (
'connector' = 'kafka',
'topic' = 'writehudi',
'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
'properties.group.id' = 'testGroup1',
'scan.startup.mode' = 'latest-offset',
'format' = 'json',
'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);

insert into
stream_mor
select
*
from
kafka;
```

2. Job 2: This Flink SQL job writes data to a COW table in streams.

```
CREATE TABLE stream_write_cow(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_cow',
'hoodie.datasource.write.recordkey.field' = 'uuid',
'write.precombine.field' = 'ts',
'write.tasks' = '4'
);

CREATE TABLE kafka(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) WITH (
'connector' = 'kafka',
'topic' = 'writehudi',
'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
'properties.group.id' = 'testGroup1',
'scan.startup.mode' = 'latest-offset',
'format' = 'json',
'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);

insert into
stream_write_cow
select
*
from
kafka;
```

3. Job 3: This Flink SQL job reads MOR and COW tables in streams, merges data, and outputs the merged data to Kafka. Verify the SQL statement of job 3 and

start it after job 1 and job 2 are started and their status is running. Otherwise, an error message may be displayed during SQL verification, indicating that the Hudi table directory cannot be found.

```
CREATE TABLE stream_mor(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_mor',
'table.type' = 'MERGE_ON_READ',
'hoodie.datasource.write.recordkey.field' = 'uuid',
'write.precombine.field' = 'ts',
'read.tasks' = '4',
'read.streaming.enabled' = 'true',
'read.streaming.check-interval' = '5',
'read.streaming.start-commit' = 'earliest'
);
CREATE TABLE stream_write_cow(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_cow',
'hoodie.datasource.write.recordkey.field' = 'uuid',
'write.precombine.field' = 'ts',
'read.tasks' = '4',
'read.streaming.enabled' = 'true',
'read.streaming.check-interval' = '5',
'read.streaming.start-commit' = 'earliest'
);

CREATE TABLE kafka(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) WITH (
'connector' = 'kafka',
'topic' = 'readhudi',
'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port',
'properties.group.id' = 'testGroup1',
'scan.startup.mode' = 'latest-offset',
'format' = 'json',
'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);

insert into
kafka
select
*
from
stream_mor union all select * from stream_write_cow;
```

NOTE

- Kafka port
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.

Step 3 Execute the following script to write data to Kafka. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances are deployed*:*Kafka port* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

In this example, the topic name is **writehudi**.

sh kafka-console-producer.sh --broker-list *IP address of the node where the Kafka instance is deployed*:*Kafka port* **----topic writehudi --producer.config /opt/client/Kafka/kafka/config/producer.properties**

Enter the message content.

```
{"uuid": "1","name":"a01","age":10,"ts":10,"p":"1"}
{"uuid": "2","name":"a02","age":20,"ts":20,"p":"2"}
```

Press **Enter** to send the message.

Step 4 Consumes Kafka topic data and reads the result of reading the Hudi table from Flink streams.

sh kafka-console-consumer.sh --bootstrap-server *IP address of the node where the Kafka Broker instance is deployed*:*Kafka port* **--topic** *Topic name* **--consumer.config** *Client directory*/**Kafka/kafka/config/consumer.properties --from-beginning**

In this example, the topic name is **readhudi**.

sh kafka-console-consumer.sh --bootstrap-server *IP address of the node where the Kafka Broker instance is deployed*:*Kafka port* **--topic readhudi --consumer.config /opt/client/Kafka/kafka/config/consumer.properties --from-beginning**

The read result is as follows (the sequence is not fixed):

```
{"uuid": "1","name":"a01","age":10,"ts":10,"p":"1"}
{"uuid": "2","name":"a02","age":20,"ts":20,"p":"2"}
{"uuid": "1","name":"a01","age":10,"ts":10,"p":"1"}
{"uuid": "2","name":"a02","age":20,"ts":20,"p":"2"}
```

----End

Precautions for Using FlinkSQL Lookup Join Hudi

(This topic is available for MRS 3.5.0 and later.)

- The **lookup.join.cache.ttl** parameter is used to control the loading period of dimension table data. The default value is 60 minutes.
- Do not use a Hudi table with over 100,000 rows of records as a dimension table, as the data will be loaded to Flink TaskManager Heap memory.
- The new and updated data in the dimension table can be loaded for calculation only after the next loading period.

The following is a SQL example:

```
CREATE TABLE hudimor(
  uuid VARCHAR(20),
  name VARCHAR(10),
  age INT,
  ts INT,
  `p` VARCHAR(20),
  PRIMARY KEY (uuid) NOT ENFORCED
) PARTITIONED BY (`p`) WITH (
  'connector' = 'hudi',
  'path' = 'hdfs://hacluster/tmp/hudimor',
  'table.type' = 'MERGE_ON_READ',
  'hoodie.datasource.write.recordkey.field' = 'uuid',
  'write.precombine.field' = 'ts',
  'lookup.join.cache.ttl' = '60min'
);
CREATE TABLE datagen(uuid varchar(20), proctime as PROCTIME()) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '1'
);
CREATE TABLE blackhole (
  uuid VARCHAR(20),
  name VARCHAR(10),
  age INT,
  ts INT,
  `p` VARCHAR(20)
) WITH ('connector' = 'blackhole');
insert into
  blackhole
select
  t1.uuid as uuid,
  t2.name as name,
  t2.age as age,
  t2.ts as ts,
  t2.p as p
FROM
  datagen AS t1
  left JOIN hudimor FOR SYSTEM_TIME AS OF t1.proctime AS t2 ON t1.uuid = t2.uuid;
```

WITH Parameters

Table 6-26 WITH parameters

Mode	Configuration Item	Mandatory	Default Value	Description
Read	read.tasks	No	4	Parallelism of the tasks for reading the Hudi table.
	read.streaming.enabled	No	false	Whether to enable stream read.
	read.streaming.start-commit	No	By default, the latest commit is the start position.	Start position (closed interval) of incremental stream and batch consumption in **yyyyMMddHHmmss** format.
	read.end-commit	No	By default, the latest commit is the end position.	End position (closed interval) of incremental stream and batch consumption in **yyyyMMddHHmmss** format.
Write	write.tasks	No	4	Parallelism of the tasks for reading data from the Hudi table.
	index.bootstrap.enabled	No	false	Whether to enable index loading. If it is enabled, the latest data in the stored table is loaded to the state at a time. If incremental data needs to be synchronized to full data and there are offline Hoodie tables available, you can enable the index loading function to write data in real time and ensure that data is unique.
	write.index_bootstrap.tasks	No	4	If indexes are loaded slowly when a job is started, you can choose a larger value for this parameter. After that, the efficiency is improved, but checkpoints are blocked in the bootstrap phase.

Mode	Configuration Item	Mandatory	Default Value	Description
	compaction.async.enabled	No	true	Whether to enable online compaction
	compaction.schedule.enabled	No	true	Whether to generate a compression plan periodically. You are advised to enable this function even if online compaction is disabled.
	compaction.tasks	No	10	Parallelism of the tasks for compacting data in the Hudi table.
	index.state.ttl	No	7D	Duration for storing indexes. The default value is 7 days. If the value is less than 0, indexes are stored permanently. Indexes are the core data structure for determining whether data is duplicate. For long-time updates, for example, updating data generated one month ago, you need to increase the value of this parameter.

Synchronizing Metadata from Flink On Hudi to Hive

After this feature is enabled, Flink automatically creates a Hudi table on Hive and adds partitions to the Hudi table when writing data to it. Then services such as SparkSQL and Hive can read data form the Hudi table.

The metadata can be synchronized with either of the following methods. The JDBC mode is used as an example in the following steps.

This step is required for MRS 3.2.0 or later.

- Synchronizing metadata to Hive in JDBC mode

```
CREATE TABLE stream_mor(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_mor',
'table.type' = 'MERGE_ON_READ',
'hive_sync.enable' = 'true',
'hive_sync.table' = 'Name of the table to be synchronized to Hive',
'hive_sync.db' = 'Name of the database to be synchronized to Hive',
'hive_sync.metastore.uris' = 'Value of hive.metastore.uris in the hive-site.xml file on the Hive client',
'hive_sync.jdbc_url' = 'Value of CLIENT_HIVE_URI in the component_env file on the Hive client'
);
```

NOTICE

- **hive_sync.jdbc_url**: If the value of **CLIENT_HIVE_URI** in the Hive client file **component_env** contains ****, delete ****.
- To use the Hive style partitioning, add the following parameters:
  - 'hoodie.datasource.write.hive_style_partitioning' = 'true'
  - 'hive_sync.partition_extractor_class' = 'org.apache.hudi.hive.MultiPartKeysValueExtractor'
- Flink on Hudi synchronizes data to Hive. Hudi is case sensitive, while Hive is case insensitive. You are not advised to use uppercase letters in fields of Hudi tables. Otherwise, data may fail to be read or written.

- Synchronizing metadata to Hive in HMS mode

```
CREATE TABLE stream_mor(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_mor',
'table.type' = 'MERGE_ON_READ',
'hive_sync.enable' = 'true',
'hive_sync.table' = 'Name of the table to be synchronized to Hive',
'hive_sync.db' = 'Name of the database to be synchronized to Hive',
'hive_sync.mode' = 'hms',
'hive_sync.metastore.uris' = 'Value of hive.metastore.uris in the hive-site.xml file on the Hive client',
'properties.hive.metastore.kerberos.principal' = 'Value of hive.metastore.kerberos.principal in the hive-site.xml file on the Hive client'
);
```

Methods with JDBC:

Step 1 Log in to Manager as user **flink_admin** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job as follows: Enter the SQL statement. After the SQL statement passes the verification, start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE stream_mor2(
uuid VARCHAR(20),
name VARCHAR(10),
age INT,
ts INT,
`p` VARCHAR(20)
) PARTITIONED BY (`p`) WITH (
'connector' = 'hudi',
'path' = 'hdfs://hacluster/tmp/hudi/stream_mor2',
'table.type' = 'MERGE_ON_READ',
'hoodie.datasource.write.recordkey.field' = 'uuid',
'write.precombine.field' = 'ts',
'write.tasks' = '4',
'hive_sync.enable' = 'true',
'hive_sync.table' = 'Name of the table to be synchronized to Hive, for example, stream_mor2',
'hive_sync.db' = 'Name of the database to be synchronized to Hive, for example, default',
```

```
'hive_sync.metastore.uris' = 'Value of hive.metastore.uris in the hive-site.xml file on the Hive client',
'hive_sync.jdbc_url' = 'Value of CLIENT_HIVE_URI in the component_env file on the Hive client'
);
CREATE TABLE datagen (
uuid varchar(20), name varchar(10), age int, ts INT, p varchar(20)
) WITH (
'connector' = 'datagen',
'rows-per-second' = '1',
'fields.p.length' = '1'
);insert into stream_mor2 select * from datagen;
```

Step 3 Wait for the Flink job to run for a period of time and continuously write the random test data generated by datagen to the Hudi table. You can click **More** > **Job Monitoring** to go to the native UI of Flink and view the job status.

Step 4 Log in to the node where the client is deployed, load environment variables, run the beeline command to log in to the Hive client, and run SQL statements to check whether the Hudi Sink table is successfully created on Hive and whether data can be read from the table.

cd /opt/hadoopclient

source bigdata_env

beeline

desc formatted default.stream_mor2;

select * from default.stream_mor2 limit 5;

show partitions default.stream_mor2;

----End

6.5.10 Creating a FlinkServer Job to Write Data to a Kafka Message Queue

This section applies to MRS 3.1.2 or later clusters.

Scenario

This section describes the data definition language (DDL) of Kafka as a source or sink table, as well as the WITH parameters and example code for creating a table, and provides guidance on how to perform operations on the FlinkServer job management page.

If your Kafka cluster is in security mode, the following example SQL statements can be used.

Prerequisites

- The HDFS, Yarn, Kafka, and Flink services have been installed in a cluster.
- The client that contains the Kafka service has been installed, for example, in the **/opt/client** directory.
- You have created a user assigned with the **FlinkServer Admin Privilege** (for example, **flink_admin**) for accessing the Flink web UI by referring to **Creating a FlinkServer Role**.

Creating a Job

Step 1 Log in to Manager as user **flink_admin** and choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link on the right of **Flink WebUI** to access the Flink web UI.

Step 2 Create a Flink SQL job by referring to **Creating a FlinkServer Job**. On the job development page, configure the job parameters as follows and start the job.

In **Basic Parameter**, select **Enable CheckPoint**, set **Time Interval(ms)** to **60000**, and retain the default value for **Mode**.

```
CREATE TABLE KafkaSource (
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_source',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);
CREATE TABLE KafkaSink(
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_sink',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port number',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',--This parameter is not required for clusters in normal mode. Delete the comma (,) in the previous line.
  'properties.security.protocol' = 'SASL_PLAINTEXT',--This parameter is not required for clusters in normal mode.
  'properties.kerberos.domain.name' = 'hadoop.System domain name'--This parameter is not required for clusters in normal mode.
);
Insert into
  KafkaSink
select
  *
from
  KafkaSource;
```

NOTE

- Kafka port
  - Value of **sasl.port** when **Authentication Mode** of the cluster is **Security Mode**, **21007** by default.
  - Value of **port** when **Authentication Mode** of the cluster is **Normal Mode**, **9092** by default. If the port number is set to **9092**, set **allow.everyone.if.no.acl.found** to **true**. The procedure is as follows:

    Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Kafka**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On the displayed page, search for **allow.everyone.if.no.acl.found**, set it to **true**, and click **Save**.
- *System domain name*: You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and check the value of **Local Domain**.
- You need to restart Flink jobs after expanding a Kafka Topic partition if you are using Flink 1.15.0 or an earlier version. Otherwise, new partitions may not be detected and consumption data may be missed. Alternatively, you can enable Kafka Topic partition detection in Flink.

  You can add the **scan.topic-partition-discovery.interval** parameter to the WITH property of the SQL Kafka source table and set the parameter to a dynamic refresh interval, for example, **5min**.

Step 3 On the job management page, check whether the job status is **Running**.

Step 4 Run the following command to check whether data is received in the sink table, that is, check whether data is properly written to the Kafka topic after **Step 5** is performed. For details, see **Managing Messages in Kafka Topics**.

sh kafka-console-consumer.sh --topic test_sink --bootstrap-server *Service IP address of the Kafka Broker instance*:*Kafka port* --**consumer.config /opt/client/Kafka/kafka/config/consumer.properties**

Step 5 View the topic and write data to the Kafka topic by referring to **Managing Messages in Kafka Topics**. After the data is written, view the execution result in the window in **Step 4**.

./kafka-topics.sh --list *--bootstrap-server* *Service IP address of the Kafka Broker instance*:*Kafka port* **--command-config** *Client directory*/**Kafka/kafka/config/client.properties**

sh kafka-console-producer.sh --broker-list *IP address of the node where Kafka instances reside*:*Kafka port number* **--topic** *Topic name* **--producer.config** *Client directory*/**Kafka/kafka/config/producer.properties**

For example, if the topic name is **test_source**, the script is **sh kafka-console-producer.sh --broker-list** *IP address of the node where Kafka instances are deployed*:*Kafka port* **--topic test_source** --**producer.config /opt/client/Kafka/kafka/config/producer.properties**.

Enter the message content.

```
1,clw,33
```

Press **Enter** to send the message.

----End

WITH Parameters

Parameter	Mandatory	Type	Description
connector	Yes	String	Connector to be used. **kafka** is used for Kafka.
topic	• Yes (Kafka functions as a sink table.) • No (Kafka functions as a source table.)	String	Topic name. • When the Kafka is used as a source table, this parameter indicates the name of the topic from which data is read. Topic list is supported. Topics are separated by semicolons (;), for example, **Topic-1; Topic-2**. • When Kafka is used as a sink table, this parameter indicates the name of the topic to which data is written. Topic list is not supported for sinks.
topic-pattern	No (Kafka functions as a source table.)	String	Topic pattern. This parameter is available when Kafka is used as a source table. The topic name must be a regular expression. **NOTE** **topic-pattern** and **topic** cannot be set at the same time.
properties.bootstrap.servers	Yes	String	List of Kafka brokers, which are separated by commas (,).
properties.group.id	Yes (Kafka functions as a source table.)	String	Kafka user group ID.
format	Yes	String	Format of the value used for deserializing and serializing Kafka messages.
properties.*	No	String	Authentication-related parameters that need to be added in security mode.
scan.topic-partition-discovery.interval	No	Duration	Interval at which the consumer dynamically discovers the created partition. Default value: **5 min**

6.6 Managing FlinkServer Jobs

6.6.1 Viewing the Health Status of FlinkServer Jobs

This topic is available for MRS 3.3.0 or later only.

Job Health Status

When a large number of Flink jobs are running in a cluster, the FlinkServer web UI provides the Flink job health management function to help you evaluate the health status of each job. You can view the health status of the current job on the page and export the health information of all jobs with just one click.

- **Healthy**: The job is healthy and running properly.
- **Subhealthy**:
  - The "ALM-45637 Flink Task Is Continuously Under Back Pressure" alarm is generated. After the alarm is cleared based on the alarm information, the health status automatically recovers to **Healthy**.
  - The "ALM-45639 Checkpointing of a Flink Job Times Out" alarm is generated. After the alarm is cleared based on the alarm information, the health status automatically recovers to **Healthy**.
- **Unhealthy**:
  - The "ALM-45636 Flink Job Checkpoints Keep Failing" alarm is generated. After the alarm is cleared based on the alarm information, the health status automatically recovers to **Healthy**.
  - The "ALM-45638 Number of Restarts After Flink Job Failures Exceeds the Threshold" alarm is generated. After the alarm is cleared based on the alarm information and the job is restarted. The health status automatically recovers to **Healthy**.

Prerequisites

- The cluster is running properly and the cluster client has been installed.
- The function of registering jobs with FlinkServer and the job alarming function have been enabled by configuring the *Client installation path*/**Flink/flink/conf/flink-conf.yaml** file before submitting a job. The parameter settings are as follows.

Table 6-27 Parameters for enabling job registration and job alarming

Parameter	Value	Description
job.register.enable	true	Whether to enable job registration with FlinkServer. Value options are as follows: • **true**: Enable • **false**: Disable

Parameter	Value	Description
job.alarm.enable	true	Whether to enable job alarming. Value options are as follows: • **true**: Enable • **false**: Disable

NOTE

If the function of registering jobs with FlinkServer is not enabled, you cannot start, develop, or stop jobs registered with FlinkServer through the client on the FlinkServer web UI.

- Ensure that the job is not submitted in session mode and the job name must be specified.

Viewing Job Health

Step 1 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Click **Job Management**. The job management page is displayed.

- Viewing job health

  On the **Job Management** page, view the health status of the current job.

  – Empty: The job is not running and has no health status.
  – Green icon: healthy
  – Yellow icon: subhealthy
  – Red icon: unhealthy

- Exporting all job health reports

  Click **Job Health Report**. The system automatically exports the health status information of all jobs to the local host, including the job name, health status, submission user, alarm information, configuration information, and start time.

  – If the health score is **0**, the job is healthy.
  – If the health score is **1**, the job is subhealthy.
  – If the health score is **2**, the job is unhealthy.

----End

6.6.2 Importing and Exporting FlinkServer Job Information

This topic is available for MRS 3.2.0 or later only.

Importing and Exporting Jobs

The FlinkServer web UI enables you only to import and export jobs, UDFs, andstream tables.

- Jobs, flow tables, and UDFs with the same name cannot be imported to the same cluster.

- When exporting a job, you need to manually select the stream tables and UDFs on which the job depends. Otherwise, a dialog box indicating that the dependent data is not selected will be displayed. The application information of a job will not be exported.
- When you export a stream table, the application information on which the stream table depends will not be exported.
- When you export UDFs, the application information on which the UDFs depend and information about jobs used by UDFs will not be exported.
- Data import and export between different applications. are supported.

NOTICE

When you import or export FlinkSQL jobs, the **password** field in the jobs will be left blank to meet security requirements. Before you submit jobs, manually enter the password.

Importing a Job

Step 1 Access the Flink web UI as a user with **FlinkServer Admin Privilege**. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Choose **System Management** > **Import Jobs**.

Step 3 Click **Select** to select a local TAR file and click **OK**. Wait until the file is imported.

NOTE

The maximum size of a local TAR file to be uploaded is 200 MB.

----End

Exporting a Job

Step 1 Access the Flink web UI as a user with **FlinkServer Admin Privilege**. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Choose **System Management** > **Export Jobs**.

Step 3 Select the data to be exported in either of the following ways. To deselect the content, click **Clear Selected Node**.

- Select the data to be exported as required.
- Click **Query Regular Expression**. On the displayed page, select the type of the data to be exported (**Table Management**, **Job Management**, or **UDF Management**), enter the keyword, and click **Query**. After the data is successfully matched, click **Synchronize**.

  NOTE

  All matched data will be synchronized after you click **Synchronize**. Currently, you cannot select some data for synchronization.

Step 4 Click **Verify**. After the verification is complete, click **OK**. Wait until the data is exported.

----End

6.6.3 Configuring Automatic Clearing of FlinkServer Job Residuals

Scenario

If a Flink task stops unexpectedly, some directories may reside in the ZooKeeper and HDFS services. To delete the residual directories, set **ClearUpEnabled** to **true**.

Procedure

Step 1 Log in to Manager.

Step 2 Choose **Cluster** > **Services** > **Flink**. On the displayed page, click the **Configurations** tab and then **All Configurations**, search for parameter **ClearUpEnabled**, and set it to **true**. For details about related parameters, see **Table 6-28**.

Table 6-28 Parameters for deleting the residual directories

Parameter	Description	Default Value	Value Range
ClearUpEnabled	Specifies whether to delete the residual directories. Set this parameter to **true** if residual directories need to be deleted; set it to **false** otherwise.	true	true and false
ClearUpPeriod	Specifies the period for deleting residual directories, in minutes.	1440	1440~2147483647
TrashDirectoryRetentionPeriod	Specifies the period for retaining residual directories, in minutes.	10080	10080~2147483647

Step 3 Click **Save**.

NOTICE

- This function deletes only the residual directories in the **/flink_base** directory of the ZooKeeper service and the **/flink/recovery** directory of the HDFS service. User-defined directories will not be deleted.
- This function does not delete the **checkpoints** directory of the HDFS service. You need to manually delete it.

----End

6.6.4 Configuring the FlinkServer Job Restart Policy

FlinkServer Job Restart Policies

Flink supports different restart policies to control whether and how to restart a job when a fault occurs. If no restart policy is specified, the cluster uses the default restart policy. You can also specify a restart policy when submitting a job. For details about how to configure such a policy on the job development page of MRS 3.1.0 or later, see **Creating a FlinkServer Job**.

The restart policy can be specified by configuring the **restart-strategy** parameter in the Flink configuration file *Client installation directory*/**Flink/flink/conf/flink-conf.yaml** or can be dynamically specified in the application code. The configuration takes effect globally. Restart policies include **failure-rate** and the following two default policies:

- **No restart**: If CheckPoint is not enabled, this policy is used by default.
- **Fixed-delay**: If CheckPoint is enabled but no restart policy is configured, this policy is used by default.

No restart Policy

When a fault occurs, the job fails and does not attempt to restart.

Configure the parameter as follows:

```
restart-strategy: none
```

fixed-delay Policy

When a fault occurs, the job attempts to restart for a fixed number of times. If the number of attempts exceeds the times you specified, the job fails. The restart policy waits for a fixed period of time between two consecutive restart attempts.

In the following example, a job fails if the job attempts to restart for three times at an interval of 10 seconds. Configure the parameters as follows:

```
restart-strategy: fixed-delay
restart-strategy.fixed-delay.attempts: 3
restart-strategy.fixed-delay.delay: 10 s
```

failure-rate Policy

When a job fails, the job restarts directly. If the failure rate exceeds the value you configured, the job is considered as failed. The restart policy waits for a fixed period of time between two consecutive restart attempts.

In the following example, a job is considered as failed if the job attempts to restart for three times at an interval of 10 minutes. Configure the parameters as follows:

```
restart-strategy: failure-rate
restart-strategy.failure-rate.max-failures-per-interval: 3
restart-strategy.failure-rate.failure-rate-interval: 10 min
restart-strategy.failure-rate.delay: 10 s
```

Selecting a Restart Policy

- If you do not want to retry a failed job, select the **No restart** policy.
- To retry a failed job, select the **failure-rate** policy. If the fixed-delay policy is used, the number of job failures may reach the maximum number of retries due to hardware faults such as network and memory faults. As a result, the job fails.

  To prevent repeated restarts when the failure-rate policy is used, configure parameters as follows:

  ```
  restart-strategy: failure-rate
  restart-strategy.failure-rate.max-failures-per-interval: 3
  restart-strategy.failure-rate.failure-rate-interval: 10 min
  restart-strategy.failure-rate.delay: 10 s
  ```

Creating a FlinkServer Job

The statements of a SQL job submitted on Flink Server are saved to the DBServer. In MRS 3.5.0 and later versions, Flink Server encrypts SQL storage by default to protect information. When "FlinkSQL" is displayed in the command output on the FlinkServer web UI, the **password** field in the SQL statement is left blank. Before you submit a job, enter the password. For a custom connector, the password field name must contain the keyword **password** to prevent the password being displayed on the page.

NOTE

Disabling SQL encryption storage may cause password leak. You are advised to retain the default setting. If you still need to disable the function, perform the following operations:

1. (Optional) Back up jobs and then delete all jobs. For details about how to back up and import jobs, see **Importing and Exporting FlinkServer Job Information**.
2. Change the value of **ENABLE_DB_ENCRYPT** to **false**.

   Log in to the active and standby FlinkServer nodes, set **ENABLE_DB_ENCRYPT** in the **$BIGDATA_HOME//FusionInsight_Flink_x.x.x/x_x_FlinkServer/etc/flinkserver_service.properties** file to **false**, save the file, and exit.
3. Restart the affected FlinkServer instance.

   On FusionInsight Manager, choose **Cluster** > **Services** > **Flink** > **Instances**, select all FlinkServer instances, click **More**, and select **Restart Instance** to restart the instances.

Step 1 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Click **Job Management**. The job management page is displayed.

Step 3 Click **Create Job**. Create a Flink SQL job or Flink Jar job, enter job information, and click **OK**. The job is created and the job development page is displayed.

Step 4 (Optional) To develop a job immediately, configure the job on the job development page.

The system allows you to add a lock to a job. The user who locks the job has all permissions of the job. Other users do not have the permissions to develop, start, or delete the locked job. However, they can forcibly acquire the lock to obtain all permissions. After this function is enabled, you can **Lock** and **Unlock** a job, or click **Acquire Lock** to obtain job permissions.

NOTE

Job locks are enabled by default. You can view the status of this function on FusionInsight Manager. This topic is available for MRS 3.3.0 or later only.

Log in to FusionInsight Manager, choose **Cluster** > **Service** > **Flink**, click **Configuration** and then **All Configurations**, and search for the **job.edit.lock.enable** parameter. If the parameter value is **true**, the function is enabled. If the parameter value is **false**, the function is disabled.

- Creating a Flink SQL job

  a. Develop the job on the job development page.

  Figure 6-12 FlinkServer job development page

  
  b. Click **Check Semantic** to check the input content and click **Format SQL** to format SQL statements.

  c. Set basic and customized parameters as required by referring to **Table 6-29** and click **Save**.

  Table 6-29 Basic parameters

Parameter	Description
Parallelism	Number of parallel jobs
Maximum Operator Parallelism	Maximum degree of parallelism of operators
JobManager Memory (MB)	Memory of JobManager The minimum value is **4096**.
Submit Queue	Queue to which a job is submitted. If this parameter is not set, the **default** queue is used.
taskManager	taskManager running parameters. ▪ **Slots**: The default value is **1**. You are advised to set this parameter to the number of CPU cores. ▪ **Memory (MB)**: The minimum value is **4096**.

Parameter	Description
Enable CheckPoint	Whether to enable CheckPoint. After CheckPoint is enabled, you need to configure the following information: ■ **Time Interval (ms)**: This parameter is mandatory. ■ **Mode**: This parameter is mandatory. The options are **EXACTLY_ONCE** and **AT_LEAST_ONCE**. ■ **Minimum Interval (ms)**: The minimum value is **10**. ■ **Timeout Duration**: The minimum value is **10**. ■ **Maximum Parallelism**: The value must be a positive integer containing a maximum of 64 characters. ■ **Whether to clean up**: This parameter can be set to **Yes** or **No**. ■ **Whether to enable incremental checkpoints**: This parameter can be set to **Yes** or **No**.
Failure Recovery Policy	Failure recovery policy of a job. The options are as follows. For details, see **Configuring the FlinkServer Job Restart Policy**. ■ **fixed-delay**: You need to configure **Retry Times** and **Retry Interval (s)**. ■ **failure-rate**: You need to configure **Max Retry Times**, **Interval (min)**, and **Retry Interval (s)**. ■ **none**

d. Click **Submit** in the upper left corner to submit the job.

- Creating a Flink JAR job

  a. Click **Select** to upload a local JAR file and set parameters by referring to **Table 6-30** or add customized parameters.

Table 6-30 Parameter configuration

Parameter	Description
Local .jar File	Upload a local JAR file. Upload a local file smaller than the threshold specified by **flinkserver.upload.jar.max.size**. The default value is **500 MB**. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Flink** > **Configurations** > **All Configurations**, search for **flinkserver.upload.jar.max.size**, and set the JAR file threshold. The value ranges from **100 MB** to **5,120 MB**.
Main Class	Main-Class type. ▪ **Default**: By default, the class name is specified based on the **Mainfest** file in the JAR file. ▪ **Specify**: Manually specify the class name.
Class Name	Class name. This parameter is available when **Main Class** is set to **Specify**.
Class Parameter	Class parameters of Main-Class (parameters are separated by spaces).
Parallelism	Number of parallel jobs Concurrent tasks of each job operator. Appropriately increasing the value will improve the overall computing performance of a job. Considering switchover overheads due to increasing threads, the maximum value is four times the number of SPUs used by the computing unit. One to two times the number of SPUs of the computing unit is the optimal.
JobManager Memory (MB)	Memory of JobManager. The minimum value is **4096**.
Submit Queue	Queue to which a job is submitted. If this parameter is not set, the **default** queue is used.
taskManager	taskManager running parameters. ▪ **Slots**: The default value is **1**. You are advised to set this parameter to the number of CPU cores. ▪ **Memory (MB)**: The minimum value is **4096**.

b. Click **Save** to save the configuration and click **Submit** to submit the job.

Step 5 Return to the job management page. You can view information about the created job, including job name, type, status, kind, and description.

After a job is created, you can start, develop, stop, edit, and delete the job, view job details, and rectify checkpoint faults in the **Operation** column of the job.

NOTE

- To read files related to the submitted job on the node as another user, ensure that the user and the user who submitted the job belong to the same user group and the user has been assigned the FlinkServer application management role. For example, **application view** is selected by referring to **Creating a FlinkServer Role**.
- You can view details about jobs in the **Running** state.
- You can rectify checkpoint faults for jobs in the **Running failed**, **Running succeeded**, or **Stop** state.
- To set whether the checkpoints of failed or canceled jobs can be retained, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flink**, click **Configurations** and then **All Configurations**, search for and set the **execution.checkpointing.externalized-checkpoint-retention** parameter of FlinkServer.
  - **DELETE_ON_CANCELLATION**: Only checkpoints of failed jobs will be retained.
  - **RETAIN_ON_CANCELLATION** (default value in MRS3.5.0 or later): Checkpoints of failed or canceled jobs will be retained.
  - **NO_EXTERNALIZED_CHECKPOINTS**(default for MRS versions earlier than 3.5.0): Checkpoints of failed or canceled jobs will not be saved.

----End

6.6.5 Adding Third-Party Dependency JAR Packages to a FlinkServer Job

This topic is available for MRS 3.3.0 or later only.

Flink allows you to run user-defined Flink jobs using third-party dependency packages. You can upload and manage dependency JAR packages on the Flink web UI and invoke required dependencies when running jobs. The dependency management function does not support semantic verification. A dependency JAR package name must start with a letter, digit, or underscore (_) and cannot exceed 32 characters. The following third-party dependencies are supported:

- Custom connector dependency: After a custom connector JAR package is uploaded, **Dependency Type** is **connector** on the Flink web UI.
- Non-custom connector dependency: After a non-custom connector JAR package, such as a job dependency package, is uploaded, **Dependency Type** is **normal** on the Flink web UI.

To use this function, you need to prepare the dependency files. If you upload dependencies to the cluster by specifying a path, you need to create an HDFS path and upload the JAR package to the HDFS.

Uploading Dependency Packages

Step 1 Log in to FusionInsight Manager and access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Click **Dependency Management**. The **Dependency Management** page is displayed.

Step 3 Click **Add Dependency**.

Table 6-31 Adding a dependency

Parameter	Description	Example
Customized connector or not	Whether the dependency is a custom connector. Set this parameter based on the site requirements. • **Yes**: The file is a custom connector dependency. • **No**: The file is a non-custom connector dependency.	Yes
Name	Name of the dependency, which must be the same as the connection name of connector in the uploaded dependency package. Dependency packages with the same name cannot be uploaded.	kafka
Register jar	Upload method of a JAR package: • **Upload File**: Upload a JAR package form the local host. • **Specify Path**: Upload a prepared dependency file from an HDFS path.	Uploading files
Upload File	If **Register jar** is set to **Upload File**, select a JAR file from the local host.	-
Specify Path	If **Register jar** is set to **Specify Path**, enter the HDFS path of the dependency file. (The JAR package must have been uploaded to the HDFS.)	/flink_upload_test/flink-connector-kafka-customization.jar
Description	Description of the dependency to be uploaded.	-

Step 4 Click **OK**

----End

Example

- Custom connector dependencies
  a. Upload a custom connector dependency by referring to **Uploading Dependency Packages**.
     For example, the dependency name is **kafka**, and the name of the custom connector JAR package is **flink-connector-kafka-customization.jar**.
  b. Create a SQL job by referring to **Creating a FlinkServer Job**. Set **connector** in the SQL statement to the dependency name, for example, **'connector'='kafka'**.

```
CREATE TABLE KafkaSinkTable (`user_id` INT, `name` VARCHAR) WITH (
  'connector' = 'kafka',
  'topic' = 'test_sink6',
  'properties.bootstrap.servers' = '192.168.20.134:21005',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'earliest-offset',
  'format' = 'csv'
);
CREATE TABLE datagen (`user_id` INT, `name` VARCHAR) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '5',
  'fields.user_id.kind' = 'sequence',
  'fields.user_id.start' = '1',
  'fields.user_id.end' = '1000'
);
insert INTO
  KafkaSinkTable
select
  *
from
  datagen;
```

- Non-Custom connector dependencies

  Upload a non-custom connector dependency for a job. For details, see **Uploading Dependency Packages**.

6.6.6 Using UDFs in FlinkServer Jobs

This section applies to MRS 3.1.2 or later clusters.

You can customize functions to extend SQL statements to meet personalized requirements. These functions are called user-defined functions (UDFs). You can upload and manage UDF JAR files on the Flink web UI and call UDFs when running jobs.

Flink supports the following three types of UDFs, as described in **Table 6-32**.

Table 6-32 Function classification

Type	Description
User-defined Scalar function (UDF)	Supports one or more input parameters and returns a single result value. For details, see **UDF Java and SQL Examples**.
User-defined aggregation function (UDAF)	Aggregates multiple records into one value. For details, see **UDAF Java and SQL Examples**.
User-defined table-valued function (UDTF)	Supports one or more input parameters and returns multiple rows or columns. For details, see **UDTF Java and SQL Examples**.

Uploading UDFs to FlinkServer

Step 1 Prepare a UDF JAR file that cannot exceed 200 MB.

Step 2 Access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 3 Click **UDF Management**. The **UDF Management** page is displayed.

Step 4 Click **Add UDF**. Select and upload the prepared UDF JAR file for **Local .jar File**.

Step 5 Enter the UDF name and description and click **OK**.

NOTE

- A maximum of 10 UDF names can be added. **Name** can be customized. **Class Name** must correspond to the UDF in the uploaded UDF JAR file.
- After the UDF JAR file is uploaded, the server retains the file for 5 minutes by default. If you click **OK** within 5 minutes, the UDF creation is complete. If you click **OK** after 5 minutes, the UDF creation fails and an error message is displayed, indicating that the local UDF file path is incorrect.

Step 6 In the UDF list, you can view information about all UDFs in the current application. You can edit or delete UDF information in the **Operation** column. (Only unused UDF items can be deleted.)

Step 7 (Optional) If you need to run or develop a job immediately, configure the job on the **Job Management** page. For details, see **Creating a FlinkServer Job**.

----End

UDF Java and SQL Examples

- UDF Java example

```
package com.xxx.udf;
import org.apache.flink.table.functions.ScalarFunction;
public class UdfClass_UDF extends ScalarFunction {
    public int eval(String s) {
        return s.length();
    }
}
```

- UDF SQL example

```
CREATE TEMPORARY FUNCTION udf as 'com.xxx.udf.UdfClass_UDF';
CREATE TABLE udfSource (a VARCHAR) WITH ('connector' = 'datagen','rows-per-second'='1');
CREATE TABLE udfSink (a VARCHAR,b int) WITH ('connector' = 'print');
INSERT INTO
  udfSink
SELECT
  a,
  udf(a)
FROM
  udfSource;
```

UDAF Java and SQL Examples

- UDAF Java example

```
package com.xxx.udf;
import org.apache.flink.table.functions.AggregateFunction;
public class UdfClass_UDAF {
    public static class AverageAccumulator  {
        public int sum;
    }
    public static class Average extends AggregateFunction<Integer, AverageAccumulator> {
        public void accumulate(AverageAccumulator acc, Integer value) {
            acc.sum += value;
        }
        @Override
        public Integer getValue(AverageAccumulator acc) {
            return acc.sum;
        }
        @Override
```

```
        public AverageAccumulator createAccumulator() {
            return new AverageAccumulator();
        }
    }
}
```

- UDAF SQL example

```
CREATE TEMPORARY FUNCTION udaf as 'com.xxx.udf.UdfClass_UDAF$Average';
CREATE TABLE udfSource (a int) WITH ('connector' = 'datagen','rows-per-
second'='1','fields.a.min'='1','fields.a.max'='3');
CREATE TABLE udfSink (b int,c int) WITH ('connector' = 'print');
INSERT INTO
  udfSink
SELECT
  a,
  udaf(a)
FROM
  udfSource group by a;
```

UDTF Java and SQL Examples

- UDTF Java example

```
package com.xxx.udf;
import org.apache.flink.api.java.tuple.Tuple2;
import org.apache.flink.table.functions.TableFunction;
public class UdfClass_UDTF extends TableFunction<Tuple2<String, Integer>> {
    public void eval(String str) {
        Tuple2<String, Integer> tuple2 = Tuple2.of(str, str.length());
        collect(tuple2);
    }
}
```

- UDTF SQL example

```
CREATE TEMPORARY FUNCTION udtf as 'com.xxx.udf.UdfClass_UDTF';
CREATE TABLE udfSource (a VARCHAR) WITH ('connector' = 'datagen','rows-per-second'='1');
CREATE TABLE udfSink (b VARCHAR,c int) WITH ('connector' = 'print');
INSERT INTO
  udfSink
SELECT
  str,
  strLength
FROM
  udfSource,lateral table(udtf(udfSource.a)) as T(str,strLength);
```

Introduction to Flink UDF Reuse

This topic is available for MRS 3.3.0 or later only.

The UDF reuse function is added to Flink SQL. When a UDF is executed for multiple times, only the first result is copied for the Nth (N > 1) execution. This ensures data consistency between multiple UDF executions and ensures that the UDF is executed only once, improving operator performance.

When configuring a Flink job, you can set **table.optimizer.function-reuse-enabled** to **true** on the Flink job development page of the Flink server web UI to enable the UDF reuse function. For details, see **Creating a FlinkServer Job**.

The following is a reuse example:

- UDF

```
class ItemExist extends ScalarFunction {
  val items: mutable.Set[String] = mutable.Set[String]()

  def eval(item: String): Boolean = {
    val exist = items.contains(item);
```

```
    if (!exist) {
      items.add(item)
    }
    exist
  }
}
```

- SQL statement

  SELECT * FROM (SELECT `a`, IfExist(b) as `exist`, `c` FROM Table1) WHERE exist IS FALSE;

- Result
  - Return value when the UDF reuse function is disabled:

    ```
    a,true,c
    ```

    Because IfExist is executed once in the WHERE condition and the result is **false**, the data has been stored in the cache. When IfExist is executed again in SELECT, **true** is returned.
  - Return value when the UDF reuse function is enabled:

    ```
    a,false,c
    ```

6.6.7 Configuring the FlinkServer UDF Sandbox

You can upload third-party JAR packages, such as UDFs and dependencies, on the Flink web UI based on job requirements, and invoke dependencies when verifying and running SQL jobs. To ensure that the uploaded JAR file is secure, the sandbox function is enabled for Flink by default. You can set the sandbox permission by setting the **flinkserver.security.policy** parameter by referring to **Configuring Permission of a Specified JAR Package** and disable the sandbox by setting the **security.manager.enabled** parameter by referring to **Disabling the FlinkServer Sandbox**.

Permissions

A permission consists of the type (mandatory), name, and allowed operation.

- Default permission
  - Property read permission: **permission java.util.PropertyPermission "*", "read"**
  - Socket permission, allowing **connect** and **resolve** to all ports: **permission java.net.SocketPermission "*", "connect,resolve"**
- Standard permission

Table 6-33 File permission

Type	Name	Allowed Operation	Example
java.io.FilePermission	• Name of a specified file • -: all files in the directory and subdirectories • *: all files in the directory	• read • write • delete • execute	• The following permission allows all files to be read, written, deleted, and executed: **permission java.io.FilePermission "<< ALL FILES>>", "read,write,delete,execute";** • The following permission allows the read of the user's home directory: **permission java.io.FilePermission "${user.home}/-", "read";**

Table 6-34 Socket permission

Type	Name	Allowed Operation	Examples
java.net.SocketPermission	• *Hostname*:*Port* • *: all addresses and ports	• accept • listen • connect • resolve	• The following permission allows all socket operations: **permission java.net.SocketPermission ":1-", "accept,listen,connect,resolve";** • The following permission allows the establishment of connections to and resolution of specific websites: **permission java.net.SocketPermission ".abc.com:1-", "connect,resolve";**

Table 6-35 Property permission

Type	Name	Allowed Operation	Examples
java.util.PropertyPermission	JVM property name to be accessed	• read • write	The following permission allows standard read of Java properties: **permission java.util.PropertyPermission "java.", "read";**

Table 6-36 Runtime permission

Type	Name
java.lang.RuntimePermission	• **accessDeclaredMembers**: allows code to use reflection to access private or protected members in other classes. • **createClassLoader**: allows code to create a class loader instance. • **createSecurityManager**: allows code to create a security manager instance, which will allow programmatic implementations to control the sandbox. This is a high-risk operation. With this permission, the UDF can modify or disable the **SecurityManager** of a service. • **exitVM**: allows the code to shut down the entire VM. • **getClassLoader**: allows code to access the class loader to obtain a specific class. • **setContextClassLoader**: allows code to set the context class loader for a thread. • **setFactory**: allows code to create a socket factory. • **setIO**: allows code to redirect **System.in** and **System.out** or **System.err** input and output streams. • **setSecurityManager**: allows code to set the security manager. • **stopThread**: allows code to invoke the **stop()** method of the thread class.

Table 6-37 Security permission

Type	Name
java.security.SecurityPermission	• **createAccessControlContext**: allows you to create a context environment for an access controller. • **getPolicy**: allows the search of classes that can implement sandbox policies. • **setPolicy**: allows you to set a class that can implement the sandbox policy. This is a high-risk operation. With this permission, the UDF can modify the policy of a service.

Table 6-38 Reflection permission

Type	Name
java.lang.reflect.ReflectPermission	**suppressAccessChecks**: allows reflection to be used to check private variables of any class.

Table 6-39 All permission

Type	Name
java.security.AllPermission	None (permission to perform any operation)

NOTE

If a third-party JAR dependency is used and the following error message is displayed, the sandbox permission is required:

```
Caused by: java.security.AccessControlException: access denied ("java.io.FilePermission" "xxxx" "read")
at java.security.AccessControlContext.checkPermission(AccessControlContext.java:472)
at java.security.AccessController.checkPermission(AccessController.java:886)
at java.lang.SecurityManager.checkPermission(SecurityManager.java:549)
at java.lang.SecurityManager.checkRead(SecurityManager.java:888)
at java.io.File.exists(File.java:825)  at com.xxx.ExpireUDF.(ExpireUDF.java:19)
```

Configuring Permission of a Specified JAR Package

Step 1 Log in to FusionInsight Manager and access the Flink web UI. For details, see **Accessing the FlinkServer Web UI**.

Step 2 Check the storage path of the JAR package.

- Record the UDF storage path.

  Click **UDF Management**. In the UDF list, view and record the storage path.

- Record the storage path of the third-party dependency.

  Click **Dependency Management**. In the dependency list, view and record the storage path.

Step 3 Configure permission for the specified dependency.

Return to FusionInsight Manager, choose **Cluster** > **Services** > **Flink** > **Configurations** > **All Configurations** > **FlinkServer (Role)** > **Customization**, set **flinkserver.security.policy** as follows, and save the settings:

- Name: Enter the storage path recorded in **Step 2**. If you need to add more paths, click the plus sign (+).
- Value: permission value, which ends with a semicolon (;). For example, **permission java.util.PropertyPermission "*", "read";permission java.net.SocketPermission "*", "connect,resolve"**. For details, see **Permissions**.

Step 4 Restart the FlinkServer instance.

Click **Instances**, select all FlinkServer instances, choose **More** > **Restart Instance**, and operate as prompted.

----End

Disabling the FlinkServer Sandbox

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **Flink** > **Configurations** > **All Configurations**.

Step 3 Search for the **security.manager.enabled** parameter and set its value to **false**.

Step 4 Click **Save**.

Step 5 Click **Instances**, select all FlinkServer instances, choose **More** > **Restart Instance**, and operate as prompted.

----End

6.7 Enterprise-Class Enhancements of Flink

6.7.1 Flink SQL Syntax Enhancement

This topic is available for MRS 3.3.0 or later only.

FlinkSQL DISTRIBUTEBY

The DISTRIBUTEBY feature is added to Flink SQL to partition data based on specified fields. A single or multiple fields are supported, solving the problem where only data needs to be partitioned. The following are some examples:

```
SELECT /*+ DISTRIBUTEBY('id') */ id, name FROM t1;
SELECT /*+ DISTRIBUTEBY('id', 'name') */ id, name FROM t1;
SELECT /*+ DISTRIBUTEBY('id1') */ id as id1, name FROM t1;
```

Processing Late Data in Flink SQL Window Functions

Window functions are added to Flink SQL to support late data processing. Currently, late data is supported in the TUMBLE, HOP, OVER, and CUMULATE window functions. The following is an example:

```
CREATE TABLE T1 (
 `int` INT,
 `double` DOUBLE,
 `float` FLOAT,
 `bigdec` DECIMAL(10, 2),
 `string` STRING,
 `name` STRING,
 `rowtime` TIMESTAMP(3),
 WATERMARK for `rowtime` AS `rowtime` - INTERVAL '1' SECOND
) WITH (
 'connector' = 'values',
);

-- The fields of the sink must be the same as the input data of the window, but the sequence can be
different.
CREATE TABLE LD_SINK(
 `float` FLOAT, `string` STRING, `name` STRING,  `rowtime` TIMESTAMP(3)
) WITH (
 'connector' = 'print',
);

SELECT  /*+ LATE_DATA_SINK('sink.name'='LD_SINK') */
  `name`,
  MIN(`float`),
  COUNT(DISTINCT `string`)
FROM TABLE(
  TUMBLE(TABLE T1, DESCRIPTOR(rowtime), INTERVAL '5' SECOND))
GROUP BY `name`, window_start, window_end
```

This feature also supports the output of the start time and end time of the current window when the window receives late data. The time can be output by adding **window.start.field** and **window.end.field** to the hint. The field type must be **timestamp**. The following is an example:

```
CREATE TABLE LD_SINK(
 `float` FLOAT, `string` STRING, `name` STRING,  `rowtime` TIMESTAMP(3), `windowStart` TIMESTAMP(3),
`windowEnd` TIMESTAMP(3)
) WITH (
 'connector' = 'print',
);

SELECT  /*+ LATE_DATA_SINK('sink.name'='LD_SINK', 'window.start.field'='windowStart',
'window.end.field'='windowEnd') */
  `name`,
  MIN(`float`),
  COUNT(DISTINCT `string`)
FROM TABLE(
  TUMBLE(TABLE T1, DESCRIPTOR(rowtime), INTERVAL '5' SECOND))
GROUP BY `name`, window_start, window_end
```

Setting Source Parallelism

This topic is available for MRS 3.3.0 or later only.

Flink SQL allows you to use the **source.parallelism** parameter to set the number of concurrent source operators to deal with data skew and back pressure and improve job performance.

This feature changes the Forward partition of source and downstream operators to the Rebalance partition. When the number of concurrent source operators is

different from the number of concurrent downstream operators (**parallelisms**) and data disorder is not allowed, enable the **DISTRIBUTEBY** feature together with this feature. For details, see **Flink SQL Syntax Enhancement**.

The following example sets the number of concurrent source operators to 2 and enables the **DISTRIBUTEBY** feature:

```
CREATE TABLE KafkaSource (
`user_id` VARCHAR,
`user_name` VARCHAR,
 `age` INT
 ) WITH (
 'connector' = 'kafka',
 'topic' = 'test_source',
 'properties.bootstrap.servers' = 'Service IP address of the Kafka broker instance:Kafka port',
 'properties.group.id' = 'testGroup',
 'scan.startup.mode' = 'latest-offset',
 'format' = 'csv',
 'properties.sasl.kerberos.service.name' = 'kafka',
 'properties.security.protocol' = 'SASL_PLAINTEXT',
  'properties.kerberos.domain.name' = 'hadoop.System domain name',
 -- Set the number of concurrent source operators.
 'source.parallelism' = '2'
 );
CREATE TABLE KafkaSink(
  `user_id` VARCHAR,
  `user_name` VARCHAR,
 `age` INT
 ) WITH (
  'connector' = 'kafka',
  'topic' = 'test_sink',
  'properties.bootstrap.servers' = 'Service IP address of the Kafka broker instance:Kafka port',
  'value.format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',
   'properties.security.protocol' = 'SASL_PLAINTEXT',
   'properties.kerberos.domain.name' = 'hadoop.System domain name'
 );
--  Insert into KafkaSink select user_id, user_name, age from KafkaSource (DISTRIBUTEBY disabled)
-- Enable DISTRIBUTEBY.
Insert into KafkaSink select/*+ DISTRIBUTEBY('user_id') */ user_id, user_name, age from KafkaSource;
```

6.7.2 Table-Level TTL for Stream Joins

This topic is available for MRS 3.3.0 or later only.

When you join two Flink streams, there is a possibility that data in one table changes rapidly (short TTL) and data in the other table changes slowly (long TTL). Currently, Flink supports only table-level TTL. To ensure join accuracy, you need to set the table-level TTL to a long time. In this case, a large amount of expired data is stored in state backends, causing great workload pressure. To reduce the pressure, you can use Hints to set different expiration time for left and right tables. The WHERE clause is not supported.

For example, set the TTL of the left table (**state.ttl.left**) to 60 seconds and that of the right table (**state.ttl.right**) to 120 seconds.

- Use Hints in the following format:
  ```
  /*+ OPTIONS('state.ttl.left'='60S', 'state.ttl.right'='120S') */
  ```
- The following is a configuration example with a SQL statement:
  - Example 1:
    ```
    CREATE TABLE user_info (`user_id` VARCHAR, `user_name` VARCHAR) WITH (
     'connector' = 'kafka',
     'topic' = 'user_info_001',
    ```

```
  'properties.bootstrap.servers' = '192.168.64.138:21005',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv'
);
CREATE table print(
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `score` INT
) WITH ('connector' = 'print');
CREATE TABLE user_score (user_id VARCHAR, score INT) WITH (
  'connector' = 'kafka',
  'topic' = 'user_score_001',
  'properties.bootstrap.servers' = '192.168.64.138:21005',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv'
);
INSERT INTO
  print
SELECT
  t.user_id,
  t.user_name,
  d.score
FROM
  user_info as t
  JOIN
  --  Set different TTLs for left and right tables.
  /*+ OPTIONS('state.ttl.left'='60S', 'state.ttl.right'='120S') */
  user_score as d ON t.user_id = d.user_id;
```

- Example 2

```
INSERT INTO
  print
SELECT
  t1.user_id,
  t1.user_name,
  t3.score
FROM
  t1
  JOIN
  --  Set different TTLs for left and right tables.
  /*+ OPTIONS('state.ttl.left' = '60S', 'state.ttl.right' = '120S') */
  (
    select
      UPPER(t2.user_id) as user_id,
      t2.score
    from
      t2
  ) as t3 ON t1.user_id = t3.user_id;
```

6.7.3 Configuring Flink SQL Client to Support SQL Verification

This topic is available for MRS 3.3.0 or later only.

Configuration Method

You can verify SQL syntax during SQL job development on the SQL Client. Running SQL commands in verification mode does not start Flink jobs.

- Verifying SQL statements
  - When you run the SQL shell command, add **-v** or **--validate** to enter the verification mode.

    sql-client.sh -v

  - When you run the SQL shell command, you can run SET to enter or exit the verification mode.
    - Enter the verification mode: **SET table.validate = true;**
    - Exit the verification mode: **SET table.validate = false;**
- Verifying SQL scripts

  When you use the **-f** parameter to specify a SQL script, add **-v** to enter the verification mode.

  sql-client.sh -f *test.sql* **-v**

Submitting a Job Using the Flink SQL Client

Step 1 Install the cluster client, for example, in **/opt/hadoopclient**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/hadoopclient

Step 4 Run the following command to initialize environment variables:

source /opt/hadoopclient/bigdata_env

Step 5 Log in to the Flink SQL client and submit a job.

1. Start a yarn-session by referring to **Using the Flink Client** and record the yarn-session ID (**yid**).

   yarn-session.sh -nm "*session-name***"**
2. Run the following command to access the Flink SQL Client:

   cd /opt/hadoopclient/Flink/flink/bin

   ./sql-client.sh

Figure 6-13 Accessing the Flink SQL Client

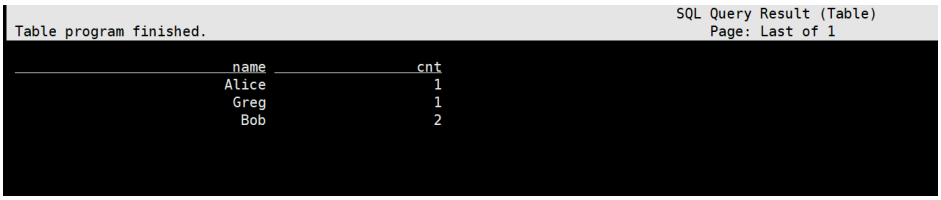
3. Set **high-availability.cluster-id** to the yarn-session ID.

   SET high-availability.cluster-id=*yarn-session ID***;**

4. Run the following SQL statement. If the execution is successful, the following information is displayed on the console.

   SELECT name, COUNT(*) AS cnt FROM (VALUES ('Bob'), ('Alice'), ('Greg'), ('Bob')) AS NameTable(name) GROUP BY name;

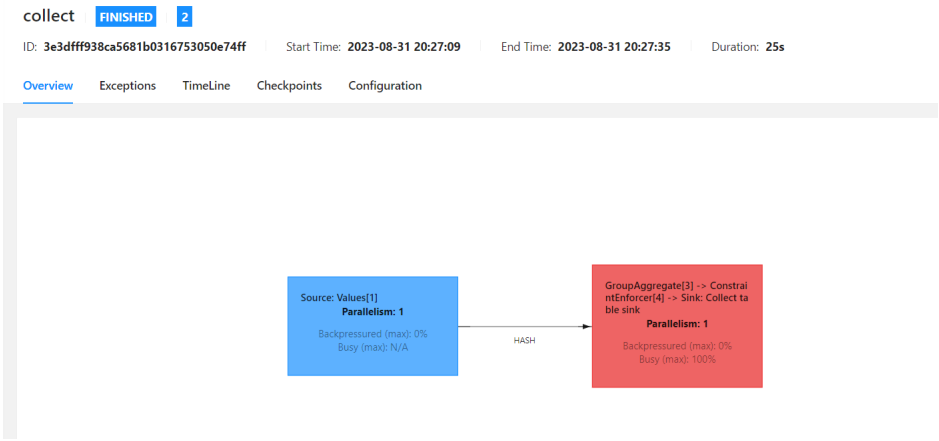
Figure 6-14 Execute result



5. View the executed job on Yarn.

   Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Yarn** > **Dashboard**, and click the link next to **ResourceManager WebUI** to go to the Yarn web UI and view the job.

Figure 6-15 Job



----End

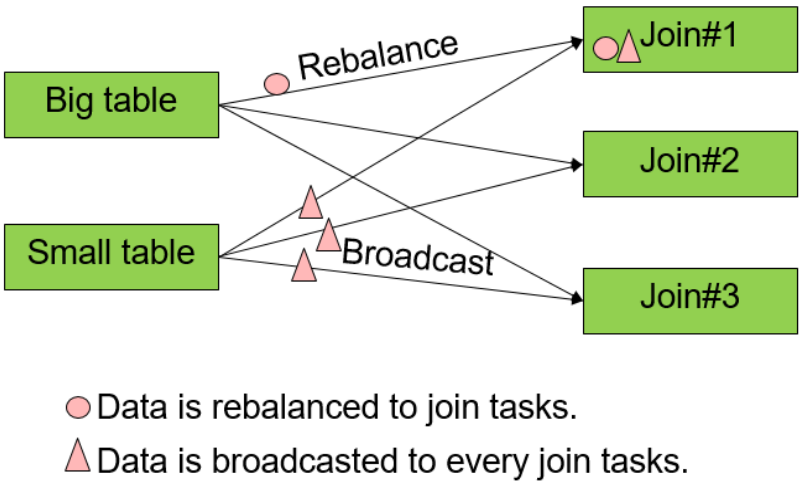
6.7.4 Enhancing the Joins of Large and Small Tables in Flink Jobs

This topic is available for MRS 3.3.0 or later only.

Joining Big and Small Tables

There are big tables and small tables when you join two Flink streams. Small table data is broadcasted to every join task, and large table data is rebalanced (distribute the data in a round robin fashion) to join tasks. This way, Flink SQL usability and job stability are improved.

Figure 6-16 Joining big and small tables



You can use Flink SQL Hints to specify the left or right table in a join as the broadcasted table and the other table as the rebalanced table. In the following SQL statement examples, table A and table C are small tables:

- Use table A as the broadcasted table.
  - Join
    ```
    SELECT /*+ BROADCAST(A) */ a2, b2 FROM A JOIN B ON a1 = b1
    ```
  - Where
    ```
    SELECT /*+ BROADCAST(A) */ a2, b2 FROM A, B WHERE a1 = b1
    ```
- Use table A and table C as broadcasted tables.
  ```
  SELECT /*+ BROADCAST(A, C) */ a2, b2, c2 FROM A JOIN B ON a1 = b1 JOIN C ON a1 = c1
  ```

NOTE

- This feature can be used with **/*+ BROADCAST(smallTable1, smallTable2) */** to be compatible with the open-source joins of two streams.
- Switching between open-source joins and this feature is not supported because this feature broadcasts data to each join task.
- Using a small table as the left table of a LEFTJOIN is not supported. Using a small table as the right table of a RIGHTJOIN is not supported.

Deduplicating Data When Joining Big and Small Tables

When you join two streams, there is a possibility that the join operator receives a large amount of duplicate data sent by one stream. Downstream operators need to process a large amount of duplicate data, affecting job performance.

For example, join fields (P1, A1, and A2) in table A with fields (P1, B1, B2, and B3) in table B to generate field C. A large amount of data in table B is updated but the fields are remain unchanged. Assume that only the B1 and B2 fields are used in the join and only the B3 field is updated. When you update table B, B1 and B2 fields should be ignored with the deduplication function.

```
select  A.A1,B.B1,B.B2 from A join B on A.P1=B.P1
```

To deduplicate table B updates, you can use Hints to set deduplication for the left table (duplicate.left) or right table (duplicate.right).

- Format
  - Set deduplication for the left table.
    ```
    /*+ OPTIONS('duplicate.left'='true')*/
    ```
  - Set deduplication for the right table.
    ```
    /*+ OPTIONS('duplicate.right'='true')*/
    ```
  - Set deduplication for both tables.
    ```
    /*+ OPTIONS('duplicate.left'='true','duplicate.right'='true')*/
    ```
- The following is an example in a SQL statement:

  For example, set deduplication for both the left table **user_info** and the right table **user_score**.

  ```
  CREATE TABLE user_info (`user_id` VARCHAR, `user_name` VARCHAR) WITH (
    'connector' = 'kafka',
    'topic' = 'user_info_001',
    'properties.bootstrap.servers' = '192.168.64.138:21005',
    'properties.group.id' = 'testGroup',
    'scan.startup.mode' = 'latest-offset',
    'value.format' = 'csv'
  );
  CREATE table print(
    `user_id` VARCHAR,
    `user_name` VARCHAR,
    `score` INT
  ) WITH ('connector' = 'print');
  CREATE TABLE user_score (user_id VARCHAR, score INT) WITH (
  ```

```
  'connector' = 'kafka',
  'topic' = 'user_score_001',
  'properties.bootstrap.servers' = '192.168.64.138:21005',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'value.format' = 'csv'
);
INSERT INTO
  print
SELECT
  t.user_id,
  t.user_name,
  d.score
FROM
  user_info as t
  JOIN
  -- Set deduplication for both left and right tables.
  user_score /*+ OPTIONS('duplicate.left'='true','duplicate.right'='true')*/ as d ON t.user_id =
d.user_id;
```

6.7.5 Exiting FlinkSQL OVER Window Upon Expiration

This topic is available for MRS 3.5.0 or later only.

The function of exiting the Flink SQL OVER window upon data expiration is added. When the existing data expires and no new data arrives, OVER aggregation results are updated and the latest calculation results are sent to the downstream operator. You can use this function by configuring the parameters as follows:

Table 6-40 Parameters for enabling the function of exiting the Flink SQL OVER window upon data expiration

Parameter	Default Value	Description
over.window.interval	-1	The interval between two pieces of adjacent data, in milliseconds. If the interval is exceeded, the OVER window registers the expiration trigger. Value options are as follows: ● **-1**: This function is disabled. ● **0**: An expiration trigger is registered for each piece of data, but the pressure on the job is increased. You can increase the value of **over.window.interval** based on the job requirements. ● Positive number: The interval between two pieces of adjacent data. If the interval is exceeded, the OVER window registers the expiration trigger.

Parameter	Default Value	Description
over.window.interval.last.rowdata	false	Whether to send only the last piece of data to the downstream operator. Value options are as follows: • **false** (default): All data that has not expired is sent. • **true**: Only the last piece of data is sent.

How to Use

When configuring a Flink job, you can add the custom parameter **over.window.interval** on the job development page of the FlinkServer web UI and set its value greater than or equal to 0 to enable the window to support the data expiration function. For details about how to create a job, see **Creating a FlinkServer Job**. This setting takes effect for all OVER windows in a job. You are advised to use this function for jobs with a single OVER window.

- Example SQL statement

```
CREATE TABLE OverSource (
  `rowtime` TIMESTAMP_LTZ(3),
  `groupId` INT,
  `value` INT,
  `name` STRING,
  `additional_field` STRING,
  `proctime` as PROCTIME(),
  WATERMARK FOR rowtime AS rowtime
) WITH (
 'connector' = 'kafka',
 'topic' = 'test_source',
 'properties.bootstrap.servers' = 'Service IP address of the Kafka broker instance:Kafka port',
 'properties.group.id' = 'testGroup',
 'scan.startup.mode' = 'latest-offset',
 'format' = 'csv',
 'properties.sasl.kerberos.service.name' = 'kafka',  --Delete this parameter if the cluster where FlinkServer is deployed is in normal mode.
 'properties.security.protocol' = 'SASL_PLAINTEXT',  --Delete this parameter if the cluster where FlinkServer is deployed is in normal mode.
 'properties.kerberos.domain.name' = 'hadoop.System domain name'  --Delete this parameter if the cluster where FlinkServer is deployed is in normal mode.
);

CREATE TABLE LD_SINK(
 `name` STRING, `groupId` INT, `rowtime` TIMESTAMP_LTZ(3),`count_zw` BIGINT,`sum_zw` BIGINT
) WITH (
 'connector' = 'print'
);

SELECT
  `name`,
  `groupId`,
  COUNT(`value`) OVER (
    PARTITION BY groupId
    ORDER BY
      proctime RANGE BETWEEN INTERVAL '10' second PRECEDING
      AND CURRENT ROW
  ) as count_zw,
  SUM(`value`) OVER (
    PARTITION BY groupId
    ORDER BY
```

```
    proctime RANGE BETWEEN INTERVAL '10' second PRECEDING
    AND CURRENT ROW
  ) as sum_zw
FROM
  OverSource
```

- SQL statement output

  For example, with **proctime** is **10:00:00**, **groupid** is **1**, and **value** is 1 to 5, five consecutive data records are imported to Flink.

  ```
  ["zw", 1, 1, 1]
  ["zw", 1, 2, 3]
  ["zw", 1, 3, 6]
  ["zw", 1, 4, 10]
  ["zw", 1, 5, 15]
  ```

  After 10:00:10, no data is imported and the window starts to exit.

  ```
  ["zw", 1, 4, 14]
  ["zw", 1, 3, 12]
  ["zw", 1, 2, 9]
  ["zw", 1, 1, 5]
  ["zw", 1, 0, 0]
  ```

6.7.6 Limiting Read Rate for Flink SQL Kafka and Upsert-Kafka Connector

This section applies to MRS 3.3.0 or later.

Scenarios

Traffic limiting is required when Kafka and upsert-kafka connector consume data.

How to Use

Add the **subtask.scan.records-per-second.limit** parameter to the created source stream table. This parameter indicates the number of Kafka records consumed in a single partition per second. The overall traffic on the source end is **min(source parallelism * subtask.scan.records-per-second.limit, kafka partitions num * subtask.scan.records-per-second.limit)**.

The following is a SQL example:

```
CREATE TABLE KafkaSource (
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_source',
  'properties.bootstrap.servers' = '<i>IP address of the Kafka broker instance</i>:<i>Kafka port</i>',
  'properties.group.id' = '<i>testGroup</i>',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'csv',
  <b>'subtask.scan.records-per-second.limit' = '1000',</b>
  'properties.sasl.kerberos.service.name' = 'kafka',
  'properties.security.protocol' = 'SASL_PLAINTEXT',
  'properties.kerberos.domain.name' = 'hadoop.<i>System domain name</i>'
);
CREATE TABLE KafkaSink(
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
```

```
  'connector' = 'kafka',
  'topic' = 'test_sink',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'csv',
  'properties.sasl.kerberos.service.name' = 'kafka',
  'properties.security.protocol' = 'SASL_PLAINTEXT',
  'properties.kerberos.domain.name' = 'hadoop.System domain name'
);
Insert into
  KafkaSink
select
  *
from
  KafkaSource;
```

6.7.7 Consuming Data in drs-json Format with FlinkSQL Kafka Connector

This section applies to MRS 3.3.0 or later.

Scenarios

FlinkSQL needs to consume data in drs-json format (a CDC message format) in Kafka.

How to Use

In the created Kafka Connector Source stream table, set **format** to **drs-json**.

The following is a SQL example:

```
CREATE TABLE KafkaSource (
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
  'connector' = 'kafka',
  'topic' = 'test_source',
  'properties.bootstrap.servers' = 'IP address of the Kafka broker instance:Kafka port',
  'properties.group.id' = 'testGroup',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'drs-json',
  'properties.sasl.kerberos.service.name' = 'kafka',
  'properties.security.protocol' = 'SASL_PLAINTEXT',
  'properties.kerberos.domain.name' = 'hadoop.System domain name'
);
CREATE TABLE printSink(
  `user_id` VARCHAR,
  `user_name` VARCHAR,
  `age` INT
) WITH (
  'connector' = 'print'
);
Insert into
  printSink
select
  *
from
  KafkaSource;
```

6.7.8 Using ignoreDelete in JDBC Data Writes

This section applies to MRS 3.3.0 or later.

Scenarios

Data in DELETE and UPDATE_BEFORE states can be filtered out when FlinkSQL writes JDBC data.

How to Use

Add **filter.record.enabled** and **filter.row-kinds** parameters to a created JDBC Connector Sink stream table.

NOTE

- The default value of **filter.record.enabled** is **false**.
- The default value of **filter.row-kinds** is **UPDATE_BEFORE, DELETE**.

The following is a SQL example:

```
CREATE TABLE user_score (
  idx varchar(20),
  user_id varchar(20),
  score bigint
) WITH (
  'connector' = 'kafka',
  'topic' = 'topic-qk',
  'properties.bootstrap.servers' = 'xxxx:21005',
  'properties.group.id' = 'test_qk',
  'scan.startup.mode' = 'latest-offset',
  'format' = 'csv'
);
CREATE TABLE mysql_output (
  idx varchar(20),
  user_id varchar(20),
  all_score bigint,
  PRIMARY KEY(idx, user_id) NOT ENFORCED
) WITH(
  'connector' = 'jdbc',
  'url' = 'jdbc:mysql://IP address of the MySQL server.MySQL server port/mysql',
  'table-name' = 'customer_t1',
  'username' = 'username', --Username for connecting the MySQL database
  'password' = 'password',--Password for connecting the MySQL database
  'filter.record.enabled' = 'true',
  'filter.row-kinds' = 'UPDATE_BEFORE'
);
insert into
  mysql_output
select
  idx,
  user_id,
  sum(score) as all_score
from
  user_score
group by
  idx,
  user_id;
```

6.7.9 Join-To-Live

Flink dual-stream join needs to store data in the state backend. Currently, RocksDB is widely used as the state backend. In scenarios where the time to live (TTL) is too long, the TTL cannot be determined, or the data traffic increases, heavy traffic increases the state data and storage pressure. As a result, job stability decreases, or TTL expiration may cause inaccurate joins.

For services whose number of joins are determined, the Join-To-Live (JTL) feature can be used to reduce the pressure on state backends. This feature determines

whether data expires based on the number of joins. It can be configured in either of the following ways:

NOTE

- This function is available for the inner join statement of Flink regular joins only.
- This function cannot be used together with job-level TTLs, table-level TTLs, or small table broadcasting.
- A primary key must be specified for a table that has a specified JTL. Otherwise, the query result may be inaccurate.

- Method 1: Using through SQL hints

  eliminate-state.left.threshold: indicates the threshold of the number of associations on the left. If the number of associations on the left exceeds the threshold, the piece of data expires.

  eliminate-state.right.threshold: indicates the threshold of the number of associations on the right. If the number of associations on the right exceeds the threshold, the piece of data expires.

  Example 1:

  ```
  SELECT * FROM t1
    JOIN /*+ OPTIONS('eliminate-state.right.threshold'='1', 'eliminate-state.left.threshold'='2') */
    t2 ON a1 = a2
  ```

  Example 2:

  ```
  SELECT a1, a2, a3 from
    t1
    join /*+ OPTIONS('eliminate-state.left.threshold'='1', 'eliminate-state.right.threshold'='2') */
    t2
    on a1 = a2
    join /*+ OPTIONS('eliminate-state.left.threshold'='3', 'eliminate-state.right.threshold'='4') */
    t3
    on a2 = a3
  ```

- Method 2: Configuring the two parameters in *Client installation path*/**Flink/flink/conf/flink-conf.yaml** for globally effective

  ```
  table.exec.join.eliminate-state.left.threshold
  table.exec.join.eliminate-state.right.threshold
  ```

6.7.10 Row Filter

This section applies to MRS 3.3.1 or later.

Scenarios

When using Flink SQL, you can set search criteria of rows to authorize a user to access specified rows and hide other rows from them.

Prerequisites

- Kerberos authentication is enabled for the cluster (the cluster is in security mode). Ranger, Hive, Flink have been installed and are running properly.
- The user, user group, or role with required permissions have been created, and the user has been added to the **hive** group.
- This feature can be used only on the FlinkServer platform.
- The default dialect is required for Flink SQL.
- The case of the filter criteria fields must be the same as that of the Flink SQL fields.

- This feature is not available for Hive view tables.

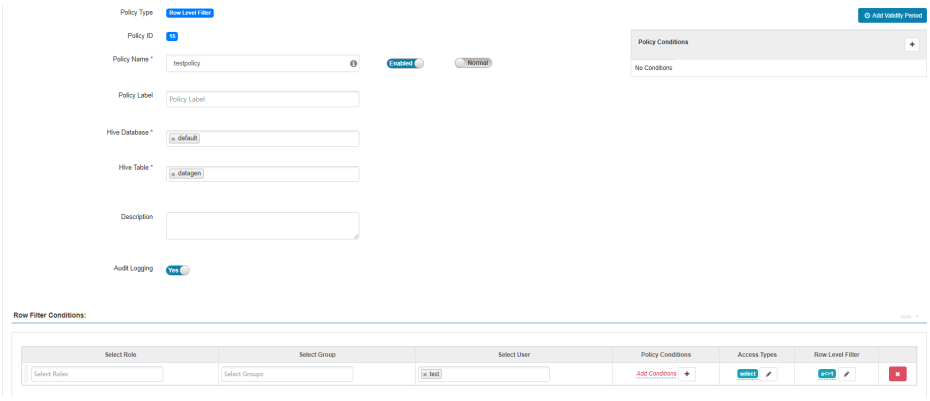
Configuring Flink SQL Row Filtering

Step 1 Configuring custom FlinkServer parameters.

1. Log in to FusionInsight Manager.
2. Choose **Cluster** > **Services** > **Flink** > **Configurations** > **All Configurations** > **FlinkServer(Role)** > **Customization** , and locate **flink.customized.configs**.
3. Add custom parameter **table.ranger.security.authorization**, set it to **true**, click **Save**, and save the settings.
4. Click the **Instances** tab, select all FlinkServer instances, choose **More** > **Restart Instance**.

Step 2 Configure Hive row filter for a specified user. For details, see **Hive Row-Level Data Filtering**.

For example, add the search criterion **a<>1** to the **datagen** table in the **default** database for the **test** user.

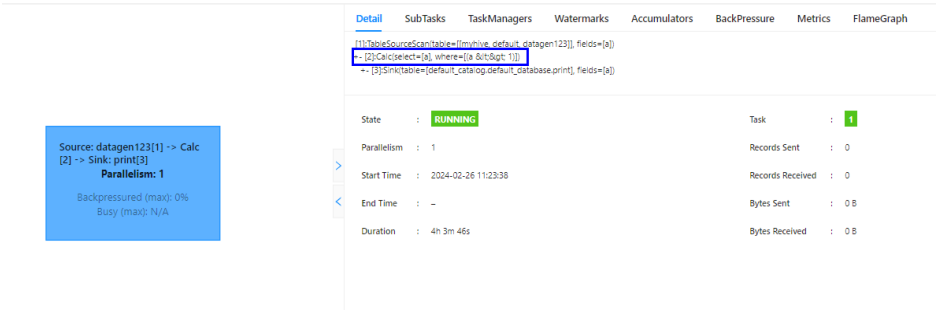


Step 3 Submit a Flink SQL job through FlinkServer as a user with the required permissions. For details, see **Creating a FlinkServer Job**.

The following is a SQL example:

```
CREATE CATALOG myhive WITH (
  'type' = 'hive',
  'hive-version' = '3.1.0',
  'default-database' = 'default',
  'cluster.name' = 'flink_hive'
);
CREATE TABLE print (a INT) WITH ('connector' = 'print');
CREATE TABLE IF NOT EXISTS myhive.`default`.datagen (a INT) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '1'
);
set table.sql-dialect = default;
insert into
  print
select
  *
from
  myhive.`default`.datagen;
```

You can view the configured search criteria on the native Flink job page. In the following example, **a<>1** has been added to the criteria.



----End

6.7.11 FlinkSQL Operator Parallelism

This section applies to MRS 3.5.0 or later.

Scenarios

For jobs submitted through CompiledPlan, the parallelism and TTL of operators are subject to the values in CompiledPlan instead of the values in **flink-conf.yaml**. FlinkSQL allows you to set the parallelism of operators by modifying CompiledPlan of a job.

When you modify CompiledPlan, do not change the JSON file structure, or the job will fail to be submitted. The save path of CompiledPlan can be an HDFS path or an OBS path. In this example, the HDFS path is used.

How to Use

Change the value of **table.exec.resource.default-parallelism** of the an operator in CompiledPlan.

Example

Step 1 Develop a FlinkServer SQL job.

On the SQL development page of FlinkServer, enter the following SQL statements by referring to **Creating a FlinkServer Job** and click **Check Semantic**:

```
set parallelism.default = 2;

CREATE TABLE print(
  uuid VARCHAR(20),
  name VARCHAR(10),
  age INT,
  ts INT
) WITH (
  'connector' = 'print'
);
CREATE TABLE datagen(
  uuid VARCHAR(20),
  name VARCHAR(10),
  age INT,
  ts INT
) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '1'
);
COMPILE PLAN 'hdfs://hacluster/tmp/plan.json' FOR insert into
  print
```

```
select
  *
from
  datagen;
```

Step 2 View and modify the operator parallelism in the CompiledPlan file.

1. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS**, click the link next to **NameNode Web UI**, and choose **Utilities** > **Browse the file system** to view and obtain the **hdfs://hacluster/tmp/plan.json** file. Click **Check Semantic**. The CompiledPlan file is generated in the HDFS. The file content is similar to the following example. The parallelism of the datagen operator (ID: 1) is **2**.
2. For example, to change the parallelism of the datagen operator to **1**, modify **"table.exec.resource.default-parallelism": "1"** and save, and then upload it to **hdfs://hacluster/tmp/plan.json**.

```

  "target" : 2,
  "shuffle" : {
    "type" : "FORWARD"
  },
  "shuffleMode" : "PIPELINED"
 } ]
}
```

Step 3 Submit the FlinkServer SQL job again.

Return to the FlinkServer SQL development page, enter the following SQL statement, and submit:

```
EXECUTE PLAN 'hdfs://hacluster/tmp/plan.json';
```

----End

6.7.12 Optimizing FlinkSQL JSON_VALUE Performance

This section applies to MRS 3.5.0 or later.

Scenarios

When the built-in JSON_VALUE function parses multiple fields of a JSON item, the parsing result of the previous JSON item is reused to improve the performance.

How to Use

When you configure a Flink job, set **table.optimizing.json-value-optimization** to **true** on the Flink job development page of the FlinkServer web UI to optimize the performance of the JSON_VALUE function. For details, see **Creating a FlinkServer Job**.

The following is an example SQL statement:

```
create table kafkaSource (
    msgValue STRING
) with (
    'connector' = 'kafka'
    ,'topic' = 'topic-1'
    ,'properties.bootstrap.servers' ='Service IP address of the Kafka Broker instance:Kafka port'
    ,'properties.group.id' = 'group-1'
    ,'value.format' = 'raw'
    ,'scan.startup.mode' = 'group-offsets'
    ,'properties.auto.offset.reset' = 'earliest'
    ,'value.fields-include' = 'EXCEPT_KEY'
);
create table print (
    id STRING,
    name STRING
) with (
      'connector' = 'print'
);
INSERT INTO print
SELECT
    JSON_VAL(msgValue, '$.id'),
    JSON_VAL(msgValue, '$.name')
from kafkaSource;
```

6.7.13 Reusing FlinkSQL Lookup Operator

This section applies to MRS 3.5.0 or later.

Scenarios

When the Lookup Join result is written to multiple sinks, you do not need to copy a Lookup Join operator for each sink. This improves job performance.

How to Use

When you configure a Flink job, set **table.optimizer.graph-merge-enabled** to **true** on the Flink job development page of the FlinkServer web UI to reuse the Lookup operator. For details, see **Creating a FlinkServer Job**.

The following is an example SQL statement:

```
create table hudimor (
  uuid varchar(20),
  name varchar(10),
  age int,
  ts timestamp
) with (
  'connector' = 'hudi',
  'table.type' = 'MERGE_ON_READ',
  'path' = 'hdfs:///tmp/hudimor',
  'lookup.cache' = 'ALL',
  'lookup.cache.ttl' = '60000',
  'lookup.cache.partitioned' = 'true',
  'lookup.parallelism' = '3'
);
CREATE TABLE datagen1 (
```

```
  uuid varchar(20),
  name varchar(10),
  age int,
  ts timestamp(6),
  proctime as PROCTIME()
) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '5'
);
create view view1 as
select
  t1.uuid as uuid,
  t1.name as name,
  t1.age as age,
  t1.ts as ts
FROM
  datagen1 AS t1
  left JOIN hudimor FOR SYSTEM_TIME AS OF t1.proctime AS t2 ON t1.uuid = t2.uuid;
CREATE TABLE blackhole1 (uuid varchar(20), name varchar(10)) WITH ('connector' = 'blackhole');
CREATE TABLE blackhole2 (uuid varchar(20), age int) WITH ('connector' = 'blackhole');
insert into
  blackhole1
select
  uuid,
  name
from
  view1;
insert into
  blackhole2
select
  uuid,
  age
from
  view1;
```

6.7.14 FlinkSQL Function Enhancements

This section applies to MRS 3.5.0 or later.

DATE_ADD Function

The DATE_ADD function is used to return the date after a specified number of days are added to a date.

- Parameters
  - Date: The data type is TIMESTAMP or STRING (format: yyyy-MM-dd HH:mm:ss). The value can be NULL.
  - Number of days to add: The data type is INT.
  - Return date: The date obtained by adding the specified number of days to the date. The data type is STRING.
- Example SQL

```
CREATE TABLE source (
  time1 TIMESTAMP
) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '1'
);
create table Sink (
  date1 string,
  date2 string,
  date3 string
) with ('connector' = 'print');
INSERT into
```

```
  Sink
select
  DATE_ADD(time1, 30) as date1,
  DATE_ADD('2017-09-15 00:00:00', 30) as date2,
  DATE_ADD(cast(null as timestamp),30) as date3
FROM source
```

Table 6-41 Return value

date1 (string)	date2 (string)	date3 (string)
2024-06-28	2017-10-15	null

DATE_SUB Function

The DATE_SUB function is used to return the date obtained by subtracting a specified number of days from a date.

- Parameter
  - Date: The data type is TIMESTAMP or STRING (format: yyyy-MM-dd HH:mm:ss). The value can be NULL.
  - Number of days to subtract: The data type is INT.
  - Return date: The date obtained by subtracting the specified number of days from the date. The data type is STRING.
- Example SQL

```
CREATE TABLE source (
  time1 TIMESTAMP
) WITH (
  'connector' = 'datagen',
  'rows-per-second' = '1'
);
create table Sink (
  date1 string,
  date2 string,
  date3 string
) with ('connector' = 'print');
INSERT into
  Sink
select
  DATE_SUB(time1,30) as date1,
  DATE_SUB('2017-09-15 00:00:00', 30) as date2,
  DATE_SUB(cast(null as timestamp),30) as date3
FROM source
```

Table 6-42 Return value

date1 (string)	date2 (string)	date3 (string)
2024-04-29	2017-08-16	null

6.7.15 Using the MultiJoin Operator in Flink SQL

This topic is available for MRS 3.5.0 or later only.

Joining wide tables with Flink's Full outer Join operator increases backend pressure and slows performance. You can use MultiJoin operator to combine wide tables, doubling the computing performance.

Restrictions on Using the MultiJoin Operator in Flink SQL

- The MultiJoin operator supports only FULL OUTER JOIN and INNER JOIN.
- The MultiJoin operator supports only equi-joins. For non-equi joins, you can use a view for filtering.
- When the MultiJoin operator is used to join multiple tables, the join keys of all tables must be the same.
- The MultiJoin operator supports only **table.exec.state.ttl** and does not support table-level TTL or JTL.
- States of Full outer join are incompatible with MultiJoin states. Jobs cannot be restored using snapshots if you switch between the two operators.

Using the MultiJoin Operator in Flink SQL

When you configure a Flink job, set **table.optimizer.multi-join-enabled** to **true** on the Flink job development page of the FlinkServer web UI to use the MultiJoin operator. For details, see **Creating a FlinkServer Job**.

The following is an example SQL statement:

```
CREATE TABLE datagen1 (
  id int,
  f1 int,
  PRIMARY KEY (id) NOT ENFORCED
) WITH (
  'connector' = 'datagen'
);

CREATE TABLE datagen2 (
  id int,
  f2 int,
  PRIMARY KEY (id) NOT ENFORCED
) WITH (
  'connector' = 'datagen'
);

CREATE TABLE datagen3 (
  id int,
  f3 int,
  PRIMARY KEY (id) NOT ENFORCED
) WITH (
  'connector' = 'datagen'
);

create view datagen3_view AS
select
  *
from
  datagen3
where
  id > 1;

CREATE TABLE print (
  id int,
  f1 int,
  f2 int,
  f3 int,
  PRIMARY KEY (id) NOT ENFORCED
) WITH (
```

```
  'connector' = 'print'
);

insert into print
select
  COALESCE(datagen1.id,datagen2.id,datagen3_view.id),
  datagen1.f1,
  datagen2.f2,
  datagen3_view.f3
from datagen1
Full outer join datagen2 on datagen1.id = datagen2.id
Full outer join datagen3_view on datagen1.id = datagen3_view.id;
```

6.8 Flink O&M Management

6.8.1 Typical Flink Configuration Parameters

Configuration Files

All Flink parameters are configurable on the client. You are advised to modify the **flink-conf.yaml** configuration file on the client. If Flink parameters are modified on FusionInsight Manager, you need to download and install the client again after the configuration is complete.

- Configuration file path: *Client installation path*/**Flink/flink/conf/flink-conf.yaml**
- File configuration format: *Key*:*Value*

  Example: **taskmanager.heap.size: 1024mb**

  A space is required between *Key*: and *Value*.

Configuration Parameter Types

- **JobManager & TaskManager**:

  JobManager and TaskManager are main components of Flink, which is used for different security and performance scenarios. The configuration items include communication ports, memory management, and connection retry.
- **Blob server**:

  The Blob server on the JobManager node is used to receive JAR files uploaded by users on the client, send JAR files to TaskManager, and transfer log files. The configuration items include ports, SSL, retries, and concurrency.
- **Distributed Coordination (via Akka)**:

  The Akka actor model is the basis of communications between a Flink client and JobManager, JobManager and TaskManager, as well as TaskManagers. Related parameters can be configured based on the network environment or optimization policy. The configuration items include the timeout settings for message sending and waiting and the Akka listening mechanism DeathWatch.
- **SSL**:

  To configure a secure Flink cluster, you need to configure SSL-related configuration items, including SSL, certificate, password, and encryption algorithm.

- **Network communication (via Netty)**:

  When Flink runs a job, data transmission and reverse pressure detection between tasks depend on Netty. In certain environments, **Netty** parameters should be configured. For advanced optimization, you can adjust some Netty configuration items. The default configuration can meet the requirements of concurrent and high-throughput tasks in a large-scale cluster.

- **JobManager Web Frontend**:

  When JobManager is started, the web server is started in the same process. You can access the web server to obtain information about the current Flink cluster, including JobManager, TaskManager, and jobs running in the cluster. Configuration items of the web server include the port, temporary directory, display items, error redirection, and security-related items.

- **File Systems**:

  When a task is running, a result file is created. You can configure the file creation behavior, including the file overwriting strategy and directory creation.

- **State Backend**:

  Flink enables HA and job exception, as well as job pause and recovery during version upgrade. Flink depends on state backend to store job states and on the restart strategy to restart a job. You can configure state backend and the restart strategy. Configuration items include the state backend type, storage path, and restart strategy.

- **Kerberos-based Security**:

  Kerberos-related configuration items must be configured in Flink's security mode. The configuration items include keytab and principal of Kerberos.

- **HA**:

  The HA mode of Flink depends on ZooKeeper. So, ZooKeeper configuration items must be configured, including the ZooKeeper address, path, and security authentication.

- **Environment**:

  In scenarios raising special requirements on JVM configuration, users can use configuration items to transfer JVM parameters to the client, JobManager, and TaskManager.

- **Yarn**:

  Flink runs on a Yarn cluster and JobManager runs on ApplicationMaster. Some configuration parameters of JobManager depend on YARN. You can configure YARN-related configurations to enable Flink to better run on YARN. The configuration items include the memory, virtual kernel, and port of YARN containers.

- **Pipeline**:

  The Netty connection is used among multiple jobs to reduce latency. In this case, NettySink is used on the server and NettySource is used on the client for data transmission. Configuration items include NettySink information storing path, range of NettySink listening port, whether to enable SSL encryption, domain of the network used for NettySink monitoring.

- **Enabling the Alarm Function for Job Submission on the Client**:

  By default, the alarm function is disabled for jobs submitted through the Flink client. To enable it, install two FlinkServer instances on the node where the

jobs are submitted and configure related parameters in the **flink-conf.yaml** file on the client.

JobManager & TaskManager

Table 6-43 JobManager & TaskManager parameters

Parameter	Description	Default Value	Mandatory
taskmanager.rpc.port	IPC port range of TaskManager	32326-32390	No
taskmanager.memory.segment-size	Size of the memory buffer used by the memory manager and network stack The unit is bytes.	32768	No
taskmanager.data.port	Data exchange port range of TaskManager	32391-32455	No
taskmanager.data.ssl.enabled	Whether to enable secure sockets layer (SSL) encryption for data transfer between TaskManagers. This parameter is valid only when the global switch **security.ssl** is enabled.	false	No
taskmanager.numberOfTaskSlots	Number of slots occupied by TaskManager. Generally, the value is configured as the number of cores of the physical machine. In **yarn-session** mode, the value can be transmitted by only the **-s** parameter. In **yarn-cluster** mode, the value can be transmitted by only the **-ys** parameter.	1	No
parallelism.default	Default degree of parallelism, which is used for jobs for which the degree of parallelism is not specified	1	No
task.cancellation.interval	Interval between two successive task cancellation attempts. The unit is millisecond.	30000	No
client.rpc.port	Akka system listening port on the Flink client.	32651-32720	No

Parameter	Description	Default Value	Mandatory
jobmanager.heap.size	Size of the heap memory of JobManager. In **yarn-session** mode, the value can be transmitted by only the **-jm** parameter. In **yarn-cluster** mode, the value can be transmitted by only the **-yjm** parameter. If the value is smaller than **yarn.scheduler.minimum-allocation-mb** in the Yarn configuration file, the Yarn configuration value is used. The unit is B/KB/MB/GB/TB.	1024mb	No
taskmanager.heap.size	Size of the heap memory of TaskManager. In **yarn-session** mode, the value can be transmitted by only the **-tm** parameter. In **yarn-cluster** mode, the value can be transmitted by only the **-ytm** parameter. If the value is smaller than **yarn.scheduler.minimum-allocation-mb** in the Yarn configuration file, the Yarn configuration value is used. The unit is B/KB/MB/GB/TB.	1024mb	No
taskmanager.network.numberOfBuffers	Number of TaskManager network transmission buffer stacks. If an error indicates insufficient system buffer, increase the parameter value.	2048	No
taskmanager.debug.memory.startLogThread	Enable this item for debugging Flink memory and garbage collection (GC)-related problems. TaskManager periodically collects memory and GC statistics, including the current utilization of heap and off-heap memory pools and GC time.	false	No
taskmanager.debug.memory.logIntervalMs	Interval at which TaskManager periodically collects memory and GC statistics.	0	No
taskmanager.maxRegistrationDuration	Maximum duration of TaskManager registration on JobManager. If the actual duration exceeds the value, TaskManager is disabled.	5 min	No

Parameter	Description	Default Value	Mandatory
taskmanager.initial-registration-pause	Initial interval between two consecutive registration attempts. The value must contain a time unit (ms/s/min/h/d), for example, 5 seconds. The time value and unit are separated by half-width spaces. ms/s/m/h/d indicates millisecond, second, minute, hour, and day, respectively.	500 ms	No
taskmanager.max-registration-pause	Maximum registration retry interval in case of TaskManager registration failures. The unit is ms/s/m/h/d.	30 s	No
taskmanager.refused-registration-pause	Retry interval when a TaskManager registration connection is rejected by JobManager. The unit is ms/s/m/h/d.	10 s	No
classloader.resolve-order	Class resolution policies defined when classes are loaded from user codes, which means whether to first check the user code JAR file (**child-first**) or the application class path (**parent-first**). The default setting indicates that the class is first loaded from the user code JAR file, which means that the user code JAR file can contain and load dependencies that are different from those used by Flink.	child-first	No
slot.idle.timeout	Timeout for a vacant slot in Slot Pool, in milliseconds.	50000	No
slot.request.timeout	Timeout for requesting a slot from Slot Pool, in milliseconds.	300000	No
task.cancellation.timeout	Timeout of task cancellation, in milliseconds. If a task cancellation times out, a fatal TaskManager error may occur. If this parameter is set to **0**, no error is reported when a task cancellation times out.	180000	No
taskmanager.network.detailed-metrics	Indicates whether to enable the detailed metrics monitoring of network queue lengths.	false	No

Parameter	Description	Default Value	Mandatory
taskmanager.network.memory.buffers-per-channel	Maximum number of network buffers used by each outgoing/incoming stream (sub-partition/input streams). In credit-based flow control, this indicates how many credits are in each input stream. It should be configured with at least 2 buffers to deliver good performance. One buffer is used to receive in-flight data in the sub-partition, and the other for parallel serialization.	2	No
taskmanager.network.memory.floating-buffers-per-gate	Number of extra network buffers used by each output gate (result partition) or input gate, indicating the amount of floating credit shared among all input channels in credit-based flow control mode. Floating buffers are distributed based on the backlog feedback (real-time output buffers in sub-partitions) and can help mitigate back pressure caused by unbalanced data distribution among sub-partitions. Increase this value if the round-trip time between nodes is long and/or the number of machines in the cluster is large.	8	No
taskmanager.network.memory.fraction	Ratio of JVM memory used for network buffers, which determines how many streaming data exchange channels a TaskManager can have at the same time and the extent of channel buffering. Increase this value or the values of **taskmanager.network.memory.min** and **taskmanager.network.memory.max** if the job is rejected or a warning indicating that the system does not have enough buffers is received. Note that the values of **taskmanager.network.memory.min** and **taskmanager.network.memory.max** may overwrite this value.	0.1	No
taskmanager.network.memory.max	Maximum memory size of the network buffer. The value must contain a unit (B/KB/MB/GB/TB).	1 GB	No

Parameter	Description	Default Value	Mandatory
taskmanager.network.memory.min	Minimum memory size of the network buffer. The value must contain a unit (B/KB/MB/GB/TB).	64 MB	No
taskmanager.network.request-backoff.initial	Minimum backoff for partition requests of input channels.	100	No
taskmanager.network.request-backoff.max	Maximum backoff for partition requests of input channels.	10000	No
taskmanager.registration.timeout	Timeout for TaskManager registration. TaskManager will be terminated if it is not successfully registered within the specified time. The value must contain a time unit (ms/s/min/h/d).	5 min	No
resourcemanager.taskmanager-timeout	Timeout interval for releasing an idle TaskManager, in milliseconds.	30000	No

Blob server

Table 6-44 Blog server parameters

Parameter	Description	Default Value	Mandatory
blob.server.port	Blob server port	32456-32520	No
blob.service.ssl.enabled	Indicates whether to enable the encryption for the blob transmission channel. This parameter is valid only when the global switch **security.ssl** is enabled.	true	Yes
blob.fetch.retries	Number of times that TaskManager tries to download blob files from JobManager.	50	No
blob.fetch.num-concurrent	Number of concurrent tasks for downloading blob files supported by JobManager.	50	No

Parameter	Description	Default Value	Mandatory
blob.fetch.backlog	Number of blob files, such as **.jar** files, to be downloaded in the queue supported by JobManager. The unit is count.	1000	No
library-cache-manager.cleanup.interval	Interval at which JobManager deletes the JAR files stored on the HDFS when the user cancels the Flink job. The unit is second.	3600	No

Distributed Coordination (via Akka)

Table 6-45 Distributed Coordination parameters

Parameter	Description	Default Value	Mandatory
akka.ask.timeout	Timeout duration of Akka asynchronous and block requests. If a Flink timeout failure occurs, this value can be increased. Timeout occurs when the machine processing speed is slow or the network is blocked. The unit is ms/s/m/h/d.	10s	No
akka.lookup.timeout	Timeout duration for JobManager actor object searching. The unit is ms/s/m/h/d.	10s	No
akka.framesize	Maximum size of the message transmitted between JobManager and TaskManager. If a Flink error occurs because the message exceeds this limit, the value can be increased. The unit is b/B/KB/MB.	10485760b	No
akka.watch.heartbeat.interval	Heartbeat interval at which the Akka DeathWatch mechanism detects disconnected TaskManager. If TaskManager is frequently and incorrectly marked as disconnected due to heartbeat loss or delay, the value can be increased. The unit is ms/s/m/h/d.	10s	No

Parameter	Description	Default Value	Mandatory
akka.watch.heartbeat.pause	Acceptable heartbeat pause for Akka DeathWatch mechanism. A small value indicates that irregular heartbeat is not accepted. The unit is ms/s/m/h/d.	60s	No
akka.watch.threshold	DeathWatch failure detection threshold. A small value may mark normal TaskManager as failed and a large value increases failure detection time.	12	No
akka.tcp.timeout	Timeout duration of Transmission Control Protocol (TCP) connection request. If TaskManager connection timeout occurs frequently due to the network congestion, the value can be increased. The unit is ms/s/m/h/d.	20s	No
akka.throughput	Number of messages processed by Akka in batches. After an operation, the processing thread is returned to the thread pool. A small value indicates the fair scheduling for actor message processing. A large value indicates improved overall performance but lowered scheduling fairness.	15	No
akka.log.lifecycle.events	Switch of Akka remote time logging, which can be enabled for debugging.	false	No
akka.startup-timeout	Timeout interval before a remote component fails to be started. The value must contain a time unit (ms/s/min/h/d).	The value is the same as the value of **akka.ask.timeout**.	No
akka.ssl.enabled	Switch of Akka communication SSL. This parameter is valid only when the global switch **security.ssl** is enabled.	true	Yes
akka.client-socket-worker-pool.pool-size-factor	Factor that is used to determine the thread pool size. The pool size is calculated based on the following formula: ceil (available processors * factor). The size is bounded by the **pool-size-min** and **pool-size-max** values.	1.0	No

Parameter	Description	Default Value	Mandatory
akka.client-socket-worker-pool.pool-size-max	Maximum number of threads calculated based on the factor.	2	No
akka.client-socket-worker-pool.pool-size-min	Minimum number of threads calculated based on the factor.	1	No
akka.client.timeout	Timeout duration of the client. The value must contain a time unit (ms/s/min/h/d).	60s	No
akka.server-socket-worker-pool.pool-size-factor	Factor that is used to determine the thread pool size. The pool size is calculated based on the following formula: ceil (available processors * factor). The size is bounded by the **pool-size-min** and **pool-size-max** values.	1.0	No
akka.server-socket-worker-pool.pool-size-max	Maximum number of threads calculated based on the factor.	2	No
akka.server-socket-worker-pool.pool-size-min	Minimum number of threads calculated based on the factor.	1	No

SSL

Table 6-46 SSL parameters

Parameter	Description	Default Value	Mandatory
security.ssl.protocol	SSL transmission protocol version.	TLSv1.2	Yes

Parameter	Description	Default Value	Mandatory
security.ssl.algorithms	Supported SSL standard algorithm. For details, visit the Java official website at: **http://docs.oracle.com/javase/8/docs/technotes/guides/security/StandardNames.html#ciphersuites**.	TLS_DHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_DHE_RSA_WITH_AES_256_GCM_SHA384,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	Yes
security.ssl.enabled	Whether to enable SSL for internal communication. This parameter is automatically configured based on the cluster installation mode.	• Security mode: **true** • Normal mode: **false**	Yes
security.ssl.keystore	Java keystore file.	-	Yes
security.ssl.keystore-password	Password used to decrypt the keystore file.	-	Yes
security.ssl.key-password	Password used to decrypt the server key in the keystore file.	-	Yes
security.ssl.truststore	**truststore** file containing the public CA certificates.	-	Yes
security.ssl.truststore-password	Password used to decrypt the truststore file.	-	Yes

Network communication (via Netty)

Table 6-47 Network communication parameters

Parameter	Description	Default Value	Mandatory
taskmanager.network.netty.num-arenas	Number of Netty memory blocks.	1	No

Parameter	Description	Default Value	Mandatory
taskmanager.network.netty.server.numThreads	Number of Netty server threads	1	No
taskmanager.network.netty.client.numThreads	Number of Netty client threads	1	No
taskmanager.network.netty.client.connectTimeoutSec	Netty client connection timeout duration. The unit is second.	120	No
taskmanager.network.netty.sendReceiveBufferSize	Size of Netty sending and receiving buffers. This defaults to the system buffer size (**cat /proc/sys/net/ipv4/tcp_[rw]mem**) and is 4 MB in modern Linux. The unit is bytes.	4096	No
taskmanager.network.netty.transport	Netty transport type, either **nio** or **epoll**	nio	No

JobManager Web Frontend

Table 6-48 JobManager Web Frontend parameters

Parameter	Description	Default Value	Mandatory
jobmanager.web.allow-access-address	Web access whitelist. IP addresses are separated by commas (,). Only whitelisted IP addresses can access the web.	*	Yes

Parameter	Description	Default Value	Mandatory
flink.security.enable	When installing a Flink cluster, you are required to select **security mode** or **normal mode**. • If **security mode** is selected, this parameter is automatically set to **true**. • If **normal mode** is selected, this parameter is automatically set to **false**. For an installed Flink cluster, you can view the configured value to determine whether the cluster is in security or normal mode.	Automatic configuration	No
rest.bind-port	The web port. Value range: 32261–32325.	32261-32325	No
jobmanager.web.history	Number of recent jobs to be displayed.	5	No
jobmanager.web.checkpoints.disable	Whether to disable checkpoint statistics.	false	No
jobmanager.web.checkpoints.history	Number of checkpoint statistical records.	10	No
jobmanager.web.backpressure.cleanup-interval	Interval for clearing unaccessed backpressure records. The unit is millisecond.	600000	No
jobmanager.web.backpressure.refresh-interval	Interval for updating backpressure records. The unit is millisecond.	60000	No
jobmanager.web.backpressure.num-samples	Number of stack tracing records for reverse pressure calculation.	100	No
jobmanager.web.backpressure.delay-between-samples	Sampling interval for reverse pressure calculation. The unit is millisecond.	50	No

Parameter	Description	Default Value	Mandatory
jobmanager.web.ssl.enabled	Whether SSL encryption is enabled for web transmission. This parameter is valid only when the global switch **security.ssl** is enabled.	false	Yes
jobmanager.web.accesslog.enable	Switch to enable or disable web operation logs. The log is stored in **webaccess.log**.	true	Yes
jobmanager.web.x-frame-options	Value of the HTTP security header **X-Frame-Options**. The value can be **SAMEORIGIN**, **DENY**, or **ALLOW-FROM uri**.	DENY	Yes
jobmanager.web.cache-directive	Whether the web page can be cached.	no-store	Yes
jobmanager.web.expires-time	Expiration duration of web page cache. The unit is millisecond.	0	Yes
jobmanager.web.access-control-allow-origin	Web page same-origin policy that prevents cross-domain attacks.	*	Yes
jobmanager.web.refresh-interval	Web page refresh interval. The unit is millisecond.	3000	Yes
jobmanager.web.logout-timer	Automatic logout interval when no operation is performed. The unit is millisecond.	600000	Yes
jobmanager.web.403-redirect-url	Web page access error 403. If 403 error occurs, the specified page will be redirected to.	Automatic configuration	Yes
jobmanager.web.404-redirect-url	Web page access error 404. If 404 error occurs, the specified page will be redirected to.	Automatic configuration	Yes
jobmanager.web.415-redirect-url	Web page access error 415. If 415 error occurs, the specified page will be redirected to.	Automatic configuration	Yes
jobmanager.web.500-redirect-url	Web page access error 500. If 500 error occurs, the specified page will be redirected to.	Automatic configuration	Yes

Parameter	Description	Default Value	Mandatory
rest.await-leader-timeout	Time of the client waiting for the leader address. The unit is millisecond.	30000	No
rest.client.max-content-length	Maximum content length that the client handles (unit: bytes).	104857600	No
rest.connection-timeout	Maximum time for the client to establish a TCP connection (unit: ms).	15000	No
rest.idleness-timeout	Maximum time for a connection to stay idle before failing (unit: ms).	300000	No
rest.retry.delay	The time that the client waits between retries (unit: ms).	3000	No
rest.retry.max-attempts	The number of retry times if a retrievable operator fails.	20	No
rest.server.max-content-length	Maximum content length that the server handles (unit: bytes).	104857600	No
rest.server.numThreads	Maximum number of threads for the asynchronous processing of requests.	4	No
web.timeout	Timeout for web monitor (unit: ms).	10000	No

File Systems

Table 6-49 File Systems parameters

Parameter	Description	Default Value	Mandatory
fs.overwrite-files	Whether to overwrite the existing file by default when the file is written.	false	No

Parameter	Description	Default Value	Mandatory
fs.output.always-create-directory	When the degree of parallelism (DOP) of file writing programs is greater than 1, a directory is created under the output file path and different result files (each parallel write program) are stored in the directory. ● If this parameter is set to **true**, a directory is created for the writing program whose DOP is 1 and a result file is stored in the directory. ● If this parameter is set to **false**, the file of the writing program whose DOP is 1 is created directly in the output path and no directory is created.	false	No

State Backend

Table 6-50 State Backend parameters

Parameter	Description	Default Value	Mandatory
state.backend.fs.checkpointdir	Path when the backend is set to **filesystem**. The path must be accessible by JobManager. Only the local mode is supported. In the cluster mode, use an HDFS path.	hdfs:///flink/checkpoints	No
state.savepoints.dir	Savepoint storage directory used by Flink to restore and update jobs. When a savepoint is triggered, the metadata of the savepoint is saved to this directory.	hdfs:///flink/savepoint	Mandatory in security mode
restart-strategy	Default restart policy, which is used for jobs for which no restart policy is specified. ● fixed-delay ● failure-rate ● none	none	No

Parameter	Description	Default Value	Mandatory
restart-strategy.fixed-delay.attempts	The retry times of the **fixed-delay** policy.	• If the checkpoint is enabled, the default value is the value of **Integer.MAX_VALUE**. • If the checkpoint is disabled, the default value is **3**.	No
restart-strategy.fixed-delay.delay	Retry interval when the fixed-delay strategy is used. The unit is ms/s/m/h/d.	• If the checkpoint is enabled, the default value is 10s. • If the checkpoint is disabled, the default value is the value of **akka.ask.timeout**.	No
restart-strategy.failure-rate.max-failures-per-interval	Maximum number of restart times in a specified period before a job fails when the fault rate policy is used.	1	No

Parameter	Description	Default Value	Mandatory
restart-strategy.failure-rate.failure-rate-interval	Retry interval when the failure-rate strategy is used. The unit is ms/s/m/h/d.	60 s	No
restart-strategy.failure-rate.delay	Retry interval when the failure-rate strategy is used. The unit is ms/s/m/h/d.	The default value is the same as the value of **akka.ask.timeout**. For details, see **Distributed Coordination (via Akka)**.	No

Kerberos-based Security

Table 6-51 Kerberos-based security parameters

Parameter	Description	Default Value	Mandatory
security.kerberos.login.keytab	Keytab file path. This parameter is a client parameter.	Configure the parameter based on actual service requirements.	Yes
security.kerberos.login.principal	A parameter on the client. If **security.kerberos.login.keytab** and **security.kerberos.login.principal** are both set, keytab certificate is used by default.	Configure the parameter based on actual service requirements.	No

Parameter	Description	Default Value	Mandatory
security.kerberos.login.contexts	Contexts of the jass file generated by Flink. This parameter is a server parameter.	Client, KafkaClient	Yes

HA

Table 6-52 HA parameters

Parameter	Description	Default Value	Mandatory
high-availability	Whether HA is enabled. Only the following two modes are supported currently: • none: Only a single JobManager is running. The checkpoint is disabled for JobManager. • ZooKeeper: – In non-Yarn mode, multiple JobManagers are supported and the leader JobManager is elected. – In Yarn mode, only one JobManager exists.	zookeeper	No
high-availability.zookeeper.quorum	ZooKeeper quorum address.	Automatic configuration	No
high-availability.zookeeper.path.root	Root directory that Flink creates on ZooKeeper, storing metadata required in HA mode.	/flink	No
high-availability.storageDir	Directory for storing JobManager metadata of state backend. ZooKeeper stores only pointers to actual data.	hdfs:///flink/recovery	No
high-availability.zookeeper.client.session-timeout	Session timeout duration on the ZooKeeper client. The unit is millisecond.	60000	No
high-availability.zookeeper.client.connection-timeout	Connection timeout duration on the ZooKeeper client. The unit is millisecond.	15000	No

Parameter	Description	Default Value	Mandatory
high-availability.zookeeper.client.retry-wait	Retry waiting time on the ZooKeeper client. The unit is millisecond.	5000	No
high-availability.zookeeper.client.max-retry-attempts	Maximum retry times on the ZooKeeper client.	3	No
high-availability.job.delay	Delay of job restart when JobManager recovers.	The default value is the same as the value of **akka.ask.timeout**.	No
high-availability.zookeeper.client.acl	Configure the ACL (open creator) of the ZooKeeper node. The ACL is automatically configured based on the security mode of the cluster.	• Security mode: The default value is **creator**. • Non-security mode: The default value is **open**.	Yes
zookeeper.sasl.disable	Whether to enable SASL authentication. This parameter is automatically configured based on the security mode of the cluster.	• Security mode: **false** • Non-security mode: **true**	Yes
zookeeper.sasl.service-name	• If the ZooKeeper server configures a service whose name is different from **ZooKeeper**, this configuration item can be set. • If service names on the client and server are inconsistent, authentication fails.	zookeeper	Yes

Environment

Table 6-53 Environment parameters

Parameter	Description	Default Value	Mandatory
env.java.opts	JVM parameter, which is transferred to the startup script, JobManager, TaskManager, and Yarn client. For example, transfer remote debugging parameters.	-Xloggc:<LOG_DIR>/gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=20M -Djdk.tls.ephemeralDHKeySize=2048 -Djava.library.path=${HADOOP_COMMON_HOME}/lib/native -Djava.net.preferIPv4Stack=true -Djava.net.preferIPv6Addresses=false -Dbeetle.application.home.path=/opt/*xxx*/Bigdata/common/runtime/security/config	No

Yarn

Table 6-54 YARN parameters

Parameter	Description	Default Value	Mandatory
yarn.maximum-failed-containers	Maximum number of containers the system is going to reallocate in case of a container failure of TaskManager The default value is the number of TaskManagers when the Flink cluster is started.	5	No

Parameter	Description	Default Value	Mandatory
yarn.application-attempts	Number of ApplicationMaster restarts. The value is the maximum value in the validity interval that is set to Akka's timeout in Flink. After the restart, the IP address and port number of ApplicationMaster will change and you will need to connect to the client manually.	2	No
yarn.heartbeat-delay	Time between heartbeats with the ApplicationMaster and Yarn ResourceManager in seconds. The unit is second.	5	No
yarn.containers.vcores	Number of virtual cores of each Yarn container	Number of TaskManager slots	No
yarn.application-master.port	ApplicationMaster port number setting. A port number range is supported.	32586-32650	No

Pipeline

Table 6-55 Pipeline parameters

Parameter	Description	Default Value	Mandatory
nettyconnector.registerserver.topic.storage	Path (on a third-party server) to information about IP address, port numbers, and concurrency of NettySink. ZooKeeper is recommended for storage.	/flink/nettyconnector	No. However, if pipeline is enabled, the feature is mandatory.
nettyconnector.sinkserver.port.range	Port range of NettySink.	28444-28843	No. However, if pipeline is enabled, the feature is mandatory.

