5 Go	23
6 Obtaining Kafka Clients	30
7 Using spring-kafka	31

1 Overview

Kafka instances are compatible with Apache Kafka and can be accessed using [open-source Kafka clients](#). In addition, if **Security Protocol** is set to **SASL_SSL**, use the DMS certificate.

This document describes how to collect instance connection information, such as the instance connection address and topic name. It also provides examples of accessing an instance in Java, Python, and Go.

The examples only demonstrate how to invoke Kafka APIs for producing and consuming messages. For more information about the APIs provided by Kafka, visit the [Kafka official website](#).

Client Network Environment

A client can access a Kafka instance in any of the following modes:

- If the client runs an Elastic Cloud Server (ECS) and is in the same region and VPC as the Kafka instance, the client can access the instance using a private network IP address.
- If the client runs an ECS, and is in the same region but not in the same VPC as the Kafka instance, the client can access the instance using one of the following methods:
 - Establish a VPC peering connection to allow two VPCs to communicate with each other. For details, see [VPC Peering Connection](#). Modify the security group of your Kafka instance as required: Allow external access over port 9092 (in plaintext) or 9093 (in ciphertext).
 - Create a cloud connection and load the VPCs that need to communicate with each other to the cloud connection. For details, see [Connecting VPCs in the Same Account](#).
 - Access a Kafka instance on a Kafka client over a private network across VPCs using a VPC endpoint. For details, see [Accessing Kafka Across VPCs Using VPCEP](#). Modify the security group to allow port 9011 for external access.
- If the client is not in the same network environment or region as the Kafka instance, the client can access the instance using a public network IP address.

To use public access, modify the security group of your Kafka instance as required: Allow external access over port 9094 (in plaintext) or 9095 (in ciphertext).

 **NOTE**

The three modes differ only in the connection address for the client to access the instance. This document takes intra-VPC access as an example to describe how to set up the development environment.

If the connection times out or fails, check the network connectivity. You can use telnet to test the connection address and port of the instance.

2 Collecting Connection Information

Before accessing a Kafka instance for message production and consumption, obtain the following information of the instance.

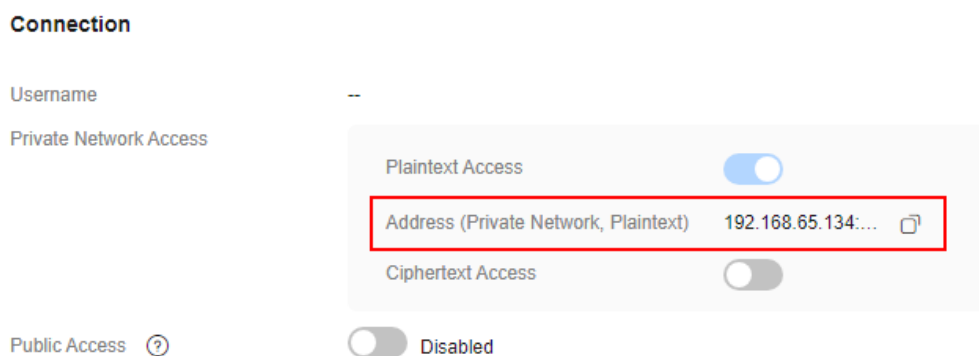

Instance Connection Address and Port

Obtain them from the **Basic Information** page on the Kafka console.

For a cluster Kafka instance that has at least three connection addresses, you are advised to configure all of the connection addresses on the client for high reliability.

For public network access, you can use the public network addresses displayed on the **Basic Information** page.

Figure 2-1 Viewing the connection addresses and ports of brokers of a Kafka instance

Topic name

Obtain the topic name from the **Topics** page of the Kafka instance console.

NOTE

If **Automatic Topic Creation** is disabled, a topic must be created first. Then a Kafka instance can be accessed from a client for message production and consumption.

Ciphertext Access

If ciphertext access is enabled for the instance, obtain the instance username and password, SASL mechanism, and security protocol. In addition, obtain the SSL certificate if the security protocol is set to **SASL_SSL**.

- Obtain the username on the **Users** page on the Kafka console. If you forget your password, obtain it again by [resetting the password](#).

Figure 2-2 Obtaining the SASL_SSL username

<input type="checkbox"/> Username	Description	Updated	Operation
<input type="checkbox"/> test	--	Jul 11, 2024 09:26:41 GMT+08:00	Reset Password Edit
<input type="checkbox"/> admin	--	Jul 11, 2024 09:40:12 GMT+08:00	Reset Password Edit Delete

- Obtain the SASL mechanism from the **Basic Information** page on the Kafka console.

If both SCRAM-SHA-512 and PLAIN are enabled, use either of them in connection configurations. For instances that were created much earlier, if **SASL Mechanism** is not displayed on the instance details page, PLAIN is used by default.

Figure 2-3 SASL mechanism in use

Connection

Username test [Reset Password](#)

Private Network Access

Plaintext Access	<input checked="" type="checkbox"/>
Address (Private Network, Plaintext)	192.168.81.92:9... Copy
Ciphertext Access	<input checked="" type="checkbox"/>
Address (Private Network, Plaintext)	192.168.81.92:9... Copy
Security Protocol	SASL_SSL

Public Access [?](#) Disabled

SASL Mechanism	SCRAM-SHA-512
----------------	---------------

- Obtain the security protocol from the **Basic Information** page on the Kafka console. For Kafka instances that were created much earlier, if **Security Protocol** is not displayed on the instance details page, SASL_SSL is used by default.

Figure 2-4 Security protocol

Connection

Username test [Reset Password](#)

Private Network Access

Plaintext Access	<input checked="" type="checkbox"/>
Address (Private Network, Plaintext)	192.168.0.20:90... Copy
Ciphertext Access	<input checked="" type="checkbox"/>
Address (Private Network, Plaintext)	192.168.0.20:90... Copy
Security Protocol	SASL_SSL

Public Access [?](#) Disabled

- If **Security Protocol** is set to **SASL_SSL**, download the certificate from the **Basic Information** page on the Kafka console.

JKS certificates are used for accessing instances in Java. CRT certificates are used for accessing instances in Python.

3 Java

3.1 Configuring Kafka Clients in Java

This section describes how to add Kafka clients in Maven, and use the clients to access Kafka instances and produce and consume messages. To check how the demo project runs in IDEA, see [Setting Up the Java Development Environment](#).

The Kafka instance connection addresses, topic name, and user information used in the following examples are available in [Collecting Connection Information](#).

Adding Kafka Clients in Maven

```
//Kafka instances are based on Kafka 1.1.0/2.3.0/2.7/3.x. Use the same version of the client.
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-clients</artifactId>
  <version>1.1.0/2.3.0/2.7.2/3.4.0</version>
</dependency>
```

Preparing Kafka Configuration Files

The following describes example producer and consumer configuration files. If ciphertext access is not enabled for the Kafka instance, comment out lines regarding the encryption. Otherwise, set configurations for encrypted access.

- Producer configuration file (the **dms.sdk.producer.properties** file in the [message production code](#))

The information in bold is specific to different Kafka instances and must be modified. Other parameters can also be added.

```
#The topic name is in the specific production and consumption code.
#####
#Information about Kafka brokers. ip:port are the connection addresses and ports used by the
instance. The values can be obtained by referring to the "Collecting Connection Information" section.
Example: bootstrap.servers=100.xxx.xxx.87:909x,100.xxx.xxx.69:909x,100.xxx.xxx.155:909x
bootstrap.servers=ip1:port1,ip2:port2,ip3:port3
#Producer acknowledgement
acks=all
#Method of turning the key into bytes
key.serializer=org.apache.kafka.common.serialization.StringSerializer
#Method of turning the value into bytes
value.serializer=org.apache.kafka.common.serialization.StringSerializer
```

```
#Memory available to the producer for buffering
buffer.memory=33554432
#Number of retries
retries=0
#####
#Comment out the following parameters if ciphertext access is not enabled.
#####
# Set the SASL authentication mechanism, username, and password.
#sasl.mechanism is the SASL mechanism. username and password are the SASL username and
password. Obtain them by referring to section "Collecting Connection Information". For security
purposes, you are advised to encrypt the username and password.
# If the SASL mechanism is PLAIN, the configuration is as follows:
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required \
  username="username" \
  password="password";
# If the SASL mechanism is SCRAM-SHA-512, the configuration is as follows:
sasl.mechanism=SCRAM-SHA-512
sasl.jaas.config=org.apache.kafka.common.security.scram.ScramLoginModule required \
  username="username" \
  password="password";

# Set security.protocol.
# If the security protocol is SASL_SSL, the configuration is as follows:
security.protocol=SASL_SSL
# ssl.truststore.location is the path for storing the SSL certificate. The following code uses the path
format in Windows as an example. Change the path format based on the actual running environment.
ssl.truststore.location=E:\\temp\\client.jks
# ssl.truststore.password is the password of the server certificate. This password is used for accessing
the JKS file generated by Java.
ssl.truststore.password=dms@kafka
# ssl.endpoint.identification.algorithm indicates whether to verify the certificate domain name. This
parameter must be left blank, which indicates disabling domain name verification.
ssl.endpoint.identification.algorithm=
# If the security protocol is SASL_PLAINTEXT, the configuration is as follows:
security.protocol=SASL_PLAINTEXT
```