Parameter	Description	Default Value	Mandatory
nettyconnector.ssl.enabled	Whether SSL encryption for the communication between NettySink and NettySource is enabled. For details about the encryption key and protocol, see **SSL**.	false	No. However, if pipeline is enabled, the feature is mandatory.
nettyconnector.message.delimiter	Delimiter used to configure the message sent by NettySink to the NettySource, which is 2-4 bytes long, and cannot contain **\n**, **#**, or space.	The default value is **$_**.	No. However, if pipeline is enabled, the feature is mandatory.

Enabling the Alarm Function for Job Submission on the Client

This function applies to MRS 3.2.0 or later.

Table 6-56 Parameters for enabling the alarm function for job submission on the client

Parameter	Description	Value	Mandatory
job.alarm.enable	Whether to enable the alarm function.	true	Yes
flinkserver.host.ip	Service IP addresses of the two FlinkServer instances	*x.x.x.x,x.x.x.x*	Yes

6.8.2 Interconnecting Flink with AOM

This topic is available for MRS 3.5.0 and later versions only.

Scenarios

Application Operations Management (AOM) is an an observable platform and provides integrated monitoring capabilities based on metrics, links, logs, and events. Flink can send monitoring indicators to AOM via Prometheus instances, making it easy to view monitored data.

This example describes how to interconnect Flink with AOM using FlinkResource, FlinkServer, or a client and upload Flink monitoring metrics to AOM.

Prerequisites

- AOM has been enabled.
- The HDFS, YARN, Kafka, and Flink components have been installed in the MRS cluster.
- The client that contains the Flink service has been installed, for example, in the /opt/client directory.

Procedure

Step 1 Create a Prometheus instance in AOM.

1. Log in to the AOM console.
2. In the navigation pane on the left, choose **Prometheus Monitoring** > **Instances**. On the displayed page, click **Add Prometheus Instance**.
3. Enter an instance name, specify the enterprise project and instance type, and click **OK**.

Table 6-57 Parameters for creating a Prometheus instance

Parameter	Description
Instance Name	Prometheus instance name. Enter a maximum of 100 characters and do not start or end with an underscore (_) or hyphen (-). Only letters, digits, underscores, and hyphens are allowed.
Enterprise Project	Enterprise project name. – If you have selected **ALL** for **Enterprise Project** on the global settings page, select an enterprise project from the drop-down list. – If you have already selected an enterprise project on the global settings page, this option will be grayed and cannot be changed.
Instance Type	Type of the Prometheus instance. Select **Common Prometheus Instance**.

4. In the instance list, click the name of the created Prometheus instance you just created. Click **Settings** in the navigation pane, and check and save the following information.

Table 6-58 Prometheus instance information

Type	Parameter	Example Data
Credential	AppSecret	00000001000000001070C6A*xx*0E2EF73

Type	Parameter	Example Data
Service Address	URL in the Configuration Code for Prometheus Remote Write pane in the **Intranet** tab	https://aom-internal-access.*xxx*/push

Step 2 Configure parameters for interconnecting with AOM on MRS.

1. Log in to FusionInsight Manager.
2. Choose **Cluster** > **Services** > **Flink** > **Configurations** > **All Configurations**.
3. Configure parameters for Flink to interconnect with AOM.
   - Interconnect with AOM through FlinkServer.

     Choose **FlinkServer(Role)** > **Customization**, add parameters in **Table 6-59** to **flink.customized.configs**, save the configuration, and restart involved FlinkServer instances.

     Table 6-59 Parameters for interconnecting Flink with AOM

Parameter Name	Value	Mandatory	Description
metrics.reporter	alarm,aom	Yes	**alarm** means FlinkServer alarms for customized parameters overwriting original Flink parameters. Set both **alarm** and **aom**.
metrics.reporter.aom.url	URL obtained from **Step 1.4**	Yes	URL for connecting to the AOM Prometheus instance.
metrics.reporter.aom.access.code	Value of AppSecret obtained from **Step 1.4**	Yes	Credential for calling the AOM Prometheus instance.
metrics.reporter.aom.factory.class	com.huawei.mrs.flink.AomMetricReporterFactroy	Yes	Implementation class for reporting Flink metrics. The fixed value is **com.huawei.mrs.flink.AomMetricReporterFactroy**
metrics.reporter.aom.interval	30s	Yes	Interval for reporting Flink metrics, in seconds.

Parameter Name	Value	Mandatory	Description
metrics.reporter.aom.version	0.1.0	No	AOM version information.
metrics.reporter.aom.filterLabelValue-Characters	true	No	Whether to filter the label value. The content that cannot be matched by [a-zA-Z0-9:_] will be filtered. ■ **true** (default value): Enable the filtering function. ■ **false**: Disable the filtering function.
metrics.reporter.aom.jobName	-	No	Name of the job. The name will be sent to the Prometheus instance as a label value.
metrics.reporter.aom.randomJobNameSuffix	true	No	Whether to add a random suffix to the job name. ■ **true** (default value): Add a random suffix. ■ **false**: Do not add a random suffix.
metrics.reporter.aom.groupingKey	-	No	Grouping key, which is the group and global label of all metrics. The value is in the format of k1=v1,k2=v2.

- Interconnect with AOM through FlinkResource.
  i. Choose **FlinkResource(Role)** > **Customization**, add parameters in **Table 6-59** to **flink.customized.configs**, save the configuration, and restart involved FlinkResource instances.
  ii. Reinstall the client or update the existing client configuration.
- Interconnect with AOM through the Flink client.
  i. Log in to the node where the client is installed as the client installation user.
  ii. Add the parameters in **Table 6-59** to the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file and save the file.

Step 3 View monitoring metrics.

After the Flink job is successfully executed, log in to the AOM 2.0 console. In the navigation pane on the left, choose **Prometheus Monitoring** > **Instances**. Click

the name of the Prometheus instance created in **Step 1**. View the monitoring information on the **Metric Management** page.

----End

6.8.3 Flink Log Overview

Log Description

Log path:

- Run logs of a Flink job: **${BIGDATA_DATA_HOME}/hadoop/data${i}/nm/containerlogs/application_${appid}/container_{$contid}**

  NOTE

  The logs of executing tasks are stored in the preceding path. After the execution is complete, the Yarn configuration determines whether these logs are gathered to the HDFS directory.

- FlinkResource run logs: **/var/log/Bigdata/flink/flinkResource**
- Run logs related to FlinkServer HA scripts (MRS 3.2.0 or later): **/var/log/Bigdata/audit/flink/flinkserver/ha**

Log archive rules:

1. FlinkResource run logs:
   - By default, service logs are backed up each time when the log size reaches 20 MB. A maximum of 20 logs can be reserved without being compressed.
   - You can set the log size and number of compressed logs on the Manager page or modify the corresponding configuration items in **log4j-cli.properties**, **log4j.properties**, and **log4j-session.properties** in *Client installation directory*/**Flink/flink/conf/** on the client.

   Table 6-60 FlinkResource log list

Type	Name	Description
FlinkResource run logs	checkService.log	Health check log
	kinit.log	Initialization log
	postinstall.log	Service installation log
	prestart.log	Prestart script log
	start.log	Startup log

2. FlinkServer service logs, HA-related logs, and audit logs.
   - By default, FlinkServer service logs, HA-related logs, and audit logs are backed up each time when the log size reaches 100 MB. The service logs are stored for a maximum of 30 days, and audit logs are stored for a maximum of 90 days.
   - You can set the log size and number of compressed logs on the Manager page or modify the corresponding configuration items in **log4j-**

cli.properties, **log4j.properties**, and **log4j-session.properties** in *Client installation directory*/**Flink/flink/conf/** on the client.

Table 6-61 FlinkServer log list

Type	Name	Description
FlinkServer run logs	checkService.log	Health check log
	checkFlinkServer.log	Health check log of FlinkServer
	localhost_access_log..*yyyy-mm-dd*.txt	URL log of FlinkServer
	start_thrift_server.out	Thrift server startup log
	thrift_server_thriftServer_*xxx*.log.last	
	cleanup.log	Cleanup log file for instance installation and uninstallation
	flink-omm-client-*IP*.log	Job startup log
	flinkserver_*yyyymmdd-x*.log.gz	Service archive log
	flinkserver.log	Service log
	flinkserver---*pidxxxx*-gc.log.*x*.current	GC log
	kinit.log	Initialization log
	postinstall.log	Service installation log
	prestart.log	Prestart script log
	start.log	Startup log
	stop.log	Stop log
	catalina.*yyyy-mm-dd*.log	Tomcat run log
	catalina.out	
	host-manager.*yyyy-mm-dd*.log	
	localhost.*yyyy-mm-dd*.log	
	manager.*yyyy-mm-dd*.log	

Type	Name	Description
Run log file related to FlinkServer HA scripts (MRS 3.2.0 or later)	ha.log	HA run log
	ha_monitor.log	HA process monitoring log
	floatip_ha.log	Floating IP address resource script log
	rcommflinkserver.log	FlinkServer resource script log
	checkHaStatus.log	HA process log
	checknode.log	HA health status log
	rs-sendAlarm.log	HA alarm sending log
	flink_roll.log	FlinkServer active/standby switchover log (active/standby switchover required)
FlinkServer audit logs	flinkserver_audit_*yyyymmdd-x*.log.gz	Audit archive log
	flinkserver_audit.log	Audit log
Stack information log (MRS 3.2.0 or later)	threadDump-<*DATE*>.log	Log printed when instances are restarted or stopped

Log Level

Table 6-62 describes the log levels supported by Flink. The priorities of log levels are ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

Table 6-62 Log levels

Level	Description
ERROR	Error information about the current event processing
WARN	Exception information about the current event processing
INFO	Normal running status information about the system and events
DEBUG	System information and system debugging information

To modify log levels, perform the following steps:

Step 1 Go to the **All Configurations** page of Flink by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

----End

NOTE

- After the configuration is complete, you do not need to restart the service. Download the client again for the configuration to take effect.
- You can also change the configuration items corresponding to the log level in **log4j-cli.properties**, **log4j.properties**, and **log4j-session.properties** in *Client installation directory*/**Flink/flink/conf/** on the client.
- When a job is submitted using a client, a log file is generated in the **log** folder on the client. The default umask value is **0022**. Therefore, the default log permission is **644**. To change the file permission, you need to change the umask value. For example, to change the umask value of user **omm**:
  - Add **umask 0026** to the end of the **/home/omm/.baskrc** file.
  - Run the **source /home/omm/.baskrc** command to make the file permission take effect.

Log Format

Table 6-63 Log formats

Type	Format	Example
Run log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2019-06-27 21:30:31,778 | INFO | [flink-akka.actor.default-dispatcher-3] | TaskManager container_e10_1498290698388_0004_02_000007 has started. | org.apache.flink.yarn.YarnFlinkResourceManager (FlinkResourceManager.java:368)

6.9 Flink Performance Tuning

6.9.1 Flink Memory GC Optimization Parameters

Scenarios

The computing of Flink depends on memory. If the memory is insufficient, the performance of Flink will be greatly deteriorated. One solution is to monitor

garbage collection (GC) to evaluate the memory usage. If the memory becomes the performance bottleneck, optimize the memory usage according to the actual situation.

If **Full GC** is frequently reported in the Container GC on the Yarn that monitors the node processes, the GC needs to be optimized.

NOTE

In the **env.java.opts** configuration item of the **conf/flink-conf.yaml** file on the client, add the **-Xloggc:<LOG_DIR>/gc.log -XX:+PrintGCDetails -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=20 -XX:GCLogFileSize=20M** parameter. The GC log is configured by default.

Procedure

- Optimize GC.

  Adjust the ratio of tenured generation memory to young generation memory. In the **conf/flink-conf.yaml** configuration file on the client, add the **-XX:NewRatio** parameter to the **env.java.opts** configuration item. For example, **-XX:NewRatio=2** indicates that ratio of tenured generation memory to young generation memory is 2:1, that is, the young generation memory occupies one third and tenured generation memory occupies two thirds.
- When developing Flink applications, optimize the partitioning or grouping operation of DataStream.
  - If partitioning causes data skew, partitions need to be optimized.
  - Do not perform concurrent operations, because some operations, WindowAll for example, to DataStream do not support parallelism.
  - Do not use set keyBy to string type.

6.9.2 Flink Job Concurrency

Scenario

The degree of parallelism (DOP) indicates the number of tasks to be executed concurrently. It determines the number of data blocks after the operation. Configuring the DOP will optimize the number of tasks, data volume of each task, and the host processing capability.

Query the CPU and memory usage. If data and tasks are not evenly distributed among nodes, increase the DOP for even distribution.

Procedure

Configure the DOP at one of the following layers (the priorities of which are in the descending order) based on the actual memory, CPU, data, and application logic conditions:

- Operator

  Call the **setParallelism()** method to specify the DOP of an operator, data source, and sink. For example:

```
final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
```

```
DataStream<String> text = [...]
DataStream<Tuple2<String, Integer>> wordCounts = text
    .flatMap(new LineSplitter())
    .keyBy(0)
    .timeWindow(Time.seconds(5))
    .sum(1).setParallelism(5);

wordCounts.print();

env.execute("Word Count Example");
```

- Execution environment

  Flink runs in the execution environment which defines a default DOP for operators, data source and data sink.

  Call the **setParallelism()** method to specify the default DOP of the execution environment. Example:

  ```
  final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
  env.setParallelism(3);
  DataStream<String> text = [...]
  DataStream<Tuple2<String, Integer>> wordCounts = [...]
  wordCounts.print();
  env.execute("Word Count Example");
  ```

- Client

  Specify the DOP when submitting jobs to Flink on the client. If you use the CLI client, specify the DOP using the **-p** parameter. Example:

  ```
  ./bin/flink run -p 10 ../examples/*WordCount-java*.jar
  ```

- System

  On the Flink client, modify the **parallelism.default** parameter in the **flink-conf.yaml** file under the conf to specify the DOP for all execution environments.

6.9.3 Flink Job Process Parameters

Scenario

In Flink on Yarn mode, there are JobManagers and TaskManagers. JobManagers and TaskManagers schedule and run tasks.

Therefore, configuring parameters of JobManagers and TaskManagers can optimize the execution performance of a Flink application. Perform the following steps to optimize the Flink cluster performance.

Procedure

Step 1 Configure JobManager memory.

JobManagers are responsible for task scheduling and message communications between TaskManagers and ResourceManagers. JobManager memory needs to be increased as the number of tasks and the DOP increases.

JobManager memory needs to be configured based on the number of tasks.

- When running the **yarn-session** command, add the **-jm MEM** parameter to configure the memory.
- When running the **yarn-cluster** command, add the **-yjm MEM** parameter to configure the memory.

Step 2 Configure the number of TaskManagers.

Each core of a TaskManager can run a task at the same time. Increasing the number of TaskManagers has the same effect as increasing the DOP. Therefore, you can increase the number of TaskManagers to improve efficiency when there are sufficient resources.

Step 3 Configure the number of TaskManager slots.

Multiple cores of a TaskManager can process multiple tasks at the same time. This has the same effect as increasing the DOP. However, the balance between the number of cores and the memory must be maintained, because all cores of a TaskManager share the memory.

- When running the **yarn-session** command, add the **-s NUM** parameter to configure the number of slots.
- When running the **yarn-cluster** command, add the **-ys NUM** parameter to configure the number of slots.

Step 4 Configure TaskManager memory.

TaskManager memory is used for task execution and communication. A large-size task requires more resources. In this case, you can increase the memory.

- When running the **yarn-session** command, add the **-tm MEM** parameter to configure the memory.
- When running the **yarn-cluster** command, add the **-ytm MEM** parameter to configure the memory.

----End

6.9.4 Flink Netty Network Communication Parameters

Scenarios

The communication of Flink is based on Netty network. The network performance determines the data switching speed and task execution efficiency. Therefore, the performance of Flink can be optimized by optimizing the Netty network.

Procedure

In the **conf/flink-conf.yaml** file on the client, change configurations as required. Exercise caution when changing default values, because default values are optimal.

- **taskmanager.network.netty.num-arenas**: Specifies the number of arenas of Netty. The default value is**taskmanager.numberOfTaskSlots**.
- **taskmanager.network.netty.server.numThreads**and**taskmanager.network.netty.client.numThreads**: specify the number of threads on the client and server. The default value is**taskmanager.numberOfTaskSlots**.
- **taskmanager.network.netty.client.connectTimeoutSec**: specifies the timeout interval for connection of TaskManager client. The default value is**120s**.

- **taskmanager.network.netty.sendReceiveBufferSize**: specifies the buffer size of the Netty network. The default value is the buffer size (cat /proc/sys/net/ipv4/tcp_[rw]mem) of the system and the value is usually 4 MB.
- **taskmanager.network.netty.transport**: specifies the transmission method of the Netty network. The default value is**nio**. The value can only be**nio**and**epoll**.

6.9.5 RocksDB State Backend of Flink Jobs

This topic is available for MRS 3.3.0 and later versions only.

Flink Job RocksDB

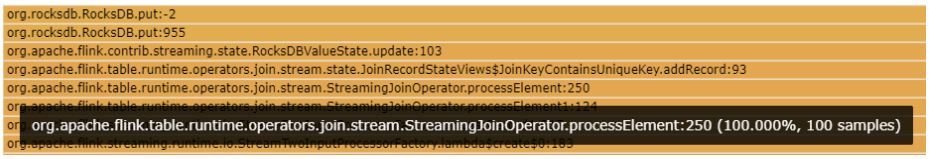
When RocksDB is enabled as the state backend for jobs, a large amount of state data causes poor read and write performance of RocksDB. You can perform the following operations to check whether the operator performance is affected by RocksDB:

- On the ThreadDump of TaskManager, check whether the operator has been executed on the RocksDB operation interface for a long time. If the following information is displayed after multiple refreshes, the operator is executed on the RocksDB operation interface for a long time.

```
Join[5] -> Calc[6] -> Sink: print[7] (1/1)#0" Id=113 RUNNABLE (in native)
    at org.rocksdb.RocksDB.put(Native Method)
    at org.rocksdb.RocksDB.put(RocksDB.java:955)
    at org.apache.flink.contrib.streaming.state.RocksDBValueState.update(RocksDBValueState.java:103)
```

- Enable the flame graph (set **rest.flamegraph.enabled** to **true**) and submit the job again to view operator hotspots. Operator hotspots reach 100% in the figure below.

  Figure 6-17 Viewing operator hotspots in a flame graph



When the RockDB read/write latency is long, you can enable RocksDB monitoring and alarm reporting to optimize RockDB parameters based on the monitoring and alarm items. After job optimization, you are advised to disable RockDB monitoring and alarm reporting because they will deteriorate RocksDB performance by 5% to 10%.

To avoid impact on other jobs, RocksDB monitoring is configured by setting user-defined parameters. This section describes how to enable RocksDB monitoring, alarm reporting, and optimization parameters.

Enabling RocksDB Monitoring for Flink Jobs

Step 1 Log in to FusionInsight Manager as a user with the FlinkServer administrator rights.

Step 2 Choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 3 Click **Job Management**. The job management page is displayed.

Step 4 Locate the job that is to be optimized and is not in the **Running** state, and click **Develop** in the **Operation** column to go to the job development page.

Step 5 In the **Custom Configuration** area on the job development page, add the following parameters and save the settings:

- Enabling RocksDB monitoring

Table 6-64 RocksDB monitoring configuration

Parameter	Value	Description
state.backend.rocksdb.metrics.hot.enabled	true	Non-statistical monitoring of RocksDB includes the monitoring items contained in RocksDB Property.
state.backend.rocksdb.metrics.statistics.enabled	true	RocksDB monitoring statistics
state.backend.rocksdb.metrics.num-immutable-mem-table	true	Monitors the number of immutable memtables in RocksDB. If the value keeps increasing or exceeds the threshold, the write performance will be affected.
state.backend.rocksdb.metrics.mem-table-flush-pending	true	Monitors the number of pending memtable flushes in RocksDB.
state.backend.rocksdb.metrics.compaction-pending	true	Monitors the number of pending compactions in RocksDB. If there are any pending compactions, **1** is returned. Otherwise, **0** is returned.
state.backend.rocksdb.metrics.background-errors	true	Monitors the number of metrics.background-errors in RocksDB.
state.backend.rocksdb.metrics.cur-size-active-mem-table	true	Monitors the approximate size of the active memtable, in bytes.
state.backend.rocksdb.metrics.cur-size-all-mem-tables	true	Monitors the approximate size of active and unflushed immutable memtables, in bytes.
state.backend.rocksdb.metrics.size-all-mem-tables	true	Monitors the approximate size of active, unflushed, and pinned memtables, in bytes.
state.backend.rocksdb.metrics.num-entries-active-mem-table	true	Monitors the total number of entries in active memtables.

Parameter	Value	Description
state.backend.rocksdb.metrics.num-entries-imm-mem-tables	true	Monitors the total number of entries in immutable memtables.
state.backend.rocksdb.metrics.num-deletes-active-mem-table	true	Monitors the total number of deleted entries in active memtables.
state.backend.rocksdb.metrics.num-deletes-imm-mem-tables	true	Monitors the total number of deleted entries in unflushed immutable memtables.
state.backend.rocksdb.metrics.estimate-num-keys	true	Monitors the number of keys in RocksDB.
state.backend.rocksdb.metrics.estimate-table-readers-mem	true	Monitors the memory used to read SST tables, excluding the memory used in the block cache (such as filters and index blocks), in bytes.
state.backend.rocksdb.metrics.num-snapshots	true	Monitors the number of unpublished snapshots in the database.
state.backend.rocksdb.metrics.num-live-versions	true	Monitors the number of real-time versions. A version is an internal data schema. If there are too many versions, RocksDB may fail to delete old versions due to query or compaction operations.
state.backend.rocksdb.metrics.estimate-live-data-size	true	Monitors the real-time data volume, in bytes (usually smaller than the size of an SST file due to space amplification).
state.backend.rocksdb.metrics.total-sst-files-size	true	Monitors the total size of SST files of all versions, in bytes. Too many files may slow down query.
state.backend.rocksdb.metrics.live-sst-files-size	true	Monitors the total size of all SST files of the latest version, in bytes. Too many files may slow down query.
state.backend.rocksdb.metrics.estimate-pending-compaction-bytes	true	Monitors the total size of compaction data, in bytes. This ensures that the size of compaction data at all levels is smaller than the target size, and other compactions beyond the levels are invalid.
state.backend.rocksdb.metrics.num-running-compactions	true	Monitors the number of running compactions. If all threads are in the **Running** state, the write performance may be affected.

Parameter	Value	Description
state.backend.rocksdb.metrics.num-running-flushes	true	Monitors the number of running flush tasks. If all threads are in the **Running** state, the write performance may be affected.
state.backend.rocksdb.metrics.actual-delayed-write-rate	true	Monitors the actual delayed write rate. If **0** is returned, there is no delay.
state.backend.rocksdb.metrics.is-write-stopped	true	Monitors whether write to RocksDB is stopped. If the write is stopped, **1** is returned. Otherwise, **0** is returned.
state.backend.rocksdb.metrics.block-cache-capacity	true	Monitors the block cache capacity.
state.backend.rocksdb.metrics.block-cache-usage	true	Monitors the memory occupied by data in the block cache.
state.backend.rocksdb.metrics.block-cache-pinned-usage	true	Monitors the memory occupied by pinned data in the block cache.
state.backend.rocksdb.metrics.compression-ratio	true	Monitors the compression ratio of each layer.
state.backend.rocksdb.metrics.compression-ratio-levelN	7	Number of layers whose compression ratio is to be monitored. The value must be at least 0 and not greater than the configured number of layers.
state.backend.rocksdb.metrics.num-files	true	Monitors the number of files at each layer.
state.backend.rocksdb.metrics.num-files-levelN	7	Number of layers whose file quantity is to be monitored. The value must be at least 0 and not greater than the configured number of layers.

Parameter	Value	Description
state.backend.rocksdb.metrics.statistics.ticker	block.cache.miss,block.cache.hit,block.cache.index.miss,block.cache.index.hit,block.cache.filter.miss,block.cache.filter.hit,block.cache.data.miss,block.cache.data.hit,bloom.filter.useful,memtable.hit,memtable.miss,l0.hit,l1.hit,l2andup.hit,stall.micros	Statistics ticker monitoring item To add a monitoring item, add it to the end of the value and separate monitoring items with commas (,).
state.backend.rocksdb.metrics.statistics.histogram	db.get.micros,db.write.micros,db.flush.micros,compaction.times.micros	Statistics straight square monitoring item To add a monitoring item, add it to the end of the value and separate monitoring items with commas (,).

- Enabling the RocksDB alarm function

Table 6-65 RocksDB alarm configuration

Configuration Item	Default Value	Description
metrics.reporter.alarm.job.alarm.rocksdb.metrics.enable	true	Whether to enable RocksDB monitoring. This function is disabled by default. This configuration is valid only when the state backend is RocksDB.
metrics.reporter.alarm.job.alarm.rocksdb.metrics.duration	180s	Interval for RocksDB to monitor alarms
metrics.reporter.alarm.job.alarm.rocksdb.metrics.print.enabled	true	Whether to print RocksDB monitoring information to TaskManager If **metrics.reporter.alarm.job.alarm.rocksdb.metrics.enable** is set to **true**, this parameter is automatically set to **true** by default.
metrics.reporter.alarm.job.alarm.rocksdb.metrics.print.interval	5min	Interval for printing RocksDB monitoring information to TaskManager
metrics.reporter.alarm.job.alarm.rocksdb.get.micros.threshold	1000	Time threshold of the Get operation, in µs. If the time consumed by a job exceeds the threshold consecutively within the period specified by **metrics.reporter.alarm.job.alarm.rocksdb.metrics.duration**, an alarm is reported.
metrics.reporter.alarm.job.alarm.rocksdb.write.micros.threshold	3000	Time threshold of the Write operation, in µs. If the time consumed by a job exceeds the threshold consecutively within the period specified by **metrics.reporter.alarm.job.alarm.rocksdb.metrics.duration**, an alarm is reported.
metrics.reporter.alarm.job.alarm.actual-delayed-write-rate.threshold	0	If the write rate of a job is limited consecutively within the period specified by **metrics.reporter.alarm.job.alarm.rocksdb.metrics.duration**, an alarm is reported. The value **0** indicates that the write rate is not limited.
metrics.reporter.alarm.job.alarm.rocksdb.background.jobs.multiplier	2	An alarm is reported when the number of flush or compaction requests exceeds the multiplier of **state.backend.rocksdb.thread.num**.

Step 6 On the **Job Management** page, click **Start** to run the job. Based on the RocksDB monitoring and alarm information, add the following parameters in the **Custom Parameters** area on the job development page to optimize the job. After job optimization is complete, you are advised to disable RocksDB monitoring and alarm reporting.

Table 6-66 RocksDB optimization parameters

Parameter	Value	Description
state.backend.rocksdb.writebuffer.count	2	Number of active and immutable memtables. If the write speed is too fast or the number of Flink threads is too small, the write is blocked. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **4**. It is recommended that the value be greater than or equal to the value of **state.backend.rocksdb.writebuffer.number-to-merge** plus 2.
state.backend.rocksdb.writebuffer.size	64MB	Memtable size
state.backend.rocksdb.thread.num	2	Number of RocksDB flush and compaction threads. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **4**.
state.backend.rocksdb.writebuffer.number-to-merge	1	Number of immutable flushes. Deduplication is performed when *n* immutable flushes are performed. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **3**.
state.backend.rocksdb.compaction.level.max-size-level-base	256MB	Total size of SSL files at level 1. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **1 GB**.
state.backend.rocksdb.compaction.level.target-file-size-base	64MB	Size of SSL files at level 1+. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **128 MB**.
state.backend.rocksdb.num_levels	7	Number of RocksDB levels
state.backend.rocksdb.level0_slowdown_writes_trigger	20	Number of files that trigger slowdown at level 0. If the value is smaller than 0, slowdown will never be triggered.
state.backend.rocksdb.level0_stop_writes_trigger	36	Maximum number of files that trigger stop at level 0

Parameter	Value	Description
state.backend.rocksdb.max_compaction_bytes	-	Maximum number of bytes in a compaction. The default value is the **state.backend.rocksdb.compaction.level.target-file-size-base** value x 25.
state.backend.rocksdb.level0_file_num_compaction_trigger	4	Compaction from level 0 to level 1 is triggered when the number of Level 0 SSTs reaches the threshold.
state.backend.rocksdb.compression	snappy	SST file compression algorithm The value can be **null**, **snapp**, **zlib**, **bzip2**, **lz4**, **lz4hc**, **xpress**, or **zstd**.
state.backend.rocksdb.bottommost_compression	snappy	The bottom layer uses heavyweight compression types to reduce space. The underlying data may be cold data. To enable this function, you are advised to use **zstd** or **zlib**. The value can be **null**, **snapp**, **zlib**, **bzip2**, **lz4**, **lz4hc**, **xpress**, or **zstd**.
state.backend.rocksdb.max_bytes_for_level_multiplier	10	Data volume multiplier factor of level 1 plus two adjacent layers
state.backend.rocksdb.hard-pending-compaction-bytes-limit	256GB	When the pending compaction size exceeds the threshold, write operations are stopped.
state.backend.rocksdb.soft-pending-compaction-bytes-limit	64GB	When the pending compaction size exceeds the threshold, the write traffic is limited.
state.backend.rocksdb.use-bloom-filter	true	Bloom filter. After this function is enabled, each newly created SST file contains a Bloom filter.
state.backend.rocksdb.block.cache-size	8MB	Cache size. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **256MB**.
state.backend.rocksdb.block.blocksize	4KB	Block size. When **SPINNING_DISK_OPTIMIZED_HIGH_MEM** is enabled, the default value is **128KB**.
state.backend.rocksdb.files.open	-1	Maximum number of opened handles, which is mainly used for SST file handles. The value **-1** indicates that the number is not limited.

----End

6.9.6 Separate Storage of Cold and Hot Data for Flink Job State Backend

This topic is available for MRS 3.3.0 or later only.

In wide table joins, each table contains a large number of fields. State backends hold a large volume of data and the processing speed is severely lowered. To solve this problem, you can enable tiered storage for hot-cold separation.

Procedure

Step 1 Install the client that contains services such as Flink and HBase. The installation path is for example, **/opt/hadoopclient**.

Step 2 Log in to the node where the client is installed as the client installation user and copy all configuration files in the **/opt/client/HBase/hbase/conf/** directory of HBase to an empty directory of all nodes where FlinkServer is deployed, for example, **/tmp/client/HBase/hbase/conf/**.

Change the owner of the configuration file directory and its upper-layer directory on the FlinkServer node to **omm**.

chown omm: /tmp/client/HBase/ -R

NOTE

- FlinkServer nodes:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Flink** > **Instances**, and check the **Service IP Address** of FlinkServer.
- If the node where a FlinkServer instance is deployed is the node where the HBase client is installed, skip this step on this node.

Step 3 Log in to Manager and choose **Cluster** > **Services** > **Flink**. Click **Configurations** then **All Configurations**, search for the **HBASE_CONF_DIR** parameter, and enter the FlinkServer directory (for example, **/tmp/client/HBase/hbase/conf/**) to which the HBase configuration files are copied in **Step 2** in **Value**.

Step 4 After the parameters are configured, click **Save**. After confirming the modification, click **OK**.

Step 5 Click **Instances**, select all FlinkServer instances, choose **More** > **Restart Instance**, enter the password, and click **OK** to restart the instances.

Step 6 Log in to FusionInsight Manager as a user with the FlinkServer administrator rights.

Step 7 Choose **Cluster** > **Services** > **Flink**. In the **Basic Information** area, click the link next to **Flink WebUI** to access the Flink web UI.

Step 8 Click **Job Management**. The job management page is displayed.

Step 9 Locate the job that is to be optimized and is not in the **Running** state, and click **Develop** in the **Operation** column to go to the job development page.

Step 10 In the **Custom Parameters** area on the **Job Development** page, add the following parameters as required and save the settings. For details about hot data (regularly used data), see **Table 6-67**. For details about cold data (data that is not required often), see **Table 6-68**.

Table 6-67 RocksDB state backend storage

Parameter	Description	Example Value
table.exec.state.cold.enabled	Whether to enable RocksDB that stores hot and cold data separately • **false** (default value): Periodic dynamic scaling is disabled. • **true**: Periodic dynamic scaling is enabled.	false
state.backend.rocksdb.cold.localdir	Directory for storing cold data	-
state.backend.rocksdb.cold.predefined-options	Predefined configuration of cold data RocksDB: • **DEFAULT** (default value): RocksDB disk is not written forcibly. You are advised to use this value. • **SPINNING_DISK_OPTIMIZED_HIGH_MEM**: Parameters for optimizing RocksDB disk write. Flink job recovery does not depend on RocksDB, so you are not advised to use the current configuration.	DEFAULT
state.backend	State backend storage medium. Set this parameter to **rocksdb**.	rocksdb

Table 6-68 HBase serves as the state backend storage for level-2 cold data

Parameter	Description	Example Value
table.exec.state.cold.enabled	Whether to enable tiered storage for hot and cold data • **false** (default value): Periodic dynamic scaling is disabled. • **true**: Periodic dynamic scaling is enabled.	false
state.backend.cold	State backend storage for cold data. Currently, only **hbase** is supported.	hbase

Parameter	Description	Example Value
table.exec.state.ttl	Timeout interval for data status changes • If **table.exec.state.cold.enabled** is **true**, this parameter indicates when hot data expires. When hot data is stored longer than the value, it becomes cold data. • If **table.exec.state.cold.enabled** is **false**, all expired data will be deleted. • Default value: 0, indicating that the data never expires.	0
state.backend.hbase.zookeeper.quorum	ZooKeeper connection address used to access HBase. Format: *Service IP address of the ZooKeeper quorumpeer instance*:*ZooKeeper client port* ,*Service IP address of the ZooKeeper quorumpeer instance*:*ZooKeeper client port* ,*Service IP address of the ZooKeeper quorumpeer instance*:*ZooKeeper client port*	192.168.10.10:24002,192.168.10.11:24002,192.168.10.12:24002
state.backend	State backend storage medium. Set this parameter to **rocksdb**.	rocksdb

NOTE

- IP address of the ZooKeeper quorumpeer instance

  To obtain IP addresses of all ZooKeeper quorumpeer instances, log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper**. On the displayed page, click **Instance** and view the IP addresses of all the hosts where the quorumpeer instances locate.
- Port number of the ZooKeeper client

  Log in to FusionInsight Manager and choose **Cluster** > **Service** > **ZooKeeper**. On the displayed page, click **Configurations** and check the value of **clientPort**.

----End

6.10 Typical Commands of the Flink Client

Before you use the Flink shell script, perform the following operations. For details, see **Using the Flink Client** to run a wordcount job.

Step 1 The Flink client has been installed, for example, in the **/opt/client** directory.

Step 2 Run the following command to initialize environment variables:

source /opt/client/bigdata_env

Step 3 If Kerberos authentication has been enabled for the cluster, configure client authentication by referring to **Step 5**. If Kerberos authentication is disabled, skip this step.

Step 4 Run the related commands according to **Table 6-69**.

Table 6-69 Flink Shell commands

Command	Description	Description
yarn-session.sh	**-at,--applicationType <arg>**: Defines the Yarn application type. **-D <property=value>**: Configures dynamic parameter. **-d,--detached**: Disables the interactive mode and starts a separate Flink Yarn session. **-h,--help**: Displays the help information about the Yarn session CLI. **-id,--applicationId <arg>**: Binds to a running Yarn session. **-j,--jar <arg>**: Sets the path of the user's JAR file. **-jm,--jobManagerMemory <arg>**: Sets the JobManager memory. **-m,--jobmanager <arg>**: Address of the JobManager (master) to which to connect. Use this parameter to connect to a specified JobManager. **-nl,--nodeLabel <arg>**: Specifies the nodeLabel of the Yarn application. **-nm,--name <arg>**: Customizes a name for the application on Yarn. **-q,--query**: Queries available Yarn resources. **-qu,--queue <arg>**: Specifies a Yarn queue. **-s,--slots <arg>**: Sets the number of slots for each TaskManager. **-t,--ship <arg>**: specifies the directory of the file to be sent. **-tm,--taskManagerMemory <arg>**: sets the TaskManager memory. **-yd,--yarndetached**: starts Yarn in the detached mode. **-z,--zookeeperNamespace <args>**: specifies the namespace of ZooKeeper. **-h**: Gets help information.	Start a resident Flink cluster to receive tasks from the Flink client.

Command	Description	Description
flink run	**-c,--class <classname>**: Specifies a class as the entry for running programs. **-C,--classpath <url>**: Specifies **classpath**. **-d,--detached**: Runs a job in the detached mode. **-files,--dependencyFiles <arg>**: File on which the Flink program depends. This parameter is available only in MRS 3.2.0 and later versions. **-n,--allowNonRestoredState**: A state that cannot be restored can be skipped during restoration from a snapshot point in time. For example, if an operator in the program is deleted, you need to add this parameter when restoring the snapshot point. **-m,--jobmanager <host:port>**: Specifies the JobManager. **-p,--parallelism <parallelism>**: Specifies the job DOP, which will overwrite the DOP parameter in the configuration file. **-q,--sysoutLogging**: Disables the function of outputting Flink logs to the console. **-s,--fromSavepoint <savepointPath>**: Specifies a savepoint path for recovering jobs. **-z,--zookeeperNamespace <zookeeperNamespace>**: specifies the namespace of ZooKeeper. **-yat,--yarnapplicationType <arg>**: Defines the Yarn application type. **-yD <arg>**: Dynamic parameter configuration. **-yd,--yarndetached**: Starts Yarn in the detached mode. **-yh,--yarnhelp**: Obtains the Yarn help. **-yid,--yarnapplicationId <arg>**: Binds a job to a Yarn session. **-yj,--yarnjar <arg>**: Sets the path to Flink jar file. **-yjm,--yarnjobManagerMemory <arg>**: Sets the JobManager memory (MB). **-ynm,--yarnname <arg>**: Customizes a name for the application on Yarn. **-yq,--yarnquery**: Queries available Yarn resources (memory and CPUs).	Submit a Flink job. 1. The **-y*** parameter is used in the **yarn-cluster** mode. 2. If the parameter is not **-y***, you need to run the **yarn-session** command to start the Flink cluster before running this command to submit a task.

Command	Description	Description
	-yqu,--yarnqueue <arg>: Specifies a Yarn queue. **-ys,--yarnslots**: Sets the number of slots for each TaskManager. **-yt,--yarnship <arg>**: Specifies the path of the file to be sent. **-ytm,--yarntaskManagerMemory <arg>**: Sets the TaskManager memory (MB). **-yz,--yarnzookeeperNamespace <arg>**: Specifies the namespace of ZooKeeper. The value must be the same as the value of **yarn-session.sh -z**. **-h**: Gets help information.	
flink info	**-c,--class <classname>**: Specifies a class as the entry for running programs. **-p,--parallelism <parallelism>**: Specifies the DOP for running programs. **-h**: Gets help information.	Display the execution plan (JSON) of the running program.
flink list	**-a,--all**: displays all jobs. **-m,--jobmanager <host:port>**: specifies the JobManager. **-r,--running:** displays only jobs in the running state. **-s,--scheduled**: displays only jobs in the scheduled state. **-z,--zookeeperNamespace <zookeeperNamespace>**: specifies the namespace of ZooKeeper. **-yid,--yarnapplicationId <arg>**: binds a job to a Yarn session. **-h**: gets help information.	Query running programs in the cluster.

Command	Description	Description
flink stop	**-d,--drain**: sends MAX_WATERMARK before the savepoint is triggered and the job is stopped. **-p,--savepointPath <savepointPath>**: path for storing savepoints. The default value is **state.savepoints.dir**. **-m,--jobmanager <host:port>**: specifies the JobManager. **-z,--zookeeperNamespace <zookeeperNamespace>**: specifies the namespace of ZooKeeper. **-yid,--yarnapplicationId <arg>**: binds a job to a Yarn session. **-h**: gets help information.	Forcibly stop a running job (only streaming jobs are supported. **StoppableFunction** needs to be implemented on the source side in service code).
flink cancel	**-m,--jobmanager <host:port>**: specifies the JobManager. **-s,--withSavepoint <targetDirectory>**: triggers a savepoint when a job is canceled. The default directory is **state.savepoints.dir**. **-z,--zookeeperNamespace <zookeeperNamespace>**: specifies the namespace of ZooKeeper. **-yid,--yarnapplicationId <arg>**: binds a job to a Yarn session. **-h**: gets help information.	Cancel a running job.
flink savepoint	**-d,--dispose <arg>**: specifies a directory for storing the savepoint. **-m,--jobmanager <host:port>**: specifies the JobManager. **-z,--zookeeperNamespace <zookeeperNamespace>**: specifies the namespace of ZooKeeper. **-yid,--yarnapplicationId <arg>**: binds a job to a Yarn session. **-h**: gets help information.	Trigger a savepoint.

Command	Description	Description
source *Client installation directory*/**bigdata_env**	None	Import client environment variables. Restriction: If the user uses a custom script (for example, **A.sh**) and runs this command in the script, variables cannot be imported to the **A.sh** script. If variables need to be imported to the custom script **A.sh**, the user needs to use the secondary calling method. For example, first call the **B.sh** script in the **A.sh** script, and then run this command in the **B.sh** script. Parameters can be imported to the **A.sh** script but cannot be imported to the **B.sh** script.
start-scala-shell.sh	local | remote <host> <port> | yarn: running mode	Start the scala shell.
sh generate_keystore.sh	-	Run the **generate_keystore.sh** script to generate security cookie, **flink.keystore**, and **flink.truststore**. You need to enter a user-defined password that does not contain number signs (#).

----End

6.11 Common Flink SQL Syntax

SELECT and WHERE

Filter using the WHERE clause.

- Syntax:

  SELECT *select_list* **FROM** *table_expression* **[WHERE** *boolean_expression* **]**

- Example:

```
SELECT price + tax FROM Orders WHERE id = 10
```

WITH

WITH provides a way to write auxiliary statements for use in a larger query. These statements, which are often referred to as Common Table Expression (CTE), can be thought of as defining temporary views that exist just for one query.

- Syntax:

  WITH <*with_item_definition***> [, ...]**

  SELECT ... FROM ...;

  <with_item_defintion>:

  with_item_name (*column_name***[, ...n]) AS (** *<select_query>* **)**

- Example:

  Define a common table expression **orders_with_total** and use it in a GROUP BY query.

```
WITH orders_with_total AS (
    SELECT order_id, price + tax AS total
    FROM Orders
)
SELECT order_id, SUM(total)
FROM orders_with_total
GROUP BY order_id;
```

Window Aggregation

Queries with a group by window aggregation will compute a single result row per group.

- Syntax:

  SELECT ...

  FROM *<windowed_table>* **-- relation applied windowing TVF**

  GROUP BY *window_start, window_end, …*

- Example:

```
SELECT window_start, window_end, SUM(price)
FROM TABLE(
TUMBLE(TABLE Bid, DESCRIPTOR(bidtime), INTERVAL '10' MINUTES))
GROUP BY window_start, window_end;
```

Window Deduplication

Window Deduplication is a special deduplication which removes rows that duplicate over a set of columns, keeping the first one or the last one for each window and partitioned keys.

- Syntax:

  SELECT *[column_list]*

  FROM (

  SELECT *[column_list]*,

  ROW_NUMBER() OVER (PARTITION BY *window_start, window_end [, col_key1...]*

  ORDER BY *time_attr [asc|desc])* **AS** *rownum*

  FROM *table_name)* **-- relation applied windowing TVF**

  WHERE *(rownum = 1 | rownum <=1 | rownum < 2)* **[AND** *conditions***]**

- Example:

```
SELECT *
FROM (
SELECT bidtime, price, item, supplier_id, window_start, window_end,
ROW_NUMBER() OVER (PARTITION BY window_start, window_end ORDER BY bidtime DESC) AS
rownum
FROM TABLE(
TUMBLE(TABLE Bid, DESCRIPTOR(bidtime), INTERVAL '10' MINUTES))
) WHERE rownum <= 1;
```

Top-N

Top-N queries ask for the N smallest or largest values ordered by columns.

- Syntax:

  SELECT *[column_list]*

  FROM (

  SELECT *[column_list],*

  ROW_NUMBER() OVER *([PARTITION BY col1[, col2...]]*

  ORDER BY *col1 [asc|desc][, col2 [asc|desc]...])* **AS** *rownum*

  FROM *table_name)*

  WHERE *rownum* **<=** *N* **[AND** *conditions***]**

- Example:

```
CREATE TABLE ShopSales (
product_id   STRING,
category     STRING,
product_name STRING,
sales        BIGINT
) WITH (...);

SELECT *
FROM (
SELECT *,
ROW_NUMBER() OVER (PARTITION BY category ORDER BY sales DESC) AS row_num
FROM ShopSales)
WHERE row_num <= 5
```

6.12 Common Issues About Flink

Avoiding Data Skew

If data skew occurs (certain data volume is extremely large), the execution time of tasks is inconsistent even though no GC is performed.

- Redefine keys. Use keys of smaller granularity to optimize the task size.
- Modify the DOP.
- Call the rebalance operation to balance data partitions.

Setting Timeout Interval for the Buffer

- During the execution of tasks, data is exchanged through network. You can set the **setBufferTimeout** parameter to specify a buffer timeout interval for data exchanging among different servers.
- If **setBufferTimeout** is set to **-1**, the refreshing operation is performed when the buffer is full to maximize the throughput. If **setBufferTimeout** is set to **0**, the refreshing operation is performed each time data is received to minimize the delay. If **setBufferTimeout** is set to a value greater than **0**, the refreshing operation is performed after the buffer times out.

  The following is an example:

```
env.setBufferTimeout(timeoutMillis);

env.generateSequence(1,10).map(new MyMapper()).setBufferTimeout(timeoutMillis);
```

Reserving Resources

Reserve certain Yarn resources in the cluster for other tasks. For example, assume that there are 100 vCPU cores and 200 GB memory. Take 90 vCPU cores and 180 GB, and reserve about 10% of the total resources for automatic task retry and recovery in case of node faults.

6.13 Flink Troubleshooting

Running the yarn-session Command Fails to Create a Flink Cluster When a Different User Is Used

There are two users with the same permissions: **testuser** and **bdpuser**. When user **testuser** is used to create a Flink cluster, no error message is displayed. While user **bdpuser** is used to create a Flink cluster, an error message is displayed during the **yarn-session.sh** command execution.

```
2019-01-02 14:28:09,098 | ERROR | [main] | Ensure path threw exception |
org.apache.flink.shaded.curator.org.apache.curator.framework.imps.CuratorFrameworkImpl
(CuratorFrameworkImpl.java:566)
org.apache.flink.shaded.zookeeper.org.apache.zookeeper.KeeperException$NoAuthException:
KeeperErrorCode = NoAuth for /flink/application_1545397824912_0022
```

This is because that the HA configuration item is not modified. In the Flink configuration file, the default value of **high-availability.zookeeper.client.acl** is

creator, indicating that only the creator has the access permission. A new user cannot access the directory on ZooKeeper. As a result, the **yarn-session.sh** command execution fails.

Perform the following steps to solve the problem:

1. Modify the value of **high-availability.zookeeper.path.root** in the **conf/flink-conf.yaml** file. For example, run the following command:
   ```
   high-availability.zookeeper.path.root: flink2
   ```
2. Submit the Flink job again.

Error Message "security.kerberos.login.keytab" Is Displayed When a Command Is Executed on the Flink Client

The client was successfully installed. When you run a client command, for example, **yarn-session.sh**, an error message is displayed, as shown in the following figure.

```
[root@host01 bin]# yarn-session.sh
2018-10-25 01:22:06,454 | ERROR | [main] | Error while trying to split key and value in configuration file /opt/flinkclient/Flink/flink/conf/flink-conf.yaml:80: "security.kerberos.login.keytab: " | org.apache.flink.configuration.GlobalConfiguration (GlobalConfiguration.java:160)
Exception in thread "main" org.apache.flink.configuration.IllegalConfigurationException: Error while parsing YAML configuration file :80: "security.kerberos.login.keytab: "
```

In a secure cluster environment, Flink requires security authentication. The security authentication is not configured on the current client.

1. Flink uses the following two authentication modes:
   - Kerberos authentication: used by Flink yarn client, Yarn Resource Manager, JobManager, HDFS, TaskManager, Kafka, and ZooKeeper
   - Internal authentication mechanism of Yarn: used between Yarn ResourceManager and ApplicationMaster
2. If security mode is enabled for a cluster, you must use the Kerberos authentication and security cookie authentication. As shown in the logs, it is found that the **security.kerberos.login.keytab** setting in the configuration file is incorrect and the security configuration is not performed.

Perform the following steps to solve the problem:

1. Download the user **keytab** file from MRS and save it to a directory on the node where the Flink client is deployed.
2. Configure the following parameters in the **flink-conf.yaml** file:
   a. Keytab path
      ```
      security.kerberos.login.keytab: /home/flinkuser/keytab/abc222.keytab
      ```
      NOTE
      - **/home/flinkuser/keytab/abc222.keytab** indicates the user directory storing the keytab file in **1**.
      - You need to ensure that the client user has the permission on the corresponding directory.

   b. Principal name
      ```
      security.kerberos.login.principal: abc222
      ```
   c. In HA mode, if ZooKeeper is configured, the Kerberos authentication configuration items must be configured.

```
zookeeper.sasl.disable: false
security.kerberos.login.contexts: Client
```

d. If you want to perform Kerberos authentication between Kafka client and Kafka broker, set the value as follows:

```
security.kerberos.login.contexts: Client,KafkaClient
```

7 Using Flume

7.1 Flume Log Collection Overview

Flume is a distributed, reliable, and highly available system for aggregating massive logs, which can efficiently collect, aggregate, and move massive log data from different data sources and store the data in a centralized data storage system. Various data senders can be customized in the system to collect data. Additionally, Flume provides simple data processes capabilities and writes data to data receivers (which is customizable).

Flume consists of the client and server, both of which are FlumeAgents. The server corresponds to the FlumeServer instance and is directly deployed in a cluster. The client can be deployed inside or outside the cluster. he client-side and service-side FlumeAgents work independently and provide the same functions.

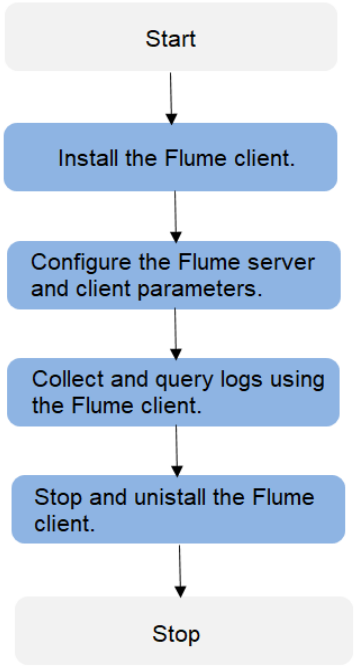
The client-side FlumeAgent needs to be independently installed. Data can be directly imported to components such as HDFS and Kafka. Additionally, the client-side and service-side FlumeAgents can also work together to provide services.

Process

Create a Flume cascading task using both Flume server and client. Perform the following operations to collect logs:

1. Installing the flume client
2. Configuring the Flume server and client parameters
3. Collecting and querying logs using the Flume client
4. Stopping and uninstalling the Flume client

Figure 7-1 Log collection process



Flume Modules

The Flume client or server consists of one or multiple agents. Each agent consists of three modules: source, channel, and sink. Data enters the source module, is transmitted to the channel, and then is sent to the sink for the next agent or a destination outside the client. **Table 7-1** describes Flume modules.

Table 7-1 Module description

Name	Description
Source	A source receives or generates data and sends the data to one or multiple channels. The source can work in either data-driven or polling mode. Typical sources include: • Sources that are integrated with the system and receives data, such as Syslog and Netcat • Sources that automatically generate event data, such as Exec and SEQ • IPC sources that are used for communication between agents, such as Avro A Source must associate with at least one channel.

Name	Description
Channel	A channel is used to buffer data between a source and a sink. After the sink transmits the data to the next channel or the destination, the cache is deleted automatically. The persistency of the channels varies with the channel types: ● Memory channel: non-persistency ● File channel: persistency implemented based on write-ahead logging (WAL) ● JDBC channel: persistency implemented based on the embedded database Channels support the transaction feature to ensure simple sequential operations. A channel can work with sources and sinks of any quantity.
Sink	Sink is responsible for sending data to the next hop or final destination and removing the data from the channel after successfully sending the data. Typical sinks include: ● Sinks that send storage data to the final destination, such as HDFS and Kafka ● Sinks that are consumed automatically, such as Null Sink ● IPC sinks that are used for communication between agents, such as Avro A sink must associate with at least one channel.

Each Flume agent can be configured with multiple source, channel, and sink modules. That is, one source sends data to multiple channels, and multiple sinks send the data to the next agent or destinations.

Multiple Flumes can be cascaded, meaning that the sink of an agent sends data to the source of another agent.

Supplementary Information

1. Flume provides the following reliability measures:
   - The transaction mechanism is implemented between sources and channels, and between channels and sinks.
   - The sink processor supports the failover and load balancing (load_balance) mechanisms.

     The following is an example of the load balancing (load_balance) configuration:

     ```
     server.sinkgroups=g1
     server.sinkgroups.g1.sinks=k1 k2
     server.sinkgroups.g1.processor.type=load_balance
     server.sinkgroups.g1.processor.backoff=true
     server.sinkgroups.g1.processor.selector=random
     ```
2. The following are precautions for the aggregation and cascading of multiple Flume clients:

  - Avro or Thrift protocol can be used for cascading.
  - When the aggregation end contains multiple nodes, evenly distribute the clients to these nodes. Do not connect all the clients to a single node.

3. The Flume client can contain multiple independent data flows. That is, multiple sources, channels, and sinks can be configured in the **properties.properties** configuration file. These components can be linked to form multiple flows.

   For example, to configure two data flows in a configuration, run the following commands:

```
server.sources = source1 source2
server.sinks = sink1 sink2
server.channels = channel1 channel2

#dataflow1
server.sources.source1.channels = channel1
server.sinks.sink1.channel = channel1

#dataflow2
server.sources.source2.channels = channel2
server.sinks.sink2.channel = channel2
```

7.2 Flume Service Model Configuration

Service Model Configuration Guide

Guide a reasonable Flume service configuration by providing performance differences between Flume common modules, to avoid a nonstandard overall service performance caused when a frontend Source and a backend Sink do not match in performance.

Only single channels are compared for description.

During Flume service configuration and module selection, the ultimate throughput of a sink must be greater than the maximum throughput of a source. Otherwise, in extreme load scenarios, the write speed of the source to a channel is greater than the read speed of sink from channel. Therefore, the channel is fully occupied due to frequent usage, and the performance is affected.

Avro Source and Avro Sink are usually used in pairs to transfer data between multiple Flume Agents. Therefore, Avro Source and Avro Sink do not become a performance bottleneck in general scenarios.

Inter-Module Performance

Based on comparison between the limit performances of modules, Kafka Sink and HDFS Sink can meet the throughput requirements when the front-end is SpoolDir Source. However, HBase Sink could become performance bottlenecks due to the low write performances thereof. As a result, data is stacked in Channel. If you have to use HBase Sink or other sinks that are prone to become performance bottlenecks, you can use **Channel Selector** or **Sink Group** to meet performance requirements.

Channel Selector

A channel selector allows a source to connect to multiple channels. Data of the source can be distributed or copied by selecting different types of selectors.

Currently, a channel selector provided by Flume can be a replicating channel selector or a multiplexing channel selector.

Replicating: indicates that the data of the source is synchronized to all channels.

Multiplexing: indicates that based on the value of a specific field of the header of an event, a channel is selected to send the data. In this way, the data is distributed based on a service type.

- Replicating configuration example:

```
client.sources = kafkasource
client.channels = channel1 channel2
client.sources.kafkasource.type = org.apache.flume.source.kafka.KafkaSource
client.sources.kafkasource.kafka.topics = topic1,topic2
client.sources.kafkasource.kafka.consumer.group.id = flume
client.sources.kafkasource.kafka.bootstrap.servers = 10.69.112.108:21007
client.sources.kafkasource.kafka.security.protocol = SASL_PLAINTEXT
client.sources.kafkasource.batchDurationMillis = 1000
client.sources.kafkasource.batchSize = 800
client.sources.kafkasource.channels = channel1 channel2

client.sources.kafkasource.selector.type = replicating
client.sources.kafkasource.selector.optional = channel2
```

Table 7-2 Parameters in the Replicating configuration example

Parameter	Default Value	Description
Selector.type	replicating	Selector type. Set this parameter to **replicating**.
Selector.optional	-	Optional channel. Configure this parameter as a list.

- Multiplexing configuration example:

```
client.sources = kafkasource
client.channels = channel1 channel2
client.sources.kafkasource.type = org.apache.flume.source.kafka.KafkaSource
client.sources.kafkasource.kafka.topics = topic1,topic2
client.sources.kafkasource.kafka.consumer.group.id = flume
client.sources.kafkasource.kafka.bootstrap.servers = 10.69.112.108:21007
client.sources.kafkasource.kafka.security.protocol = SASL_PLAINTEXT
client.sources.kafkasource.batchDurationMillis = 1000
client.sources.kafkasource.batchSize = 800
client.sources.kafkasource.channels = channel1 channel2

client.sources.kafkasource.selector.type = multiplexing
client.sources.kafkasource.selector.header = myheader
client.sources.kafkasource.selector.mapping.topic1 = channel1
client.sources.kafkasource.selector.mapping.topic2 = channel2
client.sources.kafkasource.selector.default = channel1
```

Table 7-3 Parameters in the Multiplexing configuration example

Parameter	Default Value	Description
Selector.type	replicating	Selector type. Set this parameter to **multiplexing**.

Parameter	Default Value	Description
Selector.header	Flume.selector.header	-

In a multiplexing selector example, select a field whose name is topic from the header of the event. When the value of the topic field in the header is topic1, send the event to a channel 1; or when the value of the topic field in the header is topic2, send the event to a channel 2.

Selectors need to use a specific header of an event in a source to select a channel, and need to select a proper header based on a service scenario to distribute data.

Sink Group

When the performance of a backend single sink is insufficient, and high reliability or heterogeneous output is required, you can use a sink group to connect a specified channel to multiple sinks, thereby meeting use requirements. Currently, Flume provides two types of sink processors to manage sinks in a sink group. The types are load balancing and failover.

Failover: Indicates that there is only one active sink in the sink group each time, and the other sinks are on standby and inactive. When the active sink becomes faulty, one of the inactive sinks is selected based on priorities to take over services, so as to ensure that data is not lost. This is used in high-reliability scenarios.

Load balancing: Indicates that all sinks in the sink group are active. Each sink obtains data from the channel and processes the data. In addition, during running, loads of all sinks in the sink group are balanced. This is used in performance improvement scenarios.

- Load balancing configuration examples:

```
client.sources = source1
client.sinks = sink1 sink2
client.channels = channel1

client.sinkgroups = g1
client.sinkgroups.g1.sinks = sink1 sink2
client.sinkgroups.g1.processor.type = load_balance
client.sinkgroups.g1.processor.backoff = true
client.sinkgroups.g1.processor.selector = random

client.sinks.sink1.type = logger
client.sinks.sink1.channel = channel1

client.sinks.sink2.type = logger
client.sinks.sink2.channel = channel1
```

Table 7-4 Parameters of Load Balancing configuration examples

Parameter	Default Value	Description
sinks	-	Specifies the sink list of the sink group. Multiple sinks are separated by spaces.

Parameter	Default Value	Description
processor.type	default	Specifies the type of a processor. Set this parameter to **load_balance**.
processor.backoff	false	Indicates whether to back off failed sinks exponentially.
processor.selector	round_robin	Specifies the selection mechanism. It must be round_robin, random, or a customized class that inherits AbstractSinkSelector.
processor.selector.maxTimeOut	30000	Specifies the time for masking a faulty sink. The default value is 30,000 ms.

- Failover configuration examples:

```
client.sources = source1
client.sinks = sink1 sink2
client.channels = channel1

client.sinkgroups = g1
client.sinkgroups.g1.sinks = sink1 sink2
client.sinkgroups.g1.processor.type = failover
client.sinkgroups.g1.processor.priority.sink1 = 10
client.sinkgroups.g1.processor.priority.sink2 = 5
client.sinkgroups.g1.processor.maxpenalty = 10000

client.sinks.sink1.type = logger
client.sinks.sink1.channel = channel1

client.sinks.sink2.type = logger
client.sinks.sink2.channel = channel1
```

Table 7-5 Parameters in the **failover** configuration example

Parameter	Default Value	Description
sinks	-	Specifies the sink list of the sink group. Multiple sinks are separated by spaces.
processor.type	default	Specifies the type of a processor. Set this parameter to **failover**.

Parameter	Default Value	Description
processor.priority.<sinkName>	-	Priority. **<sinkName>** must be defined in description of sinks. A sink having a higher priority is activated earlier. A larger value indicates a higher priority. **Note**: If there are multiple sinks, their priorities must be different. Otherwise, only one of them takes effect.
processor.maxpenalty	30000	Specifies the maximum backoff time of failed sinks (unit: ms).

Interceptors

The Flume interceptor supports modification or discarding of basic unit events during data transmission. You can specify the class name list of built-in interceptors in Flume or develop customized interceptors to modify or discard events. The following table lists the built-in interceptors in Flume. A complex example is used in this section. Other users can configure and use interceptions as required.

NOTE

- The interceptor is used between the sources and channels of Flume. Most sources provide parameters for configuring interceptors. You can set the parameters as required.
- Flume allows multiple interceptors to be configured for a source. The interceptor names are separated by spaces.
- The specified interceptor sequence is the order in which they are called.
- The contents inserted by the interceptor in the header can be read and used in sink.

Table 7-6 Types of built-in interceptors in Flume

Interceptor Type	Description
Timestamp Interceptor	The interceptor inserts a timestamp into the header of an event.
Host Interceptor	The interceptor inserts the IP address or host name of the node where the agent is located into the Header of an event.
Remove Header Interceptor	The interceptor discards the corresponding event based on the strings that matches the regular expression contained in the event header.

Interceptor Type	Description
UUID Interceptor	The interceptor generates a UUID string for the header of each event.
Search and Replace Interceptor	The interceptor provides a simple string-based search and replacement function based on Java regular expressions. The rule is the same as that of Java Matcher.replaceAll().
Regex Filtering Interceptor	The interceptor uses the body of an event as a text file and matches the configured regular expression to filter events. The provided regular expression can be used to exclude or include events.
Regex Extractor Interceptor	The interceptor extracts content from the original events using a regular expression and adds the content to the header of events.

Regex Filtering Interceptor is used as an example to describe how to use the interceptor. (For other types of interceptions, see the configuration provided on the official website.)

Table 7-7 Parameter configuration for **Regex Filtering Interceptor**

Parameter	Default Value	Description
type	-	Specifies the component type name. The value must be **regex_filter**.
regex	-	Specifies the regular expression used to match events.
excludeEvents	false	By default, the matched events are collected. If this parameter is set to **true**, the matched events are deleted and the unmatched events are retained.

Configuration example (**netcat tcp** is used as the source, and **logger** is used as the sink). After configuring the preceding parameters, run the **telnet** *Host name or IP address* **44444** command on the host where the Linux operating system is run, and enter a string that complies with the regular expression and another does not comply with the regular expression. The log shows that only the matched string is transmitted.

```
#define the source, channel, sink
server.sources = r1

server.channels = c1
```

```
server.sinks = k1

#config the source
server.sources.r1.type = netcat
server.sources.r1.bind = ${Host IP address}
server.sources.r1.port = 44444
server.sources.r1.interceptors= i1
server.sources.r1.interceptors.i1.type= regex_filter
server.sources.r1.interceptors.i1.regex= (flume)|(myflume)
server.sources.r1.interceptors.i1.excludeEvents= false
server.sources.r1.channels = c1

#config the channel
server.channels.c1.type = memory
server.channels.c1.capacity = 1000
server.channels.c1.transactionCapacity = 100
#config the sink
server.sinks.k1.type = logger
server.sinks.k1.channel = c1
```

NOTE

- The value of **BatchSize** of the Sink must be less than that of **transactionCapacity** of the Channel.
- Only some parameters of Source, Channel, and Sink are displayed on the Flume configuration tool page. For details, see the following configurations.
- The Customer Source, Customer Channel, and Customer Sink displayed on the Flume configuration tool page need to be configured based on self-developed code. The following common configurations are not displayed.

Common Source Configurations

- **Avro Source**

  An Avro source listens to the Avro port, receives data from the external Avro client, and places data into configured channels. Common configurations are as follows:

  Table 7-8 Common configurations of an Avro source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	avro	Specifies the type of the avro source, which must be **avro**.
bind	-	Specifies the listening host name/IP address.
port	-	Specifies the bound listening port. Ensure that this port is not occupied.

Parameter	Default Value	Description
threads	-	Specifies the maximum number of source threads.
compression-type	none	Specifies the message compression format, which can be set to **none** or **deflate**. **none** indicates that data is not compressed, while **deflate** indicates that data is compressed.
compression-level	6	Specifies the data compression level, which ranges from **1** to **9**. The larger the value is, the higher the compression rate is.
ssl	false	Specifies whether to use SSL encryption. If this parameter is set to **true**, **keystore** and **keystore-password** must be specified.
truststore-type	JKS	Specifies the Java trust store type, which can be set to **JKS** or **PKCS12**. **NOTE** Different passwords are used to protect the key store and private key of **JKS**, while the same password is used to protect the key store and private key of **PKCS12**.
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.

Parameter	Default Value	Description
keystore-type	JKS	Specifies the keystore type set after SSL is enabled, which can be set to **JKS** or **PKCS12**. **NOTE** Different passwords are used to protect the key store and private key of **JKS**, while the same password is used to protect the key store and private key of **PKCS12**.
keystore	-	Specifies the keystore file path set after SSL is enabled. This parameter is mandatory if SSL is enabled.
keystore-password	-	Specifies the keystore password set after SSL is enabled. This parameter is mandatory if SSL is enabled.
trust-all-certs	false	Specifies whether to disable the check for the SSL server certificate. If this parameter is set to **true**, the SSL server certificate of the remote source is not checked. You are not advised to perform this operation during the production.
exclude-protocols	SSLv3	Specifies the excluded protocols. The entered protocols must be separated by spaces. The default value is **SSLv3**.
ipFilter	false	Specifies whether to enable the IP address filtering.

Parameter	Default Value	Description
ipFilter.rules	-	Specifies the rules of *N* network **ipFilters**. Host names or IP addresses must be separated by commas (,). If this parameter is set to **true**, there are two configuration rules: allow and forbidden. The configuration format is as follows: ipFilterRules=allow:ip:127.*, allow:name:localhost, deny:ip:*

- **SpoolDir Source**

  SpoolDir Source monitors and transmits new files that have been added to directories in real-time mode. Common configurations are as follows:

  Table 7-9 Common configurations of a Spooling Directory source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	spooldir	Specifies the type of the spooling source, which must be set to **spooldir**.
spoolDir	-	Specifies the monitoring directory of the Spooldir source. A Flume running user must have the read, write, and execution permissions on the directory.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second
fileSuffix	.COMPLETED	Specifies the suffix added after file transmission is complete.

Parameter	Default Value	Description
deletePolicy	never	Specifies the source file deletion policy after file transmission is complete. The value can be either **never** or **immediate**. **never** indicates that the source file is not deleted after file transmission is complete, while **immediate** indicates that the source file is immediately deleted after file transmission is complete.
ignorePattern	^$	Specifies the regular expression of a file to be ignored. The default value is ^$, indicating that spaces are ignored.
includePattern	^.*$	Specifies the regular expression that contains a file. This parameter can be used together with **ignorePattern**. If a file meets both **ignorePattern** and **includePattern**, the file is ignored. In addition, when a file starts with a period (.), the file will not be filtered.
trackerDir	.flumespool	Specifies the metadata storage path during data transmission.
batchSize	1000	Specifies the number of events written to the channel in batches.
decodeErrorPolicy	FAIL	Specifies the code error policy. **NOTE** If a code error occurs in the file, set **decodeErrorPolicy** to **REPLACE** or **IGNORE**. Flume will skip the code error and continue to collect subsequent logs.
deserializer	LINE	Specifies the file parser. The value can be either **LINE** or **BufferedLine**. • When the value is set to **LINE**, characters read from the file are transcoded one by one. • When the value is set to **BufferedLine**, one line or multiple lines of characters read from the file are transcoded in batches, which delivers better performance.
deserializer.maxLineLength	2048	Specifies the maximum length for resolution by line.

Parameter	Default Value	Description
deserializer.maxBatchLine	1	Specifies the maximum number of lines for resolution by line. If multiple lines are set, **maxLineLength** must be set to a corresponding multiplier. **NOTE** When configuring the Interceptor, take the multi-line combination into consideration to avoid data loss. If the Interceptor cannot process combined lines, set this parameter to **1**.
selector.type	replicating	Specifies the selector type. The value can be either **replicating** or **multiplexing**. **replicating** indicates that data is replicated and then transferred to each channel so that each channel receives the same data, while **multiplexing** indicates that a channel is selected based on the value of the header in the event and each channel has different data.
interceptors	-	Specifies the interceptor. Multiple interceptors are separated by spaces.
inputCharset	UTF-8	Specifies the encoding format of a read file. The encoding format must be the same as that of the data source file that has been read. Otherwise, an error may occur during character parsing.
fileHeader	false	Specifies whether to add the file name (including the file path) to the event header.
fileHeaderKey	-	Specifies that the data storage structure in header is set in the <key,value> mode. Parameters **fileHeaderKey** and **fileHeader** must be used together. Following is an example if **fileHeader** is set to true: Define **fileHeaderKey** as **file**. When the **/root/a.txt** file is read, **fileHeaderKey** exists in the header in the **file=/root/a.txt** format.
basenameHeader	false	Specifies whether to add the file name (excluding the file path) to the event header.

Parameter	Default Value	Description
basenameHeaderKey	-	Specifies that the data storage structure in header is set in the <key,value> mode. Parameters **basenameHeaderKey** and **basenameHeader** must be used together. Following is an example if **basenameHeader** is set to **true**: Define **basenameHeaderKey** as **file**. When the **a.txt** file is read, **fileHeaderKey** exists in the header in the **file=a.txt** format.
pollDelay	500	Specifies the delay for polling new files in the monitoring directory. Unit: milliseconds
recursiveDirectorySearch	false	Specifies whether to monitor new files in the subdirectory of the configured directory.
consumeOrder	oldest	Specifies the consumption order of files in a directory. If this parameter is set to **oldest** or **youngest**, the sequence of files to be read is determined by the last modification time of files in the monitored directory. If there are a large number of files in the directory, it takes a long time to search for **oldest** or **youngest** files. If this parameter is set to **random**, an earlier created file may not be read for a long time. If this parameter is set to **oldest** or **youngest**, it takes a long time to find the latest and the earliest file. The options are as follows: **random**, **youngest**, and **oldest**.
maxBackoff	4000	Specifies the maximum time to wait between consecutive attempts to write to a channel if the channel is full. If the time exceeds the threshold, an exception is thrown. The corresponding source starts to write at a smaller time value. Each time the source attempts, the digital exponent increases until the current specified value is reached. If data cannot be written, the data write fails. Unit: second
emptyFileEvent	true	Specifies whether to collect empty file information and send it to the sink end. The default value is **true**, indicating that empty file information is sent to the sink end. This parameter is valid only for HDFS Sink. Taking HDFS Sink as an example, if this parameter is set to **true** and an empty file exists in the **spoolDir** directory, an empty file with the same name will be created in the **hdfs.path** directory of HDFS.

NOTE

SpoolDir Source ignores the last line feed character of each event when data is reading by row. Therefore, Flume does not calculate the data volume counters used by the last line feed character.

- **Kafka Source**

  A Kafka source consumes data from Kafka topics. Multiple sources can consume data of the same topic, and the sources consume different partitions of the topic. Common configurations are as follows:

  Table 7-10 Common configurations of a Kafka source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	org.apache.flume.source.kafka.KafkaSource	Specifies the type of the Kafka source, which must be set to **org.apache.flume.source.kafka.KafkaSource**.
kafka.bootstrap.servers	-	Specifies the bootstrap address port list of Kafka. If Kafka has been installed in the cluster and the configuration has been synchronized to the server, you do not need to set this parameter on the server. The default value is the list of all brokers in the Kafka cluster. This parameter must be configured on the client. Use commas (,) to separate multiple values of *IP address:Port number*. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).
kafka.topics	-	Specifies the list of subscribed Kafka topics, which are separated by commas (,).
kafka.topics.regex	-	Specifies the subscribed topics that comply with regular expressions. **kafka.topics.regex** has a higher priority than **kafka.topics** and will overwrite **kafka.topics**.

Parameter	Default Value	Description
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second
nodatatime	0 (Disabled)	Specifies the alarm threshold. An alarm is triggered when the duration that Kafka does not release data to subscribers exceeds the threshold. Unit: second This parameter can be configured in the **properties.properties** file.
batchSize	1000	Specifies the number of events written to the channel in batches.
batchDurationMillis	1000	Specifies the maximum duration of topic data consumption at a time, expressed in milliseconds.
keepTopicInHeader	false	Specifies whether to save topics in the event header. If the parameter value is **true**, topics configured in Kafka Sink become invalid.
setTopicHeader	true	If this parameter is set to **true**, the topic name defined in **topicHeader** is stored in the header.
topicHeader	topic	When **setTopicHeader** is set to **true**, this parameter specifies the name of the topic received by the storage device. If the property is used with that of Kafka Sink **topicHeader**, be careful not to send messages to the same topic cyclically.
useFlumeEventFormat	false	By default, an event is transferred from a Kafka topic to the body of the event in the form of bytes. If this parameter is set to **true**, the Avro binary format of Flume is used to read events. When used together with the **parseAsFlumeEvent** parameter with the same name in KafkaSink or KakfaChannel, any set **header** generated from the data source is retained.

Parameter	Default Value	Description
keepPartitionInHeader	false	Specifies whether to save partition IDs in the event header. If the parameter value is **true**, Kafka Sink writes data to the corresponding partition.
kafka.consumer.group.id	flume	Specifies the Kafka consumer group ID. Sources or proxies having the same ID are in the same consumer group.
kafka.security.protocol	SASL_PLAINTEXT	Specifies the Kafka security protocol. The parameter value must be set to PLAINTEXT in a common cluster. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).
Other Kafka Consumer Properties	-	Specifies other Kafka configurations. This parameter can be set to any consumption configuration supported by Kafka, and the **.kafka** prefix must be added to the configuration.

- **Taildir Source**

  A Taildir source monitors file changes in a directory and automatically reads the file content. In addition, it can transmit data in real time. Common configurations are as follows:

  Table 7-11 Common configurations of a Taildir source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	TAILDIR	Specifies the type of the taildir source, which must be set to TAILDIR.
filegroups	-	Specifies the group name of a collection file directory. Group names are separated by spaces.

Parameter	Default Value	Description
filegroups.<filegroupName>	-	Specifies the file path. The value must be an absolute path.
filegroups.<filegroupName>.parentDir	-	Specifies the parent directory. The value must be an absolute path.
filegroups.<filegroupName>.filePattern	-	Specifies the relative file path of the file group's parent directory. Directories can be included and regular expressions are supported. It must be used together with **parentDir**.
positionFile	-	Specifies the metadata storage path during data transmission.
headers.<filegroupName>.<headerKey>	-	Specifies the key-value of an event when data of a group is being collected.
byteOffsetHeader	false	Specifies whether each event header contains the event location information in the source file. If the parameter value is true, the location information is saved in the byteoffset variable.
maxBatchCount	Long.MAX_VALUE	Specifies the maximum number of batches that can be consecutively read from a file. If the monitored directory reads multiple files consecutively and one of the files is written at a rapid rate, other files may fail to be processed. This is because the file that is written at a high speed will be in an infinite read loop. In this case, set this parameter to a smaller value.
skipToEnd	false	Specifies whether Flume can locate the latest location of a file and read the latest data after restart. If the parameter value is true, Flume locates and reads the latest file data after restart.
idleTimeout	120000	Specifies the idle duration during file reading, expressed in milliseconds. If file content is not changed in the preset time duration, close the file. If data is written to this file after the file is closed, open the file and read data.

Parameter	Default Value	Description
writePosInterval	3000	Specifies the interval for writing metadata to a file, expressed in milliseconds.
batchSize	1000	Specifies the number of events written to the channel in batches.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second
fileHeader	false	Specifies whether to add the file name (including the file path) to the event header.
fileHeaderKey	file	Specifies that the data storage structure in header is set in the <key,value> mode. Parameters **fileHeaderKey** and **fileHeader** must be used together. Following is an example if **fileHeader** is set to true: Define **fileHeaderKey** as **file**. When the **/root/a.txt** file is read, **fileHeaderKey** exists in the header in the **file=/root/a.txt** format.

- **Http Source**

  An HTTP source receives data from an external HTTP client and sends the data to the configured channels. Common configurations are as follows:

  Table 7-12 Common configurations of an HTTP source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	http	Specifies the type of the http source, which must be set to http.
bind	-	Specifies the listening host name/IP address.
port	-	Specifies the bound listening port. Ensure that this port is not occupied.

Parameter	Default Value	Description
handler	org.apache.flume.source.http.JSONHandler	Specifies the message parsing method of an HTTP request. Two formats are supported: JSON (org.apache.flume.source.http.JSONHandler) and BLOB (org.apache.flume.sink.solr.morphline.BlobHandler).
handler.*	-	Specifies handler parameters.
exclude-protocols	SSLv3	Specifies the excluded protocols. The entered protocols must be separated by spaces. The default value is **SSLv3**.
include-cipher-suites	-	Specifies the included protocols. The entered protocols must be separated by spaces. If this parameter is left empty, all protocols are supported by default.
enableSSL	false	Specifies whether SSL is enabled in HTTP. If this parameter is set to **true**, **keystore** and **keystore-password** must be specified.
keystore-type	JKS	Specifies the keystore type, which can be **JKS** or **PKCS12**.
keystore	-	Specifies the keystore path set after SSL is enabled in HTTP.
keystorePassword	-	Specifies the keystore password set after SSL is enabled in HTTP.

- **Thrift Source**

  Thrift Source monitors the thrift port, receives data from the external Thrift clients, and puts the data into the configured channel. Common configurations are as follows:

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured.
type	thrift	Specifies the type of the thrift source, which must be set to **thrift**.
bind	-	Specifies the listening host name/IP address.

Parameter	Default Value	Description
port	-	Specifies the bound listening port. Ensure that this port is not occupied.
threads	-	Specifies the maximum number of worker threads that can be run.
kerberos	false	Specifies whether Kerberos authentication is enabled.
agent-keytab	-	Specifies the address of the keytab file used by the server. The machine-machine account must be used. You are advised to use **flume/conf/flume_server.keytab** in the Flume service installation directory.
agent-principal	-	Specifies the principal of the security user used by the server. The principal must be a machine-machine account. You are advised to use the default user of Flume: flume_server/hadoop.*<system domain name>*@*<system domain name>* **NOTE** **flume_server/hadoop.**<*system domain name*> is the username. All letters in the system domain name contained in the username are lowercase letters. For example, **Local Domain** is set to **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, and the username is **flume_server/hadoop.9427068f-6efa-4833-b43e-60cb641e5b6c.com**.
compression-type	none	Specifies the message compression format, which can be set to **none** or **deflate**. **none** indicates that data is not compressed, while **deflate** indicates that data is compressed.
ssl	false	Specifies whether to use SSL encryption. If this parameter is set to **true**, **keystore** and **keystore-password** must be specified.
keystore-type	JKS	Specifies the keystore type set after SSL is enabled.
keystore	-	Specifies the keystore file path set after SSL is enabled. This parameter is mandatory if SSL is enabled.
keystore-password	-	Specifies the keystore password set after SSL is enabled. This parameter is mandatory if SSL is enabled.

Parameter	Default Value	Description
truststore-type	JKS	Specifies the Java trust store type, which can be set to **JKS** or **PKCS12**. **NOTE** Different passwords are used to protect the key store and private key of **JKS**, while the same password is used to protect the key store and private key of **PKCS12**.
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.

Common Channel Configurations

- **Memory Channel**

  A memory channel uses memory as the cache. Events are stored in memory queues. Common configurations are as follows:

  Table 7-13 Common configurations of a memory channel

Parameter	Default Value	Description
type	-	Specifies the type of the memory channel, which must be set to **memory**.
capacity	10000	Specifies the maximum number of events cached in a channel.
transactionCapacity	1000	Specifies the maximum number of events accessed each time. **NOTE** • The parameter value must be greater than the batchSize of the source and sink. • The value of **transactionCapacity** must be less than or equal to that of **capacity**.
channelfullcount	10	Specifies the channel full count. When the count reaches the threshold, an alarm is reported.

Parameter	Default Value	Description
keep-alive	3	Specifies the waiting time of the Put and Take threads when the transaction or channel cache is full. Unit: second
byteCapacity	80% of the maximum JVM memory	Specifies the total bytes of all event bodies in a channel. The default value is the 80% of the maximum JVM memory (indicated by **-Xmx**). Unit: bytes
byteCapacityBufferPercentage	20	Specifies the percentage of bytes in a channel (%).

- **File Channel**

  A file channel uses local disks as the cache. Events are stored in the folder specified by **dataDirs**. Common configurations are as follows:

  Table 7-14 Common configurations of a file channel

Parameter	Default Value	Description
type	-	Specifies the type of the file channel, which must be set to **file**.
checkpointDir	${BIGDATA_DATA_HOME}/hadoop/data1~N/flume/checkpoint **NOTE** This path is changed with the custom data path.	Specifies the checkpoint storage directory.
dataDirs	${BIGDATA_DATA_HOME}/hadoop/data1~N/flume/data **NOTE** This path is changed with the custom data path.	Specifies the data cache directory. Multiple directories can be configured to improve performance. The directories are separated by commas (,).
maxFileSize	2146435071	Specifies the maximum size of a single cache file, expressed in bytes.

Parameter	Default Value	Description
minimumRequiredSpace	524288000	Specifies the minimum idle space in the cache, expressed in bytes.
capacity	1000000	Specifies the maximum number of events cached in a channel.
transactionCapacity	10000	Specifies the maximum number of events accessed each time. **NOTE** • The parameter value must be greater than the batchSize of the source and sink. • The value of **transactionCapacity** must be less than or equal to that of **capacity**.
channelfullcount	10	Specifies the channel full count. When the count reaches the threshold, an alarm is reported.
useDualCheckpoints	false	Specifies the backup checkpoint. If this parameter is set to **true**, the **backupCheckpointDir** parameter value must be set.
backupCheckpointDir	-	Specifies the path of the backup checkpoint.
checkpointInterval	30000	Specifies the check interval, expressed in seconds.
keep-alive	3	Specifies the waiting time of the Put and Take threads when the transaction or channel cache is full. Unit: second
use-log-replay-v1	false	Specifies whether to enable the old reply logic.

Parameter	Default Value	Description
use-fast-replay	false	Specifies whether to enable the queue reply.
checkpointOnClose	true	Specifies that whether a checkpoint is created when a channel is disabled.

- **Memory File Channel**

  A memory file channel uses both memory and local disks as its cache and supports message persistence. It provides similar performance as a memory channel and better performance than a file channel. This channel is currently experimental and not recommended for use in production. The following table describes common configuration items: Common configurations are as follows:

  Table 7-15 Common configurations of a memory file channel

Parameter	Default Value	Description
type	org.apache.flume.channel.MemoryFileChannel	Specifies the type of the memory file channel, which must be set to **org.apache.flume.channel.MemoryFileChannel**.
capacity	50000	Specifies the maximum number of events cached in a channel.
transactionCapacity	5000	Specifies the maximum number of events processed by a transaction. **NOTE** • The parameter value must be greater than the batchSize of the source and sink. • The value of **transactionCapacity** must be less than or equal to that of **capacity**.

Parameter	Default Value	Description
subqueueByteCapacity	20971520	Specifies the maximum size of events that can be stored in a subqueue, expressed in bytes. A memory file channel uses both queues and subqueues to cache data. Events are stored in a subqueue, and subqueues are stored in a queue. **subqueueCapacity** and **subqueueInterval** determine the size of events that can be stored in a subqueue. **subqueueCapacity** specifies the capacity of a subqueue, and **subqueueInterval** specifies the duration that a subqueue can store events. Events in a subqueue are sent to the destination only after the subqueue reaches the upper limit of **subqueueCapacity** or **subqueueInterval**. **NOTE** The value of **subqueueByteCapacity** must be greater than the number of events specified by **batchSize**.
subqueueInterval	2000	Specifies the maximum duration that a subqueue can store events, expressed in milliseconds.
keep-alive	3	Specifies the waiting time of the Put and Take threads when the transaction or channel cache is full. Unit: second
dataDir	-	Specifies the cache directory for local files.
byteCapacity	80% of the maximum JVM memory	Specifies the channel cache capacity. Unit: bytes
compression-type	None	Specifies the message compression format, which can be set to **none** or **deflate**. **none** indicates that data is not compressed, while **deflate** indicates that data is compressed.
channelfullcount	10	Specifies the channel full count. When the count reaches the threshold, an alarm is reported.

The following is a configuration example of a memory file channel:

```
server.channels.c1.type = org.apache.flume.channel.MemoryFileChannel
server.channels.c1.dataDir = /opt/flume/mfdata
server.channels.c1.subqueueByteCapacity = 20971520
server.channels.c1.subqueueInterval=2000
server.channels.c1.capacity = 500000
server.channels.c1.transactionCapacity = 40000
```

- **Kafka Channel**

  A Kafka channel uses a Kafka cluster as the cache. Kafka provides high availability and multiple copies to prevent data from being immediately consumed by sinks when Flume or Kafka Broker crashes.

  Table 7-16 Common configurations of a Kafka channel

Parameter	Default Value	Description
type	-	Specifies the type of the Kafka channel, which must be set to **org.apache.flume.channel.kafka.KafkaChannel**.
kafka.bootstrap.servers	-	Specifies the bootstrap address port list of Kafka. If Kafka has been installed in the cluster and the configuration has been synchronized to the server, you do not need to set this parameter on the server. The default value is the list of all brokers in the Kafka cluster. This parameter must be configured on the client. Use commas (,) to separate multiple values of *IP address:Port number*. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).

Parameter	Default Value	Description
kafka.topic	flume-channel	Specifies the Kafka topic used by the channel to cache data.
kafka.consumer.group.id	flume	Specifies the data group ID obtained from Kafka. This parameter cannot be left blank.
parseAsFlumeEvent	true	Specifies whether data is parsed into Flume events.
migrateZookeeperOffsets	true	Specifies whether to search for offsets in ZooKeeper and submit them to Kafka when there is no offset in Kafka.
kafka.consumer.auto.offset.reset	latest	Specifies where to consume if there is no offset record, which can be set to **earliest**, **latest**, or **none**. **earliest** indicates that the offset is reset to the initial point, **latest** indicates that the offset is set to the latest position, and **none** indicates that an exception is thrown if there is no offset.

Parameter	Default Value	Description
kafka.producer.security.protocol	SASL_PLAINTEXT	Specifies the Kafka producer security protocol. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT). **NOTE** If the parameter is not displayed, click **+** in the lower left corner of the dialog box to display all parameters.
kafka.consumer.security.protocol	SASL_PLAINTEXT	Specifies the Kafka consumer security protocol. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).
pollTimeout	500	Specifies the maximum timeout interval for the consumer to invoke the poll function. Unit: milliseconds
ignoreLongMessage	false	Specifies whether to discard oversized messages.
messageMaxLength	1000012	Specifies the maximum length of a message written by Flume to Kafka.

Common Sink Configurations

- **HDFS Sink**

  An HDFS sink writes data into HDFS. Common configurations are as follows:

Table 7-17 Common configurations of an HDFS sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink.
type	hdfs	Specifies the type of the hdfs sink, which must be set to **hdfs**.
hdfs.path	-	Specifies the data storage path in HDFS. The value must start with **hdfs://hacluster/**.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second
hdfs.inUseSuffix	.tmp	Specifies the suffix of the HDFS file to which data is being written.
hdfs.rollInterval	30	Specifies the interval for file rolling, expressed in seconds. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter.
hdfs.rollSize	1024	Specifies the size for file rolling, expressed in bytes. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter.
hdfs.rollCount	10	Specifies the number of events for file rolling. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter. **NOTE** Parameters **rollInterval**, **rollSize**, and **rollCount** can be configured at the same time. The parameter meeting the requirements takes precedence for compression.
hdfs.idleTimeout	0	Specifies the timeout interval for closing idle files automatically, expressed in seconds.
hdfs.batchSize	1000	Specifies the number of events written into HDFS in batches.
hdfs.kerberosPrincipal	-	Specifies the Kerberos principal of HDFS authentication. This parameter is mandatory in a secure mode, but not required in a common mode.

Parameter	Default Value	Description
hdfs.kerberosKeytab	-	Specifies the Kerberos keytab of HDFS authentication. This parameter is not required in a common mode, but in a secure mode, the Flume running user must have the permission to access **keyTab** path in the **jaas.cof** file.
hdfs.fileCloseByEndEvent	true	Specifies whether to close the HDFS file when the last event of the source file is received.
hdfs.batchCallTimeout	-	Specifies the timeout control duration when events are written into HDFS in batches. Unit: milliseconds If this parameter is not specified, the timeout duration is controlled when each event is written into HDFS. When the value of **hdfs.batchSize** is greater than 0, configure this parameter to improve the performance of writing data into HDFS. **NOTE** The value of **hdfs.batchCallTimeout** depends on **hdfs.batchSize**. A greater **hdfs.batchSize** requires a larger **hdfs.batchCallTimeout**. If the value of **hdfs.batchCallTimeout** is too small, writing events to HDFS may fail.
serializer.appendNewline	true	Specifies whether to add a line feed character (**\n**) after an event is written to HDFS. If a line feed character is added, the data volume counters used by the line feed character will not be calculated by HDFS sinks.
hdfs.filePrefix	over_%{basename}	Specifies the file name prefix after data is written to HDFS.
hdfs.fileSuffix	-	Specifies the file name suffix after data is written to HDFS.
hdfs.inUsePrefix	-	Specifies the prefix of the HDFS file to which data is being written.

Parameter	Default Value	Description
hdfs.fileType	DataStream	Specifies the HDFS file format, which can be set to **SequenceFile**, **DataStream**, or **CompressedStream**. **NOTE** If the parameter is set to **SequenceFile** or **DataStream**, output files are not compressed, and the **codeC** parameter cannot be configured. However, if the parameter is set to **CompressedStream**, the output files are compressed, and the **codeC** parameter must be configured together.
hdfs.codeC	-	Specifies the file compression format, which can be set to **gzip**, **bzip2**, **lzo**, **lzop**, or **snappy**.
hdfs.maxOpenFiles	5000	Specifies the maximum number of HDFS files that can be opened. If the number of opened files reaches this value, the earliest opened files are closed.
hdfs.writeFormat	Writable	Specifies the file write format, which can be set to **Writable** or **Text**.
hdfs.callTimeout	10000	Specifies the timeout control duration each time events are written into HDFS, expressed in milliseconds.
hdfs.threadsPoolSize	-	Specifies the number of threads used by each HDFS sink for HDFS I/O operations.
hdfs.rollTimerPoolSize	-	Specifies the number of threads used by each HDFS sink to schedule the scheduled file rolling.
hdfs.round	false	Specifies whether to round off the timestamp value. If this parameter is set to true, all time-based escape sequences (except %t) are affected.
hdfs.roundUnit	second	Specifies the unit of the timestamp value that has been rounded off, which can be set to **second**, **minute**, or **hour**.
hdfs.useLocalTimeStamp	true	Specifies whether to enable the local timestamp. The recommended parameter value is **true**.

Parameter	Default Value	Description
hdfs.closeTries	0	Specifies the maximum attempts for the **hdfs sink** to stop renaming a file. If the parameter is set to the default value **0**, the sink does not stop renaming the file until the file is successfully renamed.
hdfs.retryInterval	180	Specifies the interval of request for closing the HDFS file, expressed in seconds. **NOTE** For each closing request, there are multiple RPCs working on the NameNode back and forth, which may make the NameNode overloaded if the parameter value is too small. Also, when the parameter is set to **0**, the Sink will not attempt to close the file, but opens the file or uses **.tmp** as the file name extension, if the first closing attempt fails.
hdfs.failcount	10	Specifies the number of times that data fails to be written to HDFS. If the number of times that the sink fails to write data to HDFS exceeds the parameter value, an alarm indicating abnormal data transmission is reported.

- **Avro Sink**

  An Avro sink converts events into Avro events and sends them to the monitoring ports of the hosts. Common configurations are as follows:

  Table 7-18 Common configurations of an Avro sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink.
type	-	Specifies the type of the avro sink, which must be set to **avro**.
hostname	-	Specifies the bound host name or IP address.
port	-	Specifies the bound listening port. Ensure that this port is not occupied.

Parameter	Default Value	Description
batch-size	1000	Specifies the number of events sent in a batch.
client.type	DEFAULT	Specifies the client instance type. Set this parameter based on the communication protocol used by the configured model. The options are as follows: • **DEFAULT**: The client instance of the AvroRPC type is returned. • **OTHER**: NULL is returned. • **THRIFT**: The client instance of the Thrift RPC type is returned. • **DEFAULT_LOADBALANCING**: The client instance of the LoadBalancing RPC type is returned. • **DEFAULT_FAILOVER**: The client instance of the Failover RPC type is returned.
ssl	false	Specifies whether to use SSL encryption. If this parameter is set to **true**, **keystore** and **keystore-password** must be specified.
truststore-type	JKS	Specifies the Java trust store type, which can be set to **JKS** or **PKCS12**. **NOTE** Different passwords are used to protect the key store and private key of **JKS**, while the same password is used to protect the key store and private key of **PKCS12**.

Parameter	Default Value	Description
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.
keystore-type	JKS	Specifies the keystore type set after SSL is enabled.
keystore	-	Specifies the keystore file path set after SSL is enabled. This parameter is mandatory if SSL is enabled.
keystore-password	-	Specifies the keystore password after SSL is enabled. This parameter is mandatory if SSL is enabled.
connect-timeout	20000	Specifies the timeout for the first connection, expressed in milliseconds.
request-timeout	20000	Specifies the maximum timeout for a request after the first request, expressed in milliseconds.
reset-connection-interval	0	Specifies the interval between a connection failure and a second connection, expressed in seconds. If the parameter is set to **0**, the system continuously attempts to perform a connection.

Parameter	Default Value	Description
compression-type	none	Specifies the compression type of the batch data, which can be set to **none** or **deflate**. **none** indicates that data is not compressed, while **deflate** indicates that data is compressed. This parameter value must be the same as that of the AvroSource compression-type.
compression-level	6	Specifies the compression level of batch data, which can be set to **1** to **9**. A larger value indicates a higher compression rate.
exclude-protocols	SSLv3	Specifies the excluded protocols. The entered protocols must be separated by spaces. The default value is **SSLv3**.

- **HBase Sink**

  An HBase sink writes data into HBase. Common configurations are as follows:

  Table 7-19 Common configurations of an HBase sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink.
type	-	Specifies the type of the HBase sink, which must be set to **hbase**.
table	-	Specifies the HBase table name.
columnFamily	-	Specifies the HBase column family.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second

Parameter	Default Value	Description
batchSize	1000	Specifies the number of events written into HBase in batches.
kerberosPrincipal	-	Specifies the Kerberos principal of HBase authentication. This parameter is mandatory in a secure mode, but not required in a common mode.
kerberosKeytab	-	Specifies the Kerberos keytab of HBase authentication. This parameter is not required in a common mode, but in a secure mode, the Flume running user must have the permission to access **keyTab** path in the **jaas.cof** file.
coalesceIncrements	true	Specifies whether to perform multiple operations on the same hbase cell in a same processing batch. Setting this parameter to **true** improves performance.

- **Kafka Sink**

  A Kafka sink writes data into Kafka. Common configurations are as follows:

  Table 7-20 Common configurations of a Kafka sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink.
type	-	Specifies the type of the kafka sink, which must be set to **org.apache.flume.sink.kafka.KafkaSink**.

Parameter	Default Value	Description
kafka.bootstrap.servers	-	Specifies the bootstrap address port list of Kafka. If Kafka has been installed in the cluster and the configuration has been synchronized to the server, you do not need to set this parameter on the server. The default value is the list of all brokers in the Kafka cluster. The client must be configured with this parameter. If there are multiple values, use commas (,) to separate the values. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second
kafka.producer.acks	1	Successful write is determined by the number of received acknowledgement messages about replicas. The value **0** indicates that no confirm message needs to be received, the value **1** indicates that the system is only waiting for only the acknowledgement information from a leader, and the value **-1** indicates that the system is waiting for the acknowledgement messages of all replicas. If this parameter is set to **-1**, data loss can be avoided in some leader failure scenarios.
kafka.topic	-	Specifies the topic to which data is written. This parameter is mandatory.
allowTopicOverride	false	Specifies whether to replace the topic configured in **kafka.topic** with the topic saved in Event Header.
flumeBatchSize	1000	Specifies the number of events written into Kafka in batches.

Parameter	Default Value	Description
kafka.security.protocol	SASL_PLAINTEXT	Specifies the Kafka security protocol. The parameter value must be set to PLAINTEXT in a common cluster. The rules for matching ports and security protocols must be as follows: port 21007 matches the security mode (SASL_PLAINTEXT), and port 9092 matches the common mode (PLAINTEXT).
ignoreLongMessage	false	Specifies whether to discard oversized messages.
messageMaxLength	1000012	Specifies the maximum length of a message written by Flume to Kafka.
defaultPartitionId	-	Specifies the ID of the Kafka partition to which the events of a channel are transferred. The **partitionIdHeader** value overwrites this parameter value. By default, if this parameter is left blank, events will be distributed by the Kafka Producer's partitioner (by a specified key or a partitioner customized by **kafka.partitioner.class**).
partitionIdHeader	-	When you set this parameter, the sink will take the value of the field named using the value of this property from the event header and send the message to the specified partition of the topic. If the value does not have a valid partition, **EventDeliveryException** is thrown. If the header value already exists, this setting overwrites the **defaultPartitionId** parameter.
Other Kafka Producer Properties	-	Specifies other Kafka configurations. This parameter can be set to any production configuration supported by Kafka, and the **.kafka** prefix must be added to the configuration.

- **Thrift Sink**

  A Thrift sink converts events to Thrift events and sends them to the monitoring port of the configured host. Common configurations are as follows:

Table 7-21 Common configurations of a Thrift sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink.
type	thrift	Specifies the type of the thrift sink, which must be set to **thrift**.
hostname	-	Specifies the bound host name or IP address.
port	-	Specifies the bound listening port. Ensure that this port is not occupied.
batch-size	1000	Specifies the number of events sent in a batch.
connect-timeout	20000	Specifies the timeout for the first connection, expressed in milliseconds.
request-timeout	20000	Specifies the maximum timeout for a request after the first request, expressed in milliseconds.
kerberos	false	Specifies whether Kerberos authentication is enabled.
client-keytab	-	Specifies the path of the client **keytab** file. The Flume running user must have the access permission on the authentication file.
client-principal	-	Specifies the principal of the security user used by the client.
server-principal	-	Specifies the principal of the security user used by the server.

Parameter	Default Value	Description
compression-type	none	Specifies the compression type of data sent by Flume, which can be set to **none** or **deflate**. **none** indicates that data is not compressed, while **deflate** indicates that data is compressed.
maxConnections	5	Specifies the maximum size of the connection pool for Flume to send data.
ssl	false	Specifies whether to use SSL encryption.
truststore-type	JKS	Specifies the Java trust store type.
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.
reset-connection-interval	0	Specifies the interval between a connection failure and a second connection, expressed in seconds. If the parameter is set to **0**, the system continuously attempts to perform a connection.

Precautions

- What are the reliability measures of Flume?
  - Use the transaction mechanisms between Source and Channel as well as between Channel and Sink.
  - Sink Processor supports failover and load balancing. The following is an example of load balancing:

```
server.sinkgroups=g1
server.sinkgroups.g1.sinks=k1 k2
server.sinkgroups.g1.processor.type=load_balance
server.sinkgroups.g1.processor.backoff=true
server.sinkgroups.g1.processor.selector=random
```

- What are the precautions for the aggregation and cascading of multiple Flume agents?

- Avro or Thrift protocol can be used for cascading.
- When the aggregation end contains multiple nodes, evenly distribute the agents and do not aggregate all agents on a single node.

7.3 Installing the Flume Client

To use Flume to collect logs, you must install the Flume client on a log host. You can create an ECS and install the Flume client on it.

Prerequisites

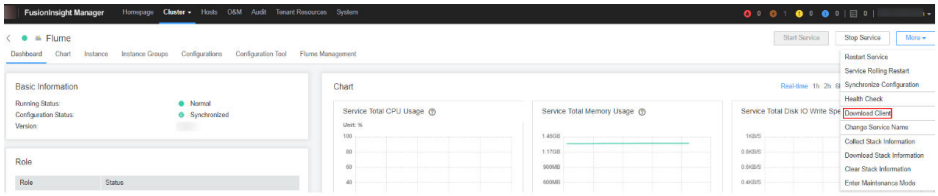
- A cluster with the Flume component has been created.
- The log host is in the same VPC and subnet with the MRS cluster.
- You have obtained the username and password for logging in to the log host.
- The installation directory is automatically created if it does not exist. If it exists, the directory must be left blank. The directory path cannot contain any space.

Installing the Flume Client

Step 1 Obtain the software package.

Log in to the FusionInsight Manager. Choose **Cluster** > *Name of the target cluster* > **Services** > **Flume**. On the Flume service page that is displayed, choose **More** > **Download Client** in the upper right corner and set **Select Client Type** to **Complete Client** to download the Flume service client file.

The file name of the client is **FusionInsight_Cluster_**<*Cluster ID*>**_Flume_Client.tar**. This section takes the client file **FusionInsight_Cluster_1_Flume_Client.tar** as an example.



Step 2 Upload the software package.

Upload the software package to a directory, for example, **/opt/client**, on the node where the Flume client is to be installed as user **user**.

NOTE

user is the user who installs and runs the Flume client.

Step 3 Decompress the software package.

Log in to the node where the Flume service client is to be installed as user **user**. Go to the directory where the installation package is installed, for example, **/opt/client**, and run the following command to decompress the installation package to the current directory:

cd /opt/client

tar -xvf FusionInsight_Cluster_1_Flume_Client.tar

Step 4 Verify the software package.

Run the **sha256sum -c** command to verify the decompressed file. If **OK** is returned, the verification is successful. Example:

sha256sum -c FusionInsight_Cluster_1_Flume_ClientConfig.tar.sha256

```
FusionInsight_Cluster_1_Flume_ClientConfig.tar: OK
```

Step 5 Decompress the package.

tar -xvf FusionInsight_Cluster_1_Flume_ClientConfig.tar

Step 6 To install the Flume client on a node outside the cluster, perform the following steps to configure the installation environment. Skip this step if you install Flume client on a node in the cluster.

1. Run the following command to install the client running environment to a new directory, for example, **/opt/Flumeenv**. A directory is automatically generated during the client installation.

   sh /opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/install.sh /opt/Flumeenv

   If the following information is displayed, the client running environment is successfully installed:

   ```
   Components client installation is complete.
   ```

2. Run the following command to set environment variables:

   source /opt/Flumeenv/bigdata_env

Step 7 Check whether the number of clients is **1**.

- If yes, use the independent installation mode and go to **Step 8**. The installation is complete.
- If no, use the batch installation mode and go to **Step 9**.

Step 8 Run the following command in the Flume client installation directory to install the client to a specified directory (for example, **opt/FlumeClient**): After the client is installed successfully, the installation is complete.

cd /opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FlumeClient

./install.sh -d *\/opt/FlumeClient* **-f** *MonitorServerService IP address or host name of the role* **-c** *User service configuration filePath for storing properties.properties* **-s** *CPU threshold* **-l /var/log/Bigdata -e** *FlumeServer service IP address or host name* **-n** *Flume*

NOTE

- **-d**: Flume client installation path
- (Optional) **-f**: IP addresses or host names of two MonitorServer roles. The IP addresses or host names are separated by commas (,). If this parameter is not configured, the Flume client does not send alarm information to MonitorServer and information about the client cannot be viewed on the FusionInsight Manager GUI.
- (Optional) **-c**: Service configuration file, which needs to be generated on the configuration tool page of the Flume server based on your service requirements by referring to **Flume Service Configuration Guide**. Upload the file to any directory on the node where the client is to be installed. If this parameter is not specified during the installation, you can upload the generated service configuration file **properties.properties** to the **/opt/FlumeClient/fusioninsight-flume-1.9.0/conf** directory after the installation.
- (Optional) **-s**: cgroup threshold. The value is an integer ranging from 1 to 100 x *N*. *N* indicates the number of CPU cores. The default threshold is **-1**, indicating that the processes added to the cgroup are not restricted by the CPU usage.
- (Optional) **-l**: Log path. The default value is **/var/log/Bigdata**. The user **user** must have the write permission on the directory. When the client is installed for the first time, a subdirectory named **flume-client** is generated. After the installation, subdirectories named **flume-client-***n* will be generated in sequence. The letter *n* indicates a sequence number, which starts from 1 in ascending order. In the **/conf/** directory of the Flume client installation directory, modify the **ENV_VARS** file and search for the **FLUME_LOG_DIR** attribute to view the client log path.
- (Optional) **-e**: Service IP address or host name of FlumeServer, which is used to receive statistics for the monitoring indicator reported by the client.
- (Optional) **-n**: Name of the Flume client. You can choose **Cluster** > *Name of the desired cluster* > **Service** > **Flume** > **Flume Management** on FusionInsight Manager to view the client name on the corresponding node.
- If the following error message is displayed, run the **export JAVA_HOME=*JDK path*** command. You can run the **echo $JAVA_HOME** command to query the JDK path.
  JAVA_HOME is null in current user,please install the JDK and set the JAVA_HOME
- When installing a cross-platform client in a cluster, go to the **/opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FusionInsight-Flume-1.9.0.tar.gz** directory to install the Flume client.

Step 9 Go to the directory for installing clients in batches.

cd /opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FlumeClient/batch_install

NOTE

When installing a cross-platform client in a cluster, go to the **/opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FusionInsight-Flume-1.9.0.tar.gz** directory to install the Flume client.

Step 10 Configure the **host_info.cfg** file. The format of the configuration file is as follows:

host_ip="",user="",password="",install_path="",flume_config_file="",monitor_server_ip="",log_path="",flume_server_ip="",cgroup_threshold="",client_name=""

NOTE

- (Mandatory) *host_ip*: IP address of the node where the Flume client is to be installed.
- (Mandatory) *user*: User name for logging in to the node where the Flume client is to be installed remotely. The user must have the crontab access permission. You can use **echo** *Username* **> /etc/cron.allow** to grant the user the permission.
- (Mandatory) *password*: Password for logging in to the Flume client to be installed remotely. There can be security risks if a configuration file contains the authentication password. You are advised to delete the configuration file or use other secure methods to keep the password.
- (Mandatory) **install_path**: Installation path of the Flume client.
- (Optional) **flume_config_file**: Configuration file for Flume running. You are advised to specify this configuration file during Flume installation. If you do not set this parameter, retain the value "" and do not delete the parameter.
- (Optional) **monitor_server_ip**: Service IP address of the Flume MonitorServer in the cluster. You can check the IP address on FusionInsight Manager. You can select either of the two IP addresses. If the IP address is not configured, the client does not send alarm information to the cluster in the scenario where a process is faulty.
- (Optional) **log_path**: Path for storing Flume run logs. If this parameter is not set, logs are recorded in **/var/log/Bigdata/flume-client**-*Index* by default. Index value: If there is only one client in this path, the value is 1. If there are multiple clients, the index value is incremented by 1.
- (Optional) **flume_server_ip**: Service IP address of the Flume server. The indicator information of the client is reported to the cluster from this node. The indicator information about the client can be displayed on the web client. If the indicator information is not configured, the client does not display the indicator information.
- (Optional) **cgroup_threshold**: cgroup threshold. The value is an integer ranging from 1 to 100 x *N*. *N* indicates the number of CPU cores. The default threshold is **-1**, indicating that the processes added to the cgroup are not restricted by the CPU usage.
- (Optional) **client_name**: Client name. The client name is displayed on the client monitoring page. If the client name is not configured, the client name is empty.
- If multiple nodes need to be added, the format is as follows:

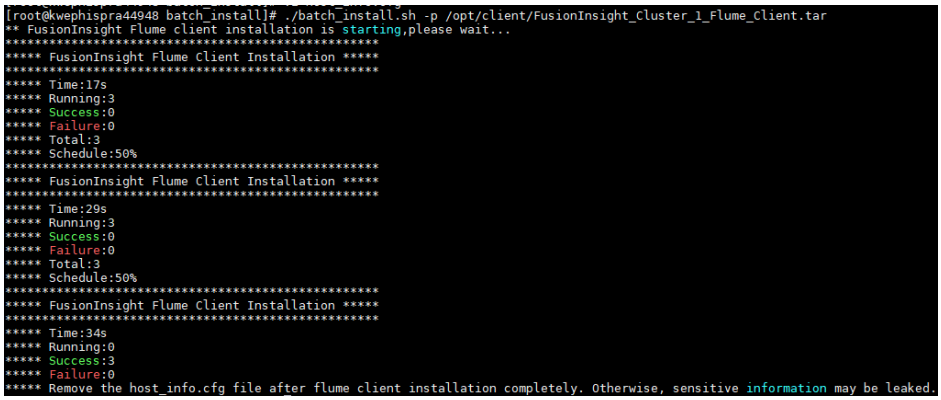
  host_ip="ip1",user="user1",password="******",install_path="/tmp/flumeclient",flume_config_file="",monitor_server_ip="xxx.xxx.xxx.xxx",log_path="",flume_server_ip="xxx.xxx.xxx.xxx",cgroup_threshold="",client_name="ip1-client-1"

  host_ip="ip2",user="user1",password="******",install_path="/tmp/flumeclient",flume_config_file="",monitor_server_ip="xxx.xxx.xxx.xxx",log_path="",flume_server_ip="xxx.xxx.xxx.xxx",cgroup_threshold="",client_name="ip2-client-1"

  host_ip="ip3",user="user1",password="******",install_path="/tmp/flumeclient",flume_config_file="",monitor_server_ip="xxx.xxx.xxx.xxx",log_path="",flume_server_ip="xxx.xxx.xxx.xxx",cgroup_threshold="",client_name="ip3-client-1"

Step 11 Run the following command to install the Flume client in batches. The installation is complete, as shown in the following figure.