- Consumer configuration file (the **dms.sdk.consumer.properties** file in the [message consumption code](#))

The information in bold is specific to different Kafka instances and must be modified. Other parameters can also be added.

```
#The topic name is in the specific production and consumption code.
#####
#Information about Kafka brokers. ip:port are the connection addresses and ports used by the
instance. The values can be obtained by referring to the "Collecting Connection Information" section.
Example: bootstrap.servers=100.xxx.xxx.87:909x,100.xxx.xxx.69:909x,100.xxx.xxx.155:909x
bootstrap.servers=ip1:port1,ip2:port2,ip3:port3
#Unique string to identify the group of consumer processes to which the consumer belongs.
Configuring the same group.id for different processes indicates that the processes belong to the same
consumer group.
group.id=1
#Method of turning the key into bytes
key.deserializer=org.apache.kafka.common.serialization.StringDeserializer
#Method of turning the value into bytes
value.deserializer=org.apache.kafka.common.serialization.StringDeserializer
#Offset reset policy
auto.offset.reset=earliest
#####
#Comment out the following parameters if ciphertext access is not enabled.
#####
# Set the SASL authentication mechanism, username, and password.
#sasl.mechanism is the SASL mechanism. username and password are the SASL username and
password. Obtain them by referring to section "Collecting Connection Information". For security
purposes, you are advised to encrypt the username and password.
# If the SASL mechanism is PLAIN, the configuration is as follows:
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required \
  username="username" \
```

```
password="password";
# If the SASL mechanism is SCRAM-SHA-512, the configuration is as follows:
sasl.mechanism=SCRAM-SHA-512
sasl.jaas.config=org.apache.kafka.common.security.scram.ScramLoginModule required \
  username="username" \
  password="password";

# Set security.protocol.
# If the security protocol is SASL_SSL, the configuration is as follows:
security.protocol=SASL_SSL
# ssl.truststore.location is the path for storing the SSL certificate. The following code uses the path
format in Windows as an example. Change the path format based on the actual running environment.
ssl.truststore.location=E:\\temp\\client.jks
# ssl.truststore.password is the password of the server certificate. This password is used for accessing
the JKS file generated by Java.
ssl.truststore.password=dms@kafka
# ssl.endpoint.identification.algorithm indicates whether to verify the certificate domain name. This
parameter must be left blank, which indicates disabling domain name verification.
ssl.endpoint.identification.algorithm=
# If the security protocol is SASL_PLAINTEXT, the configuration is as follows:
security.protocol=SASL_PLAINTEXT
```

Producing Messages

- Test code

```
package com.dms.producer;

import org.apache.kafka.clients.producer.Callback;
import org.apache.kafka.clients.producer.RecordMetadata;
import org.junit.Test;

public class DmsProducerTest {
    @Test
    public void testProducer() throws Exception {
        DmsProducer<String, String> producer = new DmsProducer<String, String>();
        int partition = 0;
        try {
            for (int i = 0; i < 10; i++) {
                String key = null;
                String data = "The msg is " + i;
                //Enter the name of the topic you created. There are multiple APIs for producing messages.
                For details, see the Kafka official website or the following code.
                producer.produce("topic-0", partition, key, data, new Callback() {
                    public void onComplete(RecordMetadata metadata,
                        Exception exception) {
                        if (exception != null) {
                            exception.printStackTrace();
                        }
                        return;
                    }
                });
                System.out.println("produce msg completed");
            }
        } catch (Exception e) {
            // TODO: Exception handling
            e.printStackTrace();
        } finally {
            producer.close();
        }
    }
}
```

- Message production code

```
package com.dms.producer;

                            is.close();
                            is = null;
                        }
                    }
                }
            }
        }
    }

    return config;
}
}
```

3.2 Setting Up the Java Development Environment

With the information collected in [Collecting Connection Information](#) and the network environment prepared for Kafka clients, you can proceed to configuring Kafka clients. This section describes how to configure Kafka clients to produce and consume messages.

Preparing Tools

- Maven
Apache Maven 3.0.3 or later can be downloaded from the [Maven official website](#).
- JDK
Java Development Kit 1.8.111 or later can be downloaded from the [Oracle official website](#).
After the installation, configure the Java environment variables.
- IntelliJ IDEA
IntelliJ IDEA can be downloaded from the [IntelliJ IDEA official website](#) and be installed.

Procedure

Step 1 Download the [demo package](#).

Decompress the package to obtain the following files.

Table 3-1 Files in the demo package

File	Directory	Description
DmsConsumer.java	.\src\main\java\com\dms\consumer	API for consuming messages
DmsProducer.java	.\src\main\java\com\dms\producer	API for producing messages
dms.sdk.consumer.properties	.\src\main\resources	Configuration information for consuming messages
dms.sdk.producer.properties	.\src\main\resources	Configuration information for producing messages
client.jks	.\src\main\resources	SSL certificate, used for SASL_SSL connection
DmsConsumerTest.java	.\src\test\java\com\dms\consumer	Test code of consuming messages
DmsProducerTest.java	.\src\test\java\com\dms\producer	Test code of producing messages
pom.xml	.\	Maven configuration file, containing the Kafka client dependencies

Step 2 In IntelliJ IDEA, import the demo project.

The demo project is a Java project built in Maven. Therefore, you need the JDK and the Maven plugin in IDEA.

Figure 3-1 Click **Import Project**.

Figure 3-2 Choose **Maven**.

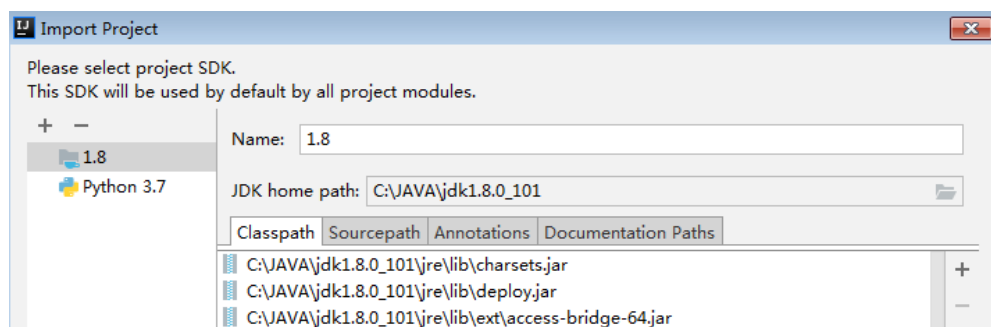

Figure 3-3 Select the **JDK**.

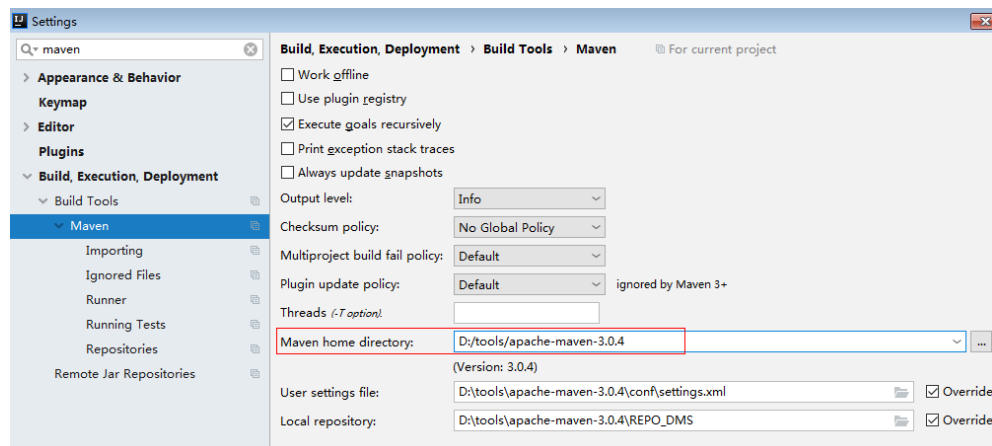

You can select other options or retain the default settings. Click **Finish**.