./batch_install.sh -p /opt/client/FusionInsight_Cluster_1_Flume_Client.tar



Step 12 Delete the password information from the **host_info.cfg** file.

After the batch installation is complete, delete the password information from the **host_info.cfg** file immediately. Otherwise, the password may be disclosed.

----End

Flume Client Cgroup Usage Guide

This section describes how to join and log out of a cgroup, query the cgroup status, and change the cgroup CPU threshold.

- **Join Cgroup**

  Assume that the Flume client installation path is **/opt/FlumeClient**, and the cgroup CPU threshold is 50%. Run the following command to join a cgroup:

  cd /opt/FlumeClient/fusioninsight-flume-1.9.0/bin

  ./flume-manage.sh cgroup join 50

  NOTE

  - This command can be used to join a cgroup and change the cgroup CPU threshold.
  - The value of the CPU threshold of a cgroup ranges from 1 to 100 x *N*. *N* indicates the number of CPU cores.

- **Check Cgroup status**

  Assume that the Flume client installation path is **/opt/FlumeClient**. Run the following commands to query the cgroup status:

  cd /opt/FlumeClient/fusioninsight-flume-1.9.0/bin

  ./flume-manage.sh cgroup status

- **Exit Cgroup**

  Assume that the Flume client installation path is **/opt/FlumeClient**. Run the following commands to exit cgroup:

  cd /opt/FlumeClient/fusioninsight-flume-1.9.0/bin

  ./flume-manage.sh cgroup exit

NOTE

- After the client is installed, the default cgroup is automatically created. If the **-s** parameter is not configured during client installation, the default value **-1** is used. The default value indicates that the agent process is not restricted by the CPU usage.
- Joining or exiting a cgroup does not affect the agent process. Even if the agent process is not started, the joining or exiting operation can be performed successfully, and the operation will take effect after the next startup of the agent process.
- After the client is uninstalled, the cgroups created during the client installation are automatically deleted.

7.4 Quickly Using Flume to Collect Node Logs

You can use Flume to import collected log information to Kafka.

Prerequisites

- A streaming cluster that contains components such as Flume and Kafka and has Kerberos authentication enabled has been created. For details, see **Buying a Custom Cluster**.
- The streaming cluster can properly communicate with the node where logs are generated.

Using the Flume Client

NOTE

You do not need to perform **Step 2** to **Step 6** for a normal cluster.

Step 1 Install the Flume client.

Install the Flume client in a directory, for example, **/opt/Flumeclient**, on the node where logs are generated by referring to **Installing the Flume Client**. The Flume client installation directories in the following steps are only examples. Change them to the actual installation directories.

Step 2 Copy the configuration file of the authentication server from the Master1 node to the *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf** directory on the node where the Flume client is installed.

The full file path is **${BIGDATA_HOME}/FusionInsight_BASE_***XXX*/**1_***X*_KerberosClient/etc/kdc.conf**. In the preceding path, **XXX** indicates the product version number. **X** indicates a random number. Replace them based on site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 3 Check the service IP address of any node where the Flume role is deployed.

Log in to FusionInsight Manager, click **Cluster**, click **Services**, and click Flume. On the displayed page, click **Instance**. For details, see **Accessing FusionInsight Manager**. Check the service IP address of any node where the Flume role is deployed.

NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Step 4 Copy the user authentication file from this node to the *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf** directory on the Flume client node.

The full file path is **${BIGDATA_HOME}/FusionInsight_Porter_***XXX*/**install/FusionInsight-Flume-***Flume component version number*/**flume/conf/flume.keytab**.

In the preceding paths, **XXX** indicates the product version number. Change it based on the site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 5 Copy the **jaas.conf** file from this node to the **conf** directory on the Flume client node.

The full file path is **${BIGDATA_HOME}/FusionInsight_Current/1_***X*_**Flume/etc/jaas.conf**.

In the preceding path, **X** indicates a random number. Change it based on the site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 6 Log in to the Flume client node and go to the client installation directory. Run the following command to modify the file:

vi conf/jaas.conf

Change the full path of the user authentication file defined by **keyTab** to the *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf** saved in **Step 4**, and save the modification and exit.

Step 7 Run the following command to modify the **flume-env.sh** configuration file of the Flume client:

vi *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf/flume-env.sh**

Add the following information after **-XX:+UseCMSCompactAtFullCollection**:

```
-Djava.security.krb5.conf=Flume client installation directory/fusioninsight-flume-1.9.0/conf/kdc.conf -Djava.security.auth.login.config=Flume client installation directory/fusioninsight-flume-1.9.0/conf/jaas.conf -Dzookeeper.request.timeout=120000
```

Example: **"-XX:+UseCMSCompactAtFullCollection -Djava.security.krb5.conf=/opt/FlumeClient/fusioninsight-flume-***Flume component version number*/**conf/kdc.conf -Djava.security.auth.login.config=/opt/FlumeClient/fusioninsight-flume-***Flume component version number*/**conf/jaas.conf -Dzookeeper.request.timeout=120000"**

Change *Flume client installation directory* to the actual installation directory. Then save and exit.

Step 8 Run the following command to restart the Flume client:

cd *Flume client installation directory*/**fusioninsight-flume-**_Flume component version number_/**bin**

./flume-manage.sh restart

Example:

cd /opt/FlumeClient/fusioninsight-flume-_Flume component version number_/**bin**

./flume-manage.sh restart

NOTE

The Flume client will be automatically restarted after being stopped. If you do not need automatic restart, run the following command:

./flume-manage.sh stop force

If you want to restart the Flume client, run the following command:

./flume-manage.sh start force

Step 9 Configure jobs based on actual service scenarios.

- Some parameters can be configured on Manager. For details, see **Non-Encrypted Transmission** or **Encrypted Transmission**.
- Set the parameters in the **properties.properties** file. The following uses SpoolDir Source+File Channel+Kafka Sink as an example.

  Run the following command on the node where the Flume client is installed. Configure and save jobs in the Flume client configuration file **properties.properties** based on actual service requirements. For details, see **Flume Service Configuration Guide**.

  vi *Flume client installation directory*/**fusioninsight-flume-**_Flume component version number_/**conf/properties.properties**

```
################################################################################
###################
client.sources = static_log_source
client.channels = static_log_channel
client.sinks = kafka_sink
################################################################################
###################
#LOG_TO_HDFS_ONLINE_1

client.sources.static_log_source.type = spooldir
client.sources.static_log_source.spoolDir = Monitoring directory
client.sources.static_log_source.fileSuffix = .COMPLETED
client.sources.static_log_source.ignorePattern = ^$
client.sources.static_log_source.trackerDir = Metadata storage path during transmission
client.sources.static_log_source.maxBlobLength = 16384
client.sources.static_log_source.batchSize = 51200
client.sources.static_log_source.inputCharset = UTF-8
client.sources.static_log_source.deserializer = LINE
client.sources.static_log_source.selector.type = replicating
client.sources.static_log_source.fileHeaderKey = file
client.sources.static_log_source.fileHeader = false
client.sources.static_log_source.basenameHeader = true
client.sources.static_log_source.basenameHeaderKey = basename
client.sources.static_log_source.deletePolicy = never

client.channels.static_log_channel.type = file
client.channels.static_log_channel.dataDirs = Data cache path. Multiple paths, separated by commas (,), can be configured to improve performance.
client.channels.static_log_channel.checkpointDir = Checkpoint storage path
client.channels.static_log_channel.maxFileSize = 2146435071
client.channels.static_log_channel.capacity = 1000000
```

```
client.channels.static_log_channel.transactionCapacity = 612000
client.channels.static_log_channel.minimumRequiredSpace = 524288000

client.sinks.kafka_sink.type = org.apache.flume.sink.kafka.KafkaSink
client.sinks.kafka_sink.kafka.topic = Topic to which data is written, for example, flume_test
client.sinks.kafka_sink.kafka.bootstrap.servers = XXX.XXX.XXX.XXX:Kafka port number,XXX.XXX.XXX.XXX:Kafka port number,XXX.XXX.XXX.XXX:Kafka port number
client.sinks.kafka_sink.flumeBatchSize = 1000
client.sinks.kafka_sink.kafka.producer.type = sync
client.sinks.kafka_sink.kafka.security.protocol = SASL_PLAINTEXT
client.sinks.kafka_sink.kafka.kerberos.domain.name = Kafka domain name. This parameter is mandatory for a security cluster, for example, hadoop.example.com.
client.sinks.kafka_sink.requiredAcks = 0

client.sources.static_log_source.channels = static_log_channel
client.sinks.kafka_sink.channel = static_log_channel
```

NOTE

- **client.sinks.kafka_sink.kafka.topic**: Topic to which data is written. If the topic does not exist in Kafka, it is automatically created by default.
- **client.sinks.kafka_sink.kafka.bootstrap.servers**: List of Kafka Brokers, which are separated by commas (,). By default, the port is **21007** for a security cluster and **9092** for a normal cluster.
- **client.sinks.kafka_sink.kafka.security.protocol**: The value is **SASL_PLAINTEXT** for a security cluster and **PLAINTEXT** for a normal cluster.
- **client.sinks.kafka_sink.kafka.kerberos.domain.name**:

  You do not need to set this parameter for a normal cluster. For a security cluster, the value of this parameter is the value of **kerberos.domain.name** in the Kafka cluster.

  In the preceding paths, **X** indicates a random number. Change it based on site requirements. The file must be saved by the user who installs the Flume client, for example, user **root**.

Step 10 After the parameters are set and saved, the Flume client automatically loads the content configured in **properties.properties**. When new log files are generated by spoolDir, the files are sent to Kafka producers and can be consumed by Kafka consumers.

----End

7.5 Configuring a Non-Encrypted Flume Data Collection Task

7.5.1 Generating Configuration Files for the Flume Server and Client

This section describes how to configure Flume server and client parameters after the cluster and the Flume service are installed to ensure proper running of the service.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**.

Generating Flume Configuration Files

Step 1 Install the Flume client.

Step 2 Configure the client parameters of the Flume role.

1. Use the Flume configuration tool on FusionInsight Manager to configure the Flume role client parameters and generate a configuration file.

   a. Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Flume** > **Configuration Tool**.

   Figure 7-2 Clicking Configuration Tool

   b. Set **Agent Name** to **client**. Select and drag the source, channel, and sink to be used to the GUI on the right, and connect them.

   For example, use SpoolDir Source, File Channel, and Avro Sink, as shown in **Figure 7-3**.

   Figure 7-3 Example for the Flume configuration tool

   
   c. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-22** based on the actual environment.

   NOTE

   - If the client parameters of the Flume role have been configured, you can obtain the existing client parameter configuration file from *client installation directory*/**fusioninsight-flume-1.9.0/conf/properties.properties** to ensure that the configuration is in concordance with the previous. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Flume** > **Configuration** > **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
   - It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-22 Parameters to be modified for the Flume role client

Parameter	Description	Example Value
ssl	Specifies whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ■ **true** indicates that the function is enabled. ■ **false** indicates that the function is not enabled.	false

d. Click **Export** to save the **properties.properties** configuration file to the local server.

2. Upload the **properties.properties** file to **flume/conf/** under the installation directory of the Flume client.

Step 3 Configure the server parameters of the Flume role and upload the configuration file to the cluster.

1. Use the Flume configuration tool on the FusionInsight Manager portal to configure the server parameters and generate the configuration file.

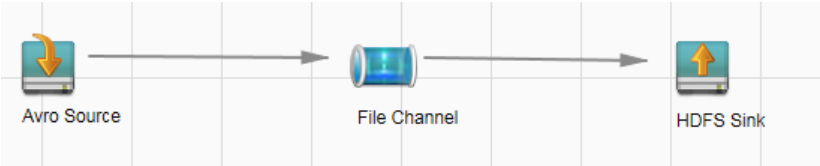
a. Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Flume** > **Configuration Tool**.

Figure 7-4 Clicking Configuration Tool

b. Set **Agent Name** to **server**. Select and drag the source, channel, and sink to be used to the GUI on the right, and connect them.

For example, use Avro Source, File Channel, and HDFS Sink, as shown in **Figure 7-5**.

Figure 7-5 Example for the Flume configuration tool



c. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-23** based on the actual environment.

NOTE

- If the server parameters of the Flume role have been configured, you can choose **Cluster** > **Services** > **Flume** > **Instance** on FusionInsight Manager. Then select the corresponding Flume role instance and click the **Download** button behind the **flume.config.file** parameter on the **Instance Configurations** page to obtain the existing server parameter configuration file. Choose **Cluster** > **Service** > **Flume** > **Configurations** > **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.
- A unique checkpoint directory needs to be configured for each File Channel.

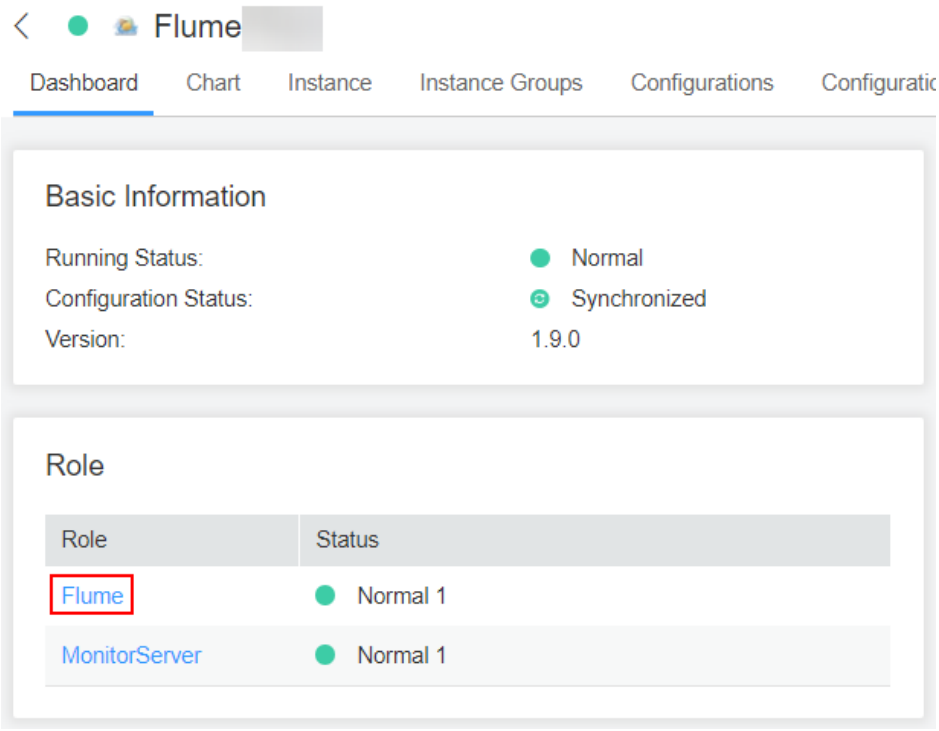
Table 7-23 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
ssl	Specifies whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ■ **true** indicates that the function is enabled. ■ **false** indicates that the function is not enabled.	false

d. Click **Export** to save the **properties.properties** configuration file to the local server.

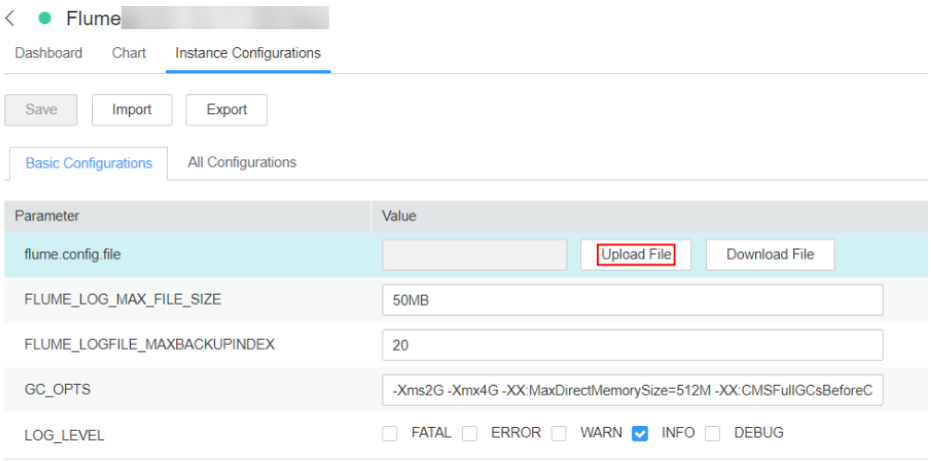
2. Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded.

Figure 7-6 Clicking the Flume role



3. On the **Instance Configurations** page, click **Upload File** next to **flume.config.file** and select the **properties.properties** file.

Figure 7-7 Uploading a file



NOTE

- An independent server configuration file can be uploaded to each Flume instance.
- This step is required for updating the configuration file. Modifying the configuration file on the background is an improper operation because the modification will be overwritten after configuration synchronization.

4. Click **Save**, and then click **OK**.
5. Click **Finish**.

----End

7.5.2 Using Flume Server to Collect Static Logs from Local Host to Kafka

This section describes how to use the Flume server to collect static logs from a local host and save them to the topic list (test1) of Kafka.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**. The configuration applies to scenarios where only the Flume is configured, for example, Spooldir Source +Memory Channel+Kafka Sink.

Prerequisites

- The cluster has been installed, including the Kafka and Flume services.
- The network environment of the cluster is secure.
- The MRS cluster administrator has understood service requirements and prepared Kafka administrator **flume_kafka**.

Procedure

Step 1 Set Flume parameters.

Use the Flume configuration tool on Manager to configure the Flume role server parameters and generate a configuration file.

1. Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Flume** > **Configuration Tool**.

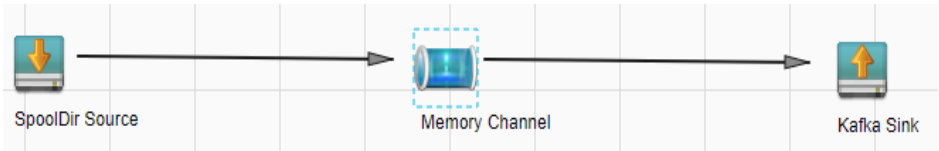
   Figure 7-8 Choosing **Configuration Tool**

2. Set **Agent Name** to **server**. Select and drag the source, channel, and sink to be used to the GUI on the right, and connect them.

   Use SpoolDir Source, Memory Channel, and Kafka Sink.

   Figure 7-9 Example for the Flume configuration tool

3. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-24** based on the actual environment.

NOTE

- If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-24 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
spoolDir	Specifies the directory where the file to be collected resides. This parameter cannot be left blank. The directory needs to exist and have the write, read, and execute permissions on the flume running user.	/srv/BigData/hadoop/data1/zb
trackerDir	Specifies the path for storing the metadata of files collected by Flume.	/srv/BigData/hadoop/data1/tracker
batchSize	Specifies the number of events that Flume sends in a batch (number of data pieces). A larger value indicates higher performance and lower timeliness.	61200
kafka.topics	Specifies the list of subscribed Kafka topics, which are separated by commas (,). This parameter cannot be left blank.	test1
kafka.bootstrap.servers	Specifies the bootstrap IP address and port list of Kafka. The default value is all Kafkabrokers in the Kafka cluster.	192.168.101.10:21007

4. Click **Export** to save the **properties.properties** configuration file to the local server.

Step 2 Upload the configuration file.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded. On the **Instance Configurations** page, click **Upload File** on the right of **flume.config.file**, select the **properties.properties** file exported in **Step 1.4**.

Step 3 Verify log transmission.

1. Log in to the Kafka client.

   cd *Kafka client installation directory*/**Kafka/kafka**

   kinit flume_kafka (Enter the password.)

2. Read data from a Kafka topic.

   bin/kafka-console-consumer.sh --topic *topic name* **--bootstrap-server** *Kafka service IP address of the node where the role instance is located*: **21007 --consumer.config config/consumer.properties --from-beginning**

   The system displays the contents of the file to be collected.

   ```
   [root@host1 kafka]# bin/kafka-console-consumer.sh --topic test1 --bootstrap-server 192.168.101.10:21007 --consumer.config config/consumer.properties --from-beginning
   Welcome to flume
   ```

----End

7.5.3 Using Flume Server to Collect Static Logs from Local Host to HDFS

This section describes how to use the Flume server to collect static logs from a local host and save them to the **/flume/test** directory on HDFS.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**. The configuration applies to scenarios where only the Flume is configured, for example, Spooldir Source +Memory Channel+HDFS Sink.

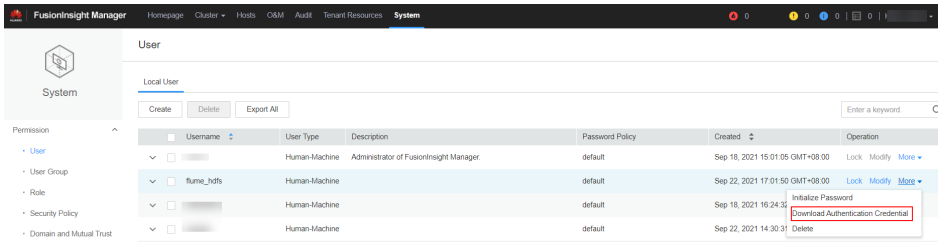
Prerequisites

- The cluster has been installed, including the HDFS and Flume services.
- The network environment of the cluster is secure.
- User **flume_hdfs** has been created, and the HDFS directory and data used for log verification have been authorized to the user.

Procedure

Step 1 On FusionInsight Manager, choose **System** > **Permission** > **User**, select user **flume_hdfs**, and choose **More** > **Download Authentication Credential** to download the Kerberos certificate file of user **flume_hdfs** and save it to the local host.

Figure 7-10 Downloading the authentication credential



Step 2 Set Flume parameters.

Use Flume on FusionInsight Manager to configure the Flume role server parameters and generate a configuration file.

1. Log in to FusionInsight Manager. Choose **Cluster** > **Services** > **Flume** > **Configuration Tool**.

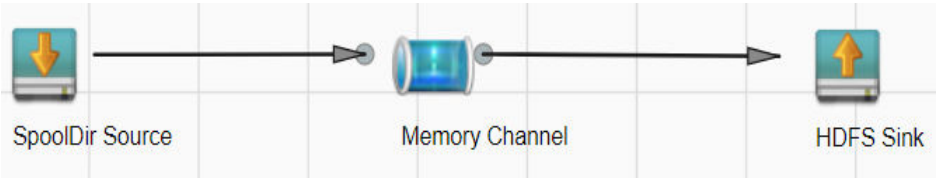
   Figure 7-11 Choosing **Configuration Tool**

2. Set **Agent Name** to **server**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   Use SpoolDir Source, Memory Channel, and HDFS Sink.

   Figure 7-12 Example for the Flume configuration tool

3. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-25** based on the actual environment.

   NOTE

   - If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
   - It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-25 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
spoolDir	Specifies the directory where the file to be collected resides. This parameter cannot be left blank. The directory needs to exist and have the write, read, and execute permissions on the flume running user.	/srv/BigData/hadoop/data1/zb
trackerDir	Specifies the path for storing the metadata of files collected by Flume.	/srv/BigData/hadoop/data1/tracker
batchSize	Specifies the number of events that Flume sends in a batch.	61200
hdfs.path	Specifies the HDFS data write directory. This parameter cannot be left blank.	hdfs://hacluster/flume/test
hdfs.filePrefix	Specifies the file name prefix after data is written to HDFS.	TMP_
hdfs.batchSize	Specifies the maximum number of events that can be written to HDFS once.	61200
hdfs.kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hdfs
hdfs.kerberosKeytab	Specifies the keytab file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hdfs**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.

Parameter	Description	Example Value
hdfs.useLocalTimeStamp	Specifies whether to use the local time. Possible values are **true** and **false**.	true

4. Click **Export** to save the **properties.properties** configuration file to the local.

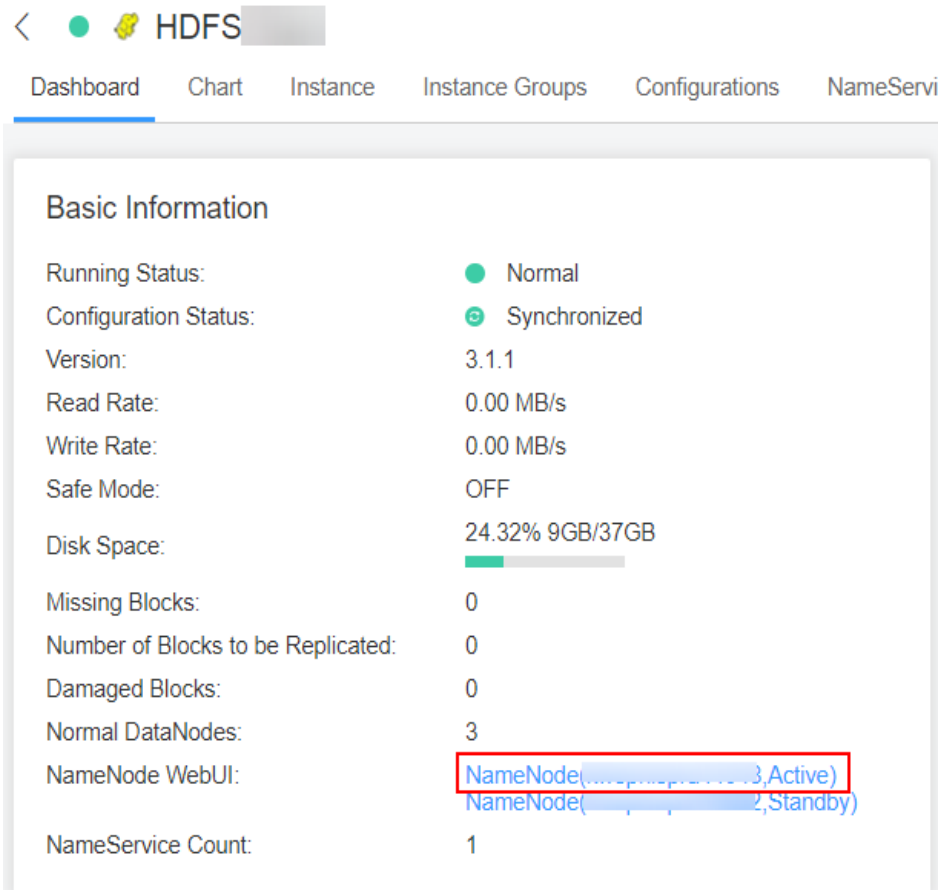
Step 3 Upload the configuration file.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded. On the **Instance Configurations** page, click **Upload File** on the right of **flume.config.file**, select the **properties.properties** file exported in **Step 2.4**.

Step 4 Verify log transmission.

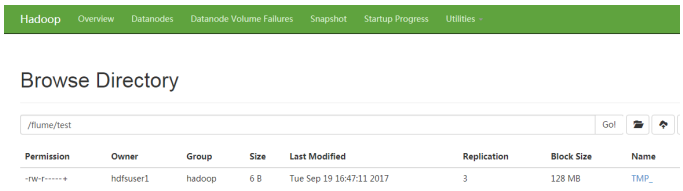
1. Log in to FusionInsight Manager as a user who has the management permission on HDFS. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **NameNode(*Node name*,Active)** link next to **NameNode WebUI** to go to the HDFS web UI. On the displayed page, choose **Utilities** > **Browse the file system**.

Figure 7-13 Accessing the HDFS WebUI



2. Check whether the data is generated in the **/flume/test** directory on the HDFS.

Figure 7-14 Checking HDFS directories and files



----End

7.5.4 Using Flume Server to Collect Dynamic Logs from Local Host to HDFS

This section describes how to use the Flume server to collect dynamic logs from a local host and save them to the **/flume/test** directory on HDFS.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**. The configuration applies to scenarios where only the Flume is configured, for example, Taildir Source +Memory Channel+HDFS Sink.

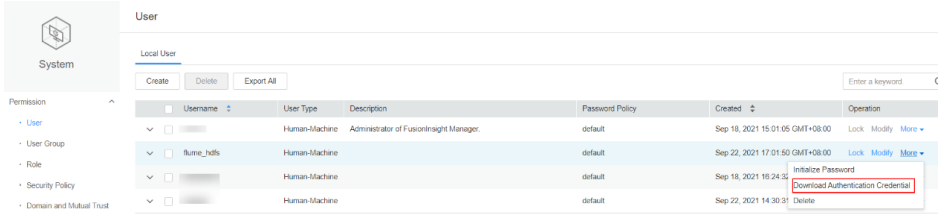
Prerequisites

- The cluster has been installed, including the HDFS and Flume services.
- The network environment of the cluster is secure.
- You have created user **flume_hdfs** and authorized the HDFS directory and data to be operated during log verification.

Procedure

Step 1 On FusionInsight Manager, choose **System > User** and choose **More > Download Authentication Credential** to download the Kerberos certificate file of user **flume_hdfs** and save it to the local host.

Figure 7-15 Downloading the authentication credential



Step 2 Set Flume parameters.

Use the Flume configuration tool on FusionInsight Manager to configure the Flume role server parameters and generate a configuration file.

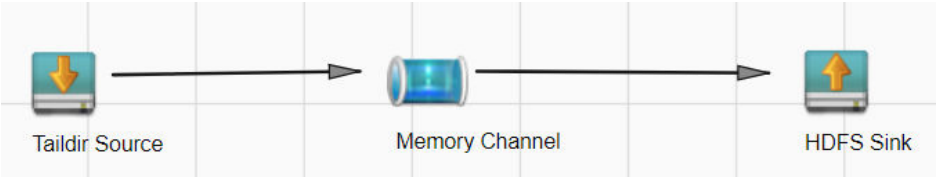
1. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab.

Figure 7-16 Choosing **Configuration Tool**

2. Set **Agent Name** to **server**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   Use Taildir Source, Memory Channel, and HDFS Sink.

   Figure 7-17 Example for the Flume configuration tool

3. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-26** based on the actual environment.

   NOTE

   - If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
   - It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-26 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
filegroups	Specifies the file group list name. This parameter cannot be left blank. The value contains the following two parts: – **Name**: name of the file group list. – **filegroups**: absolute path of dynamic log files.	-

Parameter	Description	Example Value
positionFile	Specifies the location where the collected file information (file name and location from which the file collected) is saved. This parameter cannot be left blank. The file does not need to be created manually, but the Flume running user needs to have the write permission on its upper-level directory.	/home/omm/flume/positionfile
batchSize	Specifies the number of events that Flume sends in a batch.	61200
hdfs.path	Specifies the HDFS data write directory. This parameter cannot be left blank.	hdfs://hacluster/flume/test
hdfs.filePrefix	Specifies the file name prefix after data is written to HDFS.	TMP_
hdfs.batchSize	Specifies the maximum number of events that can be written to HDFS once.	61200
hdfs.kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hdfs
hdfs.kerberosKeytab	Specifies the keytab file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hdfs**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.
hdfs.useLocalTimeStamp	Specifies whether to use the local time. Possible values are **true** and **false**.	true

4. Click **Export** to save the **properties.properties** configuration file to the local.

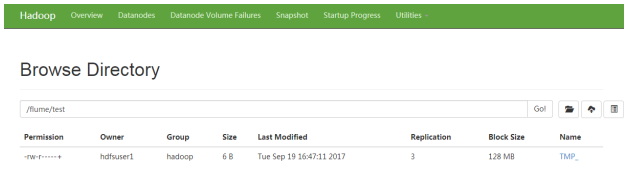
Step 3 Upload the configuration file.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded. On the **Instance Configurations** page, click **Upload File** on the right of **flume.config.file**, select the **properties.properties** file exported in **Step 2.4**.

Step 4 Verify log transmission.

1. Log in to FusionInsight Manager as a user who has the management permission on HDFS. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **NameNode(***Node name***,Active)** link next to **NameNode WebUI** to go to the HDFS web UI. On the displayed page, choose **Utilities** > **Browse the file system**.
2. Check whether the data is generated in the **/flume/test** directory on the HDFS.

Figure 7-18 Checking HDFS directories and files



----End

7.5.5 Using Flume Server to Collect Logs from Kafka to HDFS

This section describes how to use the Flume server to collect logs from the topic list (test1) of Kafka and save them to the **/flume/test** directory on HDFS.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**. The configuration applies to scenarios where only the Flume is configured, for example, Kafka Source +Memory Channel+HDFS Sink.

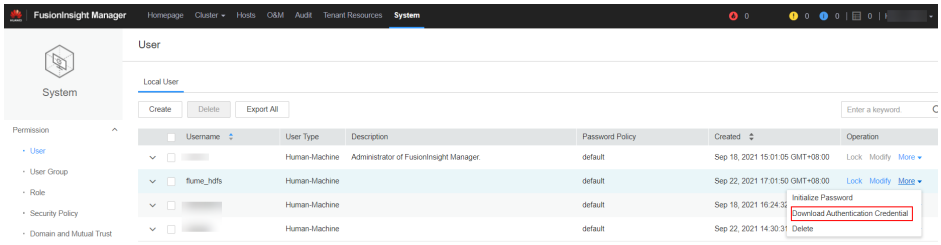
Prerequisites

- The cluster has been installed, including the HDFS, Kafka, and Flume services.
- The network environment of the cluster is secure.
- You have created user **flume_hdfs** and authorized the HDFS directory and data to be operated during log verification.

Procedure

Step 1 On FusionInsight Manager, choose **System > User** and choose **More > Download Authentication Credential** to download the Kerberos certificate file of user **flume_hdfs** and save it to the local host.

Figure 7-19 Downloading the authentication credential

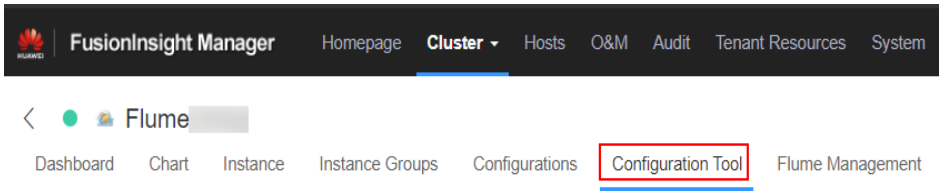


Step 2 Configure the server parameters of the Flume role.

Use the Flume configuration tool on FusionInsight Manager to configure the Flume role server parameters and generate a configuration file.

1. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab.

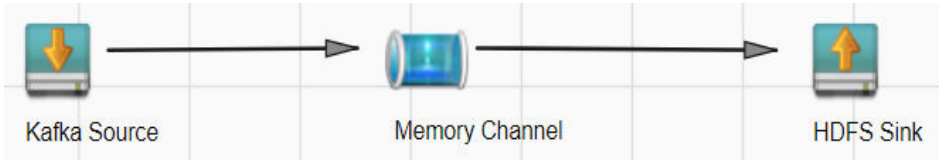
   Figure 7-20 Choosing **Configuration Tool**

2. Set **Agent Name** to **server**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   For example, use Kafka Source, Memory Channel, and HDFS Sink.

   Figure 7-21 Example for the Flume configuration tool

3. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-27** based on the actual environment.

   NOTE

   - If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
   - It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-27 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
kafka.topics	Specifies the subscribed Kafka topic list, in which topics are separated by commas (,). This parameter cannot be left blank.	test1
kafka.consumer.group.id	Specifies the data group ID obtained from Kafka. This parameter cannot be left blank.	flume
kafka.bootstrap.servers	Specifies the bootstrap IP address and port list of Kafka. The default value is all Kafka lists in a Kafka cluster. If Kafka has been installed in the cluster and its configurations have been synchronized, this parameter can be left blank.	192.168.101.10:9092
batchSize	Specifies the number of events that Flume sends in a batch (number of data pieces).	61200
hdfs.path	Specifies the HDFS data write directory. This parameter cannot be left blank.	hdfs://hacluster/flume/test
hdfs.filePrefix	Specifies the file name prefix after data is written to HDFS.	TMP_
hdfs.batchSize	Specifies the maximum number of events that can be written to HDFS once.	61200
hdfs.kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hdfs

Parameter	Description	Example Value
hdfs.kerberosKeytab	Specifies the keytab file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hdfs**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.
hdfs.useLocalTimeStamp	Specifies whether to use the local time. Possible values are **true** and **false**.	true

4. Click **Export** to save the **properties.properties** configuration file to the local.

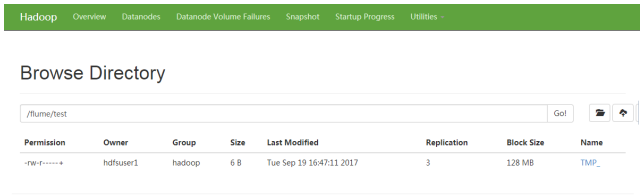
Step 3 Upload the configuration file.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded. On the **Instance Configurations** page, click **Upload File** on the right of **flume.config.file**, select the **properties.properties** file exported in **Step 2.4**.

Step 4 Verify log transmission.

1. Log in to FusionInsight Manager as a user who has the management permission on HDFS. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **NameNode(***Node name***,Active)** link next to **NameNode WebUI** to go to the HDFS web UI. On the displayed page, choose **Utilities** > **Browse the file system**.
2. Check whether the data is generated in the **/flume/test** directory on the HDFS.

Figure 7-22 Checking HDFS directories and files



----End

7.5.6 Using Flume Client to Collect Logs from Kafka to HDFS

This section describes how to use the Flume client to collect logs from the topic list (test1) of the Kafka client and save them to the **/flume/test** directory on HDFS.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**.

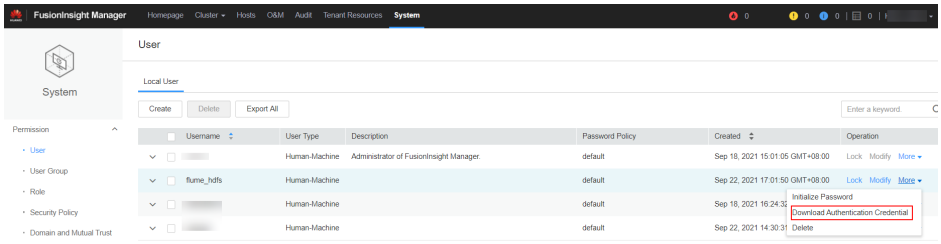
Prerequisites

- The Flume client has been installed.
- The cluster has been installed, including the HDFS, Kafka, and Flume services.
- You have created user **flume_hdfs** and authorized the HDFS directory and data to be operated during log verification.
- The network environment of the cluster is secure.

Procedure

Step 1 On FusionInsight Manager, choose **System > User** and choose **More > Download Authentication Credential** to download the Kerberos certificate file of user **flume_hdfs** and save it to the local host.

Figure 7-23 Downloading the authentication credential



Step 2 Configure the client parameters of the Flume role.

1. Use the Flume configuration tool on FusionInsight Manager to configure the Flume role server parameters and generate a configuration file.

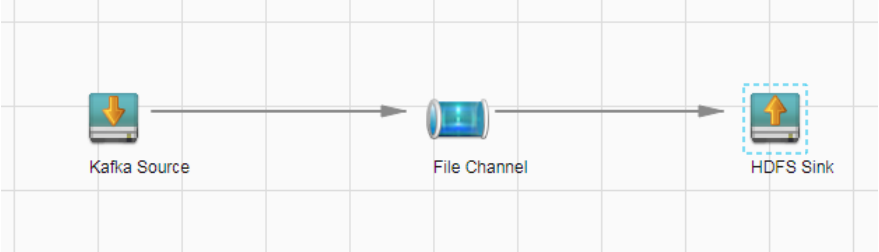
   a. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab.

   Figure 7-24 Choosing **Configuration Tool**

   
   b. Set **Agent Name** to **client**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   For example, use Kafka Source, File Channel, and HDFS Sink, as shown in **Figure 7-25**.

Figure 7-25 Example for the Flume configuration tool



c. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-28** based on the actual environment.

NOTE

- If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-28 Parameters to be modified for the Flume role client

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
kafka.topics	Specifies the subscribed Kafka topic list, in which topics are separated by commas (,). This parameter cannot be left blank.	test1
kafka.consumer.group.id	Specifies the data group ID obtained from Kafka. This parameter cannot be left blank.	flume

Parameter	Description	Example Value
kafka.bootstrap.servers	Specifies the bootstrap IP address and port list of Kafka. The default value is all Kafka lists in a Kafka cluster. If Kafka has been installed in the cluster and its configurations have been synchronized, this parameter can be left blank.	192.168.101.10:21007
batchSize	Specifies the number of events that Flume sends in a batch (number of data pieces).	61200
dataDirs	Specifies the directory for storing buffer data. The run directory is used by default. Configuring multiple directories on disks can improve transmission efficiency. Use commas (,) to separate multiple directories. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/data** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/data

Parameter	Description	Example Value
checkpointDir	Specifies the directory for storing the checkpoint information, which is under the run directory by default. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/checkpoint** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/checkpoint
transactionCapacity	Specifies the transaction size, that is, the number of events in a transaction that can be processed by the current Channel. The size cannot be smaller than the batchSize of Source. Setting the same size as batchSize is recommended.	61200
hdfs.path	Specifies the HDFS data write directory. This parameter cannot be left blank.	hdfs://hacluster/flume/test
hdfs.filePrefix	Specifies the file name prefix after data is written to HDFS.	TMP_
hdfs.batchSize	Specifies the maximum number of events that can be written to HDFS once.	61200

Parameter	Description	Example Value
hdfs.kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hdfs
hdfs.kerberosKeytab	Specifies the keytab file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hdfs**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.
hdfs.useLocalTimeStamp	Specifies whether to use the local time. Possible values are **true** and **false**.	true

d. Click **Export** to save the **properties.properties** configuration file to the local.

2. Upload the **properties.properties** file to **flume/conf/** in the Flume client installation directory.
3. To connect the Flume client to the HDFS, you need to add the following configuration:

   a. Download the Kerberos certificate of account **flume_hdfs** and obtain the **krb5.conf** configuration file. Upload the configuration file to the **fusioninsight-flume-1.9.0/conf/** directory on the node where the client is installed.

   b. In **fusioninsight-flume-1.9.0/conf/**, create the **jaas.conf** configuration file.

      vi jaas.conf

      ```
      KafkaClient {
      com.sun.security.auth.module.Krb5LoginModule required
      useKeyTab=true
      keyTab="/opt/test/conf/user.keytab"
      principal="flume_hdfs@<System domain name>"
      useTicketCache=false
      storeKey=true
      debug=true;
      };
      ```

      Values of **keyTab** and **principal** vary depending on the actual situation.

c. Obtain configuration files **core-site.xml** and **hdfs-site.xml** from **/opt/FusionInsight_Cluster_*<Cluster ID>*_Flume_ClientConfig/Flume/config** and upload them to **fusioninsight-flume-1.9.0/conf/**.

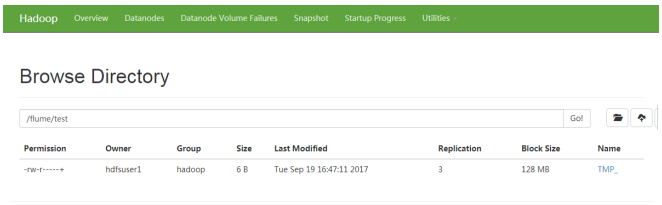
4. Go to **fusioninsight-flume-1.9.0/bin** in the installation directory of the client node and run the following command to restart the Flume process:

   ./flume-manage.sh restart

Step 3 Verify log transmission.

1. Log in to FusionInsight Manager as a user who has the management permission on HDFS. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > **Services** > **HDFS**. On the page that is displayed, click the **NameNode(*Node name*,Active)** link next to **NameNode WebUI** to go to the HDFS web UI. On the displayed page, choose **Utilities** > **Browse the file system**.
2. Check whether the data is generated in the **/flume/test** directory on the HDFS.

Figure 7-26 Checking HDFS directories and files



----End

7.5.7 Using Cascaded Agents to Collect Static Logs from Local Host to HBase

This section describes how to use the Flume client to collect static logs from a local host and save them to the **flume_test** HBase table. In this scenario, multi-level agents are cascaded.

NOTE

By default, the cluster network environment is secure and the SSL authentication is not enabled during the data transmission process. For details about how to use the encryption mode, see **Configuring an Encrypted Flume Data Collection Task**. The configuration applies to scenarios where only the server is configured, for example, Spooldir Source+File Channel+HBase Sink.

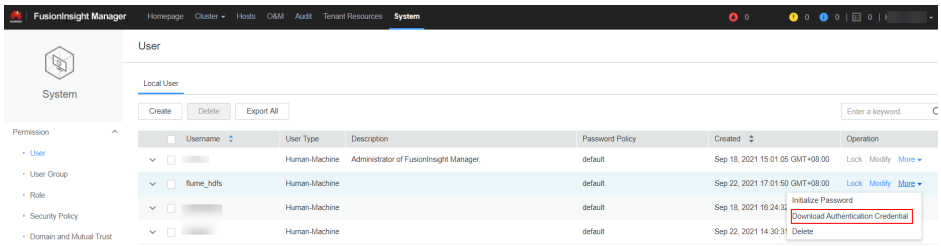
Prerequisites

- The cluster has been installed, including the HBase and Flume services.
- The Flume client has been installed.
- The network environment of the cluster is secure.
- An HBase table has been created by running the **create 'flume_test', 'cf'** command.
- The MRS cluster administrator has understood service requirements and prepared HBase administrator **flume_hbase**.

Procedure

Step 1 On FusionInsight Manager, choose **System > User** and choose **More > Download Authentication Credential** to download the Kerberos certificate file of user **flume_hbase** and save it to the local host.

Figure 7-27 Downloading the authentication credential



Step 2 Configure the client parameters of the Flume role.

1. Use the Flume configuration tool on FusionInsight Manager to configure the Flume role client parameters and generate a configuration file.

   a. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab.

   Figure 7-28 Choosing **Configuration Tool**

   
   b. Set **Agent Name** to **client**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   Use SpoolDir Source, File Channel, and Avro Sink.

   Figure 7-29 Example for the Flume configuration tool

   
   c. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-29** based on the actual environment.

NOTE

- If you want to continue using the **properties.propretites** file by modifying it, log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab, click **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

Table 7-29 Parameters to be modified for the Flume role client

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
spoolDir	Specifies the directory where the file to be collected resides. This parameter cannot be left blank. The directory needs to exist and have the write, read, and execute permissions on the flume running user.	/srv/BigData/hadoop/data1/zb
trackerDir	Specifies the path for storing the metadata of files collected by Flume.	/srv/BigData/hadoop/data1/tracker
batchSize	Specifies the number of events that Flume sends in a batch (number of data pieces). A larger value indicates higher performance and lower timeliness.	61200

Parameter	Description	Example Value
dataDirs	Specifies the directory for storing buffer data. The run directory is used by default. Configuring multiple directories on disks can improve transmission efficiency. Use commas (,) to separate multiple directories. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/data** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/data
checkpointDir	Specifies the directory for storing the checkpoint information, which is under the run directory by default. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/checkpoint** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/checkpoint

Parameter	Description	Example Value
transactionCapacity	Specifies the transaction size, that is, the number of events in a transaction that can be processed by the current Channel. The size cannot be smaller than the batchSize of Source. Setting the same size as batchSize is recommended.	61200
hostname	Specifies the name or IP address of the host whose data is to be sent. This parameter cannot be left blank. Name or IP address must be configured to be the name or IP address that the Avro source associated with it.	192.168.108.11
port	Specifies the port that sends the data. This parameter cannot be left blank. It must be consistent with the port that is monitored by the connected Avro Source.	21154

Parameter	Description	Example Value
ssl	Specifies whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ■ **true** indicates that the function is enabled. ■ **false** indicates that the client authentication function is not enabled.	false

d. Click **Export** to save the **properties.properties** configuration file to the local.

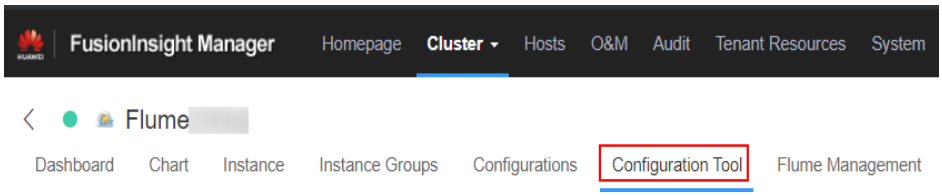
2. Upload the **properties.properties** file to **flume/conf/** under the installation directory of the Flume client.

Step 3 Configure the server parameters of the Flume role and upload the configuration file to the cluster.

1. Use the Flume configuration tool on the FusionInsight Manager portal to configure the server parameters and generate the configuration file.

a. Log in to FusionInsight Manager and choose **Cluster** > **Services**. On the page that is displayed, choose **Flume**. On the displayed page, click the **Configuration Tool** tab.

Figure 7-30 Choosing **Configuration Tool**



b. Set **Agent Name** to **server**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

For example, use Avro Source, File Channel, and HBase Sink.

Figure 7-31 Example for the Flume configuration tool

c. Double-click the source, channel, and sink. Set corresponding configuration parameters by referring to **Table 7-30** based on the actual environment.

NOTE

- If the server parameters of the Flume role have been configured, you can choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Instance** on FusionInsight Manager. Then select the corresponding Flume role instance and click the **Download** button behind the **flume.config.file** parameter on the **Instance Configurations** page to obtain the existing server parameter configuration file. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Configuration Tool** > **Import**, import the file, and modify the configuration items related to non-encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.
- A unique checkpoint directory needs to be configured for each File Channel.

Table 7-30 Parameters to be modified for the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
bind	Specifies the IP address to which Avro Source is bound. This parameter cannot be left blank. It must be configured as the IP address that the server configuration file will upload.	192.168.108.11
port	Specifies the ID of the port that the Avro Source monitors. This parameter cannot be left blank. It must be configured as an unused port.	21154

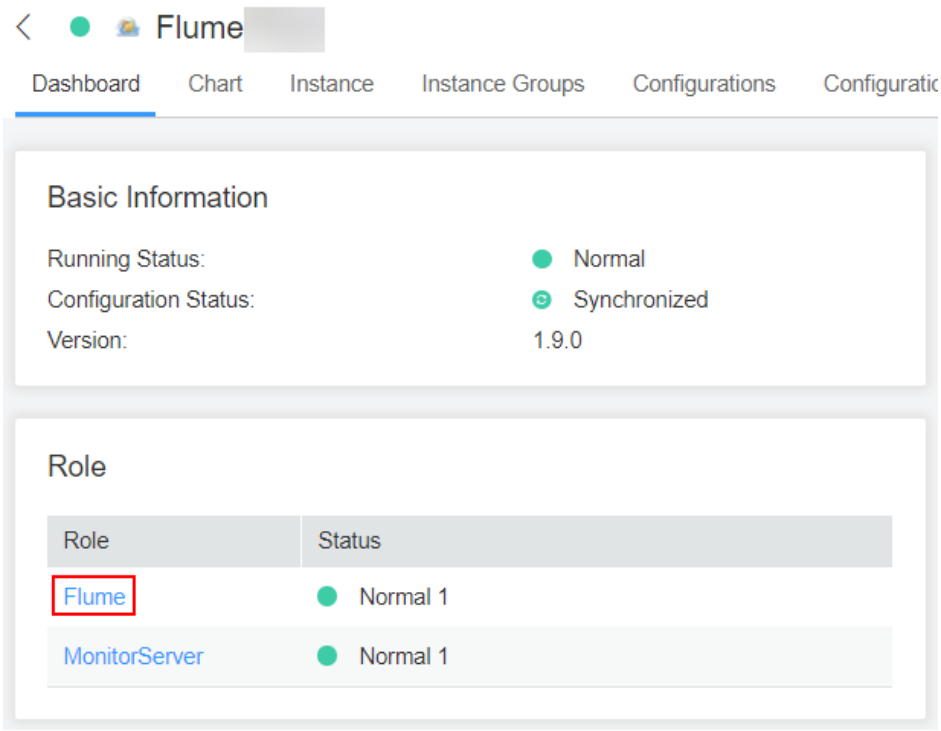
Parameter	Description	Example Value
ssl	Specifies whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ▪ **true** indicates that the function is enabled. ▪ **false** indicates that the client authentication function is not enabled.	false
dataDirs	Specifies the directory for storing buffer data. The run directory is used by default. Configuring multiple directories on disks can improve transmission efficiency. Use commas (,) to separate multiple directories. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/data** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flumeserver/data
checkpointDir	Specifies the directory for storing the checkpoint information, which is under the run directory by default. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/checkpoint** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flumeserver/checkpoint
transactionCapacity	Specifies the transaction size, that is, the number of events in a transaction that can be processed by the current Channel. The size cannot be smaller than the batchSize of Source. Setting the same size as batchSize is recommended.	61200

Parameter	Description	Example Value
table	Specifies the HBase table name. This parameter cannot be left blank.	flume_test
columnFamily	Specifies the HBase column family name. This parameter cannot be left blank.	cf
batchSize	Specifies the maximum number of events written to HBase by Flume in a batch.	61200
kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hbase
kerberosKeytab	Specifies the file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hbase**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.

   d. Click **Export** to save the **properties.properties** configuration file to the local.

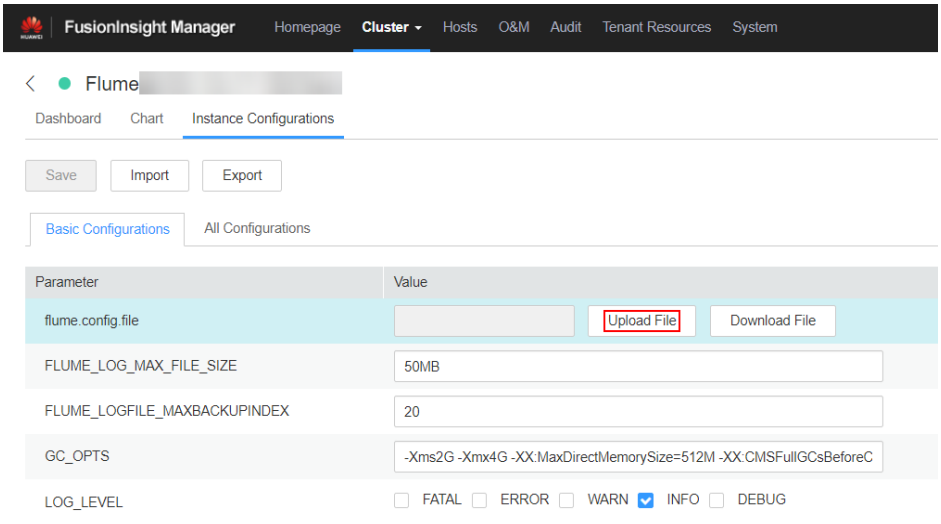
2. Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded.

Figure 7-32 Clicking the Flume role



3. On the **Instance Configurations** page, click **Upload File** next to **flume.config.file** and select the **properties.properties** file.

Figure 7-33 Uploading a file



NOTE

- An independent server configuration file can be uploaded to each Flume instance.
- This step is required for updating the configuration file. Modifying the configuration file on the background is an improper operation because the modification will be overwritten after configuration synchronization.

4. Click **Save**, and then click **OK**.

5. Click **Finish**.

Step 4 Verify log transmission.

1. Go to the directory where the HBase client is installed.

   cd /*Client installation directory***/ HBase/hbase**

   kinit flume_hbase (Enter the password.)
2. Run the **hbase shell** command to access the HBase client.
3. Run the **scan 'flume_test'** statement. Logs are written in the HBase column family by line.

```
hbase(main):001:0> scan 'flume_test'
ROW                                                COLUMN

7.6 Configuring an Encrypted Flume Data Collection Task

7.6.1 Using Cascaded Agents to Collect Static Logs from Local Host to HDFS

This section describes how to use Flume to collect static logs from a local host and save them to the **/flume/test** directory on HDFS.

Prerequisites

- The cluster, HDFS and Flume services, and Flume client have been installed.
- User **flume_hdfs** has been created, and the HDFS directory and data used for log verification have been authorized to the user.

Procedure

Step 1 Generate the certificate trust lists of the server and client of the Flume role respectively.

1. Log in to the node where the Flume server is located as user **omm**. Go to the **${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/bin** directory.

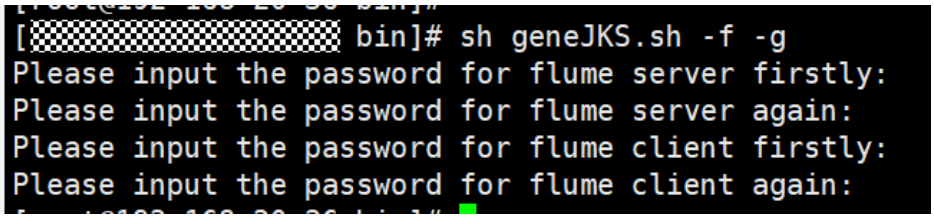
   cd ${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/bin
2. Run the following command to generate and export the server and client certificates of the Flume role:

sh geneJKS.sh -f -g

The generated certificate is saved in the **${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/conf** path .

- **flume_sChat.jks** is the certificate library of the Flume role server. **flume_sChat.crt** is the exported file of the **flume_sChat.jks** certificate. **-f** indicates whether users need to enter the password of the certificate and certificate library.
- **flume_cChat.jks** is the certificate library of the Flume role client. **flume_cChat.crt** is the exported file of the **flume_cChat.jks** certificate. **-g** indicates whether users need to enter the password of the certificate and certificate library.
- **flume_sChatt.jks** and **flume_cChatt.jks** are the SSL certificate trust lists of the Flume server and client, respectively.

Figure 7-34 Example



NOTE

All user-defined passwords involved in this section must meet the following requirements:

- Contain at least four types of the following: uppercase letters, lowercase letters, digits, and special characters.
- Contain at least eight characters and a maximum of 64 characters.
- It is recommended that the user-defined passwords be changed periodically (for example, every three months), and certificates and trust lists be generated again to ensure security.

Step 2 On FusionInsight Manager, choose **System > User** and choose **More > Download Authentication Credential** to download the Kerberos certificate file of user **flume_hdfs** and save it to the local host.

Step 3 Configure the server parameters of the Flume role and upload the configuration file to the cluster.

1. Log in to any node where the Flume role is located as user **omm**. Run the following command to go to the ${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/bin directory:

   cd ${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/bin

2. Run the following command to generate and obtain Flume server keystore password, trust list password, and keystore-password encrypted private key information. Enter the password twice and confirm the password. It is the password of the **flume_sChat.jks** certificate library.

   ./genPwFile.sh

cat password.property

3. Use the Flume configuration tool on the FusionInsight Manager portal to configure the server parameters and generate the configuration file.

   a. Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Configuration Tool**.

   Figure 7-35 Choosing **Configuration Tool**

   
   b. Set **Agent Name** to **server**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

   For example, use SpoolDir Source, File Channel, and HDFS Sink.

   Figure 7-36 Example for the Flume configuration tool

   
   c. Double-click the source, channel, and sink. Set corresponding configuration parameters by seeing **Table 7-31** based on the actual environment.

   NOTE

   - If the server parameters of the Flume role have been configured, you can choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Instance** on FusionInsight Manager. Then select the corresponding Flume role instance and click the **Download** button behind the **flume.config.file** parameter on the **Instance Configurations** page to obtain the existing server parameter configuration file. Choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Configuration Tool** > **Import**, import the file, and modify the configuration items related to encrypted transmission.
   - It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.
   - A unique checkpoint directory needs to be configured for each File Channel.

   d. Click **Export** to save the **properties.properties** configuration file to the local.

   Table 7-31 Parameters to be modified of the Flume role server

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test

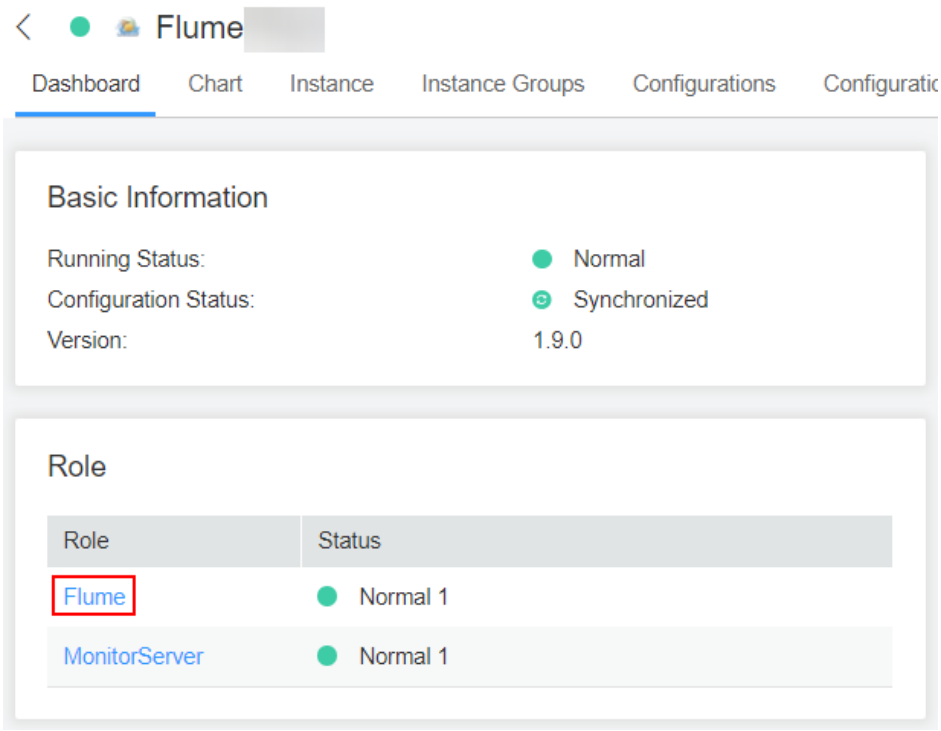
Parameter	Description	Example Value
bind	Specifies the IP address to which Avro Source is bound. This parameter cannot be left blank. It must be configured as the IP address that the server configuration file will upload.	192.168.108.11
port	Specifies the IP address to which Avro Source is bound. This parameter cannot be left blank. It must be configured as an unused port.	21154
ssl	Indicates whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ■ **true** indicates that the function is enabled. ■ **false** indicates that the client authentication function is not enabled.	true
keystore	Indicates the server certificate.	${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/conf/flume_sChat.jks
keystore-password	Specifies the password of the key library, which is the password required to obtain the keystore information. Enter the value of **password** obtained in **Step 3.2**.	-
truststore	Indicates the SSL certificate trust list of the server.	${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/conf/flume_sChatt.jks

Parameter	Description	Example Value
truststore-password	Specifies the trust list password, which is the password required to obtain the truststore information. Enter the value of **password** obtained in **Step 3.2**.	-
dataDirs	Specifies the directory for storing buffer data. The run directory is used by default. Configuring multiple directories on disks can improve transmission efficiency. Use commas (,) to separate multiple directories. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/data** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flumeserver/data
checkpointDir	Specifies the directory for storing the checkpoint information, which is under the run directory by default. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/checkpoint** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flumeserver/checkpoint
transactionCapacity	Specifies the transaction size, that is, the number of events in a transaction that can be processed by the current Channel. The size cannot be smaller than the batchSize of Source. Setting the same size as batchSize is recommended.	61200
hdfs.path	Specifies the HDFS data write directory. This parameter cannot be left blank.	hdfs://hacluster/flume/test
hdfs.inUsePrefix	Specifies the prefix of the file that is being written to HDFS.	TMP_

Parameter	Description	Example Value
hdfs.batchSize	Specifies the maximum number of events that can be written to HDFS once.	61200
hdfs.kerberosPrincipal	Specifies the Kerberos authentication user, which is mandatory in security versions. This configuration is required only in security clusters.	flume_hdfs
hdfs.kerberosKeytab	Specifies the keytab file path for Kerberos authentication, which is mandatory in security versions. This configuration is required only in security clusters.	/opt/test/conf/user.keytab **NOTE** Obtain the **user.keytab** file from the Kerberos certificate file of the user **flume_hdfs**. In addition, ensure that the user who installs and runs the Flume client has the read and write permissions on the **user.keytab** file.
hdfs.useLocalTimeStamp	Specifies whether to use the local time. Possible values are **true** and **false**.	true

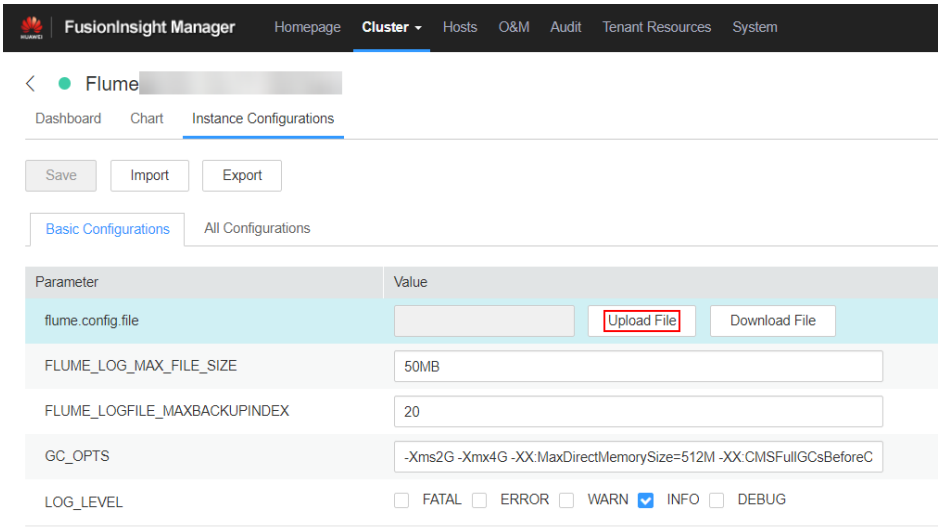
4. Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume**. In the **Instances** tab, click the Flume role whose configuration file is to be uploaded.

Figure 7-37 Clicking the Flume role



5. On the **Instance Configurations** page, click **Upload File** next to **flume.config.file** and select the **properties.properties** file.

Figure 7-38 Uploading a file



NOTE

- An independent server configuration file can be uploaded to each Flume instance.
- This step is required for updating the configuration file. Modifying the configuration file on the background is an improper operation because the modification will be overwritten after configuration synchronization.

6. Click **Save**, and then click **OK**.

7. Click **Finish**.

Step 4 Configure the client parameters of the Flume role.

1. Run the following commands to copy the generated client certificate (**flume_cChat.jks**) and client trust list (**flume_cChatt.jks**) to the client directory, for example, **/opt/flume-client/fusionInsight-flume-1.9.0/conf/**. (The Flume client must have been installed.) **10.196.26.1** is the service plane IP address of the node where the client resides.

   scp ${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/conf/flume_cChat.jks user@10.196.26.1:/opt/flume-client/fusionInsight-flume-1.9.0/conf/

   scp ${BIGDATA_HOME}/FusionInsight_Porter_xxx/install/FusionInsight-Flume-1.9.0/flume/conf/flume_cChatt.jks user@10.196.26.1:/opt/flume-client/fusionInsight-flume-1.9.0/conf/

   NOTE

   When copying the client certificate, you need to enter the password of user **user** of the host (for example, **10.196.26.1**) where the client resides.

2. Log in to the node where the Flume client is decompressed as user **user**. Run the following command to go to the client directory **/opt/flume-client/fusionInsight-flume-1.9.0/bin**.

   cd opt/flume-client/fusionInsight-flume-1.9.0/bin

3. Run the following command to generate and obtain Flume client keystore password, trust list password, and keystore-password encrypted private key information. Enter the password twice and confirm the password. The password is the same as the password of the certificate whose alias is *flumechatclient* and the password of the *flume_cChat.jks* certificate library.

   ./genPwFile.sh

   cat password.property

   NOTE

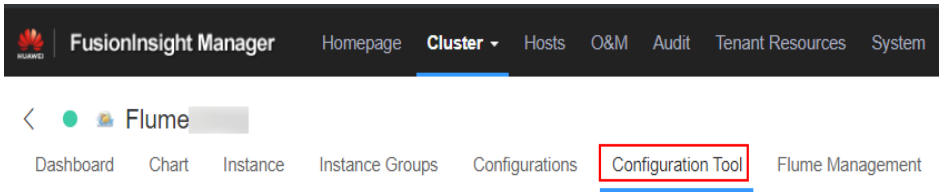
   If the following error message is displayed, run the export **JAVA_HOME=*JDKpath*** command.

   JAVA_HOME is null in current user,please install the JDK and set the JAVA_HOME

4. Run the **echo $SCC_PROFILE_DIR** command to check whether the **SCC_PROFILE_DIR** environment variable is empty.
   - If yes, run the **source .sccfile** command.
   - If no, go to **Step 4.5**.

5. Use the Flume configuration tool on FusionInsight Manager to configure the Flume role client parameters and generate a configuration file.
   a. Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Configuration Tool**.

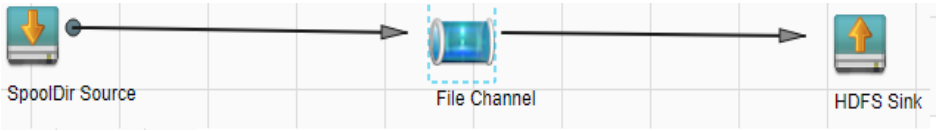
   Figure 7-39 Choosing **Configuration Tool**



b. Set **Agent Name** to **client**. Select the source, channel, and sink to be used, drag them to the GUI on the right, and connect them.

Use SpoolDir Source, File Channel, and HDFS Sink.

Figure 7-40 Example for the Flume configuration tool



c. Double-click the source, channel, and sink. Set corresponding configuration parameters by seeing **Table 7-32** based on the actual environment.

NOTE

- If the client parameters of the Flume role have been configured, you can obtain the existing client parameter configuration file from *client installation directory*/**fusioninsight-flume-1.9.0/conf/properties.properties** to ensure that the configuration is in concordance with the previous. Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Configuration Tool** > **Import**, import the file, and modify the configuration items related to encrypted transmission.
- It is recommended that the numbers of Sources, Channels, and Sinks do not exceed 40 during configuration file import. Otherwise, the response time may be very long.

d. Click **Export** to save the **properties.properties** configuration file to the local.

Table 7-32 Parameters to be modified of the Flume role client

Parameter	Description	Example Value
Name	The value must be unique and cannot be left blank.	test
spoolDir	Specifies the directory where the file to be collected resides. This parameter cannot be left blank. The directory needs to exist and have the write, read, and execute permissions on the flume running user.	/srv/BigData/hadoop/data1/zb
trackerDir	Specifies the path for storing the metadata of files collected by Flume.	/srv/BigData/hadoop/data1/tracker

Parameter	Description	Example Value
batch-size	Specifies the number of events that Flume sends in a batch.	61200
dataDirs	Specifies the directory for storing buffer data. The run directory is used by default. Configuring multiple directories on disks can improve transmission efficiency. Use commas (,) to separate multiple directories. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/data** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/data
checkpointDir	Specifies the directory for storing the checkpoint information, which is under the run directory by default. If the directory is inside the cluster, the **/srv/BigData/hadoop/dataX/flume/checkpoint** directory can be used. **dataX** ranges from data1 to dataN. If the directory is outside the cluster, it needs to be independently planned.	/srv/BigData/hadoop/data1/flume/checkpoint

Parameter	Description	Example Value
transactionCapacity	Specifies the transaction size, that is, the number of events in a transaction that can be processed by the current Channel. The size cannot be smaller than the batchSize of Source. Setting the same size as batchSize is recommended.	61200
hostname	Specifies the name or IP address of the host whose data is to be sent. This parameter cannot be left blank. Name or IP address must be configured to be the name or IP address that the Avro source associated with it.	192.168.108.11
port	Specifies the IP address to which Avro Sink is bound. This parameter cannot be left blank. It must be consistent with the port that is monitored by the connected Avro Source.	21154

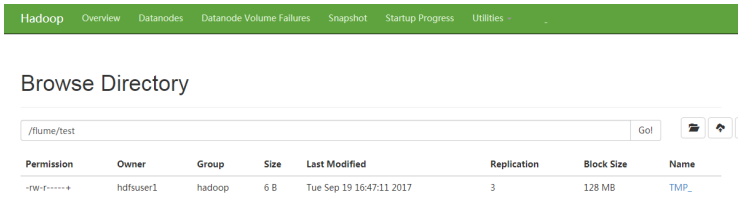
Parameter	Description	Example Value
ssl	Specifies whether to enable the SSL authentication. (You are advised to enable this function to ensure security.) Only Sources of the Avro type have this configuration item. ■ **true** indicates that the function is enabled. ■ **false** indicates that the client authentication function is not enabled.	true
keystore	Specifies the **flume_cChat.jks** certificate generated on the server.	/opt/flume-client/fusionInsight-flume-1.9.0/conf/flume_cChat.jks
keystore-password	Specifies the password of the key library, which is the password required to obtain the keystore information. Enter the value of **password** obtained in **Step 4.3**.	-
truststore	Indicates the SSL certificate trust list of the server.	/opt/flume-client/fusionInsight-flume-1.9.0/conf/flume_cChatt.jks
truststore-password	Specifies the trust list password, which is the password required to obtain the truststore information. Enter the value of **password** obtained in **Step 4.3**.	-

6. Upload the **properties.properties** file to **flume/conf/** under the installation directory of the Flume client.

Step 5 Verify log transmission.

1. Log in to FusionInsight Manager as a user who has the management permission on HDFS. For details, see **Accessing FusionInsight Manager**. Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS**, click the HDFS WebUI link to go to the HDFS WebUI, and choose **Utilities** > **Browse the file system**.
2. Check whether the data is generated in the **/flume/test** directory on the HDFS.

Figure 7-41 Checking HDFS directories and files



----End

7.7 Enterprise-Class Enhancements of Flume

7.7.1 Using the Encryption Tool of the Flume Client

You can use the encryption tool provided by the Flume client to encrypt some parameter values in the configuration file.

Step 1 Install the Flume client.

Step 2 Log in to the Flume client node and go to the client installation directory, for example, **/opt/FlumeClient**.

Step 3 Run the following command to switch the directory:

cd fusioninsight-flume-*Flume component version number***/bin**

Step 4 Run the following command to encrypt information:

./genPwFile.sh

Input the information that you want to encrypt twice.

Step 5 Run the following command to query the encrypted information:

cat password.property

NOTE

- If the encryption parameter is used for the Flume server, you need to perform encryption on the corresponding Flume server node. You need to run the encryption script as user **omm** for encryption.

----End

7.7.2 Configuring Flume to Connect to Kafka in Security Mode

This section describes how to connect to Kafka using the Flume client in security mode.

Step 1 Create a **jaas.conf** file and save it to **${***Flume client installation directory***} /conf**. The content of the **jaas.conf** file is as follows:

```
KafkaClient {
com.sun.security.auth.module.Krb5LoginModule required
useKeyTab=true
keyTab="/opt/test/conf/user.keytab"
principal="flume_hdfs@<System domain name>"
useTicketCache=false
storeKey=true
debug=true;
 };
```

Set **keyTab** and **principal** based on site requirements. The configured **principal** must have certain kafka permissions.

Step 2 Configure services. Set the port number of **kafka.bootstrap.servers** to **21007**, and set **kafka.security.protocol** to **SASL_PLAINTEXT**.

Step 3 If the domain name of the cluster where Kafka is located is changed, change the value of *-Dkerberos.domain.name* in the **flume-env.sh** file in **${***Flume client installation directory***} /conf/** based on the site requirements.

Step 4 Upload the configured **properties.properties** file to **${***Flume client installation directory***} /conf**.

----End

7.8 Flume O&M Management

7.8.1 Flume Common Configuration Parameters

Some parameters can be configured on Manager.

This section describes how to configure the sources, channels, and sinks of Flume, and modify the configuration items of each module.

For MRS 3.*x* or later, log in to FusionInsight Manager and choose **Cluster** > **Services** > **Flume**. On the displayed page, click the **Configuration Tool** tab, select and drag the source, channel, and sink to be used to the GUI on the right, and double-click them to configure corresponding parameters. Parameters such as **channels** and **type** are configured only in the client configuration file **properties.properties**, the path of which is *Flume client installation directory*/**fusioninsight-flume-***Flume version*/**conf/properties.properties**.

NOTE

You must input encrypted information for some configurations. For details on how to encrypt information, see **Using the Encryption Tool of the Flume Client**.

Common Source Configurations

- **Avro Source**

  An Avro source listens to the Avro port, receives data from the external Avro client, and places data into configured channels. **Table 7-33** lists common configurations.

  Figure 7-42 Avro Source

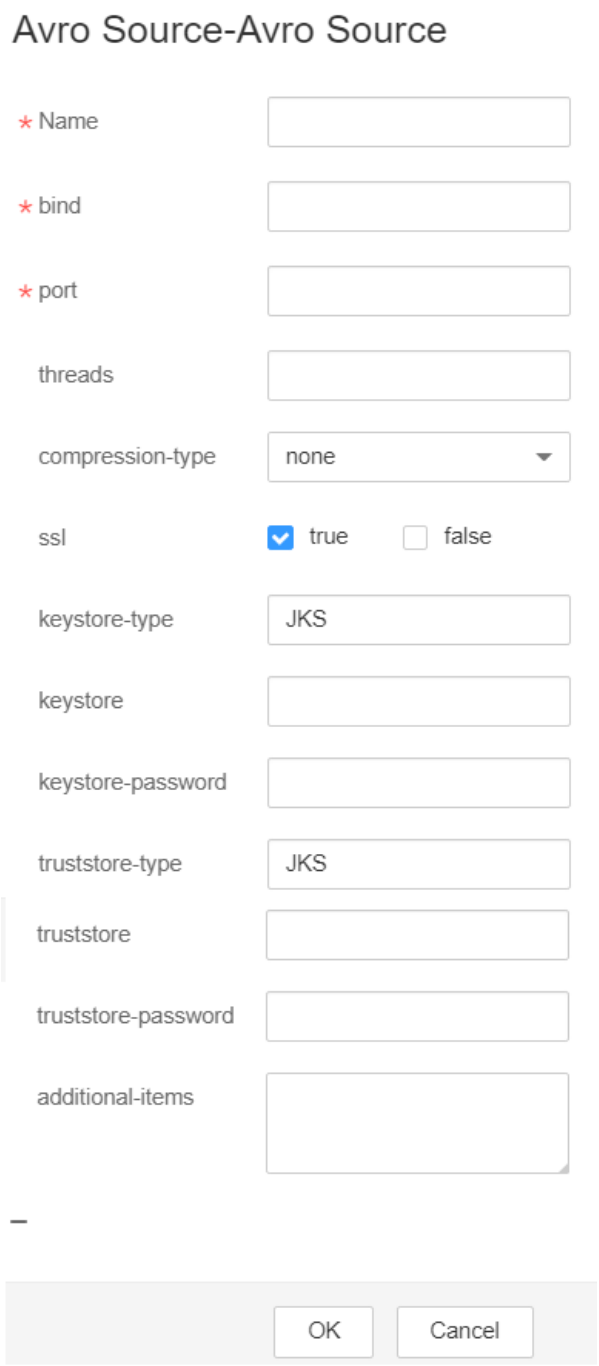


Table 7-33 Common configurations of an Avro source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured. Use spaces to separate them. In a single proxy process, sources and sinks are connected through channels. A source instance corresponds to multiple channels, but a sink instance corresponds only to one channel. The format is as follows: **<Agent >.sources.<Source>.channels = <channel1> <channel2> <channel3>...** **<Agent >.sinks.<Sink>.channels = <channel1>** This parameter can be configured only in the **properties.properties** file.
type	avro	Specifies the type, which is set to **avro**. The type of each source is a fixed value. This parameter can be configured only in the **properties.properties** file.
bind	-	Specifies the host name or IP address associated with the source.
port	-	Specifies the bound port number.
ssl	false	Specifies whether to use SSL encryption. • true • false
truststore-type	JKS	Specifies the Java trust store type. Set this parameter to **JKS** or other truststore types supported by Java.
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.

Parameter	Default Value	Description
keystore-type	JKS	Specifies the key storage type. Set this parameter to **JKS** or other truststore types supported by Java.
keystore	-	Specifies the key storage file.
keystore-password	-	Specifies the key storage password.

- **SpoolDir Source**

  A SpoolDir source monitors and transmits new files that have been added to directories in quasi-real-time mode. Common configurations are as follows:

Figure 7-43 SpoolDir Source

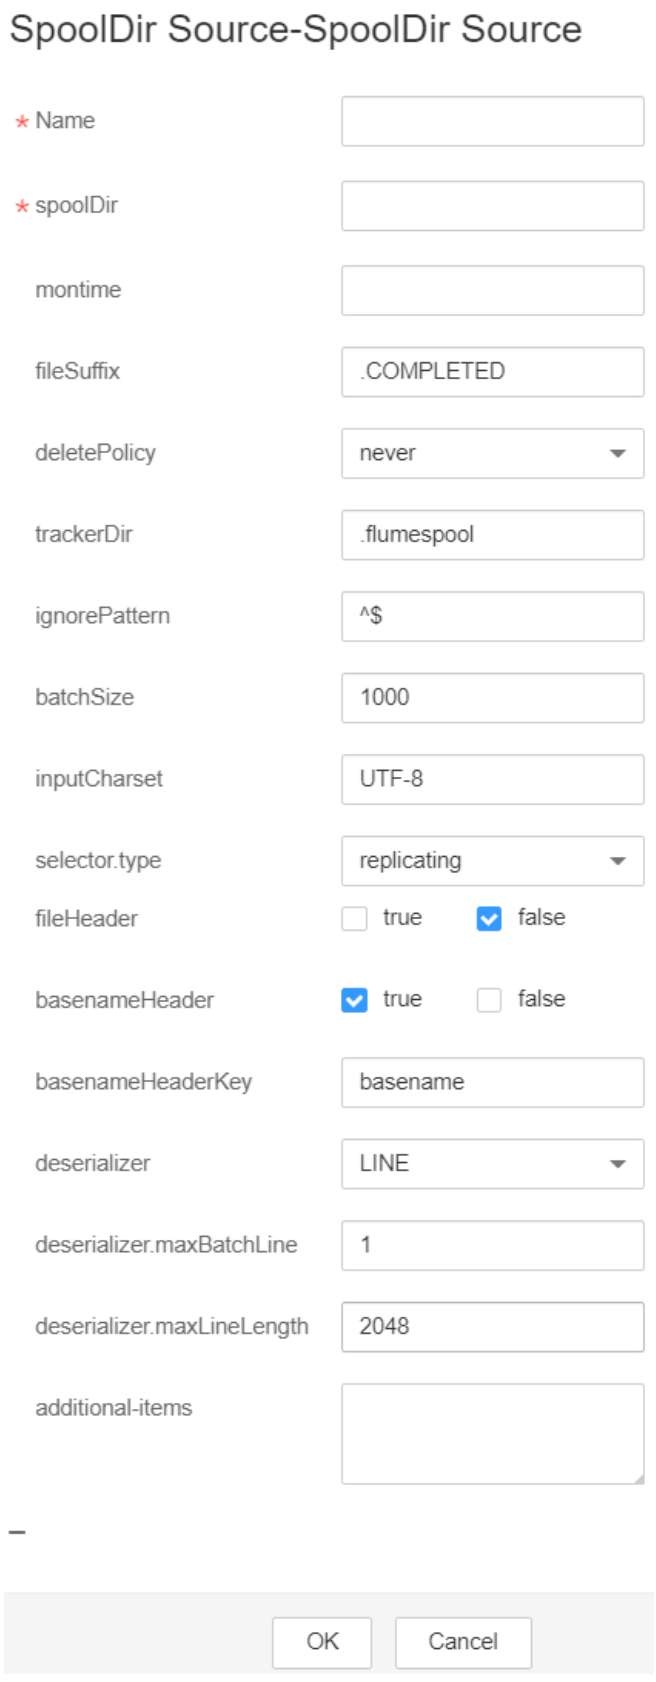

Table 7-34 Common configurations of a SpoolDir source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured. This parameter can be configured only in the **properties.properties** file.
type	spooldir	Type, which is set to **spooldir**. This parameter can be configured only in the **properties.properties** file.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second
spoolDir	-	Specifies the monitoring directory.
fileSuffix	.COMPLETED	Specifies the suffix added after file transmission is complete.
deletePolicy	never	Specifies the source file deletion policy after file transmission is complete. The value can be either **never** or **immediate**.
ignorePattern	^$	Specifies the regular expression of a file to be ignored.
trackerDir	.flumespool	Specifies the metadata storage path during data transmission.
batchSize	1000	Specifies the source transmission granularity.

Parameter	Default Value	Description
decodeErrorPolicy	FAIL	Specifies the code error policy. This parameter can be configured only in the **properties.properties** file. The value can be **FAIL**, **REPLACE**, or **IGNORE**. **FAIL**: Generate an exception and fail the parsing. **REPLACE**: Replace the characters that cannot be identified with other characters, such as U+FFFD. **IGNORE**: Discard character strings that cannot be parsed. **NOTE** If a code error occurs in the file, set **decodeErrorPolicy** to **REPLACE** or **IGNORE**. Flume will skip the code error and continue to collect subsequent logs.
deserializer	LINE	Specifies the file parser. The value can be either **LINE** or **BufferedLine**. ● When the value is set to **LINE**, characters read from the file are transcoded one by one. ● When the value is set to **BufferedLine**, one line or multiple lines of characters read from the file are transcoded in batches, which delivers better performance.
deserializer.maxLineLength	2048	Specifies the maximum length for resolution by line, ranging from 0 to 2,147,483,647.
deserializer.maxBatchLine	1	Specifies the maximum number of lines for resolution by line. If multiple lines are set, **maxLineLength** must be set to a corresponding multiplier. For example, if **maxBatchLine** is set to **2**, **maxLineLength** is set to **4096** (2048 x 2).

Parameter	Default Value	Description
selector.type	replicating	Specifies the selector type. The value can be either **replicating** or **multiplexing**. • **replicating** indicates that the same content is sent to each channel. • **multiplexing** indicates that the content is sent only to certain channels according to the distribution rule.
interceptors	-	Specifies the interceptor. This parameter can be configured only in the **properties.properties** file.

NOTE

The Spooling source ignores the last line feed character of each event when data is read by line. Therefore, Flume does not calculate the data volume counters used by the last line feed character.

- **Kafka Source**

  A Kafka source consumes data from Kafka topics. Multiple sources can consume data of the same topic, and the sources consume different partitions of the topic. Common configurations are as follows:

Figure 7-44 Kafka Source

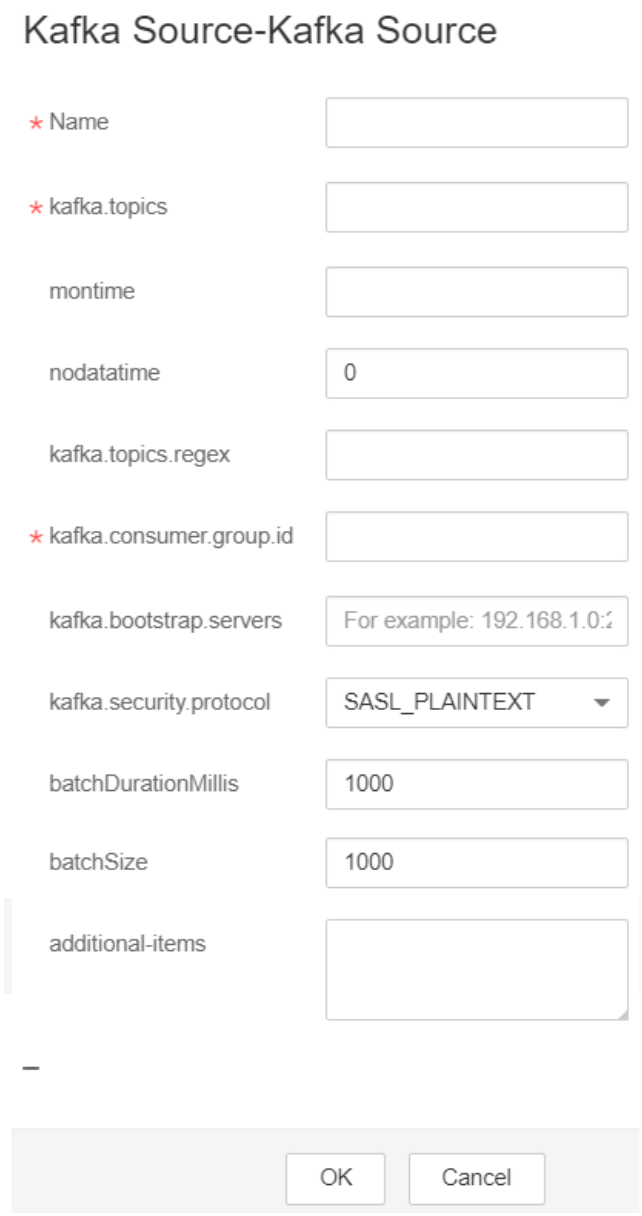

Table 7-35 Common configurations of a Kafka source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured. This parameter can be configured only in the **properties.properties** file.

Parameter	Default Value	Description
type	org.apache.flume.source.kafka.KafkaSource	Specifies the type, which is set to **org.apache.flume.source.kafka.KafkaSource**. This parameter can be configured only in the **properties.properties** file.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second
nodatatime	0 (Disabled)	Specifies the alarm threshold. An alarm is triggered when the duration that Kafka does not release data to subscribers exceeds the threshold. Unit: second
batchSize	1000	Specifies the number of events written into a channel at a time.
batchDurationMillis	1000	Specifies the maximum duration of topic data consumption at a time, expressed in milliseconds.
keepTopicInHeader	false	Specifies whether to save topics in the event header. If topics are saved, topics configured in Kafka sinks become invalid. ● true ● false This parameter can be configured only in the **properties.properties** file.
keepPartitionIn-Header	false	Specifies whether to save partition IDs in the event header. If partition IDs are saved, Kafka sinks write data to the corresponding partitions. ● true ● false This parameter can be set only in the properties.properties file.
kafka.bootstrap.servers	-	Specifies the list of Broker addresses, which are separated by commas.
kafka.consumer.group.id	-	Specifies the Kafka consumer group ID.

Parameter	Default Value	Description
kafka.topics	-	Specifies the list of subscribed Kafka topics, which are separated by commas (,).
kafka.topics.regex	-	Specifies the subscribed topics that comply with regular expressions. **kafka.topics.regex** has a higher priority than **kafka.topics** and will overwrite **kafka.topics**.
kafka.security.protocol	SASL_PLAINTEXT	Specifies the security protocol of Kafka. The value must be set to **PLAINTEXT** for clusters in which Kerberos authentication is disabled.
kafka.kerberos.domain.name	-	Specifies the value of **default_realm** of Kerberos in the Kafka cluster, which should be configured only for security clusters. This parameter can be set only in the properties.properties file.
Other Kafka Consumer Properties	-	Specifies other Kafka configurations. This parameter can be set to any consumption configuration supported by Kafka, and the **.kafka** prefix must be added to the configuration. This parameter can be set only in the properties.properties file.

- **Taildir Source**

  A Taildir source monitors file changes in a directory and automatically reads the file content. In addition, it can transmit data in real time. **Table 7-36** lists common configurations.

Figure 7-45 Taildir Source

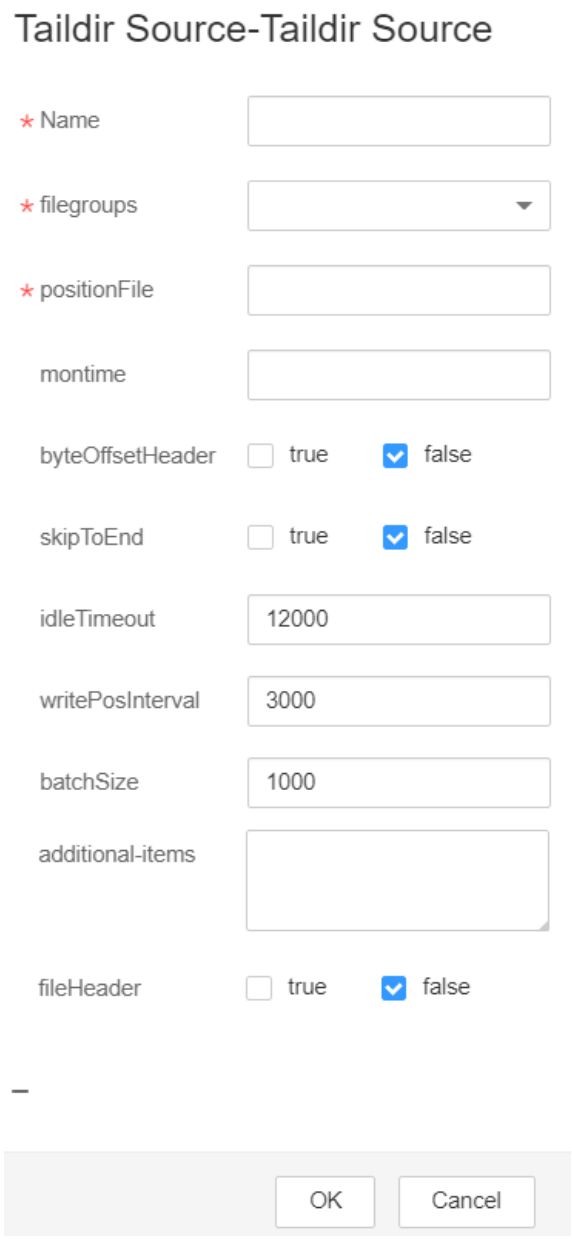

Table 7-36 Common configurations of a Taildir source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured. This parameter can be set only in the properties.properties file.

Parameter	Default Value	Description
type	taildir	Specifies the type, which is set to **taildir**. This parameter can be set only in the properties.properties file.
filegroups	-	Specifies the group name of a collection file directory. Group names are separated by spaces.
filegroups.<filegroupName>.parentDir	-	Specifies the parent directory. The value must be an absolute path. This parameter can be set only in the properties.properties file.
filegroups.<filegroupName>.filePattern	-	Specifies the relative file path of the file group's parent directory. Directories can be included and regular expressions are supported. It must be used together with **parentDir**. This parameter can be set only in the properties.properties file.
positionFile	-	Specifies the metadata storage path during data transmission.
headers.<filegroupName>.<headerKey>	-	Specifies the key-value of an event when data of a group is being collected. This parameter can be set only in the properties.properties file.
byteOffsetHeader	false	Specifies whether each event header should contain the location information about the event in the source file. The location information is saved in the **byteoffset** variable.
skipToEnd	false	Specifies whether Flume can locate the latest location of a file and read the latest data after restart.
idleTimeout	120000	Specifies the idle duration during file reading, expressed in milliseconds. If the file data is not changed in this idle period, the source closes the file. If data is written into this file after it is closed, the source opens the file and reads data.

Parameter	Default Value	Description
writePosInterval	3000	Specifies the interval for writing metadata to a file, expressed in milliseconds.
batchSize	1000	Specifies the number of events written to the channel in batches.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the source is restarted. Unit: second

- **Http Source**

  An HTTP source receives data from an external HTTP client and sends the data to the configured channels. **Table 7-37** lists common configurations.

  Figure 7-46 Http Source

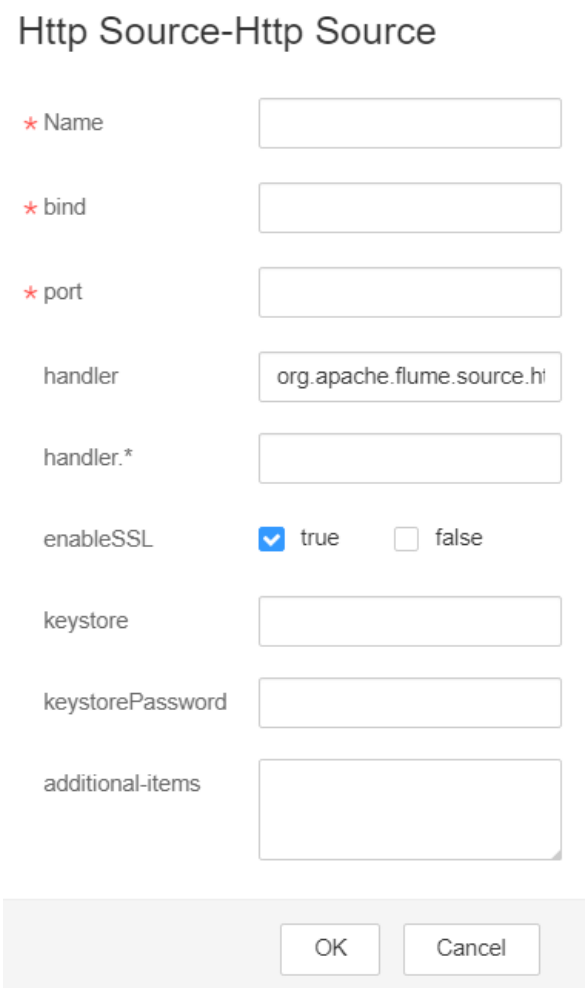

Table 7-37 Common configurations of an HTTP source

Parameter	Default Value	Description
channels	-	Specifies the channel connected to the source. Multiple channels can be configured. This parameter can be set only in the properties.properties file.
type	http	Specifies the type, which is set to **http**. This parameter can be set only in the properties.properties file.
bind	-	Specifies the name or IP address of the bound host.
port	-	Specifies the bound port.
handler	org.apache.flume.source.http.JSONHandler	Specifies the message parsing method of an HTTP request. The following methods are supported: • **org.apache.flume.source.http.JSONHandler**: JSON • **org.apache.flume.sink.solr.morphline.BlobHandler**: BLOB
handler.*	-	Specifies handler parameters.
enableSSL	false	Specifies whether SSL is enabled in HTTP.
keystore	-	Specifies the keystore path set after SSL is enabled in HTTP.
keystorePassword	-	Specifies the keystore password set after SSL is enabled in HTTP.

Common Channel Configurations

- **Memory Channel**

  A memory channel uses memory as the cache. Events are stored in memory queues. **Table 7-38** lists common configurations.

Figure 7-47 Memory Channel

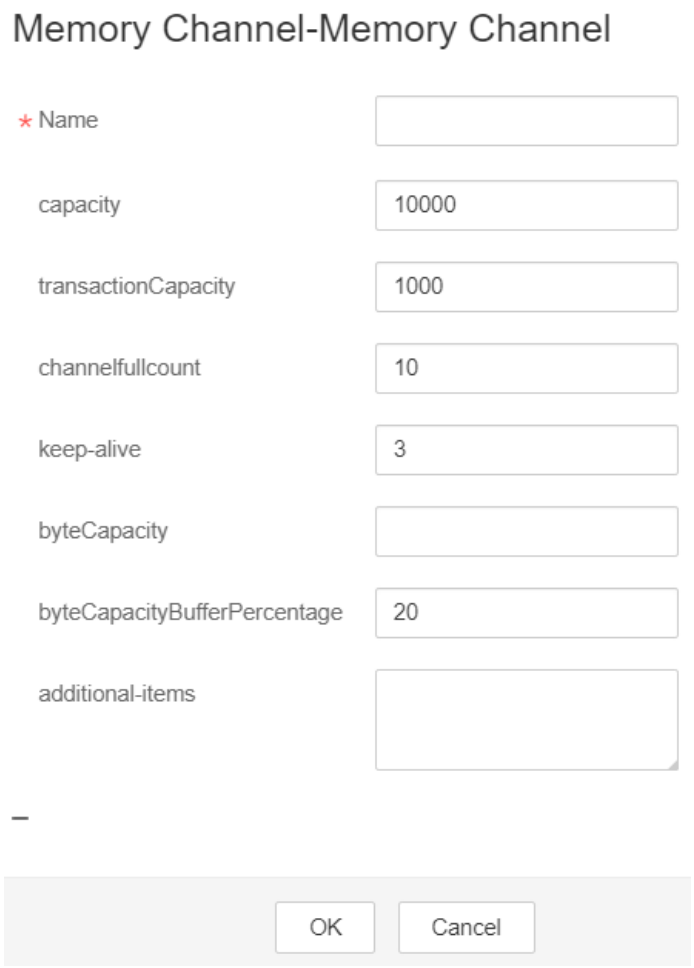

Table 7-38 Common configurations of a memory channel

Parameter	Default Value	Description
type	-	Specifies the type, which is set to **memory**. This parameter can be set only in the properties.properties file.
capacity	10000	Specifies the maximum number of events cached in a channel.
transactionCapacity	1000	Specifies the maximum number of events accessed each time.
channelfullcount	10	Specifies the channel full count. When the count reaches the threshold, an alarm is reported.

- **File Channel**

  A file channel uses local disks as the cache. Events are stored in the folder specified by **dataDirs**. Table 7-39 lists common configurations.

Figure 7-48 File Channel

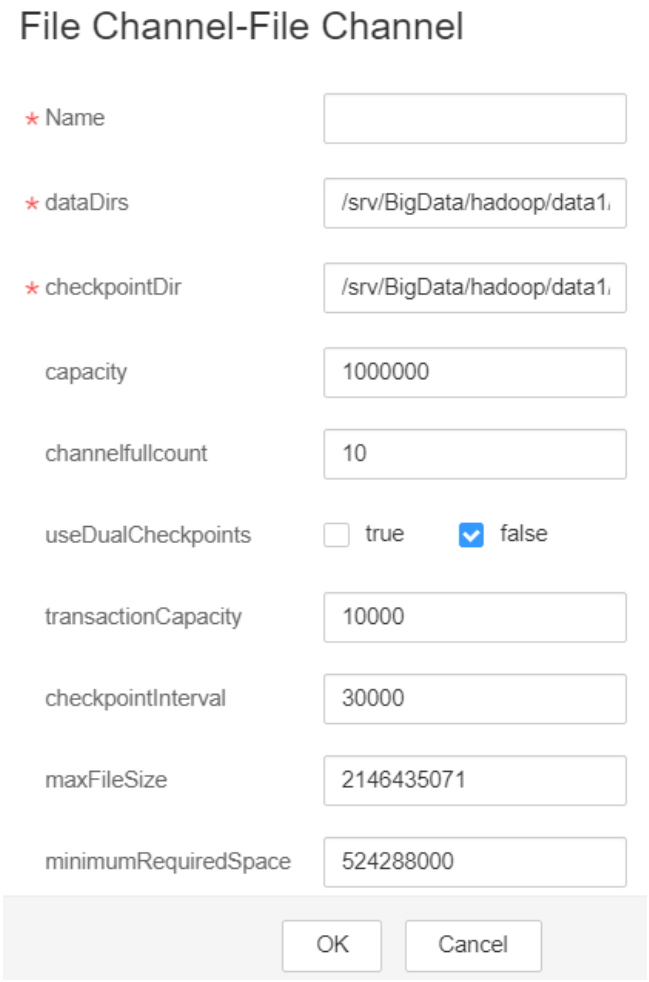

Table 7-39 Common configurations of a file channel

Parameter	Default Value	Description
type	-	Specifies the type, which is set to **file**. This parameter can be set only in the properties.properties file.
checkpointDir	${BIGDATA_DATA_HOME}/flume/checkpoint	Specifies the checkpoint storage directory.
dataDirs	${BIGDATA_DATA_HOME}/flume/data	Specifies the data cache directory. Multiple directories can be configured to improve performance. The directories are separated by commas (,).

Parameter	Default Value	Description
maxFileSize	2146435071	Specifies the maximum size of a single cache file, expressed in bytes.
minimumRequired-Space	524288000	Specifies the minimum idle space in the cache, expressed in bytes.
capacity	1000000	Specifies the maximum number of events cached in a channel.
transactionCapacity	10000	Specifies the maximum number of events accessed each time.
channelfullcount	10	Specifies the channel full count. When the count reaches the threshold, an alarm is reported.

- **Kafka Channel**

  A Kafka channel uses a Kafka cluster as the cache. Kafka provides high availability and multiple copies to prevent data from being immediately consumed by sinks when Flume or Kafka Broker crashes. **Table 10 Common configurations of a Kafka channel** lists common configurations.

Figure 7-49 Kafka Channel

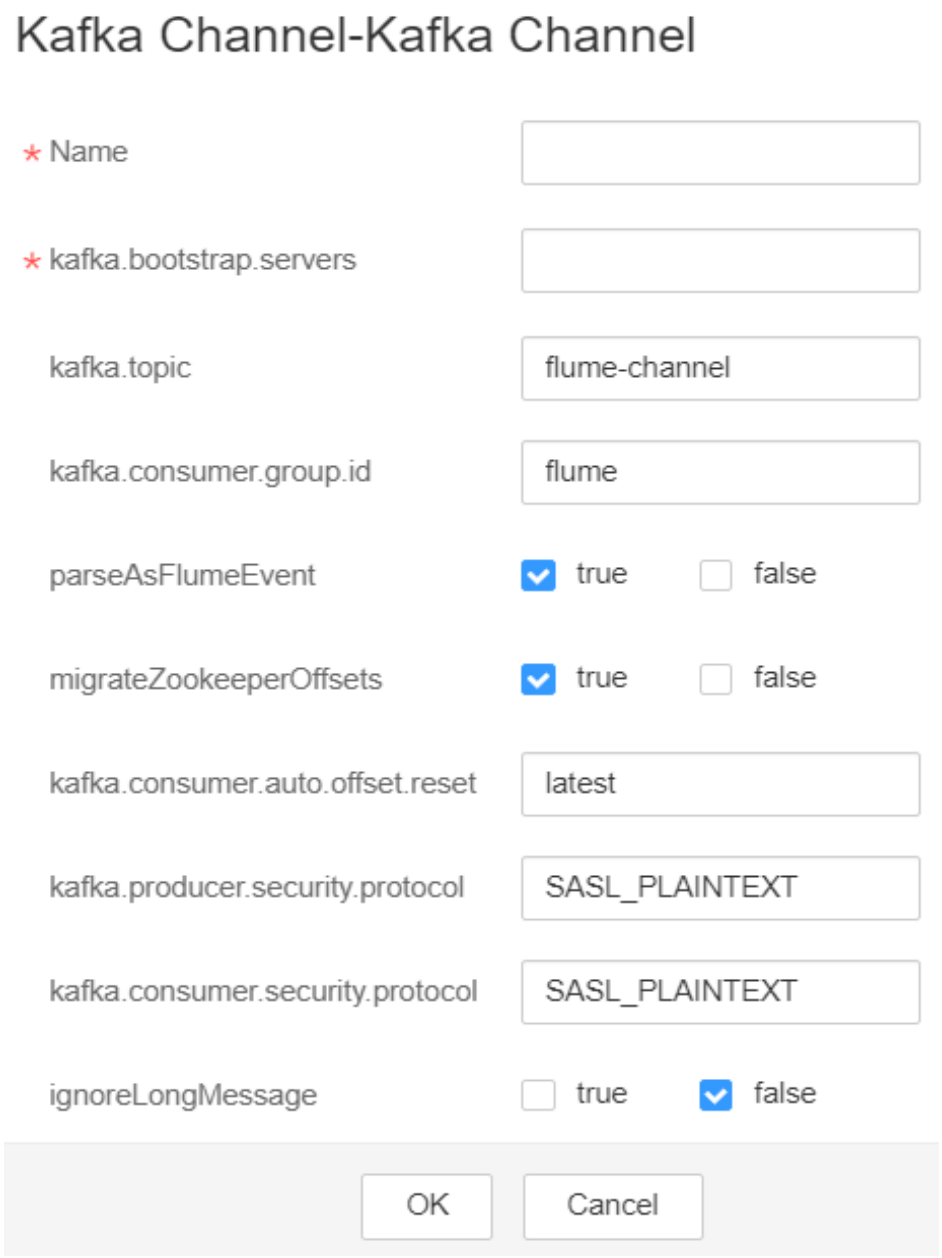

Table 7-40 Common configurations of a Kafka channel

Parameter	Default Value	Description
type	-	Specifies the type, which is set to **org.apache.flume.channel.kafka.KafkaChannel**. This parameter can be set only in the properties.properties file.
kafka.bootstrap.servers	-	Specifies the list of Brokers in the Kafka cluster.

Parameter	Default Value	Description
kafka.topic	flume-channel	Specifies the Kafka topic used by the channel to cache data.
kafka.consumer.group.id	flume	Specifies the Kafka consumer group ID.
parseAsFlumeEvent	true	Specifies whether data is parsed into Flume events.
migrateZookeeper-Offsets	true	Specifies whether to search for offsets in ZooKeeper and submit them to Kafka when there is no offset in Kafka.
kafka.consumer.auto.offset.reset	latest	Consumes data from the specified location when there is no offset.
kafka.producer.security.protocol	SASL_PLAINTEXT	Specifies the Kafka producer security protocol.
kafka.consumer.security.protocol	SASL_PLAINTEXT	Specifies the Kafka consumer security protocol.

Common Sink Configurations

- **HDFS Sink**

  An HDFS sink writes data into HDFS. **Table 7-41** lists common configurations.

Figure 7-50 HDFS Sink

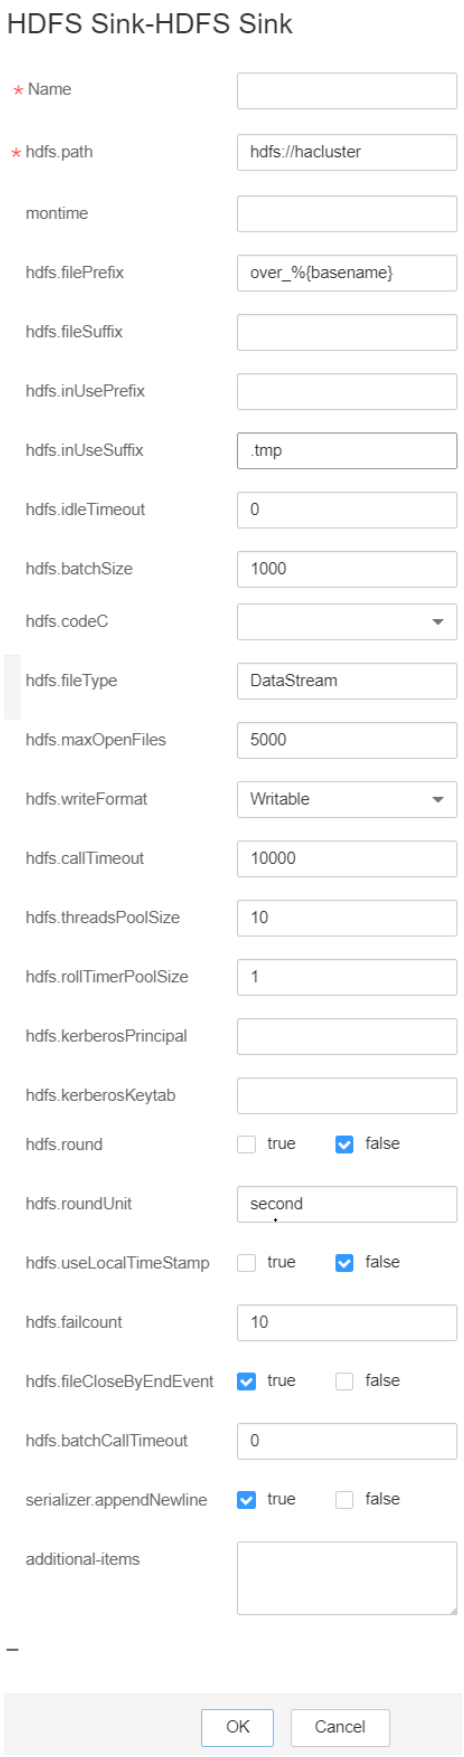

Table 7-41 Common configurations of an HDFS sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink. This parameter can be set only in the properties.properties file.
type	hdfs	Specifies the type, which is set to **hdfs**. This parameter can be set only in the properties.properties file.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second
hdfs.path	-	Specifies the HDFS path.
hdfs.inUseSuffix	.tmp	Specifies the suffix of the HDFS file to which data is being written.
hdfs.rollInterval	30	Specifies the interval for file rolling, expressed in seconds. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter.
hdfs.rollSize	1024	Specifies the size for file rolling, expressed in bytes. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter.
hdfs.rollCount	10	Specifies the number of events for file rolling. Set **hdfs.fileCloseByEndEvent** to **false** if you set this parameter.
hdfs.idleTimeout	0	Specifies the timeout interval for closing idle files automatically, expressed in seconds.
hdfs.batchSize	1000	Specifies the number of events written into HDFS at a time.
hdfs.kerberosPrincipal	-	Specifies the Kerberos username for HDFS authentication. This parameter is not required for a cluster in which Kerberos authentication is disabled.
hdfs.kerberosKeytab	-	Specifies the Kerberos keytab of HDFS authentication. This parameter is not required for a cluster in which Kerberos authentication is disabled.

Parameter	Default Value	Description
hdfs.fileCloseByEndEvent	true	Specifies whether to close the file when the last event is received.
hdfs.batchCallTimeout	-	Specifies the timeout control duration each time events are written into HDFS, expressed in milliseconds. If this parameter is not specified, the timeout duration is controlled when each event is written into HDFS. When the value of **hdfs.batchSize** is greater than 0, configure this parameter to improve the performance of writing data into HDFS. **NOTE** The value of **hdfs.batchCallTimeout** depends on **hdfs.batchSize**. A greater **hdfs.batchSize** requires a larger **hdfs.batchCallTimeout**. If the value of **hdfs.batchCallTimeout** is too small, writing events to HDFS may fail.
serializer.appendNewline	true	Specifies whether to add a line feed character (**\n**) after an event is written to HDFS. If a line feed character is added, the data volume counters used by the line feed character will not be calculated by HDFS sinks.

- **Avro Sink**

  An Avro sink converts events into Avro events and sends them to the monitoring ports of the hosts. **Table 7-42** lists common configurations.

Figure 7-51 Avro Sink

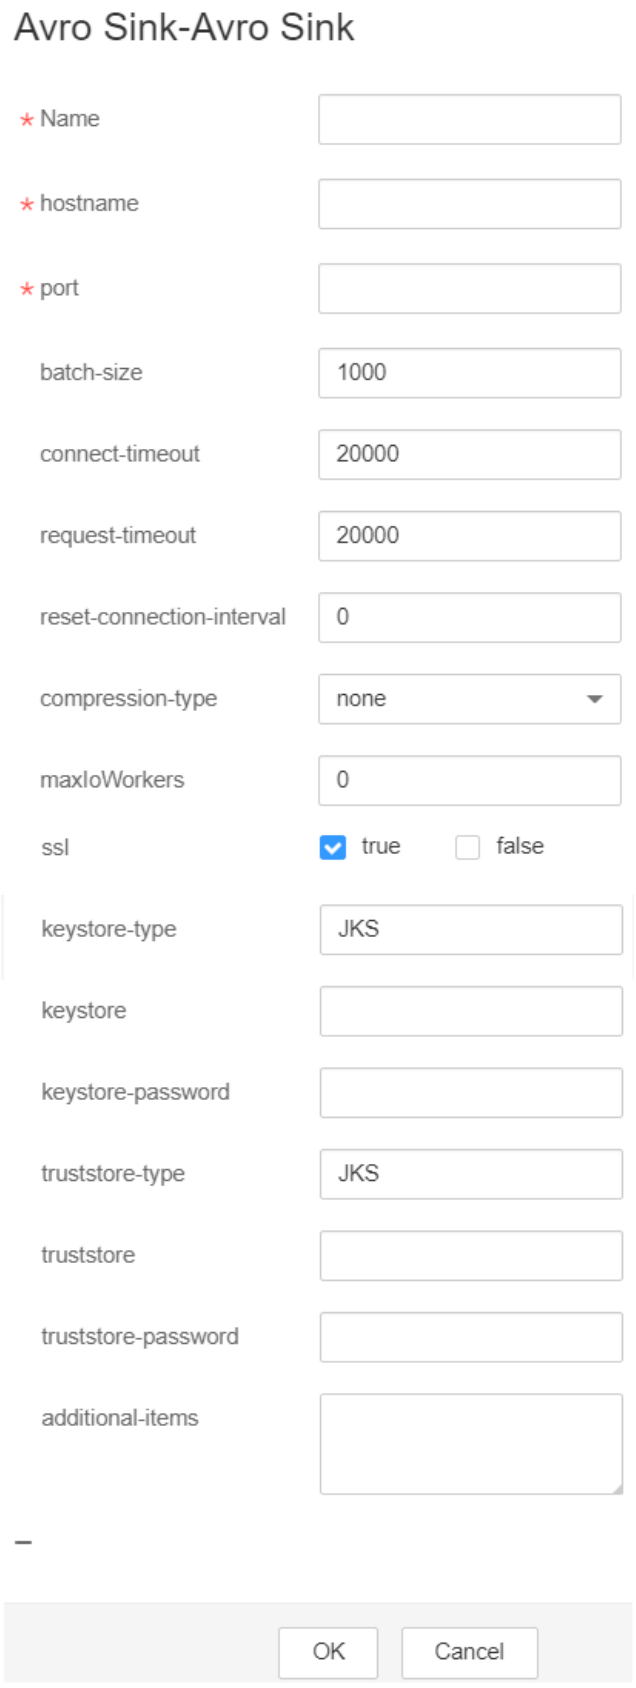

Table 7-42 Common configurations of an Avro sink

Parameter	Default Value	Description
channel	**-**	Specifies the channel connected to the sink. This parameter can be set only in the properties.properties file.
type	-	Specifies the type, which is set to **avro**. This parameter can be set only in the properties.properties file.
hostname	-	Specifies the name or IP address of the bound host.
port	-	Specifies the monitoring port.
batch-size	1000	Specifies the number of events sent in a batch.
ssl	false	Specifies whether to use SSL encryption.
truststore-type	JKS	Specifies the Java trust store type.
truststore	-	Specifies the Java trust store file.
truststore-password	-	Specifies the Java trust store password.
keystore-type	JKS	Specifies the key storage type.
keystore	-	Specifies the key storage file.
keystore-password	-	Specifies the key storage password.

- **HBase Sink**

  An HBase sink writes data into HBase. **Table 7-43** lists common configurations.

Figure 7-52 HBase Sink

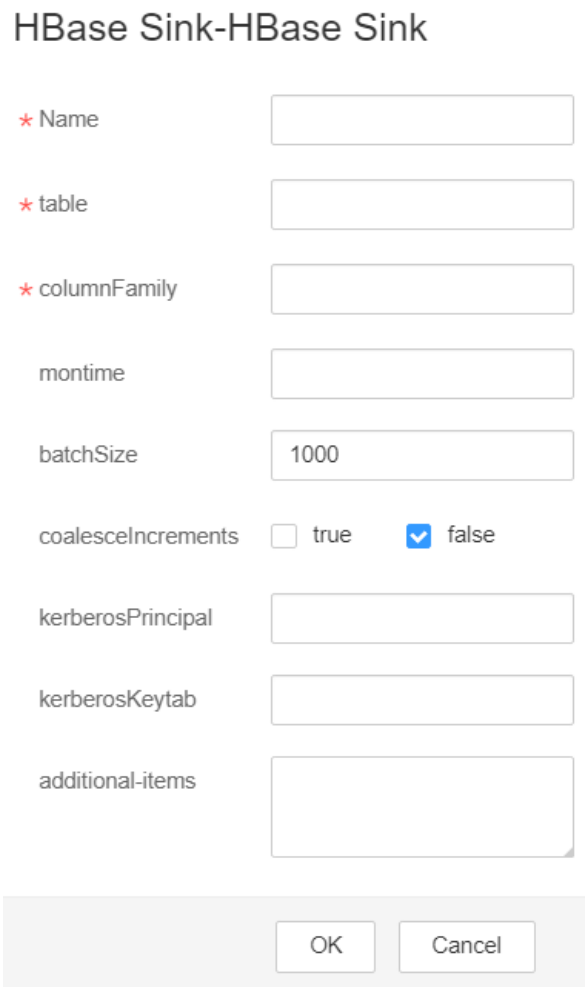

Table 7-43 Common configurations of an HBase sink

Parameter	Default Value	Description
channel	-	Specifies the channel connected to the sink. This parameter can be set only in the properties.properties file.
type	-	Specifies the type, which is set to **hbase**. This parameter can be set only in the properties.properties file.
table	-	Specifies the HBase table name.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second
columnFamily	-	Specifies the HBase column family.

Parameter	Default Value	Description
batchSize	1000	Specifies the number of events written into HBase at a time.
kerberosPrincipal	-	Specifies the Kerberos username for HBase authentication. This parameter is not required for a cluster in which Kerberos authentication is disabled.
kerberosKeytab	-	Specifies the Kerberos keytab of HBase authentication. This parameter is not required for a cluster in which Kerberos authentication is disabled.

- **Kafka Sink**

  A Kafka sink writes data into Kafka. **Table 7-44** lists common configurations.

  Figure 7-53 Kafka Sink

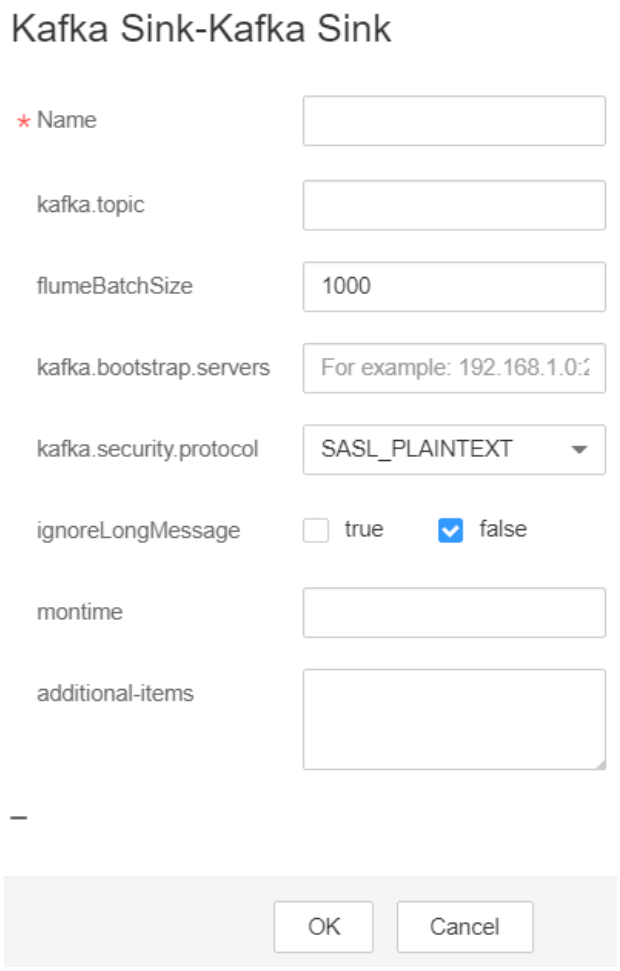

Table 7-44 Common configurations of a Kafka sink

Parameter	Default Value	Description
channel	**-**	Specifies the channel connected to the sink. This parameter can be set only in the properties.properties file.
type	-	Specifies the type, which is set to **org.apache.flume.sink.kafka.KafkaSink**. This parameter can be set only in the properties.properties file.
kafka.bootstrap.servers	-	Specifies the list of Kafka Brokers, which are separated by commas.
monTime	0 (Disabled)	Specifies the thread monitoring threshold. When the update time exceeds the threshold, the sink is restarted. Unit: second
kafka.topic	default-flume-topic	Specifies the topic where data is written.
flumeBatchSize	1000	Specifies the number of events written into Kafka at a time.
kafka.security.protocol	SASL_PLAINTEXT	Specifies the security protocol of Kafka. The value must be set to **PLAINTEXT** for clusters in which Kerberos authentication is disabled.
kafka.kerberos.domain.name	-	Specifies the Kafka domain name. This parameter is mandatory for a security cluster. This parameter can be set only in the properties.properties file.
Other Kafka Producer Properties	-	Specifies other Kafka configurations. This parameter can be set to any production configuration supported by Kafka, and the **.kafka** prefix must be added to the configuration. This parameter can be set only in the properties.properties file.

7.8.2 Flume Log Overview

Log Description

Log path: The default path of Flume log files is **/var/log/Bigdata/***Role name*.

- FlumeServer: **/var/log/Bigdata/flume/flume**
- FlumeClient: **/var/log/Bigdata/flume-client-n/flume**
- MonitorServer: **/var/log/Bigdata/flume/monitor**

Log archive rule: The automatic Flume log compression function is enabled. By default, when the size of logs exceeds 50 MB , logs are automatically compressed into a log file named in the following format: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss>.[ID]***.log.zip**. A maximum of 20 latest compressed files are reserved. The number of compressed files can be configured on the Manager portal.

Table 7-45 Flume log list

Type	Name	Description
Run logs	/flume/flumeServer.log	Log file that records FlumeServer running environment information.
	/flume/install.log	FlumeServer installation log file
	/flume/flumeServer-gc.log.*<No.>*	GC archive log file of the FlumeServer process
	/flume/prestartDvietail.log	Work log file before the FlumeServer startup
	/flume/startDetail.log	Startup log file of the Flume process
	/flume/stopDetail.log	Shutdown log file of the Flume process
	/monitor/monitorServer.log	Log file that records MonitorServer running environment information
	/monitor/startDetail.log	Startup log file of the MonitorServer process
	/monitor/stopDetail.log	Shutdown log file of the MonitorServer process
	function.log	External function invoking log file
	/flume/flume-*Username*-*Date*-*pid*-gc.log	GC log file of the Flume process
	/flume/Flume-audit.log	Audit log file of the Flume client
	/flume/startAgent.out	Process parameter log file generated before Flume startup

Type	Name	Description
Stack information log (MRS 3.2.0 or later)	threadDump-<DATE>.log	The jstack log file to be printed when the NodeAgent delivers a service stop command

Log Level

Table 7-46 describes the log levels supported by Flume.

Levels of run logs are FATAL, ERROR, WARN, INFO, and DEBUG from the highest to the lowest priority. Run logs of equal or higher levels are recorded. The higher the specified log level, the fewer the logs recorded.

Table 7-46 Log level

Type	Level	Description
Run log	FATAL	Logs of this level record critical error information about system running.
	ERROR	Logs of this level record error information about system running.
	WARN	Logs of this level record exception information about the current event processing.
	INFO	Logs of this level record normal running status information about the system and events.
	DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of Flume by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the menu bar on the left, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

----End

NOTE

The configurations take effect immediately without the need to restart the service.

Log Format

The following table lists the Flume log formats.

Table 7-47 Log format

Type	Format	Example
Run logs	<*yyyy-MM-dd HH:mm:ss,SSS*>|<*Log level*>|<*Name of the thread that generates the log*>|<*Message in the log*>|<*Location where the log event occurs*>	2014-12-12 11:54:57,316 | INFO | [main] | log4j dynamic load is start. | org.apache.flume.tools.LogDynamicLoad.start(LogDynamicLoad.java:59)
	<*yyyy-MM-dd HH:mm:ss,SSS*><*Username*><*User IP*><*Time*><*Operation*><*Resource*><*Result*><*Detail*>	2014-12-12 23:04:16,572 | INFO | [SinkRunner-PollingRunner-DefaultSinkProcessor] | SRCIP=null OPERATION=close

7.8.3 Viewing Flume Client Logs

Step 1 Install the Flume client.

Step 2 Go to the Flume client log directory (**/var/log/Bigdata** by default).

Step 3 Run the following command to view the log file:

ls -lR flume-client-*

A log file is shown as follows:

```
flume-client-1/flume:
total 7672
-rw-------. 1 root root       0 Sep  8 19:43 Flume-audit.log
-rw-------. 1 root root 1562037 Sep 11 06:05 FlumeClient.2017-09-11_04-05-09.[1].log.zip
-rw-------. 1 root root 6127274 Sep 11 14:47 FlumeClient.log
-rw-------. 1 root root    2935 Sep  8 22:20 flume-root-20170908202009-pid72456-gc.log.0.current

flume-client-1/monitor:
total 8
-rw-------. 1 root root  141 Sep  8 19:43 flumeMonitorChecker.log
-rw-------. 1 root root 2946 Sep 11 13:24 flumeMonitor.log
```

In the log file, **FlumeClient.log** is the run log of the Flume client.

----End

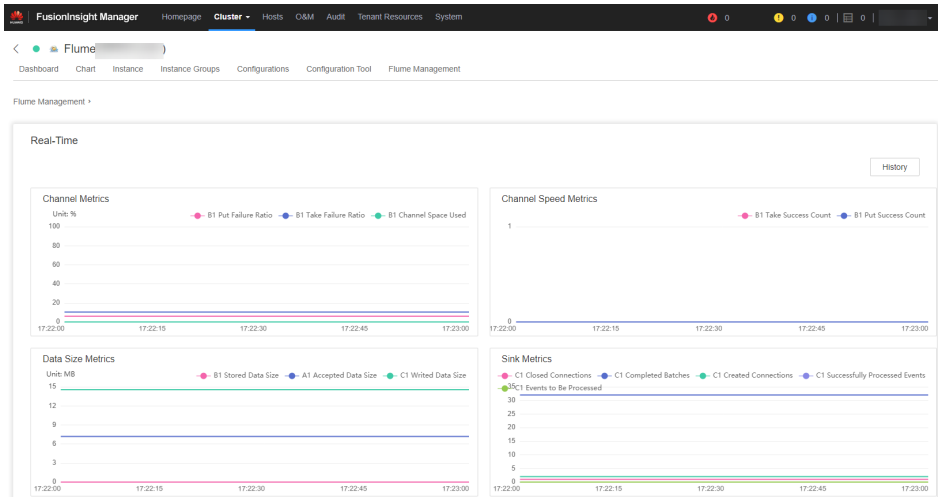
7.8.4 Viewing Flume Client Monitoring Information

The Flume client outside the FusionInsight cluster is a part of the end-to-end data collection. Both the Flume client outside the cluster and the Flume server in the cluster need to be monitored. Users can use FusionInsight Manager to monitor the Flume client and view the monitoring indicators of the Source, Sink, and Channel of the client as well as the client process status.

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **Flume** > **Flume Management** to view the current Flume client list and process status.

Figure 7-54 Viewing Flume client monitoring information on the **Flume Management** page



Step 3 Click the **Instance ID**, and view client monitoring metrics in the **Current** area.

Step 4 Click **History**. The page for querying historical monitoring data is displayed. Select a time range and click **View** to view the monitoring data within the time range.

----End

7.8.5 Stopping or Uninstalling the Flume Client

Scenario

You can stop and start the Flume client or uninstall the Flume client when the Flume data ingestion channel is not required.

Procedure

- Stop the Flume client of the Flume role.

  Assume that the Flume client installation path is **/opt/FlumeClient**. Run the following command to stop the Flume client:

  cd /opt/FlumeClient/fusioninsight-flume-*Flume component version number***/bin**

  ./flume-manage.sh stop

  If the following information is displayed after the command execution, the Flume client is successfully stopped.

  ```
  Stop Flume PID=120689 successful..
  ```

  NOTE

  The Flume client will be automatically restarted after being stopped. If you do not need automatic restart, run the following command:

  ./flume-manage.sh stop force

  If you want to restart the Flume client, run the following command:

  ./flume-manage.sh start force

- Uninstall the Flume client of the Flume role.

  Assume that the Flume client installation path is **/opt/FlumeClient**. Run the following command to uninstall the Flume client:

  cd /opt/FlumeClient/fusioninsight-flume-*Flume component version number***/inst**

  ./uninstall.sh

7.9 Common Issues About Flume

7.9.1 How Do I View Flume Logs

Flume logs are stored in **/var/log/Bigdata/flume/flume/flumeServer.log**. Most data transmission exceptions and data transmission failures are recorded in logs. You can run the following command:

tailf /var/log/Bigdata/flume/flume/flumeServer.log

- Problem: After the configuration file is uploaded, an exception occurs. After the configuration file is uploaded again, the scenario requirements are still not met, but no exception is recorded in the log.

  Solution: Restart the Flume process, run the **kill -9** *Process code* to kill the process code, and view the logs.

- Issue: **"java.lang.IllegalArgumentException: Keytab is not a readable file: /opt/test/conf/user.keytab"** is displayed when HDFS is connected.

  Solution: Grant the read and write permissions to the Flume running user.

- Problem: The following error is reported when the Flume client is connected to Kafka:

  ```
  Caused by: java.io.IOException: /opt/FlumeClient/fusioninsight-flume-1.9.0/cof//jaas.conf (No such file or directory)
  ```

  Solution: Add the **jaas.conf** configuration file and save it to the **conf** directory of the Flume client.

vi jaas.conf

```
KafkaClient {
com.sun.security.auth.module.Krb5LoginModule required
useKeyTab=true
keyTab="/opt/test/conf/user.keytab"
principal="flume_hdfs@<System domain name>"
useTicketCache=false
storeKey=true
debug=true;
};
```

Values of **keyTab** and **principal** vary depending on the actual situation.

- Problem: The following error is reported when the Flume client is connected to HBase:
  ```
  Caused by: java.io.IOException: /opt/FlumeClient/fusioninsight-flume-1.9.0/cof//jaas.conf (No such file or directory)
  ```
  Solution: Add the **jaas.conf** configuration file and save it to the **conf** directory of the Flume client.

  vi jaas.conf

  ```
  Client {
  com.sun.security.auth.module.Krb5LoginModule required
  useKeyTab=true
  keyTab="/opt/test/conf/user.keytab"
  principal="flume_hbase@<System domain name>"
  useTicketCache=false
  storeKey=true
  debug=true;
  };
  ```

  Values of **keyTab** and **principal** vary depending on the actual situation.
- Question: After the configuration file is submitted, the Flume Agent occupies resources. How do I restore the Flume Agent to the state when the configuration file is not uploaded?

  Solution: Submit an empty **properties.properties** file.

7.9.2 How Do I Use Environment Variables in the Flume Configuration File

Step 1 Log in to the node where the Flume client is installed as user **root**.

Step 2 Switch to the following directory:

cd *Flume client installation directory*/**fusioninsight-flume**-*Flume component version*/**conf**

Step 3 Add environment variables to the **flume-env.sh** file in the directory.

- Format:
  ```
  export Variable name=Variable value
  ```
- Example:
  ```
  JAVA_OPTS="-Xms2G -Xmx4G -XX:CMSFullGCsBeforeCompaction=1 -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:+UseCMSCompactAtFullCollection -DpropertiesImplementation=org.apache.flume.node.EnvVarResolverProperties"
  export TAILDIR_PATH=/tmp/flumetest/201907/20190703/1/.*log.*
  ```

Step 4 Restart the Flume instance process.

1. Log in to FusionInsight Manager.

2. Choose **Cluster** > **Services** > **Flume**. On the page that is displayed, click the **Instance** tab, select all Flume instances, and choose **More** > **Restart Instance**. In the displayed **Verify Identity** dialog box, enter the password, and click **OK**.

NOTICE

Do not restart the Flume service on FusionInsight Manager after **flume-env.sh** takes effect on the server. Otherwise, the user-defined environment variables will lost. You only need to restart the corresponding instances on FusionInsight Manager.

Step 5 In the *Flume client installation directory*/**fusioninsight-flume-***Flume component version number*/**conf/properties.properties** configuration file, reference variables in the **${***Variable name***}** format. The following is an example:

```
client.sources.s1.type = TAILDIR
client.sources.s1.filegroups = f1
client.sources.s1.filegroups.f1 = ${TAILDIR_PATH}
client.sources.s1.positionFile = /tmp/flumetest/201907/20190703/1/taildir_position.json
client.sources.s1.channels = c1
```

NOTICE

- Ensure that **flume-env.sh** takes effect before you go to **Step 5** to configure the **properties.properties** file.
- If you configure file on the local host, upload the file on FusionInsight Manager by performing the following steps. The user-defined environment variables may be lost if the operations are not performed in the correct sequence.
  1. Log in to FusionInsight Manager.
  2. Choose **Cluster** > **Services** > **Flume**. On the page that is displayed, click the **Configurations** tab, select the Flume instance, and click **Upload File** next to **flume.config.file** to upload the **properties.properties** file.

----End

7.9.3 How Do I Develop a Third-Party Flume Plug-in

Step 1 Install the Flume client, for example, in the **/opt/flumeclient** directory.

Step 2 Compress the self-developed code into a JAR package.

Step 3 Create a directory for the plug-in.

1. Go to *Flume client installation directory*/**fusionInsight-flume-*/plugins.d** and run the following command to create a directory. The directory name can be changed based on the site requirements.

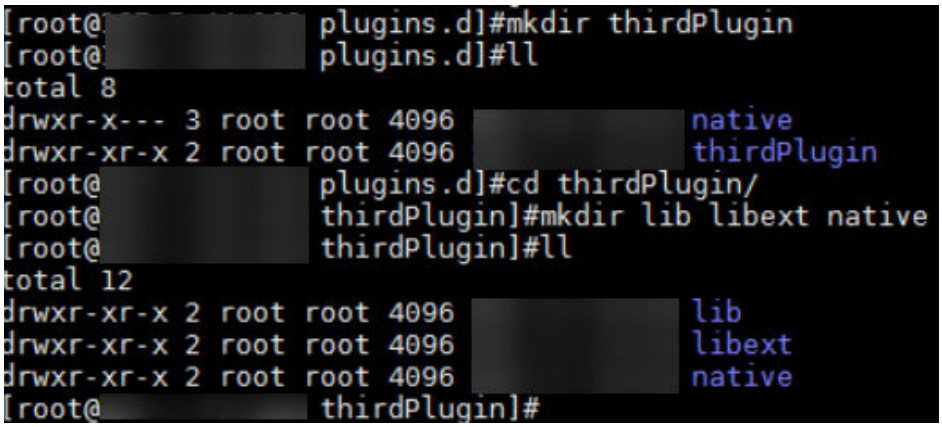
   cd /opt/flumeclient/fusioninsight-flume-1.9.0/plugins.d

   mkdir thirdPlugin

   cd thirdPlugin

   mkdir lib libext native

   The command output is displayed as follows:



2. Place the third-party JAR package in *Flume client installation directory*/**fusionInsight-flume-*/plugins.d/thirdPlugin/lib**. If the JAR package depends on other JAR packages, place the dependent JAR packages in *Flume client installation directory*/**fusionInsight-flume-*/plugins.d/thirdPlugin/libext**. Stores local library files in *Flume client installation directory*/**fusionInsight-flume-*/plugins.d/thirdPlugin/native**.

Step 4 Configure the *Flume client installation directory*/**fusionInsight-flume-*/conf/properties.properties** file.

For details about how to set parameters in the **properties.properties** file, see the parameter list in the **properties.properties** file in the corresponding typical scenario **Configuring a Non-Encrypted Flume Data Collection Task** and **Configuring an Encrypted Flume Data Collection Task**.

----End

7.9.4 How Do I Configure a Custom Flume Script

Flume supports customized scripts to be run before or after transmission for making preparations.

The Flume client is not installed

Step 1 Obtain the software package.

Log in to the FusionInsight Manager. Choose **Cluster** > *Name of the target cluster* > **Services** > **Flume**. On the Flume service page that is displayed, choose **More** > **Download Client** in the upper right corner and set **Client Type** to **Complete Client** to download the Flume service client file.

The file name of the client is **FusionInsight_Cluster_**<*Cluster ID*>**_Flume_Client.tar**. This section takes the client file **FusionInsight_Cluster_1_Flume_Client.tar** as an example.

Step 2 Upload the software package. Upload the software package to a directory, for example, **/opt/client**, on the node where the Flume client is to be installed as user **user**.

NOTE

user is the user who installs and runs the Flume client.

Step 3 Decompress the software package.

Log in to the node where the Flume service client is to be installed as user **user**. Go to the directory where the installation package is installed, for example, **/opt/client**, and run the following command to decompress the installation package to the current directory:

cd /opt/client

tar -xvf FusionInsight_Cluster_1_Flume_Client.tar

Step 4 Verify the software package.

Run the **sha256sum -c** command to verify the decompressed file. If **OK** is returned, the verification is successful. Example:

sha256sum -c FusionInsight_Cluster_1_Flume_ClientConfig.tar.sha256

```
FusionInsight_Cluster_1_Flume_ClientConfig.tar: OK
```

Step 5 Decompress the package.

tar -xvf FusionInsight_Cluster_1_Flume_ClientConfig.tar

Step 6 Configure **client.per-check.shell** in the **/opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FlumeClient/flume/conf/flume-check.properties** file on the client to point to the absolute path of **plugin.sh**.

The configuration is as follows:

client.per-check.shell=/opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FlumeClient/flume/plugins.s/plugin.sh

plugins = com.huawei.flume.services.FlumePreTransmitService

flume.check.default.interval = 15

Step 7 Configure the **/opt/client/FusionInsight_Cluster_1_Flume_ClientConfig/Flume/FlumeClient/flume/conf/plugin.conf** file and define the scripts to be invoked and related parameters.

The configuration is as follows:

RUN_PLUGIN="PLUGIN_LIST_1"

LOG_TO_HDFS_PATH="/yxs"

LOG_TO_HDFS_ENCODE_PATH="${LOG_TO_HDFS_PATH}/Flume_Encoded/"

PLUGIN_LINK_DIR="/tmp/yxs1"

PLUGIN_MV_TARGET_DIR="/tmp/yxs2"

PLUGIN_SUFFIX="COMPLETED"

PLUGIN_LIST_1="mv_complete.sh --linkdir ${PLUGIN_LINK_DIR} --mvtargetdir ${PLUGIN_MV_TARGET_DIR} --suffix ${PLUGIN_SUFFIX}"

Step 8 Install and start the Flume client. For details about how to install the client, see **Installing the Flume Client**.

----End

The Flume client has been installed

Step 1 Configure **client.per-check.shell** in the **flume-check.properties** file on the client to point to the absolute path of **plugin.sh**.

For example, if the Flume client installation path is **/opt/FlumeClient**, the **flume-check.properties** file is stored in the **/opt/FlumeClient/fusioninsight-flume-1.9.0/conf** directory,

The configuration is as follows:

client.per-check.shell=/opt/FlumeClient/fusioninsight-flume-1.9.0/plugins.s/plugin.sh

plugins = com.huawei.flume.services.FlumePreTransmitService

flume.check.default.interval = 15

Step 2 Configure **plugin.conf** to define the script to be invoked and related parameters.

For example, if the Flume client installation path is **/opt/FlumeClient**, the **plugin.conf** file is stored in the **/opt/FlumeClient/fusioninsight-flume-1.9.0/conf** directory,

The configuration is as follows:

RUN_PLUGIN="PLUGIN_LIST_1"

LOG_TO_HDFS_PATH="/yxs"

LOG_TO_HDFS_ENCODE_PATH="${LOG_TO_HDFS_PATH}/Flume_Encoded/"

PLUGIN_LINK_DIR="/tmp/yxs1"

PLUGIN_MV_TARGET_DIR="/tmp/yxs2"

PLUGIN_SUFFIX="COMPLETED"

PLUGIN_LIST_1="mv_complete.sh --linkdir ${PLUGIN_LINK_DIR} --mvtargetdir ${PLUGIN_MV_TARGET_DIR} --suffix ${PLUGIN_SUFFIX}"

Step 3 Run the following command in the **bin** directory, for example, **/opt/FlumeClient/fusioninsight-flume-1.9.0/bin**, of the client installation path to restart the Flume client:

./flume-manage.sh restart

----End

8 Using Guardian

8.1 Guardian Log Overview

Log Description

Log path: **/var/log/Bigdata/guardian/token-server**

Log archive rule: The automatic compression and archive function is enabled for Guardian run logs. When the total size of all log files exceeds 50 MB (configurable), the log files are automatically compressed into a package named in the format of **token-server.log.[***ID***]**. A maximum of 20 latest compressed files are retained. The number of compressed files and compression threshold can be configured.

Table 8-1 Guardian log list

Log Type	Log File Name	Description	Searchable on Manager
Run log	token-server.log	Guardian run log	Yes
	startDetail.log	Guardian service prestart log	Yes
	stopDetail.log	Guardian service stop log	Yes
	gc.log	Guardian service GC log	No

Log Levels

Table **Table 8-2** describes the log levels provided by Guardian.

The log levels are ERROR, WARN, INFO, and DEBUG in descending order of priority. Only logs whose levels are higher than or equal to the specified level are recorded. The higher the log level specified, the fewer the logs are recorded.

Table 8-2 Log levels

Level	Description
ERROR	Logs of this level record error information about system running
WARN	Logs of this level record exception information about the current event processing
INFO	Logs of this level record normal running status information about the system and events
DEBUG	Logs of this level record the system information and system debugging information

To modify log levels, perform the following operations:

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **Guardian**. Click **Configurations** then **All Configurations**.

Step 3 On the menu bar on the left, select the log menu of the target role.

Step 4 Select a desired log level.

Step 5 Click **Save** then **OK**.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Format

Table 8-3 describes the Guardian log format.

Table 8-3 Log format

Log Type	Format	Example
Run log	<yyyy-MM-dd HH:mm:ss,SSS>|<Log level>|<Name of the thread that generates the log>|<Location where the log event occurs>|< Location of the log event >|<Message in the log>	2024-05-23 09:54:11,696 | INFO | pool-12-thread-1-EventThread:53211544 | mrs.guardian.shaded.org.apache.curator.framework.state.ConnectionStateManager: | ConnectionStateManager.java:252 | State change: CONNECTED

9 Using HBase

9.1 Creating an HBase Permission Role

Scenario

Create and configure an HBase role on Manager as an MRS cluster administrator. The HBase role can set HBase administrator permissions and read (R), write (W), create (C), execute (X), or manage (A) permissions for HBase tables and column families.

Users can create a table, query/delete/insert/update data, and authorize others to access HBase tables after they set the corresponding permissions for the specified databases or tables on HDFS.

NOTE

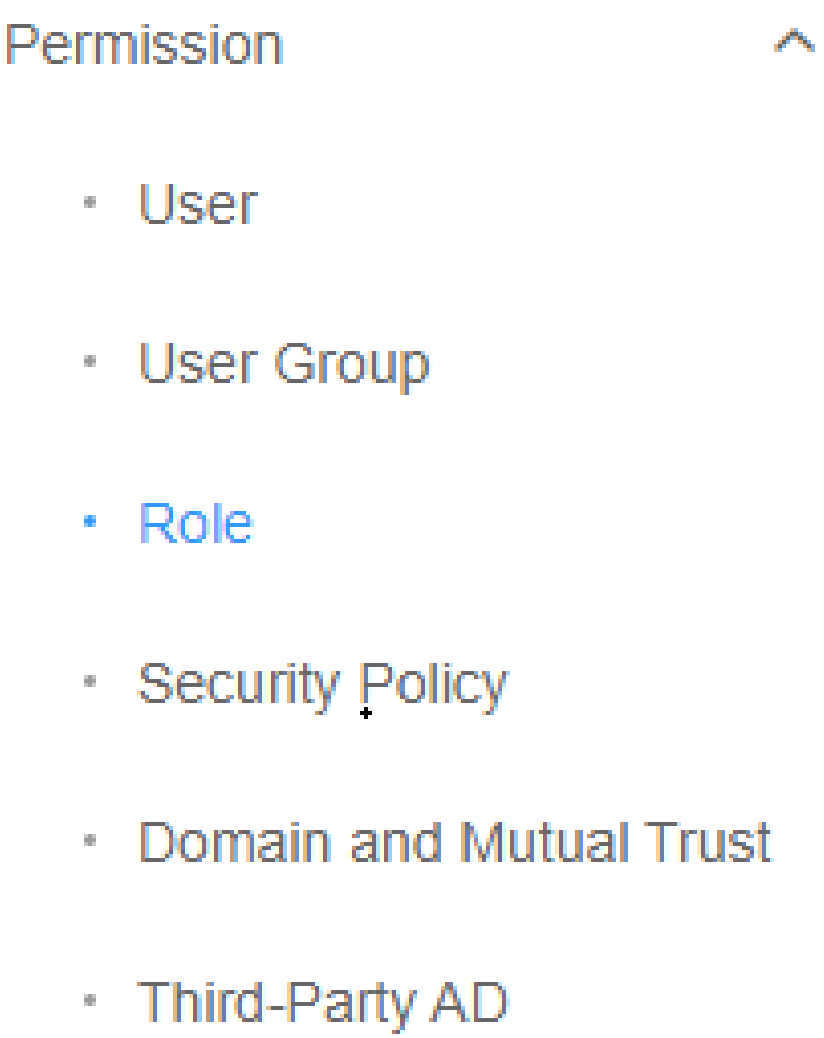
- Only clusters with Kerberos authentication enabled (security mode) support the creation of HBase roles.
- If the current component uses Ranger for permission control, you need to configure related policies based on Ranger for permission management. For details, see **Adding a Ranger Access Permission Policy for HBase**.

Prerequisites

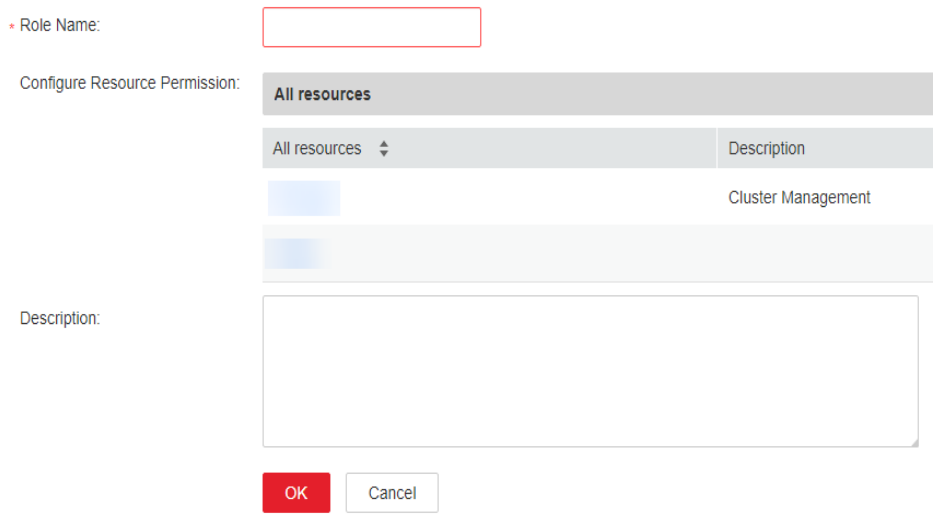
- The MRS cluster administrator has understood service requirements.
- You have logged in to Manager.

Creating an HBase Role

Step 1 On Manager, choose **System** > **Permission** > **Role**.



Step 2 On the displayed page, click **Create Role** and enter a **Role Name** and **Description**.



Step 3 Set **Permission**. For details, see **Table 9-1**.

HBase permissions:

- HBase Scope: Authorizes HBase tables. The minimum permission is read (R) and write (W) for columns.
- SUPER_USER_GROUP: HBase administrator permissions.

NOTE

Users have the read (R), write (W), create (C), execute (X), and administrate (A) permissions for the tables created by themselves.

Table 9-1 Setting HBase role resource permissions

Task	Role Authorization
Setting the HBase administrator permission	In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** and select **HBase Administrator Permission**.
Setting the permission for users to create tables	1. In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** > **HBase Scope**. 2. Click **global**. 3. In the **Permission** column of the specified namespace, select **Create** and **Execute**. For example, select **Create** and **Execute** for the default namespace **default**.
Setting the permission for users to write data to tables	1. In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**. 2. In the **Permission** column of the specified namespace, select **Write**. For example, select **Write** for the default namespace **default**. By default, HBase sub-objects inherit the permission from the parent object.
Setting the permission for users to read data from tables	1. In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**. 2. In the **Permission** column of the specified namespace, select **Read**. For example, select **Read** for the default namespace **default**. By default, HBase sub-objects inherit the permission from the parent object.

Task	Role Authorization
Setting the permission for users to manage namespaces or tables	1. In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**. 2. In the **Permission** column of the specified namespace, select **admin**. For example, select **admin** for the default namespace **default**.
Setting the permission for reading data from or writing data to columns	1. In **Configure Resource Permission**, select *Name of the desired cluster* > **HBase** > **HBase Scope** > **global** and click the specified namespace to display the tables in the namespace. 2. Click a table. 3. Click a column family. 4. Confirm whether you want to create a role? – If yes, enter the column name in the **Resource Name** text box. Use commas (,) to separate multiple columns. Select **Read** or **Write**. If there are no columns with the same name in the HBase table, a newly created column with the same name as the existing column has the same permission as the existing one. The column permission is set successfully. – If no, modify the column permission of the existing HBase role. The columns for which the permission has been separately set are displayed in the table. Go to **Step 3.5**. 5. To add column permissions for a role, enter the column name in the **Resource Name** text box and set the column permissions. To modify column permissions for a role, enter the column name in the **Resource Name** text box and set the column permissions. Alternatively, you can directly modify the column permissions in the table. If the column permissions are modified in the table and column permissions with the same name are added, the settings cannot be saved. You are advised to modify the column permission of a role directly in the table. The search function is supported.

Step 4 Click **OK**, and return to the **Role** page.

----End

9.2 Using the HBase Client

Scenario

This section describes how to use the HBase client in an O&M scenario or a service scenario.

Video Tutorial

This tutorial demonstrates how to create a table, insert data into it, and modify the table data by logging in to the HBase client after setting up an MRS cluster.

NOTE

The UI may vary depending on the version. This tutorial is for reference only.

Prerequisites

- The client has been installed. For example, the installation directory is **/opt/hadoopclient**. The client directory in the following operations is only an example. Change it to the actual installation directory.
- Service component users have been created by the MRS cluster administrator.

  A machine-machine user needs to download the **keytab** file and a human-machine user needs to change the password upon the first login.
- If a non-**root** user uses the HBase client, ensure that the owner of the HBase client directory is this user. Otherwise, run the following command to change the owner.

  chown user:group -R *Client installation directory*/**HBase**

Using the HBase Client

Step 1 Install the client. For details, see **Installing a Client**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client directory:

cd /opt/hadoopclient

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If Kerberos authentication has been enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. For details about how to configure a role with the corresponding permissions, see**Managing Roles**. To bind a role to a user, see **Creating a User**. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *Component service user*

For example, **kinit hbaseuser**.

Step 6 Run the following HBase client command:

hbase shell

----End

Common HBase client commands

The following table lists common HBase client commands. For more commands, see **http://hbase.apache.org/2.2/book.html**.

Table 9-2 HBase client commands

Command	Description
create	Used to create a table, for example, **create 'test', 'f1', 'f2', 'f3'**.
disable	Used to disable a specified table, for example, **disable 'test'**.
enable	Used to enable a specified table, for example, **enable 'test'**.
alter	Used to alter the table structure. You can run the **alter** command to add, modify, or delete column family information and table-related parameter values, for example, **alter 'test', {NAME => 'f3', METHOD => 'delete'}**.
describe	Used to obtain the table description, for example, **describe 'test'**.
drop	Used to delete a specified table, for example, **drop 'test'**. Before deleting a table, you must stop it.
put	Used to write the value of a specified cell, for example, **put 'test','r1','f1:c1','myvalue1'**. The cell location is unique and determined by the table, row, and column.
get	Used to get the value of a row or the value of a specified cell in a row, for example, **get 'test','r1'**.
scan	Used to query table data, for example, **scan 'test'**. The table name and scanner must be specified in the command.

9.3 Using HBase for Offline Data Analysis

HBase is a column-based distributed storage system that features high reliability, performance, and scalability. This section describes how to use HBase from scratch, including create a table using the client, insert data in the table, modify the table, read data from the table, delete table data, and delete the table.

Background

Suppose a user develops an application to manage users who use service A in an enterprise. The procedure of operating service A on the HBase client is as follows:

- Create the **user_info** table.
- Add users' educational backgrounds and titles to the table.
- Query user names and addresses by user ID.
- Query information by user name.
- Deregister users and delete user data from the user information table.
- Delete the user information table after service A ends.

Table 9-3 User information

ID	Name	Gender	Age	Address
12005000201	A	Male	19	City A
12005000202	B	Female	23	City B
12005000203	C	Male	26	City C
12005000204	D	Male	18	City D
12005000205	E	Female	21	City E
12005000206	F	Male	32	City F
12005000207	G	Female	29	City G
12005000208	H	Female	30	City H
12005000209	I	Male	26	City I
12005000210	J	Male	25	City J

Prerequisites

The client has been installed in a directory, for example, **/opt/client**. The client directory in the following operations is only an example. Change it to the actual installation directory. Before using the client, download and update the client configuration file, and ensure that the active management node of Manager is available.

Procedure

Step 1 Use the client on the active management node.

1. Install the client. For details, see **Installing a Client**.
2. Log in to the node where the client is installed as the client installation user and run the following command to switch to the client directory:

   cd /opt/client
3. Run the following command to configure environment variables:

   source bigdata_env
4. If Kerberos authentication has been enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. For details about how to

configure a role with the corresponding permissions, see **Creating an HBase Permission Role**. To bind a role to a user, see **Creating a User**. If Kerberos authentication is disabled for the current cluster, skip this step.

kinit *MRS cluster user*

For example, **kinit hbaseuser**.

5. Run the following HBase client command:

   hbase shell

Step 2 Run the following commands on the HBase client to implement service A.

1. Create the **user_info** user information table according to **Table 9-3** and add data to it.

   create '*user_info*',{**NAME** => 'i'}

   For example, to add information about the user whose ID is **12005000201**, run the following commands:

   put '*user_info*','*12005000201*','***i:name***','*A*'

   put '*user_info*','*12005000201*','***i:gender***','*Male*'

   put '*user_info*','*12005000201*','***i:age***','*19*'

   put '*user_info*','*12005000201*','***i:address***','*City A*'

2. Add users' educational backgrounds and titles to the **user_info** table.

   For example, to add educational background and title information about user 12005000201, run the following commands:

   put '*user_info*','*12005000201*','**i:degree**','*master*'

   put '*user_info*','*12005000201*','**i:pose**','*manager*'

3. Query user names and addresses by user ID.

   For example, to query the name and address of user 12005000201, run the following command:

   scan'*user_info*',
   {**STARTROW**=>'*12005000201*',**STOPROW**=>'*12005000201*',**COLUMNS**=>['**i:name**','**i:address**']}

4. Query information by user name.

   For example, to query information about user A, run the following command:

   scan '*user_info*',{**FILTER**=>"SingleColumnValueFilter('i','name',=,'binary:*A*')"}

5. Delete user data from the user information table.

   All user data needs to be deleted. For example, to delete data of user 12005000201, run the following command:

   - Delete all data fields of the user whose ID is 12005000201 in sequence. The following uses the **age** field as an example:

     delete '*user_info*','*12005000201*','i:age'

   - Remove all the data of the user whose ID is 12005000201.

     deleteall '*user_info*','*12005000201*'

6. Delete the user information table.

   disable '*user_info*'

   drop '*user_info*'

----End

9.4 Migrating Data to HBase Using BulkLoad

HBase data is stored in HDFS. To import data, load it from HDFS into an HBase table. Apache HBase provides the Import and ImportTsv tools for batch importing data.

- Import: imports HBase data that has been exported to HDFS using the **org.apache.hadoop.hbase.mapreduce.Import** method.
- ImportTsv: loads data in TSV format to HBase through **org.apache.hadoop.hbase.mapreduce.ImportTsv**.

For details, see **http://hbase.apache.org/2.2/book.html#tools**.

9.5 HBase Data Operations

9.5.1 Creating HBase Indexes for Data Query

Scenario

HBase is a distributed storage database of the key-value type. HIndex enables HBase indexing based on specific column values, making the retrieval of data highly efficient and fast.

Constraints

- Column families are separated by semicolons (;).
- Columns and data types must be contained in square brackets ([]).
- The column data type is specified by using -> after the column name.
- If the column data type is not specified, the default data type (string) is used.
- The number sign (#) is used to separate two index details.
- The following is an optional parameter:

  -Dscan.caching: number of cached rows when the data table is scanned.

  The default value is set to 1000.
- Indexes are created for a single region to repair damaged indexes. This function is not used to generate new indexes.

Create an HBase HIndex

Step 1 Install the HBase client. For details, see **Using the HBase Client**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Go to the client installation directory, for example, **/opt/client**.

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 6 Run the following command to access HIndex:

hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer

Table 9-4 Common HIndex commands

Function	Command
Add Index	TableIndexer-Dtablename.to.index=table1-Dindexspecs.to.add='IDX1=>cf1:[q1->datatype],[q2],[q3];cf2:[q1->datatype],[q2->datatype]#IDX2=>cf1:[q5]'
Create Index	TableIndexer -Dtablename.to.index=table1 -Dindexnames.to.build='IDX1#IDX2'
Delete Index	TableIndexer -Dtablename.to.index=table1 -Dindexnames.to.drop='IDX1#IDX2'
Disable Index	TableIndexer -Dtablename.to.index=table1 -Dindexnames.to.disable='IDX1#IDX2'
Add and Create Index	TableIndexer -Dtablename.to.index=table1 -Dindexspecs.to.add='IDX1=>cf1:[q1->datatype],[q2],[q3];cf2:[q1->datatype],[q2->datatype]#IDX2=>cf1:[q5]' -Dindexnames.to.build='IDX1'
Create Index for a Single Region	TableIndexer -Dtablename.to.index=table1 -Dregion.to.index=regionEncodedName -Dindexnames.to.build='IDX1#IDX2'

NOTE

- **IDX1**: indicates the index name.
- **cf1**: indicates the column family name.
- **q1**: indicates the column name.
- **datatype**: indicates the data type, including String, Integer, Double, Float, Long, Short, Byte and Char.

----End

9.5.2 Configuring the HBase Data Compression and Encoding Formats

Scenario

HBase encodes data blocks in HFiles to reduce duplicate keys in KeyValues, reducing used space. Currently, the following data block encoding modes are supported: NONE, PREFIX, DIFF, FAST_DIFF, and ROW_INDEX_V1. NONE indicates

that data blocks are not encoded. HBase also supports compression algorithms for HFile compression. The following algorithms are supported by default: NONE, GZ, SNAPPY, and ZSTD. NONE indicates that HFiles are not compressed.

The two methods are used on the HBase column family. They can be used together or separately.

Prerequisites

- The HBase client has been installed in a directory, for example, **/opt/client**.
- If Kerberos authentication has been enabled for HBase, you must have the corresponding operation permissions. For example, you must have the creation (C) or administration (A) permission on the corresponding namespace or higher-level items to create a table, and the creation (C) or administration (A) permission on the created table or higher-level items to modify a table. For details about how to grant permissions, see **Creating an HBase Permission Role**.

Configuring the HBase Data Compression and Encoding Formats

Setting data block encoding and compression algorithms during creation

- **Method 1: Using hbase shell**
  a. Log in to the node where the client is installed as the client installation user.
  b. Run the following command to go to the client directory:
     cd /opt/client
  c. Run the following command to configure environment variables:
     source bigdata_env
  d. If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step:
     kinit *Component service user*
     For example, **kinit hbaseuser**.
  e. Run the following HBase client command:
     hbase shell
  f. Create a table.
     create '*t1***', {NAME => '***f1***', COMPRESSION => '***SNAPPY***', DATA_BLOCK_ENCODING => '***FAST_DIFF***'}**

     NOTE

     - *t1*: indicates the table name.
     - *f1*: indicates the column family name.
     - *SNAPPY*: indicates the column family uses the SNAPPY compression algorithm.
     - *FAST_DIFF*: indicates FAST_DIFF is used for encoding.
     - The parameter in the braces specifies the column family. You can specify multiple column families using multiple braces and separate them by commas (,). For details about table creation statements, run the **help 'create'** statement in the HBase shell.

- **Method 2: Using Java APIs**

  The following code snippet shows only how to set the encoding and compression modes of a column family when creating a table. For complete code for creating a table and how to use the code to create a table, see **Creating an HBase Table** in the HBase Development Guide.

```
TableDescriptorBuilder htd = TableDescriptorBuilder.newBuilder(TableName.valueOf("t1"));// Create a descriptor for table t1.
ColumnFamilyDescriptorBuilder hcd = ColumnFamilyDescriptorBuilder.newBuilder(Bytes.toBytes("f1"));// Create a builder for column family f1.
hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);// Set the encoding mode of column family f1 to FAST_DIFF.
hcd.setCompressionType(Compression.Algorithm.SNAPPY);// Set the compression algorithm of column family f1 to SNAPPY.
htd.setColumnFamily(hcd.build())// Add the column family f1 to the descriptor of table t1.
```

Setting or modifying the data block encoding mode and compression algorithm for an existing table

- **Method 1: Using hbase shell**

  a. Log in to the node where the client is installed as the client installation user.

  b. Run the following command to go to the client directory:

     cd /opt/client

  c. Run the following command to configure environment variables:

     source bigdata_env

  d. If the Kerberos authentication is enabled for the current cluster, run the following command to authenticate the user. If Kerberos authentication is disabled for the current cluster, skip this step:

     kinit *Component service user*

     For example, **kinit hbaseuser**.

  e. Run the following HBase client command:

     hbase shell

  f. Run the following command to modify the table:

     alter '*t1***', {NAME => '***f1***', COMPRESSION => '***SNAPPY***', DATA_BLOCK_ENCODING => '***FAST_DIFF***'}**

- **Method 2: Using Java APIs**

  The following code snippet shows only how to modify the encoding and compression modes of a column family in an existing table. For complete code for modifying a table and how to use the code to modify a table, see **Modifying a Table** in HBase Development Guide.

```
TableDescriptor htd = admin.getDescriptor(TableName.valueOf("t1"));// Obtain the descriptor of table t1.
ColumnFamilyDescriptor originCF = htd.getColumnFamily(Bytes.toBytes("f1"));// Obtain the descriptor of column family f1.
builder.ColumnFamilyDescriptorBuilder hcd = ColumnFamilyDescriptorBuilder.newBuilder(originCF);// Create a builder based on the existing column family attributes.
hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);// Change the encoding mode of the column family to FAST_DIFF.
hcd.setCompressionType(Compression.Algorithm.SNAPPY);// Change the compression algorithm of the column family to SNAPPY.
admin.modifyColumnFamily(TableName.valueOf("t1"), hcd.build());// Submit to the server to modify the attributes of column family f1.
```

After the modification, the encoding and compression modes of the existing HFile will take effect after the next compaction.

9.6 Enterprise-Class Enhancements of HBase

9.6.1 Configuring HBase Global Secondary Indexes for Faster Queries

9.6.1.1 Introduction to HBase Global Secondary Indexes

Scenarios

HBase secondary indexes can be used to accelerate conditional queries with filters. HBase secondary indexes support local secondary indexes (HIndexes) and global secondary indexes (GSIs). Compared with local indexes (HIndex), global secondary indexes have better query performance and are suitable for scenarios that require high read latency.

HBase global secondary indexes use independent index tables to store index data. When a given query condition can hit an index, a full table query on a data table can be converted into an exact range query on an index table, thereby improving a query speed. After the global secondary index feature is enabled, the code on the application side does not need to be modified, which is easy to use.

NOTE

For MRS 3.3.0 or later, HBase global secondary index is enable by default. To modify the related parameters, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Confiurations** > **All Configurations**, select **RegionServer(Role)** > **Secondary Indexes** and **HMaster(Role)** > **Secondary Indexes**.

HBase global secondary indexes support the following key features:

- Composite Index

  Multiple columns can be specified as index columns (cross-column-family is supported).

- Overwrite Index

  Multiple columns or column families can be specified as overwrite columns or column families and stored in the index table in redundancy mode. This function is used to quickly query non-index columns in index query.

- Index TTL

  Index table TTL is used when TTL is enabled for a data table. To ensure consistency with the data table, the index table TTL automatically inherits the TTL of the index column and overwrites column of the data table and cannot be manually specified.

- Online index change

  Indexes can be created, deleted, and their status can be modified online without affecting data table read and write.

- Online index repair

  When the index data hit by the query is invalid, index repair can be triggered to ensure that the final query result is correct.

- Index Tool

  Supports index consistency check, index repair, index creation, deletion, and status modification, and index data rebuilding.

Restrictions on HBase Global Secondary Indexes

- Application Scenario Restrictions
  - GSI cannot be used together with HIndex. That is, local indexes and global indexes cannot be created in the same data table at the same time.
  - Index tables do not support DR.
  - Rolling upgrade is not supported for index data.
  - DISABLE, DROP, MODIFY, and TRUNCATE cannot be directly performed on index tables.
  - DDL operations on indexes allow you to modify index status, delete indexes, and create indexes. Index definitions cannot be modified. To modify index definitions, delete them and create indexes again.
- Constraints on Index Creation
  - The index name must comply with the regular expression requirements and does not support other characters. The regular expression must support the following characters: [a-zA-Z_0-9-.]:
  - The data table must exist. The index to be created cannot exist.
  - The index table does not support multiple versions.

    Indexes cannot be created on data tables with multiple versions (VERSION>1), and the version of the index table is 1.
  - The number of indexes in a single data table cannot exceed 5.

    You are not advised to create too many indexes for a single data table. If there are too many indexes, the storage cost is high and the write time is long. If more than five indexes need to be created, add the hbase.gsi.max.index.count.per.table parameter to the customized configuration hbase.hmaster.config.expandor of HMaster and set the parameter to a value greater than 5. Restart HMaster for the configuration to take effect.
  - The index name can contain a maximum of 18 characters.

    You are not advised to use an excessively long index name. To create a long index name, add the hbase.gsi.max.index.name.length parameter to the customized configuration hbase.hmaster.config.expandor of HMaster, set the parameter to a value greater than 18, and restart HMaster for the configuration to take effect.
  - Indexes cannot be created for index tables.

    Multiple indexes cannot be created in nested mode. Index tables are used only to accelerate query and do not provide data table functions.
  - Indexes that can be overwritten by existing indexes cannot be created.

    When you create an index, if the existing index can completely overwrite the new index (that is, the created index is a subset of the existing index),

the index cannot be created. Indexes with duplicate functions cause storage waste. For example, index 2 cannot be created if you perform the following operations:

Create a data table: **create't1','cf1'**

Create index 1: **hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='t1' -Dindexspecs.to.add='idx1=>cf1:[q1],[q2]'**

Create index 2: **hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='t1' -Dindexspecs.to.add='idx2=>cf1:[q1]'**

- Indexes with the same name cannot be created in the same data table. Indexes with the same name can be created in different data tables.
- The TTL of the index table column family is inherited from the original table. The TTL of the index column family must be the same.

  The TTLs of all column families in an index table are the same and are inherited from a data table. The TTLs of related column families in the data table must be the same. Otherwise, related indexes cannot be created.
- Other attributes of the user-defined index table are not supported.

- Constraints on Writing Indexes
  - Only the Put/Delete interface can be used to generate index data. When data is written to a data table in other modes (such as Increment, Append, and Bulkload), the corresponding index is not generated.
  - When the index column data is defined as the string type, do not write the special characters \x00 and \x01 (special invisible characters).
  - Do not write data to index columns by specifying timestamps.
- Constraints on Index Query
  - The index status must be ACTIVE during index query.
  - The index query does not support the query by specifying the timestamp range. If you need to query data within the time range by index, add a time column to store the timestamp of the data. Otherwise, the data table will be used for query.
  - Index query does not support range query by specifying StartRow and StopRow. If either of them is specified, the query operation does not use the index query. Instead, the Range Scan+Filter filtering function of the primary table is used.
  - Index query supports only SingleColumnValueFilter. Index acceleration cannot be triggered when other filters are used or no filter condition is used.

9.6.1.2 Creating an HBase Global Secondary Index

Scenarios

- If a large amount of data exists in a table, you can add an index to a column.
- For user tables that do not have indexes, this tool allows you to add and build indexes at the same time.

Creating an HBase Global Secondary Index

Run the following command on the HBase client to add or create an index. After the command is executed, the specified index is added to the table.

hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='*table*' **-Dindexspecs.to.add**='*idx1=>cf1:[c1->string],[c2]#idx2=>cf2:[c1->string],[c2]#idx3=>cf1:[c1];cf2:[c1]*' **-Dindexspecs.covered.family.to.add**='*idx2=>cf1*' **-Dindexspecs.covered.to.add**='*idx1=>cf1:[c3],[c4]*' **-Dindexspecs.coveredallcolumn.to.add**='*idx3=>true*' **-Dindexspecs.splitkeys.to.set**='*idx1=>[\x010,\x011,\x012]#idx2=>[\x01a,\x01b,\x01c]#idx3=>[\x01d,\x01e,\x01f]*'

The parameters are described as follows:

- **tablename.to.index**: Name of the data table for which an index is created

  NOTE

  When this parameter is used to create an index, if the data table is empty, the created index will be in **ACTIVE** state. Otherwise, the index will be in **INACTIVE** state.

- **indexspecs.to.addandbuild** (optional): Generated index data during data table creation. If the data table is too large, enabling this parameter is **not recommended**. Use an index data generation tool instead.

  NOTE

  This parameter and **tablename.to.index** cannot be used at the same time. When this parameter is used, the index will be in **BUILDING** state. After the index data is generated, the index will be in **ACTIVE** state.

- **indexspecs.to.add**: Mapping between the index name and the column in the corresponding data table (definition of index column)
- **indexspecs.covered.to.add** (optional): Column of the data table that is redundantly stored in an index (definition of overwrite column)
- **indexspecs.covered.family.to.add** (optional): Column family of the data table that is redundantly stored in an index table (definition of overwrite column)
- **indexspecs.coveredallcolumn.to.add** (optional): All data in a data table that is redundantly stored in an index table (definition of overwrite all columns)
- **indexspecs.splitkeys.to.set** (optional): Pre-partition split point of an index table. **Specify this parameter** in case the Region index table becomes a hotspot. The format of pre-partition is as follows:
  - **'#'**: separate indexes
  - **'[]'**: contain splitkeys
  - **','**: separate splitkeys

    NOTE

    Each splitkey of the pre-partition must start with **\x01**.

The parameters in the preceding command are described as follows:

- **idx1**, **idx2**, and **idx3**: index names
- **cf1** and **cf2**: column family names

- **c1**, **c2**, **c3**, and **c4**: column names
- **string**: data type. The value can be **STRING**, **INTEGER**, **FLOAT**, **LONG**, **DOUBLE**, **SHORT**, **BYTE**, or **CHAR**.

NOTE

- '**#**' is used to separate indexes, '**;**' is used to separate column families, and '**,**' is used to separate column qualifiers.
- The column name and its data type must be included in '**[]**'.
- Column names and their data types are separated by '**->**'.
- If the data type of a specific column is not specified, the default data type (string) is used.

Deleting an HBase Global Secondary Index

Run the following command on the HBase client to delete an index:

hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='*table*' **-Dindexnames.to.drop**='*idx1#idx2*'

The parameters are described as follows:

- tablename.to.index: indicates the name of the table where the index to be deleted is located.
- indexnames.to.drop: indicates the name of the index to be deleted. You can specify multiple indexes and separate them with number signs (#).

9.6.1.3 Querying an HBase Global Secondary Index

Scenarios

You can use the global secondary index tool to view the definition and status of indexes related to a data table in batches.

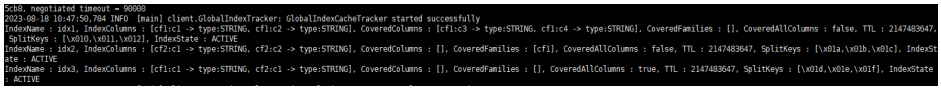
Querying an HBase Global Secondary Index

Run the following command on the HBase client to view the definition and status of the index:

Indicates the name of the hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.show=' data table.'

Figure 9-1 shows the query result. The index column definition, overwrite column definition, TTL, pre-partition information, and index status are printed.

Figure 9-1 Index query result



9.6.1.4 Changing Status of HBase Global Secondary Indexes

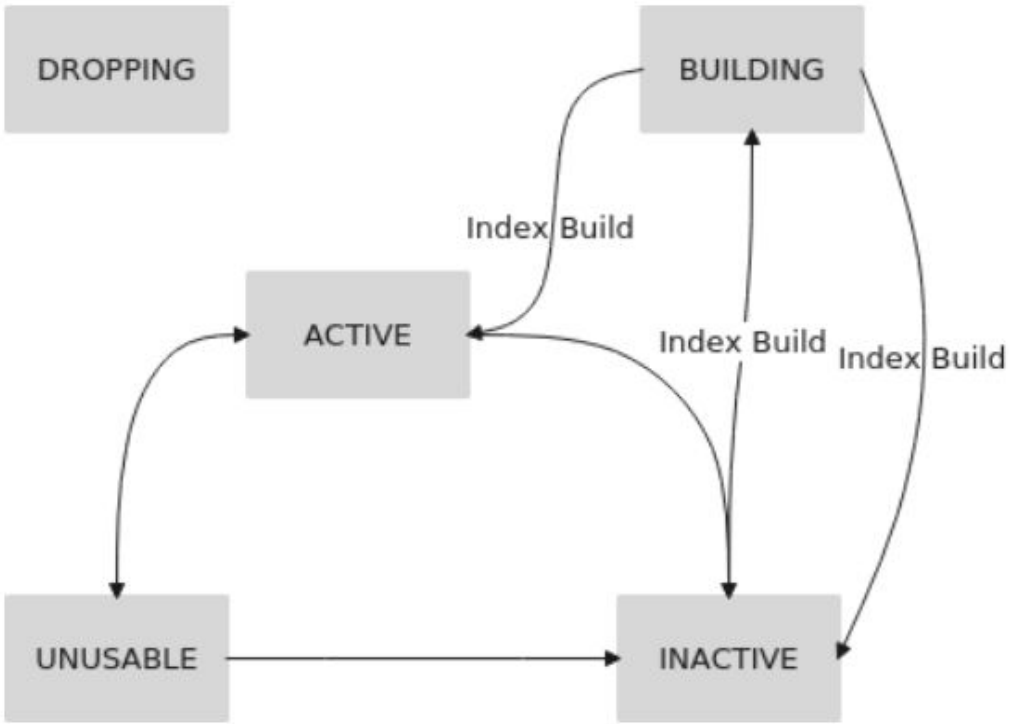
Index Status

The index status reflects the current index usage. The global secondary index supports the following five states:

- ACTIVE: The index is normal and can be read and written normally.
- UNUSABLE: The index is disabled. Index data can be written normally and cannot be used for query.
- INACTIVE: The index is abnormal. The index data is inconsistent with that in the data table. The index data for generating the index is skipped. The index cannot be used during data query.
- BUILDING: Index data is generated in batches. After the index data generation tool is executed, the index data is automatically switched to the ACTIVE state. In this state, data can be read and written properly.
- DROPPING: The index is being deleted. The index data generated for the index is skipped. The index cannot be used during data query.

The index status can be changed based on the tool. **Figure 9-2** describes the status change.

Figure 9-2 Index status transition



Scenarios

You can use the global secondary index tool to disable or enable an index.

Changing Status of HBase Global Secondary Indexes

Run the following command on the HBase client to disable or enable an index:

hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='*table*' **-D**[idx_state_opt]='*idx1*'

The related parameters are described as follows:

- tablename.to.index: indicates the name of the data table whose index status needs to be changed.
- idx_state_opt: target status of the index to be modified. The options are as follows:
  - indexnames.to.inactive: changes the status of a specified index to INACTIVE.
  - indexnames.to.active: changes the status of a specified index to ACTIVE.
  - indexnames.to.unusable: converts the specified index to the UNUSABLE state.

For example, to change the status of the idx1 index in the ACTIVE table to UNUSABLE, run the following command:

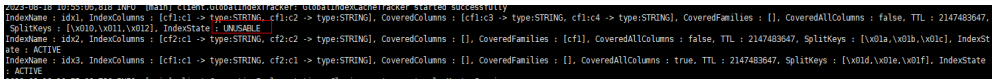
hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='table' -Dindexnames.to.unusable='idx1'

After the command is executed successfully, check the index information again.

hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.show='table'

As shown in **Figure 9-3**, the index status of idx1 has been changed.

Figure 9-3 idx1 index status



9.6.1.5 Creating HBase Global Secondary Indexes in Batches

Scenarios

If a large amount of data exists in a user table, index data of the existing data can be constructed in batches based on MapReduce tasks.

Creating HBase Global Secondary Indexes in Batches

NOTICE

- Only indexes in INACTIVE state can be built in batches. To rebuild index data, change the index status first.
- If a data table contains a large amount of data, the construction takes a long time. You are advised to run the nohup command in the background to prevent the operation from being interrupted unexpectedly.

Run the following command on the HBase client to create index data for existing data in batches:

hbase org.apache.hadoop.hbase.hindex.global.mapreduce.GlobalTableIndexer -Dtablename.to.index='*table*' **-Dindexnames.to.build**='*idx1*'

The related parameters are described as follows:

- tablename.to.index: indicates the name of the data table whose index status needs to be changed.
- indexnames.to.build: specifies the names of the indexes for which data needs to be generated in batches. You can specify multiple indexes and separate them with number signs (#).
- hbase.gsi.cleandata.enabled (optional): indicates whether to clear the index table before creating index data. The default value is false.
- (Optional) hbase.gsi.cleandata.timeout: timeout interval for clearing the index table before creating index data. The default value is 1800, in seconds.

9.6.1.6 Checking HBase Global Secondary Index Data Consistency

Scenarios

You can use the global secondary index tool to check the consistency between user data and index data. If the index data is inconsistent with user data, this tool can be used to rebuild index data.

Checking HBase Global Secondary Index Data Consistency

Run the following command on the HBase client to check data consistency. If data is inconsistent, index data will be rebuilt. The consistency check result is saved to the {NameSpace where the data table is located}:GSI_INCONSISTENCY_TABLE table.

hbase org.apache.hadoop.hbase.hindex.global.tools.GlobalHIndexConsistencyTool -dt *table1* **-n** *idx3* **-src** *BOTH* **-r**

The parameters are described as follows:

- -dt,--data-table: indicates the name of the data table to be checked.
- -n,--index-name: indicates the name of the index for which the consistency check is to be performed.
- -src,--source: indicates the check mode. The default value is BOTH. The following modes are supported:
  - INDEX_TABLE_SOURCE: The index table is used as the source table.
  - DATA_TABLE_SOURCE: The data table is used as the source table.
  - BOTH: Both index tables and data tables are source tables.
- -r,--repair: index data repair option. If this parameter is added, the index data is repaired after the check.
- (Optional) -sc,--scan-caching: size of scan caching in a MapReduce job for consistency check or repair.

9.6.1.7 Querying HBase Table Data with Global Secondary Indexes

Index-based Query HBase Table Data

In a user table with an index, you can use SingleColumnValueFilter to query data. When the query condition can match the index, the query speed is much faster than that of the original table query.

The index matching rules are as follows:

- Query by Multiple AND Conditions
  - When the columns used for query contain at least the first column of the index, using the index improves the query performance.

    For example, create a combination index for C1, C2, and C3.

    The index takes effect in the following situations:

    Filter_Condition (IndexCol1) AND Filter_Condition (IndexCol2) AND Filter_Condition (IndexCol3)

    Filter_Condition (IndexCol1) AND Filter_Condition (IndexCol2)

    Filter_Condition (IndexCol1) AND Filter_Condition (IndexCol3)

    Filter_Condition (IndexCol1)

    The index does not take effect in the following situations:

    Filter_Condition (IndexCol2) AND Filter_Condition (IndexCol3)

    Filter_Condition (IndexCol2)

    Filter_Condition (IndexCol3)
  - When you use **Index Column AND Non-Index Column** for filtering in the query, the index can improve query performance. If a non-index column hits an overwrite column, the query performance is optimal. If a non-index column needs to be frequently queried, you are advised to define it as an overwrite column. The following is an example:

    Filter_Condition (IndexCol1) AND Filter_Condition (NonIndexCol1)

    Filter_Condition (IndexCol1) AND Filter_Condition (IndexCol2) AND Filter_Condition (NonIndexCol1)
  - When multiple columns are used for query, you can specify a value range for only the last column in the combination index and set other columns to specified values

    For example, create a combination index for C1, C2, and C3. In a range query, only the value range of C3 can be set. The filter criteria are "C1 = *XXX*, C2 = *XXX*, and C3 = *Value range*".
- Query by Multiple OR Conditions

  For example, create a combination index for C1, C2, and C3.
  - When only the first field in the index column is filtered (range filtering is supported), the index can be used to improve the query performance.

    Filter_Condition (IndexCol1) OR Filter_Condition (IndexCol1) OR Filter_Condition (IndexCol1)
  - When non-index and non-index columns are filtered, indexes cannot be hit, and the query performance is not improved.

    Filter_Condition (IndexCol1) OR Filter_Condition (NonIndexCol1)

– During combined query, if the outermost layer contains the OR condition, the index cannot be matched, and the query performance is not improved.

  Filter_Condition (IndexCol1) OR Filter_Condition (NonIndexCol1)

  (Filter_Condition(IndexCol1)AND Filter_Condition (IndexCol2))OR(Filter_Condition(NonIndexCol1))

NOTE

Reduce the use of OR conditions, especially OR conditions and range conditions. When indexes are matched, large-scale query is performed and the query speed is slow.

9.6.2 Configuring HBase Local Secondary Indexes for Faster Queries

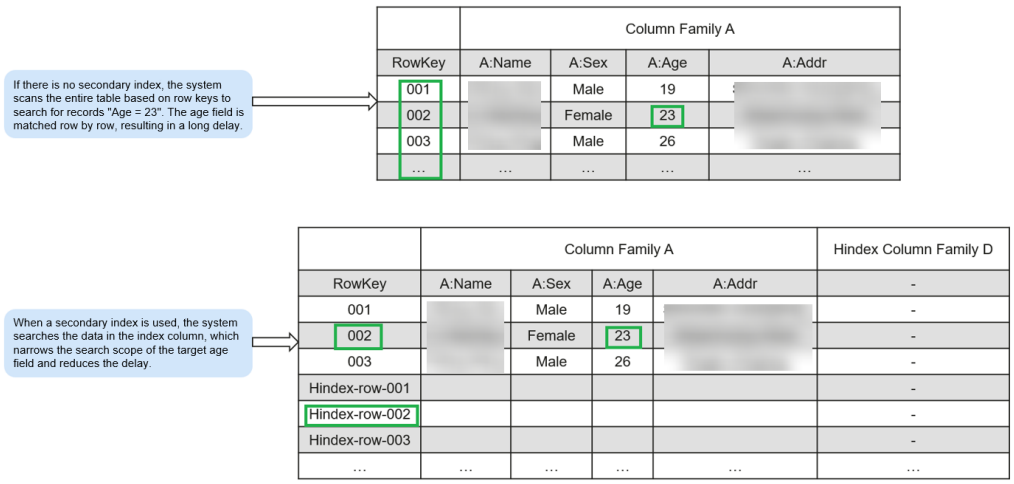
9.6.2.1 Introduction to HBase Local Secondary Indexes

Scenarios

HBase is a distributed storage database of the Key-Value type. Data in tables is sorted by dictionary based on row keys. If you query data by specifying a row key or scan data in a specific row key range, HBase can help you quickly locate the data to be read. In most cases, you need to query data whose column value is *XXX*. HBase provides the filter function to enable you to query data with a specific column value. All data is scanned in the sequence of row keys and is matched with the specific column value until the required data is found. To obtain the required data, the filter will scan some unnecessary data. As a result, the filter function cannot meet the requirements for high-performance, frequent queries.

HBase HIndex is designed to address these issues. HBase HIndex provides HBase with the capability of indexing based on specific column values, making queries faster.

Figure 9-4 HBase HIndex

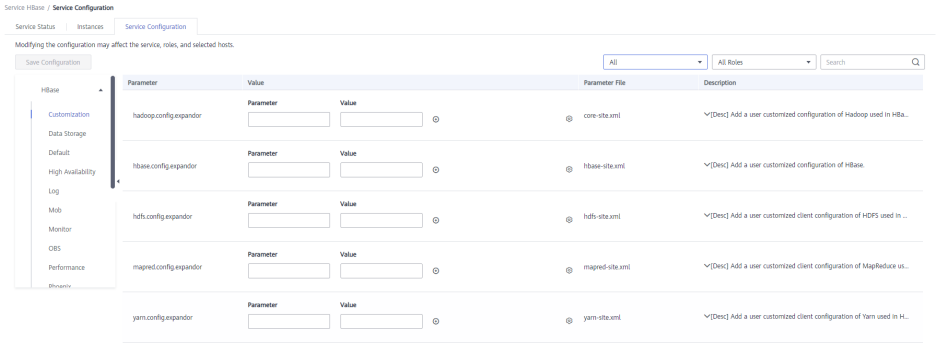


NOTE

- Rolling upgrade is not supported for index data.
- Composite index: You must add or delete all columns that participate in composite indexes. Otherwise, the data may be inconsistent.
- You should not explicitly configure any split policy to a data table where an index has been created.
- The mutation operations are not supported, such as increment and append.
- Index of the column with **maxVersions** greater than 1 is not supported.
- The value size of a column for which an index is added cannot exceed 32 KB.
- When the user data is deleted because TTL of the column family is invalid, the corresponding index data will not be deleted immediately. The index data will be deleted during major compaction.
- After an index is created, the TTL of the user column family must not be changed.
  - If the TTL of the column family is changed to a larger value after an index is created, delete the index and create one again. Otherwise, some generated index data may be deleted before the deletion of user data.
  - If the TTL of the column family is changed to a smaller value after an index is created, the index may be deleted after the deletion of user data.
- After disaster recovery is enabled for HBase tables, a secondary index is created in the active cluster and index table changes are not automatically synchronized to the standby cluster. To implement disaster recovery in this case, perform the following operations:
  1. After the secondary index is created in the active table, create a secondary index with the same schema and name using the same method in the standby cluster.
  2. In the active cluster, manually set **REPLICATION_SCOPE** of the index column family (default value: **d**) to **1**.

Configuring the HBase Local Secondary Index

1. Log in to the MRS console, click the cluster name in the existing cluster list, and choose **Components**.
2. In the component list, choose **HBase** > **Service Configuration**. In the drop-down list, switch **Basic Configuration** to **All Configurations**. The **All Configurations** page is displayed.



3. View parameters on the HBase configurations page.

Table 9-5 Parameters related to HBase Index

Navigation Path	Parameter	Default Value	Description
HMaster > System	hbase.coprocessor.master.classes	org.apache.hadoop.hbase.hindex.server.master.HIndexMasterCoprocessor,com.xxx.hadoop.hbase.backup.services.RecoveryCoprocessor,org.apache.ranger.authorization.hbase.RangerAuthorizationCoprocessor,org.apache.hadoop.hbase.security.access.ReadOnlyClusterEnabler,org.apache.hadoop.hbase.rsgroup.RSGroupAdminEndpoint	This coprocessor is used to handle Master-level operations after the HIndex function is enabled, for example, creating an index meta table, adding an index, and deleting an index, a table, and index metadata.
RegionServer > RegionServer	hbase.coprocessor.regionserver.classes	org.apache.hadoop.hbase.hindex.server.regionserver.HIndexRegionServerCoprocessor,org.apache.hadoop.hbase.JMXListener,org.apache.ranger.authorization.hbase.RangerAuthorizationCoprocessor	This coprocessor is used to handle the operations that the Master delivers to RegionServer after the HIndex function is enabled.

Navigation Path	Parameter	Default Value	Description
	hbase.coprocessor.region.classes	org.apache.hadoop.hbase.hindex.server.regionserver.HIndexRegionCoprocessor,org.apache.hadoop.hbase.security.token.TokenProvider,com.xxx.hadoop.hbase.backup.services.RecoveryCoprocessor,org.apache.ranger.authorization.hbase.RangerAuthorizationCoprocessor,org.apache.hadoop.hbase.security.access.SecureBulkLoadEndpoint,org.apache.hadoop.hbase.security.access.ReadOnlyClusterEnabler,org.apache.hadoop.hbase.coprocessor.MetaTableMetrics	This coprocessor is used to operate data in the Region after the HIndex function is enabled.

NOTE

- The preceding default values need to be configured after the HBase HIndex function is enabled. In MRS clusters that support the HBase HIndex function, the values have been configured by default.
- Ensure that the **master** parameter is configured on HMaster and the **region** and **regionserver** parameters are configured on RegionServer.

Interfaces Related to HBase Local Secondary Indexes

The APIs that use HIndex are in the **org.apache.hadoop.hbase.hindex.client.HIndexAdmin** class. The following table describes the related APIs.

Operation	API	Description	Precautions
Add an index.	addIndices()	Add an index to a table without data. Calling this API will add the specified index to a table but skips index data generation. Therefore, after this operation, the index cannot be used for the scanning and filtering operations. This API applies to scenarios where users want to add indexes in batches to tables that have a large amount of pre-existing user data. The specific operation is to use external tools such as the TableIndexer tool to build index data.	• An index cannot be modified once it is added. To modify the index, you need to delete the old index and then create a new one. • Do not create two indexes on the same column with different index names. Otherwise, storage and processing resources will be wasted. • Indexes cannot be added to a system table. • The append and increment operations are not supported when data is put into the index column. • If any fault occurs on the client except **DoNotRetryIOException**, you need to try again. • Index column families are selected from existing column families in the data table based on the following priorities in descending order: d, #, @, $, %, #0, @0, $0, %0, #1, @1 ... up to #255, @255, $255, and %255 When an index is created, the system checks whether the preceding column
	addIndicesWithData()	Add an index to a table with data. This API is used to add the specified index to the table and create index data for the existing user data. Alternatively, the API can be called to generate an index and then generate index data when the user data is being stored. Therefore, after this operation, the index can be used for the scanning and filtering operations immediately.	

Operation	API	Description	Precautions
			families exist in the table according to the preceding priority order. If the column families do not exist, the system sets the first column family that does not exist as the index column family. For example: – If the data table contains only the **d** column family, the index column family is **#** by default. – If the **d** and **#** column families already exist in the data table, the default index column family is **@**. – If the **d**, **#**, and **$** column families already exist in the data table, the index column family is **@** by default. • You can use the HIndex TableIndexer tool to add indexes without building index data.

Operation	API	Description	Precautions
Delete an index.	dropIndices()	This API is used to delete an index only. It deletes the specified index from a table but skips the corresponding index data. After this operation, the index cannot be used for the scanning and filtering operations. The cluster automatically deletes old index data during major compaction. This API applies to scenarios where a table contains a large amount of index data and **dropIndicesWithData()** is unavailable. In addition, you can use the TableIndexer tool to delete indexes and index data.	• An index can be disabled when it is in the **ACTIVE**, **INACTIVE**, or **DROPPING** state. • If you use **dropIndices()** to delete an index, ensure that the index data has been deleted before the index is added to the table with the same index name (that is, major compaction has been completed). • If you delete an index, the following information will also be deleted: – A column family with an index – Any one of column families in a combination index • Indexes and index data can be deleted together using the HIndex TableIndexer tool.
	dropIndicesWithData()	Delete index data. This API deletes the specified index and all index data corresponding to the index in a user table. After this operation, the index is completely deleted from the table and is no longer used for the scanning and filtering operations.	

Operation	API	Description	Precautions
Enable/ Disable an index.	disableIndices()	This API disables all indexes specified by a user so that they are no longer used for the scanning and filtering operations.	• An index can be enabled when the index is in the **ACTIVE**, **INACTIVE**, or **BUILDING** state. • An index can be disabled when the index is in the **ACTIVE** or **INACTIVE** state. • Before disabling an index, ensure that the index data is consistent with the user data. If no new data is added to the table when the index is disabled, the index data is consistent with the user data. • When enabling an index, you can use the TableIndexer tool to build index data to ensure data consistency.
	enableIndices()	This API enables all indexes specified by a user so that they can be used for the scanning and filtering operations.	
View the created index.	listIndices()	This API is used to list all indexes of a specified table.	N/A

Querying Data Based on HBase Local Secondary Indexes

You can use a filter to query data in a user table with an index. The query result of a user table with a single or combination index is the same as that of a table without an index, but the table with an index provides higher data query performance than the table without an index.

The index usage rules are as follows:

- Scenario 1: A single index is created for one or more columns.
  - When this column is used for AND or OR query filtering, an index can improve query performance.

    Example: Filter_Condition(IndexCol1)AND / OR Filter_Condition(IndexCol2)
  - When you use **Index Column** AND **Non-Index Column** for filtering in the query, the index can improve query performance.

Example: Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol2)AND Filter_Condition(NonIndexCol1)

- When you use **Index Column** OR **Non-Index Column** for filtering in the query but do not use an index, query performance will not be improved.

  Example: Filter_Condition(IndexCol1)AND / OR Filter_Condition(IndexCol2) OR Filter_Condition(NonIndexCol1)

- Scenario 2: A combination index is created for multiple columns.
  - When the columns to be queried are all or part of the combination index and have the same order as the combination index, using the index improves query performance.

    For example, create a combination index for C1, C2, and C3.

    - The index takes effect in the following situations:

      Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol2)AND Filter_Condition(IndexCol3)

      Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol2)

      FILTER_CONDITION(IndexCol1)

    - The index does not take effect in the following situations:

      Filter_Condition(IndexCol2)AND Filter_Condition(IndexCol3)

      Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol3)

      FILTER_CONDITION(IndexCol2)

      FILTER_CONDITION(IndexCol3)

  - When you use **Index Column** AND **Non-Index Column** for filtering in the query, the index can improve query performance.

    Examples:

    Filter_Condition(IndexCol1)AND Filter_Condition(NonIndexCol1)

    Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol2)AND Filter_Condition(NonIndexCol1)

  - When you use **Index Column** OR **Non-Index Column** for filtering in the query but do not use an index, query performance will not be improved.

    Examples:

    Filter_Condition(IndexCol1)OR Filter_Condition(NonIndexCol1)

    (Filter_Condition(IndexCol1)AND Filter_Condition(IndexCol2))OR(Filter_Condition(NonIndexCol1))

  - When multiple columns are used for query, you can specify a value range for only the last column in the combination index and set other columns to specified values

    For example, create a combination index for C1, C2, and C3. In a range query, only the value range of C3 can be set. The filter criteria are "C1 = *XXX*, C2 = *XXX*, and C3 = Value range."

HBase Local Secondary Index Query Policy Selection

Use **SingleColumnValueFilter** or **SingleColumnRangeFilter**. It will provide the definite value **column_family:qualifierpair** (called **col1**) in filter criteria.

If **col1** is the first index column in the table, any index in the table can be a candidate index used during the query. The following provides an example:

If there is an index on **col1**, the index can be used as a candidate index because **col1** is the first and the only column of the index. If there is another index on **col1** and **col2**, you can consider this index as a candidate index because **col1** is the first column in the index list. However, if there is an index on **col2** and **col1**, this index cannot be used as a candidate index because the first column in the index list is not **col1**.

The most suitable method to use the index now is that when there are multiple candidate indexes, select the most suitable index for scanning data.

You can use the following solutions to learn how to select the best index policy.

- It is better to fully match.

  Scenario: There are two indexes available, one for **col1&col2** and the other for **col1**.

  In this scenario, the second index is better than the first one, because it scans less index data.

- If there are multiple candidate multi-column indexes, select an index with fewer index columns.

  Scenario: There are two indexes available, one for **col1&col2** and the other for **col1&col2&col3**.

  In this case, you had better use the index on **col1&col2**, because it scans less index data.

NOTE

- During a query based on an index, the index state must be **ACTIVE**. You can call the **listIndices()** API to view the index state.
- To query the correct data based on the index, ensure the consistency between index data and user data.
- Run the following command to perform a complex query on the HBase shell client (assuming that an index has been created for the specified column):

  scan 'tablename', {FILTER => "SingleColumnValueFilter(family, qualifier, compareOp, comparator, filterIfMissing, latestVersionOnly)"}

  Example: **scan 'test', {FILTER => "SingleColumnValueFilter('info', 'age', =, 'binary:26', true, true)"}**

  In the preceding scenario, if you want to save the row where no column is found in the result, you should not create any index in any such column, because if the column to be queried does not exist, the row will be filtered out when SCVF is used to scan the index columns. When the SCVF whose **filterIfMissingset** is **false** (default value) scans non-index columns, rows where no column is queried will also be returned in the result. Therefore, to avoid inconsistent query results, you are advised to set **filterIfMissing** to **true** after creating SCVF for the index column.
- Run the following command on the **hbase shell** client to view the index data created for user data:

  scan 'tablename', {ATTRIBUTES => {'FETCH_INDEX_DATA' => 'true'}}

9.6.2.2 Loading Index Data in Batches and Generating Local Secondary Indexes

Scenarios

HBase provides the ImportTsv&LoadIncremental tool to load user data in batches. HBase also provides the HIndexImportTsv tool to load both the user data and index data in batches. HIndexImportTsv inherits all functions of the HBase batch data loading tool ImportTsv. If a table is not created before the HIndexImportTsv tool is executed, an index will be created when the table is created, and index data is generated when user data is generated.

Procedure

1. Run the following commands to import data to HDFS:

   hdfs dfs -mkdir <*inputdir*>

   hdfs dfs -put <local_data_file> <*inputdir*>

   For example, define the data file **data.txt** as follows:

   ```
   12005000201,Zhang San,Male,19,City a, Province a
   12005000202,Li Wanting,Female,23,City b, Province b
   12005000203,Wang Ming,Male,26,City c, Province c
   12005000204,Li Gang,Male,18,City d, Province d
   12005000205,Zhao Enru,Female,21,City e, Province e
   12005000206,Chen Long,Male,32,City f, Province f
   12005000207,Zhou Wei,Female,29,City g, Province g
   12005000208,Yang Yiwen,Female,30,City h, Province h
   12005000209,Xu Bing,Male,26,City i, Province i
   12005000210,Xiao Kai,Male,25,City j, Province j
   ```

   Run the following commands:

   hdfs dfs -mkdir /datadirImport

   hdfs dfs -put data.txt /datadirImport

2. Go to HBase shell and run the following command to create the **bulkTable** table:

   create 'bulkTable', {NAME => 'info',COMPRESSION => 'SNAPPY', DATA_BLOCK_ENCODING => 'FAST_DIFF'},{NAME=>'address'}

   After the execution is complete, exit the HBase shell.

3. Run the following commands to generate an HFile file (StoreFiles):

   hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexImportTsv -Dimporttsv.separator=*<separator>*

   -Dimporttsv.bulk.output=*</path/for/output>* **-Dindexspecs.to.add=**<indexspecs> **-Dimporttsv.columns=**<columns> tableName *<inputdir>*

   - **-Dimport.separator**: indicates a separator, for example, **-Dimport.separator=','**.
   - **-Dimport.bulk.output=</path/for/output>**: indicates the output path of the execution result. You need to specify a path that does not exist.
   - **<columns>**: Indicates the mapping of the imported data in a table, for example, **-Dimporttsv.columns=HBASE_ROW_KEY,info:name,info:gender,info:age,address:city,address:province**.

- **<tablename>**: Indicates the name of a table to be operated.
- **<inputdir>**: Indicates the directory where data is loaded in batches.
- **-Dindexspecs.to.add=<indexspecs>**: Indicates the mapping between an index name and a column, for example, **-Dindexspecs.to.add='index_bulk=>info:[age->String]'**. The index composition can be represented as follows:

  indexNameN=>familyN :[columnQualifierN-> columnQualifierDataType], [columnQualifierM-> columnQualifierDataType];familyM: [columnQualifierO-> columnQualifierDataType]# indexNameN=> familyM: [columnQualifierO-> columnQualifierDataType]

  Column qualifiers are separated by commas (,).

  Example: "index1 => f1:[c1-> String],[c2-> String]"

  Column families are separated by semicolons (;).

  Example: "index1 => f1:[c1-> String],[c2-> String]; f2:[c3-> Long]"

  Multiple indexes are separated by pound keys (#).

  Example: "index1 => f1:[c1-> String],[c2-> String]; f2:[c3-> Long]#index2 => f2:[c3-> Long]"

  The following data types are supported by columns.

  Available data types are as follows: STRING, INTEGER, FLOAT, LONG, DOUBLE, SHORT, BYTE, CHAR

  NOTE

  Data types can also be transferred in lowercase.

For example, run the following command:

hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexImportTsv -Dimporttsv.separator=',' -Dimporttsv.bulk.output=/dataOutput -Dindexspecs.to.add='index_bulk=>info:[age->String]' -Dimporttsv.columns=HBASE_ROW_KEY,info:name,info:gender,info:age,address:city,address:province bulkTable /datadirImport/data.txt

Command output:

```
[root@shap000000406 opt]# hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexImportTsv -Dimporttsv.separator=',' -Dimporttsv.bulk.output=/dataOutput -Dindexspecs.to.add='index_bulk=>info:[age->String]' -Dimporttsv.columns=HBASE_ROW_KEY,info:name,info:gender,info:age,address:city,address:province bulkTable /datadirImport/data.txt

9.6.2.3 Using TableIndexer to Generate a Local HBase Secondary Index

Scenarios

To quickly create indexes for user data, HBase provides the TableIndexer tool for you to create, add, and delete indexes using MapReduce functions. The application scenarios are as follows:

- You want to add an index for a specified column in a table where a large amount of data exists. However, if you use the **addIndicesWithData()** API to add an index, index data corresponding to the related user data will be generated, which is time-consuming. If you use **addIndices()** to create an index, index data corresponding to user data will not be generated. Therefore,

to create index data for user data, you can use the TableIndexer tool to create an index.

- If the index data is inconsistent with the user data, the tool can be used to rebuild index data.

  If you temporarily disable the index, put new data to the disabled index column, and then directly enable the index from the disabled state, index data and user data may be inconsistent. Therefore, you must rebuild all index data before using it again.
- You can use the TableIndexer tool to completely delete a large amount of existing index data from a user table.
- For user tables that do not have indexes, this tool allows you to add and build indexes at the same time.

How to Use

- **Adding a new index to a user table**

  The command is as follows:

  hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=tablename -Dindexspecs.to.add='idx_0=>cf_0:[q_0->string],[q_1];cf_1:[q_2],[q_3]#*idx_1*=>cf_1:[q_4]'

  The following parameters are required.

  - **tablename.to.index**: Indicates the name of a table for which an index is created.
  - **indexspecs.to.add**: Indicates the mapping between the index name and the column in the corresponding user table.
  - **scan.caching** (optional): Contains an integer value, indicating the number of cached rows to be transmitted to the scanner during data table scanning.

  The parameters in the preceding command are described as follows:

  - **idx_1**: Indicates an index name.
  - **cf_0**: Indicates the name of a column family.
  - **q_0**: Indicates the name of a column.
  - **string**: Indicates a data type. The parameter value can be STRING, INTEGER, FLOAT, LONG, DOUBLE, SHORT, BYTE, or CHAR.

  NOTE

  - The pound key (#) is used to separate indexes. The semicolon (;) is used to separate column families. The comma (,) is used to separate column qualifiers.
  - The column name and its data type must be included in '[]'.
  - Column names and their data types are separated by '->'.
  - If the data type of a specific column is not specified, the default data type (string) is used.
  - If **scan.caching** is not configured, the default value **1000** is used.
  - The user table must exist.
  - The index specified in the table must not exist.
  - If a column family named **d** exists in the user table, you must use the TableIndexer tool to build index data.

After the preceding command is executed, the specified index is added to the table and is in INACTIVE state. This behavior is similar to the **addIndices()** API.

- **Creating index data for existing indexes in a user table**

  The command is as follows:

  hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=tablename -Dindexnames.to.build='idx_0#idx_1'

  The following parameters are required.

  – **tablename.to.index**: Indicates the name of a table for which an index is created.

  – **indexspecs.to.build**: Indicates an index name.

  – **scan.caching** (optional): Contains an integer value, indicating the number of cached rows to be transmitted to the scanner during data table scanning.

  The parameters in the preceding command are described as follows:

  – **idx_1**: Indicates an index name.

  NOTE

  - The pound key (#) is used to separate index names.
  - If **scan.caching** is not configured, the default value **1000** is used.
  - The user table must exist.

  After the preceding command is executed, the specified index is set to the ACTIVE state. Users can use them when scanning data.

- **Deleting the existing indexes and their data from a user table**

  The command is as follows:

  hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=tablename -Dindexnames.to.drop='idx_0#idx_1'

  The following parameters are required.

  – **tablename.to.index**: Indicates the name of a table for which an index is created.

  – **indexnames.to.drop**: Indicates the name of the index that should be deleted with its data (must exist in the table).

  – **scan.caching** (optional): Contains an integer value, indicating the number of cached rows to be transmitted to the scanner during data table scanning.

  The parameters in the preceding command are described as follows:

  – **idx_1**: Indicates an index name.

  NOTE

  - The pound key (#) is used to separate index names.
  - If **scan.caching** is not configured, the default value **1000** is used.
  - The user table must exist.

  After the preceding command is executed, the specified index is deleted from the table.

- **Adding new indexes to user tables and building data based on existing data**

The command is as follows:

hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=tablename -Dindexspecs.to.add='idx_0 => cf_0:[q_0-> string],[q_1];cf_1:[q_2],[q_3]#idx_1 => cf_1:[q_4]' -Dindexnames.to.build='idx_0'

NOTE

- The parameters are the same as the previous ones.
- The user table must exist.
- The indexes specified in **indexspecs.to.add** must not exist in the table.
- The index names specified in **indexnames.to.build** must exist in the table or be part of the value of **indexspecs.to.add**.

After the preceding command is executed, all indexes specified in **indexspecs.to.add** will be added to this table, and index data will be built for all specified indexes using **indexnames.to.build**.

9.6.3 Improving HBase BulkLoad Data Migration

9.6.3.1 Importing HBase Data in Batches Using BulkLoad

Scenario

You can run commands to import data to HBase in batches and create indexes.

You can define multiple methods in **configuration.xml** for importing data in batches. You do not need to create indexes during data importing.

NOTE

- The column name consists of letters, digits, and underscores (_) and cannot contain any special characters.
- If the MapReduce job fails to be executed, rectify the fault by following the instructions provided in **Why Physical Memory Overflow Occurs If a MapReduce Task Fails?**.
- The data sources supported by BulkLoad are text files with separators.
- The client has been installed. For example, the installation directory is **/opt/hadoopclient**. The client directory in the following operations is only an example. Change it to the actual installation directory.
- If secondary indexes are created when data is imported in batches, pay attention to the following points:
  - If the column type is set to string, the string length cannot be set. For example, <column index="1" type="string" **length="1"** >COLOUMN_1</column> is not supported.
  - If the column type is set to date, the date format cannot be set. For example, <column index="13" type="date" **format="yyyy-MM-dd hh:mm:ss"**>COLOUMN_13</column> is not supported.
  - Secondary indexes cannot be created for combined columns.

Importing HBase Data in Batches Using the BulkLoad Tool

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client directory:

cd /opt/hadoopclient

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Run the following command to authenticate the current user if Kerberos authentication is enabled for the current cluster. The current user must have the permissions to submit YARN jobs, create and write HBase tables, and use HDFS.

kinit *Component service user*

Run the following command to set the Hadoop username if Kerberos authentication is not enabled for the current cluster:

export HADOOP_USER_NAME=hbase

Step 5 Run the following commands to import data to HDFS:

hdfs dfs -mkdir <*inputdir*>

hdfs dfs -put <local_data_file> <*inputdir*>

For example, define data file **data.txt** as follows:

```
001,Hadoop,citya
002,HBaseFS,cityb
003,HBase,cityc
004,Hive,cityd
005,Streaming,citye
006,MapReduce,cityf
007,Kerberos,cityg
008,LdapServer,cityh
```

Run the following command:

hdfs dfs -mkdir /datadirImport

hdfs dfs -put data.txt /datadirImport

Step 6 Go to **hbase shell**, create the table **ImportTable** and file **configuration.xml** (this file can be edited by referring to the template file in **/opt/client/HBase/hbase/conf/import.xml.template**).

For example, run the following command to create the table:

create 'ImportTable', {NAME => 'f1',COMPRESSION => 'SNAPPY', DATA_BLOCK_ENCODING => 'FAST_DIFF'},{NAME=>'f2'}

For example, the content of the customized import template file **configuration.xml** is as follows:

NOTE

- The value of **column_num** must be consistent with the number of columns in the data file.
- The specified family must correspond to the column family of the table.
- The following parameters need to be set only when secondary indexes are created during batch data import. The first letter of the index type must be capitalized, for example, **type="String"**. In the following snippets, **length="30"** indicates that the value of the index column **H_ID** cannot exceed 30 characters:

```
<indices>
   <index name="IDX1">
      <index_column family="f1">
         <qualifier type="String" length="30">H_ID</qualifier>
      </index_column>
   </index>
</indices>
```

```
<?xml version="1.0" encoding="UTF-8"?>

<configuration>
    <import id="first" column_num="3">
        <columns>
            <column index="1" type="int">SMS_ID</column>
            <column index="2" type="string">SMS_NAME</column>
            <column index="3" type="string">SMS_ADDRESS</column>
        </columns>

        <rowkey>
            SMS_ID+'_'+substring(SMS_NAME,1,4)+'_'+reverse(SMS_ADDRESS)
        </rowkey>

        <qualifiers>
            <normal family="f1">
                <qualifier column="SMS_ID">H_ID</qualifier>
                <qualifier column="SMS_NAME">H_NAME</qualifier>
                <qualifier column="SMS_ADDRESS">H_ADDRESS</qualifier>
            </normal>

            <!-- Define composite columns -->
            <composite family="f2">
                <qualifier class="com.huawei.H_COMBINE_1">H_COMBINE_1</qualifier>
                <columns>
                    <column>SMS_ADDRESS</column>
                    <column>SMS_NAME</column>
                </columns>
            </composite>

        </qualifiers>

          <indices>
            <index name="IDX1">
                <index_column family="f1">
                    <qualifier type="String" length="30">H_ID</qualifier>
                </index_column>
            </index>
        </indices>

        <badlines>SMS_ID &lt; 7000 &amp;amp;&amp;amp; SMS_NAME == 'HBase'</badlines>
    </import>
</configuration>
```

Step 7 Run the following commands to generate an HFile file:

hbase com.huawei.hadoop.hbase.tools.bulkload.ImportData -Dimport.skip.bad.lines=*true* **-Dimport.separator**=*<separator>* **-Dimport.bad.lines.output**=*</path/badlines/output>* **-Dimport.hfile.output=***</path/for/output> <configuration xmlfile> <tablename> <inputdir>*

- **-Dimport.skip.bad.lines**: If this parameter is set to **false**, the command execution stops when an inapplicable row occurs. If this parameter is set to **true**, when an inapplicable row occurs, this row is skipped and the command execution continues. If no inapplicable row is defined in **configuration.xml**, this parameter does not need to be added.
- **-Dimport.separator**: indicates a separator, for example, **-Dimport.separator=','**.
- **-Dimport.bad.lines.output**=*</path/badlines/output>*: indicates the output path of the inapplicable data row. If no inapplicable data row is defined in **configuration.xml**, this parameter does not need to be added.
- **-Dimport.hfile.output**=*</path/for/output>*: indicates the output path of the execution result.
- *<configuration xmlfile>*: points to the **configuration** file.
- *<tablename>*: indicates the name of a table to be operated.
- *<inputdir>*: data directory to be uploaded in batches.

For example, run the following command:

- **hbase com.huawei.hadoop.hbase.tools.bulkload.ImportData -Dimport.skip.bad.lines=true -Dimport.separator=',' -Dimport.bad.lines.output=/badline -Dimport.hfile.output=/hfile configuration.xml ImportTable /datadirImport**
- **hbase com.huawei.hadoop.hbase.tools.bulkload.IndexImportData -Dimport.skip.bad.lines=true -Dimport.separator=',' -Dimport.bad.lines.output=/badline -Dimport.hfile.output=/hfile configuration_index.xml IndexImportTable /datadirIndexImport**

NOTICE

- After transparent encryption is configured for HBase, when you run the bulkload command to generate an HFile, the HFile path specified by **-Dimport.hfile.output** must be a subdirectory in /*HBase root directory*/**extdata**, for example, **/hbase/extdata/bulkloadTmp/hfile**.
- After transparent encryption is configured for HBase, the HBase user who runs the bulkload command needs to be added to the **hadoop** user group of the corresponding cluster (the user group is c*<Cluster ID>*_hadoop for the cluster that is not the first installed on FusionInsight Manager, for example, **c2_hadoop**) and has the read permission on the encryption key of the HBase root directory.
- Check the permission on the **/tmp/hbase** directory and manually grant the write permission on the directory to the current user.

Step 8 Run the following command to import HFile to HBase:

- Importing data in batches:

  hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles *</path/for/output> <tablename>*

- Create a secondary index when importing data in batches:

hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexLoadIncrementalHFiles *</path/for/output> <tablename>*

For example, run the following command:

- **hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles /hfile ImportTable**
- **hbase org.apache.hadoop.hbase.hindex.mapreduce.HIndexLoadIncrementalHFiles /hfile IndexImportTable**

----End

9.6.3.2 Updating HBase Data in Batches Using BulkLoad

Scenario

Rows need to be updated in batches based on the row key naming rule, row key scope, field name, and field value.

Procedure

Run the following command to update the rows from row_start to row_stop and direct the output to **/output/destdir/**.

```
hbase com.huawei.hadoop.hbase.tools.bulkload.UpdateData
  -Dupdate.rowkey.start="row_start"
  -Dupdate.rowkey.stop="row_stop"
  -Dupdate.hfile.output=/user/output/
  -Dupdate.qualifier=f1:c1,f2
  -Dupdate.qualifier.new.value=0,a
  'table1'
```

- -Dupdate.rowkey.start="row_start": indicates that the start row number is row_start.
- -Dupdate.rowkey.stop="row_stop": indicates that the end row number is row_stop.
- -Dupdate.hfile.output=/user/output/: indicates that the output results are directed to **/user/output/**.

NOTICE

After transparent encryption is configured for HBase, see **Step 7** for precautions on batch updating.

Run the following command to load HFiles:

hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles *<path/for/output> <tablename>*

Precautions

1. During batch updating, the field value of the row that meets the requirements will be updated.

2. Batch updating cannot be performed on fields where indexes are created.
3. If you do not set the output file of the execution result, the default value is **/tmp/updatedata/***table name*.

9.6.3.3 Deleting HBase Data in Batches Using BulkLoad

Scenario

Rows need to be deleted in batches based on the row key naming rule, row key scope, field name, and field value.

Procedure

Run the following command to delete the rows from **row_start** to **row_stop** and direct the output to **/output/destdir/**.

```
hbase com.huawei.hadoop.hbase.tools.bulkload.DeleteData
  -Ddelete.rowkey.start="row_start"
  -Ddelete.rowkey.stop="row_stop"
  -Ddelete.hfile.output="/output/destdir/"
  -Ddelete.qualifier="cf1,cf0:vch,cf0:lng:1000"
  'table1'
```

- -Ddelete.rowkey.start="row_start": indicates that the start row number is row_start.
- -Ddelete.rowkey.stop="row_stop": indicates that the end row number is row_stop.
- -Ddelete.hfile.output="/output/destdir/": indicates that the output results are directed to **/output/destdir/**.
- -Ddelete.qualifier="cf1,cf0:vch,cf0:lng:1000": indicates that all columns in column family **cf1**, the **vch** column in column family **cf0**, and the column whose value is **1,000** in column **lng** in column family **cf0** are to be deleted.

NOTICE

If transparent encryption is configured for HBase, see **Step 7** for precautions on batch deletion.

Run the following command to load HFiles:

hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles <*path/for/output*> <*tablename*>

Precautions

1. If indexes have been created for column qualifier, the field cannot be deleted in batches because batch deletion cannot be performed on fields where indexes are created.
2. If you do not set output data file **delete.hfile.output** of the execution result, the default value is **/tmp/deletedata/***table name*.

9.6.3.4 Counting Rows in an HBase Table Using BulkLoad

Scenario

Collect statistics on the number of rows that meet specific requirements based on the rowkey naming rule, rowkey scope, field name, and field value.

Procedure

Count the number of rows that meet the following requirements: The rowkey is in the scope from **row_start** to **row_stop**. The field name is **f3:age** and the field value is **25**. The first two characters of the rowkey is **mi**.

```
hbase com.huawei.hadoop.hbase.tools.bulkload.RowCounter -Dcounter.rowkey.start="row_start" -Dcounter.rowkey.stop="row_stop" -Dcounter.qualifier="f3:age:25" -Dcounter.rowkey.value="substring(0,2) == 'mi'" table1
```

- **-Dcounter.rowkey.start="row_start"**: indicates that the start rowkey is **row_start**.
- **-Dcounter.rowkey.stop="row_stop"**: indicates that the end rowkey is **row_stop**.
- **-Dcounter.qualifier="f3:age:25"**: indicates that the value of column **age** in column family **f3** is **25**.
- **-Dcounter.rowkey.value="substring(0,2) == 'mi'"**: indicates that the first two values of the rowkey is **mi**.

NOTE

If **row_start** and **row_stop** are specified, data whose values are greater than or equal to **row_start** and smaller than **row_stop** is counted.

9.6.3.5 BulkLoad Configuration File

This section describes how to use the BulkLoad tool to obtain required data.

Configure a User-Defined Combined Rowkey

When using the BulkLoad tool to import HBase data in batches, users can customize combined rowkeys. Combining rowkeys using BulkLoad is to process some column names in a customized manner using some rules and combine them to generate a new rowkey.

NOTE

The column name consists of letters, digits, and underscores and cannot contain any special characters.