The demo project has been imported.

Step 3 Configure Maven.

Choose **Files > Settings**, set **Maven home directory** correctly, and select the required **settings.xml** file.

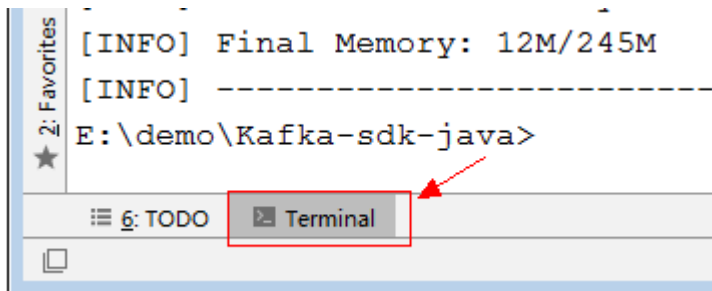

Step 4 Specify Kafka configurations.

This section uses the example of producing messages. For details, see [Producer configuration file](#).

Step 5 In the down left corner of IDEA, click **Terminal**. In terminal, run the **mvn test** command to see how the demo project goes.

Figure 3-4 Opening terminal in IDEA

The following information is displayed for the producer:

```
-----
T E S T S
-----
Running com.dms.producer.DmsProducerTest
produce msg:The msg is 0
produce msg:The msg is 1
produce msg:The msg is 2
produce msg:The msg is 3
produce msg:The msg is 4
produce msg:The msg is 5
produce msg:The msg is 6
produce msg:The msg is 7
produce msg:The msg is 8
produce msg:The msg is 9
Tests run: 1, Failures: 0, Errors: 0, Skipped: 0, Time elapsed: 138.877 sec
```

The following information is displayed for the consumer:

```
-----
T E S T S
-----
Running com.dms.consumer.DmsConsumerTest
the numbers of topic:0
the numbers of topic:0
the numbers of topic:6
ConsumerRecord(topic = topic-0, partition = 2, offset = 0, CreateTime = 1557059377179, serialized key size = -1, serialized value size = 12, headers = RecordHeaders(headers = [], isReadOnly = false), key = null, value = The msg is 2)
ConsumerRecord(topic = topic-0, partition = 2, offset = 1, CreateTime = 1557059377195, serialized key size = -1, serialized value size = 12, headers = RecordHeaders(headers = [], isReadOnly = false), key = null, value = The msg is 5)
```

----End

4 Python

This section takes Linux CentOS as an example to describe how to access a Kafka instance using a Kafka client in Python, including how to install the client, and produce and consume messages.

Before getting started, ensure that you have collected the information listed in [Collecting Connection Information](#).

Preparing the Environment

- Python

Generally, Python is pre-installed in the system. You can enter **python** or **python3** in the command line to check whether Python has been installed. The **python** command checks whether python 2.x has been installed and the **python3** command checks whether python 3.x has been installed. Try both when you are not sure of the version.

For example, if the following information is displayed, Python 3.x has been installed:

```
[root@ecs-test python-kafka]# python3
Python 3.7.1 (default, Jul 5 2020, 14:37:24)
[GCC 4.8.5 20150623 (Red Hat 4.8.5-39)] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

If Python is not installed, run the following command:

yum install python

- Kafka clients in Python

Run the following command to install a Python client of the recommended version:

- Python 2.x: **pip install kafka-python==2.0.1**
- Python 3.x: **pip3 install kafka-python==2.0.1**

Producing Messages

Step 1 Create a file on the client to store the message production sample code.

```
touch producer.py
```

producer.py indicates a file name, which can be customized.

Step 2 Run the following command to edit the file:

```
vim producer.py
```

Step 3 Write the following sample code into the file and save.

- With SASL

```
from kafka import KafkaProducer
import ssl
##Connection information
conf = {
    'bootstrap_servers': ["ip1:port1","ip2:port2","ip3:port3"],
    'topic_name': 'topic_name',
    'sasl_username': 'username',
    'sasl_password': 'password'
}

context = ssl.create_default_context()
context = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
## If Security Protocol is set to SASL_PLAINTEXT, comment out the following parameters:
context.verify_mode = ssl.CERT_REQUIRED
## The certificate file. Obtain the SSL certificate by referring to "Collecting Connection Information".
If Security Protocol is set to SASL_PLAINTEXT, comment out the following parameters:
context.load_verify_locations("phy_ca.crt")

print('start producer')
producer = KafkaProducer(bootstrap_servers=conf['bootstrap_servers'],
                        sasl_mechanism="PLAIN",
                        ssl_context=context,
                        security_protocol='SASL_SSL',
                        sasl_plain_username=conf['sasl_username'],
                        sasl_plain_password=conf['sasl_password'])

data = bytes("hello kafka!", encoding="utf-8")
producer.send(conf['topic_name'], data)
producer.close()
print('end producer')
```

The parameters in the example code are described as follows. For details about how to obtain the parameter values, see [Collecting Connection Information](#).

- **bootstrap_servers**: instance connection address and port
- **topic_name**: topic name
- **sasl_plain_username/sasl_plain_password**: The username and password set when ciphertext access is enabled for the first time, or the ones set in user creation. For security purposes, you are advised to encrypt the username and password.
- **context.load_verify_locations**: certificate file. This parameter is mandatory when **Security Protocol** is set to **SASL_SSL**. CRT certificates are used for accessing instances in Python.
- **sasl_mechanism**: SASL authentication mechanism. View it on the **Basic Information** page of the Kafka instance console. If both SCRAM-SHA-512 and PLAIN are enabled, use either of them in connection configurations. For instances that were created much earlier, if **SASL Mechanism** is not displayed on the instance details page, PLAIN is used by default.
- **security_protocol**: Kafka security protocol. Obtain it from the **Basic Information** page on the Kafka console. For Kafka instances that were created much earlier, if **Security Protocol** is not displayed on the instance details page, SASL_SSL is used by default.
 - When **Security Protocol** is set to **SASL_SSL**, SASL is used for authentication. Data is encrypted with SSL certificates for high-

security transmission. You need to configure the instance username, password, and certificate file.

- When **Security Protocol** is set to **SASL_PLAINTEXT**, SASL is used for authentication. Data is transmitted in plaintext with high performance. You need to configure the instance username and password.
- Without SASL

```
from kafka import KafkaProducer

conf = {
    'bootstrap_servers': ["ip1:port1","ip2:port2","ip3:port3"],
    'topic_name': 'topic-name',
}

print('start producer')
producer = KafkaProducer(bootstrap_servers=conf['bootstrap_servers'])

data = bytes("hello kafka!", encoding="utf-8")
producer.send(conf['topic_name'], data)
producer.close()
print('end producer')
```

The parameters in the example code are described as follows. For details about how to obtain the parameter values, see [Collecting Connection Information](#).

- **bootstrap_servers**: instance connection address and port
- **topic_name**: topic name

Step 4 Run the following command to run the sample code.

```
# Python 2.x
python producer.py

# Python 3.x
python3 producer.py
```

The following information will be displayed after the command is successfully executed.

```
[root@ecs-test ~]# python3 producer.py
start producer
end producer
[root@ecs-test ~]#
```

----End

Consuming Messages

Step 1 Create a file on the client to store the message consumption sample code.

```
touch consumer.py
```

consumer.py indicates a file name, which can be customized.

Step 2 Run the following command to edit the file:

```
vim consumer.py
```

Step 3 Write the following sample code into the file and save.

- With SASL
- ```
from kafka import KafkaConsumer
import ssl
##Connection information
```

```
conf = {
 'bootstrap_servers': ["ip1:port1","ip2:port2","ip3:port3"],
 'topic_name': 'topic_name',
 'saslname': 'username',
 'saslpw': 'password',
 'consumer_id': 'consumer_id'
}

context = ssl.create_default_context()
context = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
If Security Protocol is set to SASL_PLAINTEXT, comment out the following parameters:
context.verify_mode = ssl.CERT_REQUIRED
The certificate file. Obtain the SSL certificate by referring to "Collecting Connection Information".
If Security Protocol is set to SASL_PLAINTEXT, comment out the following parameters:
context.load_verify_locations("phy_ca.crt")

print('start consumer')
consumer = KafkaConsumer(conf['topic_name'],
 bootstrap_servers=conf['bootstrap_servers'],
 group_id=conf['consumer_id'],
 sasl_mechanism="PLAIN",
 ssl_context=context,
 security_protocol='SASL_SSL',
 sasl_plain_username=conf['saslname'],
 sasl_plain_password=conf['saslpw'])