Details about how to set **configuration.xml** to combine rowkeys are as follows. For example, combine column **SMS_ID**, the second to fourth characters of column **SMS_NAME**, and the reverse of column **SMS_SERAIL** (The parts are connected by underscores (_)).

```
<columns>
                <column index="1" type="int">SMS_ID</column>
                <column index="2" type="string">SMS_NAME</column>
                <column index="3" type="string">SMS_ADDRESS</column>
        </columns>
```

```
<rowkey>
    SMS_ID+'_'+substring(SMS_NAME,1,4)+'_'+reverse(SMS_ADDRESS)
</rowkey>
```

Table 9-6 Rowkey segment process functions

Function Prototype	Description	Example
format(data,"DataType")	Used to format string data.	For example, **format(data,"0.000")** is used to input data in "0.000" format.
converse(data,"yyyy-MM-dd","yyyyMMdd")	Used to convert the date format.	For example, **converse(data,"yyyy-MM-dd","yyyyMMdd")** is used change the date format from "yyyy-MM-dd" to "yyyyMMdd".
rand	Used to generate a random number. Only the int type is supported.	None
replace(data,"A","B")	Used to replace data.	**replace(data,"A","B")** is used to replace A with B.
reverse(data)	Used to reverse a character string.	For example, **reverse(ABC)** is used reverse "ABC" to "CBA".
substring(data,Length1,Length2), or substring(data,Length3)	Used to subtract a character string.	For example, **substring(data,1,5), or substring(data,3)** is used to subtract [1,5) or [3,data.length) from the data character string.
to_number("data")	Used to convert a character string into a numeric value. The Long type numeric value is supported.	For example, **to_number("123")** is used to convert "123" into 123. Note that "data" must be a numerical value.

Configuring Customized Rowkey Implementation

When the BulkLoad tool is used to import HBase data in batches, user-defined combined rowkeys are supported. You can compile RowKey implementation code and import combined RowKeys based on the code logic.

To configure a customized row key, perform the following steps:

Step 1 When you compile the implementation class of a custom RowKey, inherit the interface. The JAR file path of the interface is *Client installation directory*/**HBase/hbase/lib/hbase-it-bulk-load-*.jar**.

```
[com.huawei.hadoop.hbase.tools.bulkload.RowkeyHandlerInterface]
```

Interface implementation method:

```
byte[] getRowkeyBytes(String[] colsValues, RegulationDomain regulation)
```

Where

- **colsValues** indicates a collection of one original data row. Each element is a column.
- **regulation** indicates information about the configuration file to be imported. (Typically, this parameter is not used.)

Step 2 Compress the implementation class and its dependent package into a JAR file, save the file to any location on the node where the HBase client resides, and ensure that the user who executes the command has the permission to read and execute the JAR file.

Step 3 When you run the import command, add the following two configuration items:

-Dimport.rowkey.jar=*Full path of the JAR file in step 2*

-Dimport.rowkey.class=*Full class name of the user implementation class*

----End

Configuring Custom Combination Fields

You can combine fields in a customized manner using BulkLoad. Multiple columns are combined into one column in append mode.

NOTE

The column name consists of letters, digits, and underscores and cannot contain any special characters.

Details about how to combine fields into H_COMBINE_1 are as follows. For example, combine fields **SMS_SERIAL**, **SMS_ADDRESS**, and **SMS_SNAME** into **H_COMBINE_1**.

```
<!-- Define composite columns -->
                <composite family="f2">
                    <!-- define composited class name, and this class must not exists -->
                    <qualifier class="com.huawei.H_COMBINE_1">H_COMBINE_1</qualifier>
                    <columns>
                        <column>SMS_ADDRESS</column>
                        <column>SMS_NAME</column>
                    </columns>
                </composite>
```

Specifying the Field Data Type

HBase BulkLoad can read native data files, map fields in the data files to fields defined by HBase, and define data types of these fields.

You can define multiple methods in **configuration.xml** for importing data in batches.

NOTE

The column name consists of letters, digits, and underscores and cannot contain any special characters.

Details about how to specify the field data type are as follows. For example, specify data types for columns SMS_ID, SMS_NAME, SMS_ADDRESS, and SMS_SERIAL.

```
<columns>
        <column index="1" type="int">SMS_ID</column>
        <column index="2" type="string">SMS_NAME</column>
        <column index="3" type="string">SMS_ADDRESS</column>
 </columns>
```

NOTE

The supported data types include short, int, long, float, double, boolean, and string.

Defining Inapplicable Data Row

BulkLoad supports the function of defining inapplicable data rows. The inapplicable data rows are not stored in HBase. Instead, these data rows are stored in a specific file.

You can define multiple methods in **configuration.xml** for importing data in batches.

NOTE

The column name consists of letters, digits, and underscores and cannot contain any special characters.

Details about how to define inapplicable data rows are as follows:

```
<!-- Define bad line filter rule -->
<badlines>SMS_ID &lt; 7000 &amp;&amp; SMS_NAME == 'HBase'</badlines>
```

NOTE

SMS_ID < 7000 && SMS_NAME == 'HBase'

Table 9-7 lists the operators in <badlines> and corresponding parameter types.

Table 9-7 Operators and corresponding parameter types

Operator	Parameter Type
&&	The parameter type is Boolean.
&	The parameter type is integer.
|	The parameter type is integer.
^	The parameter type is integer.
/	The parameter type is digit.
==	The parameter type is string.
>=	The parameter type is digit.

Operator	Parameter Type
>	The parameter type is digit.
<<	The parameter type is integer.
<=	The parameter type is digit.
<	The parameter type is digit.
%	The parameter type is digit.
*	The parameter type is digit.
!=	The parameter type is string.
||	The parameter type is Boolean.
+	The parameter type is digit and string.
>>	The parameter type is integer.
-	The parameter type is string.
>>>	The parameter type is integer.

9.6.3.6 Configuring BulkLoad to Parse Customized Separators

Scenario

Phoenix provides CsvBulkloadTool, a batch data import tool. For details about related features, see **https://phoenix.apache.org/bulk_dataload.html**. This tool supports import of user-defined delimiters. Specifically, users can use any visible characters within the specified length as delimiters to import data files.

NOTE

This section applies only to MRS 3.2.0 or later.

Constraints

- User-defined delimiters cannot be an empty string.
- A user-defined delimiter can contain a maximum of 16 characters.

  NOTE

  A long delimiter affects parsing efficiency, slows down data import, reduces the proportion of valid data, and results in large files. Use short delimiters as possible.
- User-defined delimiters must be visible characters.

  NOTE

  A user-defined delimiter whitelist can be configured to avoid any injection issues possible. Currently, the following delimiters are supported: letters, numbers, and special characters (`~!@#$%^&*()\\-_=+\\[\\]{}\\\\|;:'\",<>./?).

- The start and end of a user-defined delimiter cannot be the same.

Description of New Parameters

The following two parameters are added based on the open source CsvBulkloadTool:

- **--multiple-delimiter(-md)**

  This parameter specifies the user-defined delimiter. If this parameter is specified, it takes effect preferentially and overwrites the **-d** parameter in the original command.

- **--multiple-delimiter-skip-check(-mdsc)**

  This parameter is used to skip the delimiter length and whitelist verification. It is not recommended.

Importing Data to HBase by User-defined Separator

Step 1 Upload the data file to the node where the client is deployed. For example, upload the **data.csv** file to the **/opt/test** directory on the target node. The delimiter is **|^[**. The file content is as follows:

```
0|^[lucy|^[81|^[city3|^[true|^[9.18914949740991|^[-22.18269890221688
1|^[zhangshan|^[46|^[city4|^[true|^[5.322036259193896|^[-38.48904063764235
2|^[james|^[11|^[city3|^[true|^[7.7681483995935885|^[-25.7800264590591
3|^[james|^[87|^[city2|^[false|^[81.60003424030911|^[-75.3247097149487
4|^[wangwu|^[35|^[city3|^[true|^[32.95621554646283|^[-53.02547887416576
5|^[james|^[71|^[city5|^[true|^[83.12680099627629|^[-10.747627215038714
6|^[wangwu|^[23|^[city1|^[false|^[91.50905273357168|^[-39.53314273786492
7|^[james|^[8|^[city2|^[false|^[12.530415667410132|^[-24.858112869804337
8|^[lucy|^[87|^[city1|^[false|^[39.39199423544571|^[-68.35869628818902
9|^[lucy|^[92|^[city3|^[true|^[33.1217894946113O6|^[-55.48365486185375
10|^[lucy|^[51|^[city5|^[true|^[32.883181700707965|^[-78.04791713353062
```

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client directory:

cd *Client installation directory*

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 Run the following command to authenticate the current user if Kerberos authentication is enabled for the current cluster. The current user must have the permissions to create HBase tables and operate HDFS.

kinit *Component service user*

Run the following command to set the Hadoop username if Kerberos authentication is not enabled for the current cluster:

export HADOOP_USER_NAME=hbase

Step 6 Run the following command to upload the data file **data.csv** in **Step 1** to an HDFS directory, for example, **/tmp**:

hdfs dfs -put /opt/test/data.csv /tmp

Step 7 Run the Phoenix client command.

sqlline.py

Step 8 Run the following command to create the **TEST** table:

CREATE TABLE TEST (ID INTEGER NOT NULL PRIMARY KEY, NAME VARCHAR, AGE INTEGER, ADDRESS VARCHAR, GENDER BOOLEAN, A DECIMAL, B DECIMAL) split on (1, 2, 3,4,5,6,7,8,9);

After the table is created, run the **!quit** command to exit the Phoenix CLI.

Step 9 Run the following import command:

hbase org.apache.phoenix.mapreduce.CsvBulkLoadTool -md '*User-defined delimiter***' -t** *Table name* **-i** *Data path*

For example, to import the **data.csv** file to the **TEST** table, run the following command:

hbase org.apache.phoenix.mapreduce.CsvBulkLoadTool -md '|^[' -t TEST -i /tmp/data.csv

Step 10 Run the following command to view data imported to the **TEST** table:

sqlline.py

SELECT * FROM TEST LIMIT 10;

```
No rows affected (2.307 seconds)
0: jdbc:phoenix:> SELECT * FROM TEST LIMIT 10;
+-----+-----------+-----+----------+--------+--------------------+----------------------+
| ID  |   NAME    | AGE | ADDRESS  | GENDER |         A          |          B           |

9.6.4 Using the Spark BulkLoad Tool to Synchronize Data to HBase Tables

To quickly synchronize Hive or Spark table data to HBase tables, you can use the Spark BulkLoad tool. It also allows you to import full or incremental data in ORC/PAQUET format.

NOTE

Pay attention to the following when using the Spark BulkLoad tool:

- For details about data type conversion, see **Table 9-8**. The date type is converted to the string type before being stored in HBase. The number, string, and Boolean types are directly converted to byte arrays and stored in HBase. The system converts the byte arrays to the corresponding types during data parsing and check whether the values are null.
- Do not directly synchronize table data of the Struct, Map, and Seq types to HBase tables. These types cannot be converted to byte arrays, and will be converted to strings instead, which may fail to be restored.

This topic is available for MRS 3.5.0 and later versions only.

Table 9-8 Data type conversion relationship

Hive/Spark table	HBase Table	Parsing Mode
TINYINT	Byte	Returns the first value in byte[].
SMALLINT	Short	Bytes.toShort(byte[])
INT/INTEGER	Integer	Bytes.toInt(byte[])
BIGINT	Long	Bytes.toLong(byte[], int, int)
FLOAT	Float	Bytes.toFloat(byte[])
DOUBLE	Double	Bytes.toDouble(byte[])
DECIMAL/ NUMERIC	BigDecimal	Bytes.toBigDecimal(byte[])
TIMESTAMP	String	Bytes.toString(byte[])
DATE	String	Bytes.toString(byte[])
STRING	String	Bytes.toString(byte[])
VARCHAR	String	Bytes.toString(byte[])
CHAR	String	Bytes.toString(byte[])
BOOLEAN	Boolean	Bytes.toBoolean(byte[])
BINARY	byte[]	No need to parse.
ARRAY	String	Bytes.toString(byte[])
MAP	String	Bytes.toString(byte[])
STRUCT	String	Bytes.toString(byte[])

Prerequisites

- The Spark and Hive services have been installed in the cluster.

- The user who imports data must have the Spark permission (the SELECT permission of the source table), HBase permission (the RWXA permission of the HBase NameSpace), and HDFS permission (the read and write permission of the HFile output directory).
- If Kerberos authentication is enabled for the cluster (the cluster is in security mode), set the value of **spark.yarn.security.credentials.hbase.enabled** to **true** in the *Spark client installation directory*/**Spark/spark/conf/spark-defaults.conf configuration** file.

Spark BulkLoad Commands

The command format is as follows:

spark-submit --master yarn --deploy-mode cluster --jars *Client installation directory*/**HBase/hbase/lib/protobuf-java-2.5.0.jar**, *Client installation directory*/**HBase/hbase/conf/* --conf spark.yarn.user.classpath.first=true --class com.huawei.hadoop.hbase.tools.bulkload.SparkBulkLoadTool** *Client installation directory*/**HBase/hbase/lib/hbase-it-bulk-load-*.jar com.huawei.hadoop.hbase.tools.bulkload.SparkBulkLoadTool***[-cf <arg>] [-comp <arg>] [-enc <arg>]* **-op** *<arg>* **-rc** *<arg> [-rn <arg>] [-sp <arg>]* **-sql** *<arg> [-sr]* **-tb** *<arg>*

NOTE

- **--jars** specifies the path of the **protobuf-java-2.5.0.jar** file and the path of the HBase client configuration file. The HBase client configuration file is stored in *Client installation directory*/**HBase/hbase/conf**.
- The number of executors, memory, and CPU can be specified in the command for resource control. For example, the following parameters can be specified during command submission:

  --driver-memory=*20G* **--num-executors=***10* **--executor-memory=***4G* **--executor-cores=***2*

Other parameters that can be configured are as follows:

- **-sql,--export-sql** *<arg>*

  Sets the SQL statements for exporting data. When reading data from Hive/Spark tables, you can set this parameter to filter out data that does not need to be synchronized.

- **-rc,--rowkey-columns** *<arg>*

  Specifies the columns that compose the HBase Rowkey in the source table. If there are multiple columns, separate them with commas (,).

  NOTICE

  The Spark BulkLoad task will fail if the query is abnormal due to incorrect SQL statements, non-exist target data, or duplicate data. Ensure that the SQL statements are correct and the data combination corresponding to Rowkey fields is unique.

- **-sp,--rowkey-separator** *<arg>*

(Optional) Specifies the separator between field values when multiple column values are used as a rowkey. The default value is **#**. The values are concentrated to form the rowkey.

NOTICE

The separator can contain only one character. Avoid the characters used by the Rowkey field value to prevent failures in parsing column values. A composite rowkey (data rowkey) consists of multiple columns separated by the specified separator. To parse this rowkey, the separator must be located to split the rowkey splitting and converts data types. For example:

A rowkey consists of two columns separated by a number sign (#). **Table 9-9** shows the corresponding relationship. The code for parsing is as follows:

```
// Locate the separator.
int idx = Bytes.indexOf(row, "#".getBytes(StandardCharsets.UTF_8)[0]);
// Split the Rowkey and convert data types.
byte[] aBytes = ArrayUtils.subarray(row, 0, idx);
String aStr = Bytes.toString(aBytes);
byte[] bBytes = ArrayUtils.subarray(row, idx + 1, row.length);
Integer bInt = bBytes == null ? null : Bytes.toInt(bBytes);
```

Table 9-9 Composite rowkey example

Column A (String)	Column B (int)	Data Rowkey
a	1	a#1
b	null	b#

- **-tb,--table** *<arg>*

  Specifies the target HBase table. If the target table does not exist, sampling will be performed and the target table will be created.

- **-op,--output-path**

  Specifies the output path of HFiles. The exported HFiles are stored in a temporary directory in this directory and will be deleted after successful import.

  NOTE

  If HDFS federation is enabled, the HFile output path and the HBase to which data is to be imported must be in the same NameService.

  Table 9-10 shows an example of mounted HDFS directory. If the HBase service directory is mounted to NS1, the output path of the Spark Bulkload tool must be mounted to NS1. You can specify the output path to the **/tmpns1** directory.

Table 9-10 HDFS directory examples

Global Directory	Target NameService	Object Directory
/hbase	NS1	/hbase

Global Directory	Target NameService	Object Directory
/tmp	hacluster	/tmp
/tmpns1	NS1	/tmpns1

- **-rn,--region-nums** *<arg>*

  Specifies the number of target HBase regions. If the target table does not exist, this parameter value will be used to pre-partition the target table. The default value is 100.

  NOTE

  Evaluate the number of regions based on the amount of data to be exported from the source table. The estimation method is as follows:

  Size of the source table (three copies) x Decompression rate of the source table x HBase data expansion rate (estimated to 10)/Upper limit of a single region (usually 10 GB)/Compression and encoding compression rate

  Evaluate the number of regions. For example, if the source table is stored in ORC format and occupies 100 GB, the decompression expansion rate of the source table can be to 5. If sampled data is SNAPPY-compressed and FAST_DIFF-encoded in the target table, the compression rate can be 3. The minimum number of regions is: 100 x 5 x 10/10/3 ≈ 167. If you need to perform incremental data synchronization later, you can set the number of regions to 200.

- **-cf,--column-family** *<arg>*

  (Optional) Specifies the column family name of the target HBase table to which data is to be imported. If the column family does not exist, data synchronization will fail. If the target table does not exist, a table that contains this column family will be created in HBase. The default column family is **info**.

- **-comp,--compression** *<arg>*

  (Optional) Specifies the compression format of the target HBase table. Currently, SNAPPY, NONE, ZSTD, and GZ are supported. If the target table does not exist, a table using the specified compression format will be created in HBase. The default compression format is **SNAPPY**.

- **-enc,--block-encoding** *<arg>*

  (Optional) Specifies the data block encoding mode of the target HBase table. Currently, NONE, PREFIX, DIFF, FAST_DIFF, and ROW_INDEX_V1 are supported. If the target table does not exist, a table using the DATA BLOCK encoding mode will be created in HBase. The default value is **FAST_DIFF**.

- **-sr,--skip-store-rowcol**

  (Optional) Specifies whether to skip the columns corresponding to the Rowkey. By default, the Rowkey columns are redundantly stored in the HBase table. This parameter allows you to reduce the storage usage by skipping Rowkey parsing when it consists of multiple columns.

- **-sm,--sampling-multiple <arg>**

  (Optional) Specified the maximum number of files can be generated in a single region to improve the tool performance. There can be more ranges during sampling.

Note: A larger value indicates more generated HFiles, which increases the HBase compaction pressure. The value range is [1,10]. The default value is 1. You are advised to set this parameter based on actual resources.

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Go to the client directory.

cd *Client installation directory*

Step 3 Configure environment variables.

source bigdata_env

Step 4 If Kerberos authentication is enabled for the cluster, authenticate the user.

kinit *Component service user*

If Kerberos authentication is disabled for the cluster, set the Hadoop username.

export HADOOP_USER_NAME=hbase

Step 5 Go to the Spark client directory and synchronize data to the target HBase table.

cd Spark/spark/bin

For example, run the following command to synchronize all data in the **test.orc_table** table to the **test:orc_table** table of HBase, use **id+uuid** as the rowkey column, and set the output path to **/tmp/orc_table**:

spark-submit --master yarn --deploy-mode cluster --jars *Client installation directory*/**HBase/hbase/lib/protobuf-java-2.5.0.jar**, *Client installation directory*/**HBase/hbase/conf/* --conf spark.yarn.user.classpath.first=true --class com.huawei.hadoop.hbase.tools.bulkload.SparkBulkLoadTool** *Client installation directory*/**HBase/hbase/lib/hbase-it-bulk-load-*.jar -sql "select * from test.orc_table" -tb "test:orc_table" -rc "id,uuid" -op "/tmp/orc_table"**

----End

9.6.5 Configuring Hot-Cold Data Separate in HBase

9.6.5.1 Configuring Separate Storage for HBase Cold and Hot Data

In a big data storage scenario, HBase table data such as order data or monitoring data grows over time. As your business develops, such data can be of a large volume and rarely used. Companies may want to use cost-effective storage to store this type of data to reduce costs.

HBase separates cold data from hot data and stores them on different media. Cold data is stored in OBS and hot data is stored in HDFS, reducing storage costs.

This function is supported only by MRS 3.3.0 or later.

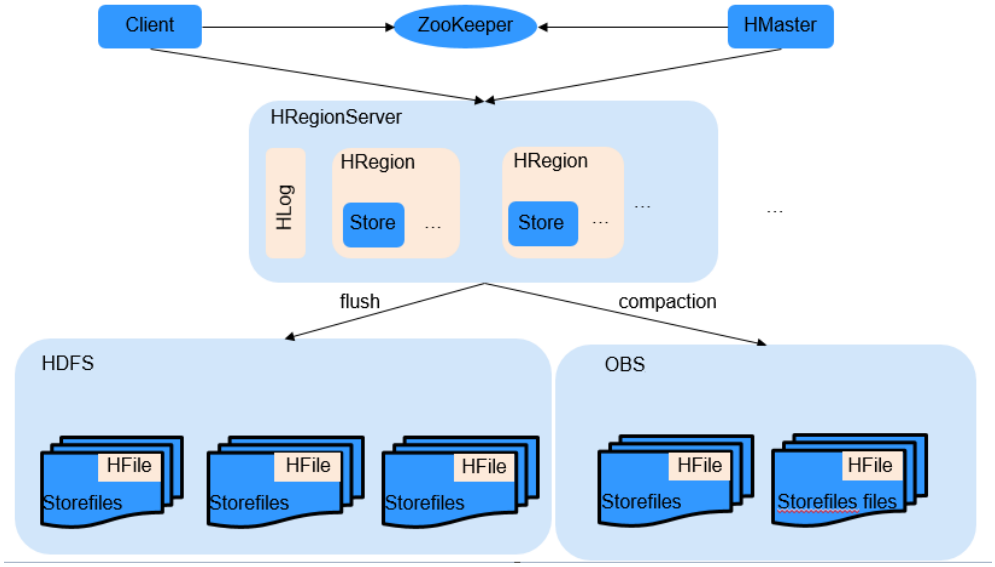
NOTE

- IOPS of data reading in OBS decreases. As a result, OBS is suitable for infrequent queries only.
- It is not a good choice to use OBS for a large number of concurrent read requests. Otherwise, exceptions may occur.

Principles

HBase supports separate cold and hot storage of data in the same table. After a user configures the time boundary between hot and cold data, HBase determines whether data is hot or cold based on the timestamp (ms) and the time boundary configured by the user. New data is stored in the hot storage and is gradually moved to the cold storage over time. You can change the time boundary for separating cold and hot data as you need. Data can be moved from the cold storage to the hot storage or vice versa.

Figure 9-5 HBase cold and hot separation principle



Configuring Separate Storage for HBase Cold and Hot Data

You can modify the HBase configuration on FusionInsight Manager to enable the cold and hot data separation feature so that cold data can be stored in OBS and hot data can be stored in HDFS.

Step 1 Interconnecting the Guardian Service with OBS. For details, see "Interconnecting the Guardian Service with OBS" section.

Step 2 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase**, and click **Configuration**. Search for and modify the following parameters:

- **fs.coldFS**: OBS file system name, for example, **obs://***OBS parallel file system name*
- **hbase.fs.hot.cold.enabled**: The default value is **false**. Set this parameter to **true**.

- **fs.obs.buffer.dir**: Set this parameter to the directory of the locally mounted data disk, for example, **/srv/BigData/data1/tmp/HBase/obs**.

Step 3 Click **Save**.

Step 4 Click **Dashboard** and click **More** > **Restart Service** to restart the HBase service. After the service is restarted, hot-cold data separation is enabled.

Step 5 Set the cold and hot boundary for the table data. For details, see **Cold-Hot Separation Commands**.

----End

9.6.5.2 Cold-Hot Separation Commands

The following content describes how to use the commands related to cold-hot separation, including shell commands and Java API commands.

Shell commands are executed on the HBase client. For details about how to install the client, see **Installing a Client**.

Setting the Hot and Cold Data Boundary of an HBase Table

- Shell
  - Create a table where data will be separately stored.

    create '*hot_cold_table*', {NAME=>'*f*', COLD_BOUNDARY=>'*86400*'}

    Required parameters are as follows:

    - **NAME** indicates the column family that requires cold-hot separation.
    - **COLD_BOUNDARY** indicates the time boundary (in seconds) for separating cold and hot data. For example, if **COLD_BOUNDARY** is set to **86400**, data that was written 86,400 seconds (one day) ago will be archived as cold data.

      NOTE

      The boundary time must be greater than the Major Compaction execution period. The default Major Compaction execution period is 7 days.
  - Disable cold-hot separation.

    alter '*hot_cold_table*', {NAME=>'*f*', COLD_BOUNDARY=>''}
  - Set cold and hot separation for an existing table or modify the cold and hot data boundary (unit: second) to convert between hot storage and cold storage. The following are some examples:
    - Convert hot data to cold data.

      1) Archive data that has been written to column **f** of the **hot_cold_table** table in more than one day (86400 seconds) to cold storage.

         alter '*hot_cold_table*', {NAME=>'*f*', COLD_BOUNDARY=>'*86400*'}

      2) Perform Major Compaction during off-peak hours to avoid affecting service performance.

         major_compact '*hot_cold_table*'

- Convert cold data to hot data.
  1) Change the value of **COLD_BOUNDARY** to **172800** to archive data that has been written to column **f** of the **hot_cold_table** table in more than one day and less than two days from the cold storage to the hot storage. Set this parameter as you need.

     alter '*hot_cold_table*', {NAME=>'*f*', COLD_BOUNDARY=>'*172800*'}
  2) Perform Major Compaction during off-peak hours to avoid affecting service performance.

     major_compact '*hot_cold_table*'

– Check whether cold-hot separation is enabled or whether the time boundary is successfully modified.

  desc '*hot_cold_table*'

```
Table hot_cold_table is ENABLED
hot_cold_table
COLUMN FAMILIES DESCRIPTION
{NAME => 'f', VERSIONS => '1', KEEP_DELETED_CELLS => 'FALSE', DATA_BLOCK_ENCODING =>
'NONE', TTL => 'FOREVER', MIN_VERSIONS => '0', REPLICATION_SCOPE => '0', BLOOMFILTER
=> 'ROW', IN_MEMORY => 'false', COMPRE
SSION => 'NONE', BLOCKCACHE => 'true', BLOCKSIZE => '65536', METADATA =>
{'COLD_BOUNDARY' => '1200'}}
1 row(s)
Quota is disabled
Took 0.0339 seconds
```

- Java API
  – Create a table where data will be separately stored.

    COLD_BOUNDARY specifies the time boundary for separating cold and hot data. The time boundary is measured in seconds. In the following example, data that was written one day ago will be archived as cold data.

```
Admin admin = connection.getAdmin();
TableName tableName = TableName.valueOf("hot_cold_table");
HTableDescriptor descriptor = new HTableDescriptor(tableName);
HColumnDescriptor cf = new HColumnDescriptor("f");
cf.setValue(HColumnDescriptor.COLD_BOUNDARY, "86400");
descriptor.addFamily(cf);
admin.createTable(descriptor);
```

  – Disable cold-hot separation.

```
HTableDescriptor descriptor = admin.getTableDescriptor(tableName);
HColumnDescriptor cf = descriptor.getFamily("f".getBytes());
cf.setValue(HColumnDescriptor.COLD_BOUNDARY, null);
admin.modifyTable(tableName, descriptor);
```

  – Enable cold-hot separation for an existing table or change the time boundary.

    COLD_BOUNDARY specifies the time boundary for separating cold and hot data. The time boundary is measured in seconds. In the following example, data that was written one day ago will be archived as cold data.

```
HTableDescriptor descriptor = admin.getTableDescriptor(tableName);
HColumnDescriptor cf = descriptor.getFamily("f".getBytes());
cf.setValue(HColumnDescriptor.COLD_BOUNDARY, "86400");
admin.modifyTable(tableName, descriptor);
```

NOTE

You must perform a major compaction before you move the data between the cold storage and the hot storage.

Writing Data

You can write data to a table with separated cold and hot storage in the same way that you write data to a regular table. Newly written data is stored in hot storage (HDFS). If the storage duration of a data record exceeds the value specified by the **COLD_BOUNDARY** parameter, the system automatically moves the data to cold storage (OBS) during the compaction process.

- Insert a data record to a table.

  Run the **put** command to insert a data record to the specified table. Specify the table name, primary key, custom column, and value. The following is an example:

  put '*hot_cold_table*','*row1*','cf:*a*','*value1*'

  The following parameters are required in the command:

  - **hot_cold_table**: table name
  - **row1**: primary key
  - **cf: a**: custom column
  - **value1**: value to insert

Querying Data

Both cold data and hot data are in the same HBase table. You can query the data only on one table. You can configure **TimeRange** to specify the time range of the data you want to query. The system automatically determines whether the hot storage, cold storage, or both will be searched based on the specified time range. If the time range is not specified during the query, only cold storage will be searched. The throughput of reading cold data is lower than that of reading hot data.

NOTE

- The cold storage is used to archive data that is rarely accessed. If your cluster receives a large number of queries that hit cold data, you can check whether the time boundary (**COLD_BOUNDARY**) is set to an appropriate value. The query performance deteriorates if data that is frequently accessed are stored in the cold storage.
- If you update a field in a row that is stored in the cold storage, the field is moved to the hot storage after the update. When this row is hit by a query that carries the **HOT_ONLY** hint or has a time range that is configured to hit hot data, only the updated field in the hot storage is returned. If you want the system to return the entire row, you must delete the **HOT_ONLY** hint from the query statement or make sure that the specified time range covers the time period from when this row is inserted to when this row is last updated. It is recommended that you do not update data that is stored in the cold storage.

- Random queries with Get
  - Shell
    - Query data in cold storage without the **HOT_ONLY** hint.

      get '*hot_cold_table*', '*row1*'
    - Query data in hot storage with the **HOT_ONLY** hint.

      get '*hot_cold_table*', '*row1*', **{HOT_ONLY=>true}**

- Query data within a time range that is specified by **TimeRange**. The system determines whether the query hits cold or hot data based on the values of **TIMERANGE** and **COLD_BOUNDARY**.

  get '*hot_cold_table*', '*row1*', {TIMERANGE => [0, 1568203111265]}

  NOTE

  TimeRange specifies the query time range. The time in the range is a UNIX timestamp, which is the number of milliseconds that have elapsed since the Unix epoch.

– Java API

- Query data in cold storage without the **HOT_ONLY** hint.

```
Get get = new Get("row1".getBytes());
```

- Query data in hot storage with the **HOT_ONLY** hint.

```
Get get = new Get("row1".getBytes());
get.setAttribute(HBaseConstants.HOT_ONLY, Bytes.toBytes(true));
```

- Query data within a time range that is specified by **TimeRange**. The system determines whether the query hits cold or hot data based on the values of **TimeRange** and **COLD_BOUNDARY**.

```
Get get = new Get("row1".getBytes());
get.setTimeRange(0, 1568203111265)
```

  NOTE

  TimeRange specifies the query time range. The time in the range is a UNIX timestamp, which is the number of milliseconds that have elapsed since the Unix epoch.

- SCAN queries

– Shell

- Query data in cold storage without the **HOT_ONLY** hint.

  scan '*hot_cold_table*', {STARTROW =>'*row1*', STOPROW=>'*row9*'}

- Query data in hot storage with the **HOT_ONLY** hint.

  scan '*hot_cold_table*', {STARTROW =>'*row1*', STOPROW=>'*row9*', **HOT_ONLY=>true**}

- Query data within a time range that is specified by **TimeRange**. The system determines whether the query hits cold or hot data based on the values of **TIMERANGE** and **COLD_BOUNDARY**.

  scan '*hot_cold_table*', {STARTROW =>'*row1*', STOPROW=>'*row9*', TIMERANGE => [0, 1568203111265]}

  NOTE

  TimeRange specifies the query time range. The time in the range is a UNIX timestamp, which is the number of milliseconds that have elapsed since the Unix epoch.

– Java API

- Query data in cold storage without the **HOT_ONLY** hint.

```
TableName tableName = TableName.valueOf("chsTable");
Table table = connection.getTable(tableName);
Scan scan = new Scan();
ResultScanner scanner = table.getScanner(scan);
```

- Query data in hot storage with the **HOT_ONLY** hint.

```
Scan scan = new Scan();
scan.setAttribute(HBaseConstants.HOT_ONLY, Bytes.toBytes(true));
```

- Query data within a time range that is specified by **TimeRange**. The system determines whether the query hits cold or hot data based on the values of **TimeRange** and **COLD_BOUNDARY**.

```
Scan scan = new Scan();
scan.setTimeRange(0, 1568203111265);
```

NOTE

TimeRange specifies the query time range. The time in the range is a UNIX timestamp, which is the number of milliseconds that have elapsed since the Unix epoch.

- Prioritizing hot data query

  HBase can search cold storage and hot storage for SCAN queries, for example, that are submitted to search all records of a customer. The query results are returned based on the timestamps when the data records are written in descending order. In most cases, hot data appears before cold data. If the SCAN queries do not carry the **HOT_ONLY** hint, HBase must scan data in both cold and hot storage. As a result, the query takes more time. If you prioritize hot data query, HBase preferentially queries hot data. Cold data is queried only when the number of rows in hot storage is less than the minimum number of rows to be queried. This reduces access to cold storage and improves the response speed.

  - Shell

    scan '*hot_cold_table*', {STARTROW =>'*row1*', STOPROW=>'*row9*',COLD_HOT_MERGE=>true}

  - Java API

```
TableName tableName = TableName.valueOf("hot_cold_table");
Table table = connection.getTable(tableName);
Scan scan = new Scan();
scan.setAttribute(HBaseConstants.COLD_HOT_MERGE, Bytes.toBytes(true));
scanner = table.getScanner(scan);
```

- Major compaction
  - Shell
    - Merge hot data areas of all partitions in a table.

      major_compact '*hot_cold_table*', nil, 'NORMAL', 'HOT'

    - Merge cold data areas of all partitions in a table.

      major_compact '*hot_cold_table*', nil, 'NORMAL', 'COLD'

    - Merge hot and cold data areas of all partitions in a table.

      major_compact '*hot_cold_table*', nil, 'NORMAL', 'ALL'

  - Java API
    - Merge hot data areas of all partitions in a table.

```
Admin admin = connection.getAdmin();
TableName tableName = TableName.valueOf("hot_cold_table");
admin. majorCompact (tableName,null, CompactType.NORMAL,
CompactionScopeType.HOT);
```

- Merge cold data areas of all partitions in a table.

```
Admin admin = connection.getAdmin();
TableName tableName = TableName.valueOf("hot_cold_table");
admin. majorCompact (tableName,null, CompactType.NORMAL,
CompactionScopeType.COLD);
```

- Merge hot and cold data areas of all partitions in a table.

```
Admin admin = connection.getAdmin();
TableName tableName = TableName.valueOf("hot_cold_table");
admin. majorCompact (tableName,null, CompactType.NORMAL,
CompactionScopeType.ALL);
```

9.6.6 Configuring RSGroup to Manage RegionServer Resource

Scenario

A large number of HBase data nodes need to be allocated to specific services based on the service scale so that resources can be exclusively used. When you allocate RegionServes to a RSGroup with the DR feature enabled for AZs, ensure that each AZ must have a RegionServer of the RSGroup so that the DR feature can take effect to ensure service reliability.

Prerequisites

- You have logged in to Manager.
- The login role has the Manager administrator rights.
- The minimum number of nodes in the RSGroup is set to the maximum value calculated in the following three scenarios.
  - To ensure service reliability, a certain number of redundant RegionServer nodes must be configured in the RSGroup to ensure that the number of redundant nodes is greater than the value calculated based on the following formula: (Total number of regions of service tables in RSGroup/ 2000) x 50%.
  - If the system catalog is in an independent RSGroup, ensure that the number of nodes in the RSGroup is greater than 2.
  - To ensure that rolling restart is not affected, if the total number of RegionServer nodes is less than 300, the number of nodes in a single RSGroup must be greater than or equal to 3. If the total number of RegionServer nodes is greater than or equal to 300, the number of nodes in a single RSGroup must be greater than or equal to the value calculated based on the following formula: Number of nodes x 1% + 1.

Possible Impact

- An RSGroup limits the available RegionServer nodes that a Region can be transferred to. If some nodes in the RSGroup are faulty or restarted in rolling mode, an alarm indicating that the number of Regions exceeds the threshold may be triggered, and the service performance may deteriorate.
- If a large number of region transfer tasks are generated when the RSGroup modification request is submitted, related RSGroup operations will fail. You need to observe the Region transfer status on the WebUI page and perform subsequent operations after transfer tasks are complete.

Configuring an RSGroup

Creating an RSGroup

Step 1 On FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **RSGroup Management**.

Step 2 Click **Add**. On the displayed page, enter the name of the RSGroup to be added. The name can contain 1 to 120 characters, including digits, letters, and underscores (_). Click **OK**.

Viewing an RSGroup

Step 3 Locate the row that contains the target RSGroup and click **View** in the **Operation** column. In the displayed dialog box, view the details about RegionServers and tables in the RSGroup.

NOTE

default is the default RSGroup of HBase. All RegionServer nodes that have been started and are not manually added to other RSGroups will be added to the **default** RSGroup.

Changing the name of an RSGroup

Step 4 Locate the row that contains the target RSGroup and click **Change Name** in the **Operation** column. In the displayed dialog box, enter a new name of the RSGroup and click **OK**. The new name must be unique.

Modifying an RSGroup

Step 5 Click the name of the target RSGroup to go to the **Modify RSGroup** page.

Step 6 Select the RegionServer instance to be allocated and click **Next**.

NOTE

- Only RegionServer instances (one or more) from the same RSGroup can be selected at a time. If the running status of RegionServers in the default RSGroup is not good, the RegionServers cannot be selected for allocation. To allocate RegionServer instances from different RSGroups, perform modification operations multiple times.
- When the cross-AZ feature is enabled, ensure that RegionServer instances of the RSGroup are allocated to each AZ. This constraint does not apply to the RSGroup allocated before the cross-AZ feature is enabled.

Step 7 Select the table to be allocated and click **Next**.

NOTE

- Only tables (one or more) from the same RSGroup can be selected at a time. To allocate RegionServer instances from different RSGroups, perform modification operations multiple times.
- The RegionServers and tables selected for allocation during RSGroup modification must belong to the same RSGroup.
- If only tables are selected during RS group modification and no RegionServer exists in the RSGroup before allocation, the modification fails.

Step 8 Click **Submit**. After the modification is successful, the RSGroup list page is displayed.

When the system displays a message indicating that the task is added to the queue, the RSGroup list page is displayed. The RSGroup modification request has

entered the task queue. Check whether the region transfer is complete on the native page as prompted and ensure that the task is successfully executed before performing subsequent operations.

Deleting an RSGroup

Step 9 On the **RSGroup Management** page, select the RSGroup to be deleted, click **Delete**, and click **OK**.

NOTE

The possible causes and solutions to RSGroup deletion failures are as follows:

- The **default** group cannot be deleted.
- The RSGroup still contains RegionServers or tables. Allocate the RegionServers or tables in the current RSGroup to another RSGroup, and then delete the RSGroup.

----End

9.6.7 Checking Slow and Oversized HBase Requests

Scenario

Query information about slow or oversized requests on the HBase shell CLI. Slow requests refer to the requests whose RPC response exceeds the threshold (value of **hbase.ipc.warn.response.time** set in the HBase service, **3000** ms by default) after you run the **hbase shell** command to query the server. Oversized requests refer to the requests whose data volume returned for each RPC exceeds the threshold (value of **hbase.ipc.warn.response.size** set in the HBase service, **5** MB by default) when you run the **hbase shell** command to query the server.

By default, each RegionServer node caches the latest 256 slow requests and oversized requests. You can adjust the cache size by configuring the **hbase.regionserver.slowlog.ringbuffer.size** parameter on the HBase service page in FusionInsight Manager.

NOTE

This section applies to MRS 3.3.0 or later.

Command Description

This operation involves the following new HBase shell commands:

- **get_slowlog_responses**: queries information about slow requests.
- **get_largelog_responses**: queries information about oversized requests.
- **clear_slowlog_responses**: clears data cached in RegionServers.

You can run the following command in the HBase shell to view how to use related commands:

help '*cmdName*'

For example, run the **help 'clear_slowlog_responses'** command to view the usage of the **clear_slowlog_responses** command.

```
hbase:010:0> help 'clear_slowlog_responses'
Clears SlowLog Responses maintained by each or specific RegionServers.
Specify array of server names for specific RS. A server name is
the host, port plus startcode of a RegionServer.
e.g.: host187.example.com,60020,1289493121758 (find servername in
master ui or when you do detailed status in shell)

Examples:

  hbase> clear_slowlog_responses                                  => clears slowlog responses from all RS
  hbase> clear_slowlog_responses ['SERVER_NAME1', 'SERVER_NAME2']  => clears slowlog responses from SERVER_NAME1,
                                                                     SERVER_NAME2
```

Viewing Request Information

The usage and supported parameters of **get_slowlog_responses** and **get_largelog_responses** are the same. This part describes how to use **get_slowlog_responses**.

You have logged in to the HBase shell CLI by referring to **Using the HBase Client**.

- Run the following command to view the slow requests of all RegionServers:

  get_slowlog_responses '*', {'LIMIT' => *50*}

  The **LIMIT** parameter specifies the number of records returned by each RegionServer. If this parameter is not specified, 10 records are returned by default.

- Run the following command to view the slow requests of a specified RegionServer:

  get_slowlog_responses ['*SERVER_NAME1***', '***SERVER_NAME2***']**

  SERVER_NAME1 and *SERVER_NAME2* indicate the server names of the RegionServers whose slow requests are to be viewed. To view the server names, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase**, click the hyperlink next to **HMaster WebUI** to access the HBase web UI, obtain the server names of all RegionServers from **ServerName** on the **Base Stats** tab in the **Region Servers** area. One or more parameters are supported.

- Run the following command to view the slow requests of a specified table and region:

  get_slowlog_responses '*', {'TABLE_NAME' => '*t1***'}**

  get_slowlog_responses '*', {'REGION_NAME' => '*hbase:meta,,1***'}**

  get_slowlog_responses '*', {'REGION_NAME' => '*hbase:meta,,1***', 'TABLE_NAME' => '***t1***', 'FILTER_BY_OP' => 'AND'}**

  TABLE_NAME and **REGION_NAME** indicate the names of the specified table and region, respectively. If **'FILTER_BY_OP' => 'AND'** is specified, each returned result must match all specified conditions. If the parameter is not specified, only any condition needs to be matched.

- Run the following command to view the slow requests of a specified user and client:

  get_slowlog_responses '*', {'USER' => '*user_name***', 'CLIENT_IP' => '***192.162.1.40:60225***'}**

  USER and **CLIENT_IP** indicate the username, client IP address, and port number to be matched. If **'FILTER_BY_OP' => 'AND'** is specified, the result that matches both **USER** and **CLIENT_IP** is returned. If the parameter is not specified, only **USER** or **CLIENT_IP** needs to be matched.

Clearing Request Information

You have logged in to the HBase shell CLI by referring to **Using the HBase Client**.

Run the following command to clear the cache of slow requests and oversized requests of all RegionServers or a specified RegionServer:

clear_slowlog_responses

clear_slowlog_responses ['*SERVER_NAME1***', '***SERVER_NAME2***']**

9.6.8 Configuring HBase Table-Level Overload Control

Scenario

When the HBase requests soar in a short period of time, the system is overloaded. As a result, the P99 latency of requests increases, which severely affects services that relay on quick responses. HBase table-level overload prevention is used to control request latency of core tables (core services).

NOTE

This section applies only to MRS 3.3.1 and later.

Procedure

Step 1 Modify the properties of core tables and set table-level priorities.

1. Log in to the node where the HBase client is installed as the client installation user and configure environment variables.

   cd *HBase client installation directory*

   source bigdata_env

2. If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to authenticate the user:

   kinit *Component service user*

3. Run the following commands to log in to the HBase client and modify the table description:

   hbase shell

   alter '*test_table***', PRIORITY=>'1'**

   NOTE

   - The table priority can be set through the **PRIORITY** property. When the value of **PRIORITY** is greater than or equal to 1, the priority is high. You are advised to set **PRIORITY** to **1**.
   - You can specify the **PRIORITY** property when creating a core table. For example:

     create '*test_table***','cf',PRIORITY=>'1'**

Step 2 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Configurations** > **All Configurations**, search for the parameters listed in **Table 9-11**, and change the parameter values.

Table 9-11 Parameters for HBase table-level overload control

Parameter	Description	Suggestion
hbase.ipc.server.default.callqueue.size.overload.threshold	RegionServer queue threshold. When the percentage of the request size in the queue exceeds the threshold, requests to low-priority tables are discarded. This configuration is used to control the request latency of core tables. When regular request restriction is enabled for protecting internal high-priority requests (the value of **hbase.ipc.server.max.default.callqueue.size.ratio** is not 0), the queue overload threshold is limited by the maximum percentage of regular requests in the queue, the final effective value is the product of the two values.	• The number of core table requests and latency requirements must be considered. A smaller value is recommended. Generally, the value ranges from 0.5 to 1.0. • The two types of overload control can be enabled independently or at the same time. RegionServer queue overload control is used when there is a large number of requests. RegionServer handler overload control is used when there is a large number of concurrent requests.
hbase.ipc.server.handler.overload.threshold	RegionServer handler threshold. When the percentage of active handlers exceeds the threshold, requests to low-priority tables are discarded. This configuration is used to control the request latency of core tables.	

Step 3 Click **Save**. In the displayed dialog box, click **OK**.

Step 4 Click **Instances**, select all RegionServer instances, and choose **More** > **Restart Instance**.

----End

9.6.9 Enabling the HBase Multicast Function

The HBase Multicast function involves two roles: Publisher (HMaster) and Listener (client). You can set **hbase.status.published** to **true** to enable this function. In MRS 3.5.0 and later versions, this function is enabled on the Publisher by default.

When the Multicast function is enabled, the Publisher observes the survival status of the current RegionServer. If there is a Dead RegionServer, the Publisher broadcasts the Dead RegionServer information. The listener configured with the broadcast address receives the information about the Dead RegionServer and automatically deletes the region location cache information on the Dead RegionServer from the connection established by the client. When the region is accessed next time, the listener obtains the latest location information so that the service side can quickly identify the faulty RegionServer and update the region location information cache.

Enabling the HBase Multicast Function

Currently, this function can be enabled on the HBase client running in an IPv4 Linux/Unix environment only. The client must be able to communicate with the service IP address of the HMaster node. Perform the following operations to enable the Multicast function based on service requirements:

Step 1 (Optional) This function is enabled and configured on the HMaster server by default. If there are other NICs besides the NICs mounted to the management IP address and service IP address on the node, log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Configurations** > **All Configurations** > **HMaster (Role)** > **Customization**, and add configurations in the **hbase.hmaster.config.expandor** customized parameter. The value of **hbase.status.multicast.ni.name** is the name of the NIC to which the service IP address is mounted.

Step 2 Log in to the node where the HBase client is installed as the client installation user.

Step 3 In *HBase client installation directory*/**HBase/hbase/conf/hbase-site.xml**, add and configure the parameters in **Table 9-12** to enable the Multicast function of the client.

Table 9-12 Parameters for enabling the function

Parameter	Description	Value
hbase.status.published	If this parameter is set to **true**, the Multicast function is enabled on the client.	true
hbase.status.multicast.address.ip	Broadcast address used by the Multicast feature. In an IPv4 network, the broadcast address is **226.1.1.3**.	226.1.1.3
hbase.status.multicast.bind.address.ip	Broadcast address bound to the client listener. In a Linux/Unix environment, the value must be the same as the broadcast address.	226.1.1.3

Parameter	Description	Value
hbase.status.multicast.ni.name	Name of the NIC used by the service IP address if a node has multiple NICs. This configuration is optional for a single-NIC node.	-

Refer to the following configurations:

```
<property>
<name>hbase.status.published</name>
<value>true</value>
</property>
<property>
<name>hbase.status.multicast.address.ip</name>
<value>226.1.1.3</value>
</property>
<property>
<name>hbase.status.multicast.bind.address.ip</name>
<value>226.1.1.3</value>
</property>
```

Step 4 Verify that the Multicast function is enabled on the client.

Start read and write tasks on the HBase client and locate the RegionServer where the target region is located. Restart the RegionServer during read/write task execution. If "ClusterStatusListener: There is a new dead server" is displayed on the client, the multicast function is enabled.

The following describes how to check whether the Multicast function is enabled for read and write tasks executed on the HBase Shell client:

1. Switch to the client installation directory, configure environment variables, and authenticate the user.

   cd *HBase client installation directory*

   source bigdata_env

   kinit *Component service user* (skip this step if Kerberos authentication is disabled for the cluster (the cluster is in normal mode))

2. Log in to the HBase client, create a table, and write data. Do not close the HBase client.

   hbase shell

   create 'test_multicast', 'f1'

   put 'test_multicast','row1','f1:q','value1'

   put 'test_multicast','row2','f1:q','value2'

   put 'test_multicast','row3','f1:q','value3'

3. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase**, and click the **HMaster(***Host name***, active)** hyperlink on the right of **HMaster WebUI** to go to the HBase web UI.
4. In the **Tables** area, click the table name **test_multicast**. In the **Table Regions** area, locate the RegionServer where the table region is located.

5. On FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Instances**, select the RegionServerServer instance queried in **Step 4.4**, and choose **More** > **Restart Instance** or **Instance Rolling Restart**.
6. If the key log "client.ClusterStatusListener: There is a new dead server" is displayed in the HBase Shell, the multicast function is enabled.

----End

9.7 HBase Performance Tuning

9.7.1 Improving the Batch Loading Efficiency of HBase BulkLoad

Scenario

HBase BulkLoad uses MapReduce jobs to directly generate files that comply with the internal data format of HBase, and then loads the generated StoreFiles to a running cluster. Compared with HBase APIs, BulkLoad saves more CPU and network resources.

ImportTSV is an HBase table data loading tool.

Prerequisites

When using BulkLoad, the output path of the file has been specified using the **Dimporttsv.bulk.output** parameter.

Procedure

Add the **Table 9-13** parameters to the BulkLoad command when performing a batch loading task.

Table 9-13 Parameter for improving BulkLoad efficiency

Parameter	Description	Value
-Dimporttsv.mapper.class	The construction of key-value pairs is moved from the user-defined mapper to reducer to improve performance. The mapper only needs to send the original text in each row to the reducer. The reducer parses the record in each row and creates a key-value) pair. **NOTE** When this parameter is set to **org.apache.hadoop.hbase.mapreduce.TsvImporterByteMapper**, this parameter is used only when the batch loading command without the *HBASE_CELL_VISIBILITY OR HBASE_CELL_TTL* option is executed. The **org.apache.hadoop.hbase.mapreduce.TsvImporterByteMapper** provides better performance.	org.apache.hadoop.hbase.mapreduce.TsvImporterByteMapper and org.apache.hadoop.hbase.mapreduce.TsvImporterTextMapper

9.7.2 Improving HBase Continuous Put Performance

Scenario

In the scenario where a large number of requests are continuously Put, setting the following two parameters to **false** can greatly improve the Put performance.

- **hbase.regionserver.wal.durable.sync**
- **hbase.regionserver.hfile.durable.sync**

When the performance is improved, there is a low probability that data is lost if three DataNodes are faulty at the same time. Exercise caution when configuring the parameters in scenarios that have high requirements on data reliability.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Configurations** > **All Configurations**. Enter the parameter name in the search box, and change the value.

Table 9-14 Parameters for improving put performance

Parameter	Description	Value
hbase.wal.hsync	Specifies whether to enable WAL file durability to make the WAL data persistence on disks. If this parameter is set to **true**, the performance is affected because each WAL file is synchronized to the disk by the Hadoop fsync.	false
hbase.hfile.hsync	Specifies whether to enable the HFile durability to make data persistence on disks. If this parameter is set to **true**, the performance is affected because each Hfile file is synchronized to the disk by the Hadoop fsync.	false

9.7.3 Improving HBase Put and Scan Performance

Scenario

HBase has many configuration parameters related to read and write performance. The configuration parameters need to be adjusted based on the read/write request loads. This section describes how to optimize read and write performance by modifying the RegionServer configurations.

Procedure

Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Configurations**, and configure the following parameters to improve the HBase data read and write performance.

- JVM GC parameters

  Suggestions on setting the RegionServer **GC_OPTS** parameter:

  - Set **-Xms** and **-Xmx** to the same value based on your needs. Increasing the memory can improve the read and write performance. For details, see the description of **hfile.block.cache.size** in **Table 9-16** and **hbase.regionserver.global.memstore.size** in **Table 9-15**.
  - Set **-XX:NewSize** and **-XX:MaxNewSize** to the same value. You are advised to set the value to **512M** in low-load scenarios and **2048M** in high-load scenarios.
  - Set **X-XX:CMSInitiatingOccupancyFraction** to be less than and equal to 90, and it is calculated as follows: **100 x (hfile.block.cache.size + hbase.regionserver.global.memstore.size + 0.05)**.

  - **-XX:MaxDirectMemorySize** indicates the non-heap memory used by the JVM. You are advised to set this parameter to **512M** in low-load scenarios and **2048M** in high-load scenarios.

    NOTE

    The **-XX:MaxDirectMemorySize** parameter is not used by default. If you need to set this parameter, add it to the **GC_OPTS** parameter.

- Put parameters

  RegionServer processes the data of the Put request and writes the data to MemStore and HLog.

  - When the size of MemStore reaches the value of **hbase.hregion.memstore.flush.size**, MemStore is updated to HDFS to generate HFiles.
  - Compaction is triggered when the number of HFiles in the column cluster of the current Region reaches the value of **hbase.hstore.compaction.min**.
  - If the number of HFiles in the column cluster of the current region reaches the value of **hbase.hstore.blockingStoreFiles**, the operation of refreshing the MemStore and generating HFiles is blocked. As a result, the Put request is blocked.

  Table 9-15 Put parameters

Parameter	Description	Default Value
hbase.wal.hsync	Indicates whether each WAL is persistent to disks. For details, see **Improving HBase Continuous Put Performance**.	true
hbase.hfile.hsync	Indicates whether HFile write operations are persistent to disks. For details, see **Improving HBase Continuous Put Performance**.	true

Parameter	Description	Default Value
hbase.hregion.memstore.flush.size	If the size of MemStore (unit: Byte) exceeds a specified value, MemStore is flushed to the corresponding disk. The value of this parameter is checked by each thread running **hbase.server.thread.wakefrequency**. It is recommended that you set this parameter to an integer multiple of the HDFS block size. You can increase the value if the memory is sufficient and the put load is heavy.	134217728
hbase.regionserver.global.memstore.size	Updates the size of all MemStores supported by the RegionServer before locking or forcible flush. It is recommended that you set this parameter to **hbase.hregion.memstore.flush.size x Number of regions with active writes/ RegionServer GC -Xmx**. The default value is **0.4**, indicating that 40% of RegionServer GC -Xmx is used.	0.4
hbase.hstore.flusher.count	Indicates the number of MemStore flush threads. You can increase the parameter value in heavy-put-load scenarios.	2
hbase.regionserver.thread.compaction.small	Indicates the number of small compaction threads. You can increase the parameter value in heavy-put-load scenarios.	10

Parameter	Description	Default Value
hbase.hstore.blockingStoreFiles	If the number of HStoreFile files in a Store exceeds the specified value, the update of the HRegion will be locked until a compression is completed or the value of **base.hstore.blockingWaitTime** is exceeded. Each time MemStore is flushed, a StoreFile file is written into MemStore. Set this parameter to a larger value in heavy-put-load scenarios.	15

- Scan parameters

  Table 9-16 Scan parameters

Parameter	Description	Default Value
hbase.client.scanner.timeout.period	Client and RegionServer parameters, indicating the lease timeout period of the client executing the scan operation. You are advised to set this parameter to an integer multiple of 60000 ms. You can set this parameter to a larger value when the read load is heavy. The unit is milliseconds.	60000
hfile.block.cache.size	Indicates the data cache percentage in the RegionServer GC –Xmx. You can increase the parameter value in heavy-read-load scenarios, in order to improve cache hit ratio and performance. It indicates the percentage of the maximum heap (-Xmx setting) allocated to the block cache of HFiles or StoreFiles.	When offheap is disabled, the default value is **0.25**. When offheap is enabled, the default value is **0.1**.

- Handler parameters

Table 9-17 Handler parameters

Parameter	Description	Default Value
hbase.regionserver.handler.count	Indicates the number of RPC server instances on RegionServer. The recommended value ranges from 200 to 400.	200
hbase.regionserver.metahandler.count	Indicates the number of program instances for processing prioritized requests. The recommended value ranges from 200 to 400.	200

9.7.4 Improving HBase Real-Time Write Efficiency

Scenario

Scenarios where data needs to be written to HBase in real time, or large-scale and consecutive put scenarios

Prerequisites

The HBase put or delete interface can be used to save data to HBase.

Procedure

- **Data writing server tuning**

  Parameter portal: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Configurations** > **All Configurations**. The All Configurations page is displayed, modify related parameter values.

  Table 9-18 Configuration items that affect real-time data writing

Parameter	Description	Default Value
hbase.wal.hsync	Controls the synchronization degree when HLogs are written to the HDFS. If the value is **true**, HDFS returns only when data is written to the disk. If the value is **false**, HDFS returns when data is written to the OS cache. Set the parameter to **false** to improve write performance.	true

Parameter	Description	Default Value
hbase.hfile.hsync	Controls the synchronization degree when HFiles are written to the HDFS. If the value is **true**, HDFS returns only when data is written to the disk. If the value is **false**, HDFS returns when data is written to the OS cache. Set the parameter to **false** to improve write performance.	true

Parameter	Description	Default Value
GC_OPTS	You can increase HBase memory to improve HBase performance because read and write operations are performed in HBase memory. **HeapSize** and **NewSize** need to be adjusted. When you adjust **HeapSize**, set **Xms** and **Xmx** to the same value to avoid performance problems when JVM dynamically adjusts **HeapSize**. Set **NewSize** to 1/8 of **HeapSize**. • **HMaster**: If HBase clusters enlarge and the number of Regions grows, properly increase the **GC_OPTS** parameter value of the HMaster. • **RegionServer**: A RegionServer needs more memory than an HMaster. If sufficient memory is available, increase the **HeapSize** value. **NOTE** When the value of **HeapSize** for the active HMaster is 4 GB, the HBase cluster can support 100,000 regions. Empirically, each time 35,000 regions are added to the cluster, the value of **HeapSize** must be increased by 2 GB. It is recommended that the value of **HeapSize** for the active HMaster not exceed 32 GB.	• HMaster -server -Xms4G -Xmx4G -XX:NewSize=512M -XX:MaxNewSize=512M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=512M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M

Parameter	Description	Default Value
		• Region Server -server -Xms6G -Xmx6G -XX:NewSize=1024M -XX:MaxNewSize=1024M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=512M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M

Parameter	Description	Default Value
hbase.regionserver.handler.count	Indicates the number of RPC server instances started on RegionServer. If the parameter is set to an excessively large value, threads will compete fiercely. If the parameter is set to an excessively small value, requests will be waiting for a long time in RegionServer, reducing the processing capability. You can add threads based on resources. It is recommended that the value be set to **100** to **300** based on the CPU usage.	200
hbase.hregion.max.filesize	Indicates the maximum size of an HStoreFile, in bytes. If the size of any HStoreFile exceeds the value of this parameter, the managed Hregion is divided into two parts.	10737418240
hbase.hregion.memstore.flush.size	On the RegionServer, when the size of MemStore that exists in memory of write operations exceeds **memstore.flush.size**, MemStoreFlusher performs the Flush operation to write the MemStore to the corresponding store in the format of HFile. If RegionServer memory is sufficient and active Regions are few, increase the parameter value and reduce compaction times to improve system performance. The Flush operation may be delayed after it takes place. Write operations continue and MemStore keeps increasing during the delay. The maximum size of MemStore is: **memstore.flush.size** x **hbase.hregion.memstore.block.multiplier**. When the MemStore size exceeds the maximum value, write operations are blocked. Properly increasing the value of **hbase.hregion.memstore.block.multiplier** can reduce the blocks and make performance become more stable. Unit: byte	134217728

Parameter	Description	Default Value
hbase.regionserver.global.memstore.size	Updates the size of all MemStores supported by the RegionServer before locking or forcible flush. On the RegionServer, the MemStoreFlusher thread performs the flush. The thread regularly checks memory occupied by write operations. When the total memory volume occupied by write operations exceeds the threshold, MemStoreFlusher performs the flush. Larger MemStore will be flushed first and then smaller ones until the occupied memory is less than the threshold. Threshold = hbase.regionserver.global.memstore.size x hbase.regionserver.global.memstore.size.lower.limit x HBase_HEAPSIZE **NOTE** The sum of the parameter value and the value of **hfile.block.cache.size** cannot exceed 0.8, that is, memory occupied by read and write operations cannot exceed 80% of **HeapSize**, ensuring stable running of other operations.	0.4

Parameter	Description	Default Value
hbase.hstore.blockingStoreFiles	Check whether the number of files is larger than the value of **hbase.hstore.blockingStoreFiles** before you flush regions. If it is larger than the value of **hbase.hstore.blockingStoreFiles**, perform a compaction and configure **hbase.hstore.blockingWaitTime** to 90s to make the flush delay for 90s. During the delay, write operations continue and the MemStore size keeps increasing and exceeds the threshold (**memstore.flush.size** x **hbase.hregion.memstore.block.multiplier**), blocking write operations. After compaction is complete, a large number of writes may be generated. As a result, the performance fluctuates sharply. Increase the value of **hbase.hstore.blockingStoreFiles** to reduce block possibilities.	15
hbase.regionserver.thread.compaction.throttle	The compression whose size is greater than the value of this parameter is executed by the large thread pool. The unit is bytes. Indicates a threshold of a total file size for compaction during a Minor Compaction. The total file size affects execution duration of a compaction. If the total file size is large, other compactions or flushes may be blocked.	1610612736
hbase.hstore.compaction.min	Indicates the minimum number of HStoreFiles on which minor compaction is performed each time. When the size of a file in a Store exceeds the value of this parameter, the file is compacted. You can increase the value of this parameter to reduce the number of times that the file is compacted. If there are too many files in the Store, read performance will be affected.	6

Parameter	Description	Default Value
hbase.hstore.compaction.max	Indicates the maximum number of HStoreFiles on which minor compaction is performed each time. The functions of the parameter and **hbase.hstore.compaction.max.size** are similar. Both are used to limit the execution duration of one compaction.	10
hbase.hstore.compaction.max.size	If the size of an HFile is larger than the parameter value, the HFile will not be compacted in a Minor Compaction but can be compacted in a Major Compaction. The parameter is used to prevent HFiles of large sizes from being compacted. After a Major Compaction is forbidden, multiple HFiles can exist in a Store and will not be merged into one HFile, without affecting data access performance. The unit is byte.	9223372036854775807
hbase.hregion.majorcompaction	Main compression interval of all HStoreFile files in a region. The unit is milliseconds. Execution of Major Compactions consumes much system resources and will affect system performance during peak hours. If service updates, deletion, and reclamation of expired data space are infrequent, set the parameter to **0** to disable Major Compactions. If you must perform a Major Compaction to reclaim more space, increase the parameter value and configure the **hbase.offpeak.end.hour** and **hbase.offpeak.start.hour** parameters to make the Major Compaction be triggered in off-peak hours.	604800000

Parameter	Description	Default Value
• hbase.regionserver.maxlogs • hbase.regionserver.hlog.blocksize	• Indicates the threshold for the number of HLog files that are not flushed on a RegionServer. If the number of HLog files is greater than the threshold, the RegionServer forcibly performs flush operations. • Indicates the maximum size of an HLog file. If the size of an HLog file is greater than the value of this parameter, a new HLog file is generated. The old HLog file is disabled and archived. The two parameters determine the number of HLogs that are not flushed in a RegionServer. When the data volume is less than the total size of MemStore, the flush operation is forcibly triggered due to excessive HLog files. In this case, you can adjust the values of the two parameters to avoid forcible flush. Unit: byte	• 32 • 134217728

- **Data writing client tuning**

  It is recommended that data is written in Put List mode if necessary, which greatly improves write performance. The length of each put list needs to be set based on the single put size and parameters of the actual environment. You are advised to do some basic tests before configuring parameters.

- **Data table writing design optimization**

  Set the following table parameters in the hbase shell to improve the data write performance of HBase.

Table 9-19 Parameters affecting real-time data writing

Parameter	Description	Default Value
COMPRESSION	The compression algorithm compresses blocks in HFiles. For compressible data, configure the compression algorithm to efficiently reduce disk I/Os and improve performance. **NOTE** Some data cannot be efficiently compressed. For example, a compressed figure can hardly be compressed again. The common compression algorithm is SNAPPY, because it has a high encoding/decoding speed and acceptable compression rate.	NONE
BLOCKSIZE	Different block sizes affect HBase data read and write performance. You can configure sizes for blocks in an HFile. Larger blocks have a higher compression rate. However, they have poor performance in random data read, because HBase reads data in a unit of blocks. Set the parameter to 128 KB or 256 KB to improve data write efficiency without greatly affecting random read performance. The unit is byte.	65536
IN_MEMORY	Whether to cache table data in the memory first, which improves data read performance. If you will frequently access some small tables, set the parameter.	false

9.7.5 Improving HBase Real-Time Read Efficiency

Scenario

Scenarios where the performance of reading HBase data needs to be improved.

Prerequisites

The get or scan interface of HBase has been invoked and data is read in real time from HBase.

Procedure

- **Data reading server tuning**

  Parameter portal: Log in to FusionInsight Manager and choose **Cluster** > **Services** > **Configurations** > **All Configurations**. The All Configurations page is displayed, modify related parameter values to improve the HBase data read performance.

Table 9-20 Configuration items that affect real-time data reading

Parameter	Description	Default Value
GC_OPTS	You can increase HBase memory to improve HBase performance because read and write operations are performed in HBase memory. **HeapSize** and **NewSize** need to be adjusted. When you adjust **HeapSize**, set **Xms** and **Xmx** to the same value to avoid performance problems when JVM dynamically adjusts **HeapSize**. Set **NewSize** to 1/8 of **HeapSize**. ● **HMaster**: If HBase clusters enlarge and the number of Regions grows, properly increase the **GC_OPTS** parameter value of the HMaster. ● **RegionServer**: A RegionServer needs more memory than an HMaster. If sufficient memory is available, increase the **HeapSize** value. **NOTE** When the value of **HeapSize** for the active HMaster is 4 GB, the HBase cluster can support 100,000 Regions. Empirically, each time 35,000 Regions are added to the cluster, the value of **HeapSize** must be increased by 2 GB. It is recommended that the value of **HeapSize** for the active HMaster not exceed 32 GB.	● HMaster -server -Xms4G -Xmx4G -XX:NewSize=512M -XX:MaxNewSize=512M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=512M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -

Parameter	Description	Default Value
		XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M • Region Server -server -Xms6G -Xmx6G -XX:NewSize=1024M -XX:MaxNewSize=1024M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=512M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCTimeStamps -XX:+PrintGC

Parameter	Description	Default Value
		DateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M
hbase.regionserver.handler.count	Indicates the number of requests that RegionServer can process concurrently. If the parameter is set to an excessively large value, threads will compete fiercely. If the parameter is set to an excessively small value, requests will be waiting for a long time in RegionServer, reducing the processing capability. You can add threads based on resources. It is recommended that the value be set to 100 to 300 based on the CPU usage.	200
hfile.block.cache.size	HBase cache sizes affect query efficiency. Set cache sizes based on query modes and query record distribution. If random query is used to reduce the hit ratio of the buffer, you can reduce the buffer size.	When **offheap** is disabled, the default value is **0.25**. When **offheap** is enabled, the default value is **0.1**.

NOTE

If read and write operations are performed at the same time, the performance of the two operations affects each other. If flush and compaction operations are frequently performed due to data writes, a large number of disk I/O operations are occupied, affecting read performance. If a large number of compaction operations are blocked due to write operations, multiple HFiles exist in the region, affecting read performance. Therefore, if the read performance is unsatisfactory, you need to check whether the write configurations are proper.

- **Data reading client tuning**

  When scanning data, you need to set **caching** (the number of records read from the server at a time. The default value is **1**.). If the default value is used, the read performance will be extremely low.

  If you do not need to read all columns of a piece of data, specify the columns to be read to reduce network I/O.

If you only need to read the row key, add a filter (FirstKeyOnlyFilter or KeyOnlyFilter) that only reads the row key.

- **Data table reading design optimization**

  Set the following table parameters in the HBase shell to improve the performance of reading HBase data in real time.

  Table 9-21 Parameters affecting real-time data reading

Parameter	Description	Default Value
COMPRESSION	The compression algorithm compresses blocks in HFiles. For compressible data, configure the compression algorithm to efficiently reduce disk I/Os and improve performance. **NOTE** Some data cannot be efficiently compressed. For example, a compressed figure can hardly be compressed again. The common compression algorithm is SNAPPY, because it has a high encoding/decoding speed and acceptable compression rate.	NONE
BLOCKSIZE	Different block sizes affect HBase data read and write performance. You can configure sizes for blocks in an HFile. Larger blocks have a higher compression rate. However, they have poor performance in random data read, because HBase reads data in a unit of blocks. Set the parameter to 128 KB or 256 KB to improve data write efficiency without greatly affecting random read performance. The unit is byte.	65536
DATA_BLOCK_ENCODING	Encoding method of the block in an HFile. If a row contains multiple columns, set **FAST_DIFF** to save data storage space and improve performance.	NONE

9.7.6 Accelerating HBase Compaction During Off-Peak Hours

Scenario

HBase allows you to set compaction throughput during off-peak hours. A large throughput can speed up compaction execution and reduce impacts on services during peak hours.

(This operation is supported only for MRS 3.3.0 or later.)

Configuring HBase Compaction Throughput Parameters

Log in to FusionInsight Manager, choose **Cluster** > **Service** > **HBase**, and click **Configuration**. In the search box, search for the parameters listed in **Table 9-22** and change the parameter values as you need. The parameter settings take effect dynamically. After the modification is saved, log in to the **hbase shell** CLI and run the **update_all_config** command to update the configuration. You do not need to restart the instance.

NOTE

To enable the HBase compaction throughput settings, neither **hbase.offpeak.start.hour** nor **hbase.offpeak.end.hour** must be **-1**.

Table 9-22 HBase compaction throughput parameters

Parameter	Description	Default Value
hbase.offpeak.start.hour	Start time of off-peak hours of the HBase cluster. The value must be an integer from **-1** to **23**. If the value is **-1**, HBase compaction throughput will not be used.	-1
hbase.offpeak.end.hour	End time of off-peak hours of the HBase cluster. The value must be an integer from **-1** to **23**. If the value is **-1**, HBase compaction throughput will not be used.	-1
hbase.hstore.compaction.throughput.offpeak	Compaction throughput during off-peak hours. The unit is byte/s.	104857600

Configuration Example

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Service** > **HBase**, and click **Configuration**. Set off-peak hours as needed. The following are examples:

- If **hbase.offpeak.start.hour** is **18** and **hbase.offpeak.end.hour** is **23**, off-peak hours are 18:00 to 23:00 every day.
- If **hbase.offpeak.start.hour** is **23** and **hbase.offpeak.end.hour** is **8**, off-peak hours are 23:00 to 8:00 the next day.

Step 2 During off-peak hours, log in to FusionInsight Manager, choose **Cluster** > **Service** > **HBase**, and click **Chart**. Check whether the value of **Compaction Queue Size-All Instances** keeps increasing and whether the values of some RegionServers in **Traffic of the RegionServer Compaction Operations-All Instances** have reached or exceeded the value of **hbase.hstore.compaction.throughput.offpeak**.

- If they are, set **hbase.hstore.compaction.throughput.offpeak** to a larger value based on the cluster disk usage and go to **Step 3**.
- If they are not, no further action is required.

Step 3 Check whether the value of **P99 Percentile RegionServer RPC Request Response Time-All Instances** keeps increasing in the HBase chart.

- If it does, go to **Step 4**.
- If it does not, no further action is required.

Step 4 Check whether the value of **Disk IO Utilization** of the host where the RegionServer is located exceeds 90%.

- If it does, reduce the write speed or expand the disk capacity.
- If it does not, no further action is required.

----End

9.7.7 Tuning HBase JVM Parameters

Scenario

When the number of clusters reaches a certain scale, the default settings of the Java virtual machine (JVM) cannot meet the cluster requirements. In this case, the cluster performance deteriorates or the clusters may be unavailable. Therefore, JVM parameters must be properly configured based on actual service conditions to improve the cluster performance.

Procedure

Navigation path for setting parameters:

The JVM parameters related to the HBase role must be configured in the **hbase-env.sh** file in the **${BIGDATA_HOME}/FusionInsight_HD_*/install/FusionInsight-HBase-2.2.3/hbase/conf/** directory of the node where the HBase service is installed.

Each role has JVM parameter configuration variables, as shown in **Table 9-23**.

Table 9-23 HBase-related JVM parameter configuration variables

Variable	Affected Role
HBASE_OPTS	All roles of HBase
SERVER_GC_OPTS	All roles on the HBase server, such as Master and RegionServer
CLIENT_GC_OPTS	Client process of HBase
HBASE_MASTER_OPTS	Master of HBase
HBASE_REGIONSERVER_OPTS	RegionServer of HBase
HBASE_THRIFT_OPTS	Thrift of HBase

Configuration example:

```
export HADOOP_NAMENODE_OPTS="-Dhadoop.security.logger=${HADOOP_SECURITY_LOGGER:-INFO,RFAS} -Dhdfs.audit.logger=${HDFS_AUDIT_LOGGER:-INFO,NullAppender} $HADOOP_NAMENODE_OPTS"
```

9.7.8 Optimization for HBase Overload

Scenario

When the HBase service peaks suddenly and a large number of requests are sent to a RegionServer/HMaster in a short period of time, the RegionServer/HMaster is overloaded. If the HBase service is overloaded, the read and write performance of the application deteriorates, GC occurs frequently on the HBase service, and even the service instance restarts.

Currently, HBase can prevent overloading. It can reject oversized requests, protect internal requests, and record improper requests, reducing the impact on HBase services in overload scenarios and ensuring service stability.

This topic is available for MRS 3.3.0 and later versions only.

Sharp Traffic Increase

When service traffic peaks, for example, the number of requests increases by 10 times, you can perform the following operations to manage the traffic:

Step 1 Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** > **Chart**, select **Handler** in the chart category on the left, and check whether "Number of Active RegionServer Handlers for Processing User Table Requests-All Instances" is used up for a long time. If they are used up, click **Configure**. The following table lists the RegionServer parameters to be configured.

Table 9-24 Optimizing parameters when RegionServer handlers are used up

Parameter	Description	Optimization
hbase.regionserver.handler.count	Number of RPC server instances started on RegionServer	Increase the value of this parameter. However, the value should be less than or equal to **1000**.
hbase.ipc.server.max.default.callqueue.size.ratio	Maximum percentage of common requests in the RegionServer queue. When the total size of common requests in the queue exceeds the threshold, the requests are discarded.	Adjust the value to about **0.8** to limit the proportion of queues occupied by external requests and protect internal requests.

Step 2 Check whether "*XXX* is too large for table *XXX*" or "Client scan caching *XXX* is too large for table *XXX*" exists in the service run logs on the application side. If yes, improper requests exist. Check the requests and reduce the data volume of each request (reduce the data volume for Put/Delete batch requests and decrease the Caching value for Scan). If services on the service side cannot be optimized temporarily, you can add or modify the following parameters in the ***Client installation directory*/HBase/hbase/conf/hbase-site.xml** file on the application side. (**This only reduces recorded alarm logs but does not relieve overload**.)

Table 9-25 Parameters for reducing recorded alarm logs

Parameter	Description	Optimization
hbase.rpc.rows.warning.threshold	Threshold of the number of data records written, updated, or deleted by the HBase client at a time. If the threshold is exceeded, a log is recorded.	Increase the value of this parameter.
hbase.client.scanner.warning.threshold.scanning.ratio	If the caching of a single scan on the HBase client is too large (40% of the maximum value by default), a log is recorded when the threshold is exceeded.	Change the value of this parameter to **1.0**.

Step 3 If the service side sends too many oversized requests, the server processes the requests slowly. As a result, the requests are stacked and overloaded. **If oversized requests can be considered as abnormal requests**, adjust the parameters in the HBase configuration on FusionInsight Manager to reject the requests. The following table lists the RegionServer parameters to be configured.

Table 9-26 Parameters for rejecting requests

Parameter	Description	Optimization
hbase.ipc.max.request.size	Maximum size of a RegionServer request. If a request is bigger than the specified size, the request is discarded. The default value is **256 MB**.	If the application retried for multiple times and "RPC data length *XXX* of received from *XXX* is greater than max allowed" is displayed in RegionServer logs, reduce the amount of data sent at a time on the application side. If the amount cannot be reduced, you can increase the value of this parameter. It is recommended that the value be less than or equal to **1 GB**.

Parameter	Description	Optimization
hbase.server.keyvalue.maxsize	Maximum size of a single cell for RegionServer write/update operations. If the value of this parameter is exceeded, RegionServer write/update operations are not allowed. The default value is **10 MB**.	If a single cell is too large, the read and write performance is degraded and abnormal data may exist. You can evaluate the data range based on the written data and set the upper limit. If the evaluation cannot be performed, you are advised to retain the default value.
hbase.rpc.rows.size.threshold.reject	Whether to reject a RegionServer request when the number of data operations in the request exceeds the specified limit.	If there is a request contains a large number of write, update, and delete operations on a node, the number of operations may exceed the value of **hbase.rpc.rows.warning.threshold**. In this case, overloading occurs and the performance deteriorates. If this parameter is set to **true**, large requests will be rejected. If the pre-partitioning is improper, too many requests may be rejected. Set this parameter to **true** only when stable.

----End

Server Restart in a Large Number of Regions

When multiple RegionServers of large-scale clusters in a number of regions (more than 100,000) are restarted at the same time, HMaster may be overloaded.

You can configure the parameters listed in **Table 9-27** in the HBase configuration on FusionInsight Manager to accelerate HMaster processing of high-priority requests and reduce HMaster overload.

Table 9-27 Parameters for handling overloading caused by online/offline switches in a large number of regions

Instance Name	Parameter	Description	Optimization
HMaster	hbase.regionserver.metahandler.count	Number of handlers used by HMaster to process high-priority requests	Increase the value of this parameter. However, the value should be less than or equal to **1000**.
	hbase.ipc.server.metacallqueue.read.ratio	Ratio of read queues in a high-priority request queue, which affects the number of meta read/write handlers	Retain the default value **0.5**.
RegionServer	hbase.regionserver.msginterval	Interval for transmitting messages between RegionServer and HMaster	Increase the value of this parameter can release the pressure on HMaster. The recommended value is **15s**.

9.7.9 Enabling CCSMap Functions

Scenario

CompactedConcurrentSkipListMap (CCSMap) optimizes the Memstore data structure and uses less memory in data write scenarios, reducing GC times for higher data write performance. You can enable this feature to handle tasks that require high data write performance.

NOTE

This section applies only to MRS 3.3.1 and later.

Procedure

Step 1 Log in to FusionInsight Manager of the cluster and choose **Cluster** > **Services** > **HBase** > **Configurations** > **All Configurations**.

Step 2 Search for and modify the following parameters to enable the CCSMap feature:

- **hbase.regionserver.memstore.class**: Memstore implementation class. Set this parameter to **org.apache.hadoop.hbase.regionserver.CCSMapMemStore**.
- **hbase.hregion.compacting.memstore.type**: Memstore memory compaction policy. Set this parameter to **NONE**.

Step 3 Click **Save**.

Step 4 Click **Instances**, select all RegionServer instances, choose **More** > **Instance Rolling Restart**, and enter the password of the user to restart the RegionServer instances.

----End

9.7.10 Enabling Succinct Trie

Scenario

Succinct Trie optimizes the HFile Block structure. It uses less cache space, reduces the cache data eviction rate, and improves the cache hit ratio. You can enable this feature to improve performance of tasks that frequently read data.

This section applies only to MRS 3.3.1 and later.

NOTICE

If Succinct Trie is enabled, open-source versions of HFiles are incompatible. If you are using an HFile to migrate data to MRS 3.2.0 or an earlier version, disable this feature and then run the **major compaction** command on the data table to generate a new HFile file.

Procedure

Step 1 Log in to FusionInsight Manager of the cluster and choose **Cluster** > **Services** > **HBase** > **Configurations**.

Step 2 In the search box, search for and modify the configuration in **Table 9-28** to enable Succinct Trie.

Table 9-28 Succinct Trie parameters

Parameter	Description	New Value	Must Be Modified
hbase.write.tries	Whether to enable Succinct Tries • **true**: Enable Succinct Tries • **false**: Disable Succinct Tries	true	Yes

Parameter	Description	New Value	Must Be Modified
hbase.tries.cache.enabled	If this parameter is set to **true**, LoudsTriesLruBlockCache uses off-heap memory to cache index blocks, reducing the eviction rate of index blocks and improving cache efficiency.	true	No
hbase.index.block.cache.size	Cache size ratio of the LoudsTriesLruBlockCache index block to the **blocksize** If the value of **blocksize** is small, you are advised to increase the value.	-	No

Step 3 Click **Save**.

Step 4 Click **Instances**, select all RegionServer instances, choose **More** > **Instance Rolling Restart**, and enter the password of the user to restart the RegionServer instances.

----End

9.8 HBase O&M Management

9.8.1 HBase Log Overview

Log Description

Log path: The default storage path of HBase logs is **/var/log/Bigdata/hbase/***Role name*.

- HMaster: **/var/log/Bigdata/hbase/hm** (run logs) and **/var/log/Bigdata/audit/hbase/hm** (audit logs)
- RegionServer: **/var/log/Bigdata/hbase/rs** (run logs) and **/var/log/Bigdata/audit/hbase/rs** (audit logs)
- ThriftServer: **/var/log/Bigdata/hbase/ts2** (run logs, **ts2** is the instance name) and **/var/log/Bigdata/audit/hbase/ts2** (audit logs, **ts2** is the instance name)

Log archive rule: The automatic log compression and archiving function of HBase is enabled. By default, when the size of a log file exceeds 30 MB, the log file is automatically compressed. The naming rule of a compressed log file is as follows:

<*Original log name*>-<*yyyy-mm-dd_hh-mm-ss*>.[*ID*].**log.zip** A maximum of 20 latest compressed files are reserved. The number of compressed files can be configured on the Manager portal.

Table 9-29 HBase log list

Type	Name	Description
Run logs	hbase-<SSH_USER>-<process_name>-<hostname>.log	HBase system log that records the startup time, startup parameters, and most logs generated when the HBase system is running.
	hbase-<SSH_USER>-<process_name>-<hostname>.out	Log that records the HBase running environment information.
	<process_name>-<SSH_USER>-<DATE>-<PID>-gc.log	Log that records HBase junk collections.
	checkServiceDetail.log	Log that records whether the HBase service starts successfully.
	hbase.log	Log generated when the HBase service health check script and some alarm check scripts are executed.
	sendAlarm.log	Log that records alarms reported after execution of HBase alarm check scripts.
	hbase-haCheck.log	Log that records the active and standby status of HMaster
	stop.log	Log that records the startup and stop processes of HBase.
Audit logs	hbase-audit-<process_name>.log	Log that records HBase security audit.

Log Level

Table 9-30 describes the log levels supported by HBase. The priorities of log levels are FATAL, ERROR, WARN, INFO, and DEBUG in descending order. Logs whose levels are higher than or equal to the specified level are printed. The number of printed logs decreases as the specified log level increases.

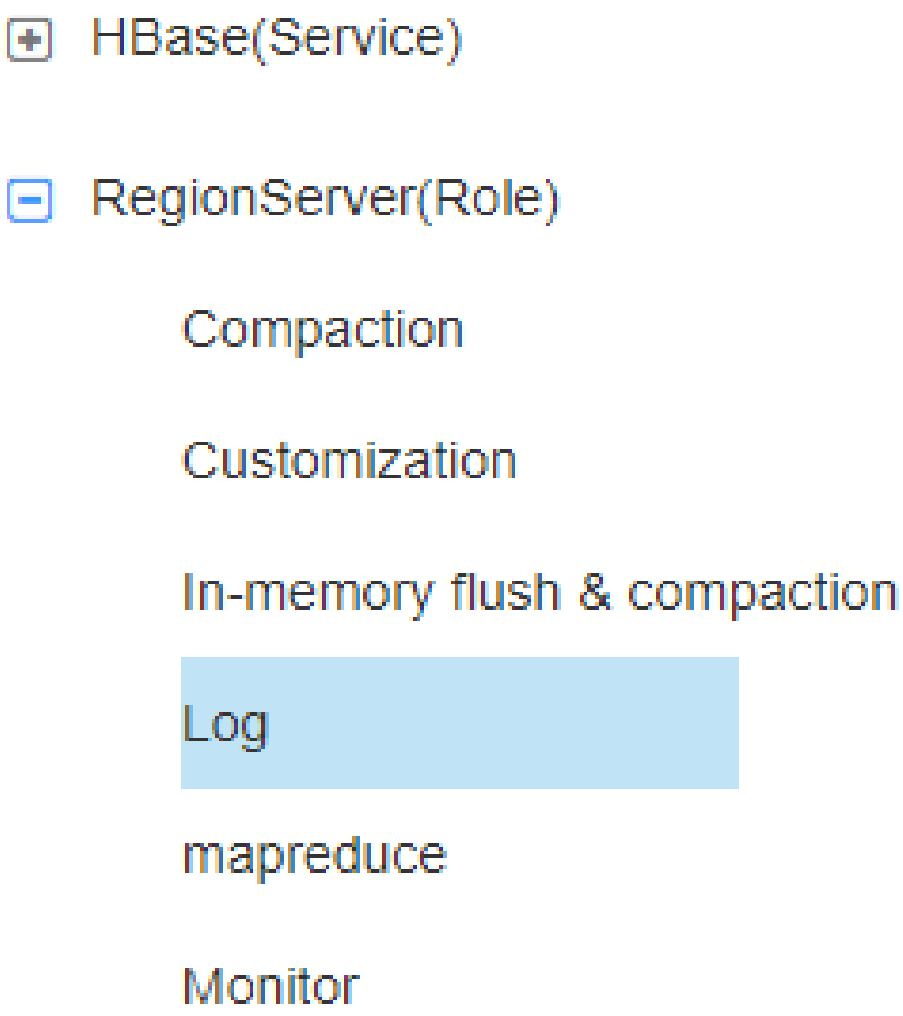
Table 9-30 Log levels

Level	Description
FATAL	Logs of this level record fatal error information about the current event processing that may result in a system crash.
ERROR	Logs of this level record error information about the current event processing, which indicates that system running is abnormal.
WARN	Logs of this level record abnormal information about the current event processing. These abnormalities will not result in system faults.
INFO	Logs of this level record normal running status information about the system and events.
DEBUG	Logs of this level record the system information and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of the HBase service. For details, see **Modifying Cluster Service Configuration Parameters**.

Step 2 On the left menu bar, select the log menu of the target role.



Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without the need to restart the service.

----End

Log Formats

The following table lists the HBase log formats.

Table 9-31 Log formats

Type	Component	Format	Example
Run logs	HMaster	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-01-19 16:04:53,558 | INFO | main | env:HBASE_THRIFT_OPTS= | org.apache.hadoop.hbase.util.ServerCommandLine.logProcessInfo(ServerCommandLine.java:113)
	RegionServer	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-01-19 16:05:18,589 | INFO | regionserver16020-SendThread(linux-k6da:2181) | Client will use GSSAPI as SASL mechanism. | org.apache.zookeeper.client.ZooKeeperSaslClient$1.run(ZooKeeperSaslClient.java:285)
	ThriftServer	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-02-16 09:42:55,371 | INFO | main | loaded properties from hadoop-metrics2.properties | org.apache.hadoop.metrics2.impl.MetricsConfig.loadFirst(MetricsConfig.java:111)
Audit logs	HMaster	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-02-16 09:42:40,934 | INFO | master:linux-k6da:16000 | Master: [master:linux-k6da:16000] start operation called. | org.apache.hadoop.hbase.master.HMaster.run(HMaster.java:581)
	RegionServer	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-02-16 09:42:51,063 | INFO | main | RegionServer: [regionserver16020] start operation called. | org.apache.hadoop.hbase.regionserver.HRegionServer.startRegionServer(HRegionServer.java:2396)

Type	Component	Format	Example
	ThriftServer	<yyyy-MM-dd HH:mm:ss,SSS>|<Log Level>|<*Thread that generates the log*>|<*Message in the log*>|<*Location of the log event*>	2020-02-16 09:42:55,512 | INFO | main | thrift2 server start operation called. | org.apache.hadoop.hbase.thrift2.ThriftServer.main(ThriftServer.java:421)

9.8.2 Configuring Region In Transition Recovery Chore Service

Scenario

In a faulty environment, there are possibilities that a region may be stuck in transition for longer duration due to various reasons like slow region server response, unstable network, ZooKeeper node version mismatch. During region transition, client operation may not work properly as some regions will not be available.

Enabling the Region Transition Recovery Function

A chore service should be scheduled at HMaster to identify and recover regions that stay in the transition state for a long time.

Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HBase** > **Configurations**. The following table describes the parameters for enabling this function.

Table 9-32 Parameters

Parameter	Description	Default Value
hbase.region.assignment.auto.recovery.enabled	Configuration parameter used to enable/disable the region assignment recovery thread feature.	true

9.8.3 Enabling Inter-Cluster Copy to Back Up Data

Scenario

DistCp is used to copy the data stored on HDFS from a cluster to another cluster. DistCp depends on the cross-cluster copy function, which is disabled by default. This function needs to be enabled in both clusters.

Modify parameters on MRS to enable cross-cluster copy.

Impact on the System

Yarn needs to be restarted to enable the cross-cluster copy function and cannot be accessed during the restart.

Prerequisites

The **hadoop.rpc.protection** parameter of the two HDFS clusters must be set to the same data transmission mode, which can be **privacy** (encryption enabled) or **authentication** (encryption disabled).

NOTE

You can log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **Configurations**, and search for **hadoop.rpc.protection**.

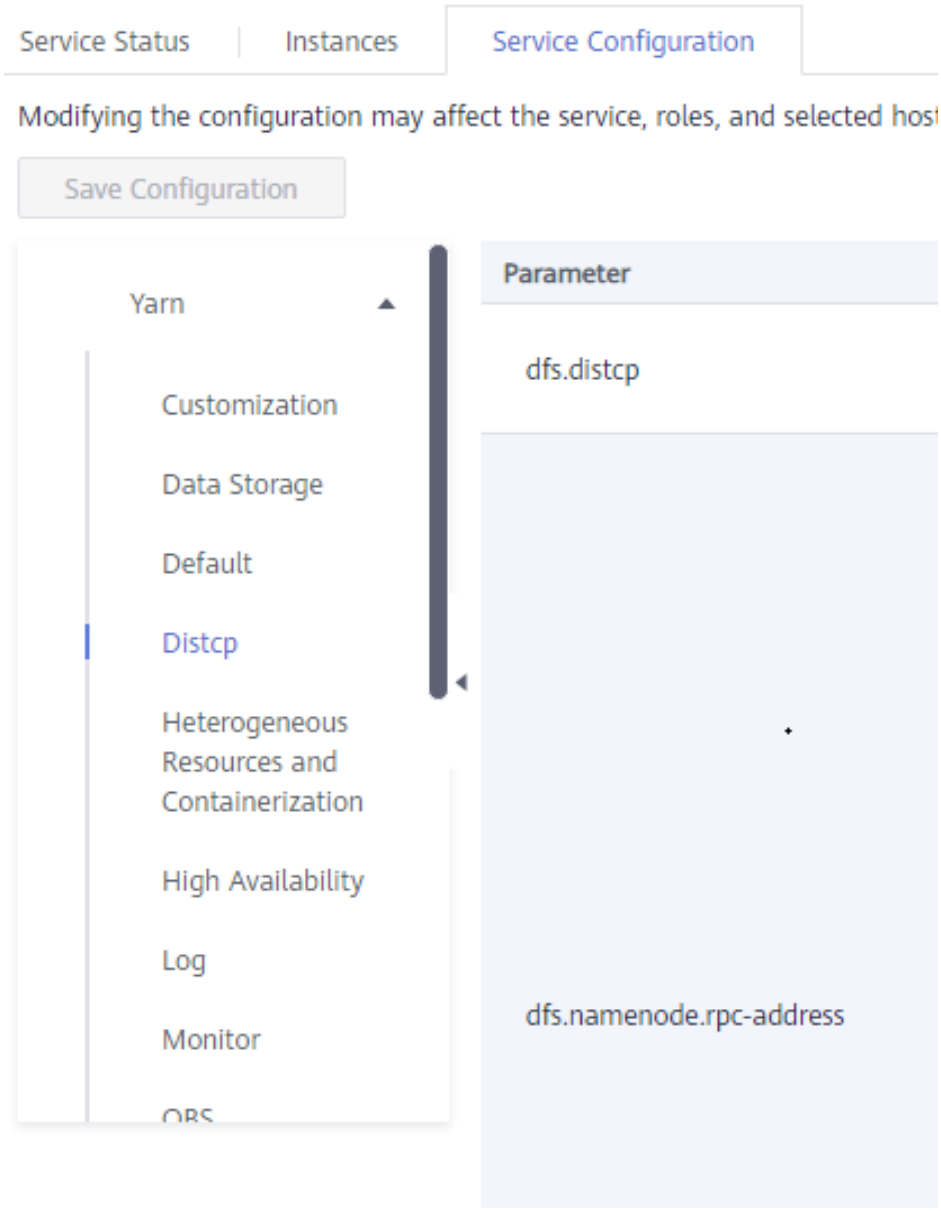
Procedure

Step 1 Go to the **All Configurations** page of the Yarn service. For details, see **Modifying Cluster Service Configuration Parameters**.

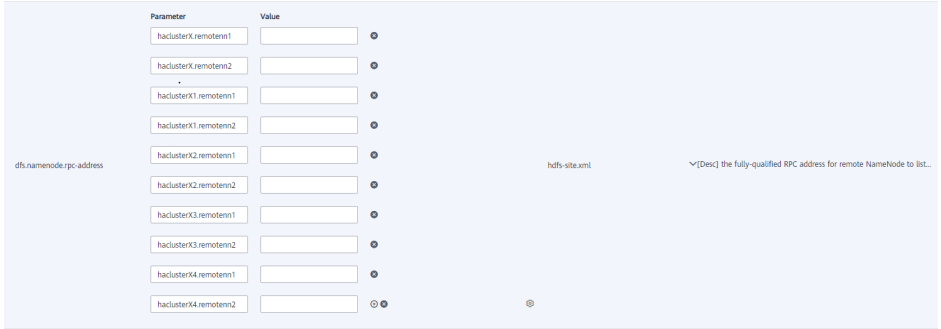
NOTE

If the **Components** tab is unavailable, complete IAM user synchronization first. (On the **Dashboard** page, click **Synchronize** on the right side of **IAM User Sync** to synchronize IAM users.)

Step 2 In the navigation pane, choose **Yarn** > **Distcp**.



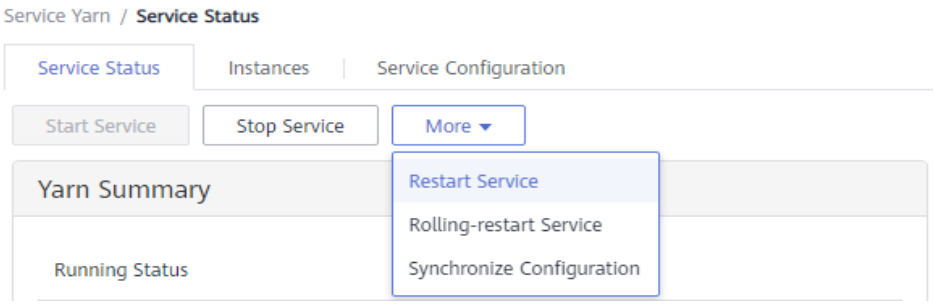
Step 3 Set **haclusterX.remotenn1** of **dfs.namenode.rpc-address** to the service IP address and RPC port number of one NameNode instance of the peer cluster, and set **haclusterX.remotenn2** to the service IP address and RPC port number of the other NameNode instance of the peer cluster. Enter a value in the *IP address:port* format.



dfs.namenode.rpc-address.haclusterX.remotenn1 and **dfs.namenode.rpc-address.haclusterX.remotenn2** do not distinguish active and standby NameNode instances. To obtain the service IP address of the NameNode instance, log in to FusionInsight Manager and choose **Cluster** > **Services** > **HDFS** > **Instances**. The NameNode RPC port can be obtained by searching for **dfs.namenode.rpc.port** on the HDFS service **configurations** page. It cannot be changed on Manager. The port cannot be changed on FusionInsight Manager.

For example, **10.1.1.1:9820** and **10.1.1.2:9820**.

Step 4 Save the configuration. On the **Dashboard** tab page, and choose **More** > **Restart Service** to restart the Yarn service.



Operation succeeded is displayed. Click **Finish**. The Yarn service is started successfully.

Step 5 Log in to the other cluster and repeat the preceding operations.

----End

9.8.4 Configuring Automatic Data Backup for Active and Standby HBase Clusters

Prerequisites

- Active and standby clusters have been installed and started.
- Time is consistent between the active and standby clusters and the NTP service on the active and standby clusters uses the same time source.
- When the HBase service of the active cluster is stopped, the ZooKeeper and HDFS services must be started and run.
- ReplicationSyncUp must be run by the system user who starts the HBase process.
- In security mode, ensure that the HBase system user of the standby cluster has the read permission on HDFS of the active cluster. This is because that it will update the ZooKeeper nodes and HDFS files of the HBase system.
- When HBase of the active cluster is faulty, the ZooKeeper, file system, and network of the active cluster are still available.

Scenarios

The replication mechanism can use WAL to synchronize the state of a cluster with the state of another cluster. After HBase replication is enabled, if the active cluster is faulty, ReplicationSyncUp synchronizes incremental data from the active cluster

to the standby cluster using the information from the ZooKeeper node. After data synchronization is complete, the standby cluster can be used as an active cluster.

Parameter Configuration

Parameter	Description	Default Value
hbase.replication.bulkload.enabled	Whether to enable the bulkload data replication function. The parameter value type is Boolean. To enable the bulkload data replication function, set this parameter to **true** for the active cluster.	**false**
hbase.replication.cluster.id	ID of the source HBase cluster. After the bulkload data replication is enabled, this parameter is mandatory and must be defined in the source cluster. The parameter value type is String.	-

Using the ReplicationSyncUp Tool

Run the following command on the hbase shell of the active cluster:

hbase org.apache.hadoop.hbase.replication.regionserver.ReplicationSyncUp -Dreplication.sleep.before.failover=1

NOTE

replication.sleep.before.failover indicates sleep time required for replication of the remaining data when RegionServer fails to start. You are advised to set this parameter to 1 second to quickly trigger replication.

Precautions

- When the active cluster is stopped, this tool obtains the WAL processing progress and WAL processing queue from the ZooKeeper Node (RS znode) and copies the queues that are not copied to the standby cluster.
- RegionServer of each active cluster has its own znode under the replication node of ZooKeeper in the standby cluster. It contains one znode of each peer cluster.
- If RegionServer is faulty, each RegionServer in the active cluster receives a notification through the watcher and attempts to lock the znode of the faulty RegionServer, including its queues. The successfully created RegionServer transfers all queues to the znode of its own queue. After queues are transferred, they are deleted from the old location.
- When the active cluster is stopped, ReplicationSyncUp synchronizes data between active and standby clusters using the information from the ZooKeeper node. In addition, WALs of the RegionServer znode will be moved to the standby cluster.

Restrictions and Limitations

If the standby cluster is stopped or the peer relationship is closed, the tool runs normally but the peer relationship cannot be replicated.

9.8.5 Configuring HBase Cluster HA and DR

9.8.5.1 Configuring HBase Active/Standby DR

Scenario

HBase disaster recovery (DR), a key feature that is used to ensure high availability (HA) of the HBase cluster system, provides the real-time remote DR function for HBase. HBase DR provides basic O&M tools, including tools for maintaining and re-establishing DR relationships, verifying data, and querying data synchronization progress. To implement real-time DR, back up data of an HBase cluster to another HBase cluster. DR in the HBase table common data writing and BulkLoad batch data writing scenarios is supported.

Prerequisites

- The active and standby clusters are successfully installed and started, and you have the administrator permissions on the clusters.
- Ensure that the network connection between the active and standby clusters is normal and ports are available.
- If the active cluster is deployed in security mode and is not managed by one FusionInsight Manager, cross-cluster trust relationship has been configured for the active and standby clusters.. If the active cluster is deployed in normal mode, no cross-cluster mutual trust is required.
- Cross-cluster replication has been configured for the active and standby clusters.
- Time is consistent between the active and standby clusters and the NTP service on the active and standby clusters uses the same time source.
- The mapping between host names and service IP addresses of all nodes in the active and standby clusters have been configured in the **hosts** file of these nodes.

  NOTE

  If the client of the active cluster is installed on a node outside the cluster, the mapping between host names and service IP addresses of all nodes in the active and standby clusters must have been configured in the **hosts** file of these nodes.
- The network bandwidth between the active and standby clusters is determined based on service volume, which cannot be less than the possible maximum service volume.
- The MRS versions of the active and standby clusters must be the same.
- The scale of the standby cluster must be greater than or equal to that of the active cluster.

Constraints

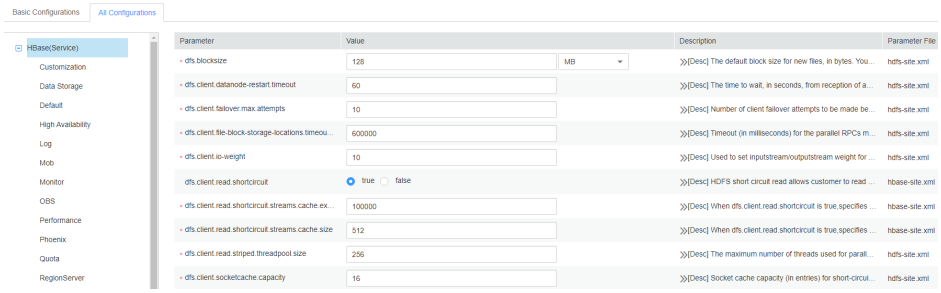
- Although DR provides the real-time data replication function, the data synchronization progress is affected by many factors, such as the service volume in the active cluster and the health status of the standby cluster. In normal cases, the standby cluster should not take over services. In extreme cases, system maintenance personnel and other decision makers determine whether the standby cluster takes over services according to the current data synchronization indicators.
- HBase clusters must be deployed in active/standby mode.
- Table-level operations on the DR table of the standby cluster are forbidden, such as modifying the table attributes and deleting the table. Misoperations on the standby cluster will cause data synchronization failure of the active cluster. As a result, table data in the standby cluster is lost.
- If the DR data synchronization function is enabled for HBase tables of the active cluster, the DR table structure of the standby cluster needs to be modified to ensure table structure consistency between the active and standby clusters during table structure modification.

Procedure

Configuring the common data writing DR parameters for the active cluster

Step 1 Log in to Manager of the active cluster.

Step 2 Choose **Cluster** > **Services** > **HBase** > **Configurations** and click **All Configurations**. The HBase configuration page is displayed.



Step 3 (Optional) **Table 9-33** describes the optional configuration items during HBase DR. You can set the parameters based on the description or use the default values.

Table 9-33 Optional configuration items

Navigation Path	Parameter	Default Value	Description
HMaster > Performance	hbase.master.logcleaner.ttl	600000	Specifies the retention period of HLog. If the value is set to **604800000** (unit: millisecond), the retention period of HLog is 7 days.

Navigation Path	Parameter	Default Value	Description
	hbase.master.cleaner.interval	60000	Interval for the HMaster to delete historical HLog files. The HLog that exceeds the configured period will be automatically deleted. You are advised to set it to the maximum value to save more HLogs.
RegionServer > Replication	replication.source.size.capacity	16777216	Maximum size of edits, in bytes. If the edit size exceeds the value, HLog edits will be sent to the standby cluster.
	replication.source.nb.capacity	25000	Maximum number of edits, which is another condition for triggering HLog edits to be sent to the standby cluster. After data in the active cluster is synchronized to the standby cluster, the active cluster reads and sends data in HLog according to this parameter value. This parameter is used together with **replication.source.size.capacity**.
	replication.source.maxretriesmultiplier	10	Maximum number of retries when an exception occurs during replication.
	replication.source.sleepforretries	1000	Retry interval (Unit: ms)
	hbase.regionserver.replication.handler.count	6	Number of replication RPC server instances on RegionServer

Configuring the BulkLoad batch data writing DR parameters for the active cluster

Step 4 Determine whether to enable the BulkLoad batch data writing DR function.

If yes, go to **Step 5**.

If no, go to **Step 8**.

Step 5 Choose **Cluster** > **Services** > **HBase** > **Configurations** and click **All Configurations**. The HBase configuration page is displayed.

Step 6 Search for **hbase.replication.bulkload.enabled** and change its value to **true** to enable the BulkLoad batch data writing DR function.

Step 7 Search for **hbase.replication.cluster.id** and change the HBase ID of the active cluster. The ID is used by the standby cluster to connect to the active cluster. The value can contain uppercase letters, lowercase letters, digits, and underscores (_), and cannot exceed 30 characters.

Restarting the HBase service and install the client

Step 8 Click **Save**. Click **Dashboard**, choose **More** > **Restart Service**, enter the password of the current user, and click OK to restart the HBase service.

Step 9 In the active and standby clusters, choose **Cluster** > **Service** > **HBase** > **More** > **Download Client** to download the client and install it. For details, see **Installing a Client**.

Adding the DR relationship between the active and standby clusters

Step 10 Log in to the node where the client of the active cluster is installed as the client installation user and log in to the HBase shell page as the **hbase** user.

cd *Client installation directory*

source bigdata_env

kinit hbase (Skip this operation for clusters where Kerberos authentication is not enabled.)

hbase shell

Step 11 Run the following command on **hbase shell** to create the DR synchronization relationship between the active cluster HBase and the standby cluster HBase.

add_peer '*Standby cluster ID***', CLUSTER_KEY => "***ZooKeeper service IP address in the standby cluster***", CONFIG => {"hbase.regionserver.kerberos.principal" => "***Standby cluster RegionServer principal***", "hbase.master.kerberos.principal" => "***Standby cluster HMaster principal***"}**

- The standby cluster ID indicates the ID for the active cluster to recognize the standby cluster. Enter an ID. The value can be specified randomly. Digits are recommended.
- The ZooKeeper address of the standby cluster includes the service IP address of ZooKeeper, the port for listening to client connections, and the HBase root directory of the standby cluster on ZooKeeper.
  - To view the service IP address of the ZooKeeper instance in the standby cluster, choose **Cluster** > **Services** > **ZooKeeper** > **Instances** on FusionInsight Manager.
  - Port for the ZooKeeper client of the standby cluster to connect to the server and root directory of the HBase of the standby cluster on ZooKeeper. You can log in to FusionInsight Manager and choose **Cluster** > **Services** > **ZooKeeper** > **Configurations**. Search for the **clientPort** and **zookeeper.znode.parent** parameters.
- Search for **hbase.master.kerberos.principal** and **hbase.regionserver.kerberos.principal** in the *Client installation directory*/**HBase/hbase/conf/hbase-site.xml** configuration file of the standby cluster.

For example, to add the DR relationship between the active and standby clusters, run the **add_peer '***Standby cluster ID***', CLUSTER_KEY =>**

"*192.168.40.2,192.168.40.3,192.168.40.4:24002:/hbase***", CONFIG => {"hbase.regionserver.kerberos.principal" => "***hbase/hadoop.hadoop.com@HADOOP.COM***", "hbase.master.kerberos.principal" => "***hbase/hadoop.hadoop.com@HADOOP.COM***"}**

Step 12 (Optional) If the BulkLoad batch data write DR function is enabled, the HBase client configuration of the active cluster must be copied to the standby cluster.

1. Create the **/hbase/replicationConf/***hbase.replication.cluster.id* ***of the active cluster*** directory in the HDFS of the standby cluster.
2. HBase client configuration file, which is copied to the **/hbase/replicationConf/***hbase.replication.cluster.id* ***of the active cluster*** directory of the HDFS of the standby cluster. For Example:

   hdfs dfs -put HBase/hbase/conf/core-site.xml HBase/hbase/conf/hdfs-site.xml HBase/hbase/conf/yarn-site.xml hdfs://*NameNode IP.25000***/hbase/replicationConf/*** ***source_cluster***

Enabling HBase DR to synchronize data

Step 13 Check whether a naming space exists in the HBase service instance of the standby cluster and the naming space has the same name as the naming space of the HBase table for which the DR function is to be enabled.

- If the same namespace exists, go to **Step 14**.
- If no, create a naming space with the same name in the HBase shell of the standby cluster and go to **Step 14**.

Step 14 In the HBase shell of the active cluster, run the following command as user **hbase** to enable the real-time DR function for the table data of the active cluster to ensure that the data modified in the active cluster can be synchronized to the standby cluster in real time.

You can only synchronize the data of one HTable at a time.

enable_table_replication '*table name***'**

NOTE

- If the standby cluster does not contain a table with the same name as the table for which real-time synchronization is to be enabled, the table is automatically created.
- If a table with the same name as the table for which real-time synchronization is to be enabled exists in the standby cluster, the structures of the two tables must be the same.
- If the encryption algorithm SMS4 or AES is configured for '*Table name*', the function for synchronizing data from the active cluster to the standby cluster cannot be enabled for the HBase table.
- If the standby cluster is offline or has tables with the same name but different structures, the DR function cannot be enabled.
- If the DR data synchronization function is enabled for some Phoenix tables in the active cluster, the standby cluster cannot have common HBase tables with the same names as the Phoenix tables in the active cluster. Otherwise, the DR function fails to be enabled or the tables with the names in the standby cluster cannot be used properly.
- If the DR data synchronization function is enabled for Phoenix tables in the active cluster, you need to enable the DR data synchronization function for the metadata tables of the Phoenix tables. The metadata tables include SYSTEM.CATALOG, SYSTEM.FUNCTION, SYSTEM.SEQUENCE, and SYSTEM.STATS.
- If the DR data synchronization function is enabled for HBase tables of the active cluster, after adding new indexes to HBase tables, you need to manually add secondary indexes to DR tables in the standby cluster to ensure secondary index consistency between the active and standby clusters.

Step 15 (Optional) If HBase does not use Ranger, run the following command as user **hbase** in the HBase shell of the active cluster to enable the real-time permission to control data DR function for the HBase tables in the active cluster.

enable_table_replication 'hbase:acl'

Creating Users

Step 16 Log in to FusionInsight Manager of the standby cluster, choose **System** > **Permission** > **Role** > **Create Role** to create a role, and add the same permission for the standby data table to the role based on the permission of the HBase source data table of the active cluster.

Step 17 Choose **System** > **Permission** > **User** > **Create** to create a user. Set the **User Type** to **Human-Machine** or **Machine-Machine** based on service requirements and add the user to the created role. Access the HBase DR data of the standby cluster as the newly created user.

NOTE

- After the permission of the active HBase source data table is modified, to ensure that the standby cluster can properly read data, modify the role permission for the standby cluster.
- If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see **Adding a Ranger Access Permission Policy for HBase**.

Synchronizing the table data of the active cluster

Step 18 After HBase DR is configured and data synchronization is enabled, check whether tables and data exist in the active cluster and whether the historical data needs to be synchronized to the standby cluster.

- If yes, a table exists and data needs to be synchronized. Log in as the HBase table user to the node where the HBase client of the active cluster is installed

and run the kinit username to authenticate the identity. The user must have the read and write permissions on tables and the execute permission on the **hbase:meta** table. Then go to **Step 19**.

- If no, no further action is required.

Step 19 The HBase DR configuration does not support automatic synchronization of historical data in tables. You need to back up the historical data of the active cluster and then manually restore the historical data in the standby cluster.

Manual recovery refers to the recovery of a single table, which can be performed through Export, DistCp, or Import.

To manually recover a single table, perform the following steps:

1. Export table data from the active cluster.

   hbase org.apache.hadoop.hbase.mapreduce.Export -Dhbase.mapreduce.include.deleted.rows=true *Table name Directory where the source data is stored*

   Example: **hbase org.apache.hadoop.hbase.mapreduce.Export -Dhbase.mapreduce.include.deleted.rows=true t1 /user/hbase/t1**

2. Copy the data that has been exported to the standby cluster.

   hadoop distcp *directory where the source data is stored on the active cluster* **hdfs://***ActiveNameNodeIP:8020/directory where the source data is stored on the standby cluster*

   ActiveNameNodeIP indicates the IP address of the active NameNode in the standby cluster.

   Example: **hadoop distcp /user/hbase/t1 hdfs://192.168.40.2:8020/user/hbase/t1**

3. Import data to the standby cluster as the HBase table user of the standby cluster.

   On the HBase shell screen of the standby cluster, run the following command as user **hbase** to retain the data writing status:

   set_clusterState_active

   The command is run successfully if the following information is displayed:

   ```
   hbase(main):001:0> set_clusterState_active
   => true
   ```

   hbase org.apache.hadoop.hbase.mapreduce.Import *-Dimport.bulk.output=Directory where the output data is stored in the standby cluster Table name Directory where the source data is stored in the standby cluster*

   hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles *Directory where the output data is stored in the standby cluster Table name*

   Example:

   ```
   hbase(main):001:0> set_clusterState_active
   => true
   ```

   hbase org.apache.hadoop.hbase.mapreduce.Import -Dimport.bulk.output=/user/hbase/output_t1 t1 /user/hbase/t1

   hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles /user/hbase/output_t1 t1

Step 20 Run the following command on the HBase client to check the synchronized data of the active and standby clusters. After the DR data synchronization function is enabled, you can run this command to check whether the newly synchronized data is consistent.

hbase org.apache.hadoop.hbase.mapreduce.replication.VerifyReplication --starttime=*Start time* **--endtime**=*End time Column family name ID of the standby cluster Table name*

NOTE

- The start time must be earlier than the end time.
- The values of **starttime** and **endtime** must be in the timestamp format. You need to run **date -d "2015-09-30 00:00:00" +%s to** change a common time format to a timestamp format.

Specify the data writing status for the active and standby clusters.

Step 21 On the **hbase shell** screen of the active cluster, run the following command as user **hbase** to retain the data writing status:

set_clusterState_active

The command is run successfully if the following information is displayed:

```
hbase(main):001:0> set_clusterState_active
=> true
```

Step 22 On the **hbase shell** screen of the standby cluster, run the following command as user **hbase** to retain the data read-only status:

set_clusterState_standby

The command is run successfully if the following information is displayed:

```
hbase(main):001:0> set_clusterState_standby
=> true
```

----End

Related Commands

Table 9-34 HBase DR

Operation	Command	Description
Set up a DR relationship.	add_peer'*Standby cluster ID*', CLUSTER_KEY => "*Standby cluster ZooKeeper service IP address*", CONFIG => {"hbase.regionserver.kerberos.principal" => "*Standby cluster RegionServer principal*", "hbase.master.kerberos.principal" => "*Standby cluster HMaster principal*"} **add_peer '1','zk1,zk2,zk3:2181:/hbase1'** **2181**: port number of ZooKeeper in the cluster	Set up the relationship between the active cluster and the standby cluster. If BulkLoad batch data write DR is enabled: 1. Create the **/hbase/replicationConf/***hbase.replication.cluster.id* ***of the active cluster*** directory in the HDFS of the standby cluster. 2. HBase client configuration file, which is copied to the **/hbase/replicationConf/***hbase.replication.cluster.id* ***of the active cluster*** directory of the HDFS of the standby cluster.
Remove the DR relationship.	**remove_peer** *'Standby cluster ID'* Example: **remove_peer '1'**	Remove standby cluster information from the active cluster.
Querying the DR Relationship	**list_peers**	Query standby cluster information (mainly Zookeeper information) in the active cluster.
Enable the real-time user table synchronization function.	**enable_table_replication** *'Table name'* Example: **enable_table_replication 't1'**	Synchronize user tables from the active cluster to the standby cluster.
Disable the real-time user table synchronization function.	**disable_table_replication** *'Table name'* Example: **disable_table_replication 't1'**	Do not synchronize user tables from the active cluster to the standby cluster.

Operation	Command	Description
Verify data of the active and standby clusters.	**bin/hbase org.apache.hadoop.hbase.mapreduce.replication.VerifyReplication --starttime=***Start time* **--endtime=***End time Column family name Standby cluster ID Table name*	Verify whether data of the specified table is the same between the active cluster and the standby cluster. The description of the parameters in this command is as follows: ● Start time: If start time is not specified, the default value **0** will be used. ● End time: If end time is not specified, the time when the current operation is submitted will be used by default. ● Table name: If a table name is not entered, all user tables for which the real-time synchronization function is enabled will be verified by default.
Switch the data writing status.	**set_clusterState_active** **set_clusterState_standby**	Specifies whether data can be written to the cluster HBase tables.

Operation	Command	Description
Add or update the active cluster HDFS configurations saved in the peer cluster.	**hdfs dfs -put -f HBase/hbase/conf/core-site.xml HBase/hbase/conf/hdfs-site.xml HBase/hbase/conf/yarn-site.xml hdfs://***Standby cluster* ***NameNode IP:PORT*****/hbase/replicationConf/***Active cluster* ***hbase.replication.cluster.id***	Enable DR for data including bulkload data. When HDFS parameters are modified in the active cluster, the modification cannot be automatically synchronized from the active cluster to the standby cluster. You need to manually run the command to synchronize configuration. The affected parameters are as follows: • fs.defaultFS • dfs.client.failover.proxy.provider.hacluster • dfs.client.failover.connection.retries.on.timeouts • dfs.client.failover.connection.retries For example, change **fs.defaultFS** to **hdfs://hacluster_sale**, HBase client configuration file, which is copied to the **/hbase/replicationConf/*hbase.replication.cluster.id of the active cluster*** directory of the HDFS of the standby cluster.
Disable replication for bulk loaded data of a single table, when **hbase.replication.bulkload.enabled** is set to **true**.	**disable_bulkload_replication** *'peerId', 'Table name'* Example: **disable_bulkload_replication '1','t1'**	If replication for bulk loaded data is enabled for the active cluster and real-time synchronization is enabled for a table, you can run this command to pause replication for bulk loaded data of the table. Run the **list_peers** command to view *peerId* in the standby cluster information. This parameter is available only in MRS 3.3.0 or later.

Operation	Command	Description
Enable replication for bulk loaded data of a single table, when **hbase.replication.bulkload.enabled** is set to **true**.	**enable_bulkload_replication 'peerId', 'Table name'** Example: **enable_bulkload_replication '1','t1'**	Replication for bulk loaded data is enabled for the active cluster, and real-time synchronization is enabled for a table. You can run this command to resume replication for bulk loaded data of the table after the function is paused. Run the **get_peer_config** *'peerId'* command to check the DR configuration of the standby cluster. If the value of a table name field that starts with **BULREP_** is **false**, replication for bulk loaded data is disabled for the table. **NOTE** • This parameter is available only in MRS 3.3.0 or later. • Data generated when replication for bulk loaded data is paused will not be synchronized after the function is resumed. • It takes several minutes for this operation to take effect on the server. To prevent bulk loaded data loss caused by synchronization latency, ensure that "Update peer configs succeed." is printed in run logs on each RegionServer after this command is executed. Then, perform subsequent operations on the active cluster.

9.8.5.2 Switching Between Active and Standby HBase Clusters

Scenario

The HBase cluster in the current environment is a DR cluster. Due to some reasons, the active and standby clusters need to be switched over. That is, the standby cluster becomes the active cluster, and the active cluster becomes the standby cluster.

Impact on the System

After the active and standby clusters are switched over, data cannot be written to the original active cluster, and the original standby cluster becomes the active cluster to take over upper-layer services.

Procedure

Ensuring that upper-layer services are stopped

Step 1 Ensure that the upper-layer services have been stopped. If not, perform operations by referring to **Configuring HBase Standby Cluster Information for Switchover**.

Disabling the write function of the active cluster

Step 2 Download and install the HBase client.

For details, see **Installing a Client**.

Step 3 On the HBase client of the standby cluster, run the following command as user **hbase** to disable the data write function of the standby cluster:

cd *Client installation directory*

source bigdata_env

kinit hbase

hbase shell

set_clusterState_standby

The command is run successfully if the following information is displayed:

```
hbase(main):001:0> set_clusterState_standby
=> true
```

Checking whether the active/standby synchronization is complete

Step 4 Run the following command to ensure that the current data has been synchronized (SizeOfLogQueue=0 and SizeOfLogToReplicate=0 are required). If the values are not 0, wait and run the following command repeatedly until the values are 0.

status 'replication'

Disabling synchronization between the active and standby clusters

Step 5 Query all synchronization clusters and obtain the value of **PEER_ID**.

list_peers

Step 6 Delete all synchronization clusters.

remove_peer *'Standby cluster ID'*

Example:

remove_peer *'1'*

Step 7 Query all synchronized tables.

list_replicated_tables

Step 8 Disable all synchronized tables queried in the **Step 7** step.

disable_table_replication *'Table name'*

Example:

disable_table_replication *'t1'*

Performing an active/standby switchover

Step 9 Reconfigure HBase DR. For details, see **Configuring HBase Active/Standby DR**.

----End

9.8.5.3 Configuring HBase Standby Cluster Information for Switchover

Scenario

MRS cluster administrators can configure HBase cluster DR to improve system availability. If the active cluster in the DR environment is faulty and the connection to the HBase upper-layer application is affected, you need to configure the standby cluster information for the HBase upper-layer application so that the application can run in the standby cluster.

Impact on the System

After a service switchover, data written to the standby cluster is not synchronized to the active cluster by default. Add the active cluster is recovered, the data newly generated in the standby cluster needs to be synchronized to the active cluster by backup and recovery. If automatic data synchronization is required, you need to switch over the active and standby HBase DR clusters.

Procedure

Step 1 Log in to FusionInsight Manager of the standby cluster.

Step 2 Download and install the HBase client.

Step 3 On the HBase client of the standby cluster, run the following command as user **hbase** to enable the data writing status in the standby cluster.

cd *Client installation directory*

source bigdata_env

kinit hbase

hbase shell

set_clusterState_active

The command is run successfully if the following information is displayed:

```
hbase(main):001:0> set_clusterState_active
=> true
```

Step 4 Check whether the original configuration files **hbase-site.xml**, **core-site.xml**, and **hdfs-site.xml** of the HBase upper-layer application are modified to adapt to the application running.

- If yes, update the related content to the new configuration file and replace the old configuration file.
- If no, use the new configuration file to replace the original configuration file of the HBase upper-layer application.

Step 5 Configure the network connection between the host where the HBase upper-layer application is located and the standby cluster.

NOTE

If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.

1. Ensure that the host where the client is installed can communicate with the hosts listed in the **hosts** file in the directory where the client installation package is decompressed.
2. If the host where the client is located is not a node in the cluster, you need to set the mapping between the host name and the IP address (service plan) in the /etc/hosts file on the host. The host names and IP addresses must be mapped one by one.

Step 6 Set the time of the host where the HBase upper-layer application is located to be the same as that of the standby cluster. The time difference must be less than 5 minutes.

Step 7 Check the authentication mode of the active cluster.

- If the security mode is used, go to **Step 8**.
- If the normal mode is used, no further action is required.

Step 8 Obtain the **keytab** and **krb5.conf** configuration files of the HBase upper-layer application user.

1. On FusionInsight Manager of the standby cluster, choose **System** > **Permission** > **User**.
2. Locate the row that contains the target user, click **More** > **Download Authentication Credential** in the **Operation** column, and download the **keytab** file to the local PC.
3. Decompress the package to obtain **user.keytab** and **krb5.conf**.

Step 9 Use the **user.keytab** and **krb5.conf** files to replace the original files in the HBase upper-layer application.

Step 10 Stop upper-layer applications.

Step 11 Determine whether to switch over the active and standby HBase clusters. If the switchover is not performed, data will not be synchronized.

- If yes, switch over the active and standby HBase DR clusters. For details, see **Switching Between Active and Standby HBase Clusters**. Then, go to **Step 12**.
- If no, go to **Step 12**.

Step 12 Start the upper-layer services.

----End

9.9 Common Issues About HBase

9.9.1 Operation Failures Occur in Stopping BulkLoad On the Client

Question

Why submitted operations fail by stopping BulkLoad on the client during BulkLoad data importing?

Answer

When BulkLoad is enabled on the client, a partitioner file is generated and used to demarcate the range of Map task data inputting.

The file is automatically deleted when BulkLoad exists on the client.

In general, if all map tasks are enabled and running, the termination of BulkLoad on the client does not cause the failure of submitted operations.However, due to the retry and speculative execution mechanism of Map tasks, a Map task is performed again if failures of the Reduce task to download the data of the completed Map task exceed the limit. In this case, if BulkLoad already exists on the client, the retry Map task fails and the operation failure occurs because the partitioner file is missing.

Therefore, it is recommended not to stop BulkLoad on the client during BulkLoad data importing.

9.9.2 How Do I Restore a Region in the RIT State for a Long Time?

Question

How do I restore a region in the RIT state for a long time?

Answer

Log in to the HMaster Web UI, choose **Procedure & Locks** in the navigation tree, and check whether any process ID is in the **Waiting** state. If yes, run the following command to release the procedure lock:

hbase hbck -j *Client installation directory*/**HBase/hbase/tools/hbase-hbck2-*.jar bypass -o** *pid*

Check whether the state is in the **Bypass** state. If the procedure on the UI is always in **RUNNABLE(Bypass)** state, perform an active/standby switchover. Run the **assigns** command to bring the region online again.

hbase hbck -j *Client installation directory*/**HBase/hbase/tools/hbase-hbck2-*.jar assigns -o** *regionName*

9.9.3 Why Does HMaster Exits Due to Timeout When Waiting for the NameSpace Table to Go Online?

Question

Why does HMaster exit due to timeout when waiting for the namespace table to go online?

Answer

During the HMaster active/standby switchover or startup, HMaster performs WAL splitting and region recovery for the RegionServer that failed or was stopped previously.

Multiple threads are running in the background to monitor the HMaster startup process.

- TableNamespaceManager

  This is a help class, which is used to manage the allocation of namespace tables and monitoring table regions during HMaster active/standby switchover or startup. If the namespace table is not online within the specified time (**hbase.master.namespace.init.timeout**, which is 3,600,000 ms by default), the thread terminates HMaster abnormally.

- InitializationMonitor

  This is an initialization thread monitoring class of the primary HMaster, which is used to monitor the initialization of the primary HMaster. If a thread fails to be initialized within the specified time (**hbase.master.initializationmonitor.timeout**, which is 3,600,000 ms by default), the thread terminates HMaster abnormally. If **hbase.master.initializationmonitor.haltontimeout** is started, the default value is **false**.

During the HMaster active/standby switchover or startup, if the **WAL hlog** file exists, the WAL splitting task is initialized. If the WAL hlog splitting task is complete, it initializes the table region allocation task.

HMaster uses ZooKeeper to coordinate log splitting tasks and valid RegionServers and track task development. If the primary HMaster exits during the log splitting task, the new primary HMaster attempts to resend the unfinished task, and RegionServer starts the log splitting task from the beginning.

The initialization of the HMaster is delayed due to the following reasons:

- Network faults occur intermittently.
- Disks run into bottlenecks.
- The log splitting task is overloaded, and RegionServer runs slowly.
- RegionServer (region opening) responds slowly.

In the preceding scenarios, you are advised to add the following configuration parameters to enable HMaster to complete the restoration task earlier. Otherwise, the Master will exit, causing a longer delay of the entire restoration process.

- Increase the online waiting timeout period of the namespace table to ensure that the Master has enough time to coordinate the splitting tasks of the RegionServer worker and avoid repeated tasks.

  hbase.master.namespace.init.timeout (default value: 3,600,000 ms)

- Increase the number of concurrent splitting tasks through RegionServer worker to ensure that RegionServer worker can process splitting tasks in parallel (RegionServers need more cores). Add the following parameters to *Client installation path* **/HBase/hbase/conf/hbase-site.xml**:

  hbase.regionserver.wal.max.splitters (default value: 2)

- If all restoration processes require time, increase the timeout period for initializing the monitoring thread.

  hbase.master.initializationmonitor.timeout (default value: 3,600,000 ms)

9.9.4 Why Does SocketTimeoutException Occur When a Client Queries HBase?

Question

Why does the following exception occur on the client when I use the HBase client to operate table data?

```
2015-12-15 02:41:14,054 | WARN  | [task-result-getter-2] | Lost task 2.0 in stage 58.0 (TID 3288, linux-175):

Answer

The memory allocated to RegionServer is too small and the number of Regions is too large. As a result, the memory is insufficient during the running, and the server responds slowly to the client. Modify the following memory allocation parameters in the **hbase-site.xml** configuration file of RegionServer:

Table 9-35 RegionServer memory allocation parameters

Parameter	Description	Default Value
GC_OPTS	Initial memory and maximum memory allocated to RegionServer in startup parameters.	-Xms8G -Xmx8G
hfile.block.cache.size	Percentage of the maximum heap (-Xmx setting) allocated to the block cache of HFiles or StoreFiles.	When **offheap** is disabled, the default value is **0.25**. When **offheap** is enabled, the default value is **0.1**.

9.9.5 Why "java.lang.UnsatisfiedLinkError: Permission denied" exception thrown while starting HBase shell?

Question

Why "java.lang.UnsatisfiedLinkError: Permission denied" exception thrown while starting HBase shell?

Answer

During HBase shell execution JRuby create temporary files under **java.io.tmpdir** path and default value of **java.io.tmpdir** is **/tmp**. If NOEXEC permission is set to /tmp directory then HBase shell start will fail with "java.lang.UnsatisfiedLinkError: Permission denied" exception.

So "java.io.tmpdir" must be set to a different path in HBASE_OPTS/ CLIENT_GC_OPTS if NOEXEC is set to /tmp directory.

9.9.6 When does the RegionServers listed under "Dead Region Servers" on HMaster WebUI gets cleared?

Question

When does the RegionServers listed under "Dead Region Servers" on HMaster WebUI gets cleared?

Answer

When an online RegionServer goes down abruptly, it is displayed under "Dead Region Servers" in the HMaster WebUI. When dead RegionServer restarts and reports back to HMaster successfully, the "Dead Region Servers" in the HMaster WebUI gets cleared.

The "Dead Region Servers" is also gets cleared, when the HMaster failover operation is performed successfully.

In cases when an Active HMaster hosting some regions is abruptly killed, Backup HMaster will become the new Active HMater and displays previous Active HMaster as dead RegionServer.

9.9.7 Insufficient Rights When Accessing Phoenix

Question

When a tenant accesses Phoenix, a message is displayed indicating that the tenant has insufficient rights.

Answer

You need to associate the HBase service and Yarn queues when creating a tenant.

The tenant must be granted additional rights to perform operations on Phoenix, that is, the RWX permission on the Phoenix system table.

Example:

Tenant **hbase**has been created. Log in to the HBase Shell as user**admin**and run the**scan 'hbase:acl'**command to query the role of the tenant. The role is**hbase_1450761169920** (in the format of tenant name_timestamp).

Run the following commands to grant rights to the tenant (if the Phoenix system table has not been generated, log in to the Phoenix client as user **admin** first and then grant rights on the HBase Shell):

grant '@hbase_1450761169920','RWX','SYSTEM.CATALOG'

grant '@hbase_1450761169920','RWX','SYSTEM.FUNCTION'

grant '@hbase_1450761169920','RWX','SYSTEM.SEQUENCE'

grant '@hbase_1450761169920','RWX','SYSTEM.STATS'

Create user **phoenix**and bind it with tenant**hbase**, so that tenant**hbase**can access the Phoenix client as user**phoenix**.

9.9.8 Insufficient Rights When Useing the HBase Bulkload Function

Question

When a tenant uses the HBase bulkload function, a message is displayed indicating that the tenant has insufficient rights.

Answer

You need to associate the HBase service and Yarn queues when creating a tenant.

Example:

Create user **user** and bind it with the tenant role with the same name.

User **user** must be granted additional rights to use the bulkload function.

The following **uses** user user as an example.

For details, see *Importing Data in Batches*. The following describes the differences:

1. Create the data file directory in **/tmp** and run the following commands:

   hdfs dfs -mkdir /tmp/datadirImport

   hdfs dfs -put data.txt /tmp/datadirImport

2. Use the **/tmp** directory of HDFS to generate HFile:

   hbase com.huawei.hadoop.hbase.tools.bulkload.ImportData -Dimport.skip.bad.lines=true -Dimport.separator=',' -Dimport.bad.lines.output=/tmp/badline -Dimport.hfile.output=/tmp/hfile configuration.xml ImportTable /tmp/datadirImport

3. Use the **/tmp** directory of HDFS to import HFile:

   hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles /tmp/hfile ImportTable

9.9.9 How Do I Fix Region Overlapping?

Question

When the hbck tool is used to check the region status, if the log contains **ERROR: (regions region1 and region2) There is an overlap in the region chain** or **ERROR: (region region1) Multiple regions have the same startkey: xxx**, overlapping exists in some regions. How do I solve this problem?

Answer

To rectify the fault, perform the following steps:

Step 1 Run the **hbase hbck -j** ${CLIENT_HOME}**/HBase/hbase/tools/hbase-hbck2-1.1.0-h0.cbu.mrs.*.jar fixInconsistencies** *tableName* command to restore the table that contains overlapping.

Step 2 Run the **hbase hbck -j** ${CLIENT_HOME}**/HBase/hbase/tools/hbase-hbck2-1.1.0-h0.cbu.mrs.*.jar listInconsistencies -run** *tableName* command to check whether overlapping exists in the restored table.

- If overlapping does not exist, go to **Step 3**.
- If overlapping exists, go to **Step 1**.

Step 3 Log in to FusionInsight Manager and choose **Cluster** > *Name of the desired cluster* > **Services** > **HBase** > **More** > **Perform HMaster Switchover** to complete the HMaster active/standby switchover.

Step 4 Run the **hbase hbck -j** ${CLIENT_HOME}**/HBase/hbase/tools/hbase-hbck2-1.1.0-h0.cbu.mrs.*.jar listInconsistencies -run** *tableName* command to check whether overlapping exists in the restored table.

- If overlapping does not exist, no further action is required.
- If overlapping still exists, start from **Step 1** to perform the recovery again.

----End

9.9.10 Restrictions on using the Phoenix BulkLoad Tool

Question

When the indexed field data is updated, if a batch of data exists in the user table, the BulkLoad tool cannot update the global and partial mutable indexes.

Answer

Problem Analysis

1. Create a table.

```
CREATE TABLE TEST_TABLE(
DATE varchar not null,
NUM integer not null,
SEQ_NUM integer not null,
ACCOUNT1 varchar not null,
ACCOUNTDES varchar,
FLAG varchar,
SALL double,
CONSTRAINT PK PRIMARY KEY (DATE,NUM,SEQ_NUM,ACCOUNT1)
);
```

2. Create a global index.

   CREATE INDEX TEST_TABLE_INDEX ON TEST_TABLE(ACCOUNT1,DATE,NUM,ACCOUNTDES,SEQ_NUM);

3. Insert data.

   UPSERT INTO TEST_TABLE (DATE,NUM,SEQ_NUM,ACCOUNT1,ACCOUNTDES,FLAG,SALL) values ('20201001',30201001,13,'367392332','sffa1','','');

4. Execute the BulkLoad task to update data.

   hbase org.apache.phoenix.mapreduce.CsvBulkLoadTool -t TEST_TABLE -i /tmp/test.csv, where the content of **test.csv** is as follows:

20201001	30201001	13	367392332	sffa888	1231243	23

5. Symptom: The existing index data cannot be directly updated. As a result, two pieces of index data exist.

```
+------------+-----------+-----------+---------------+----------------+
| :ACCOUNT1  |   :DATE   |   :NUM    | 0:ACCOUNTDES  | :SEQ_NUM  |
+------------+-----------+-----------+---------------+----------------+
| 367392332  | 20201001  | 30201001  | sffa1         | 13                |
| 367392332  | 20201001  | 30201001  | sffa888       | 13                |
+------------+-----------+-----------+---------------+----------------+
```

Solution

Step 1 Delete the old index table.

DROP INDEX TEST_TABLE_INDEX ON TEST_TABLE;

Step 2 Create an index table in asynchronous mode.

CREATE INDEX TEST_TABLE_INDEX ON TEST_TABLE(ACCOUNT1,DATE,NUM,ACCOUNTDES,SEQ_NUM) ASYNC;

Step 3 Recreate a index.

hbase org.apache.phoenix.mapreduce.index.IndexTool --data-table TEST_TABLE --index-table TEST_TABLE_INDEX --output-path /user/test_table

----End

9.9.11 Why a Message Is Displayed Indicating that the Permission is Insufficient When CTBase Connects to the Ranger Plug-ins?

Question

When CTBase accesses the HBase service with the Ranger plug-ins enabled and you are creating a cluster table, a message is displayed indicating that the permission is insufficient.

The error information is as follows:

```
ERROR: Create ClusterTable failed. Error: org.apache.hadoop.hbase.security.AccessDeniedException:

```

Answer

Check whether the current account has sufficient permissions.

The CTBase user needs to configure permission policies on the Ranger page and grant the READ, WRITE, CREATE, ADMIN, and EXECUTE permissions to the CTBase metadata table _**ctmeta**_, cluster table, and index table.

For details about how to configure permissions on the Ranger page, see **Adding a Ranger Access Permission Policy for HBase**.

9.9.12 Introduction to HBase Global Secondary Index APIs

APIs that use global indexes are in the org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin class. Related APIs are described as follows:

Operation	API	Description
Adding an index	addIndices()	Add an index to a table without data. Calling this API will add the specified index to a table but skips index data generation. This API is used to add indexes in batches to a table that contains a large amount of pre-existing user data and use the GlobalTableIndexer tool to build index data.
	addIndicesWithDa-ta()	Add an index to a table with data. This API is used to add the specified index to the table and create index data for the existing user data. Alternatively, the API can be called to generate an index and then generate index data when the user data is being stored. This API is not recommended when a data table contains a large amount of data.
Deleting a collection	dropIndices()	If only the index is deleted, both the index metadata and index data are deleted. After this operation, the index cannot be used for scan or filter operations.

Operation	API	Description
Modifying the Index Status	alterGlobalIndicesUnusable()	Disables a specified index so that it cannot be used for scan or filter operations.
	alterGlobalIndicesActive()	Enables the index specified by the user so that it can be used for the scan/filter operation.
	alterGlobalIndicesInactive()	This API is used to disable a specified index and cancel index data generation. It cannot be used for scan or filter operations. It is usually used in the index repair process.
Viewing the created index	listIndices()	It can be used to list all indexes in a given table.

9.9.13 How Do I Disable HDFS Hedged Read on HBase?

Symptom

For MRS 3.3.1 and later versions, HDFS hedged read is enabled by default to reduce read latency and adapt to network changes. For details about this function, see **Configuring HDFS Hedged Read**. **Table 9-36** describes related parameters.

Table 9-36 Parameters of HDFS hedged read

Parameter	Description	Default Value	Value Range
dfs.client.hedged.read.threshold.millis	The number of milliseconds the HDFS client waits for the first byte of the first data block before deciding whether to start a hedged read	250	Greater than or equal to 1
dfs.client.hedged.read.threadpool.size	Size of the hedged read thread pool. If this parameter is set to a value greater than 0, multiple read channels are enabled.	200	Greater than or equal to 0

HDFS hedged read may cause performance deterioration when the disk I/O is high. You need to disable this function on HBase by referring to **Procedure**.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Service** > **HBase** > **Configurations** > **All Configurations**. The **All Configurations** page is displayed.

Step 3 Search for **dfs.client.hedged.read.threadpool.size** and change its value to **0**.

Step 4 Click **Save**.

Step 5 Click **Instances**, select all RegionServer instances, and choose **More** > **Instance Rolling Restart** to apply the changes.

----End

9.10 HBase Troubleshooting

9.10.1 Why Does a Client Keep Failing to Connect to a Server for a Long Time?

Question

A HBase server is faulty and cannot provide services. In this case, when a table operation is performed on the HBase client, why is the operation suspended and no response is received for a long time?

Answer

Problem Analysis

When the HBase server malfunctions, the table operation request from the HBase client is tried for several times and times out. The default timeout value is **Integer.MAX_VALUE (2147483647 ms)**. The table operation request is retired constantly during such a long period of time and is suspended at last.

Solution

The HBase client provides two configuration items to configure the retry and timeout of the client. **Table 9-37** describes them.

Set the following parameters in the ***Client installation path*/HBase/hbase/conf/hbase-site.xml** configuration file:

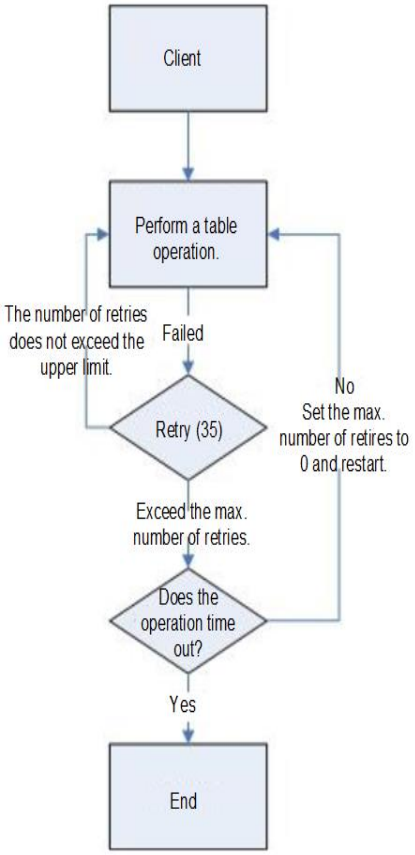
Table 9-37 Configuration parameters of retry and timeout

Parameter	Description	Default Value
hbase.client.operation.timeout	Client operation timeout period You need to manually add the information to the configuration file.	2147483647 ms

Parameter	Description	Default Value
hbase.client.retries.number	Maximum retry times supported by all retryable operations.	35

Figure 9-6 describes the working principles of retry and timeout.

Figure 9-6 Process for HBase client operation retry timeout



The process indicates that a suspension occurs if the preceding parameters are not configured based on site requirements. It is recommended that a proper timeout period be set based on scenarios. If the operation takes a long time, set a long timeout period. If the operation takes a shot time, set a short timeout period. The number of retries can be set to **(hbase.client.retries.number)*60*1000(ms)**. The timeout period can be slightly greater than **hbase.client.operation.timeout**.

9.10.2 Why May a Table Creation Exception Occur When HBase Deletes or Creates the Same Table Consecutively?

Question

When HBase consecutively deletes and creates the same table, why may a table creation exception occur?

Answer

Execution process: Disable Table > Drop Table > Create Table > Disable Table > Drop Table > And more

1. When a table is disabled, HMaster sends an RPC request to RegionServer, and RegionServer brings the region offline. When the time required for closing a region on RegionServer exceeds the timeout period for HBase HMaster to wait for the region to enter the RIT state, HMaster considers that the region is offline by default. Actually, the region may be in the flush memstore phase.
2. After an RPC request is sent to close a region, HMaster checks whether all regions in the table are offline. If the closure times out, HMaster considers that the regions are offline and returns a message indicating that the regions are successfully closed.
3. After the closure is successful, the data directory corresponding to the HBase table is deleted.
4. After the table is deleted, the data directory is recreated by the region that is still in the flush memstore phase.
5. When the table is created again, the **temp** directory is copied to the HBase data directory. However, the HBase data directory is not empty. As a result, when the HDFS rename API is called, the data directory changes to the last layer of the **temp** directory and is appended to the HBase data directory, for example, **$rootDir/data/$nameSpace/$tableName/$tableName**. In this case, the table fails to be created.

Troubleshooting Method

When this problem occurs, check whether the HBase data directory corresponding to the table exists. If it exists, rename the directory.

The HBase data directory consists of **$rootDir/data/$nameSpace/$tableName**, for example, **hdfs://hacluster/hbase/data/default/TestTable**. **$rootDir** is the HBase root directory, which can be obtained by configuring **hbase.rootdir.perms** in **hbase-site.xml**. The **data** directory is a fixed directory of HBase. **$nameSpace** indicates the nameSpace name. **$tableName** indicates the table name.

9.10.3 Why Other Services Become Unstable If HBase Sets up A Large Number of Connections over the Network Port?

Question

Why other services become unstable if HBase sets up a large number of connections over the network port?

Answer

When the OS command ***lsof*** or ***netstat*** is run, it is found that many TCP connections are in the CLOSE_WAIT state and the owner of the connections is HBase RegionServer. This can cause exhaustion of network ports or limit exceeding of HDFS connections, resulting in instability of other services. The HBase CLOSE_WAIT phenomenon is the HBase mechanism.

The reason why HBase CLOSE_WAIT occurs is as follows: HBase data is stored in the HDFS as HFile, which can be called StoreFiles. HBase functions as the client of the HDFS. When HBase creates a StoreFile or starts loading a StoreFile, it creates an HDFS connection. When the StoreFile is created or loaded successfully, the HDFS considers that the task is completed and transfers the connection close permission to HBase. However, HBase may choose not to close the connection to ensure real-time response; that is, HBase may maintain the connection so that it can quickly access the corresponding data file upon request. In this case, the connection is in the CLOSE_WAIT, which indicates that the connection needs to be closed by the client.

When a StoreFile will be created: HBase executes the Flush operation.

When Flush is executed: The data written by HBase is first stored in memstore. The Flush operation is performed only when the usage of memstore reaches the threshold or the ***flush*** command is run to write data into the HDFS.

To resolve the issue, use either of the following methods:

Because of the HBase connection mechanism, the number of StoreFiles must be restricted to reduce the occupation of HBase ports. This can be achieved by triggering HBase's the compaction action, that is, HBase file merging.

Method 1: On HBase shell client, run ***major_compact***.

Method 2: Compile HBase client code to invoke the compact method of the HBaseAdmin class to trigger HBase's compaction action.

If the HBase port occupation issue cannot be resolved through compact, it indicates that the HBase usage has reached the bottleneck. In such a case, you are advised to perform the following:

- Check whether the initial number of Regions configured in the table is appropriate.
- Check whether useless data exists.

If useless data exists, delete the data to reduce the number of storage files for the HBase. If the preceding conditions are not met, then you need to consider a capacity expansion.

9.10.4 Why Does the HBase BulkLoad Task Consisting of 210,000 Map Tasks and 10,000 Reduce Tasks Fail?

Question

The HBase bulkLoad task (a single table contains 26 TB data) has 210,000 maps and 10,000 reduce tasks, and the task fails.

Answer

ZooKeeper I/O bottleneck observation methods:

1. On the monitoring page of Manager, check whether the number of ZooKeeper requests on a single node exceeds the upper limit.
2. View ZooKeeper and HBase logs to check whether a large number of I/O Exception Timeout or SocketTimeout Exception exceptions occur.

Optimization suggestions:

1. Change the number of ZooKeeper instances to 5 or more. You are advised to set **peerType** to **observer** to increase the number of observers.
2. Control the number of concurrent maps of a single task or reduce the memory for running tasks on each node to lighten the node load.
3. Upgrade ZooKeeper data disks, such as SSDs.

9.10.5 Why Modified and Deleted Data Can Still Be Queried by Using the Scan Command?

Question

Why modified and deleted data can still be queried by using the **scan** command?

```
scan '<table_name>',{FILTER=>"SingleColumnValueFilter('<column_family>','column',=,'binary:<value>')"}
```

Answer

Because of the scalability of HBase, all values specific to the versions in the queried column are all matched by default, even if the values have been modified or deleted. For a row where column matching has failed (that is, the column does not exist in the row), the HBase also queries the row.

If you want to query only the new values and rows where column matching is successful, you can use the following statement:

```
scan '<table_name>',
{FILTER=>"SingleColumnValueFilter('<column_family>','column',=,'binary:<value>',true,true)"}
```

This command can filter all rows where column query has failed. It queries only the latest values of the current data in the table; that is, it does not query the values before modification or the deleted values.

NOTE

The related parameters of **SingleColumnValueFilter** are described as follows:

SingleColumnValueFilter(final byte[] family, final byte[] qualifier, final CompareOp compareOp, ByteArrayComparable comparator, final boolean filterIfMissing, final boolean latestVersionOnly)

Parameter description:

- family: family of the column to be queried.
- qualifier: column to be queried.
- compareOp: comparison operation, such as = and >.
- comparator: target value to be queried.
- filterIfMissing: whether a row is filtered out if the queried column does not exist. The default value is false.
- latestVersionOnly: whether values of the latest version are queried. The default value is false.

9.10.6 What Should I Do If I Fail to Create Tables Due to the FAILED_OPEN State of Regions?

Question

What should I do if I fail to create tables due to the FAILED_OPEN state of Regions?

Answer

If a network, HDFS, or Active HMaster fault occurs during the creation of tables, some Regions may fail to go online and therefore enter the FAILED_OPEN state. In this case, tables fail to be created.

The tables that fail to be created due to the preceding mentioned issue cannot be repaired. To solve this problem, perform the following operations to delete and re-create the tables:

1. Run the following command on the cluster client to repair the state of the tables:

   hbase hbck -j ${CLIENT_HOME}**/HBase/hbase/tools/hbase-hbck2-1.1.0-h0.cbu.mrs.*.jar setTableState** <table_name> **ENABLED**

2. Enter the HBase shell and run the following commands to delete the tables that fail to be created:

   disable *'<table_name>'*

   drop *'<table_name>'*

3. Create the tables using the recreation command.

9.10.7 How Do I Delete Residual Table Names in the table-lock Directory of ZooKeeper?

Question

In security mode, names of tables that failed to be created are unnecessarily retained in the table-lock node (default directory is /hbase/table-lock) of ZooKeeper. How do I delete these residual table names?

Answer

Perform the following steps:

1. On the client, run the kinit command as the hbase user to obtain a security certificate.
2. Run the ***hbase zkcli*** command to launch the ZooKeeper Command Line Interface (zkCLI).
3. Run the ***ls /hbase/table*** command on the zkCLI to check whether the table name of the table that fails to be created exists.
   - If the table name exists, no further operation is required.
   - If the table name does not exist, run ***ls /hbase/table-lock***to check whether the table name of the table fail to be created exist. If the table name exists, run the***delete /hbase/table-lock/<table>***command to delete the table name. In the***delete /hbase/table-lock/<table>***command,***<table>*** indicates the residual table name.

9.10.8 Why Does HBase Become Faulty When I Set a Quota for the Directory Used by HBase in HDFS?

Question

Why does HBase become faulty when I set quota for the directory used by HBase in HDFS?

Answer

The flush operation of a table is to write memstore data to HDFS.

If the HDFS directory does not have sufficient disk space quota, the flush operation will fail and the region server will stop.

```
Caused by: org.apache.hadoop.hdfs.protocol.DSQuotaExceededException: The DiskSpace quota of /hbase/data/<namespace>/<tableName> is exceeded: quota = 1024 B = 1 KB but diskspace consumed = 402655638 B = 384.00 MB
?at org.apache.hadoop.hdfs.server.namenode.DirectoryWithQuotaFeature.verifyStoragespaceQuota(DirectoryWithQuotaFeature.java:211)
?at org.apache.hadoop.hdfs.server.namenode.DirectoryWithQuotaFeature.verifyQuota(DirectoryWithQuotaFeature.java:239)
?at org.apache.hadoop.hdfs.server.namenode.FSDirectory.verifyQuota(FSDirectory.java:882)
?at org.apache.hadoop.hdfs.server.namenode.FSDirectory.updateCount(FSDirectory.java:711)
?at org.apache.hadoop.hdfs.server.namenode.FSDirectory.updateCount(FSDirectory.java:670)
?at org.apache.hadoop.hdfs.server.namenode.FSDirectory.addBlock(FSDirectory.java:495)
```

In the preceding exception, the disk space quota of the **/hbase/data/<namespace>/<tableName>** table is 1 KB, but the memstore data is 384.00 MB. Therefore, the flush operation fails and the region server stops.

When the region server is terminated, HMaster replays the WAL file of the terminated region server to restore data. The disk space quota is limited. As a result, the replay operation of the WAL file fails, and the HMaster process exits unexpectedly.

```
2016-07-28 19:11:40,352 | FATAL | MASTER_SERVER_OPERATIONS-10-91-9-131:16000-0 | Caught throwable while processing event M_SERVER_SHUTDOWN |
org.apache.hadoop.hbase.master.HMaster.abort(HMaster.java:2474)
java.io.IOException: failed log splitting for 10-91-9-131,16020,1469689987884, will retry
?at org.apache.hadoop.hbase.master.handler.ServerShutdownHandler.resubmit(ServerShutdownHandler.java:365)
?at org.apache.hadoop.hbase.master.handler.ServerShutdownHandler.process(ServerShutdownHandler.java:220)
?at org.apache.hadoop.hbase.executor.EventHandler.run(EventHandler.java:129)
?at java.util.concurrent.ThreadPoolExecutor.runWorker(ThreadPoolExecutor.java:1142)
?at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
?at java.lang.Thread.run(Thread.java:745)
Caused by: java.io.IOException: error or interrupted while splitting logs in [hdfs://hacluster/hbase/WALs/<RS-Hostname>,<RS-Port>,<startcode>-splitting] Task = installed = 6 done = 3 error = 3
?at org.apache.hadoop.hbase.master.SplitLogManager.splitLogDistributed(SplitLogManager.java:290)
?at org.apache.hadoop.hbase.master.MasterFileSystem.splitLog(MasterFileSystem.java:402)
?at org.apache.hadoop.hbase.master.MasterFileSystem.splitLog(MasterFileSystem.java:375)
```

Therefore, you cannot set the quota value for the HBase directory in HDFS. If the exception occurs, perform the following operations:

Step 1 Run the **kinit** *Username* command on the client to enable the HBase user to obtain security authentication.

Step 2 Run the **hdfs dfs -count -q** */hbase/data/<namespace>/<tableName>* command to check the allocated disk space quota.

Step 3 Run the following command to cancel the quota limit and restore HBase:

hdfs dfsadmin -clrSpaceQuota */hbase/data/<namespace>/<tableName>*

----End

9.10.9 HMaster Fails to Be Started After the OfflineMetaRepair Tool Is Used to Rebuild Metadata

Question

Why HMaster times out while waiting for namespace table to be assigned after rebuilding meta using OfflineMetaRepair tool and startups failed?

HMaster abort with following FATAL message,

```
2017-06-15 15:11:07,582 FATAL [Hostname:16000.activeMasterManager] master.HMaster: Unhandled exception. Starting shutdown.
java.io.IOException: Timedout 120000ms waiting for namespace table to be assigned
    at org.apache.hadoop.hbase.master.TableNamespaceManager.start(TableNamespaceManager.java:98)
    at org.apache.hadoop.hbase.master.HMaster.initNamespace(HMaster.java:1054)
    at org.apache.hadoop.hbase.master.HMaster.finishActiveMasterInitialization(HMaster.java:848)
    at org.apache.hadoop.hbase.master.HMaster.access$600(HMaster.java:199)
    at org.apache.hadoop.hbase.master.HMaster$2.run(HMaster.java:1871)
    at java.lang.Thread.run(Thread.java:745)
```

Answer

When meta is rebuilt by OfflineMetaRepair tool then HMaster wait for all region server's WAL split during start up to avoid the data inconsistency problem. HMaster trigger user regions assignment once WAL split completes. So when the cluster is in the unusual scenario, there are chances WAL splitting may take long time which depends on multiple factors like too many WALs, slow I/O, region servers are not stable etc.

HMaster should be able to finish all region server WAL splitting successfully. Perform the following steps.

1. Make sure cluster is stable, no other problem exist. If any problem occurs, please correct them first.
2. Configure a large value to **hbase.master.initializationmonitor.timeout**parameters, default value is**3600000** milliseconds.
3. Restart HBase service.

9.10.10 Why Messages Containing FileNotFoundException Frequently Displayed in the HMaster Logs?

Question

Why messages containing FileNotFoundException and no lease are frequently displayed in the HMaster logs during the WAL splitting process?

```
2017-06-10 09:50:27,586 | ERROR | split-log-closeStream-2 | Couldn't close log at hdfs://hacluster/hbase/

```

Answer

During the WAL splitting process, the WAL splitting timeout period is specified by the **hbase.splitlog.manager.timeout** parameter. If the WAL splitting process fails to complete within the timeout period, the task is submitted again. Multiple WAL splitting tasks may be submitted during a specified period. If the **temp** file is deleted when one WAL splitting task completes, other tasks cannot find the file and the FileNotFoudException exception is reported. To avoid the problem, perform the following modifications:

The default value of **hbase.splitlog.manager.timeout** is 600,000 ms. The cluster specification is that each RegionServer has 2,000 to 3,000 regions. When the cluster is normal (HBase is normal and HDFS does not have a large number of read and write operations), you are advised to adjust this parameter based on the cluster specifications. If the actual specifications (the actual average number of regions on each RegionServer) are greater than the default specifications (the default average number of regions on each RegionServer, that is, 2,000), the adjustment solution is (actual specifications/default specifications) x Default time.

Set the **splitlog** parameter in the **hbase-site.xml** file on the server. **Table 9-38** describes the parameter.

Table 9-38 Description of the **splitlog** parameter

Parameter	Description	Default Value
hbase.splitlog.manager.timeout	Timeout period for receiving worker response by the distributed SplitLog management program.	600000

9.10.11 Why Does the ImportTsv Tool Display "Permission denied"

Question

When the same Linux user (for example, user **omm**) as and a different Kerberos user (for example, user **admin**) from the Region Server are used, why does the ImportTsv tool fail to be executed and the error message "Permission denied" is displayed?

```
Exception in thread "main" org.apache.hadoop.security.AccessControlException: Permission denied:
user=admin, access=WRITE, inode="/user/omm-bulkload/hbase-staging/

```

Answer

The ImportTsv tool creates a partition file in the HBase temporary directory specified by **hbase.fs.tmp.dir** in the *Client installation path* **/HBase/hbase/conf/hbase-site.xml file.** Therefore, the client (Kerberos user) must have the **rwx** permission on the specified temporary directory to perform the ImportTsv operation. The default value of **hbase.fs.tmp.dir** is **/user/${user.name}/hbase-staging** (for example, **/user/omm/hbase-staging**). **$ {user.name}** indicates the OS username (user **omm**). The client (Kerberos user, for example, user **admin**) does not have the **rwx** permission on the directory.

To solve the preceding problem, perform the following steps:

1. On the client, set **hbase.fs.tmp.dir** to the directory of the current Kerberos user (for example, **/user/admin/hbase-staging**), or provide the **rwx** permission required by the configured directory for the client (Kerberos user).
2. Perform the ImportTsv operation again.

9.10.12 Why Are Different Query Results Returned After I Use Same Query Criteria to Query Data Successfully Imported by HBase bulkload?

Question

If the data to be imported by HBase bulkload has identical rowkeys, the data import is successful but identical query criteria produce different query results.

Answer

Data with an identical rowkey is loaded into HBase in the order in which data is read. The data with the latest timestamp is considered to be the latest data. By default, data is not queried by timestamp. Therefore, if you query for data with an identical rowkey, only the latest data is returned.

While data is being loaded by bulkload, the memory processes the data into HFiles quickly, leading to the possibility that data with an identical rowkey has a

same timestamp. In this case, identical query criteria may produce different query results.

To avoid this problem, ensure that the same data file does not contain identical rowkeys while you are creating tables or loading data.

9.10.13 HBase Fails to Recover a Task

Question

The system automatically rolls back data after an HBase recovery task fails. If "Rollback recovery failed" is displayed, the rollback fails. After the rollback fails, data stops being processed and the junk data may be generated. How can I resolve this problem?

Answer

You need to manually clear the junk data before performing the backup or recovery task next time.

Step 1 Install the cluster client in **/opt/client**.

Step 2 Run **source /opt/client/bigdata_env** as the client installation user to configure environment variables.

Step 3 Run the **kinit admin** command.

Step 4 Run **zkCli.sh -server** *business IP address of ZooKeeper*:**2181** to connect to the ZooKeeper.

Step 5 Run **deleteall /recovering** to delete the junk data. Run **quit** to disconnect ZooKeeper.

NOTE

Running this command will cause data loss. Exercise caution.

Step 6 Run **hdfs dfs -rm -f -r /user/hbase/backup** to delete temporary data.

Step 7 Log in to FusionInsight Manager and choose **O&M**. In the navigation pane on the left, choose **Backup and Restoration** > **Restoration Management**. In the task list, locate the row that contains the target task and click **View History** in the **Operation** column. In the displayed dialog box, click ⌄ before a specified execution record to view the snapshot name.

Snapshot [*snapshot name*] is created successfully before recovery.

Step 8 Switch to the client, run **hbase shell**, and then **delete_all_snapshot** '*snapshot name*.*' to delete the temporary snapshot.

----End

9.10.14 Why Does RegionServer Fail to Be Started When GC Parameters Xms and Xmx of HBase RegionServer Are Set to 31 GB?

Question

Check the **hbase-omm-*.out** log of the node where RegionServer fails to be started. It is found that the log contains **An error report file with more information is saved as: /tmp/hs_err_pid*.log**. Check the **/tmp/hs_err_pid*.log** file. It is found that the log contains **#Internal Error (vtableStubs_aarch64.cpp:213), pid=9456, tid=0x0000ffff97fdd200 and #guarantee(__ pc() <= s->code_end()) failed: overflowed buffer**, indicating that the problem is caused by JDK. How do I solve this problem?

Answer

To rectify the fault, perform the following steps:

Step 1 Run the **su - omm** command on a node where RegionServer fails to be started to switch to user **omm**.

Step 2 Run the **java -XX:+PrintFlagsFinal -version |grep HeapBase** command as user **omm**. Information similar to the following is displayed:

```
uintx HeapBaseMinAddress = 2147483648 {pd product}
```

Step 3 Change the values of **-Xms** and **-Xmx** in **GC_OPTS** to values that are not between **32G-HeapBaseMinAddress** and **32G**, excluding the values of **32G** and **32G-HeapBaseMinAddress**.

Step 4 Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HBase** > **Instance**, select the failed instance, and choose **More** > **Restart Instance** to restart the failed instance.

----End

9.10.15 Why Does the LoadIncrementalHFiles Tool Fail to Be Executed and "Permission denied" Is Displayed?

Question

Why does the LoadIncrementalHFiles tool fail to be executed and "Permission denied" is displayed when a Linux user is manually created in a normal cluster and DataNode in the cluster is used to import data in batches?

```
2020-09-20 14:53:53,808 WARN  [main] shortcircuit.DomainSocketFactory: error creating DomainSocket

    at org.apache.hadoop.hbase.tool.LoadIncrementalHFiles.run(LoadIncrementalHFiles.java:1263)
    at org.apache.hadoop.hbase.tool.LoadIncrementalHFiles.run(LoadIncrementalHFiles.java:1276)
    at org.apache.hadoop.hbase.tool.LoadIncrementalHFiles.run(LoadIncrementalHFiles.java:1311)
    at org.apache.hadoop.util.ToolRunner.run(ToolRunner.java:76)
    at org.apache.hadoop.hbase.tool.LoadIncrementalHFiles.main(LoadIncrementalHFiles.java:1333)
```

Answer

If the client that the LoadIncrementalHFiles tool depends on is installed in the cluster and is on the same node as DataNode, HDFS creates short-circuit read during the execution of the tool to improve performance. The short-circuit read depends on the **/var/run/FusionInsight-HDFS** directory (**dfs.domain.socket.path**). The default permission on this directory is **750**. This user does not have the permission to operate the directory.

To solve the preceding problem, perform the following operations:

Method 1: Create a user (recommended).

Step 1 Create a user on Manager. By default, the user group contains the **ficommon** group.

```
[root@xxx-xxx-xxx-xxx ~]# id test
uid=20038(test) gid=9998(ficommon) groups=9998(ficommon)
```

Step 2 Import data again.

----End

Method 2: Change the owner group of the current user.

Step 1 Add the user to the **ficommon** group.

```
[root@xxx-xxx-xxx-xxx ~]# usermod -a -G ficommon test
[root@xxx-xxx-xxx-xxx ~]# id test
uid=2102(test) gid=2102(test) groups=2102(test),9998(ficommon)
```

Step 2 Import data again.

----End

9.10.16 Why Is the Error Message "import argparse" Displayed When the Phoenix sqlline Script Is Used?

Question

When the sqlline script is used on the client, the error message "import argparse" is displayed.

Answer

Step 1 Log in to the node where the HBase client is installed as user **root**. Perform security authentication using the **hbase** user.

Step 2 Go to the directory where the sqlline script of the HBase client is stored and run the **python3 sqlline.py** command.

----End

9.10.17 How Do I View Regions in the CLOSED State in an ENABLED Table?

Question

How do I view regions in the CLOSED state in an ENABLED table on the HBase client?

This parameter is available only in MRS 3.3.0 or later.

Procedure

Step 1 Log in to the node on which the HBase client is installed as a client installation user.

Step 2 Go to the client installation directory and configure the environment variables:

cd *Client installation directory*

source bigdata_env

Step 3 If Kerberos authentication is enabled for the cluster (the cluster is in security mode), run the following command to perform security authentication. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), skip this step.

kinit *Component service user*

Step 4 Run the following command to check the regions in the CLOSED state in an ENABLED table:

hbase hbck -j HBase/hbase/tools/hbase-hbck2-*jar reportClosedRegions [-details] [<TABLENAME>...]

The command parameters are as follows:

- If **-details** is not specified, only the number of CLOSED regions is displayed. If **-details** is specified, the names of all CLOSED regions are displayed.

- If *TABLENAME* is not specified, all tables are queried by default.
- If "Closed region due to split" is displayed after the command is executed, the region status changes to CLOSED due to an ongoing split task. After the task is complete, the region is automatically removed from the meta table.

```
Table meta_graph is okay.
Table hbase:namespace is okay.
Table hbase:hindex is okay.
Table hbase:rsgroup is okay.
Table ns1:test1 is okay.
Table graphbaseORM_systemNotifications is okay.
Table hbase:acl is okay.
Table testComp has 1 closed regions.
Closed region due to split testComp,,1690447776336.d5f1eb4a53bf63eb688441a1e58f9835.
```

----End

9.10.18 How Can I Quickly Recover the Service When HBase Files Are Damaged Due to a Cluster Power-Off?

Symptom

The StoreFile or WAL files are damaged due to an unexpected cluster power-off. How can I quickly restore the service?

This operation is supported only for MRS 3.3.0 or later.

Cause Analysis

If the StoreFile file is damaged, related regions fail to be brought online and system keeps retry the operation. As a result, the HBase service is abnormal. If the WAL file is damaged, log splitting fails and the system keeps retry the operation. As a result, the service is abnormal. Related regions cannot be brought online and provide services for external systems.

Procedure

The HBase server provides two configuration items to determine whether to skip damaged StoreFile and WAL files. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HBase** and click **Configuration**, search for and set the parameters listed in **Table 9-39**. The parameters take effect dynamically. Save the configuration, log in to the HBase shell, and run the **update_all_config** command for the parameters to take effect.

Skipping damaged files may cause data loss. If the following parameters are set to **true** and damaged StoreFile or WAL file is skipped, **ALM-19025 Damaged StoreFile in HBase** or **ALM-19026 Damaged WAL Files in HBase** is reported, rectify the fault by referring to the alarm help.

Table 9-39 Parameters for skipping damaged files on the HBase server

Parameter	Description	Default Value
hregion.hfile.skip.errors	Whether to skip damaged HBase Files and and move them to the **/hbase/autocorrupt** or **/hbase/MasterData/autocorrupt** directory when a region is brought online. You are not advised to enable this parameter in DR scenarios.	false
hbase.hlog.split.skip.errors	Whether to skip damaged WAL files and move them to the **/hbase/corrupt** directory during log splitting.	false

9.10.19 How Do I Quickly Restore HBase After HDFS Enters the Safe Mode and the HBase Service Is Abnormal?

Symptom

For MRS 3.5.0 and later versions, the HBase service is abnormal after the HDFS enters the safe mode. How do I quickly restore the HBase service after the HDFS exits the safe mode?

Cause Analysis

After the HDFS enters the safe mode, the HBase service is abnormal and the **meta** table goes offline. After the HDFS exits the safe mode, the meta table does not go online. "No namenode available to invoke create /hbase/WALs/xxxx.meta" is displayed in the RegionServer log.

The **meta** table cannot record the online status during the online process after the HDFS fault is rectified. In addition, the number of retry times for automatic recovery of the Manager instance health check is limited. As a result, the meta table cannot be brought online. After the HDFS exits the safe mode, you need to manually restore the service.

Procedure

Step 1 Ensure that the HDFS is restored and exits the safe mode.

Step 2 Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HBase**. On the **Dashboard** page, choose **More** > **Restart Service**, enter the password of the current user, and click **OK** to restart the HBase service, and then bring the **meta** table online.

----End

10 Using HDFS

10.1 Overview of HDFS File System Directories

Hadoop Distributed File System (HDFS) implements reliable and distributed read/write of massive amounts of data. HDFS is applicable to the scenario where data read/write features "write once and read multiple times". However, the write operation is performed in sequence, that is, it is a write operation performed during file creation or an adding operation performed behind the existing file. HDFS ensures that only one caller can perform write operation on a file but multiple callers can perform read operation on the file at the same time.

This section describes the directory structure in HDFS, as shown in the following table.

Table 10-1 Directory structure of the HDFS file system

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/spark2x/sparkhive-scratch	Fixed directory	Stores temporary files of metastore session in Spark2x JDBCServer.	No	Failed to run the task.
/tmp/sparkhive-scratch	Fixed directory	Stores temporary files of metastore sessions that are executed in CLI mode using Spark2x CLI.	No	Failed to run the task.
/tmp/logs/	Fixed directory	Stores container log files.	Yes	Container log files cannot be viewed.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/carbon/	Fixed directory	Stores the abnormal data in this directory if abnormal CarbonData data exists during data import.	Yes	Error data is lost.
/tmp/Loader-${*Job name*}_${*MR job ID*}	Temporary directory	Stores the region information about Loader HBase bulkload jobs. The data is automatically deleted after the job running is completed.	No	Failed to run the Loader HBase Bulkload job.
/tmp/hadoop-omm/yarn/system/rmstore	Fixed directory	Stores the ResourceManager running information.	Yes	Status information is lost after ResourceManager is restarted.
/tmp/archived	Fixed directory	Archives the MR task logs on HDFS.	Yes	MR task logs are lost.
/tmp/hadoop-yarn/staging	Fixed directory	Stores the run logs, summary information, and configuration attributes of ApplicationMaster running jobs.	No	Services are running improperly.
/tmp/hadoop-yarn/staging/history/done_intermediate	Fixed directory	Stores temporary files in the **/tmp/hadoop-yarn/staging** directory after all tasks are executed.	No	MR task logs are lost.
/tmp/hadoop-yarn/staging/history/done	Fixed directory	The periodic scanning thread periodically moves the **done_intermediate** log file to the **done** directory.	No	MR task logs are lost.
/tmp/mr-history	Fixed directory	Stores the historical record files that are pre-loaded.	No	Historical MR task log data is lost.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/tmp/hive-scratch	Fixed directory	Stores temporary data (such as session information) generated during Hive running.	No	Failed to run the current task.
/user/{user}/.sparkStaging	Fixed directory	Stores temporary files of the SparkJDBCServer application.	No	Failed to start the executor.
/user/spark2x/jars	Fixed directory	Stores running dependency packages of the Spark2x executor.	No	Failed to start the executor.
/user/loader	Fixed directory	Stores dirty data of Loader jobs and data of HBase jobs.	No	Failed to execute the HBase job. Or dirty data is lost.
/user/loader/etl_dirty_data_dir				
/user/loader/etl_hbase_putlist_tmp				
/user/loader/etl_hbase_tmp				
/user/oozie	Fixed directory	Stores dependent libraries required for Oozie running, which needs to be manually uploaded.	No	Failed to schedule Oozie.
/user/mapred/hadoop-mapreduce-*xxx*.tar.gz	Fixed files	Stores JAR files used by the distributed MR cache.	No	The MR distributed cache function is unavailable.
/user/hive	Fixed directory	Stores Hive-related data by default, including the depended Spark lib package and default table data storage path.	No	User data is lost.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/user/omm-bulkload	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.
/user/hbase	Temporary directory	Stores HBase batch import tools temporarily.	No	Failed to import HBase tasks in batches.
/spark2xJobHistory2x	Fixed directory	Stores Spark2x eventlog data.	No	The History Server service is unavailable, and the task fails to be executed.
/flume	Fixed directory	Stores data collected by Flume from HDFS.	No	Flume runs improperly.
/mr-history/tmp	Fixed directory	Stores logs generated by MapReduce jobs.	Yes	Log information is lost.
/mr-history/done	Fixed directory	Stores logs managed by MR JobHistory Server.	Yes	Log information is lost.
/tenant	Created when a tenant is added.	Directory of a tenant in the HDFS. By default, the system automatically creates a folder in the **/tenant** directory based on the tenant name. For example, the default HDFS storage directory for **ta1** is **tenant/ta1**. When a tenant is created for the first time, the system creates the **/tenant** directory in the HDFS root directory. You can customize the storage path.	No	The tenant account is unavailable.

Path	Type	Function	Whether the Directory Can Be Deleted	Deletion Consequence
/apps{1~5}/	Fixed directory	Stores the Hive package used by WebHCat.	No	Failed to run the WebHCat tasks.
/hbase	Fixed directory	Stores HBase data.	No	HBase user data is lost.
/hbaseFileStream	Fixed directory	Stores HFS files.	No	The HFS file is lost and cannot be restored.

10.2 HDFS User Permission Management

10.2.1 Creating an HDFS Role

Scenario

This section describes how to create and configure an HDFS role on FusionInsight Manager. The HDFS role is granted the rights to read, write, and execute HDFS directories or files.

A user has the complete permission on the created HDFS directories or files, that is, the user can directly read data from and write data to as well as authorize others to access the HDFS directories or files.

NOTE

- An HDFS role can be created only in security mode.
- If the current component uses Ranger for permission control, HDFS policies must be configured based on Ranger for permission management. For details, see **Adding a Ranger Access Permission Policy for HDFS**.

Procedure

Step 1 Log in to FusionInsight Manager, and choose **System** > **Permission** > **Role**.

Step 2 On the displayed page, click **Create Role** and fill in **Role Name** and **Description**.

Step 3 Configure the resource permission. For details, see **Table 10-2**.

Table 10-2 Setting a role

Task	Operation
Setting the HDFS administrator permission	In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS, and select **Cluster Admin Operations**. **NOTE** The setting takes effect after the HDFS service is restarted.
Setting the permission for users to check and recover HDFS	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Read** and **Execute**.
Setting the permission for users to read directories or files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Read** and **Execute**.
Setting the permission for users to write data to files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified files on HDFS. 3. In the **Permission** column of the specified files, select **Write** and **Execute**.
Setting the permission for users to create or delete sub-files or sub-directories in the directory of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the path where the specified directory is saved in the HDFS. 3. In the **Permission** column of the specified directories, select **Write** and **Execute**.
Setting the permission for users to execute directories or files of other users	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Execute**.

Task	Operation
Setting the permission for allowing subdirectories to inherit all permissions of their parent directories	1. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > HDFS > **File System**. 2. Locate the save path of specified directories or files on HDFS. 3. In the **Permission** column of the specified directories or files, select **Recursive**.

NOTE

- **File System**: HDFS directory and file permission.
- Common HDFS directories are as follows:
  - **flume**: Flume data storage directory
  - **hbase**: HBase data storage directory
  - **mr-history**: MapReduce task information storage directory
  - **tmp**: temporary data storage directory
  - **user**: user data storage directory

Step 4 Click **OK**, and return to the **Role** page.

----End

10.2.2 Configuring HDFS Directory Permission

Scenario

The permission for some HDFS directories is **777** or **750** by default, which brings potential security risks. You are advised to modify the permission for the HDFS directories after the HDFS is installed to increase user security.

Procedure

Log in to the HDFS client as the administrator and run the following command to modify the permission for the **/user** directory.

The permission is set to **1777**, that is, **1** is added to the original permission. This indicates that only the user who creates the directory can delete it.

hdfs dfs -chmod 1777 */user*

To ensure security of the system file, you are advised to harden the security for non-temporary directories. The following directories are examples:

- /user:777
- /mr-history:777
- /mr-history/tmp:777
- /mr-history/done:777

- /user/mapred:755

10.3 Using the HDFS Client

Scenario

This section describes how to use the HDFS client in an O&M scenario or service scenario.

Prerequisites

- The client has been installed.

  For example, the installation directory is **/opt/client**. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite.
- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user needs to change the password upon the first login. (This operation is not required in normal mode.)

Using the HDFS Client

Step 1 Install a client. For details, see **Installing a Client**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 6 Run the HDFS Shell command. Example:

hdfs dfs -ls /

----End

Common HDFS Client Commands

The following table lists common HDFS client commands.

For more commands, see **https://hadoop.apache.org/docs/stable/hadoop-project-dist/hadoop-common/CommandsManual.html#User_Commands**.

Table 10-3 Common HDFS client commands

Command	Description	Example
hdfs dfs -mkdir *Folder name*	Used to create a folder.	**hdfs dfs -mkdir /tmp/mydir**
hdfs dfs -ls *Folder name*	Used to view a folder.	**hdfs dfs -ls /tmp**
hdfs dfs -put *Local file on the client node Specified HDFS path*	Used to upload a local file to a specified HDFS path.	**hdfs dfs -put /opt/test.txt /tmp** Upload the **/opt/test.txt** file on the client node to the **/tmp** directory of HDFS.
hdfs dfs -get *Specified file on HDFS Specified path on the client node*	Used to download the HDFS file to the specified local path.	**hdfs dfs -get /tmp/test.txt /opt/** Download the **/tmp/test.txt** file on HDFS to the **/opt** path on the client node.
hdfs dfs -rm -r -f *Specified folder on HDFS*	Used to delete a folder.	**hdfs dfs -rm -r -f /tmp/mydir**
hdfs dfs -chmod *Permission parameter File directory*	Used to configure the HDFS directory permission for a user.	**hdfs dfs -chmod 700 /tmp/test**

Client-related FAQs

1. What do I do when the HDFS client exits abnormally and error message "java.lang.OutOfMemoryError" is displayed after the HDFS client command is running?

   This problem occurs because the memory required for running the HDFS client exceeds the preset upper limit (128 MB by default). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the upper limit to 1 GB, run the following command:

   ```
   CLIENT_GC_OPTS="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source <*Client installation path*>/**/bigdata_env**

2. How do I set the log level when the HDFS client is running?

   By default, the logs generated during the running of the HDFS client are printed to the console. The default log level is INFO. To enable the DEBUG log level for fault locating, run the following command to export an environment variable:

   export HADOOP_ROOT_LOGGER=DEBUG,console

   Then run the HDFS Shell command to generate the DEBUG logs.

If you want to print INFO logs again, run the following command:

export HADOOP_ROOT_LOGGER=INFO,console

3. How do I delete HDFS files permanently?

   HDFS provides a recycle bin mechanism. Typically, after an HDFS file is deleted, the file is moved to the recycle bin of HDFS. If the file is no longer needed and the storage space needs to be released, clear the corresponding recycle bin directory, for example, **hdfs://hacluster/user/xxx/.Trash/Current/***xxx*.

10.4 Using Hadoop from Scratch

You can use Hadoop to submit wordcount jobs. Wordcount is the most classic Hadoop job and is used to count the number of words in massive text.

Procedure

Step 1 Prepare the wordcount program.

Multiple open source Hadoop sample programs are provided, including wordcount. You can download the Hadoop sample program from **https://dist.apache.org/repos/dist/release/hadoop/common/**.

For example, choose **hadoop-***x.x.x*. On the page that is displayed, click **hadoop-***x.x.x***.tar.gz** to download it. Then, decompress it to obtain **hadoop-mapreduce-examples-***x.x.x***.jar** (the Hadoop sample program) from **hadoop-***x.x.x***\share\hadoop\mapreduce**. The **hadoop-mapreduce-examples-***x.x.x***.jar** package contains the wordcount program.

NOTE

hadoop-*x.x.x* indicates the Hadoop version. Choose a version based on your requirements.

Step 2 Prepare data files.

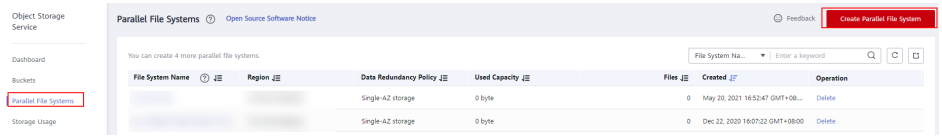
There is no format requirement for data files. Prepare one or more **.txt** files. The following are examples of the **.txt** file:

```
qwsdfhoedfrffrofhuncckgktpmhutopmma
jjpsffjfjorgjgtyiuyjmhombmbogohoyhm
jhheyeombdhuaqqiquyebchdhmamdhdemmj
doeyhjwedcrfvtgbmojiyhhqssddddddfkf
kjhhjkehdeiyrudjhfhfhffooqweopuyyyy
```

Step 3 Upload data to OBS.

1. Log in to OBS Console.
2. Click **Parallel File System** and choose **Create Parallel File System** to create a file system named **wordcount01**.

   wordcount01 is only an example. The file system name must be globally unique. Otherwise, the parallel file system fails to be created.



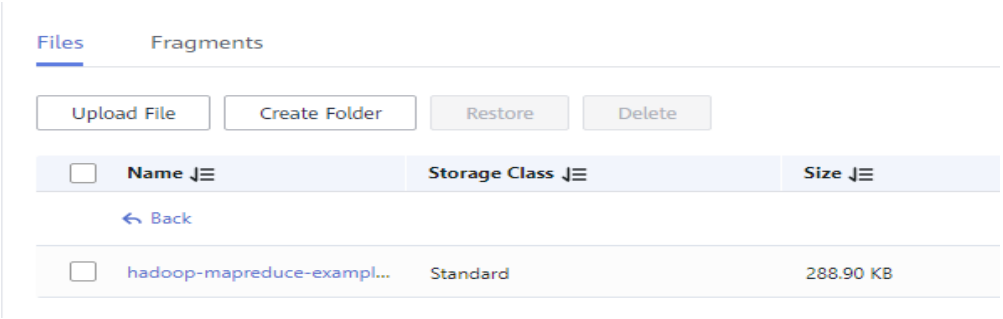
3. In the OBS file system list, click **wordcount01** and choose **Files** > **Create Folder** to create the **program** and **input** folders, as shown in **Figure 10-1**.

   Figure 10-1 Folder list of the wordcount01 file system

   
   - **program**: stores user programs.
   - **input**: stores user data files.

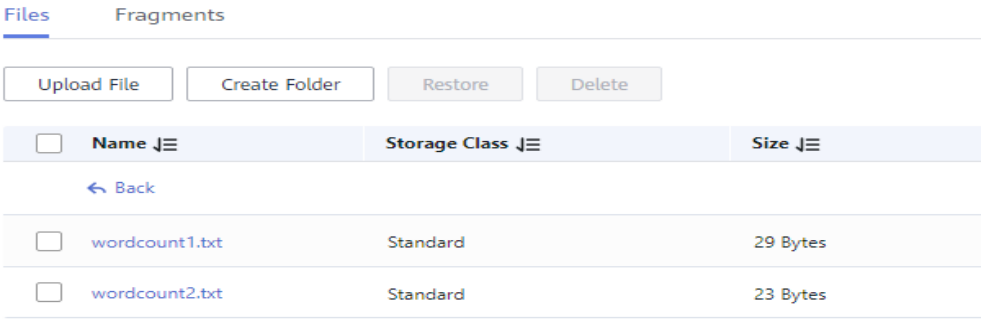
4. Go to the **program** folder, choose **Upload File** > **add file**, select the program package downloaded in **Step 1** from the local host, and click **Upload**. After the upload is complete, the page shown in **Figure 10-2** is displayed.

   Figure 10-2 Program list

5. Go to the **input** folder and upload the data file prepared in **Step 2** to the **input** folder. After the upload is complete, the page shown in **Figure 10-3** is displayed.

   Figure 10-3 Data file list

Step 4 Log in to the MRS console. In the navigation pane on the left, choose **Clusters** > **Active Clusters**. Click the cluster name. The cluster must contain Hadoop components and has been bound to an IAM agency with the OBS file system operation permission.

To view or bind an agency, perform the following steps:

1. In the **Dashboard** tab of the cluster, check whether the agency parameter has a value and whether the bound agency has the permission to operate an OBS file system.

   - If there is the agency name, the cluster has been bound to an agency.
   - If there is no agency name, go to **Step 4.2**.

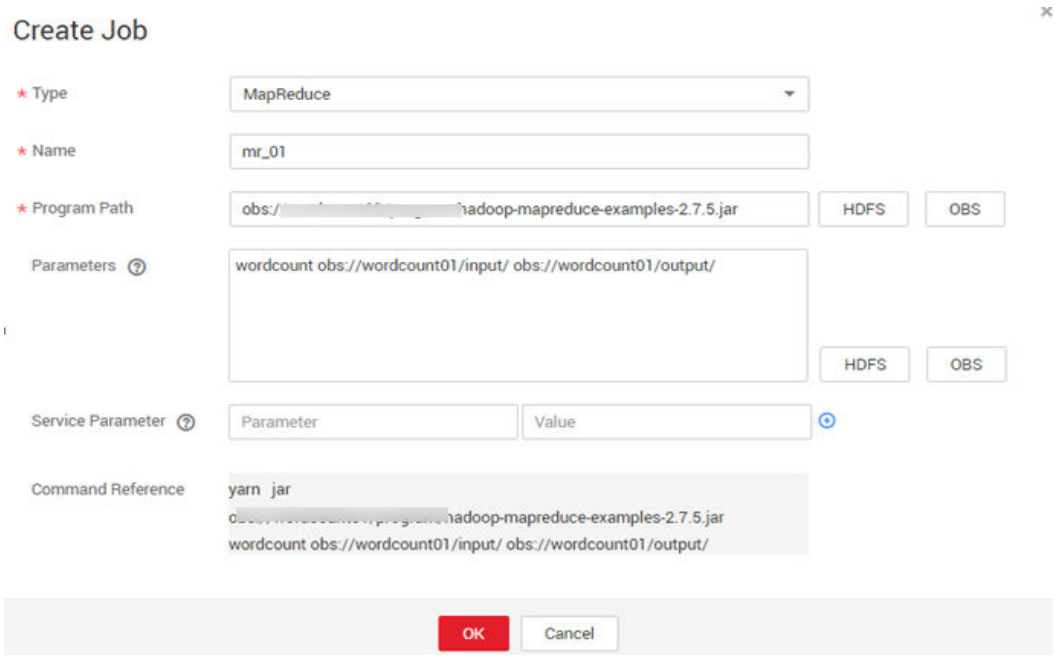
2. Click **Manage Agency** to bind an agency that has the permission to operate the OBS file system to the cluster.

   You can select the default **MRS_ECS_DEFAULT_AGENCY** agency or create an agency that has the permission to operate the OBS file system.

Step 5 Submit the wordcount job.

On the MRS console, click the **Jobs** tab and click **Create**. The **Create Job** page is displayed. For details, see **Running a MapReduce Job**.

Figure 10-4 wordcount job



- Set **Type** to **MapReduce**.
- Set **Name** to **mr_01**.
- Set the path of the executable program to the address of the program stored on the OBS, for example, **obs://wordcount01/program/hadoop-mapreduce-examples-*x.x.x*.jar**.

- Enter **wordcount obs://wordcount01/input/ obs://wordcount01/output/** in the **Parameter** pane.

  NOTE

  - Replace the OBS file system name in **obs://wordcount01/input/** with the actual name of the file system created in the environment.
  - Replace the OBS file system name in **obs://wordcount01/output/** with the name of the file system created in the actual environment. Replace **output** with a directory that does not exist based on site requirements.

- **Service Parameter** can be left blank.

A job can be submitted only when the cluster is in the **Running** state.

After a job is submitted successfully, it is in the **Accepted** state by default. You do not need to manually execute the job.

Step 6 View the job execution result.

1. Go to the **Jobs** tab page and check whether the job is successfully executed.

   It takes some time to run the job. After the job is complete, refresh the job list to view the job execution, as shown in **Figure 10-5**.

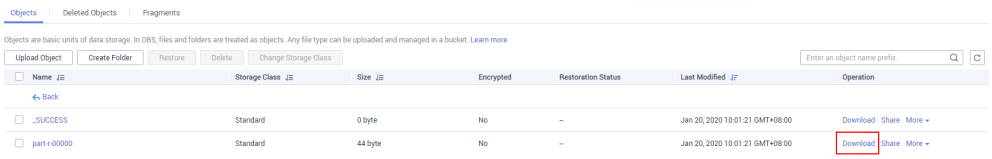
   Figure 10-5 Job list

   
   Once a job has succeeded or failed, you cannot execute it again. However, you can add or copy a job, and set job parameters to submit a job again.

2. Log in to the OBS console, go to the OBS path, and view the job output information.

   You can view output files in the **output** directory created in **Step 5**. You need to download the file to the local host and open it in text format, as shown in **Figure 10-6**.

   Figure 10-6 Output file list

----End

10.5 Configuring the Recycle Bin Mechanism

Scenario

On HDFS, deleted files are moved to the recycle bin (trash can) so that the data deleted by mistake can be restored.

You can set the time threshold for storing files in the recycle bin. Once the file storage duration exceeds the threshold, it is permanently deleted from the recycle bin. If the recycle bin is cleared, all files in the recycle bin are permanently deleted.

Configuration Description

If a file is deleted from HDFS, the file is saved in the trash space rather than cleared immediately. After the aging time is due, the deleted file becomes an aging file and will be cleared based on the system mechanism or manually cleared by users.

Parameter portal:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-4 Parameter description

Parameter	Description	Default Value
fs.trash.interval	Trash collection time, in minutes. If data in the trash station exceeds the time, the data will be deleted. Value range: 1440 to 259200	1440
fs.trash.checkpoint.interval	Interval between trash checkpoints, in minutes. The value must be less than or equal to the value of **fs.trash.interval**. The checkpoint program creates a checkpoint every time it runs and removes the checkpoint created **fs.trash.interval** minutes ago. For example, the system checks whether aging files exist every 10 minutes and deletes aging files if any. Files that are not aging are stored in the checkpoint list waiting for the next check. If this parameter is set to 0, the system does not check aging files and all aging files are saved in the system. Value range: 0 to *fs.trash.interval* **NOTE** It is not recommended to set this parameter to 0 because aging files will use up the disk space of the cluster.	60

10.6 Configuring HDFS DataNode Data Balancing

Scenario

In the HDFS cluster, unbalanced disk usage among DataNodes may occur, for example, when new DataNodes are added to the cluster. Unbalanced disk usage may result in multiple problems. For example, MapReduce applications cannot

make full use of local computing advantages, network bandwidth usage between data nodes cannot be optimal, or node disks cannot be used. Therefore, the MRS cluster administrator needs to periodically check and maintain DataNode data balance.

HDFS provides a capacity balancing program Balancer. By running Balancer, you can balance the HDFS cluster and ensure that the difference between the disk usage of each DataNode and that of the HDFS cluster does not exceed the threshold. DataNode disk usage before and after balancing is shown in **Figure 10-7** and **Figure 10-8**, respectively.

Figure 10-7 DataNode disk usage before balancing

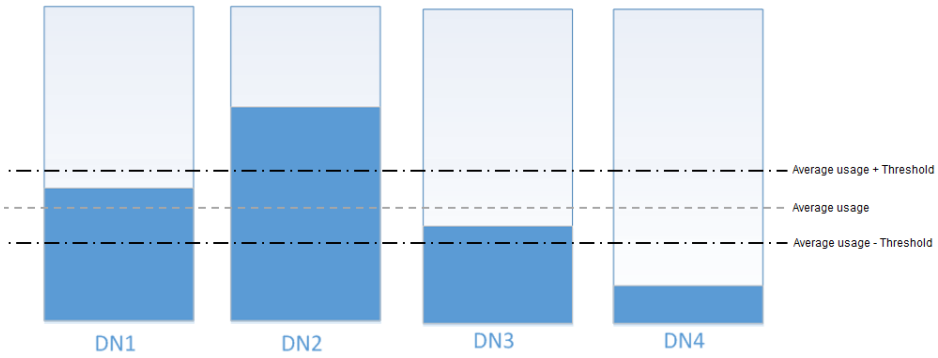


Figure 10-8 DataNode disk usage after balancing

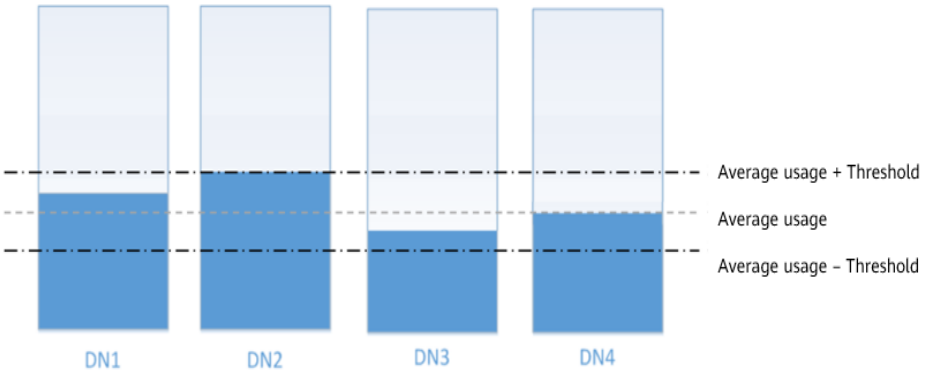


The time of the balancing operation is affected by the following two factors:

1. Total amount of data to be migrated:

   The data volume of each DataNode must be greater than (Average usage - Threshold) x Average data volume and less than (Average usage + Threshold) x Average data volume. If the actual data volume is less than the minimum value or greater than the maximum value, imbalance occurs. The system sets the largest deviation volume on all DataNodes as the total data volume to be migrated.

2. Balancer migration is performed in sequence in iteration mode. The amount of data to be migrated in each iteration does not exceed 10 GB, and the usage of each iteration is recalculated.

Therefore, for a cluster, you can estimate the time consumed by each iteration (by observing the time consumed by each iteration recorded in balancer logs) and divide the total data volume by 10 GB to estimate the task execution time.

The balancer can be started or stopped at any time.

Impact on the System

- The balance operation occupies network bandwidth resources of DataNodes. Perform the operation during maintenance based on service requirements.
- The balance operation may affect the running services if the bandwidth traffic (the default bandwidth control is 20 MB/s) is reset or the data volume is increased.

Prerequisites

The client has been installed.

Procedure

Step 1 Log in to the node where the client is installed as a client installation user. Run the following command to switch to the client installation directory, for example, **/opt/client**:

cd /opt/client

NOTE

If the cluster is in normal mode, run the **su - omm** command to switch to user **omm**.

Step 2 Run the following command to configure environment variables:

source bigdata_env

Step 3 If the cluster is in security mode, run the following command to authenticate the HDFS identity:

kinit hdfs

Step 4 Determine whether to adjust the bandwidth control.

- If yes, go to **Step 5**.
- If no, go to **Step 6**.

Step 5 Run the following command to change the maximum bandwidth of Balancer, and then go to **Step 6**.

hdfs dfsadmin -setBalancerBandwidth *<bandwidth in bytes per second>*

<bandwidth in bytes per second> indicates the bandwidth control value, in bytes. For example, to set the bandwidth control to 20 MB/s (the corresponding value is 20971520), run the following command:

hdfs dfsadmin -setBalancerBandwidth 20971520

NOTE

- The default bandwidth control is 20 MB/s. This value is applicable to the scenario where the current cluster uses the 10GE network and services are being executed. If the service idle time window is insufficient for balance maintenance, you can increase the value of this parameter to shorten the balance time, for example, to 209715200 (200 MB/s).
- The value of this parameter depends on the networking. If the cluster load is high, you can change the value to 209715200 (200 MB/s). If the cluster is idle, you can change the value to 1073741824 (1 GB/s).
- If the bandwidth of the DataNodes cannot reach the specified maximum bandwidth, modify the HDFS parameter **dfs.datanode.balance.max.concurrent.moves** on FusionInsight Manager, and change the number of threads for balancing on each DataNode to **32** and restart the HDFS service.

Step 6 Run the following command to start the balance task:

bash /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold *<threshold of balancer>*

-threshold specifies the deviation value of the DataNode disk usage, which is used for determining whether the HDFS data is balanced. When the difference between the disk usage of each DataNode and the average disk usage of the entire HDFS cluster is less than this threshold, the system considers that the HDFS cluster has been balanced and ends the balance task.

For example, to set deviation rate to 5%, run the following command:

bash /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold 5

NOTE

- The preceding command executes the task in the background. You can query related logs in the **hadoop-root-balancer-***Host name***.out** log file in the **/opt/client/HDFS/hadoop/logs** directory of the host.
- To stop the balance task, run the following command:

  bash /opt/client/HDFS/hadoop/sbin/stop-balancer.sh
- If only data on some nodes needs to be balanced, you can add the **-include** parameter in the script to specify the nodes to be migrated. You can run commands to view the usage of different parameters.

  For example, run the **bash /opt/client/HDFS/hadoop/sbin/start-balancer.sh -threshold 5 -include** *IP address 1,IP address 2,IP address 3* command.
- **/opt/client** is the client installation directory. If the directory is inconsistent, replace it.
- If the command fails to be executed and the error information **Failed to APPEND_FILE /system/balancer.id** is displayed in the log, run the following command to forcibly delete **/system/balancer.id** and run the **start-balancer.sh** script again:

  hdfs dfs -rm -f /system/balancer.id

Step 7 After you run the script in **Step 6**, the **hadoop-root-balancer-***Host name***.out** log file is generated in **/opt/client/HDFS/hadoop/logs**, the client installation directory. You can view the following information in the log:

- Time Stamp
- Bytes Already Moved
- Bytes Left To Move
- Bytes Being Moved

If message "Balance took *xxx* seconds" is displayed in the log, the balancing operation is complete.

----End

Related Tasks

Enable automatic execution of the balance task

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, search for the following parameters, and change the parameter values.

- **dfs.balancer.auto.enable** indicates whether to enable automatic balance task execution. The default value **false** indicates that automatic balance task execution is disabled. The value **true** indicates that automatic execution is enabled.
- **dfs.balancer.auto.cron.expression** indicates the task execution time. The default value **0 1 * * 6** indicates that the task is executed at 01:00 every Saturday. This parameter is valid only when the automatic execution is enabled.

  Table 10-5 describes the expression for modifying this parameter. ***** indicates consecutive time segments.

  Table 10-5 Parameters in the execution expression

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

- **dfs.balancer.auto.stop.cron.expression** indicates the task ending time. The default value is empty, indicating that the running balance task is not automatically stopped. For example, **0 5 * * 6** indicates that the balance task is stopped at 05:00 every Saturday. This parameter is valid only when the automatic execution is enabled.

  Table 10-5 describes the expression for modifying this parameter. ***** indicates consecutive time segments.

Step 3 Running parameters of the balance task that is automatically executed are shown in Table 10-6.

Table 10-6 Running parameters of the automatic balancer

Parameter	Parameter description	Default Value
dfs.balancer.auto.threshold	Specifies the balancing threshold of the disk capacity percentage. This parameter is valid only when **dfs.balancer.auto.enable** is set to **true**.	10
dfs.balancer.auto.exclude.datanodes	Specifies the list of DataNodes on which automatic disk balancing is not required. This parameter is valid only when **dfs.balancer.auto.enable** is set to **true**.	The value is left blank by default.
dfs.balancer.auto.bandwidthPerSec	Specifies the maximum bandwidth (MB/s) of each DataNode for load balancing.	20
dfs.balancer.auto.maxIdleIterations	Specifies the maximum number of consecutive idle iterations of Balancer. An idle iteration is an iteration without moving blocks. When the number of consecutive idle iterations reaches the maximum number, the balance task ends. The value **-1** indicates infinity.	5
dfs.balancer.auto.maxDataNodesNum	Controls the number of DataNodes that perform automatic balance tasks. Assume that the value of this parameter is *N*. If *N* is greater than 0, data is balanced between *N* DataNodes with the highest percentage of remaining space and *N* DataNodes with the lowest percentage of remaining space. If *N* is 0, data is balanced among all DataNodes in the cluster.	5

Step 4 Click **Save** to make configurations take effect. You do not need to restart the HDFS service.

Go to the **/var/log/Bigdata/hdfs/nn/hadoop-omm-balancer-***Host name***.log** file to view the task execution logs saved in the active NameNode.

----End

10.7 Configuring HDFS DiskBalancer

Scenario

DiskBalancer is an online disk balancer that balances disk data on running DataNodes based on various indicators. It works in the similar way of the HDFS Balancer. The difference is that HDFS Balancer balances data between DataNodes, while HDFS DiskBalancer balances data among disks on a single DataNode.

Data among disks may be unevenly distributed if a large number of files have been deleted from a cluster running for a long time, or disk capacity expansion is performed on a node in the cluster. Uneven data distribution may deteriorate the concurrent read/write performance of the HDFS, or cause service failure due to inappropriate HDFS write policies. In this case, the data density among disks on a node needs to be balanced to prevent heterogeneous small disks from becoming the performance bottleneck of the node.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-7 Parameter description

Parameter	Description	Default Value
dfs.disk.balancer.auto.enabled	Indicates whether to enable the HDFS DiskBalancer function. The default value is **false**, indicating that this function is disabled.	false
dfs.disk.balancer.auto.cron.expression	CRON expression of the HDFS disk balancing operation, which is used to control the start time of the balancing operation. This parameter is valid only when **dfs.disk.balancer.auto.enabled** is set to **true**. The default value is **0 1 * * 6**, indicating that tasks are executed at 01:00 every Saturday. For details about cron expression, see **Table 10-8**. The default value indicates that the DiskBalancer check is executed at 01:00 every Saturday.	0 1 * * 6
dfs.disk.balancer.max.disk.throughputInMBperSec	Specifies the maximum disk bandwidth that can be used for disk data balancing. The unit is MB/s, and the default value is **10**. Set this parameter based on the actual disk conditions of the cluster.	10
dfs.disk.balancer.max.disk.errors	Specifies the maximum number of errors that are allowed in a specified movement process. If the value exceeds this threshold, the movement fails.	5

Parameter	Description	Default Value
dfs.disk.balancer.block.tolerance.percent	Specifies the difference threshold between the data storage capacity and perfect status of each disk during data balancing among disks. For example, the ideal data storage capacity of each disk is 1 TB, and this parameter is set to **10**. When the data storage capacity of the target disk reaches 900 GB, the storage status of the disk is considered as perfect. Value range: 1 to 100.	10
dfs.disk.balancer.plan.threshold.percent	Specifies the data density difference that is allowed between two disks during disk data balancing. If the absolute value of the data density difference between any two disks exceeds the threshold, data balancing is required. Value range: 1 to 100.	10
dfs.disk.balancer.top.nodes.number	Specifies the top *N* nodes whose disk data needs to be balanced in the cluster.	5

To use this function, set **dfs.disk.balancer.auto.enabled** to **true** and configure a proper CRON expression. Set other parameters based on the cluster status.

Table 10-8 CRON expressions

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

Use Restrictions

1. Data can only be moved between disks of the same type. For example, data can only be moved between SSDs or between DISKs.
2. Enabling this function occupies disk I/O resources and network bandwidth resources of involved nodes. Enable this function in off-peak hours.
3. The DataNodes specified by the **dfs.disk.balancer.top.nodes.number** parameter are frequently calculated. Therefore, set the parameter to a small value.

4. Commands for using the DiskBalancer function on the HDFS client are as follows:

Table 10-9 DiskBalancer commands

Syntax	Description
hdfs diskbalancer -report -top <N>	Set *N* to an integer greater than 0. This command can be used to query the top *N* nodes that require disk data balancing in the cluster.
hdfs diskbalancer -plan <Hostname|IP Address>	This command can be used to generate a JSON file based on the DataNode. The file contains information about the source disk, target disk, and blocks to be moved. In addition, this command can be used to specify other parameters such as the network bandwidth.
hdfs diskbalancer -query <Hostname:$dfs.datanode.ipc.port>	The default port number of the cluster is 9867. This command is used to query the running status of the DiskBalancer task on the current node.
hdfs diskbalancer -execute <planfile>	In this command, **planfile** indicates the JSON file generated in the second command. Use the absolute path.
hdfs diskbalancer -cancel <planfile>	This command is used to cancel the running planfile. Use the absolute path.

NOTE

- Users running this command on the client must have the **supergroup** permission. You can use the system user **hdfs** of the HDFS service. Alternatively, you can create a user with the **supergroup** permission in the cluster and then run the command.
- Only formats and usage of commands are provided in **Table 10-9**. For more parameters to be configured for each command, run the **hdfs diskbalancer -help <command>** command to view detailed information.
- When you troubleshoot performance problems during the cluster O&M, check whether the HDFS disk balancing occurs in the event information of the cluster. If yes, check whether DiskBalancer is enabled in the cluster.
- After the automatic DiskBalancer function is enabled, the ongoing task stops only after the current data balancing is complete. The task cannot be canceled during the balancing.
- You can manually specify certain nodes for data balancing on the client.

10.8 Configuring HDFS Mover

Scenario

Mover is a new data migration tool whose working mode is similar to that of the HDFS Balancer. Mover can redistribute data in the cluster based on the configured data storage policy.

Use Mover to periodically check whether the specified HDFS file or directory in the HDFS file system meets the preset storage policy. If not, migrate data to make them meet the policy.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-10 Parameter description

Parameter	Description	Default Value
dfs.mover.auto.enable	Specifies whether to enable the data replica migration function. This function supports multiple modes. The default value is **false**, indicating that this function is disabled.	false
dfs.mover.auto.cron.expression	Specifies the CRON expression for HDFS automatic data migration, and is used to control the start time of data migration. This parameter is valid only when **dfs.mover.auto.enable** is set to **true**. The default value is **0 * * * ***, indicating that the task is executed on the hour. For details about CRON expression, see **Table 10-11**.	0 * * * *
dfs.mover.auto.hdfsfiles_or_dirs	Specifies HDFS file and directory lists that implement automatic replica migration in specified clusters. Multiple values are separated by space. This parameter is valid only when **dfs.mover.auto.enable** is set to **true**.	-

Table 10-11 CRON expressions

Column	Description
1	Minute. The value ranges from 0 to 59.
2	Hour. The value ranges from 0 to 23.
3	Date. The value ranges from 1 to 31.

Column	Description
4	Month. The value ranges from 1 to 12.
5	Week. The value ranges from 0 to 6. **0** indicates Sunday.

Use Restrictions

Run the command on the HDFS client to enable the mover function. The command format is as follows:

hdfs mover -p *<Full path or directory path of an HDFS file >*

NOTE

Users running this command on the client must have the **supergroup** permission. You can use the system user **hdfs** of the HDFS service. Alternatively, you can create a user with the **supergroup** permission in the cluster and then run the command.

10.9 Configuring HDFS NodeLabel

Scenario

You need to configure the nodes for storing HDFS file data blocks based on data features. You can configure a label expression to an HDFS directory or file and assign one or more labels to a DataNode so that file data blocks can be stored on specified DataNodes.

If the label-based data block placement policy is used for selecting DataNodes to store the specified files, the DataNode range is specified based on the label expression. Then proper nodes are selected from the specified range.

- Scenario 1: DataNodes partitioning scenario

  Scenario description:

  When different application data is required to run on different nodes for separate management, label expressions can be used to achieve separation of different services, storing specified services on corresponding nodes.

  By configuring the NodeLabel feature, you can perform the following operations:

  - Store data in **/HBase** to DN1, DN2, DN3, and DN4.
  - Store data in **/Spark** to DN5, DN6, DN7, and DN8.

Figure 10-9 DataNode partitioning scenario

NOTE

- Run the **hdfs nodelabel -setLabelExpression -expression 'LabelA[fallback=NONE]' -path /Hbase** command to set an expression for the **Hbase** directory. As shown in **Figure 10-9**, the data block replicas of files in the **/Hbase** directory are placed on the nodes labeled with the **LabelA**, that is, DN1, DN2, DN3, and DN4. Similarly, run the **hdfs nodelabel -setLabelExpression -expression 'LabelB[fallback=NONE]' -path /Spark** command to set an expression for the Spark directory. Data block replicas of files in the **/Spark** directory can be placed only on nodes labeled with **LabelB**, that is, DN5, DN6, DN7, and DN8.
- For details about how to set labels for a data node, see **Configuration Description**.
- If multiple racks are available in one cluster, it is recommended that DataNodes of these racks should be available under each label, to ensure reliability of data block placement.

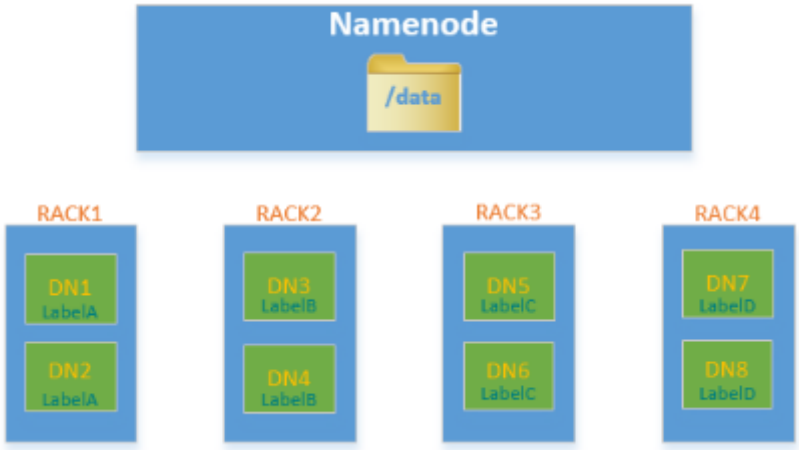
- Scenario 2: Specifying replica location when there are multiple racks

  Scenario description:

  In a heterogeneous cluster, customers need to allocate certain nodes with high availability to store important commercial data. Label expressions can be used to specify replica location so that the replica can be placed on a high reliable node.

  Data blocks in the **/data** directory have three replicas by default. In this case, at least one replica is stored on a node of RACK1 or RACK2 (nodes of RACK1 and RACK2 are high reliable), and the other two are stored separately on the nodes of RACK3 and RACK4.

Figure 10-10 Scenario example



NOTE

Run the **hdfs nodelabel -setLabelExpression -expression 'LabelA|| LabelB[fallback=NONE],LabelC,LabelD' -path /data** command to set an expression for the **/data** directory.

When data is to be written to the **/data** directory, at least one data block replica is stored on a node labeled with the LabelA or LabelB, and the other two data block replicas are stored separately on the nodes labeled with the LabelC and LabelD.

Configuration Description

- DataNode label configuration

  Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

  Table 10-12 Parameter description

Parameter	Description	Default Value
dfs.block.replicator.classname	Used to configure the DataNode policy of HDFS. To enable the NodeLabel function, set this parameter to **org.apache.hadoop.hdfs.server.blockmanagement.BlockPlacementPolicyWithNodeLabel**.	org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy

Parameter	Description	Default Value
host2tags	Used to configure a mapping between a DataNode host and a label. The host name can be configured with an IP address extension expression (for example, **192.168.1.[1-128]** or **192.168.[2-3].[1-128]**) or a regular expression (for example, **/datanode-[123]/** or **/datanode-\d{2}/**) starting and ending with a slash (/). The label configuration name cannot contain the following characters: = / \ **Note**: The IP address must be a service IP address.	-

NOTE

- The **host2tags** configuration item is described as follows:

  Assume there are 20 DataNodes which range from dn-1 to dn-20 in a cluster and the IP addresses of clusters range from 10.1.120.1 to 10.1.120.20. The value of **host2tags** can be represented in either of the following methods:

  Regular expression of the host name

  /dn-\d/ = label-1 indicates that the labels corresponding to dn-1 to dn-9 are label-1, that is, dn-1 = label-1, dn-2 = label-1, ..., dn-9 = label-1.

  /dn-((1[0-9]$)|(20$))/ = label-2 indicates that the labels corresponding to dn-10 to dn-20 are label-2, that is, dn-10 = label-2, dn-11 = label-2, ...dn-20 = label-2.

  IP address range expression

  10.1.120.[1-9] = label-1 indicates that the labels corresponding to 10.1.120.1 to 10.1.120.9 are label-1, that is, 10.1.120.1 = label-1, 10.1.120.2 = label-1, ..., and 10.1.120.9 = label-1.

  10.1.120.[10-20] = label-2 indicates that the labels corresponding to 10.1.120.10 to 10.1.120.20 are label-2, that is, 10.1.120.10 = label-2, 10.1.120.11 = label-2, ..., and 10.1.120.20 = label-2.

- Label-based data block placement policies are applicable to capacity expansion and reduction scenarios.

  A newly added DataNode will be assigned a label if the IP address of the DataNode is within the IP address range in the **host2tags** configuration item or the host name of the DataNode matches the host name regular expression in the **host2tags** configuration item.

  For example, the value of **host2tags** is **10.1.120.[1-9] = label-1**, but the current cluster has only three DataNodes: 10.1.120.1 to 10.1.120.3. If DataNode 10.1.120.4 is added for capacity expansion, the DataNode is labeled as label-1. If the 10.1.120.3 DataNode is deleted or out of the service, no data block will be allocated to the node.

- Set label expressions for directories or files.
  - On the HDFS parameter configuration page, configure **path2expression** to configure the mapping between HDFS directories and labels. If the configured HDFS directory does not exist, the configuration can succeed. When a directory with the same name as the HDFS directory is created manually, the configured label mapping relationship will be inherited by the directory within 30 minutes. After a labeled directory is deleted, a

new directory with the same name as the deleted one will inherit its mapping within 30 minutes.

- For details about configuring items using commands, see the **hdfs nodelabel -setLabelExpression** command.
- To set label expressions using the Java API, invoke the **setLabelExpression(String src, String labelExpression)** method using the instantiated object NodeLabelFileSystem. *src* indicates a directory or file path on HDFS, and **labelExpression** indicates the label expression.

- After the NodeLabel is enabled, you can run the **hdfs nodelabel -listNodeLabels** command to view the label information of each DataNode.

Block Replica Location Selection

Nodelabel supports different placement policies for replicas. The expression **label-1,label-2,label-3** indicates that three replicas are respectively placed in DataNodes containing label-1, label-2, and label-3. Different replica policies are separated by commas (,).

If you want to place two replicas in DataNode with label-1, set the expression as follows: **label-1[replica=2],label-2,label-3**. In this case, if the default number of replicas is 3, two nodes with label-1 and one node with label-2 are selected. If the default number of replicas is 4, two nodes with label-1, one node with label-2, and one node with label-3 are selected. Note that the number of replicas is the same as that of each replica policy from left to right. However, the number of replicas sometimes exceeds the expressions. If the default number of replicas is 5, the extra replica is placed on the last node, that is, the node labeled with label-3.

When the ACLs function is enabled and the user does not have the permission to access the labels used in the expression, the DataNode with the label is not selected for the replica.

Deletion of Redundant Block Replicas

If the number of block replicas exceeds the value of **dfs.replication** (number of file replicas specified by the user), HDFS will delete redundant block replicas to ensure cluster resource usage.

The deletion rules are as follows:

- Preferentially delete replicas that do not meet any expression.

  For example: The default number of file replicas is **3**.

  The label expression of **/test** is **LA[replica=1],LB[replica=1],LC[replica=1]**.

  The file replicas of **/test** are distributed on four nodes (D1 to D4), corresponding to labels (LA to LD).

  ```
  D1:LA
  D2:LB
  D3:LC
  D4:LD
  ```

  Then, block replicas on node D4 will be deleted.

- If all replicas meet the expressions, delete the redundant replicas which are beyond the number specified by the expression.

  For example: The default number of file replicas is **3**.

The label expression of **/test** is **LA[replica=1],LB[replica=1],LC[replica=1]**.

The file replicas of **/test** are distributed on the following four nodes, corresponding to the following labels.

```
D1:LA
D2:LA
D3:LB
D4:LC
```

Then, block replicas on node D1 or D2 will be deleted.

- If a file owner or group of a file owner cannot access a label, preferentially delete the replica from the DataNode mapped to the label.

Example of label-based block placement policy

Assume that there are six DataNodes, namely, dn-1, dn-2, dn-3, dn-4, dn-5, and dn-6 in a cluster and the corresponding IP address range is 10.1.120.[1-6]. Six directories must be configured with label expressions. The default number of block replicas is **3**.

- The following provides three expressions of the DataNode label in **host2labels** file. The three expressions have the same function.
  - Regular expression of the host name

    ```
    /dn-[1456]/ = label-1,label-2
    /dn-[26]/ = label-1,label-3
    /dn-[3456]/ = label-1,label-4
    /dn-5/ = label-5
    ```

  - IP address range expression

    ```
    10.1.120.[1-6] = label-1
    10.1.120.1 = label-2
    10.1.120.2 = label-3
    10.1.120.[3-6] = label-4
    10.1.120.[4-6] = label-2
    10.1.120.5 = label-5
    10.1.120.6 = label-3
    ```

  - Common host name expression

    ```
    /dn-1/ = label-1, label-2
    /dn-2/ = label-1, label-3
    /dn-3/ = label-1, label-4
    /dn-4/ = label-1, label-2, label-4
    /dn-5/ = label-1, label-2, label-4, label-5
    /dn-6/ = label-1, label-2, label-3, label-4
    ```

- The label expressions of the directories are set as follows:

  ```
  /dir1 = label-1
  /dir2 = label-1 && label-3
  /dir3 = label-2 || label-4[replica=2]
  /dir4 = (label-2 || label-3) && label-4
  /dir5 = !label-1
  /sdir2.txt = label-1 && label-3[replica=3,fallback=NONE]
  /dir6 = label-4[replica=2],label-2
  ```

  NOTE

  For details about the label expression configuration, see the **hdfs nodelabel -setLabelExpression** command.

  The file data block storage locations are as follows:

  - Data blocks of files in the **/dir1** directory can be stored on any of the following nodes: dn-1, dn-2, dn-3, dn-4, dn-5, and dn-6.
  - Data blocks of files in the **/dir2** directory can be stored on the dn-2 and dn-6 nodes. The default number of block replicas is **3**. The expression

matches only two DataNodes. The third replica will be stored on one of the remaining nodes in the cluster.

- Data blocks of files in the **/dir3** directory can be stored on any three of the following nodes: dn-1, dn-3, dn-4, dn-5, and dn-6.
- Data blocks of files in the **/dir4** directory can be stored on the dn-4, dn-5, and dn-6 nodes.
- Data blocks of files in the **/dir5** directory do not match any DataNode and will be stored on any three nodes in the cluster, which is the same as the default block selection policy.
- For the data blocks of the **/sdir2.txt** file, two replicas are stored on the dn-2 and dn-6 nodes. The left one is not stored in the node because **fallback=NONE** is enabled.
- Data blocks of the files in the **/dir6** directory are stored on the two nodes with label-4 selected from dn-3, dn-4, dn-5, and dn-6 and another node with label-2. If the specified number of file replicas in the **/dir6** directory is more than 3, the extra replicas will be stored on a node with label-2.

Restrictions

In configuration files, **key** and **value** are separated by equation signs (=), colons (:), and whitespace. Therefore, the host name of the **key** cannot contain these characters because these characters may be considered as separators.

10.10 Configuring Memory Management

Scenario

In HDFS, each file object needs to register corresponding information in the NameNode and occupies certain storage space. As the number of files increases, if the original memory space cannot store the corresponding information, you need to change the memory size.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-13 Parameter description

Parameter	Description	Default Value
GC_PROFILE	The NameNode memory size depends on the size of FsImage, which can be calculated based on the following formula: FsImage size = Number of files x 900 bytes. You can estimate the memory size of the NameNode of HDFS based on the calculation result. The value range of this parameter is as follows: • **high**: 4 GB • **medium**: 2 GB • **low**: 256 MB • **custom**: The memory size can be set according to the data size in GC_OPTS.	custom
GC_OPTS	JVM parameter used for garbage collection (GC). This parameter is valid only when **GC_PROFILE** is set to **custom**. Ensure that the **GC_OPT** parameter is set correctly. Otherwise, the process will fail to be started. **NOTICE** Exercise caution when you modify the configuration. If the configuration is incorrect, the services are unavailable.	-Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=2048

10.11 Configuring ulimit for HBase and HDFS

Symptom

When an HDFS file is opened and the number of handles is limited, the following error occurs:

```
IOException (Too many open files)
```

Procedure

You can contact the cluster administrator to increase the number of handles for each user. This is a configuration on the OS instead of that for HBase or HDFS. It is recommended that the cluster administrator set the number of handles based on the service volume of HBase and HDFS and the permissions of each user. If a user needs to frequently perform many operations on the HDFS with heavy service volume, set a large number of handles for the user to avoid the preceding error.

Step 1 Log in to operating systems of all nodes or clients in the cluster as user **root** and go to the **/etc/security** directory.

Step 2 Run the following command to edit the **limits.conf** file:

vi limits.conf

Added the following contents:

```
hdfs -       nofile  32768
hbase -      nofile  32768
```

hdfs and **hbase** indicate the OS user names used in services.

NOTE

- Only user **root** has the permission to edit the **limits.conf** file.
- If the modification does not take effect, check whether there are other **nofile** values for the OS user in the **/etc/security/limits.d** directory. Such values may overwrite the value configured in **/etc/security/limits.conf**.
- If a user needs to perform operations on HBase, it is recommended that the handle count of the user be set to more than 10,000. If a user needs to perform operations on HDFS, it is recommended that the handle count be set based on the service volume. (A small value is not recommended.) If a user needs to perform operations on HBase and HDFS, it is recommended that the handle count be set to a large value, for example, 32,768.

Step 3 You can run the following command to view the maximum number of handles of a user:

su - *user_name*

ulimit -n

The command output displays the maximum number of handles of the user. The following is an example.