for message in consumer:
 print("%s:%d:%d: key=%s value=%s" % (message.topic, message.partition,message.offset,
 message.key,message.value))

print('end consumer')
```

The parameters in the example code are described as follows. For details about how to obtain the parameter values, see [Collecting Connection Information](#).

- **bootstrap\_servers**: instance connection address and port
- **topic\_name**: topic name
- **sasl\_plain\_username/sasl\_plain\_password**: The username and password set when ciphertext access is enabled for the first time, or the ones set in user creation. For security purposes, you are advised to encrypt the username and password.
- **consumer\_id**: custom consumer group name. If the specified consumer group does not exist, Kafka automatically creates one.
- **context.load\_verify\_locations**: certificate file. This parameter is mandatory when **Security Protocol** is set to **SASL\_SSL**. CRT certificates are used for accessing instances in Python.
- **sasl\_mechanism**: SASL authentication mechanism. View it on the **Basic Information** page of the Kafka instance console. If both SCRAM-SHA-512 and PLAIN are enabled, use either of them in connection configurations. For instances that were created much earlier, if **SASL Mechanism** is not displayed on the instance details page, PLAIN is used by default.
- **security\_protocol**: Kafka security protocol. Obtain it from the **Basic Information** page on the Kafka console. For Kafka instances that were created much earlier, if **Security Protocol** is not displayed on the instance details page, SASL\_SSL is used by default.
  - When **Security Protocol** is set to **SASL\_SSL**, SASL is used for authentication. Data is encrypted with SSL certificates for high-security transmission. You need to configure the instance username, password, and certificate file.

- When **Security Protocol** is set to **SASL\_PLAINTEXT**, SASL is used for authentication. Data is transmitted in plaintext with high performance. You need to configure the instance username and password.
- Without SASL

```
from kafka import KafkaConsumer

conf = {
 'bootstrap_servers': ["ip1:port1","ip2:port2","ip3:port3"],
 'topic_name': 'topic-name',
 'consumer_id': 'consumer-id'
}

print('start consumer')
consumer = KafkaConsumer(conf['topic_name'],
 bootstrap_servers=conf['bootstrap_servers'],
 group_id=conf['consumer_id'])

for message in consumer:
 print("%s:%d:%d: key=%s value=%s" % (message.topic, message.partition,message.offset,
 message.key,message.value))

print('end consumer')
```

The parameters in the example code are described as follows. For details about how to obtain the parameter values, see [Collecting Connection Information](#).

- **bootstrap\_servers**: instance connection address and port
- **topic\_name**: topic name
- **consumer\_id**: custom consumer group name. If the specified consumer group does not exist, Kafka automatically creates one.

**Step 4** Run the following command to run the sample code.

```
Python 2.x
python consumer.py

Python 3.x
python3 consumer.py
```

The following information will be displayed after the command is successfully executed.

```
[root@ecs-test ~]# python3 consumer.py
start consumer
```

Press **Ctrl+C** to cancel.

----End

```
brokers = "ip1:port1,ip2:port2,ip3:port3"
topics = "topic_name"
user = "username"

if err = consumer.Close(); err != nil {
 log.Panicf("Error closing consumer: %v", err)
}
}
```

The parameters in the example code are described as follows. For details about how to obtain the parameter values, see [Collecting Connection Information](#).

- **brokers**: instance connection address and port
- **group**: custom consumer group name. If the specified consumer group does not exist, Kafka automatically creates one.
- **topics**: topic name

# 6 Obtaining Kafka Clients

---

Kafka instances are fully compatible with open-source clients. You can obtain [clients in other programming languages](#) and access your instance as instructed by the official Kafka website.

# 7 Using spring-kafka

This section describes how to use spring-kafka to connect to a Huawei Cloud Kafka instance to produce and consume messages. Obtain the related code from [kafka-springboot-demo](#).

The Kafka instance connection addresses, topic name, and user information used in the following examples are available in [Collecting Connection Information](#).

## Adding the spring-kafka Dependency to the pom.xml File

```
<dependency>
 <groupId>org.springframework.kafka</groupId>
 <artifactId>spring-kafka</artifactId>
</dependency>
```

## Configuring the application.properties File