```
8194
```

----End

10.12 Configuring the Number of Files in a Single HDFS Directory

Scenario

Generally, multiple services are deployed in a cluster, and the storage of most services depends on the HDFS file system. Different components such as Spark and Yarn or clients are constantly writing files to the same HDFS directory when the cluster is running. However, the number of files in a single directory in HDFS is limited. Users must plan to prevent excessive files in a single directory and task failure.

You can set the number of files in a single directory using the **dfs.namenode.fs-limits.max-directory-items** parameter in HDFS.

Procedure

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 Search for the configuration item **dfs.namenode.fs-limits.max-directory-items**.

Table 10-14 Parameter description

Parameter	Description	Default Value
dfs.namenode.fs-limits.max-directory-items	Maximum number of items in a directory Value range: 1 to 6,400,000	1048576

Step 3 Set the maximum number of files that can be stored in a single HDFS directory. Save the modified configuration. Restart the expired service or instance for the configuration to take effect.

NOTE

Plan data storage in advance based on time and service type categories to prevent excessive files in a single directory. You are advised to use the default value, which is about 1 million pieces of data in a single directory.

----End

10.13 Enterprise-Class Enhancements of HDFS

10.13.1 Configuring the HDFS Quick File Close Function

Scenario

By default, an HDFS file can be closed only if all blocks are reported (in the **COMPLETED** state). Therefore, the write performance of HDFS is affected by waiting for DataNode blocks and NameNode processing blocks to be reported. For a cluster with heavy load, the waiting consumption has a great impact on the cluster. You can configure the **dfs.namenode.file.close.num-committed-allowed** parameter of HDFS to close files in advance to improve data write performance. However, data may fail to be read because the block cannot be found or the data block information recorded in the NameNode metadata is inconsistent with that stored in the DataNode. Therefore, this feature does not apply to the scenario where data is read immediately after being written. Exercise caution when using this feature.

NOTE

This section applies to MRS 3.2.0-LTS.1 or later.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HDFS** and click the **Configurations** tab and then **All Configurations**.

Step 3 Search for and modify the **dfs.namenode.file.close.num-committed-allowed** parameter. For more information, see the following table.

Parameter	Description
dfs.namenode.file.close.num-committed-allowed	Maximum number of blocks in the **COMMITTED** state in the file to be closed. The default value is 0, indicating that this feature is disabled. If this feature is enabled, the recommended value is **1** or **2**. For example, if this parameter is set to **1**, it indicates that a file can be closed without waiting for status of the last block status to change to **COMPLETED**.

Step 4 Save the configuration.

Step 5 On the **Instance** page of HDFS, select the active and standby NameNode instances, choose **More** > **Instance Rolling Restart**, and wait until the rolling restart is complete.

----End

10.13.2 Configuring Replica Replacement Policy for Heterogeneous Capacity Among DataNodes

Scenario

By default, NameNode randomly selects a DataNode to write files. If the disk capacity of some DataNodes in a cluster is inconsistent (the total disk capacity of some nodes is large and of some nodes is small), the nodes with small disk capacity will be fully written. To resolve this problem, change the default disk selection policy for data written to DataNode to the available space block policy. This policy increases the probability of writing data blocks to the node with large available disk space. This ensures that the node usage is balanced when disk capacity of DataNodes is inconsistent.

Impact on the System

The disk selection policy is changed to **org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**. It is proven that the HDFS file write performance optimizes by 3% after the modification.

NOTE

The default replica storage policy of the NameNode is as follows:

1. First replica: stored on the node where the client resides.
2. Second replica: stored on DataNodes of the remote rack.
3. Third replica: stored on different nodes of the same rack for the node where the client resides.

If there are more replicas, randomly store them on other DataNodes.

The replica selection mechanism (**org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**) is as follows:

1. First replica: stored on the DataNode where the client resides (the same as the default storage policy).
2. Second replica:
   - When selecting a storage node, select two data nodes that meet the requirements.
   - Compare the disk usages of the two DataNodes. If the difference is smaller than 5%, store the replicas to the first node.
   - If the difference exceeds 5%, there is a 60% probability (specified by **dfs.namenode.available-space-block-placement-policy.balanced-space-preference-fraction** and default value is **0.6**) that the replica is written to the node whose disk space usage is low.
3. As for the storage of the third replica and subsequent replicas, refer to that of the second replica.

Prerequisites

The total disk capacity deviation of DataNodes in the cluster cannot exceed 100%.

Procedure

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 Modify the disk selection policy parameters when HDFS writes data. Search for the **dfs.block.replicator.classname** parameter and change its value to **org.apache.hadoop.hdfs.server.blockmanagement.AvailableSpaceBlockPlacementPolicy**.

Step 3 Save the modified configuration. Restart the expired service or instance for the configuration to take effect.

----End

10.13.3 Configuring Reserved Percentage of Disk Usage on DataNodes

Scenario

When the Yarn local directory and DataNode directory are on the same disk, the disk with larger capacity can run more tasks. Therefore, more intermediate data is stored in the Yarn local directory.

Currently, you can set **dfs.datanode.du.reserved** to configure the absolute value of the reserved disk space on DataNodes. A small value cannot meet the requirements of a disk with large capacity. However, configuring a large value for a disk with same capacity wastes a lot of disk space.

To avoid this problem, a new parameter **dfs.datanode.du.reserved.percentage** is introduced to configure the reserved percentage of the disk space.

NOTE

- If **dfs.datanode.du.reserved.percentage** and **dfs.datanode.du.reserved** are configured at the same time, the larger value of the reserved disk space calculated using the two parameters is used as the reserved space of the data nodes.
- You are advised to set **dfs.datanode.du.reserved** or **dfs.datanode.du.reserved.percentage** based on the actual disk space.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-15 Parameter description

Parameter	Description	Default Value
dfs.datanode.du.reserved.percentage	Indicates the percentage of the reserved disk space on DataNodes. The DataNode permanently reserves the disk space calculated using this percentage. The value is an integer ranging from 0 to 100.	10

10.13.4 Configuring the NameNode Blacklist

Scenario

In the existing default DFSclient failover proxy provider, if a NameNode in a process is faulty, all HDFS client instances in the same process attempt to connect to the NameNode again. As a result, the application waits for a long time and timeout occurs.

When clients in the same JVM process connect to the NameNode that cannot be accessed, the system is overloaded. The NameNode blacklist is equipped with the MRS cluster to avoid this problem.

In the new Blacklisting DFSClient failover provider, the faulty NameNode is recorded in a list. The DFSClient then uses the information to prevent the client from connecting to such NameNodes again. This function is called NameNode blacklisting.

For example, there is a cluster with the following configurations:

namenode: nn1, nn2

dfs.client.failover.connection.retries: 20

Processes in a single JVM: 10 clients

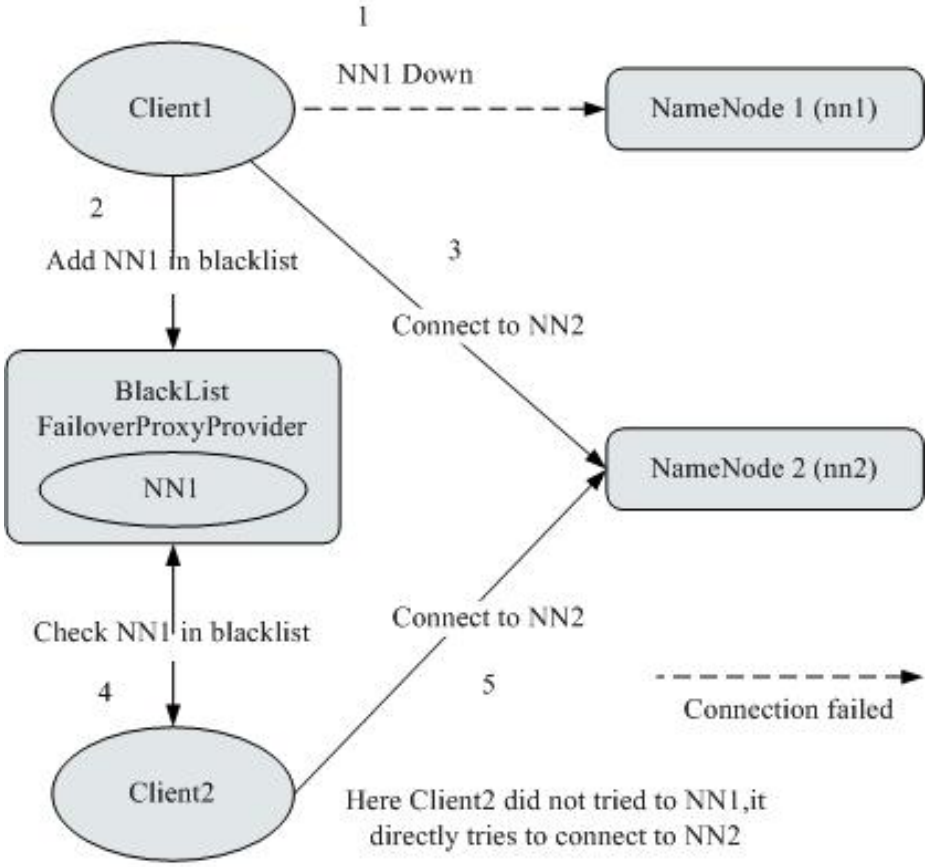
In the preceding cluster, if the active **nn1** cannot be accessed, client1 will retry the connection for 20 times. Then, a failover occurs, and client1 will connect to **nn2**. In the same way, other clients also connect to **nn2** when the failover occurs after retrying the connection to **nn1** for 20 times. Such process prolongs the fault recovery of NameNode.

In this case, the NameNode blacklisting adds **nn1** to the blacklist when client1 attempts to connect to the active **nn1** which is already faulty. Therefore, other clients will avoid trying to connect to **nn1** but choose **nn2** directly.

NOTE

If, at any time, all NameNodes are added to the blacklist, the content in the blacklist will be cleared, and the client attempts to connect to the NameNodes based on the initial NameNode list. If any fault occurs again, the NameNode is still added to the blacklist.

Figure 10-11 NameNode blacklisting working principle



Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-16 NameNode blacklisting parameters

Parameter	Description	Default Value
dfs.client.failover.proxy.provider.*[nameservice ID]*	Client Failover proxy provider class which creates the NameNode proxy using the authenticated protocol. Set this parameter to **org.apache.hadoop.hdfs.server.namenode.ha.BlackListingFailoverProxyProvider**. You can configure the observer NameNode to process read requests.	org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider

10.13.5 Configuring Encrypted Channels

Scenario

Encrypted channel is an encryption protocol of remote procedure call (RPC) in HDFS. When a user invokes RPC, the user's login name will be transmitted to RPC through RPC head. Then RPC uses Simple Authentication and Security Layer (SASL) to determine an authorization protocol (Kerberos and DIGEST-MD5) to complete RPC authorization. When you deploy a security cluster, use a secure encrypted channel and configure the following parameters: For details about secure Hadoop RPC, visit the following website:

Versions earlier than MRS 3.2.0: **https://hadoop.apache.org/docs/r3.1.1/hadoop-project-dist/hadoop-common/SecureMode.html#Data_Encryption_on_RPC**

MRS 3.2.0 or later: **https://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-common/SecureMode.html#Data_Encryption_on_RPC**

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-17 Parameter description

Parameter	Description	Default Value
hadoop.rpc.protection	**NOTICE** • The setting takes effect only after the service is restarted. Rolling restart is not supported. • After the setting, you need to download the client configuration again. Otherwise, the HDFS cannot provide the read and write services. Whether the RPC channels of each module in Hadoop are encrypted. The channels include: • RPC channels for clients to access HDFS • RPC channels between modules in HDFS, for example, RPC channels between DataNode and NameNode • RPC channels for clients to access Yarn • RPC channels between NodeManager and ResourceManager • RPC channels for Spark to access Yarn and HDFS • RPC channels for MapReduce to access Yarn and HDFS • RPC channels for HBase to access HDFS **NOTE** You can set this parameter on the HDFS component configuration page. The parameter setting takes effect globally, that is, the setting of whether the RPC channel is encrypted takes effect on all modules in Hadoop. There are three encryption modes. • **authentication**: This is the default value in normal mode. In this mode, data is directly transmitted without encryption after being authenticated. This mode ensures performance but has security risks. • **integrity**: Data is transmitted without encryption or authentication. To ensure data security, exercise caution when using this mode. • **privacy**: This is the default value in security mode, indicating that data is transmitted after authentication and encryption. This mode reduces the performance.	• Security mode: privacy • Normal mode: authentication

10.13.6 Configuring HDFS Hedged Read

This section is available for MRS 3.3.1 or later version only.

Scenario

In traditional HDFS, when a client requests to read data, it communicates with the NameNode to determine the DataNodes where the data block is and then connects to one node for data transmission. If the connected DataNode responds slowly or is faulty, the client must wait before attempting to obtain data from other replicas. There is a read latency. Enabling hedged read improves HDFS reliability in a high-latency network environment.

- Low read latency: The same data block is read from multiple data nodes at the same time.
- Adaptive to network changes: When the network is unstable or performance deteriorates on some nodes, the read efficiency of the client is improved.

Impact on the System

- Hedged read increases network loads and CPU usage because more connections and requests need to be processed. Enable this function based on the hardware and job conditions on the live network. For example, hedged read is enabled by default in a system that has three replicas. You need to set the component memory to at least three times the existing memory.
- When the disk I/O load is high (greater than 50% during peak hours), enabling hedged read may cause low disk performance deterioration.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HDFS** and click the **Configurations** tab and then **All Configurations**.

Step 3 Search for **hdfs.hdfs-site.customized.configs** and add the custom parameters listed in the following table. Set the parameters based on the site requirements.

Parameter	Description	Value Range
dfs.client.hedged.read.threshold.millis	The number of milliseconds the client waits for the first byte of the first data block before deciding whether to start a hedged read	Greater than or equal to 0
dfs.client.hedged.read.threadpool.size	Size of the hedged read thread pool. If this parameter is set to **0**, the hedged read function is disabled.	Greater than or equal to 0

Step 4 Save the settings.

Step 5 On the **Instance** page of HDFS, select all DataNode instances, choose **More** > **Instance Rolling Restart**, and wait until the rolling restart is complete.

----End

10.13.7 Configuring Fine-Grained Locks of HDFS

Scenario

In FusionInsight Manager historical versions, HDFS uses a global lock for read-write and write-write operations. However, not all read-write and write-write operations cause resource competition. Therefore, the fine-grained lock feature (FGL) is introduced in this version. FGL splits the global lock based on directories and operation types and only operations that compete for resources use the same lock, which greatly improves the read and write performance.

For example, if client 1 and client 2 write data to irrelevant directories A and B at the same time, they do not compete for resources and do not hold the same lock.

NOTE

This function is available in MRS 3.5.0 and later versions.

Procedure

Step 1 Log in to Manager as an MRS cluster administrator, for example, **admin**.

Step 2 Choose **Cluster** > **Services** > **HDFS** and click the **Configurations** tab and then **All Configurations**.

Step 3 Search for and modify the **dfs.namenode.fgl.enable** parameter. For more information, see the following table.

Parameter	Description	Remarks
dfs.namenode.fgl.enable	Specifies whether to enable the fine-grained lock. This parameter can improve the HDFS read and write performance once it is enabled.	Default value: **false**

Step 4 Save the configuration.

Step 5 On the **Instance** page of HDFS, select the active and standby NameNode instances, choose **More** > **Instance Rolling Restart**, and wait until the rolling restart is complete.

----End

10.13.8 HDFS Auto Recovery from Cluster Power-off

Scenario

HDFS data is written to the OS cache before being written to disks. HDFS considers that data write is complete after the data is written into the OS cache. The OS needs to write cached data to disks. If the cluster is powered off, the cached data will be lost and HDFS losses blocks. If this happens during HDFS startup, HDFS enters the safe mode and cannot be automatically recovered.

To solve this problem, HDFS provides the following configuration parameters to recover in the event of cluster power-off. You need to adjust the parameters based your needs.

- If **dfs.datanode.synconclose** is **true**, the system considers that the write operation is complete only after the OS cache data is written to the disk. This prevents data loss caused by cluster power-off. However, this will demange HDFS write performance.
- **dfs.namenode.safemode.threshold-pct** indicates the maximum percentage of blocks reported by DataNodes. If this threshold is reached, NameNodes automatically exit the safe mode. If this threshold is too small, there can be a large number of replicas during cluster startup.

NOTE

This function is available in MRS 3.5.0 and later versions.

Procedure

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **Cluster** > **Services** > **HDFS** and click the **Configurations** tab and then **All Configurations**.

Step 3 Search for and set the following parameters as required.

Parameter	Description	Default Value
dfs.datanode.synconclose	If this parameter is set to **false**, block data will not be written into the disk immediately in the event of power outage or system restart during the process of storing files, which may result in data loss. If this parameter is set to **true**, data loss can be avoided in the event of power outage or system restart, but the performance deteriorates. Set this parameter based on the application scenario.	false
dfs.namenode.safemode.threshold-pct	Percentage of blocks that meet the minimum replication requirements defined by **dfs.namenode.replication.min**. Value range: 0 to 1.0 • When the value is less than or equal to 0, NameNode will exit the safe mode without waiting for any blocks. • When the value is greater than 1, NameNode permanently keeps in the safe mode.	0.999999

Step 4 Save the configuration.

Step 5 In the HDFS **Instances** tab, select all NameNode and DataNode instances, choose **More** > **Instance Rolling Restart**, verify the password, confirm the operation impact, and click **OK**. Wait until the rolling restart is complete.

----End

10.14 HDFS Performance Tuning

10.14.1 Improving Write Performance

Scenario

Improve the HDFS write performance by modifying the HDFS attributes.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations** and select **All Configurations**. Enter a parameter name in the search box.

Table 10-18 Parameters for improving HDFS write performance

Parameter	Description	Default Value
dfs.datanode.drop.cache.behind.reads	Specifies whether to enable a DataNode to automatically clear all data in the cache after the data in the cache is transferred to the client. • **true**: The cached data is discarded. This parameter needs to be configured on the DataNode. You are advised to set it to **true** if data is repeatedly read only a few times, so that the cache can be used by other operations. • **false**: You are advised to set it to **false** if data is read repeatedly for many times to improve the read speed. **NOTE** This parameter is optional for improving write performance. You can configure it as needed.	false

Parameter	Description	Default Value
dfs.client-write-packet-size	Specifies the size of the client write packet. When the HDFS client writes data to the DataNode, the data will be accumulated until a packet is generated. Then, the packet is transmitted over the network. This parameter specifies the size (unit: byte) of the data packet to be transmitted, which can be specified by each job. In the 10-Gigabit network, you can increase the value of this parameter to enhance the transmission throughput.	262144

10.14.2 Improving Read Performance Using Client Metadata Cache

Scenario

Improve the HDFS read performance by using the client to cache the metadata for block locations.

NOTE

This function is recommended only for reading files that are not modified frequently. Because the data modification done on the server side by some other client is invisible to the cache client, which may cause the metadata obtained from the cache to be outdated.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, and enter the parameter name in the search box.

Table 10-19 Parameter configuration

Parameter	Description	Default Value
dfs.client.metadata.cache.enabled	Enables or disables the client to cache the metadata for block locations. Set this parameter to **true** and use it along with the **dfs.client.metadata.cache.pattern** parameter to enable the cache.	false

Parameter	Description	Default Value
dfs.client.metadata.cache.pattern	Indicates the regular expression pattern of the path of the file to be cached. Only the metadata for block locations of these files is cached until the metadata expires. This parameter is valid only when **dfs.client.metadata.cache.enabled** is set to **true**. Example: **/test.*** indicates that all files whose paths start with **/test** are read. **NOTE** • To ensure consistency, configure a specific mode to cache only files that are not frequently modified by other clients. • The regular expression pattern verifies only the path of the URI, but not the schema and authority in the case of the Fully Qualified path.	-
dfs.client.metadata.cache.expiry.sec	Indicates the duration for caching metadata. The cache entry becomes invalid after its caching time exceeds this duration. Even metadata that is frequently used during the caching process can become invalid. Time suffixes **s**/**m**/**h** can be used to indicate second, minute, and hour, respectively. **NOTE** If this parameter is set to **0s**, the cache function is disabled.	60s
dfs.client.metadata.cache.max.entries	Indicates the maximum number of non-expired data items that can be cached at a time.	65536

NOTE

Call *DFSClient#clearLocatedBlockCache()* to completely clear the client cache before it expires.

The sample usage is as follows:

```
FileSystem fs = FileSystem.get(conf);
DistributedFileSystem dfs = (DistributedFileSystem) fs;
DFSClient dfsClient = dfs.getClient();
dfsClient.clearLocatedBlockCache();
```

10.14.3 Improving the Connection Between the Client and NameNode Using Current Active Cache

Scenario

When HDFS is deployed in high availability (HA) mode with multiple NameNode instances, the HDFS client needs to connect to each NameNode in sequence to determine which is the active NameNode and use it for client operations.

Once the active NameNode is identified, its details can be cached and shared to all clients running on the client host. In this way, each new client first tries to load the details of the active Name Node from the cache and save the RPC call to the standby NameNode, which can help a lot in abnormal scenarios, for example, when the standby NameNode cannot be connected for a long time.

When a fault occurs and the other NameNode is switched to the active state, the cached details are updated to the information about the current active NameNode.

Procedure

Navigation path for setting parameters:

On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations**, select **All Configurations**, and enter the parameter name in the search box.

Table 10-20 Configuration parameters

Parameter	Description	Default Value
dfs.client.failover.proxy.provider.[nameservice ID]	Client Failover proxy provider class which creates the NameNode proxy using the authenticated protocol. If this parameter is set to **org.apache.hadoop.hdfs.server.namenode.ha.BlackListingFailoverProxyProvider**, you can use the NameNode blacklist feature on the HDFS client. If this parameter is set to **org.apache.hadoop.hdfs.server.namenode.ha.ObserverReadProxyProvider**, you can configure the observer NameNode to process read requests.	org.apache.hadoop.hdfs.server.namenode.ha.AdaptiveFailoverProxyProvider
dfs.client.failover.activeinfo.share.flag	Specifies whether to enable the cache function and share the detailed information about the current active NameNode with other clients. Set it to **true** to enable the cache function.	false

Parameter	Description	Default Value
dfs.client.failover.activeinfo.share.path	Specifies the local directory for storing the shared files created by all clients in the host. If a cache area is to be shared by different users, the directory must have required permissions (for example, creating, reading, and writing cache files in the specified directory).	/tmp
dfs.client.failover.activeinfo.share.io.timeout.sec	(Optional) Used to control timeout. The cache file is locked when it is being read or written, and if the file cannot be locked within the specified time, the attempt to read or update the caches will be abandoned. The unit is second.	5

NOTE

The cache files created by the HDFS client are reused by other clients, and thus these files will not be deleted from the local system. If this function is disabled, you may need to manually clear the data.

10.14.4 Reducing the Probability of Abnormal Client Application Operation When the Network Is Not Stable

Scenario

Clients probably encounter running errors when the network is not stable. Users can adjust the following parameter values to improve the running efficiency.

Configuration Description

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-21 Parameter description

Parameter	Description	Default Value
ha.health-monitor.rpc-timeout.ms	Timeout interval during the NameNode health check performed by ZKFC. Increasing this value can prevent dual active NameNodes and reduce the probability of application running exceptions on clients. Unit: millisecond. Value range: 30,000 to 3,600,000	180,000

Parameter	Description	Default Value
ipc.client.connect.max.retries.on.timeouts	Number of retry times when the socket connection between a server and a client times out. Value range: 1 to 256	45
ipc.client.connect.timeout	Timeout interval of the socket connection between a client and a server. Increasing the value of this parameter increases the timeout interval for setting up a connection. Unit: millisecond. Value range: 1 to 3,600,000	20,000

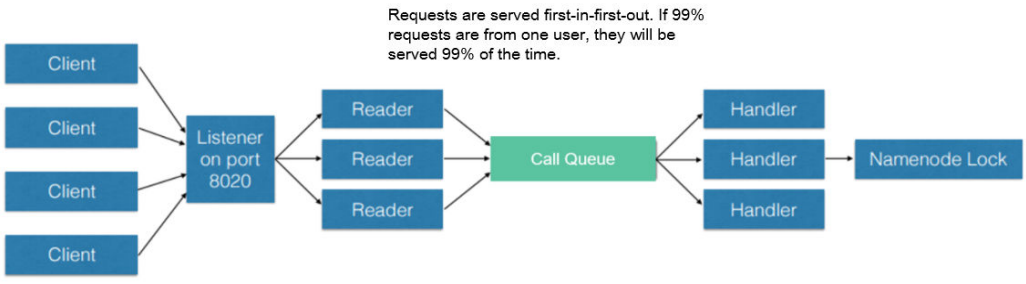
10.14.5 Optimizing HDFS NameNode RPC QoS

Scenarios

Several finished Hadoop clusters are faulty because the NameNode is overloaded and unresponsive.

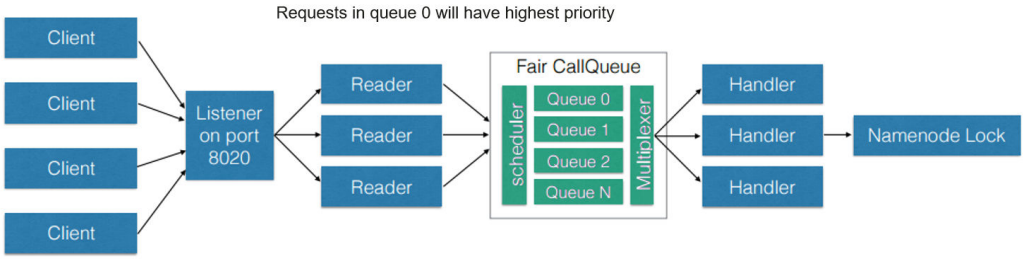
Such problem is caused by the initial design of Hadoop: In Hadoop, the NameNode functions as an independent part and in its namespace coordinates various HDFS operations, including obtaining the data block location, listing directories, and creating files. The NameNode receives HDFS operations, regards them as RPC calls, and places them in the FIFO call queue for read threads to process. Requests in FIFO call queue are served first-in first-out. However, users who perform more I/O operations are served more time than those performing fewer I/O operations. In this case, the FIFO is unfair and causes the delay.

Figure 10-12 NameNode request processing based on the FIFO call queue



The unfair problem and delaying mentioned before can be improved by replacing the FIFO queue with a new type of queue called FairCallQueue. In this way, FAIR queues assign incoming RPC calls to multiple queues based on the scale of the caller's call. The scheduling module tracks the latest calls and assigns a higher priority to users with a smaller number of calls.

Figure 10-13 NameNode request processing based on FAIRCallQueue



Configuration Description

- FairCallQueue ensures quality of service (QoS) by internally adjusting the order in which RPCs are invoked.

  This queue consists of the following parts:

  a. DecayRpcScheduler: used to provide priority values from 0 to N (the value 0 indicates the highest priority).

  b. Multi-level queues (located in the FairCallQueue): used to ensure that queues are invoked in order of priority.

  c. Multi-channel converters (provided with Weighted Round Robin Multiplexer): used to provide logic control for queue selection.

  After the FairCallQueue is configured, the control module determines the sub-queue to which the received invoking is allocated. The current scheduling module is DecayRpcScheduler, which only continuously tracks the priority numbers of various calls and periodically reduces these numbers.

  Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

  Table 10-22 FairCallQueue parameters

Parameter	Description	Default Value
ipc.*<port>*.callqueue.impl	Specifies the queue implementation class. You need to run the **org.apache.hadoop.ipc.FairCallQueue** command to enable the QoS feature.	java.util.concurrent.LinkedBlockingQueue

- RPC BackOff

  Backoff is one of the FairCallQueue functions. It requires the client to retry operations (such as creating, deleting, and opening a file) after a period of time. When the backoff occurs, the RCP server throws RetriableException. The FairCallQueue performs backoff in either of the following cases:

  – The queue is full, that is, there are many client calls in the queue.

  – The queue response time is longer than the threshold time (specified by the **ipc.<port>.decay-scheduler.backoff.responsetime.thresholds** parameter).

Table 10-23 RPC Backoff configuration

Parameter	Description	Default Value
ipc.*<port>*.backoff.enable	Specifies whether to enable the backoff. When the current application contains a large number of user callings, the RPC request is blocked if the connection limit of the operating system is not reached. Alternatively, when the RPC or NameNode is heavily loaded, some explicit exceptions can be thrown back to the client based on certain policies. The client can understand these exceptions and perform exponential rollback, which is another implementation of the RetryInvocationHandler class.	false
ipc.*<port>*.decay-scheduler.backoff.responsetime.enable	Indicate whether to enable the backoff based on the average queue response time.	false
ipc.*<port>*.decay-scheduler.backoff.responsetime.thresholds	Configure the response time threshold for each queue. The response time threshold must match the number of priorities (the value of **ipc.<port> .faircallqueue.priority-levels**). Unit: millisecond	10000,20000,30000,40000

NOTE

- **<port>** indicates the RPC port configured on the NameNode.
- The backoff function based on the response time takes effect only when **ipc.<port> .backoff.enable** is set to **true**.

10.14.6 Optimizing HDFS DataNode RPC QoS

Scenario

When the speed at which the client writes data to the HDFS is greater than the disk bandwidth of the DataNode, the disk bandwidth is fully occupied. As a result, the DataNode does not respond. The client can back off only by canceling or restoring the channel, which results in write failures and unnecessary channel recovery operations.

Configuration

The new configuration parameter **dfs.pipeline.ecn** is introduced. When this configuration is enabled, the DataNode sends a signal from the write channel when the write channel is overloaded. The client may perform backoff based on the blocking signal to prevent the system from being overloaded. This configuration parameter is introduced to make the channel more stable and reduce unnecessary cancellation or recovery operations. After receiving the signal, the client backs off for a period of time (5,000 ms), and then adjusts the backoff time based on the related filter (the maximum backoff time is 50,000 ms).

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-24 DN ECN configuration

Parameter	Description	Default Value
dfs.pipeline.ecn	After configuration, the DataNode can send blocking notifications to the client.	false

10.14.7 Performing Concurrent Operations on HDFS Files

Scenario

Performing this operation can concurrently modify file and directory permissions and access control tools in a cluster.

Impact on the System

Performing concurrent file modification operations in a cluster has adverse impacts on the cluster performance. Therefore, you are advised to do so when the cluster is idle.

Prerequisites

- The HDFS client or clients including HDFS has been installed. For example, the installation directory is **/opt/client**.

- Service component users have been created by the MRS cluster administrator. In security mode, machine-machine users need to download the keytab file. A human-machine user needs to change the password upon the first login. (This operation is not required in normal mode.)

Procedure

Step 1 Log in to the node where the client is installed as the client installation user.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, the user executing the DistCp command must belong to the **supergroup** group and run the following command to perform user authentication. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Increase the JVM size of the client to prevent out of memory (OOM). (32 GB is recommended for 100 million files.)

NOTE

The HDFS client exits abnormally and the error message "java.lang.OutOfMemoryError" is displayed after the HDFS client command is executed.

This problem occurs because the memory required for running the HDFS client exceeds the preset upper limit (128 MB by default). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>*/**HDFS/component_env**. For example, if you want to set the upper limit to 1 GB, run the following command:

CLIENT_GC_OPTS="-Xmx1G"

After the modification, run the following command to make the modification take effect:

source <*Client installation path*>/**/bigdata_env**

Step 6 Run the concurrent commands shown in the following table.

Command	Description	Function
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -setrep <rep> <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **rep** indicates the number of replicas. **path** indicates the HDFS directory.	Used to concurrently set the number of copies of all files in a directory.

Command	Description	Function
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -chown [owner][:[group]] <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **owner** indicates the owner. **group** indicates the group to which the user belongs. **path** indicates the HDFS directory.	Used to concurrently set the owner group of all files in the directory.
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -chmod <mode> <path> ...	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **mode** indicates the permission (for example, 754). **path** indicates the HDFS directory.	Used to concurrently set permissions for all files in a directory.
hdfs quickcmds [-t threadsNumber] [-p principal] [-k keytab] -setfacl [{-b|-k} {-m|-x <acl_spec>} <path> ...]|[--set <acl_spec> <path> ...]	**threadsNumber** indicates the number of concurrent threads. The default value is the number of vCPUs of the local host. **principal** indicates the Kerberos user. **keytab** indicates the Keytab file. **acl_spec** indicates the ACL list separated by commas (,). **path** indicates the HDFS directory.	Used to concurrently set ACL information for all files in a directory.

----End

10.14.8 Configuring LZC Compression

Scenario

File compression can reduce the space occupied by stored files, and fasten data reading from disks and data transmission in the network. HDFS supports two default compression formats: Gzip and Snappy. For the new compression format Lempel-Ziv compression (LZC), this section describes its configuration procedures. This compression format enhances the Hadoop compression capability. For more information about Snappy, see https://code.google.com/p/snappy/.

Configuration Description

To make the LZC compression take effect, configure the following parameters in the **core-site.xml** file (for example, *Client installation path*/**HDFS/hadoop/etc/hadoop/**) of the client:

Table 10-25 Parameter Description

Parameter	Description	Default Value
io.compression.codecs	To make LZC take effect, the following values are added to the existing compression format list: **com.huawei.hadoop.datasight.io.compress.lzc.ZCodec** **NOTE** If more than one compression format is configured, use commas (,) to separate them.	org.apache.hadoop.io.compress.BZip2Codec,org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.compress.DeflateCodec,org.apache.hadoop.io.compress.Lz4Codec,org.apache.hadoop.io.compress.SnappyCodec,org.apache.hadoop.io.compress.GzipCodec,org.apache.hadoop.io.compress.ZStandardCodec,com.huawei.hadoop.datasight.io.compress.lzc.ZCodec
io.compression.codec.lzc.class	To make the LZC compression format take effect, use the default value. If you configure this parameter, set it to **com.huawei.hadoop.datasight.io.compress.lzc.ZCodec**.	com.huaweixxx.hadoop.datasight.io.compress.lzc.ZCodec

NOTE

1. LZC does not support FSImage and SequenceFile compression.
2. HDFS provides multiple compression algorithms, including Gzip, LZ4, Snappy, and Bzip2. The compression ratio and decompression speed of these compression algorithms are as follows:

   Compression ratio in descending order: Bzip2 > Gzip > LZ4 > Snappy

   Decompression speed in descending order: LZ4 > Snappy > Gzip > Bzip2
3. Application scenarios:
   - In scenarios where speed is required, for example, intermediate data storage of MapReduce tasks, LZ4 and Snappy are recommended. However, Snappy is recommended in scenarios requiring high reliability.
   - In scenarios where the compression ratio instead of compression speed is highly required, for example, cold data storage, Bzip2 or Gzip is recommended.
4. Except LZC, the preceding compression algorithms can be implemented using Native (C language). The compression and decompression efficiency is high. You are advised to use the compression algorithm supporting Native implementation based on service scenarios.

10.14.9 Asynchronously Deleting HDFS Data

Scenario

The HDFS asynchronous deletion feature is used to delete large directories. Deleting blocks asynchronously with traffic control can effectively shorten the continuous lock period.

NOTE

This function is available in MRS 3.5.0 or later only.

Procedure

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 Enter the parameter name in the search box and **modify** the **HDFS service-level parameter** as you need.

Table 10-26 Parameters for configuring HDFS asynchronous deletion

Parameter	Description	Default Value
dfs.namenode.block.deletion.async	Whether to enable asynchronous block deletion.	true
dfs.namenode.block.deletion.lock.threshold.ms	Maximum duration for continuously lock a directory or file. After asynchronous block deletion is enabled, the specified maximum value is applied. Unit: millisecond	50

Parameter	Description	Default Value
dfs.namenode.block.deletion.lock.threshold.ms	Temporary unlock duration when the lock duration exceeds the maximum. Unit: millisecond	10

Step 3 Save the configuration.

Step 4 Click the **Instances** tab, select all instances whose configurations have expired, choose **More** > **Restart Instance**, and restart the instances as prompted.

----End

10.15 HDFS O&M Management

10.15.1 Configuring HDFS Parameters

Page Access

Go to the HDFS configurations page by referring to **Modifying Cluster Service Configuration Parameters**.

Parameter Description

Table 10-27 HDFS parameters

Parameter	Description	Default Value
fs.obs.security.provider	Implementation method of obtaining the key for accessing the OBS file system Value options are as follows: • **com.huawei.mrs.MrsObsCredentialsProvider**: obtains a credential through an MRS agency. • **com.obs.services.EcsObsCredentialsProvider**: obtains an AK/SK through the ECS service. • **com.obs.services.BasicObsCredentialsProvider**: uses the AK/SK information transferred to OBS. • **com.obs.services.EnvironmentVariableObsCredentialsProvider**: reads AK/SK information from environment variables.	com.huawei.mrs.MrsObsCredentialsProvider

10.15.2 Introduction to HDFS Logs

Log Description

Log path: The default path of HDFS logs is **/var/log/Bigdata/hdfs/***Role name*.

- NameNode: **/var/log/Bigdata/hdfs/nn** (run logs) and **/var/log/Bigdata/audit/hdfs/nn** (audit logs)
- DataNode: **/var/log/Bigdata/hdfs/dn** (run logs) and **/var/log/Bigdata/audit/hdfs/dn** (audit logs)
- ZKFC: **/var/log/Bigdata/hdfs/zkfc** (run logs) and **/var/log/Bigdata/audit/hdfs/zkfc** (audit logs)
- JournalNode: **/var/log/Bigdata/hdfs/jn** (run logs) and **/var/log/Bigdata/audit/hdfs/jn** (audit logs)
- Router: **/var/log/Bigdata/hdfs/router** (run logs) and **/var/log/Bigdata/audit/hdfs/router** (audit logs)
- HttpFS: **/var/log/Bigdata/hdfs/httpfs** (run logs) and **/var/log/Bigdata/audit/hdfs/httpfs** (audit logs)

Log archive rule: The automatic HDFS log compression function is enabled. By default, when the size of logs exceeds 100 MB, logs are automatically compressed into a log file named in the following format: *<Original log file name>-<yyyy-mm-dd_hh-mm-ss.[ID]>***.log.zip**. A maximum of 100 latest compressed files are reserved. The number of compressed files can be configured on Manager.

Table 10-28 HDFS log list

Type	Name	Description
Run log	hadoop-<SSH_USER>-<process_name>-<hostname>.log	HDFS system log, which records most of the logs generated when the HDFS system is running.
	hadoop-<SSH_USER>-<process_name>-<hostname>.out	Log that records the HDFS running environment information.
	hadoop.log	Log that records the operation of the Hadoop client.
	hdfs-period-check.log	Log that records scripts that are executed periodically, including automatic balancing, data migration, and JournalNode data synchronization detection.

Type	Name	Description
	<process_name>-<SSH_USER>-<DATE>-<PID>-gc.log	Garbage collection log file
	postinstallDetail.log	Work log before the HDFS service startup and after the installation.
	hdfs-service-check.log	Log that records whether the HDFS service starts successfully.
	hdfs-set-storage-policy.log	Log that records the HDFS data storage policies.
	cleanupDetail.log	Log that records the cleanup logs about the uninstallation of the HDFS service.
	prestartDetail.log	Log that records cluster operations before the HDFS service startup.
	hdfs-recover-fsimage.log	Recovery log of the NameNode metadata.
	datanode-disk-check.log	Log that records the disk status check during the cluster installation and use.
	hdfs-availability-check.log	Log that check whether the HDFS service is available.
	hdfs-backup-fsimage.log	Backup log of the NameNode metadata.
	startDetail.log	Detailed log that records the HDFS service startup.
	hdfs-blockplacement.log	Log that records the placement policy of HDFS blocks.
	upgradeDetail.log	Upgrade logs.
	hdfs-clean-acls-java.log	Log that records the clearing of deleted roles' ACL information by HDFS.

Type	Name	Description
	hdfs-haCheck.log	Run log that checks whether the NameNode in active or standby state has obtained scripts.
	<process_name>-jvmpause.log	Log that records JVM pauses during process running.
	hadoop-<SSH_USER>-balancer-<hostname>.log	Run log of HDFS automatic balancing.
	hadoop-<SSH_USER>-balancer-<hostname>.out	Log that records information of the environment where HDFS executes automatic balancing.
	hdfs-switch-namenode.log	Run log that records the HDFS active/standby switchover.
	hdfs-router-admin.log	Run log of the mount table management operation
	threadDump-<DATE>.log	Instance process stack log
Tomcat logs	hadoop-omm-host1.out, httpfs-catalina.<DATE>.log, httpfs-host-manager.<DATE>.log, httpfs-localhost.<DATE>.log, httpfs-manager.<DATE>.log, localhost_access_web_log.log	Tomcat run log
Audit log	hdfs-audit-<process_name>.log ranger-plugin-audit.log	Audit log that records the HDFS operations (such as creating, deleting, modifying and querying files).
	SecurityAuth.audit	HDFS security audit log.

Log Level

Table 10-29 lists the log levels supported by HDFS. The log levels include FATAL, ERROR, WARN, INFO, and DEBUG. Logs of which the levels are higher than or equal to the set level will be printed by programs. The higher the log level is set, the fewer the logs are recorded.

Table 10-29 Log levels

Level	Description
FATAL	Indicates the critical error information about system running.
ERROR	Indicates the error information about system running.
WARN	Indicates that the current event processing exists exceptions.
INFO	Indicates that the system and events are running properly.
DEBUG	Indicates the system and system debugging information.

To modify log levels, perform the following operations:

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**.

Step 2 On the left menu bar, select the log menu of the target role.

Step 3 Select a desired log level.

Step 4 Save the configuration. In the displayed dialog box, click **OK** to make the configurations take effect.

NOTE

The configurations take effect immediately without restarting the service.

----End

Log Formats

The following table lists the HDFS log formats.

Table 10-30 Log formats

Type	Format	Example
Run log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2015-01-26 18:43:42,840 | INFO | IPC Server handler 40 on 8020 | Rolling edit logs | org.apache.hadoop.hdfs.server.namenode.FSEditLog.rollEditLog(FSEditLog.java:1096)

Type	Format	Example
Audit log	*<yyyy-MM-dd HH:mm:ss,SSS>*|*<Log level>*|*<Name of the thread that generates the log>*|*<Message in the log>*|*<Location where the log event occurs>*	2015-01-26 18:44:42,607 | INFO | IPC Server handler 32 on 8020 | allowed=true ugi=hbase (auth:SIMPLE) ip=/10.177.112.145 cmd=getfileinfo src=/hbase/WALs/hghoulaslx410,16020,1421743096083/hghoulaslx410%2C16020%2C1421743096083.1422268722795 dst=null perm=null | org.apache.hadoop.hdfs.server.namenode.FSNamesystem$DefaultAuditLogger.logAuditMessage(FSNamesystem.java:7950)

10.15.3 Planning HDFS Capacity

In HDFS, DataNode stores user files and directories as blocks, and file objects are generated on the NameNode to map each file, directory, and block on the DataNode.

The file objects on the NameNode require certain memory capacity. The memory consumption linearly increases as more file objects generated. The number of file objects on the NameNode increases and the objects consume more memory when the files and directories stored on the DataNode increase. In this case, the existing hardware may not meet the service requirement and the cluster is difficult to be scaled out.

Capacity planning of the HDFS that stores a large number of files is to plan the capacity specifications of the NameNode and DataNode and to set parameters according to the capacity plans.

Capacity Specifications

- NameNode capacity specifications

  Each file object on the NameNode corresponds to a file, directory, or block on the DataNode.

  A file uses at least one block. The default size of a block is **134,217,728**, that is, 128 MB, which can be set in the **dfs.blocksize** parameter. By default, a file whose size is less than 128 MB occupies only one block. If the file size is greater than 128 MB, the number of occupied blocks is the file size divided by 128 MB (Number of occupied blocks = File size/128). The directories do not occupy any blocks.

Based on **dfs.blocksize**, the number of file objects on the NameNode is calculated as follows:

Table 10-31 Number of NameNode file objects

Size of a File	Number of File Objects
< 128 MB	1 (File) + 1 (Block) = 2
> 128 MB (for example, 128 GB)	1 (File) + 1,024 (128 GB/128 MB = 1,024 blocks) = 1,025

The maximum number of file objects supported by the active and standby NameNodes is 300,000,000 (equivalent to 150,000,000 small files). **dfs.namenode.max.objects** specifies the number of file objects that can be generated in the system. The default value is **0**, which indicates that the number of generated file objects is not limited.

- DataNode capacity specifications

  In HDFS, blocks are stored on the DataNode as copies. The default number of copies is **3**, which can be set in the **dfs.replication** parameter.

  The number of blocks stored on all DataNode role instances in the cluster can be calculated based on the following formula: Number of HDFS blocks x 3 Average number of saved blocks = Number of HDFS blocks x 3/Number of DataNodes

Table 10-32 DataNode specifications

Item	Specifications
Maximum number of blocks supported by a DataNode instance	5,000,000
Maximum number of blocks supported by a disk on a DataNode instance	500,000
Minimum number of disks required when the number of blocks supported by a DataNode instance reaches the maximum	10

Table 10-33 Number of DataNodes

Number of HDFS Blocks	Minimum Number of DataNode Roles
10,000,000	10,000,000 *3/5,000,000 = 6
50,000,000	50,000,000 *3/5,000,000 = 30
100,000,000	100,000,000 *3/5,000,000 = 60

Setting Memory Parameters

- Configuration rules of the NameNode JVM parameter

  Default value of the NameNode JVM parameter **GC_OPTS**:

  -Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=3072 -Djdk.tls.rejectClientInitiatedRenegotiation=true -Djava.io.tmpdir=${Bigdata_tmp_dir}

  The number of NameNode files is proportional to the used memory size of the NameNode. When file objects change, you need to change **-Xms2G -Xmx4G -XX:NewSize=128M --XX:MaxNewSize=256M** in the default value. The following table lists the reference values.

  Table 10-34 NameNode JVM configuration

Number of File Objects	Reference Value
10,000,000	-Xms6G -Xmx6G -XX:NewSize=512M -XX:MaxNewSize=512M
20,000,000	-Xms12G -Xmx12G -XX:NewSize=1G -XX:MaxNewSize=1G
50,000,000	-Xms32G -Xmx32G -XX:NewSize=3G -XX:MaxNewSize=3G
100,000,000	-Xms64G -Xmx64G -XX:NewSize=6G -XX:MaxNewSize=6G
200,000,000	-Xms96G -Xmx96G -XX:NewSize=9G -XX:MaxNewSize=9G
300,000,000	-Xms164G -Xmx164G -XX:NewSize=12G -XX:MaxNewSize=12G

- Configuration rules of the DataNode JVM parameter

  Default value of the DataNode JVM parameter **GC_OPTS**:

  -Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M -XX:MetaspaceSize=128M -XX:MaxMetaspaceSize=128M -XX:+UseConcMarkSweepGC -XX:+CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=65 -XX:+PrintGCDetails -Dsun.rmi.dgc.client.gcInterval=0x7FFFFFFFFFFFFE -Dsun.rmi.dgc.server.gcInterval=0x7FFFFFFFFFFFFE -XX:-OmitStackTraceInFastThrow -XX:+PrintGCDateStamps -XX:+UseGCLogFileRotation -XX:NumberOfGCLogFiles=10 -

XX:GCLogFileSize=1M -Djdk.tls.ephemeralDHKeySize=3072 -Djdk.tls.rejectClientInitiatedRenegotiation=true -Djava.io.tmpdir=${Bigdata_tmp_dir}

The average number of blocks stored in each DataNode instance in the cluster is: Number of HDFS blocks x 3/Number of DataNodes. If the average number of blocks changes, you need to change **-Xms2G -Xmx4G -XX:NewSize=128M -XX:MaxNewSize=256M** in the default value. The following table lists the reference values.

Table 10-35 DataNode JVM configuration

Average Number of Blocks in a DataNode Instance	Reference Value
2,000,000	-Xms6G -Xmx6G -XX:NewSize=512M -XX:MaxNewSize=512M
5,000,000	-Xms12G -Xmx12G -XX:NewSize=1G -XX:MaxNewSize=1G

Xmx specifies memory which corresponds to the threshold of the number of DataNode blocks, and each GB memory supports a maximum of 500,000 DataNode blocks. Set the memory as required.

Viewing the HDFS Capacity Status

- NameNode information

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **NameNode(Active)**, and click **Overview** to view information like the number of file objects, files, directories, and blocks in HDFS in **Summary** area.

- DataNode information

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **HDFS** > **NameNode(Active)**, and click **DataNodes** to view the number of blocks on all DataNodes that report alarms.

- Alarm information

  Check whether the alarms whose IDs are 14007, 14008, and 14009 are generated and change the alarm thresholds as required.

10.15.4 Changing the DataNode Storage Directory

Scenario

If the storage directory defined by the HDFS DataNode is incorrect or the HDFS storage plan changes, the MRS cluster administrator needs to modify the DataNode storage directory on FusionInsight Manager to ensure smooth HDFS running. Changing the ZooKeeper storage directory includes the following scenarios:

- Change the storage directory of the DataNode role. In this way, the storage directories of all DataNode instances are changed.

- Change the storage directory of a single DataNode instance. In this way, only the storage directory of this instance is changed, and the storage directories of other instances remain the same.

Impact on the System

- The HDFS service needs to be stopped and restarted during the process of changing the storage directory of the DataNode role, and the cluster cannot provide services before it is completely started.
- The DataNode instance needs to stopped and restarted during the process of changing the storage directory of the instance, and the instance at this node cannot provide services before it is started.
- The directory for storing service parameter configurations must also be updated.

Prerequisites

- New disks have been prepared and installed on each data node, and the disks are formatted.
- New directories have been planned for storing data in the original directories.
- The HDFS client has been installed.
- The service user **hdfs** is available.
- When changing the storage directory of a single DataNode instance, ensure that the number of active DataNode instances is greater than the value of **dfs.replication**.

Procedure

Check the environment.

Step 1 Log in to the server where the HDFS client is installed as user **root**, and run the following command to configure environment variables:

source *Installation directory of the HDFS client*/**bigdata_env**

Step 2 If the cluster is in security mode, run the following command to authenticate the user:

kinit hdfs

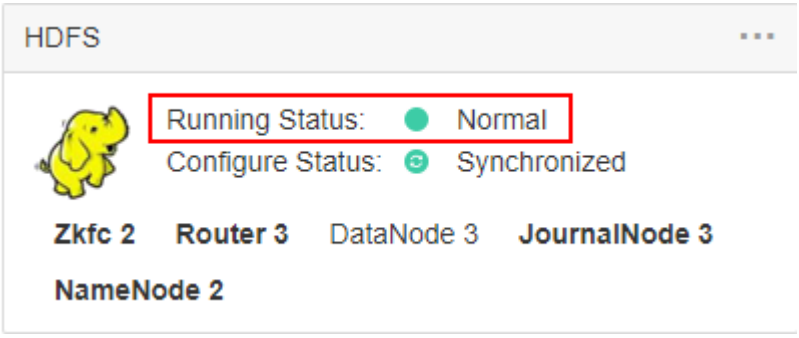
Step 3 Run the following command on the HDFS client to check whether all directories and files in the HDFS root directory are normal:

hdfs fsck /

Check the fsck command output.

- If the following information is displayed, no file is lost or damaged. Go to **Step 4**.
  ```
  The filesystem under path '/' is HEALTHY
  ```
- If other information is displayed, some files are lost or damaged. Go to **Step 5**.

Step 4 Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services**, and check whether **Running Status** of HDFS is **Normal**.



- If yes, go to **Step 6**.
- If no, the HDFS status is unhealthy. Go to **Step 5**.

Step 5 Rectify the HDFS fault.. The task is complete.

Step 6 Determine whether to change the storage directory of the DataNode role or that of a single DataNode instance:

- To change the storage directory of the DataNode role, go to **Step 7**.
- To change the storage directory of a single DataNode instance, go to **Step 12**.

Changing the storage directory of the DataNode role

Step 7 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Stop Instance** to stop the HDFS service.

Step 8 Log in to each data node where the HDFS service is installed as user **root** and perform the following operations:

1. Create a target directory (**data1** and **data2** are original directories in the cluster).

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   mkdir -p ${BIGDATA_DATA_HOME}/hadoop/data3/dn

2. Mount the target directory to the new disk. For example, mount **${BIGDATA_DATA_HOME}/hadoop/data3** to the new disk.
3. Modify permissions on the new directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R**

4. Copy the data to the target directory.

   For example, if the old directory is **${BIGDATA_DATA_HOME}/hadoop/data1/dn** and the target directory is **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   cp -af ${BIGDATA_DATA_HOME}/hadoop/data1/dn/* ${BIGDATA_DATA_HOME}/hadoop/data3/dn

Step 9 On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Configurations** > **All Configurations** to go to the HDFS service configuration page.

Change the value of **dfs.datanode.data.dir** from the default value **%{@auto.detect.datapart.dn}** to the new target directory, for example, **${BIGDATA_DATA_HOME}/hadoop/data3/dn**.

For example, the original data storage directories are **/srv/BigData/hadoop/data1**, **/srv/BigData/hadoop/data2**. To migrate data from the **/srv/BigData/hadoop/data1** directory to the newly created **/srv/BigData/hadoop/data3** directory, replace the whole parameter with **/srv/BigData/hadoop/data2, /srv/BigData/hadoop/data3**. Separate multiple storage directories with commas (,). In this example, changed directories are **/srv/BigData/hadoop/data2**, **/srv/BigData/hadoop/data3**.

Step 10 Click **Save**. Choose **Cluster** > *Name of the desired cluster* > **Services**. On the page that is displayed, start the services that have been stopped.

Step 11 After the HDFS is started, run the following command on the HDFS client to check whether all directories and files in the HDFS root directory are correctly copied:

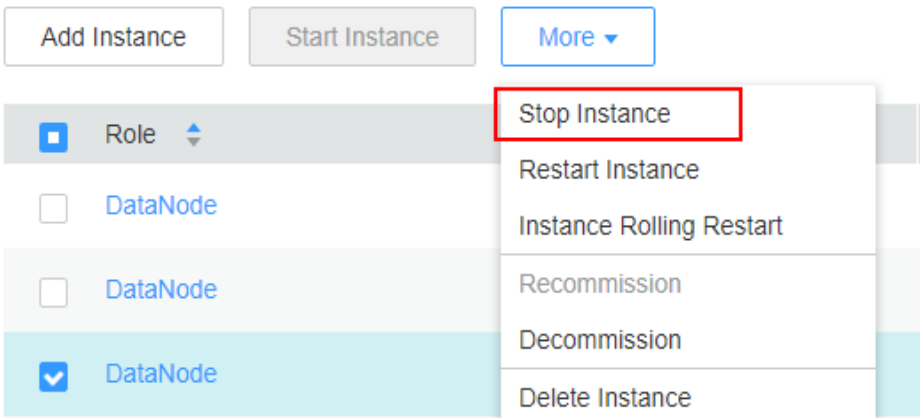
hdfs fsck /

Check the fsck command output.

- If the following information is displayed, no file is lost or damaged, and data replication is successful. No further action is required.
  ```
  The filesystem under path '/' is HEALTHY
  ```
- If other information is displayed, some files are lost or damaged. In this case, check whether **8.4** is correct and run the **hdfs fsck** *Name of the damaged file* **-delete** command.

Changing the storage directory of a single DataNode instance

Step 12 Choose **Cluster** > *Name of the desired cluster* > **Services** > **HDFS** > **Instance**. Select the HDFS instance whose storage directory needs to be modified, and choose **More** > **Stop Instance**.



Step 13 Log in to the DataNode node as user **root**, and perform the following operations:

1. Create a target directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   mkdir -p ${BIGDATA_DATA_HOME}/hadoop/data3/dn
2. Mount the target directory to the new disk.

For example, mount **${BIGDATA_DATA_HOME}/hadoop/data3** to the new disk.

3. Modify permissions on the new directory.

   For example, to create a target directory **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following commands:

   chmod 700 ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R and **chown omm:wheel ${BIGDATA_DATA_HOME}/hadoop/data3/dn -R**

4. Copy the data to the target directory.

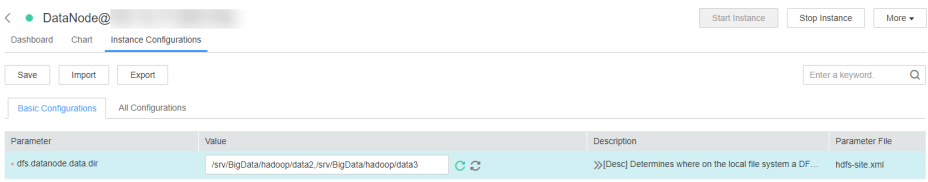
   For example, if the old directory is **${BIGDATA_DATA_HOME}/hadoop/data1/dn** and the target directory is **${BIGDATA_DATA_HOME}/hadoop/data3/dn**, run the following command:

   cp -af ${BIGDATA_DATA_HOME}/hadoop/data1/dn/* ${BIGDATA_DATA_HOME}/hadoop/data3/dn

Step 14 On FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Service** > **HDFS** > **Instance**. Click the specified DataNode instance and go to the **Configurations** page.

Change the value of **dfs.datanode.data.dir** from the default value **%{@auto.detect.datapart.dn}** to the new target directory, for example, **${BIGDATA_DATA_HOME}/hadoop/data3/dn**.

For example, the original data storage directories are **/srv/BigData/hadoop/data1,/srv/BigData/hadoop/data2**. To migrate data from the **/srv/BigData/hadoop/data1** directory to the newly created **/srv/BigData/hadoop/data3** directory, replace the whole parameter with **/srv/BigData/hadoop/data2,/srv/BigData/hadoop/data3**.



Step 15 Click **Save**, and then click **OK**.

Operation succeeded is displayed. click **Finish**.

Step 16 Choose **More** > **Restart Instance** to restart the DataNode instance.

----End

10.15.5 Configuring the Damaged Disk Volume

Scenario

In the open source version, if multiple data storage volumes are configured for a DataNode, the DataNode stops providing services by default if one of the volumes is damaged. You can change the value of **dfs.datanode.failed.volumes.tolerated** to specify the number of damaged disk volumes that are allowed. If the number of damaged volumes does not exceed the threshold, DataNode continues to provide services.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-36 Parameter description

Parameter	Description	Default Value
dfs.datanode.failed.volumes.tolerated	Specifies the number of damaged volumes that are allowed before the DataNode stops providing services. By default, there must be at least one valid volume. The value **-1** indicates that the minimum value of a valid volume is **1**. The value greater than or equal to **0** indicates the number of damaged volumes that are allowed.	–1

10.15.6 Setting the Maximum Lifetime and Renewal Interval of a Token

Scenario

In security mode, users can flexibly set the maximum token lifetime and token renewal interval in HDFS based on cluster requirements.

Configuration Description

Navigation path for setting parameters:

Go to the **All Configurations** page of HDFS and enter a parameter name in the search box by referring to **Modifying Cluster Service Configuration Parameters**.

Table 10-37 Parameter description

Parameter	Description	Default Value
dfs.namenode.delegation.token.max-lifetime	This parameter is a server parameter. It specifies the maximum lifetime of a token. Unit: milliseconds. Value range: 10,000 to 10,000,000,000,000	604,800,000
dfs.namenode.delegation.token.renew-interval	This parameter is a server parameter. It specifies the maximum lifetime to renew a token. Unit: milliseconds. Value range: 10,000 to 10,000,000,000,000	86,400,000

10.15.7 Running the DistCp Command

Scenario

DistCp is a tool used to perform large-amount data replication between clusters or in a cluster. It uses MapReduce tasks to implement distributed copy of a large amount of data.

Prerequisites

- The Yarn client or a client that contains Yarn has been installed. For example, the installation directory is **/opt/client**.
- Service users of each component are created by the MRS cluster administrator based on service requirements. In security mode, machine-machine users need to download the keytab file. A human-machine user must change the password upon the first login. (Not involved in normal mode)
- To copy data between clusters, you need to enable the inter-cluster data copy function on both clusters.

Procedure

Step 1 Log in to the node where the client is installed.

Step 2 Run the following command to go to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 If the cluster is in security mode, the user group to which the user executing the DistCp command belongs must be **supergroup** and the user run the following command to perform user authentication. In normal mode, user authentication is not required.

kinit *Component service user*

Step 5 Run the DistCp command. The following provides an example:

hadoop distcp hdfs://hacluster/source hdfs://hacluster/target

----End

Common Usage of DistCp

1. The following is an example of the commonest usage of DistCp:
   ```
   hadoop distcp -numListstatusThreads 40 -update -delete -prbugpaxtq hdfs://cluster1/source hdfs://cluster2/target
   ```

NOTE

In the preceding command:

- **-numListstatusThreads** specifies the number of threads for creating the list of 40 copied files.
- **-update -delete** specifies that files at the source location and the target location are synchronized, and that files with excessive target locations are deleted. If you need to copy files incrementally, delete **-delete**.
- If **-prbugpaxtq** and **-update** are used, it indicates that the status information of the copied file is also updated.
- **hdfs://cluster1/source** indicates the source location, and **hdfs://cluster2/target** indicates the target location.

2. The following is an example of data copy between clusters:

```
hadoop distcp hdfs://cluster1/foo/bar hdfs://cluster2/bar/foo
```

NOTE

The network between cluster1 and cluster2 must be reachable, and the two clusters must use the same HDFS version or compatible HDFS versions.

3. The following are multiple examples of data copy in a source directory:

```
hadoop distcp hdfs://cluster1/foo/a \
hdfs://cluster1/foo/b \
hdfs://cluster2/bar/foo
```

The preceding command is used to copy the folders a and b of cluster1 to the **/bar/foo** directory of cluster2. The effect is equivalent to that of the following commands:

```
hadoop distcp -f hdfs://cluster1/srclist \
hdfs://cluster2/bar/foo
```

The content of **srclist** is as follows. Before running the DistCp command, upload the **srclist** file to HDFS.

```
hdfs://cluster1/foo/a
hdfs://cluster1/foo/b
```

4. **-update** indicates that a to-be-copied file does not exist in the target location, or the content of the copied file in the target location is updated; and **-overwrite** is used to overwrite existing files in the target location.

The following is an example of the difference between no option and any one of the two options (either **update** or **overwrite**) that is added:

Assume that the structure of a file at the source location is as follows:

```
hdfs://cluster1/source/first/1
hdfs://cluster1/source/first/2
hdfs://cluster1/source/second/10
hdfs://cluster1/source/second/20
```

Commands without options are as follows:

```
hadoop distcp hdfs://cluster1/source/first  hdfs://cluster1/source/second  hdfs://cluster2/target
```

By default, the preceding command creates the **first** and **second** folders at the target location. Therefore, the copy results are as follows:

```
hdfs://cluster2/target/first/1
hdfs://cluster2/target/first/2
hdfs://cluster2/target/second/10
hdfs://cluster2/target/second/20
```

The command with any one of the two options (for example, **update**) is as follows:

```
hadoop distcp -update hdfs://cluster1/source/first  hdfs://cluster1/source/second  hdfs://cluster2/target
```

The preceding command copies only the content at the source location to the target location. Therefore, the copy results are as follows:

```
hdfs://cluster2/target/1
hdfs://cluster2/target/2
hdfs://cluster2/target/10
hdfs://cluster2/target/20
```

NOTE

- If files with the same name exist in multiple source locations, the DistCp command fails.
- If neither **update** nor **overwrite** is used and the file to be copied already exists in the target location, the file will be skipped.
- When **update** is used, if the file to be copied already exists in the target location but the file content is different, the file content in the target location is updated.
- When **overwrite** is used, if the file to be copied already exists in the target location, the file in the target location is still overwritten.

5. The following table describes other command options:

Table 10-38 Other command options

Option	Description
-p[rbugpcaxtq]	When **-update** is also used, the status information of a copied file is updated even if the content of the copied file is not updated. **r**: number of copies **b**: size of a block **u**: user to which the files belong **g**: user group to which the user belongs **p**: permission **c**: check and type **a**: access control **t**: timestamp **q**: quota information
-i	Failures ignored during copying
-log <logdir>	Path of the specified log
-v	Additional information in the specified log
-m <num_maps>	Maximum number of concurrent copy tasks that can be executed at the same time
-numListstatusThreads	Number of threads for constituting the list of copied files. This option increases the running speed of DistCp.
-overwrite	File at the target location that is to be overwritten

Option	Description
-update	A file at the target location is updated if the size and check of a file at the source location are different from those of the file at the target location.
-append	When **-update** is also used, the content of the file at the source location is added to the file at the target location.
-f <urilist_uri>	Content of the **<urilist_uri>** file is used as the file list to be copied.
-filters	A local file is specified whose content contains multiple regular expressions. If the file to be copied matches a regular expression, the file is not copied.
-async	The **distcp** command is run asynchronously.
-atomic {-tmp <tmp_dir>}	An atomic copy can be performed. You can add a temporary directory during copying.
-bandwidth	The transmission bandwidth of each copy task. Unit: MB/s.
-delete	The files that exist in the target location is deleted but do not exist in the source location. This option is usually used with **-update**, and indicates that files at the source location are synchronized with those at the target location and the redundant files at the target location are deleted.
-diff <oldSnapshot> <newSnapshot>	The differences between the old and new versions are copied to a file in the old version at the target location.
-skipcrccheck	Whether to skip the cyclic redundancy check (CRC) between the source file and the target file.
-strategy {dynamic| uniformsize}	The policy for copying a task. The default policy is **uniformsize**, that is, each copy task copies the same number of bytes.

FAQs of DistCp

1. When you run the DistCp command, if the content of some copied files is large, you are advised to change the timeout period of MapReduce that executes the copy task. It can be implemented by specifying the **mapreduce.task.timeout** in the DistCp command. For example, run the following command to change the timeout to 30 minutes:

   ```
   hadoop distcp -Dmapreduce.task.timeout=1800000 hdfs://cluster1/source hdfs://cluster2/target
   ```

   Or, you can also use **filters** to exclude the large files out of the copy process. The command example is as follows:

   ```
   hadoop distcp -filters /opt/client/filterfile hdfs://cluster1/source hdfs://cluster2/target
   ```

In the preceding command, *filterfile* indicates a local file, which contains multiple expressions used to match the path of a file that is not copied. The following is an example:

```
.*excludeFile1.*
.*excludeFile2.*
```

2. If the DistCp command unexpectedly quits, the error message "java.lang.OutOfMemoryError" is displayed.

   This is because the memory required for running the copy command exceeds the preset memory limit (default value: 128 MB). You can change the memory upper limit of the client by modifying **CLIENT_GC_OPTS** in *<Client installation path>***/HDFS/component_env**. For example, if you want to set the memory upper limit to 1 GB, refer to the following configuration:

   ```
   CLIENT_GC_OPTS="-Xmx1G"
   ```

   After the modification, run the following command to make the modification take effect:

   source {*Client installation path*}**/bigdata_env**

3. When the dynamic policy is used to run the DistCp command, the command exits unexpectedly and the error message "Too many chunks created with splitRatio" is displayed.

   The cause of this problem is that the value of **distcp.dynamic.max.chunks.tolerable** (default value: 20,000) is less than the value of **distcp.dynamic.split.ratio** (default value: 2) multiplied by the number of Maps. This problem occurs when the number of Maps exceeds 10,000. You can use the **-m** parameter to reduce the number of Maps to less than 10,000.

   ```
   hadoop distcp -strategy dynamic -m 9500 hdfs://cluster1/source hdfs://cluster2/target
   ```

   Alternatively, you can use the **-D** parameter to set **distcp.dynamic.max.chunks.tolerable** to a large value.

   ```
   hadoop distcp -Ddistcp.dynamic.max.chunks.tolerable=30000 -strategy dynamic hdfs://cluster1/source hdfs://cluster2/target
   ```

10.15.8 Configuring NFS

Scenario

Before deploying a cluster, you can deploy a Network File System (NFS) server based on requirements to store NameNode metadata to enhance data reliability.

If the NFS server has been deployed and NFS services are configured, you can follow operations in this section to configure NFS on the cluster. These operations are optional.

Procedure

Step 1 Check the permission of the shared NFS directories on the NFS server to ensure that the server can access NameNode in the MRS cluster.

Step 2 Log in to the active NameNode as user **root**.

Step 3 Run the following commands to create a directory and assign it write permissions:

mkdir ${BIGDATA_DATA_HOME}/namenode-nfs

chown omm:wheel ${BIGDATA_DATA_HOME}/namenode-nfs

chmod 750 ${BIGDATA_DATA_HOME}/namenode-nfs

Step 4 Run the following command to mount the NFS to the active NameNode:

mount -t nfs -o rsize=8192,wsize=8192,soft,nolock,timeo=3,intr *IP address of the NFS server*:*Shared directory* **${BIGDATA_DATA_HOME}/namenode-nfs**

For example, if the IP address of the NFS server is **192.168.0.11** and the shared directory is **/opt/Hadoop/NameNode**, run the following command:

mount -t nfs -o rsize=8192,wsize=8192,soft,nolock,timeo=3,intr 192.168.0.11:/opt/Hadoop/NameNode ${BIGDATA_DATA_HOME}/namenode-nfs

Step 5 Perform **Step 2** to **Step 4** on the standby NameNode.

NOTE

The names of the shared directories (for example, **/opt/Hadoop/NameNode**) created on the NFS server by the active and standby NameNodes must be different.

Step 6 Log in to FusionInsight Manager, and choose **Cluster** > *Name of the desired cluster* > **Service** > **HDFS** > **Configuration** > **All Configurations**.

Step 7 In the search box, search for **dfs.namenode.name.dir**, add **${BIGDATA_DATA_HOME}/namenode-nfs** to **Value**, and click **Save**. Separate paths with commas (,).

Step 8 Click **OK**. On the **Dashboard** tab page, choose **More** > **Restart Service** to restart the service.

----End

10.16 Common commands of the HDFS client

Using the HDFS Client

Step 1 Install a client. For details, see **Installing a Client**.

Step 2 Log in to the node where the client is installed as the client installation user.

Step 3 Run the following command to go to the client installation directory:

cd /opt/client

Step 4 Run the following command to configure environment variables:

source bigdata_env

Step 5 If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.

kinit *Component service user*

Step 6 Run the HDFS Shell command. Example:

hdfs dfs -ls /

----End

Common HDFS Client Commands

The following table lists common HDFS client commands.

For more commands, see **https://hadoop.apache.org/docs/stable/hadoop-project-dist/hadoop-common/CommandsManual.html#User_Commands**.

Table 10-39 Common HDFS client commands

Command	Description	Example
hdfs dfs -mkdir *Folder name*	Used to create a folder.	**hdfs dfs -mkdir /tmp/mydir**
hdfs dfs -ls *Folder name*	Used to view a folder.	**hdfs dfs -ls /tmp**
hdfs dfs -put *Local file on the client node Specified HDFS path*	Used to upload a local file to a specified HDFS path.	**hdfs dfs -put /opt/test.txt /tmp** Upload the **/opt/test.txt** file on the client node to the **/tmp** directory of HDFS.
hdfs dfs -get *Specified file on HDFS Specified path on the client node*	Used to download the HDFS file to the specified local path.	**hdfs dfs -get /tmp/test.txt /opt/** Download the **/tmp/test.txt** file on HDFS to the **/opt** path on the client node.
hdfs dfs -rm -r -f *Specified folder on HDFS*	Used to delete a folder.	**hdfs dfs -rm -r -f /tmp/mydir**
hdfs dfs -chmod *Permission parameter File directory*	Used to configure the HDFS directory permission for a user.	**hdfs dfs -chmod 700 /tmp/test**

10.17 Common Issues About HDFS

10.17.1 Why Does the Distcp Command Fail in the Secure Cluster, Causing an Exception?

Question

Why distcp command fails in the secure cluster with the following error displayed?

Client side exception

```
Invalid arguments: Unexpected end of file from server
```

Server side exception

```
javax.net.ssl.SSLException: Unrecognized SSL message, plaintext connection?
```

Answer

The preceding error may occur if **webhdfs://** is used in the distcp command. The reason is that the big data cluster uses the HTTPS mechanism, that is, **dfs.http.policy** is set to **HTTPS_ONLY** in **core-site.xml** file. To avoid the error, replace **webhdfs://** with **swebhdfs://** in the file.

For example:

./hadoop distcp swebhdfs://IP:PORT/testfile hdfs://IP:PORT/testfile1

10.17.2 When Does a Balance Process in HDFS, Shut Down and Fail to be Executed Again?

Question

After I start a Balance process in HDFS, the process is shut down abnormally. If I attempt to execute the Balance process again, it fails again.

Answer

After a Balance process is executed in HDFS, another Balance process can be executed only after the **/system/balancer.id** file is automatically released.

However, if a Balance process is shut down abnormally, the **/system/balancer.id** has not been released when the Balance is executed again, which triggers the **append /system/balancer.id** operation.

- If the time spent on releasing the **/system/balancer.id** file exceeds the soft-limit lease period 60 seconds, executing the Balance process again triggers the append operation, which preempts the lease. The last block is in construction or under recovery status, which triggers the block recovery operation. The **/system/balancer.id** file cannot be closed until the block recovery completes. Therefore, the append operation fails.

  After the **append /system/balancer.id** operation fails, the exception message **RecoveryInProgressException** is displayed.

  ```
  org.apache.hadoop.ipc.RemoteException(org.apache.hadoop.protocol.RecoveryInProgressException): Failed to APPEND_FILE /system/balancer.id for DFSClient because lease recovery is in progress. Try again later.
  ```

- If the time spent on releasing the **/system/balancer.id** file is within 60 seconds, the original client continues to own the lease and the exception AlreadyBeingCreatedException occurs and null is returned to the client. The following exception message is displayed on the client:

  ```
  java.io.IOException: Cannot create any NameNode Connectors.. Exiting...
  ```

Either of the following methods can be used to solve the problem:

- Execute the Balance process again after the hard-limit lease period expires for 1 hour, when the original client has released the lease.

- Delete the **/system/balancer.id** file before executing the Balance process again.

10.17.3 "This page can't be displayed" Is Displayed When Internet Explorer Fails to Access the Native HDFS UI

Question

Occasionally, nternet Explorer 9, Explorer 10, or Explorer 11 fails to access the native HDFS UI.

Symptom

Internet Explorer 9, Explorer 10, or Explorer 11 fails to access the native HDFS UI, as shown in the following figure.

Cause

Some Internet Explorer 9, Explorer 10, or Explorer 11versions fail to handle SSL handshake issues, causing access failure.

Solution

Refresh the page.

10.17.4 HDFS WebUI Cannot Properly Update Information About Damaged Data

Question

1. When errors occur in the **dfs.datanode.data.dir** directory of DataNode due to the permission or disk damage, HDFS WebUI does not display information about damaged data.
2. After errors are restored, HDFS WebUI does not timely remove related information about damaged data.

Answer

1. DataNode checks whether the disk is normal only when errors occur in file operations. Therefore, only when a data damage is detected and the error is reported to NameNode, NameNode displays information about the damaged data on HDFS WebUI.
2. After errors are fixed, you need to restart DataNode. During restarting DataNode, all data states are checked and damaged data information is uploaded to NameNode. Therefore, after errors are fixed, damaged data information is not displayed on the HDFS WebUI only by restarting DataNode.

10.17.5 The HDFS Client Is Unresponsive When the NameNode Is Overloaded for a Long Time

Question

When the NameNode node is overloaded (100% of the CPU is occupied), the NameNode is unresponsive. The HDFS clients that are connected to the overloaded NameNode fail to run properly. However, the HDFS clients that are newly connected to the NameNode will be switched to a backup NameNode and run properly.

Answer

The default configuration must be used (as described in **Table 10-40**) when the error preceding described occurs: the **keep alive** mechanism is enabled for the RPC connection between the HDFS client and the NameNode. The **keep alive** mechanism will keep the HDFS client waiting for the response from server and prevent the connection from being out timed, causing the unresponsiveness of the HDFS client.

Perform the following operations to the unresponsive HDFS client:

- Leave the HDFS client waiting. Once the CPU usage of the node where NameNode locates drops, the NameNode will obtain CPU resources and the HDFS client will receive a response.
- If you do not want to leave the HDFS client running, restart the application where the HDFS client locates to reconnect the HDFS client to another idle NameNode.

Procedure:

Configure the following parameters in the *client installation path*/**HDFS/hadoop/etc/hadoop/core-site.xml** file on the client.

Table 10-40 Parameter description

Parameter	Description	Default Value
ipc.client.ping	If the **ipc.client.ping** parameter is configured to **true**, the HDFS client will wait for the response from the server and periodically send the **ping** message to avoid disconnection caused by **tcp timeout**. If the **ipc.client.ping** parameter is configured to **false**, the HDFS client will set the value of **ipc.ping.interval** as the timeout time. If no response is received within that time, timeout occurs. To avoid the unresponsiveness of HDFS when the NameNode is overloaded for a long time, you are advised to set the parameter to **false**.	true

Parameter	Description	Default Value
ipc.ping.interval	If the value of **ipc.client.ping** is **true**, **ipc.ping.interval** indicates the interval between sending the ping messages. If the value of **ipc.client.ping** is **false**, **ipc.ping.interval** indicates the timeout time for connection. To avoid the unresponsiveness of HDFS when the NameNode is overloaded for a long time, you are advised to set the parameter to a large value, for example **900000** (unit ms) to avoid timeout when the server is busy.	60000

10.17.6 Why are There Two Standby NameNodes After the active NameNode Is Restarted?

Question

Why are there two standby NameNodes after the active NameNode is restarted?

When this problem occurs, check the ZooKeeper and ZooKeeper FC logs. You can find that the sessions used for the communication between the ZooKeeper server and client (ZKFC) are inconsistent. The session ID of the ZooKeeper server is **0x164cb2b3e4b36ae4**, and the session ID of the ZooKeeper FC is **0x144cb2b3e4b36ae4**. Such inconsistency means that the data interaction between the ZooKeeper server and ZKFC fails.

Content of the ZooKeeper log is as follows:

```
2015-04-15 21:24:54,257 | INFO | CommitProcessor:22 | Established session 0x164cb2b3e4b36ae4 with negotiated timeout 45000 for client /192.168.0.117:44586 | org.apache.zookeeper.server.ZooKeeperServer.finishSessionInit(ZooKeeperServer.java:623)
2015-04-15 21:24:54,261 | INFO | NIOServerCxn.Factory:192-168-0-114/192.168.0.114:2181 | Successfully authenticated client: authenticationID=hdfs/hadoop@<System domain name>; authorizationID=hdfs/hadoop@<System domain name>. | org.apache.zookeeper.server.auth.SaslServerCallbackHandler.handleAuthorizeCallback(SaslServerCallbackHandler.java:118)
2015-04-15 21:24:54,261 | INFO | NIOServerCxn.Factory:192-168-0-114/192.168.0.114:2181 | Setting authorizedID: hdfs/hadoop@<System domain name> | org.apache.zookeeper.server.auth.SaslServerCallbackHandler.handleAuthorizeCallback(SaslServerCallbackHandler.java:134)
2015-04-15 21:24:54,261 | INFO | NIOServerCxn.Factory:192-168-0-114/192.168.0.114:2181 | adding SASL authorization for authorizationID: hdfs/hadoop@<System domain name> | org.apache.zookeeper.server.ZooKeeperServer.processSasl(ZooKeeperServer.java:1009)
2015-04-15 21:24:54,262 | INFO | ProcessThread(sid:22 cport:-1): | Got user-level KeeperException when processing sessionid:0x164cb2b3e4b36ae4 type:create cxid:0x3 zxid:0x20009fafc txntype:-1 reqpath:n/a Error Path:/hadoop-ha/hacluster/ActiveStandbyElectorLock Error:KeeperErrorCode = NodeExists for /hadoop-ha/hacluster/ActiveStandbyElectorLock | org.apache.zookeeper.server.PrepRequestProcessor.pRequest(PrepRequestProcessor.java:648)
```

Content of the ZKFC log is as follows:

```
2015-04-15 21:24:54,237 | INFO | main-SendThread(192-168-0-114:2181) | Socket connection established to 192-168-0-114/192.168.0.114:2181, initiating session | org.apache.zookeeper.ClientCnxn$SendThread.primeConnection(ClientCnxn.java:854)
```

```
2015-04-15 21:24:54,257 | INFO | main-SendThread(192-168-0-114:2181) | Session establishment complete

org.apache.hadoop.ha.ActiveStandbyElector.processWatchEvent(ActiveStandbyElector.java:547)
2015-04-15 21:24:54,264 | INFO | main-EventThread | Successfully authenticated to ZooKeeper using SASL. |
org.apache.hadoop.ha.ActiveStandbyElector.processWatchEvent(ActiveStandbyElector.java:573)
```

Answer

- Cause Analysis

  After the active NameNode restarts, the temporary node **/hadoop-ha/hacluster/ActiveStandbyElectorLock** created on ZooKeeper is deleted. After the standby NameNode receives that information that the **/hadoop-ha/hacluster/ActiveStandbyElectorLock** node is deleted, the standby NameNode creates the /**hadoop-ha/hacluster/ActiveStandbyElectorLock** node in ZooKeeper in order to switch to the active NameNode. However, when the standby NameNode connects with ZooKeeper through the client ZKFC, the session ID of ZKFC differs from that of ZooKeeper due to network issues, overload CPU, or overload clusters. In this case, the watcher of the standby NameNode fails to detect that the temporary node has been successfully created, and fails to consider the standby NameNode as the active NameNode. After the original active NameNode restarts, it detects that the **/hadoop-ha/hacluster/ActiveStandbyElectorLock** already exists and becomes the standby NameNode. Therefore, both NameNodes are standby NameNodes.

- Solution

  You are advised to restart two ZKFCs of HDFS on FusionInsight Manager.

10.17.7 DataNode Is Normal but Cannot Report Data Blocks

Question

The DataNode is normal, but cannot report data blocks. As a result, the existing data blocks cannot be used.

Answer

This error may occur when the number of data blocks in a data directory exceeds four times the upper limit (4 x 1 MB). And the DataNode generates the following error logs:

```
2015-11-05 10:26:32,936 | ERROR | DataNode:[[[DISK]file:/srv/BigData/hadoop/data1/dn/]] heartbeating to

The number of data blocks in the data directory is displayed as **Metric**. You can monitor its value through **http://<datanode-ip>:<http-port>/jmx**. If the value is greater than four times the upper limit (4 x 1 MB), you are advised to configure multiple drives and restart HDFS.

Recovery procedure:

1. Configure multiple data directories on the DataNode.

   For example, configure multiple directories on the DataNode where only the **/data1/datadir** directory is configured:

   ```
   <property> <name>dfs.datanode.data.dir</name> <value>/data1/datadir</value> </property>
   ```

   Configure as follows:

   ```
   <property> <name>dfs.datanode.data.dir</name> <value>/data1/datadir/,/data2/datadir,/data3/
   datadir</value> </property>
   ```

   NOTE

   You are advised to configure multiple data directories on multiple disks. Otherwise, performance may be affected.

2. Restart the HDFS.
3. Perform the following operation to move the data to the new data directory:

   mv */data1/datadir/current/finalized/subdir1 /data2/datadir/current/finalized/subdir1*

4. Restart the HDFS.

10.17.8 Can I Delete or Modify the Data Storage Directory in DataNode?

Question

- In DataNode, the storage directory of data blocks is specified by **dfs.datanode.data.dir.** Can I modify **dfs.datanode.data.dir** to modify the data storage directory?
- Can I modify files under the data storage directory?

Answer

During the system installation, you need to configure the **dfs.datanode.data.dir** parameter to specify one or more root directories.

- During the system installation, you need to configure the dfs.datanode.data.dir parameter to specify one or more root directories.

- Exercise caution when modifying dfs.datanode.data.dir. You can configure this parameter to add a new data root directory.
- Do not modify or delete data blocks in the storage directory. Otherwise, the data blocks will lose.

NOTE

Similarly, do not delete the storage directory, or modify or delete data blocks under the directory using the following parameters:

- dfs.namenode.edits.dir
- dfs.namenode.name.dir
- dfs.journalnode.edits.dir

10.17.9 Failed to Calculate the Capacity of a DataNode when Multiple data.dir Directories Are Configured in a Disk Partition

Question

The capacity of a DataNode fails to calculate when multiple data.dir directories are configured in a disk partition.

Answer

Currently, the capacity is calculated based on disks, which is similar to the ***df*** command in Linux. Ideally, users do not configure multiple data.dir directories in a disk partition. Otherwise, all data will be written to the same disk, greatly deteriorating the performance.

You are advised to configure them as below.

For example, if a node contains the following disks:

```
host-4:~ # df -h
Filesystem      Size  Used  Avail  Use%  Mounted on
/dev/sda1       352G  11G    324G   4%    /
udev            190G  252K  190G   1%    /dev
tmpfs           190G  72K    190G   1%    /dev/shm
/dev/sdb1       2.7T  74G    2.5T   3%    /data1
/dev/sdc1       2.7T  75G    2.5T   3%    /data2
/dev/sdd1       2.7T  73G    2.5T   3%    /da
```

Recommended configuration:

```
<property>
<name>dfs.datanode.data.dir</name>
<value>/data1/datadir/,/data2/datadir,/data3/datadir</value>
</property>
```

Unrecommended configuration:

```
<property>
<name>dfs.datanode.data.dir</name>
<value>/data1/datadir1/,/data2/datadir1,/data3/datadir1,/data1/datadir2,data1/datadir3,/data2/datadir2,/
data2/datadir3,/data3/datadir2,/data3/datadir3</value>
</property>
```

10.17.10 Why Data in the Buffer Is Lost If a Power Outage Occurs During Storage of Small Files

Question

Why data in the buffer is lost if a power outage occurs during storage of small files?

Answer

Because of a power outage, the blocks in the buffer are not written to the disk immediately after the write operation is completed. To enable synchronization of blocks to the disk, set **dfs.datanode.synconclose** to **true** in the *client installation path*/**HDFS/hadoop/etc/hadoop/hdfs-site.xml** file.

By default, **dfs.datanode.synconclose** is set to **false**. This improves the performance but can cause a buffer data loss in the case of a power outage, and therefore, it is recommended that **dfs.datanode.synconclose** be set to **true** even if this may affect the performance. You can determine whether to enable the synchronization function based on your actual situation.

10.17.11 Why Is the Storage Type of File Copies DISK When the Tiered Storage Policy Is LAZY_PERSIST?

Question

When the storage policy of the file is set to **LAZY_PERSIST**, the storage type of the first replica should be **RAM_DISK**, and the storage type of other replicas should be **DISK**.

But why is the storage type of all copies shown as **DISK** actually?

Answer

When a user writes into a file whose storage policy is **LAZY_PERSIST**, three replicas are written one by one. The first replica is preferentially written into the DataNode where the client is located. The storage type of all replicas is **DISK** in the following scenarios:

- If the DataNode where the client is located does not have the RAM disk, the first replica is written into the disk of the DataNode where the client is located, and other replicas are written into the disks of other nodes.
- If the DataNode where the client is located has the RAM disk, and the value of **dfs.datanode.max.locked.memory** is not specified or smaller than the value of **dfs.blocksize** (To obtain the parameter value, log in to FusionInsight Manager and choose **Cluster > Services > HDFS > Configuration > All Configurations**, and search for this parameter.), the first replica is written into the disk of the DataNode where the client is located, and other replicas are written into the disks of other nodes.

10.17.12 Blocks Miss on the NameNode UI After the Successful Rollback

Question

Why are some blocks missing on the NameNode UI after the rollback is successful?

Answer

This problem occurs because blocks with new IDs or genstamps may exist on the DataNode. The block files in the DataNode may have different generation flags and lengths from those in the rollback images of the NameNode. Therefore, the NameNode rejects these blocks in the DataNode and marks the files as damaged.

Scenarios:

1. Before an upgrade:

   Client A writes some data to file X. (Assume A bytes are written.)

2. During an upgrade:

   Client A still writes data to file X. (The data in the file is A + B bytes.)

3. After an upgrade:

   Client A completes the file writing. The final data is A + B bytes.

4. Rollback started:

   The status will be rolled back to the status before the upgrade. That is, file X in NameNode will have A bytes, but block files in DataNode will have A + B bytes.

Recovery procedure:

1. Obtain the list of damaged files from NameNode web UI or run the following command to obtain:

   hdfs fsck <filepath> -list-corruptfileblocks

2. Run the following command to delete unnecessary files:

   hdfs fsck <corrupt file path> - delete

   NOTE

   Deleting a file is a high-risk operation. Ensure that the files are no longer needed before performing this operation.

3. For the required files, run the **fsck** command to obtain the block list and block sequence.
   - In the block sequence table provided, use the block ID to search for the data directory in the DataNode and download the corresponding block from the DataNode.
   - Write all such block files in appending mode based on the sequence to construct the original file.

     Example:

     File 1--> blk_1, blk_2, blk_3

Create a file by combining the contents of all three block files from the same sequence.

- Delete the old file from HDFS and rewrite the new file.

10.18 HDFS Troubleshooting

10.18.1 Why Is "java.net.SocketException: No buffer space available" Reported When Data Is Written to HDFS

Question

Why is an "java.net.SocketException: No buffer space available" exception reported when data is written to HDFS?

This problem occurs when files are written to the HDFS. Check the error logs of the client and DataNode.

The client logs are as follows:

Figure 10-14 Client logs

```
2017-07-05 21:58:06,459 INFO  [htable-pool3-t1] ipc.AbstractRpcClient: RPC Server Kerberos principal name for service=ClientService is hbase/hadoop.hadoop123.com@HADOOP12

```

Answer

The preceding problem may be caused by network memory exhaustion.

You can increase the threshold of the network device based on the actual scenario.

Example:

```
[root@xxxxx ~]# cat /proc/sys/net/ipv4/neigh/default/gc_thresh*
128
512
1024
[root@xxxxx ~]# echo 512 > /proc/sys/net/ipv4/neigh/default/gc_thresh1
[root@xxxxx ~]# echo 2048 > /proc/sys/net/ipv4/neigh/default/gc_thresh2
[root@xxxxx ~]# echo 4096 > /proc/sys/net/ipv4/neigh/default/gc_thresh3
[root@xxxxx ~]# cat /proc/sys/net/ipv4/neigh/default/gc_thresh*
512
2048
4096
```

You can also add the following parameters to the **/etc/sysctl.conf** file. The configuration takes effect even if the host is restarted.

```
net.ipv4.neigh.default.gc_thresh1 = 512
net.ipv4.neigh.default.gc_thresh2 = 2048
net.ipv4.neigh.default.gc_thresh3 = 4096
```

10.18.2 NameNode Startup Is Slow

Question

The NameNode startup is slow when it is restarted immediately after a large number of files (for example, 1 million files) are deleted.

Answer

It takes time for the DataNode to delete the corresponding blocks after files are deleted. When the NameNode is restarted immediately, it checks the block information reported by all DataNodes. If a deleted block is found, the NameNode generates the corresponding INFO log information, as shown below:

```
2015-06-10 19:25:50,215 | INFO  | IPC Server handler 36 on 25000 | BLOCK* processReport:
blk_1075861877_2121067 on node 10.91.8.218:9866 size 10249 does not belong to any file |
org.apache.hadoop.hdfs.server.blockmanagement.BlockManager.processReport(BlockManager.java:1854)
```

A log is generated for each deleted block. A file may contain one or more blocks. Therefore, after startup, the NameNode spends a large amount of time printing

logs when a large number of files are deleted. As a result, the NameNode startup becomes slow.

To address this issue, the following operations can be performed to speed up the startup:

1. After a large number of files are deleted, wait until the DataNode deletes the corresponding blocks and then restart the NameNode.

   You can run the ***hdfs dfsadmin -report*** command to check the disk space and check whether the files have been deleted.

2. If a large number of the preceding logs are generated, you can change the NameNode log level to **ERROR** so that the NameNode stops printing such logs.

   After the NameNode is restarted, change the log level back to **INFO**. You do not need to restart the service after changing the log level.

10.18.3 NameNode Fails to Be Restarted Due to EditLog Discontinuity

Question

If a JournalNode server is powered off, the data directory disk is fully occupied, and the network is abnormal, the EditLog sequence number on the JournalNode is inconsecutive. In this case, the NameNode restart may fail.

Symptom

The NameNode fails to be restarted. The following error information is reported in the NameNode run logs:

```
2019-11-08 16:30:28,399 | ERROR | main | Failed to start namenode. | NameNode.java:1732
java.io.IOException: There appears to be a gap in the edit log.  We expected txid 13698019, but got txid 13698088.
        at org.apache.hadoop.hdfs.server.namenode.MetaRecoveryContext.editLogLoaderPrompt(MetaRecoveryContext.java:94)
        at org.apache.hadoop.hdfs.server.namenode.FSEditLogLoader.loadEditRecords(FSEditLogLoader.java:278)
        at org.apache.hadoop.hdfs.server.namenode.FSEditLogLoader.loadFSEdits(FSEditLogLoader.java:188)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.loadEdits(FSImage.java:924)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.loadFSImage(FSImage.java:771)
        at org.apache.hadoop.hdfs.server.namenode.FSImage.recoverTransitionRead(FSImage.java:331)
        at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.loadFSImage(FSNamesystem.java:1108)
        at org.apache.hadoop.hdfs.server.namenode.FSNamesystem.loadFromDisk(FSNamesystem.java:727)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.loadNamesystem(NameNode.java:638)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.initialize(NameNode.java:700)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.<init>(NameNode.java:943)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.<init>(NameNode.java:916)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.createNameNode(NameNode.java:1655)
        at org.apache.hadoop.hdfs.server.namenode.NameNode.main(NameNode.java:1725)
```

Solution

1. Find the active NameNode before the restart, go to its data directory (you can obtain the directory, such as **/srv/BigData/namenode/current** by checking the configuration item **dfs.namenode.name.dir**), and obtain the sequence number of the latest FsImage file, as shown in the following figure:

```

```

2. Check the data directory of each JournalNode (you can obtain the directory such as**/srv/BigData/journalnode/hacluster/current** by checking the value of the configuration item **dfs.journalnode.edits.dir**), and check whether the sequence number starting from that obtained in step 1 is consecutive in edits files. That is, you need to check whether the last sequence number of the previous edits file is consecutive with the first sequence number of the next edits file. (As shown in the following figure, edits_0000000000013259231-0000000000013259237 and edits_0000000000013259239-0000000000013259246 are not consecutive.)

```
-rw-------. 1 omm wheel     575 Oct  2 00:43 edits_0000000000013259159-0000000000013259166
-rw-------. 1 omm wheel     576 Oct  2 00:43 edits_0000000000013259167-0000000000013259174
-rw-------. 1 omm wheel     575 Oct  2 00:45 edits_0000000000013259175-0000000000013259182
-rw-------. 1 omm wheel     575 Oct  2 00:45 edits_0000000000013259183-0000000000013259190

-rw-------. 1 omm wheel     575 Oct  2 01:05 edits_0000000000013259337-0000000000013259344
```

3. If the edits files are not consecutive, check whether the edits files with the related sequence number exist in the data directories of other JournalNodes or NameNode. If the edits files can be found, copy a consecutive segment to the JournalNode.
4. In this way, all inconsecutive edits files are restored.
5. Restart the NameNode and check whether the restart is successful. If the fault persists, contact technical support.

10.18.4 Standby NameNode Fails to Be Restarted When the System Is Powered off During Metadata (Namespace) Storage

Question

When the standby NameNode is powered off during metadata (namespace) storage, it fails to be started and the following error information is displayed.

```
2015-12-04 11:49:12,121 | ERROR | main | Failed to load image from FS

```

Answer

When the standby NameNode is powered off during metadata (namespace) storage, it fails to be started and the MD5 file is damaged. Remove the damaged fsimage and start the standby NameNode to rectify the fault. After the rectification, the standby NameNode loads the previous fsimage and reproduces all edits.

Recovery procedure:

1. Run the following command to remove the damaged fsimage:

   rm -rf ${BIGDATA_DATA_HOME}/namenode/current/fsimage_0000000000000096

2. Start the standby NameNode.

10.18.5 Why Does DataNode Fail to Start When the Number of Disks Specified by dfs.datanode.data.dir Equals dfs.datanode.failed.volumes.tolerated?

Question

If the number of disks specified by **dfs.datanode.data.dir** is equal to the value of **dfs.datanode.failed.volumes.tolerated**, DataNode startup will fail.

Answer

By default, the failure of a single disk will cause the HDFS DataNode process to shut down, which results in the NameNode scheduling additional replicas for each block that is present on the DataNode. This causes needless replications of blocks that reside on disks that have not failed.

To prevent this, you can configure DataNodes to tolerate the failure of dfs.data.dir directories; Log in to FusionInsight Manager, choose **Cluster > Services > HDFS > Configuration > All Configurations**, and search for **dfs.datanode.failed.volumes.tolerated.** For example, if the value for this parameter is 3, the DataNode will only shut down after four or more data directories have failed. This value is respected on DataNode startup.

When we are configuring tolerate volumes which should be always less than the configured volumes or else we can keep this as -1 which is equal to n-1 (where n is number of disks) then DataNode will not be shut down.

10.18.6 Why Does Array Border-crossing Occur During FileInputFormat Split?

Question

When HDFS calls the FileInputFormat getSplit method, the ArrayIndexOutOfBoundsException: 0 appears in the following log:

```
java.lang.ArrayIndexOutOfBoundsException: 0
at org.apache.hadoop.mapred.FileInputFormat.identifyHosts(FileInputFormat.java:708)
at org.apache.hadoop.mapred.FileInputFormat.getSplitHostsAndCachedHosts(FileInputFormat.java:675)
at org.apache.hadoop.mapred.FileInputFormat.getSplits(FileInputFormat.java:359)
at org.apache.spark.rdd.HadoopRDD.getPartitions(HadoopRDD.scala:210)
at org.apache.spark.rdd.RDD$$anonfun$partitions$2.apply(RDD.scala:239)
at org.apache.spark.rdd.RDD$$anonfun$partitions$2.apply(RDD.scala:237)
at scala.Option.getOrElse(Option.scala:120)
at org.apache.spark.rdd.RDD.partitions(RDD.scala:237)
at org.apache.spark.rdd.MapPartitionsRDD.getPartitions(MapPartitionsRDD.scala:35)
```

Answer

The elements of each block correspondent frame are as below: /default/rack0/:,/default/rack0/datanodeip:port.

The problem is due to a block damage or loss, making the block correspondent machine ip and port become null. Use **hdfs fsck** to check the file blocks health state when this problem occurs, and remove damaged block or restore the missing block to re-computing the task.

10.18.7 The Standby NameNode Fails to Be Started Because It Is Not Started for a Long Time

Symptom

The standby NameNode is not started for a long time. After the **edits** file is automatically deleted due to the aging policy, this file cannot be found when the NameNode is restarted. As a result, an error is reported.

```
There appears to be a gap in the edit log. We expected txid XXX, but got txid XXX.
```

Solution

Step 1 Go to the **All Configurations** page of HDFS by referring to **Modifying Cluster Service Configuration Parameters**, search for **dfs.namenode.name.dir** and check the value to obtain the NameNode data directory, for example, **/srv/BigData/namenode/current**.

Step 2 On the HDFS service page, click the **Instances** tab to view and record the service IP addresses of the active and standby NameNodes.

Step 3 Log in to the faulty standby NameNode as user **root** and back up the **fsimage** file in the data directory obtained in **Step 1**. For example, back up the data to the **/srv/BigData/namenode/current.bak** directory.

mv /srv/BigData/namenode/current/ /srv/BigData/namenode/current.bak

Step 4 Log in to the active NameNode as the **root** user and run the following command to copy the **fsimage** file to the standby NameNode:

scp -rp /srv/BigData/namenode/current/ {*IP address of the standby NameNode***}:/srv/BigData/namenode/**

chown omm:wheel /srv/BigData/namenode/current -R

Step 5 Restart the standby NameNode and check whether restart is successful. If the operation fails, contact technical support.

----End

11 Using HetuEngine

11.1 Overview of HetuEngine Interactive Query

HetuEngine supports quick joint query of multiple data sources and GUI-based data source configuration and management. You can quickly add a data source on the HSConsole page.

The following table lists the data sources supported by HetuEngine of the current version.

Table 11-1 List for connecting HetuEngine to data sources

HetuEngine Mode	Data Source	Data Source Mode	Supported Data Source Version
Security mode	Hive	Security mode	MRS 3.x and FusionInsight 6.5.1
	HBase		MRS 3.x and FusionInsight 6.5.1
	HetuEngine		MRS 3.1.1 and later
	GaussDB		GaussDB 200 and GaussDB A 8.0.0 and later
	Hudi		MRS 3.1.2 and later
	ClickHouse		MRS 3.1.1 and later
	IoTDB		MRS 3.2.0 and later
	MySQL		MySQL 5.7, MySQL 8.0, and later
	Oracle		Oracle 12 and later
	GBase		GBase8a V950 and later
Normal mode	Hive	Normal mode	MRS 3.x and FusionInsight 6.5.1
	HBase		MRS 3.x and FusionInsight 6.5.1

HetuEngine Mode	Data Source	Data Source Mode	Supported Data Source Version
	Hudi		MRS 3.1.2 and later
	ClickHouse		MRS 3.1.1 and later
	IoTDB		MRS 3.2.0 and later
	GaussDB	Security Mode	GaussDB 200 and GaussDB A 8.0.0 and later
	MySQL		MySQL 5.7, MySQL 8.0 and later
	Oracle		Oracle 12 and later
	GBase		GBase8a V950 and later

Operations such as adding, configuring, and deleting a HetuEngine data source takes effect dynamically without restarting the cluster.

A configured data source takes effect dynamically and you cannot disable this function. By default, the interval for a data source to dynamically take effect is 60 seconds. You can change the interval to a desired one by changing the value of **catalog.scanner-interval** in **coordinator.config.properties** and **worker.config.properties** by referring to **Step 3.5** in **Creating a HetuEngine Compute Instance**. See the following example.

```
catalog.scanner-interval =120s
```

HetuEngine supports query pushdown. It can push down queries or partial queries to connected data sources. This means that special predicates, aggregate functions, or other operations can be passed to the underlying database or file system for processing. Query pushdown brings the following benefits:

1. Improves the overall query performance.
2. Reduces the network traffic between HetuEngine and data sources.
3. Reduces the load of remote data sources.

Whether HetuEngine supports query pushdown depends on specific connectors and the underlying data sources or storage systems related to the connectors.

NOTE

- The data source cluster and the HetuEngine cluster must use different domain names. Two data sources (Hive, HBase, and Hudi) with the same domain name cannot be connected to HetuEngine at the same time.
- Nodes in the data source cluster and the HetuEngine cluster can communicate with each other on the service plane.

11.2 HetuEngine User Permission Management

11.2.1 HetuEngine User Permissions

HetuEngine provides the following two permission control models when Kerberos authentication is enabled for the cluster (the cluster is in security mode). By default, the Ranger permission model is used. When Kerberos authentication is disabled for the cluster (the cluster is in normal mode), the Ranger permission model is provided but disabled by default.

- For details about the Ranger model, see **HetuEngine Ranger-based Permission Control**.
- For details about the MetaStore model, see **HetuEngine MetaStore-based Permission Control**.

The following table lists the differences between Ranger and MetaStore. Both Ranger and MetaStore support user, user group, and role authentication.

Table 11-2 Differences between Ranger and MetaStore

Permission Control Mode	Permission Model	Supported Data Source	Description
Ranger	PBAC	Hive, HBase, Elasticsearch, GaussDB, HetuEngine, ClickHouse, IoTDB, Hudi, MySQL	Row filtering, column masking, and fine-grained permission control are supported.
MetaStore	RBAC	Hive	-

Permission Principles and Constraints

- Accessing data sources in the same cluster using HetuEngine

  If Ranger authentication is enabled for HetuEngine, the PBAC permission policy of Ranger is used for authentication.

  If Ranger authentication is disabled for HetuEngine, the RBAC permission policy of MetaStore is used for authentication.
- Accessing data sources in different clusters using HetuEngine

  The permission policy is controlled by the permissions of the HetuEngine client and the data source. (In Hive scenarios, it depends on HDFS.)
- When querying a view, you only need to grant the select permission on the target view. When querying a join table using a view, you need to grant the select permission on the view and table.
- Columns in GaussDB and HetuEngine data sources cannot be masked.

NOTE

When the permission control type of HetuEngine is changed, the HetuEngine service, including the HetuEngine compute instance running on the HSConsole page, needs to be restarted.

HetuEngine Ranger-based Permission Control

By default, Ranger authentication is used for newly installed clusters. For clusters upgraded from earlier versions or clusters where Ranger authentication is manually disabled, you can enable Ranger authentication again by referring to the following content.

For a cluster with Ranger authentication enabled, cluster administrators can use Ranger to configure the permissions to manage databases, tables, and columns of data sources for HetuEngine users. For details, see **Adding a Ranger Access Permission Policy for HetuEngine**.

Step 1 Log in to FusionInsight Manager.

Step 2 If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), add the **ranger.usersync.sync.source** parameter. If Kerberos authentication is enabled for the cluster (the cluster is in security mode), skip this step.

1. Choose **Cluster** > **Services** > **Ranger**. Click **Configurations** then **All Configurations**.
2. Search for the **ranger.usersync.config.expandor** parameter, set its name to **ranger.usersync.sync.source**, set its value to **ldap**, and save the settings.
3. On the **Dashboard** page, click **More** > **Restart Service** in the upper right corner, enter the password, and restart Ranger.

   NOTE

   For MRS 3.5.0 and later versions, run the following commands:

   To use Ranger for permission control when Kerberos authentication is disabled for the cluster (the cluster is in normal mode), choose Cluster > **Services** > **Ranger** > **Configurations** > **All Configurations**, search for **ranger.usersync.sync.source**, and ensure that the value is **ldap**, otherwise, change the value to **ldap**. Save the modification and restart Ranger.

Step 3 Choose **Cluster** > **Services** > **HetuEngine** > **More** > **Enable Ranger**.

Step 4 Choose **Cluster** > **Services** > **HetuEngine**. Click **More** and select **Restart Service**.

Step 5 Restart the compute instance on HSConsole.

----End

HetuEngine MetaStore-based Permission Control

- Constraints: This function applies only to Hive data sources.

  When multiple HetuEngine clusters are deployed for collaborative computing, the metadata is centrally managed by the management cluster. Data computing is performed in all clusters. The user permission for accessing HetuEngine clusters must be configured in the management cluster. Users who belong to the Hive user group and share the same name are added to all compute instances.

- Enabling MetaStore Authentication

  a. Log in to FusionInsight Manager.

  b. Choose **Cluster** > **Services** > **HetuEngine**. Click **More** and select **Disable Ranger**.

c. Choose **Cluster** > **Services** > **HetuEngine**. Click **More** and select **Restart Service**.

d. Restart the compute instance on the HSConsole page.

- MetaStore Permission

  Similar to Hive, HetuEngine is a data warehouse framework built on Hadoop, providing storage of structured data like SQL.

  Permissions in a cluster must be assigned to roles which are associated to users or user groups. Users can obtain permissions only by binding a role or joining a group that is bound with a role.

  HetuEngine permission management is performed by the permission system to manage users' operations on the database, ensuring that different users can operate databases independently and securely. A user can operate another user's tables and databases only with the corresponding permissions. Otherwise, operations will be rejected.

  HetuEngine permission management integrates the functions of Hive permission management. MetaStore service of Hive and the function of granting permissions on the web page are required to enable the HetuEngine permission management.

  - Granting permissions on the web page: HetuEngine supports only granting permissions on the web page. On Manager, choose **System** > **Permission** to add or delete a user, user group, or a role, and to grant or cancel permissions.
  - Obtaining and judging a service: When the DDL and DML commands are received from the client, HetuEngine will obtain the client user's permissions on database information from MetaStore, and check whether the required permissions are included. If the required permissions have been obtained, the user's operations are allowed. If the permissions are not obtained, the user's operation will be rejected. After the MetaStore permission check is passed, ACL permission also needs to be checked on HDFS.

- HetuEngine Permission Model

  If a user uses HetuEngine to perform SQL query, the user must be granted with permissions of HetuEngine databases and tables (include external tables and views). The complete permission model of HetuEngine consists of the metadata permission and HDFS file permission. Permissions required to use a database or a table are just one type of HetuEngine permission.

  - Metadata permissions

    Metadata permissions are controlled at the metadata level. Similar to traditional relational databases, the HetuEngine database contains the CREATE and SELECT permissions. Tables and columns contain the SELECT, INSERT, UPDATE, and DELETE permissions. HetuEngine also supports the owner permission OWNERSHIP and cluster administrator permission ADMIN.

  - Data file permissions (that is, HDFS file permissions)

    HetuEngine database and table files are stored in HDFS. The created databases or tables are saved in the **/user/hive/warehouse** directory of HDFS by default. The system automatically creates subdirectories named after database names and database table names. To access a database or

a table, the corresponding file permissions (read, write, and execute) on the HDFS are required.

To perform various operations on HetuEngine databases or tables, you need to associate the metadata permission and the HDFS file permission. For example, to query HetuEngine data tables, you need to associate the metadata permission SELECT with the READ and EXECUTE permissions on HDFS files.

To use the management function of FusionInsight Manager GUI to manage the permissions of HetuEngine databases and tables, you only need to configure the metadata permission, and the system will automatically associate and configure the HDFS file permission. In this way, operations on the interface are simplified, improving efficiency.

- HetuEngine Application Scenarios and Related Permissions

  A user needs to join in the Hive group if a database is created using the HetuEngine service, and role authorization is not required. Users have all permissions on the databases or tables created by themselves in Hive or HDFS. They can create tables, select, delete, insert, or update data, and grant permissions to other users to allow them to access the tables and corresponding HDFS directories and files.

  A user can access the tables or database only with permissions. Permissions required for the user vary depending on different HetuEngine scenarios.

  Table 11-3 Typical HetuEngine scenarios and required permissions

Typical Scenario	Required Permission
Using HetuEngine tables, columns, or databases	Permissions required in different scenarios are as follows: • To create a table, the CREATE permission is required. • To query data, the SELECT permission is required. • To insert data, the INSERT permission is required.

  In some special HetuEngine scenarios, other permissions must be configured separately.

Table 11-4 Typical HetuEngine authentication scenarios and required permissions

Scenario	Required Permission
Creating HetuEngine databases, tables, and foreign tables, or adding partitions to created tables or foreign tables when data files specified by Hive users are saved to other HDFS directories except **/user/hive/warehouse**.	The directory must exist, the client user must be the owner of the directory, and the user must have the **Read**, **Write**, and **Execute** permissions on the directory. The user must have the **Read** and **Execute** permissions of all the upper-layer directories of the directory.
Performing operations on all databases and tables in Hive	The user must be added to the **supergroup** user group, and be assigned the ADMIN permission.

- Configuring Permissions for SparkSQL Tables, Columns, and Databases

  After MetaStore authentication is enabled, if a user needs to access HetuEngine tables or databases created by other users, the user needs to be granted with related permissions. HetuEngine supports permission control based on columns for strict permission control. If a user needs to access some columns in tables created by other users, the user must be granted the permission for columns.