```
Kafka
Broker information of the Kafka instance. ip.port indicates the connection address and port number of
the instance.
spring.kafka.bootstrap-servers=ip1:port1,ip2:port2,ip3:port3
Producer Configuration
spring.kafka.producer.retries=0
spring.kafka.producer.batch-size=16384
spring.kafka.producer.buffer-memory=33554432
spring.kafka.producer.key-serializer=org.apache.kafka.common.serialization.StringSerializer
spring.kafka.producer.value-serializer=org.apache.kafka.common.serialization.StringSerializer
Consumer Configuration
spring.kafka.consumer.group-id=test-consumer-group
spring.kafka.consumer.auto-offset-reset=earliest
spring.kafka.consumer.enable-auto-commit=true
spring.kafka.consumer.auto-commit-interval=100
spring.kafka.consumer.key-deserializer=org.apache.kafka.common.serialization.StringDeserializer
spring.kafka.consumer.value-deserializer=org.apache.kafka.common.serialization.StringDeserializer
SASL Configuration (Delete the following configuration if SASL is disabled.)
Set the SASL authentication mechanism, username, and password.
spring.kafka.properties.sasl.mechanism is the SASL mechanism. username and password are the SASL
username and password. Obtain them by referring to section "Collecting Connection Information". For
security purposes, you are advised to encrypt the username and password.
If the SASL mechanism is PLAIN, the configuration is as follows:
spring.kafka.properties.sasl.mechanism=PLAIN
spring.kafka.properties.sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule required \
 username="username" \
 password="password";
If the SASL mechanism is SCRAM-SHA-512, the configuration is as follows:
spring.kafka.properties.sasl.mechanism=SCRAM-SHA-512
spring.kafka.properties.sasl.jaas.config=org.apache.kafka.common.security.scram.ScramLoginModule
required \
```

```
username="username" \
password="password";

Set spring.kafka.security.protocol.
If the security protocol is SASL_SSL, the configuration is as follows:
spring.kafka.security.protocol=SASL_SSL
spring.kafka.ssl.trust-store-location is the path for storing the SSL certificate. The following code uses the
path format in Windows as an example. Change the path format based on the actual running environment.
spring.kafka.ssl.trust-store-location=file:D:\\temp\\client.jks
spring.kafka.ssl.trust-store-password is the password of the server certificate. This password does not
need to be modified. It is used for accessing the JKS file generated by Java.
spring.kafka.ssl.trust-store-password=dms@kafka
spring.kafka.properties.ssl.endpoint.identification.algorithm indicates whether to verify the certificate
domain name. This parameter must be left blank, which indicates disabling domain name verification.
spring.kafka.properties.ssl.endpoint.identification.algorithm=
If the security protocol is SASL_PLAINTEXT, the configuration is as follows:
spring.kafka.security.protocol=SASL_PLAINTEXT
```

## Producing Messages

```
package com.huaweicloud.dms.example.producer;

import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.kafka.core.KafkaTemplate;
import org.springframework.scheduling.annotation.Scheduled;
import org.springframework.stereotype.Component;

import java.util.UUID;

/**
 * @author huaweicloud DMS
 */
@Component
public class DmsKafkaProducer {
 /**
 * Topic name. Use the actual topic name.
 */
 public static final String TOPIC = "test_topic";

 @Autowired
 private KafkaTemplate<String, String> kafkaTemplate;

 /**
 * One message is produced every five seconds as scheduled.
 */
 @Scheduled(cron = "*/*5 * * * * ?")
 public void send() {
 String message = String.format("{id:%s,timestamp:%s}", UUID.randomUUID().toString(),
System.currentTimeMillis());
 kafkaTemplate.send(TOPIC, message);
 System.out.println("send finished, message = " + message);
 }
}
```

## Consuming Messages

```
package com.huaweicloud.dms.example.consumer;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.springframework.kafka.annotation.KafkaListener;
import org.springframework.stereotype.Component;

import java.util.Optional;

/**
 * @author huaweicloud DMS
 */
@Component
public class DmsKafkaConsumer {
```

```
/**
 * Topic name. Use the actual topic name.
 */
private static final String TOPIC = "test_topic";

@KafkaListener(topics = {TOPIC})
public void listen(ConsumerRecord<String, String> record) {
 Optional<String> message = Optional.ofNullable(record.value());
 if (message.isPresent()) {
 System.out.println("consume finished, message = " + message.get());
 }
}
}
```