  NOTE

  - Any permission for a table in the database is automatically associated with the HDFS permission for the database directory to facilitate permission management. When any permission for a table is canceled, the system does not automatically cancel the HDFS permission for the database directory to ensure performance. In this case, users can only log in to the database and view table names.
  - When the query permission on a database is added to or deleted from a role, the query permission on tables in the database is automatically added to or deleted from the role. This mechanism is inherited from Hive.
  - In HetuEngine, the name of a column of the **struct** type data cannot contain special characters, that is, characters other than letters, digits, and underscores (_). If the column name of the struct data type contains special characters, the column cannot be displayed on the FusionInsight Manager console when you grant permissions to roles on the **Role** page.

  Procedure

  a. Log in to FusionInsight Manager.
  b. Choose **System** > **Permission** > **Role**.
  c. Click **Create Role**, and set **Role Name** and **Description**.
  d. In the **Configure Resource Permission** area, choose *Name of the desired cluster* > **Hive** and set role permissions. For details, see **Table 11-5**.

     - **Hive Admin Privilege**: Hive administrator permission.
     - **Hive Read Write Privileges**: Hive data table management permission, which is the operation permission to set and manage the data of created tables.

NOTE

- Hive role management supports the administrator permission, and the permissions of accessing tables and views, without granting the database permission.
- The permissions of the Hive administrator do not include the permission to manage HDFS.
- If there are too many tables in the database or too many files in tables, the permission granting may last a while. For example, if a table contains 10,000 files, the permission granting lasts about 2 minutes.

Table 11-5 Setting a role

Task	Operation
Setting the permission to query a table of another user in the default database	1. In the **View Name** area, click **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of a specified table, choose **Select**.
Setting the permission to import data to a table of another user in the default database	1. In the **View Name** area, click **Hive Read Write Privileges**. 2. Click the name of the specified database in the database list. Tables in the database are displayed. 3. In the **Permission** column of the specified indexes, select **Delete** and **Insert**.

e. Click **OK**. Return to the **Role** page.

NOTE

After the role is created, you can create a HetuEngine user and assign related role permissions to the user by referring to **Creating a HetuEngine Permission Role**.

Table 11-6 describes the permission requirements when SQL statements are processed in HetuEngine.

Table 11-6 Using HetuEngine tables, columns, or data

Scenario	Required Permission
DESCRIBE TABLE	Select
ANALYZE TABLE	Select and Insert
SHOW COLUMNS	Select
SHOW TABLE STATUS	Select

Scenario	Required Permission
SHOW TABLE PROPERTIES	Select
SELECT	Select
EXPLAIN	Select
CREATE VIEW	Select, Grant Of Select, and Create
CREATE TABLE	Create
ALTER TABLE ADD PARTITION	Insert
INSERT	Insert
INSERT OVERWRITE	Insert and Delete
ALTER TABLE DROP PARTITION	Table-level Alter and Delete, and column-level Select
ALTER DATABASE	Hive Admin Privilege

11.2.2 Creating a HetuEngine Permission Role

Before using the HetuEngine service in a security cluster, a cluster administrator needs to create a user and grant operation permissions to the user to meet service requirements.

HetuEngine users are classified into administrators and common users. The default HetuEngine administrator group is **hetuadmin**, and the user group of HetuEngine common users is **hetuuser**.

- Users associated with the **hetuadmin** user group can obtain the O&M administrator permissions on the HetuEngine HSConsole web UI and HetuEngine compute instance web UI.
- Users associated with the **hetuuser** user group can obtain the SQL execution permission. They also have permissions to access the HSConsole web UI, view information about clusters of associated tenants and basic information about all data sources, access the web UI of compute instances, and query and maintain SQL statements of the current user.

If Ranger authentication is enabled and you need to configure the permissions to manage databases, tables, and columns of data sources for a user after it is created, see **Adding a Ranger Access Permission Policy for HetuEngine**.

Before you use the HetuEngine service, ensure that the tenant to be associated with the HetuEngine user has been planned and created.

Creating a HetuEngine User

Creating a HetuEngine administrator

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User** > **Create**.

Step 3 Enter a username, for example, **hetu_admin**.

Step 4 Set **User Type** to **Human-machine**.

Step 5 Set **Password** and confirm your password.

Step 6 In the **User Group** area, click **Add** to add the **hive**, **hetuadmin**, **hadoop**, **hetuuser**, and **yarnviewgroup** user groups for the user.

Step 7 In the **Primary Group** drop-down list, select **hive** as the primary group.

Step 8 In the **Role** area, click **Add** to assign the **default**, **System_administrator**, and desired tenant role permissions to the user.

Step 9 Click **OK**.

----End

Creating a common HetuEngine user

Step 1 Log in to FusionInsight Manager.

Step 2 Choose **System** > **Permission** > **User** > **Create**.

Step 3 Enter a username, for example, **hetu_test**.

Step 4 Set **User Type** to **Human-machine**.

Step 5 Set **Password** and confirm your password.

Step 6 In the **User Group** area, click **Add** to add the **hetuuser** user group for the user.

NOTE

- Ranger authentication is enabled for the HetuEngine service in the MRS cluster by default. HetuEngine common users only need to be associated with the **hetuuser** user group. If Ranger authentication is disabled, you must associate the user with the **hive** user group and set it as the primary group. Otherwise, the HetuEngine service may be unavailable.
- If Ranger authentication is enabled and you need to configure the permissions to manage databases, tables, and columns of data sources for a user after it is created, see **Adding a Ranger Access Permission Policy for HetuEngine**.

Step 7 In the **Role** area, click **Add** to assign the **default** or desired tenant role permissions to the user.

Step 8 Click **OK**.

----End

11.2.3 Configuring Proxy User Authentication

This topic is available for MRS 3.3.0 or later.

You can use Ranger to authenticate a specified proxy user in HetuEngine for FusionInsight Manager user authentication. When you use the HetuEngine client, you can set **--session-user** to specify a proxy user.

For details about how to create an authentication user or proxy user, see **Creating a HetuEngine Permission Role**.

You need to enable Ranger authentication and grant the proxy user the permissions to manage the databases, tables, and columns of the data source. For details, see **Adding a Ranger Access Permission Policy for HetuEngine**.

- Kerberos authentication is enabled for the cluster (the cluster is in security mode)

  a. Use **kinit** to specify a user to be authenticated, for example, **hetuadmin1**. (The user must be a HetuEngine administrator and added to the **supergroup** user group to authenticate other users.)

     kinit hetuadmin1

     Enter the password as prompted and change the password upon your first login.

  b. Use **--session-user** to specify a proxy user, for example, **user1**.

     hetu-cli --session-user user1

- Kerberos authentication is disabled for the cluster (the cluster is in normal mode)

  Use **--user** to specify a user to be authenticated, for example, **user** (must belong to the **hetuuser** user group). Use **--session-user** to specify a proxy user, for example, **user1**.

  hetu-cli --user user --session-user user1

NOTE

This function is not suitable when both HiveMetastore data source authentication and multi-user mapping are enabled.

11.3 Quickly Using HetuEngine to Access Hive Data Source

This section describes how to use HetuEngine to connect to the Hive data source and query database tables of the Hive data source of the cluster through HetuEngine.

Prerequisites

- The HetuEngine and Hive services and their dependent services (DBService, KrbServer, ZooKeeper, HDFS, Yarn, and MapReduce) have been installed in the cluster and are running properly.
- If Kerberos authentication has been enabled for the cluster, you need to create a HetuEngine user and grant related permissions to the user in advance. For details, see **Creating a HetuEngine Permission Role**. In addition, you need to configure the permissions to manage the databases, tables, and columns of the data source for the user using Ranger. For details, see **Adding a Ranger Access Permission Policy for HetuEngine**.
- The cluster client has been installed in a directory, for example, **/opt/client**.

Procedure

Step 1 Create and start a HetuEngine compute instance.

1. Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.
2. In the **Basic Information** area on the **Dashboard** tab page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.
3. Click **Compute Instance** then **Create Configuration**.
   a. In the **Basic Configuration** area, set **Tenant** to the tenant associated with the user and configure **Instance Deployment Timeout Period (s)** and **Node Count**.
   b. Configure parameters in the **Coordinator Container Resource Configuration**, **Worker Container Resource Configuration**, and **Advanced Configuration** areas based on the actual resource plan. For details about the parameter configuration, see **Creating a HetuEngine Compute Instance** or retain the default values.

      NOTICE

      When you create a compute instance, you only need to apply for a few resources to test basic functions. You need to configure parameters based on actual service requirements and available resources. For details, see **Configuring HetuEngine Resource Groups** and **Configuring the Number of HetuEngine Worker Nodes**.

   c. Set **Start Now** to **Yes**, click **OK**, and wait until the instance configuration is complete.

Step 2 Log in to the node where the HetuEngine client is installed and run the following command to switch to the client installation directory:

cd /opt/client

Step 3 Run the following command to configure environment variables:

source bigdata_env

Step 4 Authenticate or specify a user.

- For a cluster in security mode, run the following command to authenticate the user:

  kinit *HetuEngine operation user*

  Example:

  kinit hetu_test

  Enter the password as prompted and change the password upon your first login.

- For a cluster in normal mode, run the following command to authenticate the user:

  hetu-cli --user *HetuEngine operation user*

  Example:

hetu-cli --user hetu_test

Step 5 Run the following command to log in to the catalog of the data source. You can choose to log in to the data source through ZooKeeper or HSFabric by configuring the **--mode** parameter.

- Through ZooKeeper (This mode is used by default if **--mode** is not configured.)

  hetu-cli --catalog *Data source name*

  For example, run the following command:

  hetu-cli --catalog hive

- Through HSFabric (Ensure that HSFabric instances exist.)

  hetu-cli --mode hsfabric --catalog *Data source name*

  For example, run the following command:

  hetu-cli --mode hsfabric --catalog hive

  NOTE

  - The default name of the Hive data source of the cluster is **hive**. To connect to data sources outside the cluster, configure external data sources on HSConsole by referring to **Adding a HetuEngine Data Source**.
  - It takes about 120 seconds for your first login to the client because the HetuEngine cluster needs to be started in the background.
  - Method to enable strict tenant verification for MRS 3.3.0 and later versions:

    HetuEngine provides service-level default resource queue configuration items. If no tenant information is specified, the default Yarn tenant is used. Multiple users may use the same queue by default.

    If you need to isolate resources and properly allocate SQL statements to specified queues, you can enable strict tenant verification by setting **tenant.strict.mode.enabled** to **true** and use the **--tenant** parameter to specify the queues when you use the client.

    Log in to Manager, choose **Cluster** > **Services** > **HetuEngine**, click **Configurations** and then **All Configurations**, search for **tenant.strict.mode.enabled**, set it to **true**, and save the settings. Click **Instance**, select all instances whose configurations expired, click **More**, select **Restart Instance**, and restart the instances as prompted for the configurations to take effect.
  - If strict tenant verification is enabled and cross-domain functions of HetuEngine are used, you need to set the **hsfabric.local.tenant** parameter of the HetuEngine data source. For details, see **Adding a Cross-Cluster HetuEngine Data Source**.

  Parameter description

  - **--mode**: Optional. The mode used to log in to a data source.
  - **--catalog**: Optional. The name of a specified data source.
  - **--tenant**: Optional. The tenant resource queue started by the cluster. If this parameter is not specified, the default tenant queue is used. To use this parameter, the service user must have the role permission of the tenant. For a cluster of MRS 3.3.0 or later versions:
    - This parameter is mandatory if strict verification is disabled.
    - This parameter is mandatory if strict verification is enabled.
  - **--schema**: Optional. The name of the schema of the data source to be accessed.
  - **--user**: Mandatory in normal mode. The name of the user who logs in to the client to execute services. The user must have at least the role of the queue specified by **--tenant** and cannot be an OS user.
  - You can run the **hetu-cli --help** command to view other parameters.

```
java -Djava.security.auth.login.config=/opt/client/HetuEngine/hetuserver/conf/jaas.conf -
Dzookeeper.sasl.clientconfig=Client -Dzookeeper.auth.type=kerberos -Djava.security.krb5.conf=/opt/client/
```

```
KrbClient/kerberos/var/krb5kdc/krb5.conf -Djava.util.logging.config.file=/opt/client/HetuEngine/hetuserver/
conf/hetuserver-client-logging.properties -jar /opt/client/HetuEngine/hetuserver/jars/hetu-cli-*-
executable.jar --catalog hive --deployment-mode on_yarn --server https://
10.112.17.189:24002,10.112.17.228:24002,10.112.17.150:24002?
serviceDiscoveryMode=zooKeeper&zooKeeperNamespace=hsbroker --krb5-remote-service-name HTTP --
krb5-config-path /opt/client/KrbClient/kerberos/var/krb5kdc/krb5.conf
hetuengine>
```

Step 6 Run the following command to view the database information:

show schemas;

```
    Schema
--------------------
 default
 information_schema
(2 rows)
Query 20230228_064136_00023_9kpap@default@HetuEngine, FINISHED, 3 nodes
Splits: 36 total, 36 done (100.00%)
0:02 [2 rows, 35B] [0 rows/s, 15B/s]
```

----End

11.4 Creating a HetuEngine Compute Instance

Scenario

This section describes how to create a HetuEngine compute instance. If you want to stop the cluster where compute instances are successfully created, you need to manually stop the compute instances first. If you want to use the compute instances after the cluster is restarted, you need to manually start them.

A single tenant can create multiple compute instances to balance loads, improving performance and fault tolerance (for MRS 3.3.0 and later versions only).

Prerequisites

- You have created a user for accessing the HetuEngine web UI, for example, **hetu_user**. For details, see **Creating a HetuEngine Permission Role**.
- You have created a tenant in the cluster to be operated. Ensure that the tenant has sufficient memory and CPUs when modifying the HetuEngine compute instance configuration.

  NOTE

  - You must use a leaf tenant when you create a HetuEngine compute instance because YARN jobs can only be submitted to the queues of a leaf tenant.
  - To avoid uncertainties caused by resource competition, you are advised to create independent resource pools for tenants used by HetuEngine.

- The startup of HetuEngine compute instances depends on Python 3. Ensure that Python 3 has been installed on all nodes in the cluster and the Python soft link has been added to the **/usr/bin/** directory. For details, see **Python Not Exist When a HetuEngine Compute Instance Failed to Start**.
- The HetuEngine service is running properly.

Procedure

Step 1 Log in to FusionInsight Manager as user **hetu_user** and choose **Cluster** > **Services** > **HetuEngine**.

Step 2 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 3 Click **Compute Instance** then **Create Configuration** and configure the compute instance parameters.

1. Set parameters in the **Basic Configuration** area. For details about the parameters, see **Table 11-7**.

Table 11-7 Basic configuration

Parameter	Description	Example Value
Tenant	Tenant to which the instance belongs. Only tenants without compute instances can be selected for new compute instances.	Select a value from the **Tenant** drop-down list.
Instance Deployment Timeout Period (s)	Timeout interval for starting a compute instance by Yarn service deployment. The system starts timing when the compute instance is started. If the compute instance is still in the **Creating** or **Starting** state after the time specified by this parameter expires, the compute instance status is displayed as **Error** and the compute instance that is being created or started on Yarn is stopped.	300 The value ranges from 1 to 2147483647.
Instance Count	The number of compute instances created under the current tenant. You can configure multiple compute instances for automatic load balancing and higher concurrency. **NOTICE** When you configure multiple compute instances: – Ensure that the cluster resources are sufficient. For multiple instances of a single tenant, required resources are single instance resources multiplied by the number of instances. The compute instance specifications must be the same. – Use short connections and use HSFabric for connecting HetuEngine, which enables better scheduling and a more balanced load.	1 Value range: 1 to 50

2. Set parameters in the **Coordinator Container Resource Configuration** area. For details about the parameters, see **Table 11-8**.

Table 11-8 Parameters for configuring Coordinator container resources

Parameter	Description	Example Value
Container Memory (MB)	Memory size (MB) allocated by Yarn to a single container of the compute instance Coordinator	Default value: 5120 The value ranges from 1 to 2147483647.
vcore	Number of vCPUs (vCores) allocated by Yarn to a single container of the compute instance Coordinator	Default value: 1 The value ranges from 1 to 2147483647.
Quantity	Number of containers allocated by Yarn to the compute instance Coordinator	Default value: 2 The value ranges from 1 to 3.
JVM	Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HetuEngine** > **Configurations**. On the **All Configurations** tab page, search for **extraJavaOptions**. The value of this parameter in the **coordinator.jvm.config** parameter file is the value of the JVM parameter.	-

3. Set parameters in the **Worker Container Resource Configuration** area. For details about the parameters, see **Table 11-9**.

Table 11-9 Parameters for configuring Worker container resources

Parameter	Description	Example Value
Container Memory (MB)	Memory size (MB) allocated by Yarn to a single container of the compute instance Worker	Default value: 10240 The value ranges from 1 to 2147483647.
vcore	Number of vCPUs (vCores) allocated by Yarn to a single container of the compute instance Worker	Default value: 1 The value ranges from 1 to 2147483647.
Quantity	Number of containers allocated by Yarn to the compute instance Worker	Default value: 2 The value ranges from 1 to 256.

Parameter	Description	Example Value
JVM	Log in to FusionInsight Manager and choose **Cluster** > **Services** > **HetuEngine** > **Configurations**. On the **All Configurations** tab page, search for **extraJavaOptions**. The value of this parameter in the **worker.jvm.config** parameter file is the value of the JVM parameter.	-

4. Set parameters in the **Advanced Configuration** area. For details about the parameters, see **Table 11-10**.

Table 11-10 Advanced configuration parameters

Parameter	Description	Example Value
Ratio of Query Memory	This parameter indicates the ratio of the node query memory to the JVM memory and is set to 0.7 by default. When it is set to 0, the compute function is disabled. In this case, you can start the compute instance only if the value of -Xmx in the JVM configuration is no less than the sum of memory.heap-headroom-per-node and query.max-memory-per-node configured for the coordinator or worker.	0.7
Scaling	If auto scaling is enabled, you can increase or decrease the number of workers without restarting the instance. However, the instance performance may deteriorate. In multi-instance mode, automatic scaling cannot be enabled. For details about the parameters for enabling dynamic scaling, see **Configuring the Number of HetuEngine Worker Nodes**.	-
Maintenance Instance	To enable automatic refresh for materialized views, there must be one compute instance that is set as the maintenance instance and the compute instance is globally unique. If there are multiple compute instances, only one compute instance can be used as the maintenance instance.	-

5. Configure **Custom Configuration** parameters. You can add custom parameters to a specified parameter file. Select the specified parameter file from the **Parameter File** drop-down list.
   - You can click **Add** to add custom configuration parameters.
   - You can click **Delete** to delete custom configuration parameters.

- You can set **Parameter File** to **resource-groups.json** to configure the resource group mechanism. **Table 11-11** describe the resource group configuration parameter. For details about how to configure a resource group, see **Configuring HetuEngine Resource Groups**.

  Table 11-11 Resource group configuration parameter

Parameter	Description	Example Value

resourcegroups	Resource management group configuration of the cluster. Select **resource-groups.json** from the drop-down list of the parameter file.	{
		"rootGroups": [{
		"name": "global",
		"softMemoryLimit": "100%",
		"hardConcurrencyLimit": 1000,
		"maxQueued": 10000,
		"killPolicy": "no_kill"
		}],
		"selectors": [{
		"group": "global"
		}]
		}

  NOTE

  - After a custom parameter is configured in the **coordinator.config.properties**, **worker.config.properties**, **log.properties**, and **resource-groups.json** parameter files, if the parameter already exists in another specified parameter file, the value of this custom parameter will replace the values of this parameter in the specified parameter file. If the custom parameter does not exist in another specified parameter file, the custom parameter is added to the specified parameter file.
  - **killPolicy**: After a query is submitted to worker, if the total memory usage exceeds **softMemoryLimit**, you can select one of the following policies to terminate running queries:
    - **no_kill** (default value): Do not terminate the queries.
    - **recent_queries**: Terminate the queries based on the execution sequence in descending order.
    - **oldest_queries**: Terminate the queries based on the execution sequence.
    - **finish_percentage_queries**: Terminate the queries based on query execution percentage. The query with the smallest percentage of execution will be terminated first.
    - **high_memory_queries**: Terminate the queries based on memory usage. Queries with high memory usage are terminated first to free up more memory with the minimum number of query terminations. If the memory usage of two queries is less than 10%, the query with slower progress (smaller execution percentage) is terminated. If the difference between the execution percentages of two queries is less than 5%, the query with larger memory usage is terminated.

6. Determine whether to start the instance immediately after the configuration is complete.
   - If yes, the instance is automatically restarted immediately after the configuration is complete.
   - If no, you need to manually start the instance after the configuration is complete.

Step 4 Click **OK** and wait until the instance configuration is complete.

----End

Precautions for Maintaining Compute Instances

- During the restart or rolling restart of the HetuEngine service, do not create, start, stop, or delete HetuEngine compute instances on HSConsole.
- By default, a maximum of 10 compute instances can be in the starting, creating, deleting, stopping, scaling out, scaling in, or rolling restart state at the same time. O&M tasks that exceed 10 will wait to be executed in the background. To change the number of concurrent tasks, log in to FusionInsight Manager, choose **HetuEngine** and click the **Configurations** tab and then **All Configurations**. On the displayed page, search for **hsbroker.event.task.executor.threads** and change its value.
- Precautions for restarting HetuEngine compute instances
  - During the restart or rolling restart of HetuEngine compute instances, do not perform any change operations on the data sources on the HetuEngine and HetuEngine web UI, including restarting HetuEngine and changing its configurations.
  - If a compute instance has only one coordinator or worker node, do not perform a rolling restart of the instance.
  - If the number of worker nodes is greater than 10, the rolling restart of the instance may take more than 200 minutes. During this period, do not perform other O&M operations.
  - During the rolling restart of compute instances, HetuEngine releases YARN resources and applies for them again. Ensure that the CPU and memory of YARN are sufficient for starting 20% workers and YARN resources are not preempted by other jobs. Otherwise, the rolling restart will fail.

    Viewing YARN resources: Log in to FusionInsight Manager and choose **Tenant Resources**. On the navigation pane on the left, choose **Tenant Resources Management** to view the available queue resources of YARN in the **Resource Quota** area.

    Viewing the CPU and memory of a worker container: Log in to FusionInsight Manager as a user who can access the HetuEngine WebUI and choose **Cluster** > **Services** > **HetuEngine**. In the **Basic Information** area, click the link next to **HSConsole WebUI** to go to the HSConsole page. Click **Operation** in the row where the target instance is located and click **Configure**.
  - During the rolling restart, ensure that Application Manager of coordinators or workers in the YARN queue runs stably.
- HetuEngine compute instance restart exception handling
  - If Application Manager of coordinators or workers in the YARN queues is restarted during the rolling restart, the compute instances may be abnormal. In this case, you need to stop the compute instances and then start the compute instance for recovery.
  - After the rolling restart of a compute instance fails, the instance is in the subhealthy state. As a result, the configuration or number of coordinator or worker nodes may become inconsistent. In this case, the subhealthy

state of the compute instance cannot be automatically recovered. You need to manually check and rectify the fault, perform the rolling restart again, or stop and then restart the compute instance.

Compute Instance Statuses

After a compute instance is created, you can view information about the created instance on the **Compute Instance** tab page, including the tenant name, number of instances, instance status, and total resources. Instance statuses are as follows:

Figure 11-1 Compute instance statuses

- Green icon: The instance is in the running or subhealthy state.
- Red icon: The instance is faulty.
- Gray icon: The instance has been stopped and is to be started.
- Blue icon: The instance is in other states, including scaling out, scaling in, rolling restart, creating, starting, safely starting, shutting down, safely shutting down, terminating, terminated, and stopping.

11.5 Adding a HetuEngine Data Source

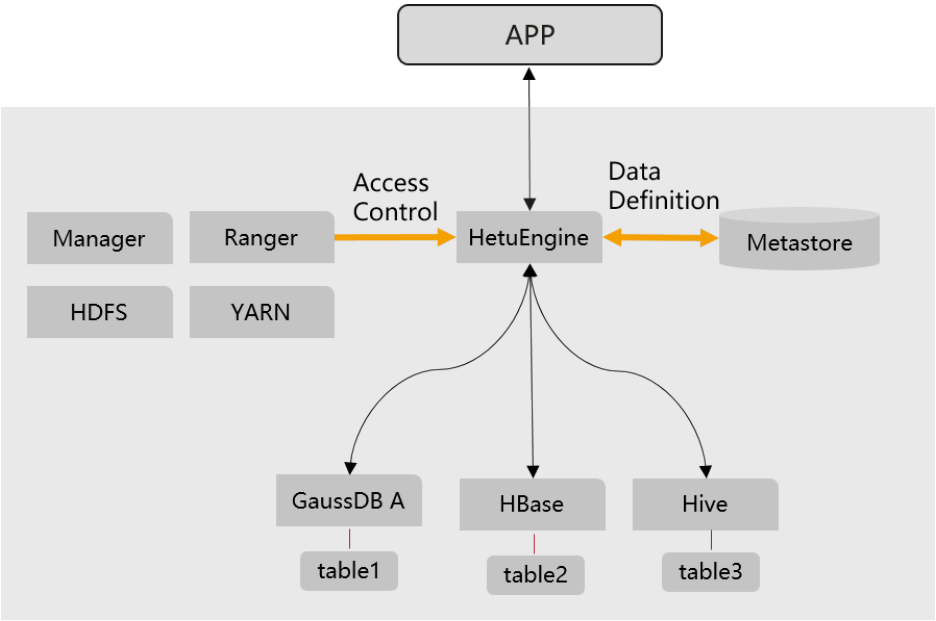
11.5.1 Using HetuEngine to Access Data Sources Across Sources and Domains

Using the HetuEngine Cross-Source Function

Companies often store large amounts of data from different sources in databases and warehouses to manage and collect information. However, having data from different sources with a variety of structures and scattered storage can make it expensive and time-consuming to query across all of them.

HetuEngine provides unified standard SQL statements to implement cross-source collaborative analysis, simplifying cross-source analysis operations.

Figure 11-2 HetuEngine cross-source analysis



Technologies and Advantages

- Compute pushdown: When HetuEngine is used for cross-source collaborative analysis, HetuEngine enhances the compute pushdown capability from the dimensions listed as follows to improve access efficiency.
  - Basic pushdown: predicate, projection, subquery, and limit
  - Aggregate pushdown: GROUP BY, ORDER BY, COUNT, SUM, MIN, and MAX
  - Operator pushdown: <, >, LIKE, and OR.
- Multi-source heterogeneous data: Collaborative analysis supports both structured data sources such as Hive, GaussDB, and ClickHouse, and unstructured data sources such as HBase and Elasticsearch.
- Global metadata: A mapping table is provided to map unstructured schemas to structured schemas, enabling HetuEngine to access HBase using SQL statements. Global management for data source information is provided.
- Global permission control: Data source permissions can be opened to Ranger through HetuEngine for centralized management and control.

Usage Guide of Cross-Source Analysis

HetuEngine supports quick joint query of multiple data sources and GUI-based data source configuration and management. You can quickly add the following data sources on the HSConsole page by referring to **Overview of HetuEngine Interactive Query**:

- **Adding a Hive Data Source**
- **Adding a Hudi Data Source**
- **Adding a ClickHouse Data Source**
- **Adding a GaussDB Data Source**

- **Adding an HBase Data Source**
- **Adding a Cross-Cluster HetuEngine Data Source**
- **Adding an IoTDB Data Source**
- **Adding a MySQL Data Source**
- **Adding an Oracle Data Source**
- **Adding a GBase Data Source**

Process of Using Cross-Source Collaborative Analysis

1. Log in to the HetuEngine client by referring to **Quickly Using HetuEngine to Access Hive Data Source**.
2. Register data sources such as Hive, HBase, and GaussDB A.

```
hetuengine> show catalogs;
 Catalog
----------
dws
hive
hive_dg
hbase
system
systemremote
(6 rows)
```

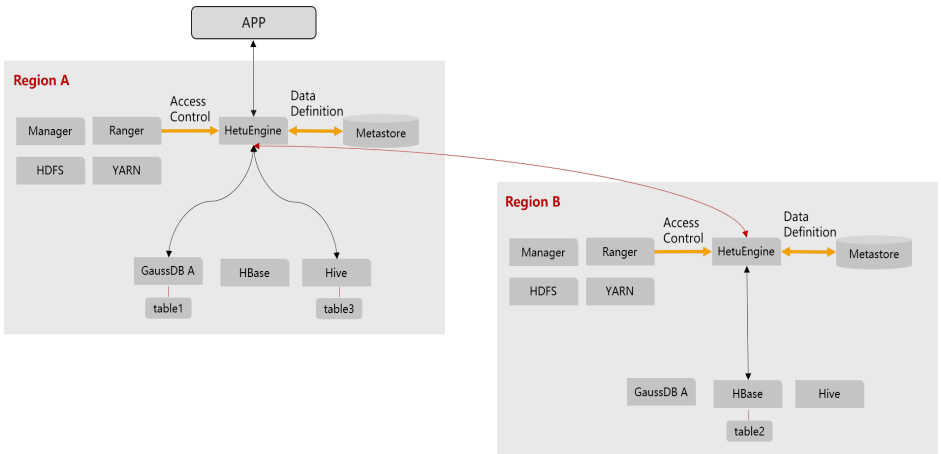
3. Compile SQL statements for cross-source collaborative analysis.

```
select * from hive_dg.schema1.table1 t1 join hbase.schema3.table3 t2 join dws.schema02.table4 t3 on t1.name = t2.item and t2.id = t3.cardNo;
```

HetuEngine Cross-Domain Function

HetuEngine provide unified standard SQL to implement efficient access to multiple data sources distributed in multiple regions (or data centers), shields data differences in the structure, storage, and region, and decouples data and applications.

Figure 11-3 HetuEngine cross-region functions



Key Technologies and Advantages

- No single-point failure bottleneck: HSFabric supports horizontal scale-out and multi-channel parallel transmission, maximizing the transmission rate. Cross-domain latency is no longer a bottleneck.

- Better computing resource utilization: Data compression and serialization tasks are delivered to Worker for parallel computing.
- Efficient serialization: The data serialization format is optimized to reduce the amount of data to be transmitted at the same data volume level.
- Streaming transmission: Based on HTTP 2.0 stream, ensure the universality of the HTTP protocol and reduce the repeated invoking of RPC during the transmission of a large amount of data.
- Resumable transmission: A large amount of data is prevented from being retransmitted after the connection is interrupted abnormally during data transmission.
- Traffic control: The network bandwidth occupied by data transmission can be limited by region to prevent other services from being affected due to exclusive traffic occupation in cross-region limited bandwidth scenarios.

Using a Cross-Domain Function

Prerequisites:

- At least one HSFabric instance has been deployed on the data nodes of the local and remote clusters.
- The nodes where the HSFabric instances of the local and remote clusters have been deployed can communicate with each other.

Procedure

Step 1 Open the data source in the local domain. You can create a virtual schema to shield the real schema information and instance information of the physical data source in the local domain from remote access requests. The remote end can use the virtual schema name to access the data source in the local domain.

```
CREATE VIRTUAL SCHEMA hive01.vschema01 WITH (
  catalog = 'hive01',
  schema = 'ins1'
);
```

Step 2 Register the data source of the HetuEngine type on the remote HetuEngine and add the local domain HetuEngine by referring to **Adding a Cross-Cluster HetuEngine Data Source**.

Step 3 Use cross-domain collaborative analysis.

```
// 1. Open the hive1.ins2 data source on the remote HetuEngine.
CREATE VIRTUAL SCHEMA hive1.vins2 WITH (
  catalog = 'hive1',
  schema = 'ins2'
);

// 2. Register three types of data sources, including Hive, GaussDB A, and HetuEngine, on HetuEngine in the local domain.
hetuengine> show catalogs;
  Catalog
-----------
dws
hetuengine_dc
hive
hive_dg
system
systemremote
(6 rows)

// 3. Perform cross-source collaborative analysis on HetuEngine in the local domain.
```

```
select * from hive_dg.schema1.table1 t1 join hetuengine_dc.vins2.table3 t2 join dws.schema02.table4 t3 on
t1.name = t2.item and t2.id = t3.cardNo;
```

----End

11.5.2 Adding a Hive Data Source

Introduction to Hive Data Sources

During HetuEngine installation, the co-deployed Hive data source (which is in the same cluster as HetuEngine) is interconnected by default. The data source name is **hive** and cannot be deleted. Some default configurations, such as the data source name, data source type, server principal, and client principal, cannot be modified. When the environment configuration changes, for example, the local domain name of the cluster is changed, restarting the HetuEngine service can automatically synchronize the configurations of the co-deployed Hive data source, such as server principal and client principal.

- Currently, HetuEngine supports data sources of the following data formats: AVRO, TEXT, RCTEXT, ORC, Parquet, and SequenceFile.
- When HetuEngine interconnects with Hive, you cannot specify multiple delimiters during table creation. However, if the MultiDelimitSerDe class is specified as the serialization class for a Hive data source to create a multi-delimiter table in text format, you can query the table using HetuEngine.
- The Hive data source interconnected with HetuEngine supports Hudi table redirection. This function is available to MRS 3.3.0 or later. Hudi table access requests are redirected to the Hudi connector, so the advanced functions of the Hudi connector are available. To use this function, you need to configure the target Hudi data source, ensure that the Metastore URL of the Hudi data source is the same as that of the current Hive data source, and enable Hudi redirection for the Hive data source.
- To use the isolation function of Hive Metastore, you need to configure **HIVE_METASTORE_URI_HETU** on Hive and restart the Hsbroke instance of the HetuEngine service to update the Hive Metastore URI.

Add a Hive data source outside a cluster on HSConsole.

Prerequisites for Adding a Hive Data Source

- The domain name of the cluster where the data source is located must be different from the HetuEngine cluster domain name.
- The cluster where the data source is located and the HetuEngine cluster nodes can communicate with each other.
- In the **/etc/hosts** file of all nodes in the cluster where HetuEngine is located, add the mapping between the host names and IP addresses of the cluster where the data source to be connected is located, and add **10.10.10.10 hadoop.***System domain name* in the **/etc/hosts** file (for example, **10.10.10.10 hadoop.hadoop.com**). Otherwise, HetuEngine cannot connect to the nodes that are not in the cluster based on the host name.
- A HetuEngine compute instance has been created.

Procedure for Adding a Hive Data Source

Step 1 Obtain the **hdfs-site.xml** and **core-site.xml** configuration files of the Hive data source cluster.

1. Log in to FusionInsight Manager of the cluster where the Hive data source is located.
2. In the upper right corner of the homepage, click **Download Client** to download the complete client to the local PC as prompted.
3. Decompress the downloaded client file package and obtain the **core-site.xml** and **hdfs-site.xml** files in the **FusionInsight_Cluster_1_Services_ClientConfig/HDFS/config** directory.
4. Check whether the **core-site.xml** file contains the **fs.trash.interval** configuration item. If not, add the following configuration items:

```
<property>
<name>fs.trash.interval</name>
<value>2880</value>
</property>
```

5. Change the value of **dfs.client.failover.proxy.provider.***NameService name* in the **hdfs-site.xml** file to **org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider**.

   For example, if the NameService name is **hacluster**, the configuration is as follows:

```
<property>
<name>dfs.client.failover.proxy.provider.hacluster</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
```

NOTICE

If the Hive data source to be interconnected is in the same Hadoop cluster with HetuEngine, you can log in to the HDFS client and run the following commands to obtain the **hdfs-site.xml** and **core-site.xml** configuration files. For details, see **Using the HDFS Client**.

hdfs dfs -get /user/hetuserver/fiber/restcatalog/hive/core-site.xml

hdfs dfs -get /user/hetuserver/fiber/restcatalog/hive/hdfs-site.xml

Step 2 Obtain the **user.keytab** and **krb5.conf** files of the proxy user of the Hive data source.

1. Log in to FusionInsight Manager of the cluster where the Hive data source is located.
2. Choose **System** > **Permission** > **User**.
3. Locate the row that contains the target data source user, click **More** in the **Operation** column, and select **Download Authentication Credential**.
4. Decompress the downloaded package to obtain the **user.keytab** and **krb5.conf** files.

   NOTE

   The proxy user of the Hive data source must be associated with at least the **hive** user group.

Step 3 Obtain the MetaStore URL and the Principal of the server.

1. Decompress the client package of the cluster where the Hive data source is located and obtain the **hive-site.xml** file from the **FusionInsight_Cluster_1_Services_ClientConfig/Hive/config** directory.
2. Open the **hive-site.xml** file and search for **hive.metastore.uris**. The value of **hive.metastore.uris** is the value of MetaStore URL. Search for **hive.server2.authentication.kerberos.principal**. The value of **hive.server2.authentication.kerberos.principal** is the value of Principal on the server.

Step 4 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 5 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 6 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **Hive** for **Data Source Type**.
2. Configure parameters in the **Hive Configuration** area. For details, see **Table 11-12**.

Table 11-12 Hive Configuration

Parameter	Description	Example Value
Driver	The default value is **fi-hive-hadoop**.	fi-hive-hadoop
hdfs-site File	Select the **hdfs-site.xml** configuration file obtained in **Step 1**. The file name is fixed.	-
core-site File	Select the **core-site.xml** configuration file obtained in **Step 1**. The file name is fixed.	-
yarn-site File	Obtain the file from the **Yarn/config** directory on the data source client. Upload this file only when the Hudi data source is connected.	-
krb5 File	Configure this parameter when the security mode is enabled. It is the configuration file used for Kerberos authentication. Select the **krb5.conf** file obtained in **Step 2**.	krb5.conf
Enable Data Source Authentication	Whether to use the permission policy of the Hive data source for authentication. If Ranger is disabled for the HetuEngine service, select **Yes**. If Ranger is enabled, select **No**.	No

3. In the **Metastore Configuration** area, configure the parameters according to **Table 11-13**.

Table 11-13 MetaStore Configuration

Parameter	Description	Example Value
Metastore URL	URL of the MetaStore of the data source. For details, see **Step 3**.	thrift://10.92.8.42:21088,thrift://10.92.8.43:21088,thrift://10.92.8.44:21088
Hudi Redirection (available for MRS 3.3.0 or later)	This parameter is available only when the Metastore URL of the target Hudi data source is the same as that of the current Hive data source. This function redirects Hudi table access request to the Hudi connector, so the advanced functions of the Hudi connector can be used.	No
Hudi Data Source (available for MRS 3.3.0 or later)	This parameter is required for Hudi redirection. All configured Hudi data sources are displayed in the drop-down list box. Select only the Hudi data source that has the same Metastore URL.	-
Security Authentication Mechanism	After the security mode is enabled, the default value is **KERBEROS**.	KERBEROS
Server Principal	Configure this parameter when the security mode is enabled. Value of **hive-site.xml** in **hive.server2.authentication.kerberos.principal** on the data source client. It specifies the username with domain name used by meta to access MetaStore. For details, see **Step 3**.	hive/hadoop.hadoop.com@HADOOP.COM

Parameter	Description	Example Value
Client Principal	Configure this parameter when the security mode is enabled. The parameter format is as follows: *username for accessing MetaStore*@*domain name (uppercase)*. *Username for accessing MetaStore* is the user to which the **user.keytab** file obtained in **Step 2** belongs. **NOTE** You can log in to FusionInsight Manager, choose **System** > **Permission** > **Domain and Mutual Trust**, and view the value of **Local Domain**, which is the current system domain name, for example, HADOOP.COM.	admintest@HADOOP.COM
Keytab File	Configure this parameter when the security mode is enabled. It specifies the keytab credential file of the MetaStore user name. The file name is fixed. Select the **user.keytab** file obtained in **Step 2**.	user.keytab

4. Configure parameters in the **Connection Pool Configuration** area. For details, see **Table 11-14**.

   Table 11-14 Connection Pool Configuration

Parameter	Description	Example Value
Enable Connection Pool	Whether the connection pool is enabled when Hive MetaStore is accessed.	Yes
Maximum Connections	Maximum number of connections between a single Coordinator and Hive Metastore. Value range: 20 to 200; default value: 50	50

5. Configure parameters in **Hive User Information Configuration**. For details, see **Table 11-15**.

   Hive User Information Configuration and **HetuEngine-Hive User Mapping Configuration** must be used together. When HetuEngine is connected to the Hive data source, user mapping enables HetuEngine users to have the same permissions of the mapped Hive data source user. Multiple HetuEngine users can correspond to one Hive user.

Table 11-15 Hive User Information Configuration

Parameter	Description
Data Source User	Data source user information If the data source user is set to **hiveuser1**, a HetuEngine user mapped to **hiveuser1** must exist. For example, create **hetuuser1** and map it to **hiveuser1**.
Keytab File	Obtain the authentication credential of the user corresponding to the data source.

6. (Optional) Configure parameters in the **HetuEngine-Hive User Mapping Configuration** area. For details, see **Table 11-16**.

Table 11-16 HetuEngine-Hive User Mapping Configuration

Parameter	Description
HetuEngine User	HetuEngine user information.
Data Source User	Data source user information, for example, **hiveuser1** (data source user configured in **Table 11-15**)

7. (Optional) Modify custom configurations.
   - You can click **Add** to add custom configuration parameters by referring to **Table 11-17**.

Table 11-17 Custom parameters

Parameter	Description	Example Value
hive.metastore.connection.pool.maxTotal	Maximum number of connections in the connection pool.	50 (The value ranges from 20 to 200.)
hive.metastore.connection.pool.maxIdle	Maximum number of idle threads in the connection pool. When the number of idle threads reaches the maximum number, new threads are not released. Default value: **8**	8 (The value ranges from 0 to 200 and cannot exceed the maximum number of connections.)

Parameter	Description	Example Value
hive.metastore.connection.pool.minIdle	Minimum number of idle threads in the connection pool. When the number of idle threads reaches the minimum number, the thread pool does not create new threads. Default value: **0**	0 (The value ranges from 0 to 200 and cannot exceed the value of **hive.metastore.connection.pool.maxIdle**.)
hive.rcfile.time-zone	Adjusts the binary-encoded timestamp value to a specific time zone. When the table storage format is **RCBINARY** or **RCFILE**, the query result of timestamp data inserted by HetuEngine in Hive 3.1.0 or later is 8 hours earlier than that in HetuEngine. In this case, set this parameter to **UTC**. Default value: **JVM default** (obtaining the local time zone from JVM)	UTC
hive.orc.use-column-names	Whether to access ORC storage files by column name. The options are as follows: ■ **true**: yes ■ **false** (default value): no	false
hive.parquet.use-column-names	Whether to access Parquet storage files by column name. The options are as follows: ■ **true**: yes ■ **false** (default value): no	false
hive.hdfs.wire-encryption.enabled	This parameter needs to be added and set to **false** if the **hadoop.rpc.protection** parameter of the HDFS is set to **authentication** or **integrity**.	false

Parameter	Description	Example Value
hive.strict-mode-restrictions	You can configure the following constraints to restrict user query: ■ **NONE**: no constraints ■ **DISALLOW_EXCEEDED_SCAN_ON_PARTITION** (default value): The maximum number of partitions scanned in a single Hive partitioned table cannot be greater than the value of **hive.max-partitions-per-scan**.	DISALLOW_EXCEEDED_SCAN_ON_PARTITION
hive.ignore-absent-partitions	Query whether any file is missing in a partition. Value options are as follows: ■ **true**: Queries whether files are missing in the partition. ■ **false**: Do not query whether files are missing in the partition. In this case, an error is reported. If this parameter is left blank when data sources are manually connected, **false** is used by default.	true

– You can click **Delete** to delete custom configuration parameters.

NOTE

- You can prefix **coordinator.** or **worker.** to the custom parameters so that the parameters apply only to coordinator or worker nodes. For example, if you prefix **worker.** to **hive.metastore.connection.pool.maxTotal**, the custom parameter becomes **worker.hive.metastore.connection.pool.maxTotal**. If you set this new parameter to **50**, it indicates that a maximum number of 50 connections are allowed for worker nodes to access Hive MetaStore. If a custom parameter is not prefixed, the custom parameter is available for both coordinator and worker nodes.
- By default, the maximum number of connections for coordinator nodes to access Hive MetaStore is 50, and the maximum and minimum numbers of idle data source connections are 8 and 0, respectively. The maximum number of connections for worker nodes to access Hive MetaStore is 20, and the maximum and minimum numbers of idle data source connections are both 0.
- **hive.max-partitions-per-scan**: The maximum number of partitions scanned in a single Hive partitioned table. The default value is **100000**.
- The default value of **hive.ignore-absent-partitions** of the Hive data source co-deployed during HetuEngine installation is **true**.

8. Click **OK**.

Step 7 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 8 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog hive_1 --schema default

Step 9 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

Hive Data Type Mapping

Currently, Hive data sources support the following data types: BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, REAL, DOUBLE, DECIMAL, NUMERIC, DEC, VARCHAR, VARCHAR (X), CHAR, CHAR (X), STRING, DATE, TIMESTAMP, TIME WITH TIMEZONE, TIMESTAMP WITH TIME ZONE, TIME, ARRAY, MAP, STRUCT, and ROW.

Performance Optimization

- Metadata caching

Hive connectors support metadata caching to provide metadata requests for various operations faster. For details, see **Adjusting HetuEngine Metadata Caching**.

- Dynamic filtering

  Enabling dynamic filtering helps optimize the calculation of the Join operator of Hive connectors. For details, see **Enabling Dynamic Filtering in HetuEngine**.

- Query with partitioning conditions

  Creating a partitioned table and querying data with partitioning filter criteria help filter out some partition data, improving performance.

- INSERT statement optimization

  You can improve insert performance by setting **task.writer-count** to **1** and choosing a larger value for **hive.max-partitions-per-writers**. For details, see **Optimizing HetuEngine INSERT Statements**.

Constraints on Hive Data Sources

- The DELETE syntax can be used to delete data from an entire table or a specified partition in a partitioned table.
- The Hive metabase does not support schema renaming, that is, the ALTER SCHEMA RENAME syntax is not supported.

11.5.3 Adding a Hudi Data Source

HetuEngine supports the query of COW/MOR table data. Configure a Hudi data source on HSConsole.

NOTE

HetuEngine cannot read Hudi bootstrap tables.

Prerequisites for Adding a Hudi Data Source

- You have created the proxy user of the Hudi data source. The proxy user is a human-machine user and must belong to the **hive** group.
- In the **/etc/hosts** file of all nodes in the cluster where HetuEngine is located, add the mapping between the host names and IP addresses of the cluster where the data source to be connected is located, and add **10.10.10.10 hadoop.***System domain name* in the **/etc/hosts** file (for example, **10.10.10.10 hadoop.hadoop.com**). Otherwise, HetuEngine cannot connect to the nodes that are not in the cluster based on the host name.
- You have created a HetuEngine administrator by referring to **Creating a HetuEngine Permission Role**.

Procedure for Adding a Hudi Data Source

Step 1 Obtain the **hdfs-site.xml** and **core-site.xml** configuration files of the Hudi data source cluster.

1. Log in to FusionInsight Manager of the cluster where the Hudi data source is.
2. In the upper right corner of the homepage, click **Download Client** to download the complete client to the local PC as prompted.

3. Decompress the downloaded client file package and obtain **core-site.xml** and **hdfs-site.xml** from the **FusionInsight_Cluster_1_Services_ClientConfig/HDFS/config** directory.
4. Check whether the **core-site.xml** file contains the **fs.trash.interval** configuration item. If not, add the following configuration items:

```
<property>
<name>fs.trash.interval</name>
<value>2880</value>
</property>
```

5. Change the value of **dfs.client.failover.proxy.provider.***NameService name* in the **hdfs-site.xml** file to **org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider**.

   For example, if the NameService name is **hacluster**, the configuration is as follows:

```
<property>
<name>dfs.client.failover.proxy.provider.hacluster</name>
<value>org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider</value>
</property>
```

NOTICE

If the Hudi data source to be connected and HetuEngine are in the same Hadoop cluster, obtain the **hdfs-site.xml** and **core-site.xml** configuration files from the HDFS client of the cluster. To be specific, log in to the HDFS client by referring to **Using the HDFS Client** and run the following commands:

hdfs dfs -get /user/hetuserver/fiber/restcatalog/hive/core-site.xml

hdfs dfs -get /user/hetuserver/fiber/restcatalog/hive/hdfs-site.xml

Step 2 Obtain the **user.keytab** and **krb5.conf** files of the proxy user of the Hudi data source.

1. Log in to FusionInsight Manager of the cluster where the Hudi data source is.
2. Choose **System** > **Permission** > **User**.
3. Locate the row that contains the target data source user, click **More** in the **Operation** column, and select **Download Authentication Credential**.
4. Decompress the downloaded package to obtain **user.keytab** and **krb5.conf**.

   NOTE

   The proxy user of the Hive data source must be associated with at least the **hive** user group.

Step 3 Obtain the MetaStore URL and the Principal of the server.

1. Decompress the client package of the cluster where the Hudi data source is and obtain the **hive-site.xml** file from the **FusionInsight_Cluster_1_Services_ClientConfig/Hive/config** directory.
2. Open **hive-site.xml** and search for **hive.metastore.uris**. The value of **hive.metastore.uris** is the value of MetaStore URL. Search for **hive.server2.authentication.kerberos.principal**. The value of **hive.server2.authentication.kerberos.principal** is the value of Principal on the server.

Step 4 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 5 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 6 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **Hudi** for **Data Source Type**.
2. In the **Hudi Configuration** area, configure the parameters according to **Table 11-18**.

Table 11-18 Hudi configuration

Parameter	Description	Example Value
Driver	The default value is **hudi**.	hudi
hdfs-site File	Select the **hdfs-site.xml** configuration file obtained in **Step 1**. The file name is fixed.	-
core-site File	Select the **core-site.xml** configuration file obtained in **Step 1**. The file name is fixed.	-
krb5 File	Configure this parameter when the security mode is enabled. It is the configuration file used for Kerberos authentication. Select the **krb5.conf** file obtained in **Step 2**.	krb5.conf

3. In the **Metastore Configuration** area, configure the parameters according to **Table 11-19**.

Table 11-19 MetaStore Configuration

Parameter	Description	Example Value
Metastore URL	URL of the MetaStore of the data source. For details, see **Step 3**.	thrift://10.92.8.42:21088,thrift://10.92.8.43:21088,thrift://10.92.8.44:21088
Security Authentication Mechanism	After the security mode is enabled, the default value is **KERBEROS**.	KERBEROS

Parameter	Description	Example Value
Server Principal	Configure this parameter when the security mode is enabled. It specifies the username with domain name used by meta to access MetaStore. For details, see **Step 3**.	hive/hadoop.hadoop.com@HADOOP.COM
Client Principal	Configure this parameter when the security mode is enabled. The parameter format is as follows: *Username for accessing MetaStore*@*Domain name (uppercase)*.**COM**. *Username for accessing MetaStore* is the user to which the **user.keytab** file obtained in **Step 2** belongs.	admintest@HADOOP.COM
Keytab File	Configure this parameter when the security mode is enabled. It specifies the keytab credential file of the MetaStore username. The file name is fixed. Select the **user.keytab** file obtained in **Step 2**.	user.keytab

4. Click **OK**.

Step 7 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 8 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog hudi --schema default

Step 9 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

Hudi Data Type Mapping

Currently, the Hudi data source supports the following data types: INT, BIGINT, FLOAT, DOUBLE, DECIMAL, STRING, DATE, TIMESTAMP, BOOLEAN, BINARY, MAP, STRUCT and ARRAY.

Performance Optimization

- Metadata caching

  Hudi connectors support metadata caching to provide metadata requests for various operations faster. For details, see **Adjusting HetuEngine Metadata Caching**.

- Dynamic filtering

  Enabling dynamic filtering helps optimize the calculation of the Join operator of Hudi connectors. For details, see **Enabling Dynamic Filtering in HetuEngine**.

- Query with partition conditions

  Creating a partitioned table and querying data with partition filter criteria help filter out some partition data, improving performance.

Constraints on Hudi Data Source

Hudi data sources support only the QUERY operation.

11.5.4 Adding a ClickHouse Data Source

In a ClickHouse data source, a schema or database cannot contain tables with the same name but different case formats, for example, cktable (lowercase), CKTABLE (uppercase), and CKtable (uppercase and lowercase). Otherwise, HetuEngine cannot use the tables in the schema or database.

Procedure for Adding a ClickHouse Data Source

Step 1 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 2 In the **Basic Information** area on the **Dashboard** tab page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 3 Choose **Data Source** and click **Add Data Source**. On the **Add Data Source** page that is displayed, configure parameters.

1. In the **Basic Configuration** area, configure **Name** and choose **JDBC** > **ClickHouse** for **Data Source Type**.
2. Configure parameters in the **ClickHouse Configuration** area. For details, see **Table 11-20**.

Table 11-20 ClickHouse Configuration

Parameter	Description	Example Value
Driver	The default value is **clickhouse**.	clickhouse
JDBC URL	JDBC URL of the ClickHouse data source. – If the ClickHouse data source uses IPv4, the format is **jdbc:clickhouse://<host>:<port>**. – If the ClickHouse data source uses IPv6, the format is **jdbc:clickhouse://[<host>]:<port>**. – To obtain the value of **<host>**, log in to Manager of the cluster where the ClickHouse data source is located, choose **Cluster** > **Services** > **ClickHouse** > **Instance**, and view the ClickHouseBalancer service IP address. Select an IP address randomly. Currently, only one IP address can be entered. – To obtain the value of **<port>**, log in to Manager of the cluster where the ClickHouse data source is located, click **Cluster**, choose **Services** > **ClickHouse**, click **Configurations**, and click **All Configurations**. If the ClickHouse data source is in security mode, check the HTTPS port number of the ClickHouseBalancer instance, that is, the value of **lb_https_port**. If the ClickHouse data source is in normal mode, check the HTTP port number of the ClickHouseBalancer instance, that is, the value of **lb_http_port**.	**jdbc:clickhouse://10.162.156.243:21426** or **jdbc:clickhouse://10.162.156.243:21425**
Username	Username used for connecting to the ClickHouse data source.	Change the value based on the username being connected with the data source.
Password	User password used for connecting to the ClickHouse data source.	Change the value based on the user password for connecting to the data source.

Parameter	Description	Example Value
Case-sensitive Table/ Schema Name	Whether to support case-sensitive schema/ table names of the data source. HetuEngine supports case-sensitive schema/table names of the data source. – **No**: If multiple table names exist in the same schema of a data source, for example, **cktable** (lowercase), **CKTABLE** (uppercase), and **CKtable** (lowercase and uppercase), only **cktable** (lowercase) can be used by HetuEngine. – **Yes**: Only one table name can exist in the same schema of the data source, for example, **cktable** (lowercase), **CKTABLE** (uppercase), or **CKtable** (lowercase and uppercase). Otherwise, all tables in the schema cannot be used by HetuEngine.	-

3. (Optional) Customize the configuration.

   You can click **Add** to add custom configuration parameters. Configure custom parameters of the ClickHouse data source. For details, see **Table 11-21**.

Table 11-21 Custom parameters of the ClickHouse data source

Parameter	Description	Example Value
use-connection-pool	Whether to use the JDBC connection pool.	true
jdbc.connection.pool.maxTotal	Maximum number of connections in the JDBC connection pool.	8
jdbc.connection.pool.maxIdle	Maximum number of idle connections in the JDBC connection pool.	8
jdbc.connection.pool.minIdle	Minimum number of idle connections in the JDBC connection pool.	0
jdbc.connection.pool.testOnBorrow	Whether to check the connection validity when using a connection obtained from the JDBC connection pool.	false
clickhouse.map-string-as-varchar	Whether to convert the ClickHouse data source of the String and FixedString types to the Varchar type. Default value: **true**	true

Parameter	Description	Example Value
clickhouse.socket-timeout	Timeout interval for connecting to the ClickHouse data source. Unit: millisecond Default value: **120000**	120000
case-insensitive-name-matching.cache-ttl	Timeout interval for caching case-sensitive names of schemas or tables of the data sources. Unit: minute Default value: **1**	1

You can click **Delete** to delete custom configuration parameters.

4. Click **OK**.

Step 4 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 5 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog clickhouse_1 --schema default

Step 6 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

ClickHouse Data Type Mapping

Mapping from ClickHouse data types to HetuEngine data types

ClickHouse Data Type	HetuEngine Data Type
BOOLEAN	BOOLEAN
UInt8	SMALLINT
UInt16	INTEGER

ClickHouse Data Type	HetuEngine Data Type
UInt32	BIGINT
UInt64	DECIMAL(20, 0)
Int8	TINYINT
Int16	SMALLINT
Int32	INTEGER
Int64	BIGINT
Float32	REAL
Float64	DOUBLE
Decimal(P, S)	DECIMAL(P, S)
Decimal32(S)	DECIMAL(P, S)
Decimal64(S)	DECIMAL(P, S)
Decimal128(S)	DECIMAL(P, S)
IPv4	VARCHAR
IPv6	VARCHAR
UUID	VARCHAR
Enum8	VARCHAR
Enum16	VARCHAR
String	VARCHAR / VARBINARY
Fixedstring(N)	VARCHAR / VARBINARY
Date	DATE
DateTime	TIMESTAMP

Performance Optimization

- Subquery pushdown

  The query pushdown function is supported to improve query speed.
- Scalar UDF pushdown

  The Scalar UDF pushdown function is enabled by default. Before you use this function, create a mapping function in HetuEngine as needed.

Constraints on ClickHouse Data Source

- HetuEngine supports interconnecting with ClickHouse using the following SQL syntaxes: SHOW CATALOGS, SCHEMAS, TABLES, COLUMNS, DESCRIBE, USE, and SELECT TABLE/VIEW.

- Tables and views that support interconnection between HetuEngine and ClickHouse:

Item	Supported Table and View
Tables that support interconnection between HetuEngine and ClickHouse	Local table (MergeTree)
	Replicated table (ReplicatedReplacingMergeTree)
	Distributed table
Views that support interconnection between HetuEngine and ClickHouse	Normal view
	Materialized view

11.5.5 Adding a GaussDB Data Source

Add a GaussDB JDBC data source on HSConsole.

Prerequisites for Adding a GaussDB Data Source

- The cluster where the data source is located and the HetuEngine cluster nodes can communicate with each other.
- In the **/etc/hosts** file of all nodes in the cluster where HetuEngine is located, add the mapping between the host names and IP addresses of the cluster where the data source to be connected is located, and add **10.10.10.10 hadoop.***System domain name* in the **/etc/hosts** file (for example, **10.10.10.10 hadoop.hadoop.com**). Otherwise, HetuEngine cannot connect to the nodes that are not in the cluster based on the host name.
- A HetuEngine compute instance has been created.

Procedure for Adding a GaussDB Data Source

Step 1 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 2 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 3 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **JDBC** > **GAUSSDB-A** for **Data Source Type**.
2. Configure parameters in the **GAUSSDB-A Configuration** area. For details, see **Table 11-22**.

Table 11-22 GAUSSDB-A Configuration

Parameter	Description	Example Value
Driver	The default value is **gaussdba**.	gaussdba
JDBC URL	JDBC URL for connecting to GaussDB A. The format is as follows: **jdbc:postgresql://***CN service IP address***:***Port number***/***Database name* **NOTE** If SSL is enabled for the GaussDB database, add the following SSL-related parameter to the URL: **ssl=true&sslfactory=org.postgresql.ssl.NonValidatingFactory**	– SSL is disabled for the GaussDB database: jdbc:postgresql://10.0.136.1:25308/postgres – SSL is enabled for the GaussDB database: jdbc:postgresql://10.0.136.1:25308/postgres?ssl=true&sslfactory=org.postgresql.ssl.NonValidatingFactory
Username	Username for connecting to the GaussDB data source.	Change the value based on the username being connected with the data source.
Password	Password for connecting to the GaussDB data source.	Change the value based on the username and password for connecting to the data source.

3. (Optional) Configure GaussDB user information according to **Table 11-23**.

   GaussDB User Information Configuration and **HetuEngine-GaussDB User Mapping Configuration** must be used together. When HetuEngine is connected to the GaussDB data source, HetuEngine users can have the same permissions of the mapped GaussDB data source user through mapping. Multiple HetuEngine users can correspond to one GaussDB user.

   In the GaussDB database, the created user name must comply with the identifier naming convention and contain a maximum of 63 characters. If a username contains uppercase letters, the database automatically converts the uppercase letters into lowercase letters. To create a username that contains uppercase letters, enclose the username with double quotation marks (""). Therefore, you must use the converted username to set the **Data Source User** parameter.

   The examples are as follows:

   – If the user name created in the GaussDB database is **Gaussuser1**, the value of **Data Source User** must be **gaussuser1**.

- If the user name created in the GaussDB database is **"Gaussuser1"**, the value of **Data Source User** must be **Gaussuser1**.

Table 11-23 GaussDB User Information Configuration

Parameter	Description
Data Source User	Data source user name If the data source user is set to **gaussuser1**, a HetuEngine user mapped to **gaussuser1** must exist. For example, create **hetuuser1** and map it to **gaussuser1**.
Password	User authentication password of the corresponding data source

4. (Optional) Configure HetuEngine-GaussDB user mapping according to **Table 11-24**.

   Multiple HetuEngine accounts are configured in the format of **HetuEngine User** and **Data Source User** key-value pairs, corresponding to one of the users configured in the **GaussDB User Information Configuration** area. When different HetuEngine users are used to access GaussDB, different GaussDB usernames and passwords can be used.

   Table 11-24 HetuEngine-GaussDB User Mapping Configuration

Parameter	Description
HetuEngine User	HetuEngine username
Data Source User	Data source user, for example, **gaussuser1** (data source user configured in **Table 11-23**)

5. (Optional) Customize the configuration.
   - You can click **Add** to add custom configuration parameters. Configure custom parameters of the GaussDB data source. For details, see **Table 11-25**.

     Table 11-25 Custom parameters of the GaussDB data source

Parameter	Description	Example Value
use-connection-pool	Whether to use the JDBC connection pool.	true
jdbc.connection.pool.maxTotal	Maximum number of connections in the JDBC connection pool.	8
jdbc.connection.pool.maxIdle	Maximum number of idle connections in the JDBC connection pool.	8

Parameter	Description	Example Value
jdbc.connection.pool.minIdle	Minimum number of idle connections in the JDBC connection pool.	0
join-pushdown.enabled	▪ **true**: JOIN statements can be pushed down to the data source for execution. ▪ **false**: JOIN statements are not pushed down to the data source for execution. As a result, more network and compute resources are consumed.	true
join-pushdown.strategy	The JOIN push-down function should be enabled in advance. Value options are as follows: ▪ **AUTOMATIC**: cost-based JOIN pushdown ▪ **EAGER**: JOIN pushdown as much as possible	AUTOMATIC
source-encoding	GaussDB data source encoding mode.	UTF-8
multiple-cnn-enabled	Whether to use the GaussDB multi-CN configuration. To use it, ensure that the JDBC connection pool is disabled and the JDBC URL format is as follows: jdbc:postgresql://host:port/database,jdbc:postgresql://host:port/database,jdbc:postgresql://host:port/database.	false
parallel-read-enabled	Whether to use the parallel data read function. If the parallel data read function is enabled, the actual number of splits is determined based on the node distribution and the value of **max-splits**. Multiple connections to the data source will be created for parallel read operations. The dependent data source should support the load.	false

Parameter	Description	Example Value
split-type	Type of the parallel data read function. ■ **NODE**: The degree of parallelism (DOP) is categorized based on the GaussDB data source DataNodes. ■ **PARTITION**: The DOP is categorized based on table partitions. ■ **INDEX**: The DOP is categorized based on table indexes.	NODE
max-splits	Maximum degree of parallelism.	5
use-copymanager-for-insert	Whether to use CopyManager for batch import.	false
unsupported-type-handling	If the connector does not support the data of a certain type, convert it to VARCHAR. ■ After the **CONVERT_TO_VARCHAR** parameter is configured, the data of BIT VARYING, CIDR, MACADDR, INET, OID, REGTYPE, REGCONFIG and POINT types are converted to the varchar type during query and data of these types can only be read. ■ The default value is IGNORE, indicating that unsupported types will be not displayed in the result.	CONVERT_TO_VARCHAR
max-bytes-in-a-batch-for-copymanager-in-mb	Maximum volume of data imported by CopyManager in a batch, in MB.	10
decimal-mapping	By default, data of the DECIMAL, NUMBER, or NUMERIC type whose precision is not specified or exceeds the maximum precision of 38 digits is ignored. You can map the data to the DECIMAL(38, *x*) data type by setting the **decimal-mapping=allow_overflow** parameter. The value of *x* is the value of **decimal-default-scale**.	allow_overflow

Parameter	Description	Example Value
decimal-default-scale	Decimal precision when data of the DECIMAL, NUMBER, or NUMERIC type is mapped into DECIMAL(38, *x*). The value ranges from 0 to 38 and the default value is **0**.	0
case-insensitive-name-matching	HetuEngine supports case-sensitive table and schema names of the GaussDB data source. ■ **false**: Only schemas or tables whose names contain only lowercase letters can be queried. The default value is **false**. ■ **true**: If there are no schemas or tables with the same name after the case-insensitive matching, the schemas or tables can be queried. Otherwise, the schemas or tables cannot be queried.	false

  - You can click **Delete** to delete custom configuration parameters.

6. Click **OK**.

Step 4 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 5 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog gaussdb_1 --schema admin

Step 6 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

GAUSSDB Data Type Mapping

GaussDB Data Type	HetuEngine Data Type
BOOLEAN	BOOLEAN
TINYINT	TINYINT
SMALLINT	SMALLINT
INTEGER	INTEGER
BINARY_INTEGER	INTEGER
BIGINT	BIGINT
SMALLSERIAL	SMALLINT
SERIAL	INTEGER
BIGSERIAL	BIGINT
FLOAT4 (REAL)	REAL
FLOAT8(DOUBLE PRECISION)	DOUBLE PRECISION
DECIMAL[p (,s)]	DECIMAL[p (,s)]
NUMERIC[p (,s)]	DECIMAL[p (,s)]
CHAR(n)	CHAR(n)
CHARACTER(n)	CHAR(n)
NCHAR(n)	CHAR(n)
VARCHAR(n)	VARCHAR(n)
CHARACTER VARYING(55)	VARCHAR(n)
VARCHAR2(n)	VARCHAR(n)
NVARCHAR2(n)	VARCHAR
TEXT(CLOB)	VARCHAR
DATE	TIMESTAMP
TIMESTAMP	TIMESTAMP
UUID	UUID
JSON	JSON

Constraints on GaussDB Data Source

- The following syntaxes are not supported: GRANT, REVOKE, SHOW GRANTS, SHOW ROLES, and SHOW ROLE GRANTS.

- The UPDATE and DELETE syntaxes cannot be used to filter clauses containing cross-catalog conditions, for example, **UPDATE mppdb.table SET column1=value WHERE column2 IN (SELECT column2 from hive.table)**.
- The UPDATE syntax cannot be used to update the DATE, TIMESTAMP, and VARBINARY fields.
- WHERE statements whose condition is REAL cannot be queried, for example, **SELECT * FROM mppdb.table WHERE column1 = REAL '1.1'**.
- The DELETE syntax cannot be used to filter clauses containing subqueries, for example, **DELETE FROM mppdb.table WHERE column IN (SELECT column FROM mppdb.table1)**.
- HetuEngine supports a maximum precision of 38 digits for GaussDB data sources, including the DECIMAL, NUMBER, and NUMERIC data types.
- If either end of a predicate contains a subquery, the predicate will not be pushed down. For example, if a subquery exists after the example statement **count(*)**, the predicate will not be pushed down, but the **min** function in the subquery can be pushed down.

```
select count(*) from item where i_current_price = (select min(i_current_price) from item);
```

11.5.6 Adding an HBase Data Source

This section describes how to add an HBase data source on HSConsole.

Prerequisites for Adding an HBase Data Source

- The domain name of the cluster where the data source is located must be different from the HetuEngine cluster domain name.
- The cluster where the data source is located and the HetuEngine cluster nodes can communicate with each other.
- In the **/etc/hosts** file of all nodes in the cluster where HetuEngine is located, add the mapping between the host names and IP addresses of the cluster where the data source to be connected is located, and add **10.10.10.10 hadoop.***System domain name* in the **/etc/hosts** file (for example, **10.10.10.10 hadoop.hadoop.com**). Otherwise, HetuEngine cannot connect to the nodes that are not in the cluster based on the host name.
- A HetuEngine compute instance has been created.
- The SSL communication encryption configuration of ZooKeeper in the cluster where the data source is located must be the same as that of ZooKeeper in the cluster where HetuEngine is located.

  NOTE

  To check whether SSL communication encryption is enabled, log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper** > **Configurations** > **All Configurations**, and enter **ssl.enabled** in the search box. If the value of **ssl.enabled** is **true**, SSL communication encryption is enabled. If the value is **false**, SSL communication encryption is disabled.

Procedure for Adding an HBase Data Source

Step 1 Obtain the **hbase-site.xml**, **hdfs-site.xml**, and **core-site.xml** configuration files of the HBase data source.

1. Log in to FusionInsight Manager of the cluster where the HBase data source is located.
2. In the upper right corner of the homepage, click **Download Client** to download the complete client as prompted.
3. Decompress the downloaded client file package and obtain the **hbase-site.xml**, **core-site.xml**, and **hdfs-site.xml** files in the **FusionInsight_Cluster_1_Services_ClientConfig/HBase/config** directory.

Step 2 Obtain the **user.keytab** and **krb5.conf** files of the proxy user of the HBase data source.

1. Log in to FusionInsight Manager of the cluster where the HBase data source is located.
2. Choose **System** > **Permission** > **User**.
3. Locate the row that contains the target data source user, click **More** in the **Operation** column, and select **Download Authentication Credential**.
4. Decompress the downloaded package to obtain the **user.keytab** and **krb5.conf** files.

NOTE

The proxy user of the data source must have the permission to perform HBase operations.

Step 3 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 4 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 5 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **HBase** for **Data Source Type**.
2. Configure parameters in the **HBase Configuration** area. For details, see **Table 11-26**.

Table 11-26 HBase Configuration

Parameter	Description	Example Value
Driver	The default value is **hbase-connector**.	hbase-connector

Parameter	Description	Example Value
ZooKeeper Quorum Address	Service IP addresses of all quorumpeer instances of the ZooKeeper service for the data source. If the ZooKeeper service of the data source uses IPv6, you need to specify the client port number in the ZooKeeper Quorum address. Log in to FusionInsight Manager, choose **Cluster** > **Services** > **ZooKeeper** > **Instance**, and view the IP addresses of all the hosts housing the quorumpeer instances.	– IPv4: 10.10.10.10,10.10.10.11,10.10.10.12 – IPv6: [10:10::10:11]:24002
ZooKeeper Client Port Number	Port number of the ZooKeeper client. Log in to FusionInsight Manager and choose **Cluster** > **Service** > **ZooKeeper**. On the **Configurations** tab page, check the value of **clientPort**.	2181
HBase RPC Communication Protection	Set this parameter based on the value of **hbase.rpc.protection** in the **hbase-site.xml** file obtained in **Step 1**. – If the value is **authentication**, set this parameter to **No**. – If the value is **privacy**, set this parameter to **Yes**.	No
Security Authentication Mechanism	After the security mode is enabled, the default value is **KERBEROS**.	KERBEROS
Principal	Configure this parameter when the security authentication mechanism is enabled. Set the parameter to the user to whom the **user.keytab** file obtained in **Step 2** belongs.	user_hbase@HADOOP2.COM
Keytab File	Configure this parameter when the security mode is enabled. It specifies the security authentication key. Select the **user.keytab** file obtained in **Step 2**.	user.keytab
krb5 File	Configure this parameter when the security mode is enabled. It is the configuration file used for Kerberos authentication. Select the **krb5.conf** file obtained in **Step 2**.	krb5.conf

Parameter	Description	Example Value
hbase-site File	Configure this parameter when the security mode is enabled. It is the configuration file required for connecting to HDFS. Select the **hbase-site.xml** file obtained in **Step 1**.	hbase-site.xml
core-site File	Configure this parameter when the security mode is enabled. This file is required for connecting to HDFS. Select the **core-site.xml** file obtained in **Step 1**.	core-site.xml
hdfs-site File	Configure this parameter when the security mode is enabled. This file is required for connecting to HDFS. Select the **hdfs-site.xml** file obtained in **Step 1**.	hdfs-site.xml

3. (Optional) Customize the configuration.
4. Click **OK**.

Step 6 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 7 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog hbase_1 --schema default

Step 8 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

Step 9 Create a structured mapping table.

The format of the statement for creating a mapping table is as follows:

```
CREATE TABLE schemaName.tableName (
  rowId VARCHAR,
  qualifier1 TINYINT,
  qualifier2 SMALLINT,
  qualifier3 INTEGER,
  qualifier4 BIGINT,
  qualifier5 DOUBLE,
  qualifier6 BOOLEAN,
  qualifier7 TIME,
```

```
  qualifier8 DATE,
  qualifier9 TIMESTAMP
)
WITH (
column_mapping =
'qualifier1:f1:q1,qualifier2:f1:q2,qualifier3:f2:q3,qualifier4:f2:q4,qualifier5:f2:q5,qualifier6:f3:q1,qualifier7:f3:q2,
qualifier8:f3:q3,qualifier9:f3:q4',
row_id = 'rowId',
hbase_table_name = 'hbaseNamespace:hbaseTable',
external = true
);
```

NOTICE

The value of **schemaName** must be the same as that of **hbaseNamespace** in **hbase_table_name**.

- Supported mapping tables: Mapping tables can be directly associated with tables in the HBase data source or created and associated with new tables that do not exist in the HBase data source.
- Supported data types in a mapping table: VARCHAR, TINYINT, SMALLINT, INTEGER, BIGINT, DOUBLE, BOOLEAN, TIME, DATE, and TIMESTAMP
- The following table describes the keywords in the statements for creating mapping tables.

Table 11-27 Keywords in the statements for creating mapping tables

Keyword	Type	Mandatory	Default Value	Remarks
column_mapping	String	No	All columns belong to the same Family column family.	Specify the mapping between columns in the mapping table and column families in the HBase data source table. To associate a table in the HBase data source, set this parameter to the same value as that configured in the HBase data source. To create a table that does not exist in the HBase data source, configure this parameter. Value format: *Mapping table column name*:*HBase column family*.*HBase column name*. Mapping table column names must be in lowercase. HBase column names must be the same as that in HBase.

Keyword	Type	Mandatory	Default Value	Remarks
row_id	String	No	First column in the mapping table	Column name corresponding to the rowkey table in the HBase data source
hbase_table_name	String	No	N/A	Tablespace and table name of the HBase data source to be associated. Use a colon (:) to separate them. The default tablespace is **default**. If a new table that does not exist in the HBase data source is created, **hbase_table_name** does not need to be specified.
external	Boolean	No	true	If **external** is set to **true**, the table is a mapping table in the HBase data source and the original table in the HBase data source cannot be deleted. If **external** is set to false, the table in the HBase data source is deleted when the **Hetu-HBase** table is deleted.

----End

HBase Data Type Mapping

HBase is a byte-based distributed storage system that stores all data types as byte arrays. To represent HBase data in HetuEngine, select a data type that matches the value of the HBase column qualifier for the HetuEngine column qualifier by creating a mapping table in HetuEngine.

Currently, HetuEngine column qualifiers support the following data types: VARCHAR, TINYINT, SMALLINT, INTEGER, BIGINT, DOUBLE, BOOLEAN, TIME, DATE, and TIMESTAMP.

Performance Optimization

- Predicate pushdown

  Queries support pushdown of most operators. The following predicate conditions are supported: **=**, **>=**, **>**, **<**, **<=**, **!=**, **IN**, **NOT IN**, **IS NULL**, **IS NOT NULL**, and **BETWEEN AND**.

- Batch GET query

  Multiple row keys to be queried are encapsulated into one List<Get> in the HBase API, and then the list is requested to query data. In this way, each row key does not need to initiate a request separately.

- HBase single-table query range scanning optimization

  The HBase single-table query range scanning optimization is to automatically infer the start and end addresses of rowkeys based on the predicate conditions of HBase columns and configure the start and end addresses of HBase scan during tableScan for higher access performance.

  For example, assume that the rowkey of the HBase data table consists of four columns: **building_code**:**house_code**:**floor**:**uuid**. For the search criteria **where building_code = '123' and house_code = '456'**, the HetuEngine single-table query optimization scans only columns whose rowkey range prefixes are 123 to 456, improving performance.

  To enable the single HBase table query range scanning optimization function, add the custom parameter **hbase.rowkey.adaptive.optimization.enabled** to **5.3** and set it to **true**.

  In addition, you need to specify the columns and separators of rowkeys in the table creation property of table creation statements.

  Table 11-28 Columns and separators of HBase rowkeys

Table Property	Description	Example Value
row_id_construct_columns	Columns of rowkeys in an HBase data table	building_code:house_code:floor:uuid
row_id_construct_columns_terminal	Separator of columns of rowkeys in an HBase data table	:

  For example, a table creation statement containing a rowkey consisting of four columns building_code:house_code:floor:uuid is as follows:

```
CREATE TABLE test.table_hbase_test (
row_id string,
col1 string,
col2 string,
col3 string,
building_code string,
house_code string,
floor string,
uuid string)
WITH (column_mapping = '
col1:attr:col1,
col2:attr:col2,
col3:attr:col3,
building_code:attr:building_code,
house_code:attr:house_code,
floor:attr:floor,
uuid:attr:uuid',
row_id = 'row_id',
row_id_construct_columns = 'building_code:house_code:floor:uuid',
row_id_construct_columns_terminal = ':',
hbase_table_name='test:table_hbase_test',
external = true)
```

- Dynamic filtering optimization for HBase multi-table join query

  HBase supports dynamic filtering optimization.

  To enable the dynamic filtering function, enable the HBase single table query range scanning optimization function, add the custom parameter **enable-**

dynamic-filtering in the **coordinator.config.properties** and **worker.config.properties** parameter files of compute instances, and set the parameter to **true**. For details, see **Step 3.5**.

Constraints on HBase Data Source

The ALTER and VIEW syntaxes are not supported.

11.5.7 Adding a Cross-Cluster HetuEngine Data Source

This section describes how to add another HetuEngine data source on the HSConsole page for a cluster in security mode.

Procedure for Adding a Cross-Cluster HetuEngine Data Source

Step 1 Obtain the **user.keytab** file of the proxy user of the HetuEngine cluster in a remote domain.

1. Log in to FusionInsight Manager of the HetuEngine cluster in the remote domain.
2. Choose **System** > **Permission** > **User**.
3. Locate the row that contains the target data source user, click **More** in the **Operation** column, and select **Download Authentication Credential**.
4. The **user.keytab** file extracted from the downloaded file is the user credential file.

Step 2 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**. The **HetuEngine** service page is displayed.

Step 3 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**. The HSConsole page is displayed.

Step 4 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **HetuEngine** for **Data Source Type**.
2. Configure parameters in the **HetuEngine Configuration** area. For details, see **Table 11-29**.

Table 11-29 HetuEngine Configuration

Parameter	Description	Example Value
Driver	The default value is **hsfabric-initial**.	hsfabric-initial
Username	Configure this parameter when the security mode is enabled. It specifies the user who accesses the remote HetuEngine. Set the parameter to the user to whom the **user.keytab** file obtained in **Step 1** belongs.	hetu_test

Parameter	Description	Example Value
Keytab File	Configure this parameter when the security mode is enabled. This is the Keytab file of the user who accesses the remote DataCenter. Select the **user.keytab** file obtained in **Step 1**.	user.keytab
Two Way Transmission	This parameter indicates whether to enable bidirectional transmission for cross-domain data transmission. The default value is **Yes**. – **Yes**: Two-way transmission: Requests are forwarded to the remote HSFabric through the local HSFabric. If two-way transmission is enabled, the local HSFabric address must be configured. – No: Unidirectional transmission: Requests are directly sent to the remote HSFabric.	Yes
Local Configuration	Host IP address and port number of the HSFabric instance that is responsible for external communication of the HetuEngine service in the local MRS cluster. 1. Log in to FusionInsight Manager of the local cluster, choose **Cluster** > **Services** > **HetuEngine** > **Instance**, and check the service IP address of the HSFabric. 2. Click **HSFabric**, choose **Instance Configuration**, and check the value of **server.port**. The default value is **29900**.	192.162.157.32:29900
Remote Address	Host IP address and port number of the HSFabric instance that is responsible for external communication of the HetuEngine service in the remote MRS cluster. 1. Log in to FusionInsight Manager of the remote cluster, choose **Cluster** > **Services** > **HetuEngine** > **Instance**, and check the service IP address of the HSFabric. 2. Click **HSFabric**, choose **Instance Configuration**, and check the value of **server.port**. The default value is **29900**.	192.168.1.1:29900

Parameter	Description	Example Value
Region	Region to which the current request initiator belongs. The value can contain only digits and underscores (_).	0755_01
Receiving Data Timeout (s)	Timeout interval for receiving data, in seconds.	60
Total Task Timeout (s)	Total timeout duration for executing a cross-domain task, in seconds.	300
Tasks Used by Worker Nodes	Number of tasks used by each worker node to receive data.	5
Data Compression	– **Yes**: Data compression is enabled. – **No**: Data compression is disabled.	Yes

3. (Optional) Customize the configuration.
   – You can click **Add** to add custom configuration parameters. Configure custom parameters of the HetuEngine data source. For details, see **Table 11-30**.

Table 11-30 Custom parameters of the HetuEngine data source

Parameter	Description	Example Value
hsfabric.health.check.time	Interval for checking the HSFabric instance status, in seconds.	60
hsfabric.subquery.pushdown	Whether to enable cross-domain query pushdown. The function is enabled by default. ▪ **true**: enables cross-domain query pushdown. ▪ **false**: disables cross-domain query pushdown.	true

Parameter	Description	Example Value
hsfabric.local.tenant (available for MRS 3.3.0 or later)	Tenant queue used by the remote HetuEngine for computing ■ If this parameter is not set, the system randomly selects the tenant to which the user belongs based on the configured user. ■ If this parameter is set, the specified tenant will be used. This parameter applies to scenarios where strict tenant verification is enabled.	-

  - You can click **Delete** to delete custom configuration parameters.

4. Click **OK**.

Step 5 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 6 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog hetuengine_1 --schema default

Step 7 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

Cross-Cluster HetuEngine Data Type Mapping

Currently, HetuEngine data sources support the following data types: BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, REAL, DOUBLE, DECIMAL, VARCHAR, CHAR, DATE, TIMESTAMP, ARRAY, MAP, TIME WITH TIMEZONE, TIMESTAMP WITH TIME ZONE, and TIME.

Performance Optimization

The query pushdown function is supported to improve query speed.

This function is enabled by default. You can also enable it by adding related custom parameters according to **Step 4.3**.

Constraints on Cross-Cluster HetuEngine Data Source

The following syntaxes are not supported: CREATE, ALTER, DROP VIEW, INSERT OVERWRITE, UPDATE, and DELETE.

INSERT is not supported for cross-domain data sources.

11.5.8 Adding an IoTDB Data Source

This section applies to MRS 3.2.0 or later.

Add an IoTDB JDBC data source on HSConsole of a cluster in security mode.

Prerequisites for Adding an IoTDB Data Source

- The domain name of the cluster where the data source is located must be different from that of the HetuEngine cluster.
- The cluster where the data source is located and the HetuEngine cluster nodes can communicate with each other.
- A HetuEngine compute instance has been created.
- By default, SSL is enabled for the IoTDB service in a security cluster. After SSL is enabled, you need to upload the **truststore.jks** file. For details about how to obtain the file, see **Using the IoTDB Client**.

Procedure for Adding an IoTDB Data Source

Step 1 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**.

Step 2 On the **Dashboard** tab page that is displayed, find the **Basic Information** area, and click the link next to **HSConsole WebUI**.

Step 3 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **JDBC** > **IoTDB** for **Data Source Type**.
2. Configure parameters in the **IoTDB Configuration** area by referring to **Table 11-31**.

Table 11-31 IoTDB configuration parameters

Parameter	Description	Example Value
Driver	The default value is **iotdb**.	iotdb

Parameter	Description	Example Value
JDBC URL	JDBC URL for connecting to IoTDB. – If the IoTDB data source uses an IPv4 address, the format is **jdbc:iotdb://** *P address 1 of the IoTDBServer service, IP address 2 of the IoTDBServer service*:*Port*. – If the IoTDB data source uses an IPv6 address, the format is **jdbc:iotdb://[** *P address 1 of the IoTDBServer service, IP address 2 of the IoTDBServer service*]:*Port*.	– IPv4: **jdbc:iotdb://10.10.10.11,10.10.10.12:22260** – IPv6: **jdbc:iotdb://[10:10::10:11,10:10::10:12]:22260**
Username	IoTDB username for connecting to the IoTDB data source	**NOTE** If the cluster where IoTDB resides is in non-security mode, set this parameter to the default IoTDB user **root**.
Password	Password of the IoTDB username for connecting to the IoTDB data source	**NOTE** If the cluster where the IoTDB service is installed is in non-security mode, obtain the password of user **root** from the administrator of this cluster.
Enable SSL	Whether SSL is enabled for the IoTDB service. SSL is enabled by default in a security cluster.	Yes
truststore File	After SSL is enabled for IoTDB, upload the **truststore.jks** file.	-

NOTE

- Service IP addresses of IoTDBServer:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **IoTDB**. On the page that is displayed, click the **Instance** tab. On this tab page, check **Service IP Address** of IoTDBServer.

- Port number:

  Log in to FusionInsight Manager, choose **Cluster** > **Services** > **IoTDB**. On the page that is displayed, click the **Configurations** tab. On this tab page, search for and check the value of **IOTDB_SERVER_RPC_PORT**. The default value is **22260**.

3. (Optional) Add custom configurations as needed.

4. Click **OK**.

Step 4 Log in to the node where the cluster client is located and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/client

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this step.)

Step 5 Run the following command to log in to the catalog of the data source:

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog iotdb_1 --schema root.ln

Step 6 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

IoTDB Data Type Mapping

IoTDB Data Type	HetuEngine Data Type
BOOLEAN	BOOLEAN
INT32	BIGINT
INT64	BIGINT
FLOAT	DOUBLE
DOUBLE	DOUBLE
TEXT	VARCHAR

Function Enhancement

- IoTDB can configure any label fields for time series. These IoTDB label fields and other data sources can be jointly queried through HetuEngine.
- Any nodes from the IoTDB database level to the time series can be used as tables for data query on HetuEngine.

Constraints on IoTDB Data Source

- IoTDB data cannot be created but can be queried.
- The IoTDB user who uses HetuEngine for query must at least be configured with the read permission on the root directory.

11.5.9 Adding a MySQL Data Source

This section applies to MRS 3.3.0 or later.

You can interconnect HetuEngine with MySQL data sources to access and query MySQL data. This section describes how to add a MySQL JDBC data source on HSConsole.

Prerequisites for Adding a MySQL Data Source

- The data source and the HetuEngine cluster nodes can communicate with each other.
- If Kerberos authentication is enabled for the cluster (the cluster is in security mode), create a HetuEngine administrator user. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), create a HetuEngine service user, and assign the HDFS administrator permission to the user. That is, the user is added to both the **hadoop** and **hadoopmanager** user groups. For details about how to create a user, see **Creating a HetuEngine Permission Role**.
- A HetuEngine compute instance has been created. For details, see **Creating a HetuEngine Compute Instance**.
- You have obtained the IP address, port number, username, and password for logging in to the MySQL database.

Constraints on Interconnection Between HetuEngine and MySQL Data Sources

- HetuEngine supports interconnecting with MySQL using the following SQL syntaxes: SHOW CATALOGS, SCHEMAS, TABLES, COLUMNS, DESCRIBE, USE, and SELECT TABLE/VIEW.
- The schema and table names of MySQL data sources supported by HetuEngine are case insensitive.
- Predicate pushups or pushdowns are not allowed on columns of text types such as CHAR or VARCHAR.

  For example, if **name** is a column of the VARCHAR type, the predicates of the following two queries cannot be pushed down.

  ```
  SELECT * FROM nation WHERE name>'abcd';
  SELECT * FROM nation WHERE name='abcd';
  ```

Configuring a MySQL Data Source

Installing a cluster client

Step 1 Install the cluster client that contains the HetuEngine service in the **/opt/hadoopclient** directory.

Prepare the MySQL driver

Step 2 Obtain the MySQL driver file (*xxx*.jar) from the MySQL official website. The supported versions are MySQL 5.7, MySQL 8.0, and later versions.

Step 3 Upload the MySQL driver file to the cluster where HetuEngine is deployed.

You can use either of the following methods:

- Upload the file to HDFS on FusionInsight Manager.
  a. Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HDFS**.
  b. In the **Basic Information** area on the **Dashboard** page, click the link next to **NameNode Web UI**.
  c. Select **Utilities** > **Browse the file system**, click  , and create the **/user/hetuserver/fiber/extra_file/driver/mysql** directory.
  d. Go to the **/user/hetuserver/fiber/extra_file/driver/mysql** directory and click  to upload the MySQL driver file obtained in **Step 2**.
  e. Click the value in the **Permission** column in the row containing the driver file, select **Read** and **Write** in the **User** column, **Read** in the **Group** column, and **Read** in the **Other** column, and click **Set**.
- Run HDFS commands to upload the file.
  a. Log in to the node where the HDFS service client is deployed and switch to the client installation directory, for example, **/opt/hadoopclient**.

     cd /opt/hadoopclient
  b. Configure environment variables.

     source bigdata_env
  c. If the cluster is in security mode, authenticate the user. For a normal cluster, user authentication is not required.

     kinit *HetuEngine administrator username*

     Enter the password as prompted.
  d. Run the following commands to create **/user/hetuserver/fiber/extra_file/driver/mysql**, upload the MySQL driver obtained in **Step 2**, and modify the permission:

     hdfs dfs -mkdir -p /user/hetuserver/fiber/extra_file/driver/mysql

     hdfs dfs -put ./*MySQL driver file* **/user/hetuserver/fiber/extra_file/driver/mysql**

     hdfs dfs -chmod -R 644 /user/hetuserver/fiber/extra_file/driver/mysql

Configuring a MySQL Data Source

Step 4 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**.

Step 5 In the displayed**Dashboard** tab, find the **Basic Information** area, and click the link next to **HSConsole WebUI**.

Step 6 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. In the **Basic Configuration** area, configure **Name** and choose **JDBC** > **MySQL** for **Data Source Type**.
2. In the **MySQL Configuration** area, configure the parameters according to **Table 11-32**.

Table 11-32 MySQL configuration

Parameter	Description	Example Value
Driver	The default value is **mysql**.	mysql
Driver Name	Select the MySQL driver that has been uploaded in **Step 2**. The driver format is *xxx*.jar.	mysql-connector-java-8.0.11.jar
JDBC URL	JDBC URL for connecting to MySQL. Format: **jdbc:mysql://***IP address of the MySQL database*:*Port number*. The default port number is **3306**.	– IPV4: jdbc:mysql://10.10.10.11:3306 – IPV6: jdbc:mysql://[10:10::10:11]:3306
Username	MySQL username for connecting to the MySQL data source	-
Password	Password of the MySQL username for connecting to the MySQL data source	-

3. (Optional) Customize the configuration.

   Click **Add** to add custom configuration parameters. Configure custom parameters of the MySQL data source. For details, see **Table 11-33**.

Table 11-33 Custom parameters of the MySQL data source

Parameter	Description	Example Value
mysql.auto-reconnect	Whether to reconnect automatically – **true** (default value): Enable automatic reconnection. – **false**: Disable automatic reconnection.	true
mysql.max-reconnects	Maximum number of reconnection attempts. The default value is 3.	3
mysql.jdbc.use-information-schema	Whether the driver should use INFORMATION_SCHEMA to derive the information used by DatabaseMetaData.	true
use-connection-pool	Whether to use the JDBC connection pool. The default value is **false**.	false
jdbc.connection.pool.maxTotal	Maximum number of connections in the JDBC connection pool. The default value is **8**.	8

Parameter	Description	Example Value
jdbc.connection.pool.maxIdle	Maximum number of idle connections in the JDBC connection pool. The default value is **8**.	8
jdbc.connection.pool.minIdle	Minimum number of idle connections in the JDBC connection pool. The default value is **0**.	0
case-insensitive-name-matching	The schema and table names of MySQL data sources supported by HetuEngine are case sensitive. – **false** (default value): Only schemas and tables whose names contain only lowercase letters can be queried. – **true**: ▪ If no schema or table is matched ignoring case sensitivity, the schema and table can be queried. ▪ If schemas and tables are matched ignoring case sensitivity, the schema and table cannot be queried.	false
case-insensitive-name-matching.cache-ttl	Timeout interval for caching case-sensitive schema and table names of the MySQL data source. The default value is 1 minute.	1m
dynamic-filtering.enabled	Whether dynamic filters will be pushed down to JDBC queries. – **true** (default value): Enable pushdown. – **false**: Disable pushdown.	true
dynamic-filtering.wait-timeout	The maximum duration that HetuEngine will wait to collect dynamic filters from the build side of the connection before starting a JDBC query. Using a larger value may result in a more detailed dynamic filter. However, the latency of some queries is increased. The default value is 20s.	20s
unsupported-type-handling	How data types that are not supported by the connector will be processed – **CONVERT_TO_VARCHAR**: Convert unsupported types to **VARCHAR** and allow only read operations on them. – **IGNORE** (default value): Do not display the unsupported types.	IGNORE

Parameter	Description	Example Value
join-pushdown.enabled	Whether join pushdown is enabled. – **true** (default value): Enable join pushdown. – **false**: Disable join pushdown.	true
join-pushdown.strategy	Policy used to evaluate whether the Join operation is pushed down. – **AUTOMATIC** (default value): Enable cost-based connection pushdown. – **EAGER**: Push down joins as much as possible. Even if table statistics are unavailable, using **EAGER** will push down joins, which may cause query performance deterioration. Use **EAGER** only in test and troubleshooting scenarios.	AUTOMATIC

Click **Delete** to delete custom configuration parameters.

4. Click **OK**

Step 7 Log in to the node where the cluster client is deployed and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/hadoopclient

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this command.)

Step 8 Log in to the catalog of the data source.

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog mysql_1 --schema mysql

Step 9 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

Mapping Between MySQL and HetuEngine Data Types

Mapping from MySQL data types to HetuEngine data types

MySQL Type	HetuEngine Data Type
BIT	BOOLEAN
BOOLEAN	TINYINT
TINYINT	TINYINT
SMALLINT	SMALLINT
INTEGER	INTEGER
BIGINT	BIGINT
DOUBLE PRECISION	DOUBLE
FLOAT	REAL
REAL(m, d)	REAL(m, d)
DECIMAL(p, s)	DECIMAL(p, s)
CHAR(n)	CHAR(n)
VARCHAR(n)	VARCHAR(n)
TINYTEXT	VARCHAR(255)
TEXT	VARCHAR(65535)
MEDIUMTEXT	VARCHAR(16777215)
LONGTEXT	VARCHAR
ENUM(n)	VARCHAR(n)
BINARY, VARBINARY, TINYBLOB, BLOB, MEDIUMBLOB, LONGBLOB	VARBINARY
JSON	JSON
DATE	DATE
TIME(n)	TIME(n)
DATETIME(n)	TIMESTAMP(n)
TIMESTAMP(n)	TIMESTAMP(n)

11.5.10 Adding an Oracle Data Source

This topic is available for MRS 3.5.0 and later versions only.

HetuEngine allows you to configure, access, and query the Oracle data source. This topic guides you to add an Oracle JDBC data source on the HSConsole page of the cluster.

Prerequisites

- The data source and the HetuEngine cluster nodes can communicate with each other.
- If Kerberos authentication is enabled for the cluster (the cluster is in security mode), create a HetuEngine administrator user. If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), create a HetuEngine service user, and assign the HDFS administrator permission to the user. That is, the user is added to both the **hadoop** and **hadoopmanager** user groups. For details about how to create a user, see **Creating a HetuEngine Permission Role**.
- A HetuEngine compute instance has been created. For details, see **Creating a HetuEngine Compute Instance**.
- You have obtained the IP address, port, database instance name or PDB name, username, and password of the Oracle database.

Constraints on the Interconnection with Oracle Data Sources

- Currently, the Oracle data source is read-only by default. Oracle 12 and later versions are supported.
- The schema and table names of Oracle data sources supported by HetuEngine are case insensitive.
- The following syntaxes are not supported: CREATE SCHEMA, ALTER SCHEMA, DROP SCHEMA, INSERT INTO, SELECT, INSERT OVERWRITE, UPDATE, ANALYZE and VIEW.
- Columns of the CLOB, NCLOB, BLOB, or RAW(n) Oracle types or columns of the Trino data type that are mapped to these types do not support predicate pushdown.

  For example, **name** is a column of the VARCHAR type in HetuEngine and is mapped to NCLOB in Oracle. The predicates of the following two queries are not pushed down:

  ```
  SELECT * FROM nation WHERE name>'abcd';
  SELECT * FROM nation WHERE name='abcd';
  ```

- If you specify a WHERE clause, DELETE can be executed only when the predicate in the WHERE clause can be completely pushed down to Oracle.

Configuring the Oracle Data Source

Installing a cluster client

Step 1 Install the cluster client that contains the HetuEngine service in the **/opt/hadoopclient** directory.

Preparing the Oracle driver

Step 2 Obtain the Oracle driver file from the Oracle official website. The format is **ojdbc***xxx***.jar**, for example, **ojdbc8.jar**.

The name of the driver file to be uploaded must meet the following verification rules: The prefix of the driver file must be **ojdbc** and the end be **jar**. The version number in the middle can be any characters, but the total length cannot exceed 80 characters and the file cannot be larger than 100 MB.

Step 3 Upload the Oracle driver file to the cluster where HetuEngine is deployed.

You can use either of the following methods:

- Upload the file to HDFS on FusionInsight Manager.
  a. Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HDFS**.
  b. In the **Basic Information** area on the **Dashboard** page, click the link next to **NameNode Web UI**.
  c. Choose **Utilities** > **Browse the file system** and click  to create the **/user/hetuserver/fiber/extra_file/driver/oracle** directory.
  d. Go to the **/user/hetuserver/fiber/extra_file/driver/oracle** directory and click  to upload the Oracle driver file obtained in **Step 2**.
  e. Click the value in the **Permission** column in the row containing the driver file, select **Read** and **Write** in the **User** column, **Read** in the **Group** column, and **Read** in the **Other** column, and click **Set**.
- Run HDFS commands to upload the file.
  a. Log in to the node where the HDFS service client is deployed and switch to the client installation directory, for example, **/opt/hadoopclient**.
     cd /opt/hadoopclient
  b. Configure environment variables.
     source bigdata_env
  c. If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.
     kinit *HetuEngine administrator username*
     Enter the password as prompted.
  d. Create the **/user/hetuserver/fiber/extra_file/driver/oracle** directory, upload the Oracle driver obtained in **Step 2**, and modify the permission.
     hdfs dfs -mkdir -p /user/hetuserver/fiber/extra_file/driver/oracle
     hdfs dfs -put ./*Oracle driver file* **/user/hetuserver/fiber/extra_file/driver/oracle**
     hdfs dfs -chmod -R 644 /user/hetuserver/fiber/extra_file/driver/oracle

Configuring the Oracle data source

Step 4 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**.

Step 5 In the **Basic Information** area in the **Dashboard** tab, click the link next to **HSConsole Web UI** to access the HSConsole page.

Step 6 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. Configure the basic information, enter the data source name, and select **JDBC** > **Oracle** as the data source type.
2. Configure the parameters in the **Oracle Configuration** area. For details, see **Table 1 Oracle configuration**.

Table 11-34 Oracle configuration

Parameter	Description	Example Value
Driver Name	Select the Oracle driver that has been uploaded in **Step 2**. The format is *ojdbcxxx*.**jar**.	ojdbc8.jar
JDBC URL	JDBC URL for connecting to the Oracle database. The default port is 1521. The following formats are available: – **jdbc:oracle:thin***@IP address of the Oracle database*:*Port*/*Oracle* PDB name – **jdbc:oracle:thin***@IP address of the Oracle database*:*Port*:*OracleDatabase instance name*	– jdbc:oracle:thin:@192.168.1.1:1521/orclpdb – jdbc:oracle:thin:@192.168.1.1:1521:orcl
Username	Oracle username for connecting to the Oracle data source.	-
Password	Oracle user password for connecting to the Oracle data source.	-

3. (Optional) Customize the configuration.

   Click **Add** to add custom configuration parameters. For details, see **Table 11-35**.

Table 11-35 Custom parameters for the Oracle data source

Parameter	Description	Example Value
case-insensitive-name-matching	The schema and table names of the Oracle data source supported by HetuEngine are case sensitive. – **false** (default value): Schemas and tables whose names contain only lowercase letters can be queried. – **true**: ▪ If no schema or table is matched ignoring case sensitivity, the schema and table can be queried. ▪ If schemas and tables are matched ignoring case sensitivity, the schema and table cannot be queried.	false
case-insensitive-name-matching.cache-ttl	Timeout interval for caching case-sensitive schema and table names of the Oracle data source. The default value is **1m** (1 minute).	1m
dynamic-filtering.enabled	Whether dynamic filters will be pushed down to JDBC queries. – **true** (default value): Enable pushdown. – **false**: Disable pushdown.	true
dynamic-filtering.wait-timeout	Maximum duration for which HetuEngine waits to collect dynamic filters from where the connection is built before starting a JDBC query. Using a larger value may result in a more detailed dynamic filter. However, the latency of some queries is increased. The default value is 20s.	20s
unsupported-type-handling	How data types that are not supported by the connector will be processed. – **CONVERT_TO_VARCHAR**: Convert unsupported types to **VARCHAR** and allow only read operations on them. Only the types in the data type mapping table are supported. – **IGNORE** (default value): Do not display the unsupported types.	IGNORE

Parameter	Description	Example Value
join-pushdown.enabled	Whether to enable join pushdown. Join pushdown may adversely affect some query statements. – **true**: Enable Join pushdown. – false (default value): Disable join pushdown.	false
join-pushdown.strategy	Policy used to evaluate whether Join is pushed down. – **AUTOMATIC** (default value): Enable cost-based connection pushdown. – **EAGER**: Push down joins as much as possible. Even if table statistics are unavailable, using **EAGER** will push down joins, which may cause query performance deterioration. Use **EAGER** only in test and troubleshooting scenarios.	AUTOMATIC
oracle.number.default-scale	Number of decimal places of the HetuEngine Decimal type mapped to the Oracle Number data type (which does not have specified precision and decimal places). By default, this parameter is not set and the column is not supported.	5
oracle.remarks-reporting.enabled	Whether to expose metadata comments. – **true**: Expose metadata annotations. – **false** (default): Metadata annotations are not exposed through the REMARKS column.	false
oracle.synonyms.enabled	Whether to enable the synonym function. HetuEngine disables the support for Oracle SYNONYM by default for performance reasons. – **true**: The synonym function is enabled. – **false** (default value): The synonym function is disabled.	false
oracle.source-encoding	Character set code of the remote data source environment, which is used to prevent garbled characters – ZHS16GBK or GBK – AL32UTF8 or UTF-8 (default value)	UTF-8

You can click **Delete** to delete custom configuration parameters.

4. Click **OK**

Step 7 Log in to the node where the cluster client is deployed and run the following commands to switch to the client installation directory and authenticate the user:

cd /opt/hadoopclient

source bigdata_env

kinit *User performing HetuEngine operations* (If the cluster is in normal mode, skip this command.)

Step 8 Log in to the catalog of the data source.

hetu-cli --catalog *Data source name* **--schema** *Database name*

For example, run the following command:

hetu-cli --catalog oracle_1 --schema oralce

Step 9 Run the following command. If the database table information can be viewed or no error is reported, the connection is successful.

show tables;

----End

Mapping Between Oracle and HetuEngine Data Types

Constraints:

- HetuEngine cannot directly read data of the Number type whose precision and scale are not set in the Oracle database. You need to add the custom parameter **oracle.number.default-scale=s** to the data source configuration to map the data type to the **decimal(38, s)** type.
- HetuEngine cannot read columns whose p – s > 38 in the **Number(p, s)** data type.
- The date type in the Oracle database is stored in seconds. Therefore, the data type mapped to HetuEngine is **timestamp(0)**.
- If the decimal precision of the second in the timestamp data queried by HetuEngine is greater than 3, a value is truncated to three decimal places instead of being rounded off.
- The time and date formats supported by the JDBC driver are different. So, an error may occur when the date and time earlier than **1582-10-15** are inserted or queried.
- **VARCHAR(n)** in HetuEngine is mapped to **VARCHAR2(n CHAR)** in Oracle. If **n** is greater than 4000, it is mapped to **NCLOB**. **CHAR(n)** is mapped to **CHAR(n CHAR)**. If **n** is greater than 2000, it is also mapped to **NCLOB**.
- HetuEngine cannot write **CHAR** and **VARCHAR** data types to columns with improper lengths.
- When you use **CREATE TABLE AS** to create an **NCLOB** column from a **CHAR** value, the suffix space in the initial value is removed. However, if you insert a **CHAR** value into an existing **NCLOB** column, the suffix space is retained.

Table 11-36 Mapping from Oracle to HetuEngine data types

Oracle Type	HetuEngine Data Type
NUMBER(p, s)	DECIMAL(p, s)
NUMBER(p)	DECIMAL(p, 0)
FLOAT[(p)]	DOUBLE
BINARY_FLOAT	REAL
BINARY_DOUBLE	DOUBLE
VARCHAR2(n CHAR)	VARCHAR(n)
VARCHAR2(n BYTE)	VARCHAR(n)
NVARCHAR2(n)	VARCHAR(n)
CHAR(n)	CHAR(n)
NCHAR(n)	CHAR(n)
CLOB	VARCHAR
NCLOB	VARCHAR
RAW(n)	VARBINARY
BLOB	VARBINARY
DATE	TIMESTAMP(0)
TIMESTAMP(p)	TIMESTAMP(3)
TIMESTAMP(p) WITH TIME ZONE	TIMESTAMP(3) WITH TIME ZONE

Table 11-37 Mapping from HetuEngine to Oracle data types

HetuEngine Type	Oracle Type
TINYINT	NUMBER(3)
SMALLINT	NUMBER(5)
INTEGER	NUMBER(10)
BIGINT	NUMBER(19)
DECIMAL(p, s)	NUMBER(p, s)
REAL	BINARY_FLOAT
DOUBLE	BINARY_DOUBLE
VARCHAR	NCLOB
VARCHAR(n)	VARCHAR2(n CHAR) or NCLOB

HetuEngine Type	Oracle Type
CHAR(n)	CHAR(n CHAR) or NCLOB
VARBINARY	BLOB
DATE	DATE
TIMESTAMP	TIMESTAMP(3)
TIMESTAMP WITH TIME ZONE	TIMESTAMP(3) WITH TIME ZONE

Function Enhancement

The connector allows you to directly query the underlying database. Only the native Oracle syntax is supported because complete statements are pushed down to and executed in the Oracle database. The connector can be used to access Oracle functions that are unavailable in HetuEngine or when you want to execute some statements faster on the Oracle side.

```
SELECT * FROM TABLE(
  oracle.system.query(
    query => 'SELECT * FROM tpch.nation'));
```

11.5.11 Adding a GBase Data Source

This topic is available for MRS 3.5.0 and later versions only.

HetuEngine allows you to configure, access, and query the GBase data source. This topic guides you to add an GBase JDBC data source on the HSConsole page of the cluster.

Prerequisites

- The data source and the HetuEngine cluster nodes can communicate with each other.
- In the **/etc/hosts** file of all nodes in the cluster where HetuEngine is deployed, add the host names in the cluster where the data source to be interconnected is deployed and the IP address mappings.
- If Kerberos authentication has been enabled for the cluster (security mode), create a HetuEngine administrator. If Kerberos authentication has been disabled for the cluster (normal mode), create a HetuEngine service user and grant the HDFS administrator permission to the user. That is, when you create a user, add the user to both the **hadoop** and **hadoopmanager** user groups, for details about how to create a user, see **Creating a HetuEngine Permission Role**.
- A HetuEngine compute instance has been created. For details, see **Creating a HetuEngine Compute Instance**.
- You have obtained the IP address, port number, username, and password for logging in to the GBase database.

Constraints on the Interconnection with GBase Data Sources

- HetuEngine supports interconnecting with GBase using the following SQL syntaxes: SHOW CATALOGS, SCHEMAS, TABLES, COLUMNS, DESCRIBE, USE, and SELECT TABLE/VIEW.
- The schema and table names of GBase data sources supported by HetuEngine are case insensitive.

Configuring the GBase Data Source

Installing a cluster client

Step 1 Install the cluster client that contains the HetuEngine service in the **/opt/hadoopclient** directory.

Preparing the GBase driver

Step 2 Obtain the GBase driver file in JAR format from GBase's official website. The version must be **gbase-connector-java-9.5.0.1-build1-bin.jar** or later.

Step 3 Upload the GBase driver file to the cluster where HetuEngine is deployed.

You can use either of the following methods:

- Upload the file to HDFS on FusionInsight Manager.
  a. Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HDFS**.
  b. In the **Basic Information** area on the **Dashboard** page, click the link next to **NameNode Web UI**.
  c. Choose **Utilities** > **Browse the file system** and click  to create the **/user/hetuserver/fiber/extra_file/driver/gbase** directory.
  d. Go to the **/user/hetuserver/fiber/extra_file/driver/gbase** directory and click  to upload the GBase driver file obtained in **Step 2**.
  e. Click the value in the **Permission** column in the row containing the driver file, select **Read** and **Write** in the **User** column, **Read** in the **Group** column, and **Read** in the **Other** column, and click **Set**.
- Run HDFS commands to upload the file.
  a. Upload the obtained GBase driver file to any directory on the node where the HDFS service client is deployed.
  b. Log in to the node where the HDFS service client is deployed and switch to the client installation directory, for example, **/opt/hadoopclient**.
     cd /opt/hadoopclient
  c. Configure environment variables.
     source bigdata_env
  d. If the cluster is in security mode, run the following command to authenticate the user. In normal mode, user authentication is not required.
     kinit *HetuEngine administrator username*
     Enter the password as prompted.

e. Create the **/user/hetuserver/fiber/extra_file/driver/gbase** directory, upload the GBase driver obtained in **Step 2**, and modify the permission.

hdfs dfs -mkdir -p /user/hetuserver/fiber/extra_file/driver/gbase

hdfs dfs -put *GBase driver file path* **/user/hetuserver/fiber/extra_file/driver/gbase**

hdfs dfs -chmod -R 644 /user/hetuserver/fiber/extra_file/driver/gbase

Configuring the GBase data source

Step 4 Log in to FusionInsight Manager as a HetuEngine administrator and choose **Cluster** > **Services** > **HetuEngine**.

Step 5 In the **Basic Information** area on the **Dashboard** page, click the link next to **HSConsole WebUI**.

Step 6 Choose **Data Source** and click **Add Data Source**. Configure parameters on the **Add Data Source** page.

1. Configure the basic information, enter the data source name, and select **JDBC** > **GBase** as the data source type.
